Abstract

Background: Effective medication management is one of the essential preconditions for enabling polymedicated home-dwelling older adults with multiple chronic conditions to remain at home and preserve their quality of life and autonomy. Lack of effective medication management predisposes older adults to medication-related problems (MRPs) and adverse health outcomes, which can lead to the degradation of a patient's acute clinical condition, physical and cognitive decline, exacerbation of chronic medical conditions, and avoidable health care costs. Nonetheless, it has been shown that MRPs can be prevented or reduced by using well-coordinated, patient-centered, interprofessional primary care interventions.

Objective: This study aimed to explore the feasibility and acceptability of an evidence-based, multicomponent, interprofessional intervention program supported by informal caregivers to decrease MRPs among polymedicated home-dwelling older adults with multiple chronic conditions.

Methods: This quasi-experimental, pre-post, multisite pilot, and feasibility study will use an open-label design, with participants knowing the study's objectives and relevant information, and it will take place in primary health care settings in Portugal and Switzerland. The research population will comprise 30 polymedicated, home-dwelling adults, aged ≥65 years at risk of MRPs and receiving community-based health care, along with their informal caregivers and health care professionals.

Results: Before a projected full-scale study, this pilot and feasibility study will focus on recruiting and ensuring the active collaboration of its participants and on the feasibility of expanding this evidence-based, multicomponent, interprofessional intervention program throughout both study regions. This study will also be essential to projected follow-up research programs on informal caregivers' multiple roles, enhancing their coordination tasks and their own needs. Results are expected at the end of 2024.

Conclusions: Designing, establishing, and exploring the feasibility and acceptability of an intervention program to reduce the risks of MRPs among home-dwelling older adults is an underinvestigated issue. Doing so in collaboration with all the different actors involved in that population's medication management and recording the first effects of the intervention will make this pilot and feasibility study's findings very valuable as home care becomes an ever more common solution.

Introduction

Background

Older adults with multiple chronic health conditions—particularly those with cognitive impairment—frequently depend on complex medication regimens [1]. Although the use of ≥5 medications, known as polypharmacy [2], may be clinically appropriate in many cases, inappropriate prescriptions may put older adults at a greater risk of medication-related problems (MRPs) and adverse health outcomes [3,4]. MRPs can lead to degradation in a patient's acute clinical condition, physical and cognitive decline, an exacerbation of chronic medical conditions, and avoidable health care costs [5,6]. This public health issue has been highlighted in various European countries, including Portugal and Switzerland [7,8].

Nonetheless, MRPs have been demonstrated to be preventable or reducible using well-coordinated, patient-centered, interprofessional primary care [4,5,9]. Current evidence-based strategies for medication safety and the prevention of MRPs include medication reconciliation, systematic and comprehensive reviews of prescribed medications (including deprescribing), and electronic medication management systems [10,11]. Medication reconciliation is a well-documented evidence-based practice involving creating and updating a single list of an older adult's currently prescribed medications [12] and then systematically and comprehensively reviewing them. Prior research has shown that hospital discharge documents received by primary care professionals are frequently inaccurate and lack key information [13]. Regular medication reconciliation reduces medication errors owing to consistent communication during transitions of care, including changes in clinical settings, medical practitioners, or the level of care [14]. Regularly and systematically reviewing prescribed medications is a straightforward, effective means of reducing inappropriate prescribing and prescribing cascades and is, therefore, a preventive strategy for avoiding MRPs [15]. Inappropriate prescribing includes potentially inappropriate medications and potential prescribing omissions [15]. Existing assessment tools—such as the STOPP (Screening Tool of Older Persons' Prescriptions) and START (Screening Tool to Alert to Right Treatment) criteria—recognize the dual nature of inappropriate prescribing by including a list of potentially inappropriate medications (STOPP criteria) and potential prescribing omissions (START criteria) [16]. Complementary to this, the regularly updated American Geriatrics Society's Beers Criteria is a list of potentially inappropriate medications that older adults should avoid in most situations or in connection with particular health conditions [17]. By reducing inappropriate prescriptions, medication reviews also prevent prescribing cascades—a phenomenon in which an MRP is misinterpreted as a new medical condition, leading to the inadvertent prescription of a new, unnecessary medication to treat it [18].

Implementing effective primary care medication management for home-dwelling older adults with multiple chronic conditions should be a priority to address and prevent adverse health outcomes, avoid hospital admissions, promote and maintain autonomy in their daily lives, and, consequently, help them remain at home [19]. Primary care management requires interprofessional collaboration across different health care and social care providers, organizations, and departments [20]. Indeed, the complexity of dealing with home-dwelling older adults with multiple chronic conditions and needs leads them to be significant users of health services and consult different health care professionals [21]. Besides prescribers—usually general practitioners (GPs) and different specialist physicians—pharmacists, nurses, and other allied health professionals may also be involved in medication management [20]. Collaborative home medication reviews (ie, involving a GP and pharmacist) have demonstrated their effectiveness in preventing, detecting, and resolving MRPs among home-dwelling older adults [20]. Furthermore, adherence to prescribed medication can be improved by pharmacist- and nurse-led interventions [22-25]. However, the number of health care professionals consulted by home-dwelling older adults has been directly associated with fragmented and uncoordinated care [20]. Moreover, different health care professionals may have different treatment preferences, leading to differing prescriptions. Thus, home-dwelling older adults with multiple chronic conditions often receive inefficient and ineffective care [26] or uncoordinated care, even though they are more likely to benefit from it [27]. Failure to coordinate care contributes to MRPs [20]. Older adults who consult ≥3 health care professionals report receiving conflicting advice, making it difficult for them to know whose guidance they should follow. Inadequate explanations about medication result in omissions and incorrect dosages, but they can also lead to anxiety and confusion among older adults [28]. Older adults' safety could benefit from a more empowering approach, with health care providers sharing information on best practices in medication management and agreeing on responsibilities with older adults and their informal caregivers [29]. The World Health Organization defines empowerment as "a process in which patients understand their role, are given the knowledge and skills by their health care provider to perform a task in an environment that recognizes community and cultural differences and encourages patient participation" [30]. Four components have been reported as being fundamental to the process of patient empowerment: (1) they understand their own role, (2) they acquire sufficient knowledge to engage with their health care provider, (3) they develop skills, and (4) there is a facilitating environment [31]. To the best of our knowledge, these 4 components have never been explored for empowering older adults' and informal caregivers' medication management

XSL•FO
RenderX

skills and promoting their active engagement in reducing the risk of MRPs.

In addition to health care professionals' contributions to effective medication management and identifying the risks of MRPs, informal caregivers could help ensure the safe and appropriate use of medication at home by older adults with multiple chronic conditions, notably among those who may also have a cognitive impairment or psychopathological disorder [32-34]. Informal caregivers are defined as any family member, neighbor, or friend who assists a dependent older adult. That assistance, help, care, or physical presence must be regular for ≥6 months, for at least 2 basic or instrumental activities of daily living, or to ensure patient safety [35]. Further interventional studies are required to explore how informal caregivers can be efficiently supported in their roles as medication managers, notably through the use of up-to-date, accurate, and easily understandable medication plans. Primary health care professionals should be assigned the task of cooperating with informal caregivers and integrating their shared decision-making experiences [32-34].

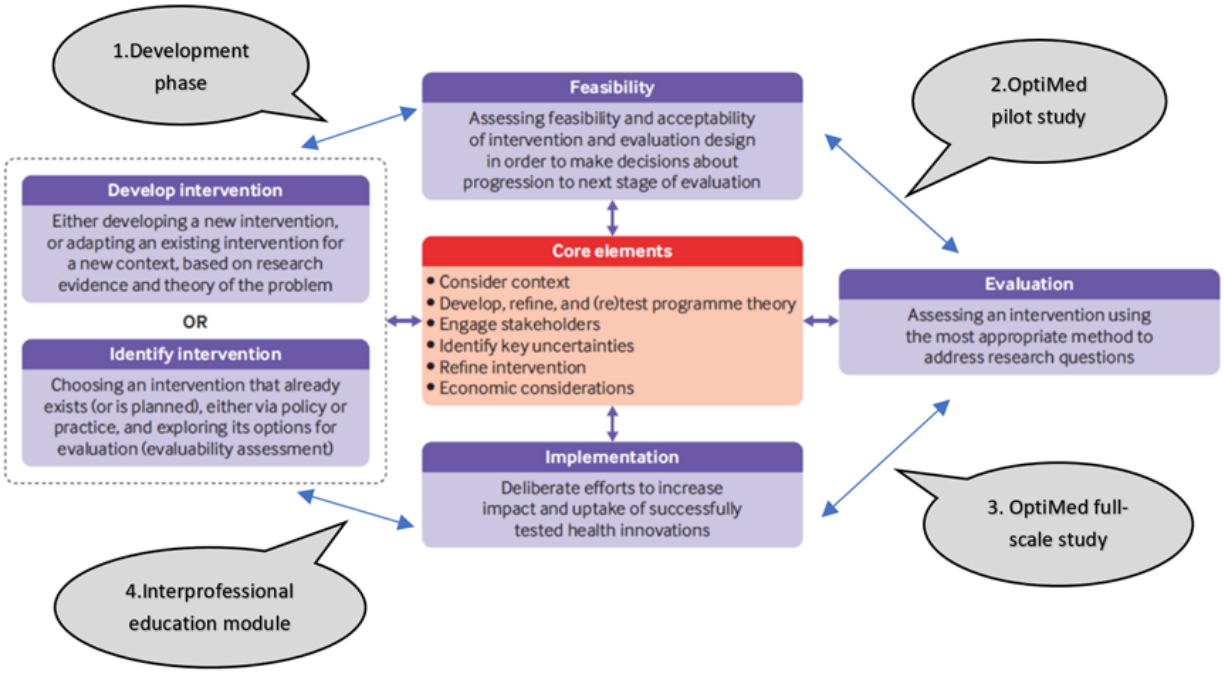
Previous research has shown the effectiveness of interprofessional intervention programs for reducing MRPs. These programs include risk assessments, health education for older adults and their informal caregivers, digital applications, and specialized counseling services or interventions provided by pharmacists and advanced practice nurses [32-34]. These elements should be tested in a standardized, evidence-based, multicomponent, interprofessional intervention program that embeds care in the context of where and how older adults live to prevent the onset or progression of MRPs.

Objectives

Before conducting a full-scale study with sufficient statistical power, a pilot and feasibility study is critical in the process of developing and testing the intervention. This is "a small-scale test of the methods and procedures to be used on a larger scale" [36]. Thus, our pilot and feasibility study's goal is not to test hypotheses about our intervention's impact but to assess the feasibility and acceptability of our approach [37].

Pilot Study Design

This quasi-experimental, pre-post, multisite pilot and feasibility study will focus on the feasibility components using an open-label design with participants knowing the study's objectives and relevant information. This will support the development of a standardized, evidence-based, multicomponent, interprofessional intervention program to reduce MRPs.



The OptiMed Pilot Study's Framework

Intervention studies in primary care are typically complex, multicomponent, interprofessional, and standardized, requiring considerable planning to be conducted successfully [38]. Thus, in accordance with the Medical Research Council's framework guidelines, we carefully planned the different steps required for the successful execution of this project with sufficient statistical power and the necessary number of participants in both countries (Figure 1) [39]. Designing the OptiMed pilot and feasibility study protocol is part of the development phase, which includes developing all the study's different components: identifying research gaps and the risks of MRPs, describing relevant concepts, and designing the intervention. Although the OptiMed pilot study (phase 2) will allow us to explore and test the feasibility of conducting the full-scale OptiMed study (phase 3), the latter will assess the effectiveness of the evidence-based, multicomponent, interprofessional medication management intervention program for polymedicated home-dwelling older adults. A comparative analysis of the resources used (costs) and outcomes obtained (effectiveness) will help estimate the health and non–health costs and benefits of this intervention program. As a secondary end point, we also expect to develop and implement a Swiss-Portuguese interprofessional training course about optimizing medication management among polymedicated home-dwelling older adults receiving community-based health care (phase 4).

Furthermore, the following 4 concurrently interacting components that improve the primary care of home-dwelling older adults with multiple chronic conditions—previously identified by Boult and Wieland [40]—will help to operationalize and implement the intervention program: (1) appropriate tools to comprehensively assess the risks associated with MRPs; (2) evidence-based, multicomponent, interprofessional care planning, interventions, and monitoring; (3) the promotion of active engagement in that care by patients and informal caregivers; and (4) coordination between professionals to ensure the best patient care. All 4 concurrent interacting components were tailored to meet the patient's goals and preferences. In this pilot study, these 4 components will be integrated into a medication management program focused on the context surrounding polypharmacy. Assigning roles and respecting the competencies of each member of the program's interprofessional team is key to ensuring optimal coordination and a systematic team approach.

Methods

Participants, Interventions, and Outcomes

Study Setting

The OptiMed pilot study will be conducted in 2 primary health care centers (PHCs): the PHC "Unidade de Saúde Familiar Santiago–Marrazes" in Leiria, Portugal, and another in the French-speaking part of Switzerland.

Eligibility Criteria

The research population will include polymedicated home-dwelling adults aged ≥65 years, both men and women, at risk of MRPs and receiving community-based health care. Purposive sampling will recruit older adults taking ≥4 medicines per day and presenting with a risk of an MRP, as assessed using the doMESTIC risk tool, whose psychometric validation is ongoing. The criterion of ≥4 drugs is based on the Delphi study that developed this tool [41]. Older adult participants at risk of MRPs will be integrated into our investigation if their informal caregiver is involved in medication management and they provide informed written consent to participate. On the basis of our clinical experience, being a significant partner in an older adult's medication management involves at least one of the following activities: accompanying the patient to health consultations, assistance in obtaining medication, collecting or delivering medication, assistance with preparing or taking medication, monitoring effectiveness and side effects, assistance in maintaining the medication schedule, and organizing home care support.

Furthermore, throughout the investigation, each participant will be accompanied by the health care professionals designated as the professional most involved in their medication management. Table 1 presents the inclusion and exclusion criteria for each group of participants.

XSL•FO
RenderX

Table 1. Inclusion and exclusion criteria for OptiMed pilot study participants.

Participants	Inclusion criteria	Exclusion criteria
Study participants		
Polymedicated home-dwelling older adults	• Aged ≥65 years for both men and women • People with multiple chronic conditions (≥2) • Managing at least 4 ore than 90 days [2] (explored during recruitment) • At risk of MRPs[a] identified using the doMESTIC RISK[b] tool • Living alone or with a partner in a rural or urban area • Supported by a primary health care center • An informal caregiver is involved in medication management • Given their written informed consent (Multimedia Appendix 1)	• Unable to speak and understand French (Swiss site) or Portuguese (Portuguese site) • Moderate or severe dementia criteria (≥10 on the 6-CIT[c]) • No risk of MRPs (doMESTIC RISK tool score <5[d]) • No informal caregiver
Collaborating participants		
Informal caregivers	• Designated by the older adult as the most significant informal caregiver involved in their medication management • Aged ≥18 years • Given their written informed consent (Multimedia Appendix 2)	• Unable to speak and understand French (Swiss site) or Portuguese (Portuguese site) • Moderate or severe dementia criteria (≥10 on the 6-CIT) • No risk of MRPs (doMESTIC RISK tool score <5[d]) • No informal caregiver
Nurse primary care manager	• Working for a primary health care center • Designated by the older adult as playing a key role in their medication management • Given their written informed consent (Multimedia Appendix 3)	• Student • Apprentice
Community pharmacist	• Working in a community pharmacy • Designated by the older adult as playing a key role in their medication management • Given their written informed consent (Multimedia Appendix 3)	• Student • Apprentice
Physician	• Older adult's general practitioner or specialist physician • Designated by the older adult as playing a key role in medication management • Given their written informed consent (Multimedia Appendix 3)	• Student • Apprentice

[a]MRP: medication-related problem.

[b]doMESTIC RISK: Medication Safety in Home Care.

[c]6-CIT: 6-item Cognitive Impairment Test.

[d]As assessed by the research team.

Primary and Secondary Feasibility and Acceptability Outcomes

The primary objective of this pilot study is to explore the feasibility and acceptability of an evidence-based, multicomponent, interprofessional intervention program with the support of informal caregivers to decrease MRPs among polymedicated home-dwelling older adults with multiple chronic conditions. As per Eldridge et al [42], a feasibility study "asks whether something can be done, should we proceed with it, and if so, how." Therefore, in line with the Medical Research Council's framework guidance [39], our study will gather information about the feasibility of recruitment, participant retention, intervention adherence (adherence to instructions by participants), intervention fidelity, and intervention dose [36,43] (Textbox 1 [44]). The quantitative cutoff point for our feasibility outcomes will be successful with at least 70% of participants [45]. Given the older adult participants' advanced age and chronic health conditions, the number of withdrawals for health reasons may be higher than in other studies. Acceptability will be assessed by measuring participants' satisfaction with each assessment instrument, home visits, and the targeted education plan. The secondary objective is to test the different data collection tools planned for use in the full study.

XSL•FO
RenderX

Textbox 1. Outcomes and measurements of the OptiMed pilot study's feasibility and acceptability, based on the United States National Center for Complementary and Integrative Research recommendations [44].

- Measurements of feasibility
  - The target population is recruited: the number screened per month, the number enrolled per month, and the average time between screening and enrollment
  - Study participants are retained: treatment-specific retention rates for study measurements and reasons for dropouts
  - Study participants adhere to their instructions: treatment-specific rates of adherence to the study protocol (in-person session attendance, homework, home sessions, etc) and treatment-specific measurements of competencies
  - The medication review is successful: treatment-specific fidelity rates, time invested, number of discrepancies between professional sources, number of discrepancies between patient-reported medication use and professional sources, number of questions, number of items needing clarification, number of recommendations made by the pharmacist, and number of pharmacist's recommendations adopted by the physician
  - The credibility of each component of the interprofessional intervention program is assessed as positive: ratings for treatment-specific expectations of benefit
  - The relationship between the dose of nursing [46] and response to the program is measured: amount, frequency, intensity, and duration
  - Study displays clinical relevance: how participants perceive the intervention program, using patient-reported outcome measures [47]. Identify what is relevant for participants (such as quality of life or remaining at home). Enabling a choice of which outcomes from the pilot study will go into the intervention
- Measurements of acceptability
  - Participants are satisfied with each assessment instrument, home visits, and the targeted education plan: acceptability ratings are calculated using quantitative assessments, reasons for dropouts, and treatment-specific preference ratings (pre- and postintervention)
  - Assessments are not considered too burdensome: the proportion of planned assessments that are completed; duration of assessment visits; reasons for dropouts; ease of use of the doMESTIC RISK tool; ease of use of the structured medication review template

According to the Consensus-based Standards for the Selection of Health Measurement Instruments (COSMIN) recommendations [48], if the pilot study is conclusive, then the full-scale OptiMed study will adopt the standardized Core Outcome Set for its clinical trials of a medication review for multimorbid older adult patients with polypharmacy, as previously reported by Beuscart et al [49] in 2018 (Multimedia Appendix 4).

Study Intervention

Completing the intervention program with 1 participant requires 5 weeks. After the older adult participant has been recruited via their nurse primary care manager working for their PHC, the intervention's first component involves their baseline assessment at a meeting conducted by a research nurse (t0). The research is explained to the older participant in detail, both orally and in writing, and the consent form is signed (Multimedia Appendix 1). After this, the older participant is asked to answer some sociodemographic and health-related questions and provide a complete list of their current medication prescription. The research nurse completes a questionnaire on the risk of MRPs—doMESTIC risk questionnaire (Multimedia Appendix 5). A first meeting was also conducted individually with the informal caregiver (who will also answer some sociodemographic and health-related questions and describe their role in medication management; Multimedia Appendix 6). The older adult participant is asked to identify the health care professionals (GP or specialist, nurse primary care manager, or community pharmacist) most involved in their medication management.

The second component involves a review of the prescribed medications in week 1 (t1), including a medication reconciliation and a structured medication analysis by the study's partnering pharmacist to identify drugs with a high risk of MRPs among older adults. This will use the STOPP and START criteria, and undertreated indications or missed therapies will use the START criteria [16]. The older adult participant's physician will be invited to participate in the review of prescribed medications in collaboration with the study's partnering pharmacist. They will discuss validated, evidence-based, and internationally recognized guidelines to reconsider beneficial or nonbeneficial therapies or to simplify and focus on specific care goals and adjust medications to be consistent with the guidelines. If the older adult participant's physician adopts none of the proposed changes, despite the medication review (t1) highlighting their relevance, the research team will inform the older adult participant of their physician's decision and invite them to proceed with the study.

On the basis of the baseline assessment (t0), the research nurse will use a joint consultation in week 2 to explore the needs and care goals of the older adult participant and their informal caregiver to reduce the risk of MRPs (t2). In collaboration with the designated health care professionals, the research nurse will then design a targeted patient-centered education plan to empower older adult participants' medication management and reduce the risk of MRPs (t2). This is based on a four-step patient empowerment process: (1) the patient understands their role, (2) the patient acquires sufficient knowledge to engage with their health care professionals, (3) the patient improves their skills, and (4) there is a facilitating environment [31]. Each older adult participant's plan will be unique and consider their preferences, medication literacy, and treatment adherence.

XSL•FO
RenderX

During weeks 3 and 4 (t3), the research nurse will help the older adult participant and their informal caregiver to implement their targeted education plan (t2) aimed at empowering their medication management and promoting their active engagement in reducing the risks of MRPs. Two joint consultations will be organized among the older adult participant, their informal caregiver, and the research nurse (once each week). During planned home visits, the nurse will periodically evaluate the older adult participant's medication status (primary and secondary outcomes) and promote communication between different professional and nonprofessional actors involved in medication management.

The research nurse will complete a final assessment (t4) of each older adult participant's risks of MRPs in week 5 (35-40 days after t0) in collaboration with the study's partnering pharmacist. The occurrence of MRPs and medication-related hospital admissions will be investigated. Finally, the health care professionals designated by the older adult participant will assess the acceptability of the interprofessional intervention program aimed at reducing MRPs by completing a final questionnaire (Multimedia Appendix 7). The pilot study will explore possible biases so that they can be correctly addressed in the full study (Multimedia Appendix 8) [36,38].

As already described, the medication management intervention program guiding OptiMed's pilot study comprises 4 components based on concurrently interacting processes previously identified by Boult et al [40] (Multimedia Appendix 9).

The schedule of enrollment, interventions, and assessments is presented in Table 2. The pilot study will be conducted over 12 months, including the recruitment phase (Multimedia Appendix 10).

Sample Size and Recruitment

On the basis of the study by Hogget al [51], we planned to recruit 30 older adult participants (15 men and 15 women), 30 informal caregivers, and 30 health care professionals in collaboration with 2 PHCs: the Unidade de Saúde Familiar Santiago–Marrazes in Leiria, Portugal, and another in the French-speaking part of Switzerland. Nurse primary care managers partnering with the project will briefly explain the study to polymedicated home-dwelling older adults who meet the inclusion criteria. Eligible participants will be asked for permission to provide their names to the researchers, and a research team member will telephone them to ask for their agreement to participate in the study. If they agree, the first meeting with a research team member will be organized at the older adult participant's home or the PHC in the following few days. Given the 2 countries' different primary health care practices, eligible participants in Switzerland will be met at home, whereas participants in Portugal will be met at the PHC. Consenting older adult participants will be asked to designate the most significant informal caregiver, aged ≥18 years, involved in their medication management, and the research team will invite them to participate in the study. The older adult participants will be asked to designate the health care professionals (GPs or specialist physicians, nurse primary care managers, or community pharmacists) who are most prominently involved in their medication management. During the first meeting, the research nurse will explain the study's nature, purpose, and procedures to the older adult participant, along with its expected duration, potential risks and benefits, and any discomfort it may entail. Each older adult participant will be informed that participation in the study is voluntary, that they may withdraw from it at any time, and that the withdrawal will not affect their subsequent medical assistance and treatment.

Data Collection, Management, and Analysis

Data Collection Methods

Data on older adult participants' health status will be collected using the 6-item Cognitive Impairment Test (6-CIT), Tilburg Frailty Indicator (TFI), and the diagnosis list based on the 11th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD-11). Current medication, previous MRPs, and the doMESTIC RISK tool will provide data on the risks of future MRPs and will be collected, when possible, from routinely collected PHC data or directly from older adult participants and their informal caregivers.

XSL•FO
RenderX

Sociodemographic data and information about informal caregivers' contributions to their relatives' medication management will be collected. We will collect sociodemographic and professional data from health care professionals (GPs, nurse primary care managers, and community pharmacists), along with information about medication monitoring and follow-up, how they teach and train older adults and informal caregivers on medication management, how they assess their cognitive capacity to manage medication, stakeholder collaboration, and medication management.

The study will also collect participants' opinions on the acceptability of each intervention, reasons for dropout, and treatment-specific preference ratings (before and after the intervention).

Except for the doMESTIC risk tool, whose psychometric validation is ongoing, all other instruments in the study have demonstrated their reliability and validity in previous studies. Table 3 describes the measurements taken, the instruments used for data collection, and their respective purposes. To promote data quality, the nurses and pharmacists partnering with the study will undergo two 1-hour training sessions on assessment.

Table 3. Measurements and instruments used for data collection.

Participants	Measurements and instruments	Purpose
Study participants		
Home-dwelling older adults		
	Sociodemographic data (baseline assessment, t0; Multimedia Appendix 5)	Describe older adult participants' profiles (birthdate, gender household size, number of hospitalizations, and the date of the last hospitalization, etc)
	Six-item Cognitive Impairment Test (t0; Multimedia Appendix 5)	Perform brief cognitive screening recommended for use in primary care settings [52]
	TFI[a] (self-administered or at t0; Multimedia Appendix 5)	Assess multidimensional frailty among older adult participants via a self-administered questionnaire [53]
	11th revision of the ICD-11[b] diagnosis list (t0)	Describe older adult participants' morbidities based on the ICD-11 [54]. The list is useful when doing a medication analysis and evaluating prescription adequacy
	Current medication lists (t0)	Perform medication analysis (overuse, underuse, potentially inappropriate medications, and clinically significant drug-drug interactions) and medication reconciliation (number of discrepancies and clarifications needed)
	Previous MRPs[c] (t0)	Describe the history of past MRPs
	doMESTIC RISK Tool (t0 and final assessment, t4)	Identify older adult participants at a high risk of MRPs [41]
	Acceptability of the intervention [55] (t4; Multimedia Appendix 5)	Collect older adult participants' opinions on the acceptability of the medication management intervention program
Collaborating participants		
Informal caregivers		
	Sociodemographic data (t0; Multimedia Appendix 6)	Describe informal caregivers' profiles and their relationships with older adult participants
	Involvement in medication management (t0; Multimedia Appendix 6)	Describe types, frequencies, and intensities of informal caregivers' support activities
	Acceptability of the intervention [55] (t4; Multimedia Appendix 6)	Collect informal caregivers' opinions on the acceptability of the medication management intervention program
Health care professionals (nurse primary care manager, community pharmacist, and physician)		
	Sociodemographic and professional data (t0; Multimedia Appendix 7)	Describe professional caregivers' profiles and baseline involvement in medication management
	Acceptability of the intervention [55] (t4; Multimedia Appendix 7)	Collect professional caregivers' opinions on the acceptability of the medication management intervention program

Study Instruments

6-Item Cognitive Impairment Test

6-CIT was selected for the cognitive screening of older adult participants because it is brief, simple to apply, and requires no special training for administration. The 6-Item Orientation-Memory-Concentration Test was originally developed by Katzman et al [56] by shortening the Mental Status Test by Blessed et al [57]. The 6-CIT involves 3 temporal orientation tests (year, month, and time), 2 attention tests (counting backward from 20 to 1, reciting the months of the year in reverse), and 1 short-term memory test (a 5-item address) [52]. Scored out of 28, higher scores indicate greater impairment. The 6-CIT has been used in a broad range of settings, including screening for dementia in primary care, cognitive screening in acute care, large population-based studies, and Alzheimer disease studies [52]. In primary care, the English version's internal consistency (Cronbach α), stability over time (Pearson *r*), and agreement between successive tests (Cohen κ) reached values of .58, 0.62, and 0.45, respectively [58]. Sensitivity and specificity reached values of 0.49 and 0.92 at the 7/8 cutoff and 0.32 and 0.98 at the 10/11 cutoff, respectively [58]. The Portuguese version of the 6-CIT (6-CIT-P) presented a high test-retest reliability coefficient (r=0.95, P<.001; n=54), indicating good temporal stability [59]. 6-CIT-P has also shown strong internal consistency (Cronbach α=.88), and the corrected item-total correlations ranged between 0.32 and 0.90, representing a moderate-to-strong correlation between the items and total score. The 6-CIT-P and mini-mental state examination scores were strongly negatively correlated (r=−0.90) because of the polarity of the tests, indicating an acceptable convergent validity. The Global 6-CIT showed good sensitivity and specificity (82.78% and 84.84%, respectively) compared with the mini-mental state examination [59]. The French version is currently undergoing a validation study.

Tilburg Frailty Indicator

As polypharmacy has been associated with a higher incidence of frailty [60,61], the TFI will be used to assess multidimensional frailty among home-dwelling older adults [53]. Unlike other frailty assessment instruments, TFI does not focus exclusively on the physical dimension of frailty and does not include disability and diseases in its assessment. This contributes to a holistic perspective of human functioning in the community (including the physical, psychological, and social domains). The TFI consists of 2 parts: part A contains 10 questions on the determinants of frailty and multi-morbidity, whereas part B uses 15 questions to examine 3 domains of frailty (physical, psychological, and social) [53]. Each question is scored as 1 or 0. A total score of ≥5 suggests that a person is frail and the greater the score, the greater the degree of frailty is considered significant. The original English version's internal coherence demonstrated a satisfactory Cronbach α coefficient of .73 [62]. Construct validity between the different domains revealed significant Pearson correlation coefficients (P<.05): r=0.42 between the physical and psychological domains; r=0.19 between the physical and social domains; and r=0.18 between the psychological and social domains. Convergent and divergent validities were considered to be good. The TFI demonstrated good temporal-fidelity stability, with a frailty score of 0.90 after 2 weeks and 0.79 after 1 year [62]. The Portuguese version of the TFI showed good internal consistency (KR-20=0.78) and test-retest reliability (r=0.91), with Cohen κ coefficients showing substantial agreement for most items [63]. The French version is currently under validation.

doMESTIC RISK Tool

The doMESTIC RISK tool is used to identify patients at high risk of MRPs [41]. It is based on home-care–specific risk factors for medication safety as derived from the literature. Experts prioritized the tool's suggested items using a 2-round Delphi study. The final tool was statistically validated using a systematic medication review involving 150 home care patients. The tool's subsequent weighting improved the model's overall quality and resulted in a final doMESTIC RISK tool with 10 risk factors. The tool's strengths are its specific focus on the home care setting and the interprofessional input necessary for its completion [41]. French and Portuguese versions of the original tool will be used. The reliability, validity, and responsiveness of the doMESTIC RISK tool are being measured based on a quantitative analysis of field tests (factor analysis and item response theory) [48,64]. In this pilot study, an older adult's risk of MRPs and whether the medication management intervention program contributes to decreasing it will be assessed by 2 nurse research assistants in collaboration with 2 pharmacists using the doMESTIC RISK tool at the baseline assessment (t0) and the final assessment (t4).

Participant Retention and Completing Follow-up

On the basis of the best practice guidance [65], the following strategies will be used to promote the retention of older adult participants and informal caregivers and to complete follow-up:

- Involving informal caregivers.
- Allowing rest between measurements and interviews, as needed.
- Meeting older adult participants at home during visits by the PHC's home care services (Switzerland).
- Arranging transport to the meeting location or reimbursing transportation costs (Portugal).
- Keeping meetings short (<1 hour).
- Providing opportunities to build social support through organized educational sessions within the targeted plan.
- Keeping in touch by scheduling appointments in advance and sending reminders to both the older adult participant and informal caregiver.
- Providing regular feedback to study participants.

Participants will be able to withdraw their consent to participate in the study at any time, without having to justify themselves. Participants who discontinue, drop out, or deviate from the intervention program will be briefly interviewed to learn when and why they did so, and an intention-to-treat analysis will be conducted. In case of withdrawal from the study, the data collected will be anonymized using secuTrial search software and stored on secure servers at the School of Health Sciences, HES-SO Valais-Wallis, or at ciTechCare, Polytechnic of Leiria.

XSL•FO
RenderX

Data Management

All data will be entered into the secuTrial electronic data capture system, either at the School of Health Sciences, HES-SO Valais-Wallis, or at ciTechCare, Polytechnic of Leiria. Original study forms will be scanned, stored electronically with limited access, and kept on file at the HES-SO and ciTechCare sites. Data entry screens will resemble the paper forms approved by the ethics committees. Data consistency will be ensured through various mechanisms, including referential data rules, valid values, range checks, and consistency checks against data already stored in the database (longitudinal checks). Checks will be applied when data are entered into a specific field and before they are committed permanently to the database. Modifications to the data in the database will be documented via an audit trail. Data in the secuTrial database will be retrievable through data entry applications. The types of activities that individual users may undertake will be regulated by the privileges associated with their user identification code and password.

The 2-country roll-out will allow greater standardization of the evidence-based, multicomponent intervention program for a future, full-scale, quasi-experimental, pre-post study. However, raw data will not be shared between countries, and the results obtained will be discussed only after being analyzed separately in each country. A joint publication is planned using aggregated data from the pilot study results.

Statistical Methods

The pilot study will compute descriptive statistics as distributions and central tendencies, as well as inferential statistics, to provide power analyses for the pilot study's proposed sample size. The pilot study's results will help provide a power analysis of the sample needed for a fully powered pre-post study. Analyses will be conducted in collaboration with a biostatistician using an up-to-date version of the SPSS software.

Handling Missing Data and Dropouts

We do not expect any missing data, as the protocol is limited and properly adapted to the potential participants' characteristics. The OptiMed pilot study will consider missing data and dropout rates as significant results for organizing recruitment, intervention adherence, acceptability, and subject retention in the full-scale study. Nevertheless, to fully evaluate the different components of the pilot study, we will replace dropouts with new participants until 30 of them have completed the study. Given the intervention program's 5-week duration and the older adult participants' multiple chronic health conditions (as they are all polymedicated), it is difficult to anticipate how many will complete the intervention and how many may interrupt it for health or availability reasons. This is also one of the rationales for conducting a pilot feasibility study before conducting a full-scale study.

Monitoring

Data Monitoring

secuTrial will help in monitoring both the pilot study and the full-scale study. Data monitoring will inform us of aspects of the study's conduct, such as ongoing recruitment, and help identify any need for adjustment.

Lausanne University Hospital's Clinical Trial Unit (CHUV-CTU) and Leiria's Regional Health Administration ("Administração Regional de Saúde" – ARS) will check the electronic case report forms (eCRFs) for consistency and completeness throughout the study. If an issue is detected, the monitor will open a query in the secuTrial software, and the investigator will be able to answer and correct the data in that software as needed. An overall data consistency check will be performed by the study monitor and the designated data manager. Any actions required to fix the data issues will be reported in the eCRFs. A final export of the data set will enable us to completely remove participants' identities, and the database will be locked.

Risk-Benefit Assessment

The research team will not add or change any medication. However, based on a medication review (made following validated, evidence-based, and internationally recognized guidelines), the study's partnering pharmacist may provide suggestions to older adult participants' GPs or specialist physicians. Thus, by participating in the project, older adult participants may be exposed to minor risks, such as a temporary alteration of their usual condition, if their physician modifies their treatment after discussion with the study's partnering pharmacist to avoid MRPs.

Medication management will be performed using validated, internationally recognized, and evidence-based guidelines for older adults. The medication management intervention program proposed to the older adult participants and their informal caregivers will be tailored (in intensity and duration) to each individual and will consider their health and medication literacy. This is important to avoid a lack of follow-up, particularly among those with a possible undiagnosed mild cognitive impairment. Older adult participants, informal caregivers, and prescribers should benefit from a more empowering approach to medication management.

Insurance

In case of any study-related damage or injury, the School of Health Sciences, HES-SO Valais-Wallis, and ciTechCare, Polytechnic of Leiria, may be liable for compensation, except for claims that arise from misconduct or gross negligence.

Auditing

Overview

CHUV-CTU and ARS will regularly monitor data quality and completeness. They will audit source documents in Switzerland and Portugal, respectively, with at least 1 research site monitoring visit every 6 months in each country throughout the study. The primary objectives of this study are education, support, and problem solving. The monitors will discuss the protocol in detail and identify and clarify any areas of weakness. The investigators will practice entering data so that the study monitors are assured of their proficiency in all aspects of data entry, query response, and communication with the CHUV-CTU and ARS. The monitors will audit the overall data quality and

XSL•FO
RenderX

completeness, examine source documents and interview investigators, and confirm that the research site has complied with the protocol's requirements. The monitors will verify that all adverse events were correctly documented and consistent with the protocol's definition. They will review source documents (ICD-11 diagnosis list, current medication lists, and associated reports from PHCs) as needed to determine whether the data reported in secuTrial are complete and accurate. They will confirm that the regulatory binder is complete and that all associated documents are up to date. The regulatory binder should include the protocol, informed consent forms, ethics approval from both countries, and investigator agreements.

If a problem is identified during a visit (eg, poor communication with the CHUV-CTU and ARS, inadequate or insufficient staff to conduct the study, and missing study documents), the monitors will assist the research site in resolving its issues. Visits and electronic monitoring will focus on source document reviews and confirmation of adverse events. Monitors will verify the following variables for all study participants: date of birth, sex, signed informed consent, eligibility criteria, treatment assignment, adverse events, and end point. All parties involved will keep participants' data strictly confidential.

Ethics Approval

Ethics approval was obtained from the Human Research Ethics Committee of the Canton of Vaud (Commission cantonale d'éthique de la recherche sur l'être humain), Switzerland (2021-01843), and Leiria's ARS, Portugal (80-2021).

Protocol Amendments

Any substantial changes made to the study setup or organization, protocol, or relevant study documents will be submitted to the CER-VD and ARS for approval before implementation. In an emergency, deviations from the protocol may be made to protect human subjects' rights, safety, or well-being without the Ethics Committee's prior approval. Such deviations will be promptly documented and reported to the CER-VD and ARS.

Consent to Participate

All study participants will be provided with a participant information sheet and a consent form describing the study and providing sufficient information for them to make an informed decision about participation (Multimedia Appendices 4, 5, and 6). Participants will have up to 2 weeks to decide whether to participate in the study. Formal consent will be obtained using an approved consent form before the participant is sent for any study procedure. The investigator will sign and date the informed consent form simultaneously with the participant, 1 copy will be given to the study participant and the other will be retained in a secure location as part of the study records. Participants will also be requested to provide written informed consent for reusing the data in an encoded form.

Before the pilot study, the intervention program will be pretested on 3 to 4 study participants to evaluate how long, intense, and tiring it is. Participants' autonomy will be respected, and study participation will be voluntary. They will be able to refuse further participation or drop out of the study at any time. However, once collected, data will not be deleted. Throughout the process, the research team will tell the truth and ensure that it misleads neither its research partners nor the participants.

Older adult participants, their informal caregivers, and collaborating health care professionals will receive no compensation for their involvement in this research project. However, the study participants will benefit from the intervention program and provide superior support for medication management.

Confidentiality and Access to Data

Participant data will be handled with the utmost discretion and will only be accessible to authorized personnel who require that data to fulfill their duties within the scope of the study. In the eCRFs and other study-specific documents, participants will only be identified using their unique participant numbers. Study participants will be coded as follows: OPTIMED-01, OPTIMED-02, etc. Any links between that code and the participant's real identity will be protected by secuTrial, and only the research team will have access to the data collected. The types of activities that individual users may undertake will be regulated by the privileges associated with their user identification code and password. The original study forms will be scanned, stored electronically with limited access, and kept on a secure server at the School of Health Sciences, HES-SO Valais-Wallis, and at ciTechCare, Polytechnic of Leiria, for 20 years after the completion of the study.

Dissemination Policy

Knowledge transfer activities will promote this pilot study at professional and scientific conferences for primary health care professionals, within hospital care units, and to informal caregivers', patients', and older adults' associations. The findings of the pilot study will be submitted to a peer-reviewed journal.

Results

This paper describes the development of a pre-post, multisite pilot, and feasibility study to explore the feasibility and acceptability of an interprofessional intervention program to decrease MRPs among polymedicated, home-dwelling older adults with multiple chronic conditions. We expect our findings to provide sufficient methodological evidence regarding the rationale, design, and planning of the intervention to warrant a full-scale study. This methodological evidence will include approaches to recruitment and obtaining consent, ensuring adherence to each phase of the intervention program, and easing the burden of assessments. Although this pilot and feasibility study did not have sufficient statistical power to provide estimates of effect size, we expect that our findings will provide useful data to help define the final components of the full-scale study and research strategies.

Discussion

Designing, constructing, and exploring the effectiveness of an intervention program to reduce the risk of MRPs among home-dwelling older adults, in collaboration with all the different actors involved in their medication management, is an

XSL•FO
RenderX

emerging but underinvestigated issue. Current knowledge in this area was developed in academic settings and acute and long-term care facilities; however, little is known about this topic in home care settings. Regarding the prevention of MRPs, research to date has been unable to simultaneously integrate the roles and perceptions of polymedicated home-dwelling older adults with multiple chronic conditions, their informal caregivers, and their health care professionals [66]. To close these gaps, our interprofessional intervention has been coconstructed with older adults and their informal caregivers and could contribute significantly to preventing hospital admissions, rehospitalizations, institutionalization in long-term care facilities, and early death. This could also limit the economic impact of MRPs on the already stretched health care systems [67]. The OptiMed study is a tailored intervention program based on a clear allocation of roles to reduce the risk of MRPs among home-dwelling older adults. This medication management program is underpinned by a complex intervention framework that includes development, implementation, and sustainability milestones [39]. It also considers the 4-fold aim of enhancing the patient's experience, improving population health, reducing costs, and improving health care professionals' working lives [68].

Acknowledgments

This research was funded by the Joint Swiss-Portuguese Academic Programme of the University of Applied Sciences and Arts Western Switzerland (HES-SO) and the Foundation for Science and Technology (grant 105 995). The funding organization had no role in the study design, and it will have no role in the collection, analysis, or interpretation of data, writing the intended manuscript, or in the decision to publish the results.

Data Availability

The data sets used and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

FP and HV developed the original concepts. SGP, MdAD, CMM, and HV provided conceptual and methodological expertise in study design. CMM is the principal author of the doMESTIC risk tool. FP and HV were the major contributors to writing the manuscript. All authors have read, edited, and approved the final manuscript.

Abstract

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder, with its currently approved drugs, including riluzole and edaravone, showing limited therapeutic effects. Therefore, safe and effective drugs are urgently necessary. EPI-589 is an orally available, small-molecule, novel redox-active agent characterized by highly potent protective effects against oxidative stress with high blood-brain barrier permeability. Given the apparent oxidative stress and mitochondrial dysfunction involvement in the pathogenesis of ALS, EPI-589 may hold promise as a therapeutic agent.

Objective: This protocol aims to describe the design and rationale for the EPI-589 Early Phase 2 Investigator-Initiated Clinical Trial for ALS (EPIC-ALS).

Methods: EPIC-ALS is an explorative, open-labeled, single-arm trial that evaluates the safety and tolerability of EPI-589 in patients with ALS. This trial consists of 12-week run-in, 24-week treatment, and 4-week follow-up periods. Patients will receive 500 mg of EPI-589 3 times daily over the 24-week treatment period. Clinical assessments include the mean monthly change of Amyotrophic Lateral Sclerosis Functional Rating Scale–Revised total score. The biomarkers are selected to analyze the effect on oxidative stress and neuronal damage. The plasma biomarkers are 8-hydroxy-2′-deoxyguanosine (8-OHdG), 3-nitrotyrosine

XSL•FO
RenderX

(3-NT), neurofilament light chain (NfL), phosphorylated neurofilament heavy chain (pNfH), homocysteine, and creatinine. The cerebrospinal fluid biomarkers are 8-OHdG, 3-NT, NfL, pNfH, and ornithine. The magnetic resonance biomarkers are fractional anisotropy in the corticospinal tract and N-acetylaspartate in the primary motor area.

Results: This trial began data collection in September 2021 and is expected to be completed in October 2023.

Conclusions: This study can provide useful data to understand the characteristics of EPI-589.

KEYWORDS

amyotrophic lateral sclerosis; biomarker; clinical trial; magnetic resonance imaging; oxidative stress

Introduction

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease that is characterized by progressive upper and lower motor neuronal dysfunction and loss [1]. The mean survival time is 3-5 years after the onset [2]. ALS is diagnosed in 1-2 individuals per 100,000 each year in most countries, whereas its prevalence is approximately 5 cases per 100,000 people, reflecting the rapid disease lethality [3]. The pathogenic processes underlying ALS are considered multifactorial, including complex interaction of genetic factors, oxidative stress, excitotoxicity, and protein aggregation, as well as impaired RNA processing, axonal transport, and mitochondrial function [4]. Thus far, only a few interventional drugs, including the antiglutamatergic small molecule riluzole [5] and the antioxidant edaravone [6], have been approved by the United States Food and Drug Administration for ALS. Riluzole prolongs survival by only 2-3 months [5]. Edaravone, a strong antioxidant and free radical scavenger [7], slows down the loss of motor function in patients with ALS by 33% compared with a placebo [6,8]. A retrospective study demonstrated that edaravone prolonged tracheostomy-free survival [9], and a 5‐year prospective observational study is ongoing to investigate the long-term safety and effects of edaravone on ALS [10,11]. In addition, a cohort study, using propensity score matching, found safety but not disease-modifying benefit of long-term intravenous edaravone for patients with ALS [12]. Considering these circumstances, new therapies for ALS are highly anticipated.

A redox homeostasis dysfunction that causes oxidative stress has been linked to ALS pathogenesis [13], and markers of oxidative stress, such as 3-nitrotyrosine (3-NT) [14,15] and 8-hydroxy-2′-deoxyguanosine (8-OHdG) [16], are reportedly upregulated in the tissue of patients with ALS [17]. As the disease progresses, nutritional deficiency, cachexia, psychological stress, and impending respiratory failure become evident in ALS, which may be associated with a further increased oxidative stress [18]. EPI-589, also known as (R)-troloxamide quinone, is an orally available, blood-brain barrier–penetrable small-molecule designed as a novel redox-active agent to facilitate catalytic activity on oxidative stress control and mitochondrial energy metabolism. EPI-589 was more potent than edaravone in protecting the cells in an oxidative stress and mitochondrial dysfunction model [19,20]. In wobbler mice experiments, EPI-589 revealed dose-dependent effects to slow motor function deterioration [20,21]. Moreover, nonclinical study results revealed that EPI-589 had effects on 8-OHdG and neurofilament [20]. Given the apparent oxidative stress and mitochondrial dysfunction involvement in ALS pathogenesis, EPI-589 may hold promise as a potential therapeutic agent. In a phase 1 study, EPI-589 at 1500 mg per day was well-tolerated [22]. An early phase 2 trial (ClinicalTrials.gov identifier NCT02460679) revealed that EPI-589 at 500 mg twice daily was safe and well-tolerated with effects on disease progression in patients with ALS. However, the modes of action of EPI-589 for ALS remain unclear, and thus, further analysis is needed to elucidate its effects. Herein, we planned an early phase 2, single-arm, open-labeled exploratory trial of EPI-589 (EPI-589 Early Phase 2 Investigator-Initiated Clinical Trial for ALS [EPIC-ALS]). The primary objective of EPIC-ALS is to evaluate the safety and tolerability of EPI-589 at 500 mg 3 times daily for patients with ALS. The exploratory objectives are to monitor clinical course when receiving EPI-589 and to explore plasma, cerebrospinal fluid (CSF), and magnetic resonance imaging (MRI) results for potential EPI-589 biomarkers. An important characteristic of EPIC-ALS is the evaluation of multiple biomarker measurements in parallel with clinical assessment before, during, and after the intervention in patients with ALS. Here we provide an outline of the clinical trial protocol of EPIC-ALS version 1.0, which was prepared on July 29, 2021.

Methods

Study Setting

This investigator-initiated, open-labeled, multicenter, single-arm, and early phase 2 exploratory trial is designed to assess the safety and tolerability. Preliminary efficacy including clinical assessments and biomarkers of EPI-589 will be evaluated in patients with sporadic ALS. Patients will be recruited from the following ALS centers in Japan: Tokushima University Hospital, Aichi Medical University Hospital, and Osaka University Hospital. The total trial duration for each patient is 40 weeks, composed of 12-week run-in, 24-week treatment, and 4-week follow-up periods.

Eligibility Criteria

Patients' inclusion and exclusion criteria are depicted in Textbox 1. Patients will be assessed for the inclusion criteria 1-9, 11, and 12 at screening, 10 and 11 at the run-in period enrollment,

XSL•FO
RenderX

and 11 again at the treatment period enrollment. Patients will need to meet none of the exclusion criteria at screening, run-in, and treatment period enrollment.

Textbox 1. Inclusion/exclusion criteria.

Inclusion criteria

1. Patient providing written informed consent to participate in this trial. (If the patient is underage at the time of consent, written consent from the patient's legal representative is required in addition to the written consent from the patient.)
2. Patient between 18 and 79 years of age (inclusive) at the time of consent.
3. Patient diagnosed with clinically definite, probable, or probable laboratory-supported sporadic amyotrophic lateral sclerosis (ALS) by the revised El Escorial criteria.
4. Onset of ALS within 1.5 years at screening.
5. Patient with mean monthly progression rate (calculated as follows: mean progression rate = [score at screening − score at onset]/time from onset to screening [expressed as the number of months rounded to one decimal place]) faster than −0.3 calculated based on Amyotrophic Lateral Sclerosis Functional Rating Scale–Revised (ALSFRS-R) total scores during the period from onset to screening (score at onset 48).
6. Patient whose score for each of the first 9 questions of ALSFRS-R is ≥2 points at screening.
7. Patient whose score for each of the 3 respiration-related questions (dyspnea, orthopnea, and breathing insufficiency) of ALSFRS-R is 4 points at screening.
8. Patient whose score for the swallowing-related question of ALSFRS-R is ≥3 points at screening.
9. Patient whose % slow vital capacity is ≥80% at screening. (A predicted value for % slow vital capacity was calculated using the equation of Baldwin et al [23].)
10. Patient on riluzole must be on a stable dose and regimen for at least 30 days prior to enrollment in the run-in period.
11. Patient who is able to visit the trial site as an outpatient.
12. Patient who agrees to provide blood sample to be used for genetic analysis.

Exclusion criteria

1. Patient who has concurrent or a history of clinically significant severe disease besides ALS and who is considered by the principal investigator or subinvestigator ineligible for the trial.
2. Patient who has concurrent psychiatric disorder, cognitive disorder, or Parkinson disease.
3. Patient who has undergone tracheostomy.
4. Patient who has used a noninvasive respiratory support device.
5. Patient who has a history of or concurrent drug allergy or severe allergic disease (eg, anaphylactic shock).
6. Patient with concurrent or a history (≤5 years before informed consent) of malignant tumor.
7. Patient from whom cerebral spinal fluid cannot be collected.
8. Patient who is unable to undergo magnetic resonance imaging (including diffusion tensor imaging and magnetic resonance spectroscopy).
9. Patient whose aspartate aminotransferase and alanine aminotransferase levels at screening are ≥3 times higher than the upper limit of normal.
10. Patient whose creatinine kinase at screening is ≥2.5 times higher than the upper limit of normal.
11. Patient whose estimated glomerular filtration rate at screening is <45 mL/min/1.73 m^2.
12. Patient who is or who may be pregnant or who is breastfeeding.
13. Patient who or whose partner wishes to be pregnant or who does not agree to use adequate contraceptive methods during the period from informed consent to 30 days after the final dose of the investigational drug.
14. Patient who has used edaravone within 30 days before the enrollment in the run-in period.
15. Patient who has changed the dosing regimen of riluzole or who has discontinued the use of riluzole later than the date of informed consent.
16. Patient who has previously received EPI-589.
17. Patient who participated in another clinical trial before the provision of consent for this trial and received another investigational drug within 30 days before consent for this trial (or within 5 times the half-life of another investigational drug if 5 times the half-life of another investigational drug is longer than 30 days) or patient who is participating or scheduled to participate in another clinical trial at the time of consent for the present trial.
18. Patient who has received cell therapy or gene therapy before provision of informed consent.
19. Patient who is, in the opinion of the principal investigator or subinvestigator, unsuitable to participate in this trial.

XSL•FO
RenderX

Interventions

Patients will be administered EPI-589 at 500 mg (2 tablets of 250 mg) 3 times daily at least 60 minutes before meals during the 24-week treatment period. Based on the previous phase 1 results [22], when administered under fed conditions, the C_{max} decreased to 62.6% of the C_{max} under fasting conditions. Area under the curve was comparable between the fasted and fed states. Therefore, the timing of administration was decided "before meals" to maximize the exposure. Sumitomo Pharma Co., Ltd. will provide EPI-589 free of charge. Eligible patients should be on a stable dose of riluzole. Patients will be prohibited from the concomitant use of drugs with antioxidant potential, including edaravone, coenzyme Q10, and minocycline, as well as other potentially effective ALS drugs and therapies to evaluate the effects of EPI-589 on oxidative stress (Multimedia Appendix 1).

Outcomes, Patient Timeline, and Data Management

Trial assessments and procedures per visit are presented in Multimedia Appendix 2. Genetic analysis, including C9orf72 repeat expansion and whole-exome sequence, will be performed to avoid confounding due to genetic effects. Genetic analysis for C9orf72 repeat expansion will be evaluated at Tokushima University, whereas the whole-exome sequencing will be conducted at TAKARA Bio Inc.

The clinical course will be assessed by the change in Amyotrophic Lateral Sclerosis Functional Rating Scale–Revised (ALSFRS-R) scores, as well as by the mean change rate of ALSFRS-R scores per month, time to death, tracheostomy, whole-day use of noninvasive positive pressure ventilation, and physical findings. Variations in ALSFRS-R scores between assessors may be minimized by having each assessor master the scale in advance through a training program. Physical findings include slow vital capacity, manual muscle test total score, grip strength, the modified Norris scale total score, and the Amyotrophic Lateral Sclerosis Assessment Questionnaire-40 (ALSAQ-40) total score.

The safety will be evaluated by adverse events, laboratory tests, vital signs, 12-lead electrocardiogram, and the Columbia-Suicide Severity Rating Scale. To rule out any contraindication for receiving EPI-589, laboratory tests will be performed by a local laboratory, along with urinalysis and urine pregnancy tests.

The biomarkers in plasma and CSF were set to analyze the effect on oxidative stress (8-OHdG and 3-NT), neuronal damage (neurofilament light chain [NfL] and phosphorylated neurofilament heavy chain [pNfH]), and others such as ornithine, creatinine, and homocysteine. Plasma biomarkers are 8-OHdG, 3-NT, NfL, pNfH, homocysteine, and creatinine. CSF biomarkers are 8-OHdG, 3-NT, NfL, pNfH, and ornithine. Plasma and CSF samples will be immediately centrifuged after collection at 3000 rpm (1750*g*) for 10 minutes at 4°C and stored at −80°C at each site. The samples will be gathered and analyzed at a laboratory center.

The MRI data will be obtained with a 3.0-Tesla scanner at each site (Tokushima University Hospital and Osaka University Hospital, GE Healthcare; Aichi Medical University Hospital, Siemens Healthineers). The sequences will consist of T2-weighted imaging, 3D T1-weighted imaging, diffusion tensor imaging (30 motion probing gradient directions, b=1000 s/mm^2), and magnetic resonance spectroscopy (MRS) obtained with point-resolved spectroscopy with short and long echo time (30 and 135 ms, respectively) in the bilateral primary motor area, with a total scan time of less than 30 minutes for each patient. Optional sequences will include synthetic MRI with magnetic resonance image compilation and chemical exchange saturation transfer echo-planar imaging in the primary motor area. The imaging acquisition parameters were standardized beforehand (Multimedia Appendix 3). Anonymized MRI data will be sent to the Imaging Review Committee at Tokushima University. MRI biomarkers are diffusion tensor imaging–derived fractional anisotropy and apparent diffusion coefficient in the corticospinal tract; cerebral cortex parameters derived from 3D T1-weighted imaging; and *N*-acetylaspartate adjusted by creatine, choline, or creatine + choline measured by MRS in the primary motor area [24]. MRI biomarker values will be harmonized across the 3 institutions using healthy control MRI data obtained in an ancillary multicenter study.

Data will be abstracted into standardized data collection forms at patient enrollment. The ALSFRS-R will be assessed every 4 weeks through this trial. Clinical parameter assessments, including the manual muscle test, grip strength, modified Norris scale, and ALSAQ-40, are set to be evaluated at visits 2, 3, 6, and 9, where plasma biomarkers at visits 2, 3, 6, 9, and 10; CSF and MRI biomarkers at visits 2, 3, and 9; and optional MRI biomarkers at visits 6 and 10 will be collected and evaluated. Data will be monitored and audited by an independent contract research organization (CMIC Co., Ltd.).

Severe adverse events (SAEs) will be reported by the investigator within 24 hours of awareness by telephone, fax, email, or written document. As the secondary reporting, "SAEs reporting" will be submitted within 7 days of the investigator's awareness if detailed information is not included in the primary reporting. However, in case of an adverse reaction that should be reported to the regulatory authority within 7 days, care should be taken to obtain information within the period for reporting to the regulatory authority. The Safety Monitoring Board will review data on SAEs. The Safety Monitoring Board is an organization independent of the trial representative, coordinating investigator, investigators, subinvestigators, or contract research organization, and has authority to recommend the discontinuation of the study if there is any safety concern. The investigator, after consultation with the coordinating investigator, will seek advice from the Safety Monitoring Board about the continuation or discontinuation of the study as needed and determine measures to be taken. If an SAE (eg, death or a life-threatening event) is observed, for which a causal relationship with the investigational drug cannot be ruled out, enrollment will be suspended and a review of the Safety Monitoring Board will be sought.

The coordinating investigator will terminate or interrupt the entire trial in the following cases: (1) death or a life-threatening SAE, for which a relationship with the investigational drug cannot be ruled out, occurs (patient enrollment should be suspended in this case); (2) following the Safety Monitoring

XSL•FO
RenderX

Board's recommendation on the termination or interruption of the entire trial, the coordinating investigator judges that the entire trial should be terminated or interrupted; (3) the Institutional Review Board recommends that the entire trial should be terminated or interrupted; (4) a change is made to the development policy of the coordinating investigator; (5) the regulatory authority recommends the termination of the trial; (6) any other situations, where partial or complete termination or interruption of the trial is needed, occur.

Telephone Survey

Telephone-based assessment will be permitted for the evaluation of adherence, ALSFRS-R score, events, tracheostomy, concomitant medications and therapies, and adverse events at visits TEL1, TEL2, 5, 7, or 8 because the ALSFRS-R telephone-based assessment was shown as reliable as in-person visits [25,26]. However, the telephone-based assessment will be used only in a state of emergency, including the COVID-19 pandemic, other infection pandemics, natural disaster, and terrorism, to ensure patient safety. Consecutive telephone-based assessment is prohibited.

Sample Size and Recruitment

Based on the results of the previous early phase 2 trial (NCT02460679), and also in light of the feasibility of this study, 10 patients were selected as the target sample size. Information on this trial will be disseminated via press coverage and websites to achieve timely adequate patient enrollment.

Statistical Analysis

The primary analysis, based on intention-to-treat principles, includes the full analysis set (FAS) including patients who received at least one dose of the investigational product and had a baseline measurement and at least one postbaseline measurement of efficacy endpoints or biomarkers, regardless of any protocol deviation. The secondary analysis includes the per-protocol set excluding patients with medication compliance of less than 70%, patients whose dosing period was less than 8 weeks, and patients with an important protocol deviation from FAS. The analysis with the per-protocol set is performed as a sensitivity analysis that confirms the consistency of FAS results. All patients who received EPI-589 are included in the safety analysis.

Changes of 20%-25% or greater in the ALSFRS-R slope would be a clinically meaningful effect [27]. Based on the finding, responders are defined as patients with an improvement in the rate of declined ALSFRS-R total score by 30% compared with the rate in the run-in period. The detailed definition of responders is presented in the following section.

> [The mean change of ALSFRS-R total score per month in the treatment period (each visit) – The mean change of ALSFRS-R total score per month in the run-in period]/|The mean change per month of ALSFRS-R total score in the run-in period| × 100 ≥30%.

The proportion of responder and CI will be calculated for each visit. In addition, a Z-test will be performed for the binomial proportion assuming a 10% threshold for the proportion of responders. However, patients with no change or increase in the ALSFRS-R total score in the run-in period will be excluded from this analysis. A total of 10 patients with a 2-sided α of .1 will provide more than 80% power to reject the null hypothesis (the proportion of responders equals 10%) based on a previous clinical trial (NCT02460679).

The mean ALSFRS-R changes per month will be compared between the run-in and treatment periods using the paired *t* test. In addition, the mixed model will be used to compare the ALSFRS-R slope between the run-in and treatment periods. Some evidence suggested that functional decline may not be linear [28-30]; however, a previous open-label 24-week extension study revealed that ALSFRS-R scores changed almost linearly from baseline through 48 weeks in the edaravone treatment group [8]. The change from baseline and the change per month for all continuous efficacy endpoints will be descriptively summarized at each visit and compared between the run-in and treatment periods using the paired *t* test. The number and percentage of patients with each outcome will be summarized by visit for parameters with categorical outcomes. Time to event since the first dose of the study drug will be analyzed by the Kaplan-Meier method and plotted by the Kaplan-Meier curve. The statistical significance will be set at a 2-sided level of .1. All analysis will be conducted using SAS software (version 9.4 or higher; SAS Institute Inc.).

We will also provide a list of adverse events, the number of patients completing the study, the CONSORT (Consolidated Standards of Reporting Trials) flow diagram, and the mean changes from baseline in the biomarkers. Individual data trajectories in a panel plot will also be made.

Patient and Public Involvement

Patients or the public were not involved in the design, conduct, reporting, or dissemination plans of our research.

Ethics Approval and Dissemination

This trial was approved by the Institutional Review Board of Tokushima University Hospital in August 2021 (approval number 2125 [03-10]), Aichi Medical University Hospital in October 2021 (approval number 202115), and Osaka University Hospital in November 2021 (approval number 219005-A) based on the Declaration of Helsinki, Good Clinical Practice, and associated Japanese regulations. The protocol has been approved by the Japanese regulatory authority Pharmaceuticals and Medical Devices Agency before the commencement of the trial. This trial was registered at the Japan Registry of Clinical Trials (JRCT ID: jRCT2061210031; registered on August 27, 2021 and last modified on July 25, 2022). Substantial amendments of the protocol must be approved by each institutional review board. Written informed consent will be obtained from all potentially eligible patients after the investigators provide a detailed explanation. Personal information about potential and enrolled patients will be masked to protect confidentiality before, during, and after the trial. If health injury (eg, adverse drug reaction) occurs in the patient in association with this trial, the head of the trial site will follow necessary procedures including provision of adequate medical care to the patient. For death/physical impediment that is within the scope of

XSL•FO
RenderX

compensation, compensation will be paid in accordance with the terms and conditions of a clinical trial insurance contract. Compensation will not be paid if the health injury is not related to the trial or is caused by the patient's intentional misconduct or gross negligence or the protocol treatment has no beneficial effects. This trial received funding from Sumitomo Pharma Co., Ltd.

Results

This trial began data collection in September 2021 and is expected to be completed in October 2023. The ancillary study to obtain healthy control MRI data has been approved by the Ethics Committee of Tokushima University Hospital (approved on May 31, 2021; No. 3997), the Aichi Medical University School of Medicine Ethical Review Board, and the Osaka University Research Ethics Committee. The principal and coordinating investigators (YI and KF) will have access to the final trial data set. The results will be disseminated by presentations at scientific meetings and published in a peer-reviewed scientific journal.

Discussion

The pathogenic processes that underlie ALS remain unclear; however, accumulating evidence suggests that oxidative stress and mitochondrial dysfunction may play a pivotal role [4]. Oxidative stress is typically defined as an imbalanced production of free oxygen radicals, reactive oxygen species (ROS), or reactive nitrogen species. The mitochondrial wall contains the respiratory chain, which consumes 85%-90% of the total oxygen that is consumed by the body, but also produces the highest ROS levels in the cell due to electrons that escape from the respiratory chain and oxygen molecules that are incompletely reduced in aerobic metabolism [1]. Neurons are particularly susceptible to damage from oxidative stress for the following reasons [31]. First, neurons are remarkably large cells with large metabolic and high oxygen demand causing increased ROS production [32-34]. Second, motor neurons express relatively low calcium-binding protein levels. Thus, excess calcium ions tend to enter the mitochondria, leading to increased ROS production [35,36]. Third, some protective antioxidant protein expression is lower in motor neurons than in other cell types [37,38]. Patients with familial and sporadic ALS have elevated oxidative damage biomarkers in the spinal cord and motor cortex, mostly in large ventral horn motor neurons [14,39-41].

Edaravone is an antioxidant drug that is approved for ALS, which improves motor functions or oxidative stress in mutant SOD1 transgenic mice and rats and patients with ALS [6,42-46]. Edaravone reacts with oxidative radicals by an electron transfer reaction that consumes edaravone anion, which is converted to edaravone radical. Edaravone radical is transformed into 4,5-dione via edaravone peroxyl radicals with molecular oxygen reaction, followed by hydrolysis, to afford 2-oxo-3-(phenylhydrazone)-butanoic acid [47]. Edaravone increases nuclear factor erythroid 2–related factor 2 (Nrf2) expression, an oxidative stress inhibitor [48]. The overexpression of Nrf2 in astrocytes significantly delayed the onset and extended the survival in the SOD1-G93A mouse model of ALS [49]. Nrf2 overexpression in astrocytes reversed SOD1-G93A toxicity and protected the motor neurons from neurodegeneration in the SOD1-G93A mouse model [49]. In humans, edaravone significantly reduced the oxidative stress biomarkers, including 3-NT, in CSF of patients with ALS at an early stage [46]. However, edaravone has a limited effect, thus more effective drugs are urgently needed.

EPI-589 offers an effective novel antioxidant for ALS with advantages in drug delivery because it is orally bioavailable and is a small-molecule catalyst with high blood-brain barrier permeability. Previous studies revealed antioxidant reactions of the reduced EPI-589 form in the cell-free system. Moreover, EPI-589 is expected to not be hydrolyzed when scavenging radicals and to preserve the repeated catalytic activity. *In vitro* studies have revealed EPI-589 as more protective of cell viability against oxidative stress than edaravone (approximately 1000 times more potent with a difference in half maximal effective concentration for fibroblast cells derived from patients with ALS with FUS c.1566G>A mutation and SOD1 E50K mutation) [19,20].

A phase 1 trial in healthy participants (jRCT2071210022) [22] revealed that EPI-589 was safe and well-tolerated as a single daily dose of up to 1000 mg. In addition, EPI-589 was safe and well-tolerated when participants received 750 mg 2 times daily (1500 mg per day) in the multiple-dose part. In a phase 2 open-label trial (NCT02460679), 19 patients with ALS received EPI-589 500 mg 2 times daily. As in the phase 1 studies, no EPI-589–related SAEs were observed and most adverse events were mild or moderate. In our trial, we set the dose of EPI-589 to 500 mg 3 times daily because 1500 mg per day is the maximum daily dose used in the previous phase 1 study. Although EPI-589 500 mg 2 times daily showed possible efficacy on ALS progression in a phase 2 open-label trial (NCT02460679), given that the terminal elimination half-life of EPI-589 is relatively short [22], dosing 3 times a day rather than 2 times a day is preferable to maximize the efficacy.

EPI-589 slowed the symptomatic and pathophysiological progression of the wobbler mouse motor neuron disease model, with a higher effect than edaravone or riluzole [20,21,50]. Moreover, the disease-modifying effect was higher in the concomitant use of EPI-589 and riluzole than a single use of EPI-589 [20,50]. Thus, patients with concomitant use of riluzole were considered eligible for this trial.

We planned to monitor potential biomarkers throughout the trial duration to gain insight into the modes of action of EPI-589 in human patients. EPI-589 acts as a redox-active protectant against oxidative stress under experimental conditions relevant to ALS. Therefore, we will analyze the oxidative stress biomarkers (8-OHdG and 3-NT) as well as neuronal damage biomarkers (NfL and pNfH) [51] in plasma and CSF to obtain robust data to support this concept. We will evaluate other relevant factors, including ornithine in CSF and creatinine and homocysteine in plasma. Of these, plasma 3-NT, which reflects peroxynitrite-mediated oxidative damage, has been studied in multiple sclerosis [52] and Parkinson disease [53] but not in ALS. Moreover, prior studies revealed that a wobbler mouse model had a significantly increased plasma pNfH and decreased

XSL•FO
RenderX

N-acetylaspartate level on MRS in the spinal cord compared with the wild type; EPI-589 administration improved these biomarkers [20]. These results suggest the effect on motor neurodegeneration, thus we set to evaluate *N*-acetylaspartate in the primary motor area. In addition, previous reports showed longitudinal changes in fractional anisotropy in the corticospinal tract that correlated with the slope of ALSFRS-R [54,55]. Therefore, we will assess fractional anisotropy in the corticospinal tract.

This trial has a couple of limitations. First, the trial size is relatively small. Second, this is an open-labeled, single-arm trial. Instead of a placebo, the 12-week run-in period will be used as control. As the primary objective of this trial is to evaluate safety and tolerability, placebo-controlled trials will be needed to confirm the efficacy.

In summary, this trial will evaluate the safety and tolerability of EPI-589 in combination with longitudinal changes in clinical parameters and biomarker candidates of plasma, CSF, and MRI. Data of the multiple biomarkers will help assess the modes of action of EPI-589 on ALS. This pilot trial will provide insights into the variability of efficacy endpoints and the feasibility of the next large randomized controlled trial.

Acknowledgments

This work was supported by Sumitomo Pharma Co, Ltd (Osaka, Japan). Sumitomo Pharma Co, Ltd supported to prepare the protocol and will provide the investigational drug under the agreement. This work was partly supported by Grants-in-Aid from the Research Committee of CNS Degenerative Diseases, Research on Policy Planning and Evaluation for Rare and Intractable Diseases, Health, Labour and Welfare Sciences Research Grants, and the Ministry of Health, Labour and Welfare, Japan. Abstract

Background: Road traffic injuries (RTIs) are a leading cause of death and unintentional injuries globally. They claim 1.35 million lives and produce up to 50 million injuries each year, causing a major drain on health systems. Despite this high burden, there is a lack of robust data on the long-term consequences of RTIs, specifically the level of disability experienced by many survivors and its impact on their everyday lives.

Objective: This study aims to characterize RTIs, disability level, and related consequences affecting adult road traffic crash survivors in 5 low- and middle-income countries (LMICs). In addition, this study estimates the role of demographic and crash- and treatment-related factors in predicting adverse outcomes and disability as well as examining the disability level among patients with RTIs, likelihood of return to normal life, and the environmental factors that may influence these outcomes after discharge from the hospital.

Methods: This prospective observational study was conducted at selected hospitals in Bangladesh, Cambodia, Ethiopia, Mexico, and Zambia. The study sample included all adult patients with RTIs admitted to the hospital for at least 24 hours. Consecutive sampling was performed until the minimum required sample size of 400 was reached for each participating country. Data were collected from patients or their caregivers using a hospital-based surveillance tool administered at the participating sites as well as a telephone-based follow-up instrument administered 1, 3, and 6 months after discharge. Descriptive analysis and multivariate models will be used to estimate the contribution of a range of factors in predicting adverse outcomes, disability, and return to normal life.

Results: Enrollment began in June 2021 and was completed in April 2022. Follow-up data collection ended in September 2022. Data analysis is currently underway, with results expected for publication in mid-2023. Expected results include estimates of disability among patients with RTIs as well as identifying the predictors of adverse outcomes, disability, and the likelihood of return to normal life.

Conclusions: Research findings will help better understand the long-term burden of disability from RTIs in the 5 LMICs and the challenges facing survivors of road traffic crashes. They will be used to inform interventions aimed at improving the health care, social, physical, and policy conditions in LMICs that can facilitate recovery and rehabilitation for patients with RTIs, reduce the burden of disability, and enhance their participation in society.

Introduction

Background

Road traffic crashes are a leading cause of trauma admissions in hospitals worldwide [1-3]. They claim 1.35 million lives and cause up to 50 million injuries each year, causing a major burden on health systems and other services [4]. According to the Global Burden of Disease Study, between 1990 and 2019, road traffic injuries (RTIs) were among the top 10 contributors to the increase in global disability adjusted life years (DALYs) [5]. In 2019, RTIs ranked seventh among the leading causes of global DALYs for all age groups and first for people aged 10 to 49 years [5].

Despite some recent improvements in global road safety, there have been persistent disparities in the burden of RTIs across world regions [4,6]. In 2019, RTIs accounted for 3.8% of the total deaths in Africa, 3.0% in the Eastern Mediterranean, 2.4% in South-East Asia, 2.3% in the Western Pacific, 2.2% in the Americas, and 0.8% in Europe [6]. In addition, RTI-induced death and disability are disproportionately higher in low- and middle-income countries (LMICs) than in high-income countries [6]. As in many other aspects of health, disparities exist in the risks and consequences affecting people with RTIs. For example, RTIs are the leading cause of death among children and young adults aged between 5 and 29 years [7]. They disproportionately affect males aged <29 years, who are far more likely to be involved in road crashes compared with females, and people from lower socioeconomic backgrounds have a higher likelihood of RTI-induced death and injury [7]. Other risk factors include driving speed; vulnerability of road users (eg, pedestrians and motorcyclists); nonuse of safety equipment (ie, motorcyclist helmets, seatbelts, and child seats); distracted driving; driving under the influence of alcohol or drugs; unsafe road infrastructure; unsafe vehicles; inadequate enforcement of traffic laws; and inadequate postcrash care [7]. These risk factors not only increase the likelihood of a road traffic crash but are also linked to the characteristics and impact of RTIs themselves. This research landscape on road traffic crashes in LMICs demonstrates important associations between crash circumstances and the consequences of RTIs. Studies have shown that crash circumstances (eg, method of transportation to the hospital, type of road user, alcohol use, and type of vehicle) are associated with morbidity and mortality after an RTI [8-13].

Research findings on RTI-induced disabilities demonstrate a high prevalence of disability among patients with RTIs in LMICs and highlight marked disparities in the experiences of injury, disability, and socioeconomic impact linked to sociodemographic, crash, and injury characteristics of patients with RTIs [10,12,14-18]. Despite their burden, many LMICs lack reliable and high-quality surveillance data on RTIs [4,19]. Only 66% of middle-income countries and 74% of low-income countries have trauma registry systems [20]. Surveillance data on the rate and severity of RTI-induced disabilities are also lacking in LMICs [4]. In addition, differences in methodologies and approaches to disability measurement underscore the continued need for more data to understand the consequences of RTIs beyond initial clinical outcomes [10,12,21,22]. The World Health Organization International Classification of Functioning, Disability, and Health framework defines disability as the interaction between a health condition (ie, an injury, disease, or disorder) and contextual factors, which include both personal and environmental factors. According to the International Classification of Functioning, Disability, and Health, environmental factors have a direct effect on disability outcomes caused initially by health conditions [23]. However, little is known about the impact of environmental barriers on the functioning of patients with RTIs after the initial treatment. Thus, a thorough understanding of disability after receiving trauma care is necessary to understand the extent to which environmental factors, such as access to medical and rehabilitation services, social support, and the physical environment, contribute to the recovery of patients with RTIs and the severity of their disability.

Goal of This Study

The primary goal of this study is to develop a clear understanding of RTIs and their consequences in LMICs to inform advocacy actions and policies. The specific aims of this study are to describe the characteristics and initial treatment outcomes of RTIs; estimate the role of demographic, crash-related, and treatment-related factors in predicting injury severity and disability-related outcomes; and estimate the impact of environmental barriers on the level of disability experienced by patients with RTIs after hospital discharge. Our study focuses on measuring constructs within disability (activities and participation) as well as the environmental barriers that may affect them to generate the evidence needed to inform interventions and policies that address the specific needs of patients with RTIs after treatment.

Methods

Study Design and Settings

This prospective observational study was conducted at 9 selected hospitals in Bangladesh, Cambodia, Ethiopia, Mexico, and Zambia (Table 1). According to the Global Burden of Disease report, the 2019 death rate (per 100,000) due to RTIs was 5.41 in Bangladesh, 17.53 in Cambodia, 8.56 in Ethiopia, 16.89 in Mexico, and 12.53 in Zambia [24]. By contrast, the number of DALYs per 100,000 lost due to nonfatal injuries was 549.61 in Bangladesh, 1006.57 in Cambodia, 546.35 in Ethiopia, 945.19 in Mexico, and 768.33 in Zambia [24].

University Teaching Hospital	Lusaka	2,524,000

[a]On the basis of 2018 United Nations, Department of Economic and Social Affairs population estimates for metropolitan areas (Dhaka and Cuernavaca), urban agglomerations (Phnom Penh and Lusaka), and cities proper (Addis Ababa and Kyiv) [25]. Axochiapan, Cuautla, and Temixco (Mexico) populations are based on 2020 estimates from the National Institute of Statistics and Geography (INEGI) [26].

Countries were selected to include representation in each region of the world where the World Bank operates, although we were unable to include a site from the Middle East and North Africa. Ukraine was originally selected as the site for Europe and Central Asia; however, we could not include it in the study because of the current conflict affecting the country. Hospitals were identified and selected based on previous research collaborations between national research teams and the study authors. Where possible, hospitals that were designated as trauma centers or that were present in large urban centers were prioritized. Some countries have included >1 hospital to achieve the desired sample size.

Eligibility Criteria

The study population included adults (aged ≥18 years) of either sex admitted to the hospital because of a moderate to severe RTI, which is defined as the injury being severe enough to require hospitalization for at least 24 hours. Study participants included patients admitted to the emergency department as well as other relevant hospital departments or units (eg, neurosurgical or orthopedic surgery units). Participants were able to give consent or had a suitable proxy who gave consent on their behalf if they were unable to do so. Individuals were excluded from the study if they were aged <18 years, were discharged <24 hours after being admitted to the hospital, or were unable to communicate verbally and did not have a proxy.

Study Sample

For the hospital surveillance portion of the study, we estimated the proportion of moderate to severe injuries in the target population of patients with RTIs. The required sample size for each country was calculated using the following equation:

$$n = p \times (1 - p) \times (z / e)^2 \textbf{(1)}$$

where n is the sample size required for a large population, p is the proportion of the population sustaining severe injuries from a road traffic crash, z is the confidence level, and e is the margin of error. p is based on the estimate that 30% of the adult study population may sustain moderate to severe injuries from road traffic crashes according to studies in LMICs [10,12,21]. z is defined as 1.96 (for a 95% confidence level [α]) and e at 5%. With these considerations, the sample size is calculated to be 323, which indicates that this is an adequate sample size for estimating the proportion of moderate to severe injuries from the total population of patients with RTIs in participating hospitals. Given the sample size calculations and accounting for 20% of the combined refusal and attrition, a minimum target sample size of 400 was set for each participating country. Consecutive sampling was done such that every patient who met the inclusion criteria was selected until the required sample size was reached at the participating hospital or hospitals in each country.

For the disability portion of the study that follows the recruited patients with RTI at 3 time points within 6 months after discharge, the sample included those patients who were identified at the first follow-up. Using α value of 0.05, a sample of 320 (based on 20% loss to follow-up 6 months after discharge), and a 0.5 baseline measure adjustment (correlation of repeated measures), the study has 99% statistical power to

XSL•FO
RenderX

detect a 0.3 SD difference in the mean disability score between patients without a supportive environment (ie, those who report facing environmental barriers) compared with those with a supportive environment.

Recruitment and Data Collection

Overview

Patients were screened for inclusion and exclusion criteria by the data collectors at each facility at the following two points: (1) upon arrival at the emergency department and (2) at discharge from any department of the hospital. This allowed us to capture patients who came directly to the hospital, as well as patients who were transferred from other facilities and bypassed the emergency department.

Two instruments that were used for data collection are a hospital-based RTI surveillance tool and a follow-up disability-related assessment questionnaire (Table 2). The hospital-based RTI surveillance tool includes the following: (1) general patient information, (2) prehospital care, (3) RTI details, (4) initial clinical assessment and care provided, (5) disposition, (6) payment information, and (7) disability history.

Table 2. Data collection instruments.

Instrument	Content	Data source	Data collection method	Data collection time points
Hospital-based RTI[a] surveillance tool	Sociodemographic characteristics, crash circumstances, prehospital care provided, clinical assessment, and disposition	Medical records	In-person	During hospital stay
Hospital-based RTI surveillance tool	Cost or payment information and history of disability	Patient or proxy interview	In-person	During hospital stay (day of discharge)
Disability assessment and environmental factors tool	Demographic characteristics, activity limitations, participation restrictions, use of or need for assistive devices, perceived return to preinjury activities, and environmental factors	Patient or proxy interview	Phone-based	1, 3, and 6 months after discharge

[a]RTI: road traffic injury.

The disability follow-up questionnaire consists of 3 modules. Module A includes selected questions from the short form of the World Health Organization Disability Assessment Survey 2.0 (WHODAS 2.0), which is a general disability instrument that measures limitations in performance in 6 life domains that are understanding and communicating, getting around, self-care, getting along with people, life activities, and participation in society [27]. Module B includes questions pertaining to returning to normal life and work and questions about assistive devices. Module C, which was administered only at 3- and 6-month follow-up time points, includes selected questions from the short form of the Craig Hospital Inventory of Environmental Factors (CHIEF) version 3 [28]. CHIEF measures perceived physical, social, and political barriers to societal participation for people with disabilities [28].

Informed consent was obtained from the patients (or proxy) in the hospital for enrollment in the study. Both study instruments were pretested with 5 to 7 patients in each participating country before the start of data collection.

Hospital-Based Data Collection

As part of RTI hospital surveillance, data was collected by obtaining information from the patient's medical record and by conducting interviews with the patient (or caregiver) directly. We aimed to extract the following information from the medical record, depending on the availability (Textbox 1): sociodemographic information (age, sex, education, employment status, current partnership status, total number of persons living in household, and annual household income); prehospital care (if care was provided, by whom, type of care provided, mode of arrival at hospital, and transport time to hospital); RTI details (type of road, type of vehicle, mobile use, counterpart, and safety equipment use); and initial clinical assessment and care provided (vital signs, initial Glasgow Coma Scale, suspected alcohol and drug use, treatment, region of injury, pathology, operation, and number of days in the intensive care unit). We collected the following information through patient (or proxy) interviews: payment information (if a fee was paid, amount paid, type of service paid for, hospitalization cost, means of payment, and annual household income) and disability history (if the patient had a disability before RTI, severity of the disability, and domains affected by the disability). We also attempted to gather data from the patient or proxy if it was missing in the medical records, as appropriate.

XSL•FO
RenderX

Textbox 1. Variables from hospital-based surveillance tool.

Sociodemographic variables

- Age group in years (18-24, 25-44, 45-64, 65-74, and >75)
- Sex (male or female)
- Educational level (no formal education, primary, secondary, college or university, professional, graduate, vocational or technical, and other)
- Employment status (daily-wage laborer, salary worker, self-employed, military, homemaker, student, retired, beggar, unemployed, unable to work, and other)
- Partnership or marital status (currently married, cohabiting, separated, divorced, widowed, and never married)
- Number of persons in household
- Annual household income (local currency)

Prehospital care variables

- Care provided at scene (yes, no, or unknown)
- Who provided care (person involved, bystander, relative, friend, police, ambulance staff, emergency medical technician, unknown, and other)
- What care was provided (C-spine immobilization, fracture immobilization, control of bleeding, wound care, Cardiopulmonary Resuscitation, intravenous fluids, and other)
- Mode of arrival to hospital (walk-in, auto-rickshaw, car, ambulance, taxi, motorized 2-wheeler, and other)
- Transport time to hospital (0-30 min, 30 min-1 hour, 1-2 hours, 2-6 hours, 6-24 hours, and >24 hours)

Crash characteristics (road traffic injury [RTI] details)

- Time of injury (day, evening, and night)
- Type of road (highway, main road, side street, village road, and other)
- Type of road user (pedestrian, driver, passenger, and other)
- Type of vehicle (car, minibus or van, bus, bicycle, motorcycle, truck or lorry, auto-rickshaw, and other)
- Mechanism of injury of pedestrian (boarding or exiting bus, boarding or exiting other vehicle, standing or walking on side of road, and crossing the road)
- Counterpart (car, minibus or van, bus, animal, auto-rickshaw, motorcycle, bicycle, nonmotorized vehicle, truck or lorry, other, skid or rollover, fall form moving vehicle, stationary or fixed object, and other)
- Mobile phone use (yes or no)
- Safety equipment (helmet, seatbelt, and other) used (yes or no)
- Suspected alcohol use with 6 hours of RTI (yes or no)
- Suspected substance use within 6 hours of RTI (yes or no)

Hospital variables

- Physiological Assessment
  - Glasgow Coma Scale (mild 13-15, moderate 9-12, and severe 3-8)
  - Systolic blood pressure (mm Hg; <90, 90-120, and >120)
  - Diastolic blood pressure (mm Hg; <60, 60-80, and >80)
  - Pulse rate (<60, 60-90, and >90)
  - Respiratory rate (<12, 1-18, and >18)
  - Lost consciousness (yes or no)
- Patient care
  - Emergency room patient (yes or no)
  - Anatomy (anatomical region, site of most severe injury; head and neck, face; chest, abdomen, extremities, and external)
  - Number of severely injured sites (1-3)
  - Pathology (none, concussion, muscle injury, etc)
  - Treatment (none, operation, observation, antibiotics, etc)

XSL•FO
RenderX

- Operation (internal-fixation, external-fixation, laparotomy, amputation, etc)
- Intensive care unit (ICU; yes or no)
- Number of days in ICU

- Disposition
  - Disposition (died in hospital, discharged to rehabilitation, discharged to home, transferred to another hospital, absconded or left against medical advice, other, and unknown)

- Cost or payment
  - Pay fee upon arrival (yes or no)
  - Amount paid (local currency)
  - Type of service paid for (registration, medicine, x-rays, laboratory tests, blood transfusion, and other)
  - Hospitalization cost (local currency)
  - Means of payment (had money of his or her own, borrowed from family or friends, took a loan, sold assets, and other)
  - Annual household income (local currency)

- Disability history
  - Preexisting disability (yes or no)
  - Severity of disability or impairment (none, mild, moderate, severe, and extreme)
  - Life domains affected (understanding and communicating, getting around, self-care, managing domestic life, getting along with people, engaging in major life areas, and participation in society)

Follow-up Data Collection

Using participant contact information provided at the hospital, data collectors called each study participant 1 month, 3 months, and 6 months after hospital discharge to conduct follow-up interviews. Data collectors asked questions about their level of functioning using the WHODAS 2.0 short form (module A). The WHODAS 2.0, a valid and reliable instrument for several patient populations, was developed to allow for comparison across cultures based on a study spanning 19 countries [27]. The instrument consists of 36 items that ask about difficulty in performing activities in the last 30 days, scored on a 5-point Likert scale, as follows: 0=No difficulty, 1=Mild difficulty, 2=Moderate difficulty, 3=Severe difficulty, and 4=Extreme difficulty or inability to do.

WHODAS 2.0's shortened form consists of 12 items. The short form has been found to be valid and reliable among populations with RTIs in LMICs [29,30]. Scores are calculated for each subscale by adding points from each response. The minimum and maximum total scores of WHODAS 2.0 are 0 to 48, with higher scores indicating higher levels of disability [27]. Three additional questions ask about the number of days participants experienced difficulties in the past 30 days (Table 3).

Module B contains 5 questions. Two questions ask about whether the participants have returned to their preinjury activity and if they have returned to work for those previously employed. Three questions ask about the current use of assistive devices or modifications to their home, the type of equipment or modifications used, and for those reporting not using any, whether they need such assistive devices or modifications. Module C uses 12 selected questions from the CHIEF instrument [28]. This instrument has been implemented and validated in several LMICs [31-36]. The first 3 questions ask whether the participants have the same opportunities as other people to participate and take advantage of the areas of education, employment, and leisure. Nine questions ask about the barriers to participation in activities since the injury. Participants report the frequency of experiencing these barriers (ie, daily, weekly, monthly, monthly, or never). If the item occurs, participants are asked to report the magnitude of this problem (ie, big problem or small problem). The CHIEF questions used in module C were slightly modified from their original form by asking the participants to think about barriers since the occurrence of the injury rather than in the past 12 months.

XSL•FO
RenderX

Table 3. List of variables for the follow-up instrument.

Module and measures	Variables
A[a]	
Understanding and communicating (cognition)	• Difficulty in concentrating on doing something for 10 minutes • Difficulty in learning a new task
Getting around (mobility)	• Difficulty standing for long periods such as 30 min • Difficulty in walking a long distance such as a kilometer
Life activities	• Difficulty in taking care of household responsibilities • Difficulty in day-to-day work or school
Participation in society	• Difficulty in joining in community activities • How emotionally affected by health problems (response options for this item are 0=Not Affected, 1=Mildly Affected, 2=Moderately Affected, 3=Severely Affected, and 4=Extremely Affected)
Self-care	• Difficulty in washing whole body • Difficulty in getting dressed
Getting along with people	• Difficulty in dealing with people you do not know • Difficulty in maintaining a friendship
Number of days with difficulties	• Overall, in the past 30 days, how many days were these difficulties present? • In the past 30 days, for how many days were you totally unable to carry out your usual activities or work because of any health condition? • In the past 30 days, not counting the days that you were totally unable, for how many days did you cut back or reduce your usual activities or work because of any health condition?
B[b]	
Return to usual activity	• Return to normal life or usual activity (yes or no) • Return to work (yes or no)
Assistive devices	• Currently using personal equipment, special adapted devices, and or physical modifications to home (yes or no) • Type of equipment used (mobility aids, hearing aids, visual aids, communication aids, cognitive aids, physical modifications, devices for performing tasks, other) • Need for assistive devices (yes or no)
C[c]	
Having equal opportunities as other people	• Education (yes or no) • Employment (yes or no) • Recreation or leisure (yes or no)
Services and assistance barriers[d]	• Experience problem with availability of transportation • Experience problem with availability of information • Experience problem with availability of health care services • Need for help at home and not getting it easily
Attitudes or support barriers[d]	• Experience prejudice and discrimination
Work or school barriers[d]	• Experience problem with people's attitudes at school or work • Need help at school or work and did not get it easily
Policy barriers[d]	• Experience difficulty due to government programs and policies
Physical environment barriers[d]	• Experience difficulty with natural environment (temperature, terrain, climate, etc)

[a]Variables from World Health Organization Disability Assessment Survey 2.0 short form (module A). Response options: 0=No Difficulty, 1=Mild Difficulty, 2=Moderate Difficulty, 3=Severe Difficulty, 4=Extreme Difficulty or Cannot Do.

[b]Variables related to return to usual activities and assistive devices (module B).

[c]Variables from Craig Hospital Inventory of Environmental Factors (module C).

[d]Response options: 4=Daily, 3=Weekly, 2=Monthly, 1=Less than Monthly, 0=Never, Not applicable.

Data Collection Training, Storage, and Management

Data collectors were trained on the study protocols, and each local team of data collectors and data managers will conduct regular reviews of the data to identify any issues in the data collection process or data quality. The Survey Solutions software developed by the World Bank was used for data collection [37]. Survey Solutions can operate in mixed mode, and data can be collected offline on tablets (computer-assisted personal interviewing), on the web using a web interface (computer-assisted web interviewing), or via phone interviews (computer-assisted web interviewing). Data from the hospital surveillance instrument will be linked to the follow-up data through a unique participant ID. Android-based devices are used to collect, store, and transfer hospital-based and follow-up data. The collected data are transmitted to the survey headquarters for real-time quality control and analysis. The software works offline in areas with limited internet access and later synchronizes data once the internet access is available.

Ethics Approval

Ethics approval was obtained from the ERES Converge institutional review board in Zambia (reference number 2021-Jan-003), National Ethics Committee for Health Research in Cambodia (reference number 018 NECHR), the institutional review board of the Ethiopian Public Health Association (reference number OG/039/21), the Centre for Injury Prevention and Research in Bangladesh Ethical Review Committee (reference number 2021/01), and the Instituto Nacional de Salud Pública in Mexico (reference number 1729), as well as the George Washington University's Office of Human Research.

Potential participants were informed of the aims and content of the study and were required to give written, informed consent before enrollment. The participants did not receive any compensation for their participation in the study. All data collected in the Survey Solutions software for this study was deidentified.

Statistical Analysis

Overview

Stata 14 (StataCorp) will be used for the data analysis [38]. First, descriptive statistics will be generated for several variables captured in the hospital-based tool to examine the demographic, clinical, and treatment characteristics of the initial study sample. Descriptive statistics of disability-related variables collected through the follow-up survey will also be generated at each follow-up measurement occasion. Comparing the descriptive statistics of the sample at each time point will help to identify selection bias because of loss to follow-up.

Analyses of the follow-up data will include cross-sectional and linear mixed models to assess the relationship between different predictors (eg, hospital variables) and the study's 2 key outcome variables (ie, disability score and perceived return to usual activities) at the 3 follow-up time points. The analyses will adjust for differences at baseline (eg, disability history) and confounding variables.

Cross-sectional Analysis

To identify significant predictors of disability, a bivariate analysis will be performed at each follow-up time point by regressing the overall disability score against each of the explanatory variables from the hospital-based tool (ie, sociodemographic, preexisting disability, crash circumstances, prehospital, and hospital variables); use of assistive devices from the follow-up tool; and environmental barriers and previous disability score (for the second and third follow-up). Given the large number of variables in the hospital-based tool, there are many potential covariates. A critical assessment will be done to identify the most important independent variables to include in a linear regression model. Variables that show a significant association with the outcome in the bivariate analysis as well as those with associations found in the literature will be retained in the regression model. In addition, testing for multicollinearity in each of the regression models will be performed by determining the variance inflation factor, in which values >10 will be investigated. Collinear variables will be dropped iteratively until the model no longer has variables with a variance inflation factor >10. These measures will ensure that the regression model estimates of the coefficients are stable. This analysis will be repeated using logistic regression and *return to preinjury activity* as the outcome variable.

Attrition Analysis

Because disability-related data will be collected longitudinally (repeated measures), it is expected that the sample size at the third follow-up will be smaller than that from the previous follow-ups. An attrition analysis will be performed to test for correlation between demographic and clinical variables and loss to follow-up at each measurement occasion. It is expected that loss to follow-up will be between 4% and 28% at the 6-month follow-up [22,39]. The relationship between nonparticipation in the follow-up and sociodemographic, crash, and clinical variables (collected at the hospital) will be examined to assess whether loss to follow-up from each measurement occasion is associated with the possible predictors of the study outcomes.

Longitudinal Analysis Using Mixed Effects Model

Using panel data, the change in the main outcomes of interest (disability score and perceived return to preinjury activity) across the 3 follow-up points will be examined (Table 4). First, attrition analysis will be performed with panel data (all rounds of data collection) to assess whether clinical characteristics such as injury severity and disability score predict loss to follow-up. The loss to follow-up variable will be coded according to the follow-up responses and regressed against injury and disability severity variables. Imputation techniques will also be considered to handle missing data and increase the sample size, depending on the results from the attrition analysis.

XSL•FO
RenderX

Table 4. Key outcome variables from the follow-up instrument.

Indicator	Survey questions	Specifications
Disability score	WHODAS[a] 2.0's shortened form consists mainly of 12 questions capturing the following domains: understanding and communicating; getting around; self-care; getting along with people; life activities; and participation in society. Response options: 0=No Difficulty, 1=Mild Difficulty, 2=Moderate Difficulty, 3=Severe Difficulty, 4=Extreme Difficulty or Cannot Do.	Scores are calculated for each subscale by adding the points from each response. The minimum and maximum total scores are 0-48, where higher scores indicate higher levels of disability.
Perceived return to preinjury activity or "normal life"	As of today, do you consider yourself to have returned to your normal life or to doing your usual activities your injury? Response options: Yes; No.	This question is intended to capture whether the participant has returned to their usual activities as they see it. Participants may consider themselves to have returned to usual activities or normal life *because of or despite* using an assistive device, whereas other participants may consider themselves not back to "normal" life if they have to use a device or rely on a modification to their physical space. Because this tool is focused on activities and participation, we define "return to normal life" as being able to do the things one was able to do before their injury.

[a]WHODAS: World Health Organization Disability Assessment Survey.

Next, descriptive analysis will be conducted for the complete cases (participants in all 3 follow-up rounds), followed by longitudinal analysis, which will account for the correlation between repeated measures and heterogeneity of variance inherent to longitudinal data. A mixed effects model will be used for the analysis, which accounts for both fixed effects (population-averaged response) and random effects (subject-specific) [40]. This model allows for the comparison of changes in disability scores over time and can accommodate continuous covariates as well as incomplete data [40].

Finally, although we assume a linear relationship in the response over time, this may be relaxed to include a quadratic term for time in the model or a log transformation. *P* values will be considered significant at .1. The longitudinal analysis will be replicated for repeated binary measurements of the return to preinjury activities outcome variable, using logistic regression to model the binary outcome.

Results

Enrollment in the study began in June 2021 and was completed in April 2022. Follow-up data collection ended in September 2022. Data analysis is currently underway, with results expected for publication in mid-2023.

Discussion

Principal Findings

The proposed study will provide an estimate of the burden on patients due to RTI-induced disability in several LMICs. It will also provide a thorough understanding of the rate and severity of RTI-induced disability and its impact on road traffic crash survivors by examining disability scores and perceived return to preinjury activities. The data will identify disparities in recovery from RTIs and return to preinjury activity or "normal life" based on differences in environmental factors surrounding crash survivors after hospitalization. This will provide an opportunity to uncover barriers that impede recovery and return to usual activities, including service and assistance barriers as well as physical, social, and policy barriers.

Strengths

This study uses a prospective design to develop estimates of disability among patients with RTIs using a validated instrument 1 month, 3 months, and 6 months after injury from 9 hospitals in 5 LMICs. Implementing a multicountry design provides a large sample size that will strengthen the accuracy of our findings, reduce the margin of error, and increase the generalizability of the findings. This prospective design will allow for a better understanding of the predictors that influence the recovery process and provide more efficient estimates of the effects of time-varying covariates, such as injury severity or treatment.

Limitations

This study has a few limitations. The first limitation is related to sampling. With only a small number of hospitals in each country, our sample is not nationally representative. The study populations that were recruited at these hospitals are not necessarily representative of the injuries and treatment-related factors in each country because of differences in the regional and facility-specific characteristics of the participating hospitals and their patient populations. Thus, the study's findings will not be generalizable at the country level. In addition, our sample size calculation may not properly reflect the complexity of sample variations, meaning that a sample size of 400 is insufficient for estimating the national disability burden of road traffic crashes, especially for subgroups. Furthermore, because the sample only includes adults with moderate to severe injury, this study will not estimate the full extent of the burden of RTIs because it excludes injuries of children and minors. Second, the COVID-19 pandemic and related restrictions have caused some hospitals to make changes in their inpatient and outpatient case prioritization procedures that may have affected eligibility and recruitment. For example, patients with RTIs with moderate injury who may have normally been admitted to the inpatient ward may have been discharged within 24 hours and scheduled for outpatient procedures. This would render them ineligible

XSL•FO
RenderX

for the study and could have created difficulties to achieve the desired sample size as well as potentially cause sampling bias. Even outside of COVID-19, some eligible cases in sampling may have been missed because of premature discharge or transfer of hospital. For example, it is possible that some patients were discharged within 24 hours of admission for unknown reasons despite having moderate to severe RTIs. Similarly, patients who bypassed the emergency department may have also been missed despite our best efforts to recruit eligible patients. Third, a significant portion of the study is longitudinal, which uses phone-based interviews to conduct follow-up data collection, so there is a threat of loss to follow-up. Potential loss to follow-up will reduce the sample size and potentially bias results if missingness is directly linked to health and demographic variables. Fourth, it is likely that the study will have missing data at the hospital level because much of the patient information will be extracted from medical records by nonclinical data collectors. A fifth limitation of this study is that we were not able to collect injury severity score, an important measure of severe injury, because physicians in the participating sites in this study do not routinely calculate this measure. However, other variables were collected, which can act as proxy measures to assess injury severity. Finally, we did not measure the quality of care provided or factors such as psychosocial stress and pain that may directly affect disability-related outcomes.

Conclusions

This research will be key to expanding the evidence base needed to develop strategies to improve the quality of life and lessen the social and economic burden on those with crash-induced disability. Thus, the findings of this study will help advocate not only for improved road safety but also for informed decision-making by the government to adopt and implement appropriate policies and interventions to address factors contributing to the severity of RTIs and associated disabilities and the contexts under which they occur.

Dissemination Plan

This research is intended for public health professionals, researchers, trauma care providers, rehabilitation providers, policy makers, and advocates interested in the link between RTIs and disability and rehabilitation. Findings from this study will be reported in peer-reviewed journal articles and conference presentations and shared with the study participants. Publications will be authored jointly by country teams.

Acknowledgments

This study was funded by the UK Aid under the Multi-Donor Trust Fund Phase 3 funded by the Foreign, Commonwealth & Development Office and the Department for Health and Social Care, through the World Bank's Global Road Safety Facility Comprehensive Road Safety Research Projects to Improve Global Road Safety.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

SM, NP, and AAH conceptualized the study, and HER, KN, LWM, and MKK helped develop the protocol. MKK and HER drafted the manuscript, and all the other authors critically revised the manuscript for important intellectual content. All authors have approved the final version of the manuscript for publication.

Conflicts of Interest

SM, KN, and LM were employed by the donor agency. AAH, NP, HER, and MKK received funding from the World Bank to support this study.

Abstract

Background: With aging of the population, the search for alternative models of care adapted to older people with dependency is necessary. In this setting, foster families (1-3 older people per family) could be an alternative to nursing homes, residential care facilities, or community- and home-based care.

Objective: The KArukera Study of Ageing in Foster Families is a prospective cohort study designed to investigate the care pathways of older people with dependency in foster care over a year. The 1-year hospitalization rate (main objective), cost of hospitalization, incidence of mortality, prevalence of geriatric syndromes, and quality of life of residents will be assessed. Quality of life and burnout of their respective foster caregivers will also be studied.

Methods: This study cohort will include 250 older people living in foster families in Guadeloupe (French West Indies), as well as their respective foster caregivers. Both older people and caregivers will be interviewed concurrently on site at three time points: (1) at baseline, (2) at 6 months, and (3) at 12 months. For older people, we will collect anthropometric measures, cognitive impairment, depressive and anxiety symptoms, functional abilities, physical frailty, information on general health status, quality of life, and care pathways (hospitalization, mortality, and medical and paramedical consultations). We will also assess the quality of life and burnout symptoms of family caregivers at each follow-up. A phone update of vital status (alive or death) and care pathways of residents will be carried out at 3 and 9 months after the baseline examination.

Results: Recruitment opened in September 2020 and ended in May 2021, with 109 older people recruited and 56 respective foster caregivers. The 1-year follow-up was ended in June 2022. Data analyses are ongoing and the first results are expected to be published in May 2023.

Conclusions: Foster families are a potentially innovative way to accommodate dependent older people. This study could help define the clinical profile of older people adapted to foster families in the transition from frailty to dependency. The effectiveness of foster families, in terms of hospitalizations and mortality, will be compared with other models of care, particularly nursing homes. In this setting, a twin study carried out in nursing homes in Guadeloupe with similar aims and outcomes will be conducted. Beyond mortality and morbidity, the numerous outcomes will allow us to assess the evolution of geriatric syndromes over time.

Introduction

The Caribbean region is a heterogeneous canvas of autonomous states and dependent territories of sovereign states. In this area, the French West Indies constitute a specific cultural topic. A total of 90% of its population is of African descent. Although the official language is French, the medical and cultural realities are quite different from mainland France. There is little epidemiological data on this population, despite strong specificities, in terms of prevalence of specific diseases (hypertension, diabetes, etc), specific genetic risk factors, and socioeconomic characteristics or access to health care [1].

On January 1, 2016, there were officially 394,110 inhabitants in Guadeloupe, a number that has been decreasing by 0.5% every year since 2011 [2]. This decrease is the result of both a slowdown in demographic growth and a constant negative net migration rate, due to high unemployment rates and lack of economic prospects. As a result, by 2030, people older than 65 could represent 28% of the population [2] and the number of dependent older people should double. This older population will have age-related medical problems, especially chronic (hypertension, diabetes, and cancer) or neuropsychiatric pathologies. An increase in dependency and its associated consequences, such as an increase in hospitalizations and nursing home admissions, is to be expected. Early detection is lacking, and general practitioners cannot compensate for the shortage of medical specialists. In the current context, the economic, medical, social, and human stakes are considerable and finding the appropriate care option for older people with dependency has become a critical issue.

Despite strong family support, living at home is sometimes difficult or impossible for seniors and their caregivers [3] (heavy dependency, exhaustion of caregivers, regular decompensation of chronic pathologies, etc). Moreover, social isolation, social vulnerability, and loneliness among older people living at home [4,5] increase the risk of adverse health events, notably mortality [6]. The most developed and successful model for dependent persons in high- and middle-income countries is the nursing homes. However, the transition from one's home to a nursing home usually disrupts residents' social life and lifestyle, and institutionalized older people experience a steeper cognitive decline than community-dwelling people [7], as well as a drop in quality of life [8] and an increase in psychotropic drug use [9]. For these reasons, we need to study alternative and transitional care models between home care and nursing home care, such as foster families. Because fostered older people (while still moving out of their own homes) are taken care of within a family context instead of a nursing home or other collective settings, foster care placement processes could be an alternative to institutionalization. This model has developed to a greater extent over the last few years in Guadeloupe. Nearly 200 foster families care for about 300 dependent older people, whereas there are 21 nursing homes for approximately 1500 residents. Foster caregivers, after getting official approval and attending a 20-hour training course, usually accommodate 1 to 3 people in exchange for a monthly fee. Their mission is to ensure the well-being of their residents and to enable them to maintain close social and family relationships. Other professionals may also provide additional nursing care if necessary. Little is known about the characteristics of foster caregivers and their residents. Two decades ago, a study from Cébula and Horel [10] showed that 61% of fostered older people were older than 80 years in France, and two-thirds were women. Every 6 of 10 older people lived at home or with their own family before entering foster care, and foster care was requested by the older person's household in 63% of cases. Most foster caregivers were women (96%). Two-thirds of the foster caregivers were between 40 and 60 years old, and 16% of them were older than 60 years. Every 8 of 10 foster caregivers were "partnered people," the majority of them being single-family home owners (95%). Nearly half of the foster caregivers were in a nonemployment situation (inactive, unemployed, integration, and training) before obtaining their foster caregiver license. The cost of foster family accommodation for seniors depends on the number of caregiving hours, because of the length and frequency of stay (in 94% of cases, it is a full time) and geographical location. The monthly fee includes rent, services rendered, a maintenance allowance, and a daily allowance. Monthly cost ranges from €1400 to €2100 (US $1521.98 to US $2282.97) per month [11].

Foster families have also been tried out in others countries (eg, United States, Belgium, Italy, Russia, and Finland), but few scientific studies have assessed its effectiveness and efficiency. A Cochrane meta-analysis published in 2015 compiled 10 studies comparing home care or foster care with nursing home care for 16,377 older participants [12]. Because of the methodological limitations of the studies included, the meta-analysis failed to determine whether or not this type of accommodation was the most efficient in terms of mortality reduction, physical function, quality of life, or hospitalization rates. Indeed, the available studies relied on small samples and had high risks of bias (design bias, evaluation bias), and the baseline characteristics of the participants were very heterogeneous. Three 30-year-old studies focusing on foster care in the United States were included [13-15]. Two of them are of interest [13,15]. Braun and Rose [13] compared 269 older participants: 100 lived in foster care, 101 in nursing homes, and 68 at home. After 3 months, Activities of Daily Living (ADL) scores only improved in the foster care group, and costs were lower than those for the other 2 groups (US $28 per day vs US $74 for nursing homes and US $45 for home). There was no difference in morbidity, defined as the number of infections, injuries, skin problems, and hospitalizations. In their randomized study on 112 participants in foster care or nursing homes, followed for 12 months, Oktay and Volland [15] found no difference in mortality rates between settings (32.0% vs 28.8%). Stabilization or improvement of ADL and cognitive status, as well as overall lower health care expenses (25% less), was in favor of foster care. Nevertheless, nursing home residents' level of satisfaction compared favorably with that of foster family residents. In any case, available data are scarce, assessed with short follow-ups, lack essential clinical outcomes, and definitely need to be updated.

To date, we do not know whether foster care is an alternative to nursing home care, as suggested by the limited existing literature, or a transitional care setting between home care and

XSL•FO
RenderX

nursing home care. Epidemiological and medicoeconomic data on older people in foster families are essential to assess the relevance of this type of care, in particular, according to the severity of dementia or the degree of dependence in ADLs. Several issues need to be clarified: what is the residents' annual hospitalization rate and the associated costs? What is the health care pathway of residents in terms of consultations with general practitioners, specialists, and paramedics? What is the prevalence of geriatric syndromes in this population, and the incidence of mortality? What is the incidence of pneumonia, the leading cause of death and emergency hospitalization in older people? What is the quality of life of the residents and their foster caregivers? The Karukera Study of Ageing in Foster Families (KASAF) is a prospective cohort study, designed to investigate these questions. This longitudinal study will assess the health status and medical and economic data of 250 foster family residents and their foster caregivers over a year.

Methods

Overview

The KASAF is a prospective, longitudinal cohort carried out in Guadeloupe (French West Indies), France, among foster families for older adults. This study will collect the socio-medico-economic data of older residents of foster families over a year, with a focus on hospital admissions. We will collect data using face-to-face interviews with the participants and their foster caregivers at baseline and after 6 and 12 months, and using phone interviews with the foster caregivers after 3 and 9 months.

Objectives

This study is an epidemiological study that aims to explore the characteristics of foster family residents and caregivers. We have identified a number of outcomes that may provide insight on their profile. As hospitalization is the main expensive item in the health trajectories of older people [16], the primary objective of the KASAF is to study hospital admission rates of residents of foster families over a year.

Several secondary objectives are also targeted: length of hospital stays during the 12-month follow-up period; number of consultations with a general practitioner, a medical specialist, or a paramedical professional; global cost of hospital stays; prevalence of geriatric syndromes (frailty, undernutrition, depressive symptoms, incontinence and dependency, sensory impairments; falls; polypharmacy; bedsores; and cognitive impairment); incidence of lower respiratory tract infection; quality of life of foster care recipients and their foster caregivers; and burnout in foster caregivers.

Study Sample

A total of 250 residents will be recruited over 6 months among the 300 older residents currently in foster families. The primary end point will be the hospitalization rate at 12 months. A 30% hospital admission rate over a year has been reported in the Incidence of pNeumonia and related ConseqUences in nursing home Resident study in nursing home residents [16]. A change in the hospitalization rate from 30% to 15% would be considered as significant from a clinical and public health point of view. For an risk of 5% and 250 participants, the expected CI will be 4.4% for a hospitalization rate of 15% and 5.7% for a 30% rate.

Study Recruitment

Inclusion Criteria

To be eligible for the study, residents must be older than 60 years. They must live in a foster family in Guadeloupe and benefit from the French social security.

Exclusion Criteria

The only exclusion criterion is refusal from the resident or his or her legal guardian to participate in the study.

Preinclusion Visit

Before the start of inclusions, residents, their families, and the foster caregivers will be informed of the goals and methods of the KASAF via information meetings and emailing campaigns.

The on-site investigator will screen for eligible participants among the residents of the foster family he or she is responsible for and will visit every resident meeting the criteria. He or she will inform them of the aims of the study, the computerized processing of their personal data, the access to their data in the local PMSI (Program for Medicalization of Information Systems [Programme de médicalisation des systèmes d'information]) server, and their right to object to their participation at any given time. An information leaflet will be given to every participant and to the referring professional caregiver identified by the investigator to complete the interviews. Foster caregivers and residents have a right to oppose the collection of their personal data.

Data Collection

At inclusion, nurses, geriatricians, and psychologists will collect sociodemographic, health-related, and psychosocial information. The inclusion visit is the first on-site interview and will be followed by 4 visits: 2 on-site visits 6 and 12 months after the inclusion visit, and 2 phone interviews 3 and 9 months after the inclusion visit (Table 1).

The interviewers will be conducted by health care professionals: psychologists, interns, and nurses, trained by the INSERM Team SEPIA (UMR 1219) from the University of Bordeaux, a team having expertise in implementing cohort studies.

Table 1. Expected timeline for the KASAF[a].

Time line	Goal
July-September 2020	• Ethics Committee approval • Registration on ClinicalTrials.gov
September 2020	• Training sessions for the interviewers
November 2020-May 2021	• Inclusion period
February 2021-February 2022	• 3-, 6-, and 9-month follow-up
February 2022-May 2022	• End of 12-month follow-up (end of data collection)
June 2022-March 2023	• Data analysis
From May 2023	• Scientific communications

[a]KASAF: Karukera Study of Ageing in Foster Families.

On-site Interviews

Participants will be interviewed at baseline, after 6 months, and after 12 months. At each visit, different function domains will be assessed to measure (1) the ability to perform ADLs (eg, personal care, eating, and mobility) and (2) the ability to perform instrumental ADLs (eg, using the telephone, shopping, and managing finances). In fact, the interview implies both a physical evaluation (grip strength, gait speed, and blood pressure) and a cognitive and a psychological assessment. The estimated time for completion is 30 minutes but may vary depending on the participant's physical and cognitive status. Each of the participants will remain in the study for further follow-up interviews even if he or she is unable to answer, and reasons for incomplete data will be documented by the interviewers. Interviewers may split the visit into 2 parts to respect the participant's rhythm and to avoid missing data.

During on-site visits, foster caregivers will provide their own sociodemographic data (as well as information on the caregiving burden borne) and those of the elders to be cared for. Thus, both the quality of life of foster caregivers and the main sociodemographic or health data of the participants (eg, medical history, medication, nutrition, and ADL/Instrumental Activities of Daily Living [IADL] performance) are the primary focus of the study.

Phone Interviews

Interviewers will phone the foster caregivers twice to collect data on participants 3 and 9 months after the first visit. This phone call will provide an update on the mortality status of foster elders and health care services (ie, types and frequency of use). In the event of the death of a participant, date and cause of death will be sought and documented whenever possible.

Outcomes

Information on health care pathway comprises hospitalizations and consultations with general practitioners, specialists, and paramedics.

Primary Outcome

The main outcome is the number of hospitalizations over a year. The French hospital discharge database (PMSI) will provide information on hospital admissions. This information will be retrieved with the approval of the participants or their legal representative. Information on hospital admissions will also be collected from the foster caregiver for confirmation.

Secondary Outcomes

The secondary outcomes are as follows:

1. Length of hospital stays during the 12-month follow-up period, in terms of days and nights, will be collected. The number of consultations with a general practitioner, a medical specialist, or paramedical professional will be reported on the case report forms (CRFs). This information will mainly be collected during interviews with the foster caregiver using the RUD-Lite scale (Resource Utilization in Dementia questionnaire) [17]. This scale assesses the use of health care resources by people with dementia. The foster caregiver will complete this questionnaire at baseline and at subsequent follow-up visits (T3, T6, T9, and T12).
2. Global cost of hospitalization will be retrieved from the local PMSI databases.
3. Vital status (alive or deceased) will be collected at T3, T6, T9, and T12.
4. For the diagnosis of lower respiratory tract infections, at least two of the following symptoms must be present and a doctor must confirm the clinical evidence: (1) cough (starting or worsening), which may produce phlegm; (2) specific clinical signs during auscultation; (3) fever (≥38 °C); (4) chest pain; (5) rapid, shallow breathing (≥25 per minute); and (6) confusion or increased dependency [16].
5. Geriatric syndromes [18] in participants will be assessed at T0, T6, and T12 as follows:
    - Frailty will be assessed using Fried's phenotype [19], that is, 5 predefined physical frailty criteria such as weight loss, slowness, low physical activity, weakness, and exhaustion. This will be analyzed as a dichotomous variable, that is, 1=frail and 0=not frail.

XSL•FO
RenderX

- The level of cognitive deterioration of the participants will be assessed using the Mini-Mental State Examination (MMSE) [20,21]. This 30-item scale assesses the severity of cognitive deterioration through items such as orientation, learning, attention, arithmetic, memory, language, and constructive praxis. The scale is rated from 0 to 30, reflecting the level of cognitive impairment.
- Depression will be assessed using the Center for Epidemiologic Studies—Depression Scale (CES-D) [22] validated in French by Fuhrer and Rouillon [23]. This 20-item questionnaire assesses depressive symptomatology, including 4 positive polarity items (happiness, self-worth, confidence, and enjoyment). The frequency of symptom occurrence during the past week is assessed by the participant using a 4-point Likert scale (never, occasionally, quite often, and frequently). The score ranges from 0 to 60. The higher the score, the more significant the symptomatology. High depressive symptomatology corresponds to a score above 16. Data will be collected at baseline, T6, and T12. For statistical analyses, the variable will be dichotomized (1=presence of depression and 0=absence of depression).
- The total number of medications taken by participants will be collected directly from the RUD-Lite questionnaire, at T0, T3, T6, T9, and T12, to assess polypharmacy.
- The total number of falls since the last visit will be collected at each follow-up from the foster caregivers.
- The Short Physical Performance Battery [24,25] will help to assess sarcopenia. Three subtests measure lower-extremity functions: keeping balance (feet side-by-side, semitandem, tandem balance position, to be kept for 10 s each); walking 4 m at usual pace, yielding a gait speed ratio (meter per second); standing up and sitting down 5 times as quickly as possible with the arms folded. Each movement is scored 0-4 points out of a total score from 0 to 12, with higher scores showing better physical performance. If the total score is below 8, there is a risk of sarcopenia. For the analyses, the variable will be dichotomized accordingly (1=sarcopenia; 0=no sarcopenia).
- Undernutrition will be assessed with the short version of the Mini Nutritional Assessment [26]. This questionnaire assesses nutritional status. A score below 12 indicates probable undernutrition. For the analyses, the variable will be dichotomized accordingly (1=undernutrition; 0=no undernutrition).
- Sensory impairments (audition and vision) will be collected by directly asking the foster caregiver. Variables will be dichotomized accordingly (1=hearing/vision impairment; 0=hearing/vision impairment).
- The level of independence in ADL and incontinence will be assessed using the Katz scale [27], a 6-item scale assessing independence in 6 basic ADLs: bathing, toileting, transferring, eating, dressing, and incontinence. For each activity, a score of 1 indicates complete autonomy, a score of 0.5 indicates partial autonomy, and a score of 0 indicates complete dependency.
- The level of independence in IADL will be assessed using the Lawton IADL scale [28]. The Lawton IADL scale measures 8 items: using the telephone, shopping, preparing food, housekeeping, doing laundry, using transportation, handling medications, and handling finances. The score is from 0 to 8; a score of 8 indicates total autonomy, and 0 indicates total dependency. In France, the Autonomy, Gerontology Iso-Resources (AGGIR) questionnaire has been developed by public authorities to quickly assess the degree of dependency of elderly people and assign a dependency group, ranging from 0 (bedridden, completely dependent) to 6 (no help required, the person is autonomous in everyday activities).
- Psychological and behavioral symptoms in dementia will be assessed with the short version of the NeuroPsychiatric Inventory or NPI [29,30]. This scale assesses the psychological, behavioral manifestations (agitation, hallucinations, apathy, etc), neurovegetative symptoms (sleep and appetite), and the impact on the professional's workload.

6. Feeling of loneliness will be captured with the 14th item of the CES-D [22,23]: I felt lonely. The answer possibilities are never, occasionally, often, and frequently. The answer "often" or "frequently" indicates a feeling of loneliness.
7. Risk of developing pressure ulcers will be assessed with the Braden scale, and pressure ulcers will be classified according to the National Pressure Ulcer Advisory Panel, European Pressure Ulcer Advisory Panel, and Pan Pacific Pressure Injury Alliance [31].
8. Quality of life and adaptation will be assessed as follows:
    - Quality of life of the participant will be assessed at baseline, T6, and T12 using the Questionnaire Quality of Life—Alzheimer's Disease (QoL-AD) [32,33]. This 13-item questionnaire assesses the participant's physical condition, mood, relationships with friends and family, financial difficulties, and overall quality of life. The questionnaire is to be administered to both seniors and caregivers, and thus is based on both self-rated health problems and proxy ratings from foster families. The items are evaluated using a 4-point ordinal scale ranging from poor to excellent, with a total score ranging from 13 to 52. For the weighted score, the participant's score is multiplied by 2, the caregiver's score is added, and the total is divided by 3 to bring the score back to the initial scale. In the proxy version, the foster caregiver will be asked to try to give the answer they think the participant would give.
    - Health-related quality of life of the participant will be assessed with the EQ-5D questionnaire [34]. This questionnaire assesses health conditions. It is the most widely used questionnaire in medicoeconomic analyses. It allows health outcomes to be assessed in terms of quality-adjusted life-years (QALYs). This indicator summarizes the length and quality of life in a single figure. The result of a cost-utility analysis is expressed

XSL•FO
RenderX

in terms of the cost of gaining one QALY (ie, 1 year lived in perfect health). To estimate QALY, health-related quality of life is designed on a continuum from 0 (death) to 1 (perfect health). Each health status is thus assigned a weight of 0 to 1; the higher the score, the higher the corresponding quality of life.

- On the first page, the participant has to indicate, for each of the 5 dimensions assessed (mobility, independence, routine activities, pain or discomfort, and anxiety or depression), the state in which he or she finds himself or herself, by choosing 1 of the 3 options with increasing severity: no problems, problems, and extreme problems. The answers can be combined to describe the residents' health status, using a 5-digit number corresponding to the 5 answers.
- On the second page, the participant assesses his or her overall health using a standard vertical 20 cm visual analog scale (EuroQol visual analog scale), graduated from 0 to 100, from "best imaginable state of health" to "worst imaginable state of health."
- The score will be collected at T0, T6, and T12. The interviewer will use both the participant version and the proxy version. In the proxy version, the foster caregiver will be asked to try to give the answer they think the participant would give.

- Adaptation to the nursing home setting will be assessed at baseline, T6, and T12 using the Castonguay and Ferron scale [35]. This is a 17-item scale designed to identify who do not experience a favorable adaptation to the living conditions in nursing homes. The participants answer yes or no to a series of statements about their daily life and habits in the residence. A score of 16 or 17 indicates a good general adaptation to life in the residence, whereas a score of 11 or less indicates significant difficulties.
- Foster caregivers' quality of life will be assessed with the Medical Outcomes Study Short-Form General Health Survey—36 items (SF-36) [36], a widely validated health-related quality of life questionnaire that uses questions on physical, social, and psychological domains.
- Symptoms of burnout will be assessed with the Professional Quality of Life (Pro-QoL) scale [37]. This 30-item questionnaire yields 3 domain-specific scores: compassion fatigue (ie, the pleasure of being able to do your job well), work satisfaction, and burnout in helping professionals.

Table 2 shows an overview of data collection at each follow-up.

[q]SF-36: Short-Form General Health Survey—36 items.

Expected Timeline

The first participant was included on November 16, 2020. The 1-year follow-up was ended in June 2022 (Table 1).

Patient and Public Involvement

There was no patient or public involvement in the design and conduct of this study. Nevertheless, we have had discussions with associations of foster caregivers who would like to use our results to strengthen their professional training.

Data Analysis

First, the analysis will describe the number of included participants, the inclusion curve (evolution of the number of people included between the first and last inclusion), the number of theoretical visits, the number of visits actually made, and the ratio of both (number of visits made or number of theoretical visits).

A description of the rate and causes of death and study dropout will also be provided.

The following quantitative variables described in terms of number of staff, mean, and interindividual SD and 95% CI of the mean, median, range, and IQR values: number of hospitalizations, total length of hospitalization, total cost related to hospitalizations, total number of consultations with a general practitioner, total cost of low respiratory infections, total number of falls, MMSE score, total number of drugs, NPI score, QoL-AD score, SF-36 score, and Pro-QoL score.

Qualitative variables (ordinal: AGGIR grid, feeling of loneliness; dichotomous: vital status; presence or absence: frailty syndrome, depression, undernutrition, visual impairment, hearing impairment, incontinence, ADL dependency, IADL dependence) of participants at inclusion will be described in terms of frequency and number.

Comparisons between the 3 times (T0, T6, and T12) will be performed using repeated-measures ANOVA for quantitative variables and the Cochran-Armitage test for trend for qualitative variables.

Statistical analyses will be performed using the RStudio software (version 2.7; Posit Software).

Quality Control

During the study, quality control will be carried out by the project manager and the clinical research assistant. All interviewers will be required to attend training on data collection and data reporting. Under no circumstances should the names or addresses of the individuals concerned be made clear.

The electronic CRF will allow single data entry, which will be double checked by the investigators. Data management will be performed using the Capture System software (Clinsight). The Clinsight web-based module will allow remote access to the database, with a 128-bit SSL encryption. Each interviewer will have a personal and unique name and access code that will allow him or her to enter and correct data—everything is documented and saved every day on another server.

Ethics and Dissemination

The KASAF is an observational study involving human participants without any identified risk for the participants' safety. In accordance with this status, the need for a signed consent form has been waived off by the regulating bodies (law 2012-300). Residents will be provided with an information leaflet outlining the key points of the study. Participation is voluntary and residents can refuse to participate or discontinue participation at any time without prejudice. Considering the high proportion of family foster residents with cognitive impairment, the on-site investigator will ensure that the residents have understood the implications of their participation. If the resident is under guardianship and/or is unable to understand, nonopposition from the legal guardian or a documented contact person will be sought as well.

Nonopposition or opposition will be documented in the participant's medical file.

This study will be carried out in accordance with state laws regulating research involving human participants and with the Helsinki declaration.

The KASAF was registered under the RGB-ID number 2020-A00620-39 and was approved by the French Sud Méditerranée III Ethics Committee on July 1, 2020. Data analysis will be performed on-site (University Hospital, Guadeloupe). All documents related to this research will be archived for 15 years after completion of the study.

Results

Recruitment opened in September 2020 and ended in May 2021, with 109 older people recruited and 56 respective foster caregivers. The 1-year follow-up was ended in June 2022. Data analyses are ongoing, and the first results are expected to be published in May 2023.

Discussion

Foster families are a potentially innovative way to accommodate older people with dependency. Epidemiological data from the study will describe the clinical characteristics of older people in foster families. Beyond mortality and morbidity, the numerous outcomes will allow assessing the evolution of geriatric syndromes over time. In addition, this study will also look at the sociodemographic profile of foster family caregivers—who are not necessarily health professionals—in terms of age, life course, quality of life, or burnout. It may offer a basis for specific training courses and help the authorities to better characterize the requirements an applicant must meet to become a fully-fledged foster caregiver.

This descriptive study could help define the place of the foster family in the transition from frail elderly to dependent elderly status. Indeed, foster family could also be an intermediate stage

XSL•FO
RenderX

between home care and nursing home care. The epidemiological data obtained will be compared with data from other management systems. In this perspective, we will conduct a twin study in nursing home, the KArukera Study of Aging in EHPAD (KASEHPAD) study, which will take place in 14 nursing homes in Guadeloupe. Both studies will have similar designs and objectives. The protocol for the KASEHPAD study has been registered on ClinicalTrials.gov (NCT04587466). If patient characteristics are similar, it will be possible to compare mortality, hospitalization rates, and all variables of interest, including cost of care, between these 2 care settings. Depending on the profile of the KASAF's participants, we could also compare foster care with home care or residential care facilities [38]. The collection of epidemiological data in foster family is therefore an essential step to carry out randomized studies between these different care pathways, with the aim of determining the most effective and efficient care.

Foster families have never been formally assessed, the most robust results dating back to 30 years. In theory, it is less expensive than nursing homes for the community, but in the absence of scientific studies on the associated health outcomes (number of hospitalizations, deaths, etc), this model has not been validated and remains rare in metropolitan France. Yet, foster caregivers could be valuable assets in health care, thanks to their intimate knowledge of older persons and their pathologies, compared with nursing home staff, which have a high turnover, thus reducing avoidable hospitalizations and medical consultations.

Moreover, in the event of a health crisis such as the one experienced with the COVID-19 pandemic, measures of isolation and social distancing are much easier to implement, as foster family residents live in small family units, usually have single rooms, with less comings and goings than in nursing homes. The collected data will be used for exploring the characteristics of the foster home residents with aims that might not be considered today (1) because they are out of topic and (2) because science evolves.

This study presents limitations. We will not have access to data from informal caregivers, who could provide different insights on the participant's state of mind or daily life. Also, cost analyses will focus only on hospitalization costs. This is why an ancillary study will be carried out after the end of the KASAF, using information from the national health insurance database. This study will accurately assess the cost of the entire health care pathway, including nursing, medical transportation, and other health care expenses. Finally, the KASAF does not include randomized interventions versus nursing home limiting causal interpretations of the results.

We hope that our results will help introduce more rationality into social and economic debates, sometimes led by accounts of personal experiences and extrapolated indicators, often for lack of robust data, and help ensure that public health policies are based on sound scientific evidence. Indeed, our data will be used to support the coordination of institutional funding bodies, especially resource allocation.

Acknowledgments

We would like to thank the SEPIA Team from Bordeaux for their precious methodological support, as well as Valérie Soter, Christine Rambhojan, and Mélanie Petapermal for their regulatory support. This study was supported by a grant from the Conseil Départemental de la Guadeloupe, Saint-Martin, and Saint-Barthélemy (grant 2020/DPAPH/DRM). The funding body had no role in the design of the study and collection, analysis, and interpretation of data and in writing the manuscript.

Data Availability

The data sets generated during and analyzed in this study are available from the corresponding author on reasonable request.

Authors' Contributions

RV, DB-M, and MT-T wrote the initial protocol. DB-M and RV wrote the manuscript. MT-T, NS-T, JFD, and HA reviewed and updated the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Women with intellectual and developmental disabilities (IDD) do not undergo breast and cervical cancer screening at the same rate as women without IDD. IDDs are diagnosed in childhood, are lifelong, and involve difficulties in adaptive behaviors and intellectual functioning. Native American women also experience disparities in breast and cervical cancer screenings. Despite known disparities, women with IDD are often not included in health promotion programs, and there is a need for evidence-based programming for those with intersectional identities, such as Native American women with IDD.

Objective: This study aims to assess the feasibility and acceptability of My Health My Choice (MHMC), an adaptation of the Women Be Healthy 2 program. There are 2 parts to the study: adaptation of the Women Be Healthy 2 program and feasibility and acceptability testing of MHMC.

Methods: Individuals aged over 18 years who identify as Native American females with IDD and their caregivers (N=30 women-caregiver dyads) are eligible for the study. Participants, who are affiliated with 2 partnering sites in Arizona (1 rural and 1 urban), complete pre- and postsurveys assessing knowledge, self-efficacy, and screening expectations before and immediately after completing the program. In addition, all participants complete brief satisfaction surveys after each of the 6 educational sessions. A subsample of Native American women with an IDD (n=12), caregivers (n=12), and community health educators (n=2) who participate in the MHMC program will provide semistructured qualitative input regarding the content, delivery, and cultural relevance of the program.

Results: The adaptation of the culturally responsive MHMC program was completed in August 2021. In November 2021, the project team began recruitment for feasibility and acceptability studies. Feasibility will be examined using participation metrics, and acceptability will be measured using satisfaction measures. Pre- and postmeasures in cancer screening knowledge, self-efficacy, and screening expectations will examine improvements among participants.

Conclusions: The results of feasibility and acceptability testing of MHMC will guide future implementation studies of the program.

Introduction

Background

About 1 in 4 adults in the United States report living with a disability [1]. Among US adults with disabilities, the prevalence of disability is higher among Native American populations and among young adults (aged 18-44 years), cognitive disabilities (including intellectual and developmental disabilities [IDD]) are the most prevalent [1]. IDDs are disabilities diagnosed in childhood that involve difficulty with adaptive behaviors and can include limitations in intellectual functioning [2].

Cancer Screening in Women With Disabilities and Native American Women

Although screening rates for Native American women with IDD are not available, we do have data that indicate suboptimal screening in the intersectional population, especially regarding cervical cancer screening. Women with disabilities, particularly those with IDD, do not undergo cancer screening at the same rate as those without disabilities [3,4]. One reason that individuals with IDD do not receive cervical cancer screening may be that they have been perceived as asexual [5] and are thus less likely to receive comprehensive preventive sexual health care than women without IDD or other disabilities. For example, women with IDD are less likely to receive human papillomavirus screening compared with women without IDD [6]. While nearly 3 quarters of individuals with IDD (74%) reported having had a mammogram (vs 65.6% of women in the general population), only 57% of women with IDD reported cervical cancer screening in the past 3 years (vs 68.1% of women in the general population) [5-7]. Native American women are also less likely than the general population to undergo breast cancer screening (56.7% vs 71.5%, respectively) and cervical cancer screening (76.9% vs 83%, respectively) [8-10].

Factors Influencing Adherence to Cancer Screening

The complex interplay among disability, culture, and health system-level factors complicates adherence to cancer screening. Many Native American people in the United States live in rural areas that present unique challenges to participating in preventive health care and require persistence to complete screenings [11,12]. Individuals with disabilities face cultural biases that affect the way health care professionals perceive them and may influence their preventive health care, including cancer screening [13,14]. Women with IDD and Native American women are at an increased risk of interpersonal violence [15-19]. In addition, individuals with IDD have experienced ableism and trauma in broader society and health care interactions [17], and those who are also Native American experience historical trauma [18]. Historical trauma refers to the violence imposed on Native American communities over multiple generations and includes US policies of forced relocation, family separation, and the prohibition of spiritual activities [20]. While violence and trauma arise from different histories, these individual and collective experiences may result in hesitance to engage with health care institutions [18]. We discuss our approach to address these experiences in the *Theoretical Frameworks* section.

Furthermore, family and support networks may influence adherence. Culturally responsive health education programs for people with IDD [21] and Native American communities [22] often involve families or other supporters. Women with IDD who live at home with their families are less likely to receive preventive health care services compared with those living in residential facilities [23]. Individuals from racial and ethnic minority groups, including Native Americans, are more likely to live with family caregivers compared with residential facilities [24]. Specifically, in Arizona, where this research is being conducted, 78% of individuals with IDD live with family caregivers [25]. Research indicates that caregivers (including family, friends, or paid support professionals) may believe that cancer screenings are unnecessary or that they do not want to make decisions for a person who cannot communicate their consent. Caregivers believe that by avoiding screening, they protect a woman with IDD from discomfort during screening or a possible cancer diagnosis [26]. Adding to the complexity of women's self-advocacy, women with IDD living with family caregivers have less knowledge about breast and cervical cancer screenings compared with women with IDD living alone or with a spouse [27,28].

Efforts to develop educational resources specific for women with IDD to encourage breast and cervical cancer screening have demonstrated promising results [29-31]. *Women Be Healthy 2 (WBH2)* was developed to assist women with IDD who had expressed difficulties with or had never undergone breast or cervical cancer screening. After attending the *WBH2* program, participants showed improved knowledge about breast and cervical cancer screenings [31]. However, the *WBH2* curriculum was not implemented with Native American women; therefore, its relevance for this population is uncertain. In collaboration with community partners, this project aims to test the feasibility and acceptability of *My Health My Choice* (MHMC), an adaptation of the *WBH2* program for Native American women with IDD, to improve their cancer screening knowledge and self-efficacy.

XSL•FO
RenderX

Original Intervention—WBH2

WBH2 was selected for adaptation and testing, as a previous implementation of the program led to knowledge gains regarding breast and cervical cancer screenings among women with IDD [31]. *WBH2* consisted of 11 twice-a-week 60-minute sessions focused on the education about breast and cervical cancer screening, self-advocacy skill development, and techniques for anxiety reduction in women with IDD. The classes contained information on mammography or Papanicolaou testing, preparation for mammography or Papanicolaou testing procedures, breast and pelvic anatomy, and tools and skills for cancer screening visits. The course content was taught in an interactive way. For example, instructors read scenarios and asked students to consider what they would do if they were confronted with the challenges in the scenarios. Field trips to health providers to touch and see the equipment used in cancer screenings were also part of *WBH2*. *WBH2* did not proactively include caregivers as colearners in the program. *WBH2* was implemented and tested in a population of White and African American–identifying women with IDD attending urban adult day programs in a southeastern state in the United States [31]. Adult day programs are professionally run programs that adults with IDD attend to receive community living and other health-related programming [32].

Theoretical Frameworks

Overview

This project is guided by the social model of disability [33] and socio-ecological model [34], which acknowledge the influence of political, social, and interpersonal structures on health. These frameworks allow the study team to complete a multilevel assessment of cancer screening disparities experienced by Native American women with IDD, which needs to be addressed in the content and structure of the education program. In the final refinement and testing of the culturally informed curriculum, we used the social cognitive theory (SCT) [35] in the design of our intervention, since it has been used previously by other researchers as a theory to affect cancer screening behavior change among Native American women [36]. SCT includes a construct, reciprocal determinism, which frames the interactions of women with IDD and influences their decisions to complete cancer screenings. This theory guides our data collection and analysis and is inclusive of other concepts, such as trauma-informed care and self-determination.

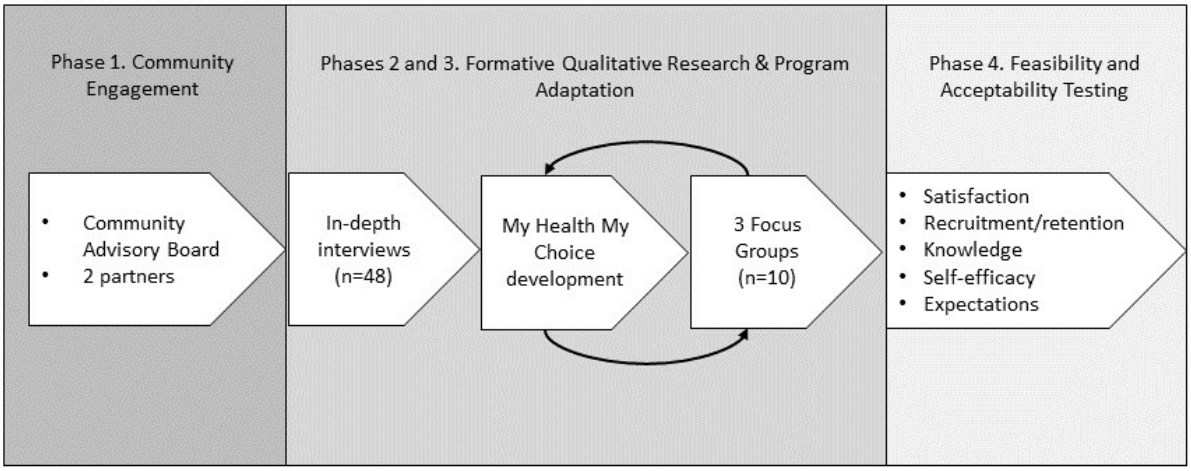
Trauma-Informed Approach and Self-determination

Within SCT, using a trauma-informed approach addresses internal and external reinforcements and their impact on health care decision-making. Trauma-informed approaches can also address the expectations construct in SCT, as women may have expectations about cancer screenings, based on previous trauma-inducing health care interactions. Trauma-informed approaches aim to prevent future retraumatization by providing a wide variety of delivery methods [37,38]. The program includes training for interventionists on trauma-informed methods and identifying potential behavioral triggers so that they are prepared to handle situations in which a program participant finds the course material emotionally difficult. The program also creates a safe space with ground rules for the discussion of topics.

Another important framing concept for this project is self-determination, which is central to both the Native American community and the IDD self-advocacy movement [39,40]. Self-determination among adults with IDD means making one's own decisions regarding one's needs and has been found to be a critical component for maintaining a good quality of life and for addressing population-level health disparities [41,42]. Among Native Americans, self-determination is necessary to reclaim ownership and control of community resources to meet the needs of the Native American population. Native American self-determination is needed for research on Native American populations [43]. This project promotes self-determination throughout the research process, as a community-engaged approach requires researchers and community members to work in equal partnerships through data collection, data analysis, and dissemination [44].

Objectives and Research Aims

The long-term goal of this community-engaged research project is to decrease breast and cervical cancer disparities among Native American women with IDD through culturally responsive and universally designed education in a southwestern US state. This paper provides a study protocol for an ongoing community-engaged research study focused on addressing breast and cervical cancer screening disparities among Native American women with IDD, via the delivery of a health education program titled MHMC. Here, we briefly describe how we used community-engaged methods to develop the MHMC program and then describe the feasibility and acceptability testing methods.



Methods

Project Timeline

This project was initiated in September 2017 with the establishment of an advisory board and relationship-building with community partners in the research project. Once urban and rural community partnerships were established, the project team began 2 steps of formative qualitative research to inform the adaptation of *WBH2 (September 2019-August 2021)*. The project team began feasibility and acceptability testing of MHMC in November 2021. Figure 1 illustrates the study flow, including the phases of development, implementation, and testing of MHMC described in further detail below.

XSL•FO
RenderX

Figure 1. Study flow.

Ethics Approval

The study was approved by the Institutional Review Board of the University of Arizona (STUDY00000034, September 28, 2021, with original protocol number 1709856263, approved September 27, 2017), with a ceded review by the Northern Arizona University Institutional Review Board (protocol #1132744-7). The study was also approved by all required tribally affiliated entities.

Phase 1: Community Engagement

This study uses a community-engaged approach. Similar to Community-Based Participatory Research, community-engaged research is an equity-based approach that involves communities throughout the research process by considering important elements of the community (eg, resources and strengths that the community brings) [43,45,46]. This approach also consists of building trust with communities and involving community members throughout all phases of the project, including defining, implementing, and engaging in research. This project utilizes an advisory board design to serve as an element of community feedback and research oversight. This 11-person advisory board includes community members with familial ties to Native American women with IDD and representatives from cancer control programs, Native American health programs, and disability services. The advisory board has met quarterly for 1 to 2 hours since the inception of the project to provide ongoing supervision and feedback on the project, including ideas about how the program could be enhanced to meet community needs and suggestions for implementation. Early in the project, the advisory board was asked for input on initial revisions to *WBH2*, offering thoughts about the content and structure, including the need for cancer diagnosis information and for a reduction in the number of sessions [47]. A community-engaged approach was chosen for the project because of the growing recognition of the importance of including community members as partners in research efforts focused on addressing health [48,49].

Phase 2: Formative Qualitative Research

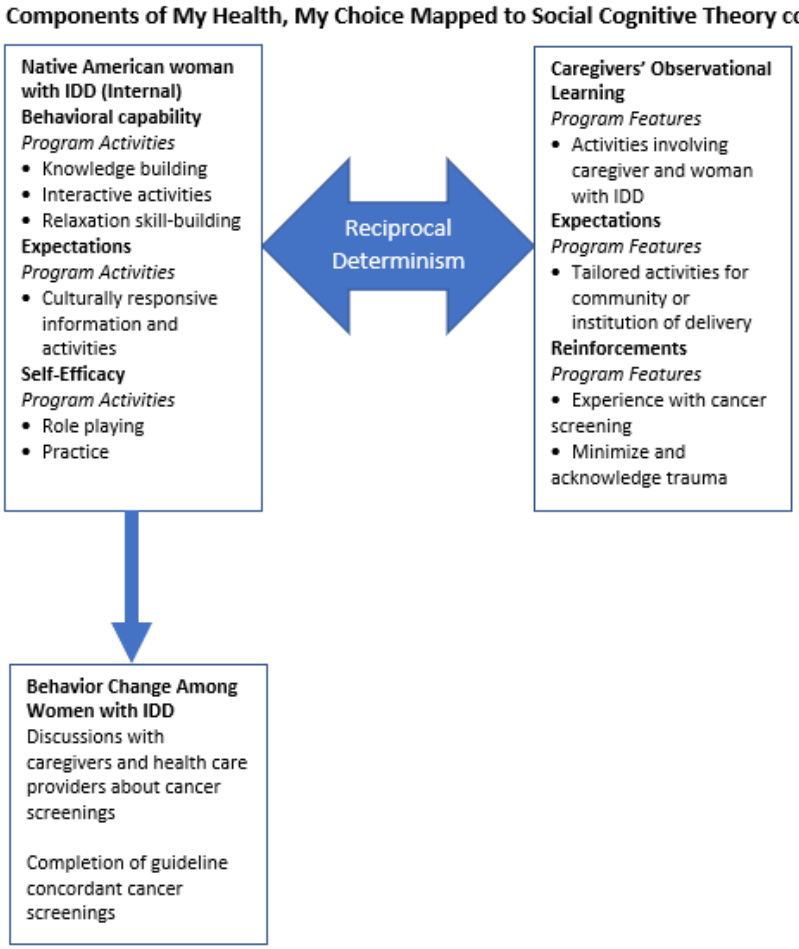
Cultural adaptation of the *WBH2* curriculum in partnership with a Native American urban health and social services provider and a Native American rural cancer screening and support provider was complete at the time of this writing. Cultural adaptation occurs in 2 steps. In step one, individual in-depth interviews with Native American women with IDD, caregivers, health care and disability providers, and community members were completed. The results of the interviews [50] were discussed with the advisory board and members suggested program activities to address these findings. The results of the interviews provided an initial framework for culturally adapting the program, now called MHMC. Formative research and advisory board feedback on the findings led to changes in the program's content and structure, including how and by whom it should be delivered. A total of 3 focus groups (n=10) were completed with both partner sites and throughout the state of Arizona to review and update the program. Preliminary program recommendations were reviewed via focus group discussions at each partner site with partner site program staff, caregivers, and Native American women with IDD to help the team refine the program.

Our community partners represent multiple tribal identities; one represents one tribe in the state, and the other is an urban Indian center that serves tribal members from all over the United States living in Southern Arizona. Acknowledging the diversity of tribal groups and the diversity among women with IDD allows the project to identify the diversity and commonality of experiences with breast and cervical cancer screening among Native American women with IDD.

Phase 3: Adapting the Program (MHMC)

Overview

The adapted program takes place in six 1-hour sessions provided weekly over the course of 6 weeks. The education program addresses the personal, interpersonal, and environmental barriers to cancer screening experienced by Native American women with IDD. The program's six learning objectives include (1) identify healthy lifestyle habits for women, (2) practice managing anxiety about cancer screenings, (3) identify what cancer is and the parts of the body being screened for cancer, (4) learn about breast cancer screening, (5) learn about cervical cancer screening, and (6) practice self-advocacy in health care. Figure 2 shows a screenshot of a program element. Key components include engaging Native American women with



XSL•FO
RenderX

IDD and their care providers in discussions regarding cancer screening decisions, bringing in culturally relevant ways to share knowledge, and providing resources for dealing with the next steps in the case of screening results that require diagnostic testing. Below, we discuss how each of these components aligns with the constructs of the SCT. Finally, we describe how the COVID-19 pandemic generated additional curriculum delivery decisions. Figure 3 provides a summary of the SCT constructs aligned with program features.

Figure 2. My Health My Choice (MHMC) program component.

Figure 3. Components of My Health My Choice mapped to the social cognitive theory constructs. IDD: intellectual and developmental disabilities.

XSL•FO
RenderX

Caregiver Involvement

Involving caregivers in the MHMC intervention addresses the central concept of SCT, reciprocal determinism, as women will make individual decisions regarding cancer screenings (internal) in collaboration with their caregivers, who can reinforce the decision.

Native American Cultural Elements

Native American cultural elements were also included in the program. The content highlights self-advocacy, using peers from the same Native American community to deliver the intervention, and ensuring that indigenous female healers rather than male healers are included. Culturally relevant imagery and metaphors are used to share the concepts of health, cancer, and self-advocacy. Providing culturally relevant materials may help address SCT constructs of reinforcement and expectations. Reinforcements are responses to behavioral choices that may influence future behaviors. Providing culturally relevant concepts to explain the importance of cancer screening may reinforce or encourage the decision to undergo cancer screening. Expectations are expected consequences of completing an activity. Demonstrating that participating in cancer screening is something that is expected and culturally accepted through culturally relevant materials may encourage screening.

Hands-on Activities and Anxiety Management

The use of hands-on activities and anxiety reduction techniques is provided with the intent to build knowledge, skills, and confidence through observational and experiential learning about cancer screenings among women with IDD and their caregivers. Within SCT, one must have self-efficacy (or confidence) as well as behavioral capability (knowledge and skills) to initiate a behavior. Observational learning in SCT refers to behavior change that can be encouraged through observations of modeled behavior. The program provides opportunities for hands-on activities to improve knowledge and understanding about a healthy body and cancer screening. The program includes tactile craft activities that demonstrate what will happen to a breast during a mammogram (ie, pressing a stress ball between your hands) and teaching about parts of the body involved in cancer screening (ie, creating a uterus and cervix with a baby sock). The stress ball activity can also help with anxiety in women with IDD about breast cancer screening as it shows pain visually (eg, showing a stress ball being squeezed in the mammogram machine) but also communicates how pain and discomfort pass. Each session opens and closes with relaxation technique exercises for women to practice managing their anxiety around cancer screening. Finally, women with IDD and their caregivers in the program also write out their plans and action steps to participate in cancer screening.

COVID-19 Modifications to Delivery of the MHMC Program

The plans for implementing the MHMC program were modified because of the COVID-19 pandemic. The project team modified the program to be delivered remotely to dyads of Native American women with IDD and their caregivers. Each participant has a MHMC toolkit delivered to their home with printouts of educational resources and items needed for hands-on activities. For women residing in urban areas with adequate internet access, the program is delivered via Zoom by a health educator. For women residing in more rural areas with limited or inconsistent internet access, the program is delivered over the phone by a health educator. A project website was developed to distribute educational materials. Videos were produced at each partner site using imagery and voice overs (ie, social story format) to walk women through the process of getting a Papanicolaou test and a mammogram with a local provider.

Phase 4: Feasibility and Acceptability Testing

Overview

The study's second aim, which is currently being completed, tests the feasibility and acceptability of MHMC and explores knowledge, self-efficacy, and screening expectation outcomes among Native American women with IDD and their caregivers. The culturally adapted MHMC program is implemented by female community health educators affiliated with our 2 community partners. Native American women with IDD (and their caregivers; N=30 student-caregiver dyads and n=15 dyads per partner site) complete pre- and postsurveys assessing knowledge, self-efficacy, and screening expectations before and immediately after completing the program. In addition, all participants complete brief satisfaction surveys following each of the 6 educational sessions (Multimedia Appendix 1). A subsample of Native American women with IDD (n=12), caregivers (n=12), and community health educators (n=2) who participated in the *My Health, My Choice* program provide semistructured qualitative input regarding the content, delivery, and cultural relevance of the program. Finally, the team tracks recruitment, attendance, demographic information, completion rates, and fidelity data for each session throughout the program.

The inclusion criteria for our second study aim are as follows: women with IDD must self-identify as Native American women with IDD and report being born a girl and caregivers must self-identify as caregivers for Native American women with IDD. Both types of participants must reside in Arizona, be aged over 18 years, and speak English or the other Native American language spoken in rural areas. Participating Native American women with IDD may choose a caregiver to participate in the program with them. The caregiver could be a family member, friend, legal guardian, or a paid support professional. If the caregiver identifies as a male, the questions collected at baseline and follow-up do not include information about their receipt of or intention to get screened for breast or cervical cancer. The following sections and Table 1 describe the measures and timing of the data collection (ie, T_0 is time zero and T_1 is time 1) used to evaluate the feasibility and acceptability of MHMC.

[a]IDD: intellectual and developmental disabilities.

[b]Data not collected at the time point.

Demographics and Screening History

We collect demographic information for each Native American woman with IDD (program participants) and their caregivers. Demographic information includes age, gender identity, disability status, race, ethnicity, level of education, employment status, health insurance coverage, home residence (ie, in one's own home or group home), and guardianship status. In addition to demographic data, we collect information about the participant and female caregiver breast and cervical cancer screening history using questions from the PhenX toolkit [51]. Funded by the National Institutes of Health, the PhenX toolkit is a collection of standard data collection protocols for conducting biomedical research, thus allowing cross-study analysis [51].

Knowledge and Self-efficacy

We collect the following data from each MHMC participant at baseline and follow-up: (1) breast cancer screening knowledge, self-efficacy, and screening expectations (female participants only) and (2) cervical cancer screening knowledge, self-efficacy, and screening expectations (female participants only). Mammography knowledge is measured using the Mammography Preparedness Measure developed by Wang et al [52] to measure the understanding of mammography's purpose and the procedure itself among women with IDD. Verbally administered, the instrument asks the participant to role-play, providing advice to the interviewer, who will be getting a mammogram. Questions are asked using plain language about the body parts checked by a mammogram, why it is used, how it is done, and how often it should happen. Parallel questions to assess cervical cancer screening or Papanicolaou testing knowledge along with scripts for both knowledge assessments were created by the authors of this study and are presented in Tables 2 and 3. We further adapted this instrument by including images of a mammography machine and an exam table with stirrups, as visual supports can assist individuals with IDD in processing information [53,54].

Self-efficacy refers to an individual's perception of their capacity to perform certain tasks in their life [35]. To assess self-efficacy in breast and cervical cancer screening, we modified the colorectal cancer self-efficacy instrument [55] that has been used in a Native American population [56], as shown in Table 3. Participants view an image of a ladder and read a script that is loosely based on the self-anchoring striving scale by Cantril. [57]. The bottom of the ladder corresponds with a score of zero, or *not sure at all* and the top of the ladder corresponds with a score of 10 for *very sure*. Participants are asked the following question, "Imagine that this ladder is a way of picturing your confidence, or how sure you are that you can do something. The top of the ladder indicates that you are very sure, and the bottom indicates that you are not sure at all. For these next questions, what place on the ladder (or number between 0 and 10) matches how sure you feel?" Native American women with IDD and their female caregivers are then asked 4 questions regarding their ability to *decide* and to *get* a cancer screening (Tables 4 and 5). Both male and female caregivers are asked parallel self-efficacy questions regarding their confidence in *supporting* a woman with a disability that they care for through the cancer screening process.

Table 2. Breast and cervical cancer screening knowledge assessments script.[a]

Knowledge of breast cancer	Knowledge of cervical cancer
Script: *"A mammogram is a machine that looks for cancer in your body. Here is a picture of a mammogram machine. Today I am pretending to go to the doctor's office and will be asked to get a mammogram."* (Show image)	Script: *"Here is a picture of an exam table I would lay down on to get a Pap test*[b]*. Today I am pretending to go to the doctor's office and will be asked to get a Pap test."* (Show image)
"Think back to a time that you went to the doctor's office. Now, I want you to pretend that you are at the doctor's office with me. I need your help in understanding what the doctor is asking me to do. Thank you for helping me."	*"Think back to a time that you went to the doctor's office. Now, I want you to pretend that you are at the doctor's office with me. I need your help in understanding what the doctor is asking me to do. Thank you for helping me."*
"Do your best. If you don't know the answer it is okay."	*"Do your best. If you don't know the answer it is okay."*
"Please make sure you help me on your own, do not have your family or others help you."	*"Please make sure you help me on your own, do not have your family or others help you."*

[a]Questions regarding knowledge of breast cancer were adapted from the Mammography Preparedness Measure [52], and cervical cancer knowledge questions were modeled on these questions.

[b]Pap test: Papanicolaou.

Table 3. Breast and cervical cancer screening knowledge assessments.

Breast cancer questions	Answers considered correct	Cervical cancer questions	Answers considered correct
What part of the body is the mammogram for?	Breast (or any reasonable slang term)	What body part is a Pap[a] test for?	Cervix, or inside the vagina, or private parts (or any reasonable slang term)
Why would I have a mammogram?	To check for cancer, must include cancer and screening (not curing, etc)	Why would I have a Pap test?	To check for cancer, must include cancer and screening (not curing, etc)
Would I have to take my clothes off for a mammogram?	Yes, top only, shirt and bra, etc	Would I have to take my clothes off for a Pap test?	Yes, bottom only, pants, underwear
When I have the mammogram how long will I be in the machine?	Any answer under 30 min	When I have my Pap test, how long will it take?	Any answer under 10 min.
How often am I supposed to have a mammogram?	Every year or every other year, annually, or based on when your doctor recommends	How often should I have a Pap test?	Every 5 years or based on when your doctor recommends

[a]Pap test: Papanicolaou test.

Table 4. Breast cancer and cervical cancer screening self-efficacy assessment script[a].

Script	Assessment
Script: imagine that this ladder is a way of picturing your confidence, or how sure you are that you can do something. The top of the ladder means that you are very sure, and the bottom means you are not sure at all. For these next questions, what place on the ladder (or number between 0 and 10) matches how sure you feel." [b]	

[a]Original instrument measuring self-efficacy in colorectal cancer screening was assessed using a four-point scale by McQueen et al [55] and further described in a Native American context by Frerichs et al [56].

[b]Adapted from self-anchoring striving scale by Cantril [57].

Table 5. Breast cancer and cervical cancer screening self-efficacy assessments.

Original question[a]	Breast or cervical cancer screening questions[b]	Caregiver modification[c]
How sure are you that you can decide whether or not to get screened for colon cancer?	How sure are you that you can *decide whether or not to get a mammogram/Pap*[d]*test?*	...support the woman with a disability that you care for in deciding whether or not to get a mammogram/Pap test?
How sure are you that you can complete colon cancer screening?	How sure are you that you can *get a mammogram/Pap test?*	...support the woman with a disability that you care for to get a mammogram/Pap test?
How sure are you that you can complete colon cancer testing even if you are nervous about it?	How sure are you that you can *get a mammogram/Pap test, even if you are nervous about it?*	...support the woman with a disability that you care for to get a mammogram/Pap test, even if she is nervous about it?
How sure are you that you can do what is needed to prepare for colon cancer screening?	How sure are you that you can do what is needed to prepare for a mammogram/Pap test?	Not assessed

[a]The original survey had 8 questions, of which we use 4.

[b]Mammogram and Papanicolaou test asked as separate questions.

[c]Text in this column replaces underlined words from the previous column.

[d]Pap test: Papanicolaou.

Cancer Screening Expectations

Using the same ladder image described for self-efficacy questions, participants are asked to rank how they feel about planning to get a screening with zero, indicating that they are not planning to get a screening to 10 that they are definitely planning to participate in cancer screenings. Native American women with IDD and their female caregivers are asked 3 questions regarding their personal expectations to get cancer screening (Table 6). Both male and female caregivers are asked about their expectations in assisting the woman they care for to get their cancer screening (Table 6).

Table 6. Questions assessing participant and caregiver expectations for getting, or assisting with getting, a mammogram or Papanicolaou test[a].

Breast or cervical cancer expectation questions[b]	Caregiver modification[c]
I plan to get a mammogram or Pap test[d].	Assist the woman with a disability I care for in getting
I plan to discuss getting a mammogram or Pap test with my doctor.	Support the woman with a disability I care for to discuss
I plan to discuss getting a mammogram or Pap test with people who support me (for example: family member, friend, staff, helper, direct support professional).	Not assessed

[a]0 to 10 scale, shown via a ladder for self-efficacy questions in Table 4.

[b]Mammogram and Papanicolaou test asked as separate questions.

[c]Text in this column replaces underlined words from previous column.

[d]Pap test: Papanicolaou.

Acceptability

The acceptability of the program is captured by asking program participants to complete a brief satisfaction survey regarding the session's format and content immediately after each session. Program feasibility is assessed by tracking the attendance and completion rates of all participants across all 6 sessions. A subsample of Native American women with IDD (12/30, 40%), caregivers (12/30, 40%), and community health educators (2/4, 50%) who participated in the *My Health, My Choice* program complete semistructured qualitative interviews regarding the content, delivery, and cultural relevance of the program. Fidelity is measured using data collected from Community Health Educators after each session. Data points include session start or end time, delivery method, challenges in delivery, ratings of the session, and participant engagement.

Analyses

Preliminary analyses of quantitative and qualitative data will be shared with the advisory board to assist with interpretation. On the basis of the advisory board input, we will finalize the analyses and determine the next steps for the research.

Statistical Analysis

Our primary outcomes will be participation metrics (feasibility and acceptability) including the percentage of women who choose to participate, the percentage of enrolled participants at each session, and the percentage of enrolled participants retained through the last session. A sample size of 30 Native American women with IDD and their caregivers from rural (15/30, 50% woman-caregiver dyads) and urban (15/30, 50% woman-caregiver dyads) settings will allow us to estimate participation and retention rates within an SE of 9% overall or within an SE of 13% within each setting (rural vs urban). Our secondary quantitative outcomes will be pretest to posttest differences for each of the following measures: (1) cancer screening knowledge and expectancy among Native American women with IDD; (2) self-efficacy scale for Native American women with IDD; (3) cancer screening knowledge and expectancy among caregivers; and (4) self-efficacy scale for caregivers. Assuming an attrition rate of 20%, a study with a

XSL•FO
RenderX

sample size of 24 will provide 90% power to detect a standardized effect size of 0.66, that is, approximately two-third of SD in pre- and posttest scores. The 90% power estimate is conservative because it assumes the independence of the observations. However, when assessing these outcomes in the final analysis, we will address within-site (rural vs urban) and within-workshop session (1-6) correlation using mixed effects models. The proposed effect size of 0.66 is realistic based on a similar pre-poststudy conducted by Swaine et al [31], for which the effect size for composite score improvement was 0.83. For all other proposed comparisons, we believe that two-thirds of effect size represents a substantive improvement. We have not controlled for multiple comparisons in these analyses, but we note that the main purpose of this study was to be descriptive in nature, providing mean and variance estimates to be used for powering a future randomized controlled trial. All calculations herein assumed 2-sided tests with an α of .05.

Additional exploratory analysis will be conducted to assess relationships with variables that the investigators and previous research studies have identified as potentially influential on outcomes, such as participant residence (eg, group home, living independently, living with family, and urban or rural), the type of care provider attending the workshop (eg, paid and family), receipt of services from the state (eg, Medicaid, Indian Health Services, and Division of Developmental Disabilities), and the level of support needed. Specifically, we will examine whether changes in knowledge, attitudes, beliefs, and self-efficacy vary according to each of these variables. On the basis of previous studies, we anticipate that women who live in a group home or with the family will show greater knowledge and self-efficacy gains [26] and that women with greater support needs may show lower gains in knowledge and self-efficacy [31]. Because of the exploratory nature of this assessment, no adjustments will be made for multiple testing, and *P* values near .05 will be interpreted cautiously.

Qualitative Analysis

In-depth interviews will be transcribed and coded. Using methods for ensuring reliability among coders, transcriptions will be coded individually by separate members of the research team, who will then meet to analyze for agreement and reproducibility [58]. Coding will be completed in an iterative fashion, with initial (a priori) codes being drawn from the literature and additional codes based on themes that emerge from the data [59]. This modified grounded theory approach has been used by other qualitative researchers and proposed as a "best practice" to ensure content validity [60].

Advisory Board Involvement

Our advisory board will work with us to interpret quantitative and qualitative findings. The study team will present the findings at a quarterly advisory board meeting, inviting members who are interested in engaging in one-on-one discussions about the data with the university-based study team. Discussions with the advisory board will focus on understanding the data in light of the following topics: meeting community needs, opportunities for additional collaboration, and plans for further implementation.

Results

This community-engaged research project began in September 2017. The study team developed a productive advisory board and established 2 community partnerships. Together, the university and community partners have completed a qualitative needs assessment to guide the development of a culturally responsive *My Health, My Choice* cancer screening education program for Native American women with IDD (September 2019–August 2021). The findings of in-depth semistructured interviews with Native American women with IDD (n=12), caregivers (n=11), disability and health care providers (n=20), and community members (n=2) in rural and urban contexts guided the adaptation of the program and have been reported in a separate manuscript [50]. Major adaptations to the content include information about integrating traditional and biomedical healing, and culturally relevant activities. Adaptations to the program structure include shortening its length and transforming it into remote delivery because of the COVID-19 pandemic. Importantly, female health educators are members of native communities. The MHMC program is provided by local community health educators using phone or video conferencing and web- or paper-based learning materials. The feasibility and acceptability testing of the MHMC educational program began in November 2021 with the goal of recruiting 30 dyads of Native American women with IDD and their respective caregivers. Measures were carefully selected based on their prior use and validation among Native Americans [55,56] or individuals with IDD [52].

Discussion

Overview

This paper describes a study protocol for a community-engaged and ongoing research project focused on addressing cancer screening disparities among Native American women with IDD. Given the paucity of research regarding health care decision-making among those living with intersectional identities (Native Americans with IDD) in the United States, a community-engaged approach is necessary. To date, the project team has built a community-relevant, trauma-informed, and universally designed cancer screening education program for Native American women with IDD. The significance of this study lies not only in its community-engaged approach, but also in its theoretical approach (SCT), which accounts for the multifactorial influences of trauma on screening behavior and incorporates them into the intervention.

Principal Findings

We anticipate that the MHMC program will prove acceptable as assessed by a brief satisfaction survey, and feasible, as assessed by tracking attendance and completion rates of participants across all 6 sessions. We also expect to see an increase in cancer screening knowledge and self-efficacy across all participants.

Strengths and Limitations

As noted in the introduction, the lack of screening adherence data for Native American women with IDD limits our ability

XSL•FO
RenderX

to understand the broad significance of this study. However, throughout the project, the team presented at local community events and participated as educational vendors to stay connected with local community needs. As others have noted, community engagement can be helpful for establishing mutually productive and collaborative relationships with Native American communities [39]. Our approach to community engagement is a strength for understanding the health and health care experiences of a largely underrepresented group of individuals in health disparities research, Native American women with IDD. Given this study's partnerships with specific Native American communities, the results of this work may not be generalizable to other groups of women with IDD from other Native American communities. However, these findings can provide a model for supporting Native American women with IDD in planning for cancer screenings, while considering the personal resources available to them.

Dissemination Plans

In addition to the development and public availability of MHMC, the study team has published 3 manuscripts covering the state of research on cancer screening and treatment for individuals with IDD and the lessons learned from our community-engaged processes [45,61-62]. A fourth manuscript sharing detailed results of community-based qualitative formative research has been published [50], and the results of feasibility and acceptability testing will also be submitted for publication.

Acknowledgments

We would like to acknowledge our partners, HOPI Cancer Support Services, and the Tucson Indian Center.

This project was funded through the Partnership for Native American Cancer Prevention, National Cancer Institute U54CA143924 (University of Arizona Cancer Center) and U54CA143925 (Northern Arizona University).

Data Availability

These data are not publicly available. Separate approvals must be obtained from tribal and community partners.

Abstract

Background: Type 1 diabetes mellitus (T1DM) is less common than type 2 diabetes mellitus but is increasing in frequency in South Africa. It tends to affect younger individuals, and upon diagnosis, exogenous insulin is essential for survival. In South Africa, the health care system is divided into private and public health care systems. The private system is well resourced, whereas the public sector, which treats more than 80% of the population, has minimal resources. There are currently no studies in South Africa, and Africa at large, that have evaluated the immediate and long-term costs of managing people living with T1DM in the public sector.

Objective: The primary objective was to quantify the cost of health care resource utilization over a 12-month period in patients with controlled and uncontrolled T1DM in the public health care sector. In addition, we will project costs for 5, 10, and 25 years and determine if there are cost differences in managing subsets of patients who achieve glycemic control (hemoglobin A_{1c} [HbA_{1c}] <7%) and those who do not.

Methods: The study was performed in accordance with Good Epidemiological Practice. Ethical clearance and institutional permissions were acquired. Clinical data were collected from 2 tertiary hospitals in South Africa. Patients with T1DM, who provided written informed consent, and who satisfied the inclusion criteria were enrolled in the study. Data collection included demographic and clinical characteristics, acute and chronic complications, hospital admissions, and so on. We plan to perform a cost-effectiveness analysis to quantify the costs of health care utilization in the preceding 12 months. In addition, we will estimate projected costs over the next 10 years, assuming that study participants maintain their current HbA_{1c} level. The cost-effectiveness analysis will be modeled using the IQVIA CORE Diabetes Model. The primary outcome measures are incremental quality-adjusted life years, incremental costs, incremental cost-effectiveness ratios, and incremental life years.

Results: Ethical clearance and institutional approval were obtained (reference number 200407). Enrollment began on February 9, 2021, and was completed on August 24, 2021, with 224 participants. A database lock was performed on October 29, 2021. The statistical analysis and clinical study report were completed in January 2022.

Conclusions: At present, there are no data assessing the short- and long-term costs of managing patients with T1DM in the South African public sector. It is hoped that the findings of this study will help policy makers optimally use limited resources to reduce morbidity and mortality in people living with T1DM.

Introduction

Background

Approximately 11.3% of the South African population is living with diabetes [1], and according to a Statistics South Africa report on mortality and causes of death released in 2020, diabetes is the second most common cause of death in the country [2]. Although type 2 diabetes mellitus (T2DM) is more prevalent than type 1 diabetes mellitus (T1DM), the incidence of T1DM is increasing annually at rates of 2% to 5% [1].

T1DM is an autoimmune disease typically occurring in childhood or early adulthood, resulting in the inability to produce enough insulin because of the destruction of insulin-producing islet cells in the pancreas [2]. It is a debilitating disease with life-threatening acute and chronic complications such as diabetic ketoacidosis, coronary heart disease, cerebrovascular disease, retinopathy, and nephropathy. The financial burden associated with the management of this disease is significant [3]. Early diagnosis and intervention can improve morbidity and mortality. Despite improving globally, diabetes management in developing countries is lagging, predisposing people living with diabetes to increased morbidity and mortality [4].

Health care in South Africa is characterized by 2 disparate systems: a well-resourced private sector that serves the minority and the poorly resourced public sector that serves approximately 83% (50 million) of the population [5]. Individuals using the private health care system are either funded via medical aids/insurance or self-funded. Some individuals use both the private and public health care systems, using the latter when their medical aid funds have depleted or when they are facing monetary constraints [6].

The public health sector in South Africa is challenged with a multitude of illnesses including the HIV and tuberculosis epidemic and diseases of lifestyle [7]. Noncommunicable diseases are, however, a leading cause of death among adults in sub-Saharan Africa, which have a disproportionate impact on the economically active population [7].

Economic data from the United States indicate that the future cost implications of T1DM and its related emergency and long-term complications may have an unsustainable impact on patients and health care systems [8].

Epidemiological data on T1DM highlight a marked disparity in remaining life expectancy of people living with diabetes by income group. Although multifactorial, this disparity reinforces the need to improve access to diabetes education, blood glucose monitoring, skilled health care, and insulin [9]. Given the limited resources of the public health care system in South Africa and the large patient numbers under care, rational decision-making is required to optimally use limited human and financial resources.

The rising prevalence of T1DM, paralleled with the high mortality and morbidity of people living with diabetes, presents a challenge to health care systems and policy makers, particularly in the developing world [10]. Considering this, more effort should be channeled into reducing the financial burden on health care systems and patients [11]. To appropriately address the financial implications of managing people living with diabetes, pharmacoeconomic data are required. Unfortunately, to the best of our knowledge, there remain no data on the immediate and long-term costs of managing people with T1DM in the public health care setting.

It is through assessing and quantifying the health care resource utilization of patients living with T1DM that effective management initiatives can be implemented. Furthermore, this knowledge may help develop policies to ensure the optimal use of scarce resources.

Rationale

The public health care sector has very limited data in general and specifically on people living with diabetes. Given that diabetes mellitus is one of the leading causes of death in South Africa, it is important to quantify and optimize resource utilization for patients with diabetes mellitus in the public health care sector. The resource utilization data generated from this study could assist with future policy development and optimization of care by considering the cost of illness, the cost of treatment, and optimal clinical outcomes.

Definitions

An uncontrolled hemoglobin A_{1c} (HbA_{1c}) reading will be defined as a reading ≥7%, and controlled T1DM will be defined as an HbA_{1c} reading <7% [12].

Study Objectives

Primary Objective

The primary objective was to quantify the cost of health care resource utilization over a 12-month period in patients with controlled and uncontrolled T1DM in the public health care sector.

Secondary Objective

The secondary objective was to quantify the cost of health care resource utilization in patients with T1DM with controlled (HbA_{1c} <7%) versus uncontrolled (HbA_{1c} ≥7%) blood glucose level over a 12-month period and to compare the cost over a modeled 5-, 10-, and 25-year time horizon.

XSL•FO
RenderX

Methods

Study Design

This was a national, multicenter, and observational study where a representative sample of patients was observed. Data were collected retrospectively over a 12-month period preceding the date of informed consent from patient chart data in the South African public health care sector.

Duration of Study Participation

A single visit was planned during which a patient signed an informed consent form to be included in the retrospective chart review. Eligibility criteria were confirmed and verified during the visit.

Selection of Patients

Consecutive patients who fulfilled the eligibility criteria were enrolled at each site. Competitive recruitment was used for this study.

Withdrawal Criteria

Withdrawal of informed consent was possible at the request of the patient or investigator.

Sample Size

A sample population of 224 consenting patients with T1DM fulfilling the eligibility criteria was recruited to participate in the chart review. Patients were recruited from 2 sites.

Determination of Sample Size

The sample size was calculated using SAS (version 9.4; SAS Institute) based on the assumption that both sites have a total population of 1129 patients with T1DM. The recommended HbA_{1c} readings were also taken into consideration; it was recommended that adults maintain an HbA_{1c} reading that is less than 7% to be classified as controlled T1DM. It was further assumed that 20% of the sample will have HbA_{1c} readings that are less than 7%. The population was also assumed to be normally distributed, using a margin of error of 5% and a confidence level of 95%; the sample size was calculated using the following formula:

where n_r is the required sample size,  is the corresponding standard normal variate for 5% type 1 error, P is the proportion of the population whose HbA_{1c} readings are <7%, and d is the margin of error set to 0.05.

The result was further adjusted relative to the population size of 1129 patients:

where N is the population size and n_a is the adjusted sample size relative to the population size.

The total sample size was 224 patients, adjusted for a 10% rate of patient files that may not be evaluable because of missing or incomplete data.

The inclusion and exclusion criteria are given in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Signed informed consent at enrollment in the study
- Adults aged ≥18 years
- Patients with type 1 diabetes mellitus whose diagnosis had been confirmed
- History of being on human insulin therapy treatment for 12 months preceding the date of informed consent
- At least 1 hemoglobin A_{1c} reading recorded in the patient chart in the 12 months preceding the date of informed consent

Exclusion criteria

- Patients with type 2 diabetes mellitus
- Patients with gestational diabetes
- Patients with chronic pancreatitis
- Patients with latent autoimmune diabetes in adulthood
- Patients with maturity-onset diabetes in their youth
- Patients on analog insulin therapy (rapid acting and long acting)

Modalities of Recruitment

Each investigator included consecutive subjects who met the eligibility criteria. This consecutive recruitment limited biases of subject selection. If the first patient did not fulfill the eligibility criteria or declined to participate, the investigator continued with the next patient until the enrollment target for the study was reached. A patient only signed the informed consent form once they were fully informed about the study and understood the information provided to them in the consent form. A patient-tracking log form was used to document

XSL•FO
RenderX

enrollment and ensure anonymity. Travel reimbursement was allocated per patient in line with local regulations.

Selection of Investigators

The investigators were chosen based on the following criteria: tertiary hospitals in South Africa and institutions with available comprehensive patient charts and records.

Analysis Populations

The full analysis set consisted of all patients included in the study, meeting all inclusion criteria and not meeting any exclusion criteria or withdrawal criteria. The per-protocol set consisted of patients who met all inclusion criteria and had no major protocol violations.

Statistical Methods

The data management team developed a statistical analysis plan before the database lock, which detailed the statistical analysis to be performed as well as the populations for analysis. A population review meeting was held after all data had been collected and cleaned and before the final database lock to determine which patients were analyzed in preparation for this retrospective analysis study.

Statistical analysis was performed after the database lock once all study data had been collected and cleaned. The statistical analysis was performed using SAS (version 9.4; SAS Institute).

Analysis Variables

All the patients in the analysis population were included in the data set for analyses. The analysis of data collected in this study was mainly descriptive. All collected data and end point variables were summarized using descriptive statistics.

Descriptive Analyses Included

For continuous variables, descriptive statistics included the number of patients, mean, SD, median, minimum, and maximum. Frequencies and percentages were displayed for categorical data. Percentages by categories were based on the number of patients with no missing data. Analysis was calculated according to the diagnosis group (uncontrolled vs controlled T1DM), as appropriate.

Modeling

The IQVIA CORE Diabetes Model (CDM) will be used to evaluate the health care resource utilization over a 12-month period in patients with controlled and uncontrolled T1DM in the public health care sector. Furthermore, the model will be used to project 5-, 10-, and 25-year costs.

Ethical Principles

This study was conducted in accordance with the principles laid by the 18th World Medical Assembly and all subsequent amendments [13]. Institutional permissions were received before the initiation of the study. Observation of both global and local regulations, including local data protection regulations, was maintained. Only data captured in patient records in the 12 months preceding the provision of informed consent were included in the study data. Participants were informed that their study-related data would be used by the sponsor in accordance with the local data protection law.

Results

Ethics clearance (reference number 200407) and institutional permissions were acquired. Funding was awarded and enrollment began on February 9, 2021, and was completed on August 24, 2021, with 224 participants. A database lock was performed on October 29, 2021. The statistical analysis and clinical study report were completed in January 2022.

Discussion

It is known that uncontrolled diabetes is associated with diabetic ketoacidosis and microvascular and macrovascular complications, which have associated cost implications. T1DM is a leading cause of morbidity, mortality, and health care resource utilization globally. Because the onset of T1DM typically arises early, effective disease management is imperative to limit its health and economic impact [14]. Existing literature has highlighted the higher cost of treating T1DM compared with T2DM [15]. To understand the economic impact of T1DM, the IQVIA CDM is used to evaluate the health care resource utilization over a 12-month period in patients with controlled and uncontrolled T1DM in the public health care sector. In addition, 5-, 10-, and 25-year projected costs are intended to be modeled to understand how costs change with the duration of the disease, assuming that patients maintain their current HbA_{1c} level.

Our discussion will largely focus on explaining the IQVIA CDM model, as it is a key instrument used to determine health resource utilization in this study.

The IQVIA CDM is a computer simulation model developed to determine the long-term health outcomes and economic consequence of interventions in T1DM and T2DM. The model is accessible on a licensed basis over the internet [16]. This is a non–product-specific diabetes analysis tool that performs real-time simulations taking into account intensive or conventional insulin therapy, oral antidiabetic drugs, screening and treatment strategies for microvascular complications, treatment strategies for end-stage complications, and multifactorial interventions [17].

The model simulates disease progression in both T1DM and T2DM. The IQVIA CDM is designed to take surrogate end points and translate them into long-term health economic outcomes. For example, HbA_{1c} is a surrogate marker that is linked to life expectancy [18].

Within the CDM, disease progression is based on a series of interdependent Markov submodels that simulate the progression of disease-related complications (angina, myocardial infarction, congestive heart failure, stroke, peripheral vascular disease, diabetic retinopathy, macular edema, cataract, hypoglycemia, ketoacidosis, nephropathy, end-stage renal disease, neuropathy, foot ulcer, and amputation) and other-cause mortality. The model is a fixed-time increment (annual) stochastic simulation with each submodel using time, state, and diabetes-type dependent probabilities. Monte Carlo simulations are performed at the individual patient level using tracker variables to accommodate complex interactions between submodels. The

XSL•FO
RenderX

progression of relevant physiological parameters (eg, HbA_{1c}, systolic blood pressure, lipids, and BMI) is simulated based on long-term epidemiological data, and event risk is constantly updated on the basis of these risk factors. The model facilitates interconnectivity and interaction between the modeled complications, representing the complex and varied sequelae of diabetes [19].

Analyses can be performed on patient cohorts, defined in terms of age, gender, baseline risk factors, and pre-existing complications. Economic and clinical data in the disease management module can be edited by the user, ensuring adaptability by allowing the inclusion of new data as they become available and facilitating the creation of country, health maintenance organization, or provider-specific versions of the model. In analyses, patients remain on initial treatment either for a set period of time or until a threshold of HbA_{1c} is reached; treatment duration and thresholds are set according to individual country practice [18].

A core outcome of the model is the estimate of the incremental cost per quality-adjusted life year gained. The model therefore requires the input of a comprehensive set of utility weightings for each model state. In version 9.0 of the CDM, default utilities are updated through the systematic review and subsequent assimilation of utility data into a utility data set consistent with the National Institute for Clinical Excellence reference case and applicable across multiple geographies [3]. Quality-of-life values are then calculated for every patient in each year of the simulation and used to estimate the average quality-adjusted life expectancy. Utilities are assessed on a scale from 0 to 1, where 0 represents death (no quality of life) and 1 indicates a healthy person without complications. In effect, for each acute event that occurs during 1 year of the simulation, a quality-of-life disutility value is used to adjust the overall quality-of-life utility value for the patient. Disutilities range from 1 to 0 and therefore cause the quality-of-life utility to either decrease or remain constant. After an event, patients change state, and the new state is associated with different state utilities. A minimum approach is applied to the estimation of utilities—in the case of multiple events, the lower utility is applied for that period. This is a simple and well-established approach to the application of utilities in the case of multiple interdependent health states [17,19].

Clinical and economic outcomes are calculated within the model using a nonparametric bootstrapping approach. This process simulates the lifetime progression of diabetes in a cohort of hypothetical patients repeating the process over numerous simulations. If 1000 patients are run through 1000 iterations, this produces 1000 mean values of clinical effectiveness and lifetime costs, which are then used to generate a scatter plot diagram and acceptability curves to express the likelihood of a treatment being cost-effective versus a comparator. In the base-case analyses, second-order uncertainty is not applied, and stability of outcomes is reached through a run of 1000 patients through 1000 iterations. There is an existing and emerging body of evidence looking to quantify health care resource utilization and appropriately describe economic considerations in the management of people living with T1DM [14,15]. There is, however, a lack of such data within developing nations that are required to facilitate policy discussions pertaining to the health and economic impact of T1DM in South Africa.

Limitations

The study limitations include the retrospective study design and selection of only 2 health care facilities. Data entries were reliant on a chart review and hence entries from the treating health care worker.

Conclusions

For chronic diseases such as T1DM, providing treatments and therapies that produce the best clinical outcomes while containing health care expenses is a matter of importance for providers, policy makers, and research at large. Quantifying the economic burden of T1DM is needed to effectively implement treatment strategies and policies that are cost-effective.

Data Availability

The data sets generated during this study are in various stages of manuscript publication and development, and thus are not currently available to the public.

Conflicts of Interest

KN, NR, and LS are employees of Sanofi, South Africa. Sanofi markets analog insulins within the diabetes therapeutic area. PN was a previous medical manager at Sanofi, South Africa.

Abstract

Background: One of the factors influencing health and well-being is dietary patterns. Data on food consumption are necessary for evaluating and developing community nutrition policies. Few studies on Jordanians' food consumption and dietary habits at various ages have been conducted, despite the increased prevalence of overweight, obesity, and chronic diseases. This will be the first study focusing on Jordanians' food consumption patterns that includes children, adolescents, adults, and older adults.

Objective: This cross-sectional study aims to describe the design and methodology of the Jordan's Population-based Food Consumption Survey, 2021-2022, which was developed to collect data on food consumption, including energy, nutrients, and food group intake, from a representative sample of Jordanians and to determine the prevalence of overweight and obesity and their relationship to food consumption.

Methods: Participants were selected by stratified random sampling, using the *Estimated Population of the Kingdom by Governorate, Locality, Sex, and Households, 2020* as the sampling frame. The food consumption survey sample was at the population level, representing gender and age classes (8-85 years old). The data collection period was 6 months. Food consumption was assessed using 24-hour dietary recall (2 nonconsecutive days, 1 week apart) interviews representing weekdays and weekends. In addition to data on food consumption, information on the use of food supplements, sociodemographic and socioeconomic status, and health was gathered. Weight, height, and waist circumference were all measured.

Results: The survey included 632 households with 2145 participants, of which 243 (11.3%) were children, 374 (17.4%) were adolescents, 1428 (66.6%) were adults, and 99 (4.6%) were older adults. Three food consumption databases were used to stratify the mean 24-hour dietary recall food consumption into energy intake, carbohydrates, proteins, fats, fiber, vitamins and minerals, and food groups. BMI was calculated and classified as normal, overweight, or obese. Central obesity was classified as normal or abnormal based on the waist-to-height ratio. The survey results will be disseminated based on age, energy, nutrient, and food group consumption. The prevalence of overweight and obesity by age group will be presented, as well as a comparison to the situation in Eastern Mediterranean countries.

Conclusions: The survey data will be helpful in nutritional studies, assessing changes in dietary patterns, and developing and evaluating nutrition or health policies. It will be a solid base for developing a future national surveillance system on food consumption patterns with comprehensive food consumption, physical activity, biochemical, and blood pressure data.

KEYWORDS

household; food consumption; 24-hour dietary recall; children; adolescents; adults; older adults; overweight; obesity

Introduction

The prevalence of noncommunicable diseases (NCDs) such as cardiovascular disease, high blood pressure, diabetes mellitus, and several forms of cancer has increased globally, as has obesity and overweight, and these trends have been linked to each other [1]. One of the major modifiable risk factors for obesity and NCDs is dietary patterns [2] and nutrient intake [3-6]. There has been a global movement in diet quality and nutrient intake toward a more Westernized pattern, which is characterized by a diet that is higher in added sugar, processed foods, fast food, and saturated fat while consuming fewer fruits, vegetables, dairy products, and fiber-rich foods [2,6,7]. This shift has been linked to the prevalence of obesity and NCDs being studied widely. To address these issues, various researchers have proposed studying general dietary patterns by looking at how foods and nutrients are consumed together as a solution. Numerous researchers have looked into the relationship between dietary habits and obesity. Thus, food consumption surveys are conducted worldwide [6,8].

In some countries, such as the United Kingdom [9] and the United States, continuous surveys are conducted over time [10]. At the same time, some surveys are conducted regularly (annually or biennial), such as in Germany [11], Italy [12], and Mexico [13]. Some surveys, on the other hand, are conducted irregularly, such as in France [14], Brazil [15], and Ireland [16]. Other surveys were carried out to assess dietary patterns, energy or nutrient intakes, or foods and beverages consumption in specific population subgroups or regions [17,18]. Food consumption surveys attempt to estimate the amount of food consumed by individuals. The outcomes vary from country to country and even within the same country due to differences in age, gender, and socioeconomic level.

The 24-hour dietary recall (24-h DR) is one of the most commonly used methods to assess food consumption. In some countries, all participants were subjected to multiple recalls [19,20]; however, in others, duplicate recalls were applied to a subsample of participants. The 24-h DR was carried out in a face-to-face or telephone interview using 24-h DR sheets or software to allow the structured and standardized collection of dietary intake data [21].

Other less common methods were used for estimating food consumption, including the food frequency questionnaire and dietary records [12,16].

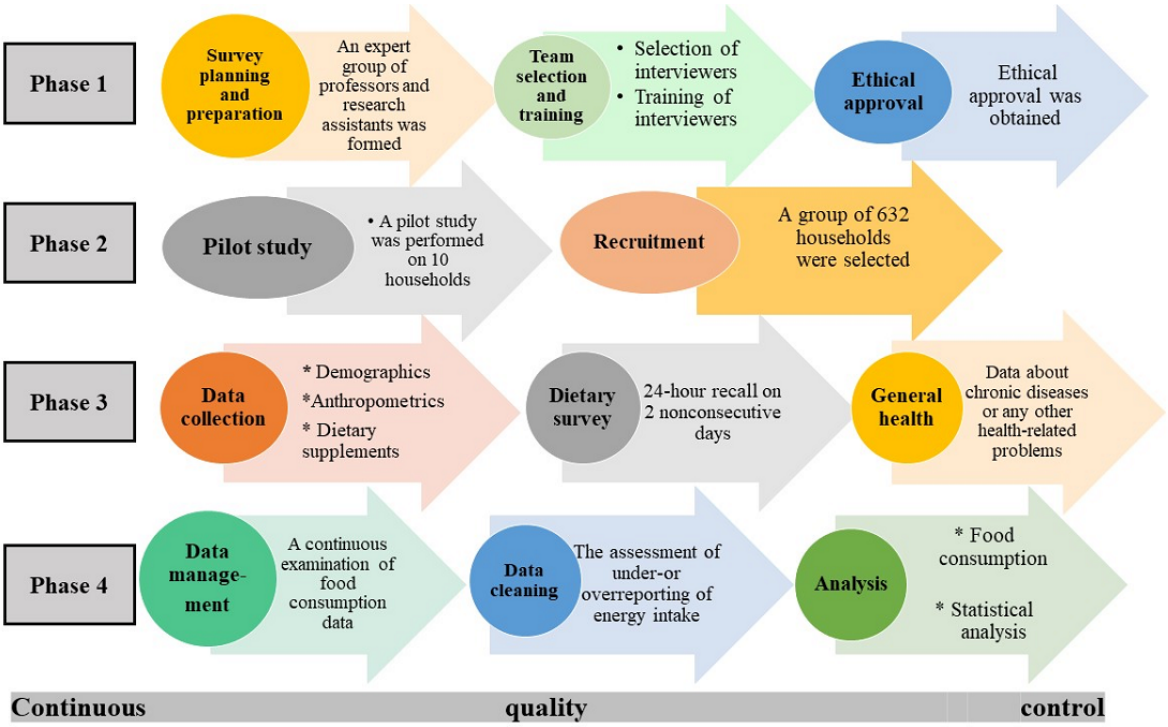
Many countries use the results of dietary and nutrition surveys to monitor their population's nutritional status, reveal trends in their health and dietary practices, determine links between food and health, identify populations at nutritional risk, and develop and implement nutritional policies tailored to reflect changes in dietary consumption [22-24].

The novelty of this study arises from the fact that it is the first to investigate the food consumption of different age groups in the Jordanian community, as well as obesity indices. Furthermore, the food consumption data were collected following the COVID-19 pandemic and its effects on food intake, body weight, and physical activity, primarily during school and university closures due to lockdowns. Therefore, this study aims to describe the design and methodology of Jordan's Population-based Food Consumption Survey (JPFCS), 2021-2022, which was developed to collect dietary habits and nutritional status in a representative sample of the general Jordanian population.

The specific study objectives were as follows:

- To evaluate the energy and nutrient intake in the general Jordanian population, including children
- To examine the differences in food, energy, and nutrient intake among different subgroups of the population and to identify subgroups at risk for a deficient or excessive intake of specific foods or nutrients
- To determine the prevalence of overweight and obesity in the Jordanian population and the correlation with food and nutrient intakes

Methods



Design and Study Population

The JPFCS is a population-based cross-sectional study on household food consumption patterns that was conducted within all regions of the Hashemite Kingdom of Jordan between October 2021 and March 2022. Jordanians aged ≥8 years were defined as children, adolescents, adults, and older adults in the JPFCS study. Obtaining 24-h DR for children aged <8 years is difficult, especially out-of-home food intake (food eaten in schools, kindergarten, and daycare centers). Therefore, the data reliability is higher among children aged ≥8 years [22].

This study included 4 phases. The first phase included survey planning, questionnaire preparation, interviewer selection and training, and obtaining ethical approval. The second phase involved conducting a pilot study and selecting households. The third phase included data collection from eligible household members on demographics, health, anthropometrics, and food consumption. The final phase will involve data management and analysis. The study protocol flowchart is presented in Figure 1.

XSL•FO
RenderX

Figure 1. Flowchart of the study protocol.

Sampling Frame

Jordan covers 89,342 km^2, with 10.8 million people in 2020 [25]. Geographically, the governorates of Jordan are located in 1 of 3 regions: the Central Region (Amman, Madaba, Balqa, and Zarqa), the Northern Region (Irbid, Mafraq, Ajloun, and Jarash), and the Southern Region (Aqaba, Karak, Ma'an, and Tafila). Each region has 4 governorates, including several districts and subdistricts, as shown in Figure 2. About 4.5 million people live in the Amman Governorate, almost half the country's population.

As a sampling frame, a sample of Jordanian households was selected using the *Estimated Population of the Kingdom by Governorate, Locality, Sex, and Households, 2020* [25]. The sample size was calculated using the following formula:

$$n=N*X / (X + N - 1)$$

where N is the population size and

$$X=Z_{\alpha/2}^2 \times p \times (1 - p) / MOE^2$$

where $Z_{\alpha/2}$ is the critical value of the normal distribution at $\alpha/2$ (eg, for a confidence level of 95%, α is .05, and the critical value is 1.96), *MOE* is the margin of error, *p* is the sample proportion.

A minimum sample size of 664 households was required. The number of governorate-selected households was calculated using the percentage of each region's households in the overall number of Jordanian households, as shown in Table 1.

XSL•FO
RenderX

Figure 2. Map of regions and governorates in Jordan and the number of invited households.

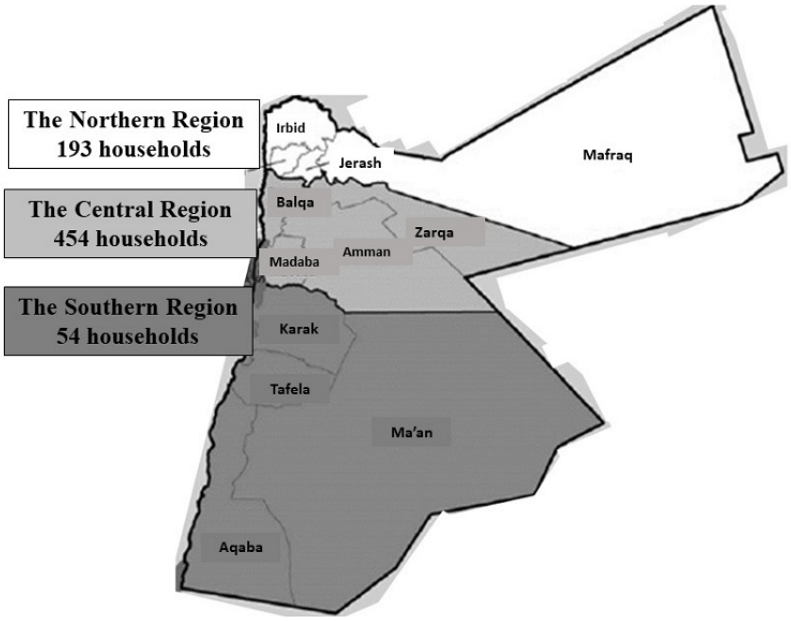


Table 1. Households distribution across regions.

Region	Households in each region (n=2,241,909), n (%)	Invited households, n (%)
Central	1,453,166 (64.8)	454 (64.8)
Northern	615,650 (27.5)	193 (27.5)
Southern	173,093 (7.7)	54 (7.7)
Total	2,241,909 (100)	701 (100)

Informed Consent

Individuals who agreed to participate in the survey received detailed information about the survey objectives and what was expected from them; a disclosure of the survey's requirements to preserve confidentiality, risks, and benefits; and a clear description of their decision to participate freely or not in the survey. After being presented with a detailed survey description, parents were asked for oral approval for their children to participate. No incentive money was offered for taking part in the survey. All data were recorded anonymously. Therefore, participants cannot be identified directly or through identifiers linked to the participants. At the start of the first home visit, participants or parents of children aged <12 years provided written informed consent.

Ethics Approval

The Institutional Board Review committee at The Hashemite University reviewed and approved the survey protocol (No.7/13/2020/2021).

Fieldwork Team: Management and Recruitment

During the project's development, an expert group of professors and research assistants was formed, which appointed a primary coordinator, 3 co-coordinators, and a data entry specialist. The group was responsible for planning this survey domain, determining and developing the instruments, conducting the training, monitoring data collection, and planning the cleaning and organization processing of the data.

In all, 14 interviewers with nutrition backgrounds joined the group because of the need for a thorough knowledge of the available foods on the market and the recipes usually prepared within the study population. The population density determined the number of interviewers assigned to each region: 9 were assigned to the Central Region, 3 to the Northern Region, and 2 to the Southern Region.

JPFCS Instruments

Structured Questionnaire and Data Management

A structured questionnaire was used to obtain information. The coding scheme of the participant's questionnaire consisted of a 5-digit number that includes the governorate number, subgovernorate number, interviewer number, household number, and participant number.

After signing the consent form, a face-to-face interview with the participant obtained sociodemographic information on age, gender, number of household members, and monthly household income. General health data and intake of dietary supplements of the participants were also obtained. Questions on the presence of chronic diseases or other health-related problems were included.

Anthropometrics, including weight, height, and waist circumference, were measured. Interviews were conducted at the participant's home at their convenience (usually outside working hours). Interviewers were encouraged to provide flexibility concerning appointment times. Additionally, the first

XSL•FO
RenderX

24-h DR was collected during these face-to-face interviews, whereas the second 24-h DR was collected by telephone.

Dietary Survey Tools

Dietary assessment was performed by the 24-h DR method on 2 nonconsecutive days (weekday and weekend). After respondents completed the questionnaire, the interviewer asked the respondent to recall and state the foods, beverages, and dietary supplements consumed in the preceding day, including their quantity, most commonly from midnight to midnight in the previous day. The interviewer obtained the first recall in a face-to-face interview with the eligible household member. The 24-h DR was typically completed in 20-40 minutes for each household member. The second recall representing the weekend was obtained by phone and showed acceptable estimates of the means and distributions of nutrient intakes among groups of individuals [26].

Food Description

All foods, beverages, and dietary supplements were recorded per food consumption occasion (morning, midmorning, noon, afternoon, evening, and late evening). As this was the collection of the first recall during face-to-face interviews, the date and day of the recall were recorded. In addition, all consumed foods or beverages; estimated amounts; methods of preparation; and brand names, if available, were documented. Interviewers used the multiple-pass method recommended by the United States Department of Agriculture. A 5-step dietary interview included multiple passes through the 24-h DR of the previous day, during which participants received cues to help them remember and describe the foods they consumed [27].

Portion Size Determination

Estimating portion sizes is an integral part of the dietary assessment. Various portion estimating aids have been developed, such as household measurement items (eg, standard measuring glasses, cups, teaspoons, and tablespoons), food models, food portions (obtained from fact sheets and manufacturer's information presented on the product's containers), food pictures, and other visual aids that may be used to help the participants judge and report portion size.

Participants in this survey were assisted in describing the actual quantity of food or beverage consumed by giving them a well-known idea about the quantity by using a colored food atlas containing over 100 foods, and composite recipes comprising photos of various foods and meals regularly consumed in Jordanian diets were created. For each food item, at least four photographs showed portion sizes. However, to our knowledge, no comprehensive food atlas has been developed in Jordan.

The photographs were categorized into different groups: bread and grains, fruits and vegetables, milk and dairy products, meat and meat alternatives, sweets and desserts, fat, and composite dishes. In addition, photographs of standard measurement devices in the Jordanian diet, such as cups, teaspoons, and tablespoons, were included.

Dietary Supplements

This section highlights the usage of dietary supplements: the frequency and type of dietary supplements. Usually, the use of dietary supplements was recovered by 2 methods. The first method used the 24-h DR; dietary supplements were recorded per consumption occasion and quantified and described as consumed [28]. The second method asked the frequency of use, in the last 12 months, of a predefined list of different dietary supplement types (eg, supplements of vitamins, such as D and folate; supplements of minerals, such as calcium and iron; supplements of multivitamins; and supplements of fatty acids, herbs, plants, and probiotics) [28].

Dietary Database

The detailed food consumption data were entered into a food composition database. Three food composition databases were used: ESHA's Food Processor nutrition analysis software (version 11:0; ESHA Research); *Composition of Local Jordanian Food Dishes* [29]; and *Lebanon Food Composition Data: Traditional Dishes, Arabic Sweets, and Market Foods* [30]. The final dietary variables that will be generated will represent the average of 2 recalls and be used for further analyses. Data about the total daily energy intake, macronutrients, vitamins, and minerals will be evaluated for all age groups.

Training of Interviewers

Smaller-group interviewers received 1-day training from the subnational coordinators and Zoom training (Zoom Video Communications) upon need. The training content included general study information, study objectives, instructions on the interviewer's attitudes, coding scheme, procedures for completion of the 24-h DR, and the use of the colored photographic food atlas. Interviewers were provided with the protocol for home visits and telephone calls, the content of the questionnaires, and the anthropometric measurement procedure. New interviewers recruited during the fieldwork received the same training except individually. In total, the training was repeated at least five times.

Anthropometrics

Anthropometric measurements, including height (cm), weight (kg), and waist circumference (cm), were performed on children and adults according to standard procedures by a trained nutritionist. Height was measured to the nearest centimeter, with participants in a standing position with light clothing and barefoot, using a portable wall stadiometer. Body weight was measured in the same conditions to the nearest tenth of a kilogram using a digital scale (Microlife WS 50). Waist circumference was measured using an anthropometric tape at the narrowest point between the lower costal border and the iliac crest. BMI (kg/m^2) was calculated from the height and weight measurements according to the Quetelet formula [22]: $BMI = weight\ (kg) / height\ (m^2)$, and the waist-to-height ratio was calculated by dividing the participant's waist circumference by his or her height [22].

XSL•FO
RenderX

Quality Controls

The following quality control steps were taken before, during, and after data collection:

1. A pilot study was performed for 10 households on the tools of the study to enhance the quality of the collected information.
2. Interviewers were chosen for their knowledge of 24-h DR interviews, market foods, traditional recipes, and anthropometric measurements. Furthermore, those having a solid background in the assessment of nutritional status, both theoretical and practical, and having received adequate training to conduct anthropometric measurements and assess food intake in various ways while studying at the university were chosen.
3. Training of the interviewers before data collection via face-to-face and Zoom meetings
4. A WhatsApp (Meta Platforms) group was formed to facilitate communication between the national coordinator, subnational coordinators, data entry specialists, and interviewers. It responds to and clarifies any study-related issue.
5. A continuous examination of food consumption data as they are entered into the nutrition analysis software
6. As an essential issue to consider, the assessment of under- or overreporting of energy intake was carried out using the cutoff points and method proposed by Goldberg et al [31] and Black [32].

Statistical Analysis

Data analysis was performed using SPSS software (version 22.0; IBM Corp). The normality of the distributions will be assessed through the Kolmogorov-Smirnov test and kurtosis and skewness values. Continuous variables will be presented as mean values and standard deviations, percentages for numerical variables, and frequencies (n and %) for categorical variables. This analysis will be stratified by sex and age.

Inferential statistics such as the Student *t* test (2-tailed), chi-square test, and independent samples *t* test (2-tailed) will be used based on the sample distribution and test statistics. Statistical significance will be accepted at $P<.05$, with a 95% confidence level.

Results

Sample Size

A representative sample of 701 households was randomly invited, and 632 households were included in the study, with a 90.2% response rate. A total of 2721 household members were approached, with a response rate of 78.8% (n=2145). Female subjects who were pregnant or lactating and children aged <8 years in the selected households were excluded from the study. The overall refusal rate of the included household members was 7.7% (210/2721). The hierarchical chart for household sampling, participant distribution, the number of excluded individuals, response rates, and refusals by region is shown in Figure 3.

The age groups for eligible male and female household members were as follows: 8-12, 13-19, 20-64, and ≥65 years. Table 2 summarizes the number of subjects interviewed for each sex of children, adolescents, adults, and older adults.

The 2145 subjects were divided into 4 age groups: 11.3% (n=243) were children (8-12 years), 17.4% (n=374) were adolescents (13-19 years), 66.6% (n=1428) were adults (20-64 years), and 4.6% (n=99) were older adults (≥65 years; Table 2).

The data collected included weight, height, and waist circumference measurements; the response rate for those measurements was high, with the lowest response rate (117/119, 98.3%) for waist circumference in girls aged 8-12 years. The collection of the second 24-h DR for dietary assessment revealed the lowest response rate (114/124, 91.9%) in boys aged 8-12 years (Table 3).

Before estimating nutrient and food group intakes, participants will be divided into 3 groups based on energy intake: underreporters, plausible reporters, and overreporters; plausible reporters will only be considered when estimating nutrient and food group intakes. The survey results will be disseminated in national and international scientific journals.

Both 24-h DRs combined	114 (91.9)	115 (96.6)	157 (96.3)	206 (97.6)	601 (98.8)	808 (98.5)	50 (100)	48 (98.0)

[a]WC: waist circumference.

[b]24-h DR: 24-hour dietary recall.

Discussion

Expected Findings

The study aimed to describe the design and methodology of a population-based food consumption survey to evaluate energy, nutrient, and food group intake in various age groups and the relationship with the prevalence of overweight and obesity.

Food consumption patterns in Jordan have not been studied at the population level. The published studies focused on specific age groups, such as food consumption among university students [33,34] and food and nutrient consumption in certain disease cases [35,36]. These studies used a food frequency questionnaire to focus on food group consumption, whereas 24-h DR was rarely used. Some of the studies mentioned above were pilot studies or had small sample sizes. Furthermore, food consumption data for various age groups and households are still scarce in many Middle Eastern countries.

The total number of respondents in this study was 2145, divided into 4 age groups: children, adolescents, adults, and older adults. The findings of this study will concentrate on food consumption

XSL•FO
RenderX

patterns, food group consumption, macronutrient consumption, and some micronutrient consumption, as well as anthropometric indices of obesity such as BMI and weight-to-height ratio in the studied age groups. In line with this protocol, Bel and de Ridder [37] completed a national survey on the Belgian national food consumption data collection in 2200 individuals (aged 10-64 years). Food intake data were collected with 2 nonconsecutive 24-h DRs.

Data from national studies will assist governments and international organizations in supplying statistical elements that will eventually advise national social security and health policies [38]. Additionally, this population-based survey will shed light on the whole population's energy intake, risk assessment, and nutritional status studies, with essential suggestions for developing policies [37,38].

Strengths and Limitations

Among study limitations, the household sample size was smaller than recommended; biochemical data, blood pressure measurements, food safety, hygiene, and lifestyle pattern were not included. Moreover, it was challenging to collect data about food consumption for children aged <8 years. However, among the study's strengths is that the protocol was similar to other population-based dietary surveys. Participants in the survey were from both sexes and were distributed in all representative age groups in Jordan. Additionally, the distribution of interviews on weekdays and seasonality was confirmed. The core strength of this protocol is that the dietary assessment was completed following the standards of the Jordanian diet and Arabic regions that covers food and nutrient intake, nutritional status, and eating habits. Furthermore, precise and comprehensive food consumption data are crucial for the food consumption assessment based on the food atlas prepared and introduced by the team workers.

Future Perspectives

As the first population-based household survey, it will provide updated information about dietary habits and food consumption patterns for various age groups, especially because it was conducted following the COVID-19 pandemic. The findings serve as a descriptive baseline for future follow-up and a critical starting point for future food consumption pattern studies of some Jordanian age groups.

Conclusions

This population-based food consumption survey aims to collect data on the food consumption of a sample representing various age groups. It will provide the most comprehensive evaluation of food consumption, identify the components of consumed food and their nutrient contents, examine energy and nutrient intakes, and identify the prevalence of overweight and obesity in the Jordanian community. It will serve as a solid nutritional background for future studies, help assess dietary patterns changes, develop and evaluate nutrition policies, and serve as a solid foundation for developing a future national surveillance system on food consumption patterns.

Acknowledgments

The authors would like to thank all the participants who spent time to participate in this study, without whom this work would not be possible. We would also like to thank the interviewers who assisted us in gathering data.

Authors' Contributions

All authors have read and agreed to the published version of the manuscript.

Abstract

Background: Antibiotic resistance is an individual and public health problem; multidrug-resistant infections could cause an estimated 10 million deaths worldwide by 2050. Unnecessary use of antimicrobials is the most important cause of resistance generation in the community, and an estimated 80% of antimicrobials are prescribed in primary health care, frequently for urinary tract infections (UTIs).

Objective: This paper presents the protocol for the first phase of the Urinary Tract Infections in Catalonia (Infeccions del tracte urinari a Catalunya) project. We aim to examine the epidemiology of the different types of UTIs in Catalonia (an autonomous community in Spain) and their diagnostic and therapeutic management by health professionals. Furthermore, we aim to evaluate the correlation between types and total consumption of antibiotics for recurrent UTIs in 2 cohorts of women with the presence and severity of infectious complications of urological origin, especially pyelonephritis and sepsis, and 2 potentially serious infections: pneumonia and COVID-19.

Methods: The study is a population-based observational cohort study including adults with a diagnosis of UTI registered in the Information System for the Development of Research in Primary Care (in Catalan: Sistema d'informació per al desenvolupament de la investigació en atenció primària), the Minimum Basic Data Sets of Hospital Discharges and Emergency Departments (in Catalan: Conjunt mínim bàsic de dades a l'hospitalització d'aguts i d'atenció urgent), and data from the Hospital Dispensing Medicines Register (in Catalan: Medicació hospitalària de dispensació ambulatòria) of Catalonia from the period between 2012 and 2021. We will evaluate the variables obtained from the databases to analyze the proportion of different types of UTIs, the percentage of adequate antibiotic treatments prescribed or received for recurrent UTIs according to the national guidelines, and the proportion of UTIs with complications.

Results: We expect to describe the epidemiology of UTIs in Catalonia from 2012 to 2021, as well as describe the diagnostic and therapeutic management of UTIs by health professionals.

XSL•FO
RenderX

Conclusions: We expect to find a high percentage of UTI cases with inadequate management according to the national guidelines, considering that on many occasions UTIs are treated with second- or third-line antibiotic therapies with a preference for the longest regimens. Furthermore, the use of antibiotic suppressive therapies, or prophylaxis, in recurrent UTIs will likely be highly variable. Moreover, we aim to determine whether women with recurrent UTIs treated with antibiotic suppressive therapies have a higher incidence and severity of potentially serious future infections, with special attention to acute pyelonephritis, urosepsis, COVID-19, and pneumonia, compared to women who receive antibiotic treatment after they present with a UTI. This is an observational study of data from administrative databases that will not allow causality analysis. The limitations of the study will be handled according to the appropriate statistical methods.

Introduction

It is estimated that 10 million people could die worldwide by 2050 from infections caused by multidrug-resistant pathogens if urgent measures are not taken to combat the problem of antimicrobial resistance, mainly among gram-negative bacteria and especially enterobacteria [1]. Antibiotic resistance is an individual health and public health problem; increasing community resistance can prolong the infectious process, increase the risk of infecting other individuals, and in the long term, lead to increased costs. Inappropriate use of antibiotics increases the frequency of related and sometimes serious side effects and causes increased mortality [2,3]. Unnecessary use of antimicrobials is the most important cause of resistance generation in the community, and it is estimated that 80% of antimicrobials are prescribed in primary health care (PHC) [4].

Urinary tract infections (UTIs) are a common infection in PHC, and most patients are treated with antibiotics [5-7]. In Spain, UTIs represent the second most frequent cause of antibiotic prescriptions [8]. Almost 60% of women experience at least one episode during their lifetime [9,10]. Antibiotic treatment of uncomplicated UTIs is, in most cases, empirical, and the selection of the antimicrobial is made according to the most frequently involved pathogen and local resistance. Several studies have suggested that up to 50% of antibiotic prescriptions are inappropriate [11-13]. There is a tendency to use broad-spectrum antibiotics, which do not usually provide substantial improvements in efficacy over narrower-spectrum antibiotics and instead favor increased resistance [4].

Approximately 80% of cases of uncomplicated UTI are caused by *Escherichia coli*, so empirical treatment should cover this pathogen [14-16]. The resistance of uropathogens to classical antibiotics has increased significantly in recent years in Spain [17]. Various studies in Spain have described resistant *E coli* infections and shown that a high percentage are resistant to penicillins. A study published in 2017 that was conducted in our setting among patients with community-acquired pyelonephritis showed that 23% were resistant to ciprofloxacin, while 1% were resistant to fosfomycin [18]. In the program of surveillance of nosocomial infections in the hospitals of Catalonia (Vigilància de les infeccions nosocomials als hospitals de Catalunya [VINCat; all non-English abbreviations are in Catalan unless otherwise noted]), a local database from Catalonia (an autonomous community in Spain) that is part of the Antimicrobial Optimization Program (Programa d'optimització de l'ús d'antimicrobians [PROA]), it was shown that in 2020 *E coli* had a high sensitivity to fosfomycin (96.6%) and nitrofurantoin (98.5%); by contrast, its sensitivity to the amoxicillin/clavulanic acid combination, cotrimoxazole, and quinolones was much lower (75%, 74%, and 72%, respectively) [19]. Resistance of enterobacteria to third-generation cephalosporins, mediated by the production of extended-spectrum β-lactamases, is a growing problem in *E coli* and *Klebsiella pneumoniae* strains. Data from the VINCat PROA 2020 report show that the proportions of β-lactamase-producing *E coli* and *K pneumoniae* urinary tract infections in the community in Catalonia were 9% and 11%, respectively [19]. UTIs caused by resistant microorganisms are associated with longer symptom duration than infections caused by sensitive strains, and treatment is more likely to fail [20].

According to the recommendations of the Infectious Diseases Society of America, empirical antibiotherapy should not be used when resistance rates exceed 20% for all strains [21]. This means that the use of combined amoxicillin/clavulanic acid, as well as quinolones and cotrimoxazole, should no longer be recommended for empirical treatment of UTIs in our country. Current guidelines in PHC recommend prescribing a single dose of 3 grams of fosfomycin trometamol or nitrofurantoin for 5 to 7 days [22,23]. The rationale for this strategy is to specifically target the etiologic agents causing acute cystitis based on knowledge of the local resistance patterns to antimicrobials of the most frequent uropathogens [24]. In recent years, the use of fosfomycin as the therapy of choice for these infections has increased significantly in Spain. However, more than half of all physicians prefer the use of short-course therapies to single doses [25]. One of the reasons mentioned by professionals for not giving first-line treatments is to prevent complications, the most frequent being acute pyelonephritis; however, there is currently no predictive scale available to determine the risk that a UTI will worsen to pyelonephritis. Only 26% of antibiotic prescriptions for uncomplicated UTI were for fosfomycin

XSL•FO
RenderX

trometamol (3-gram single dose) or nitrofurantoin in primary care management in Barcelona in the entire year 2020 (unpublished data).

Another dilemma faced by practitioners is the recommendation to give suppressive antibiotic treatment lasting more than 6 months to women who have repeated UTIs (defined as more than 2 UTIs in the last 6 months or more than 3 in the last year) [26]. However, this practice is not exempt from potential risks. In a recent article, a clear correlation was reported between a history of antibiotic use in the previous 2 years and the severity of COVID-19 (with severity defined as a variable combining death, hospitalization, and the presence of pneumonia), based on data from the Information System for the Development of Research in Primary Care (Sistema d'informació per al desenvolupament de la investigació en atenció primària [SIDIAP]) [27]. This correlation was very strong when antibiotics were taken in the previous 2 months, when there were more than 5 antibiotic regimens in the last 2 years, and when antibiotics were used that are critical and should be reserved for special cases, such as cephalosporins and quinolones. In addition, prudent use of antibiotics is necessary due to the increase in antibiotic resistance [3,28].

Urine culture requests are not always made according to guidelines. As early as 2000, it was documented that 44% of requests were made for cases of asymptomatic bacteriuria, a condition for which they should not be ordered and there should be no treatment [29]. In 2014, 92% of urine cultures that were ordered for a second time for patients with a UTI were not necessary [30]. In 2019, a range of 21% to 42% of requests for urine cultures were for uncomplicated UTIs in Barcelona city primary care management (in Spanish: gerencia *de atención primaria de Barcelona ciudad*), depending on the primary care center (unpublished data). The ordering of urine cultures for women with cystitis is only recommended in cases of (1) uncomplicated cystitis that, despite adequate antibiotic treatment, remains symptomatic (posttreatment urine cultures are used), (2) recurrent cystitis (pretreatment urine cultures are used), and (3) cystitis in pregnancy (both pretreatment and posttreatment urine cultures are used) [14]. The use of these tests when they are not necessary leads to antibiotic overprescription; moreover, since in many cases they are requested for cases of bacteriuria in elderly people who have been treated with antibiotics many times, the results of antibiograms recommend the prescription of second-line antibiotics for uropathogens that are often multidrug-resistant.

For all the above reasons, we propose the current protocol for the Urinary Tract Infections in Catalonia (Infeccions del tracte urinari a Catalunya [ITUCAT]) study, consisting of 4 work packages (WPs) that will be implemented successively in 3 phases, to evaluate different objectives related to UTIs in the adult population in Catalonia and investigate specific aspects of this condition in this population. The first phase of the project, which is presented in this paper, includes the first 2 WPs. WP 1 will evaluate the management of UTIs in Catalonia, and WP 2 aims to evaluate the correlation of antibiotic use for repeated UTIs with the presence of infectious complications in adult women. Subsequently, we will carry out the second phase with the data obtained from the first phase. At this stage, the aim is to create a scale to predict acute pyelonephritis in patients with UTI by evaluating clinical variables; this will be WP 3. Finally, in the third phase, we will perform WP 4, which aims to determine the degree of inadequacy in requests for urine cultures based on clinical practice guidelines and to establish the basis for a training intervention.

The study described in this paper corresponds to the first phase, which includes WP 1 and WP 2.

Methods

Study Design and Population

This is a population-based observational cohort study. The inclusion period was from January 1, 2012, to December 31, 2021. The study population was patients aged ≥18 years with a diagnosis of UTI registered in SIDIAP during the study period. UTI diagnoses included the International Statistical Classification of Diseases and Related Health Problems, 10th Revision (ICD-10) codes (Table 1).

XSL•FO
RenderX

Table 1. Health problems included in the study and their International Statistical Classification of Diseases and Related Health Problems, 10th Revision codes.

ICD-10 codes	Health problems
N10	Acute tubule-interstitial nephritis
N30	Cystitis
N30.0	Acute cystitis
N30.1	Interstitial cystitis (chronic)
N30.2	Other chronic cystitis
N30.3	Trigonitis
N30.8	Other cystitis
N30.9	Cystitis, unspecified
N34	Urethritis and urethral syndrome
N34.1	Nonspecific urethritis
N34.3	Urethral syndrome, unspecified
N39.0	Urinary tract infection, site not specified
N41	Inflammatory diseases of prostate
N41.0	Acute prostatitis
N41.1	Chronic prostatitis
N41.3	Prostatocystitis
N45	Orchitis and epididymitis
N45.0	Orchitis, epididymitis, and epididymo-orchitis with abscess
N45.9	Orchitis, epididymitis, and epididymo-orchitis without abscess

Data Collection and Data Sources

The data needed to carry out the project will be obtained from the SIDIAP database, the Minimum Basic Data Sets (Conjunt mínim bàsic de dades [CMBD]) of Hospital Discharges and Emergency Departments (Conjunt mínim bàsic de dades a d'hospitalització d'aguts [CMBD-HA] and Conjunt mínim bàsic de dades d'atenció urgent [CMBD-UR], respectively) registries, and data from the Hospital Dispensing Medicines Register (Medicació hospitalària de dispensació ambulatòria [MHDA]).

The SIDIAP contains pseudonymized clinical information from the Electronic Health Records in Primary Care (Estació clínica d'atenció primària) program [31], which is the electronic health records program for PHC of the Catalan Health Institute (Institut català de la salut [ICS]) in Catalonia. The ICS manages 279 PHC centers, covering a population of 5.8 million people (approximately 80% of the Catalan population). Among this adult population, information is available for more than 3384 PHC medical staff members.

The information recorded in SIDIAP contains sociodemographic data; health conditions, coded by ICD-10 [32]; clinical parameters; tobacco and alcohol use; diagnostic procedures; PHC laboratory test results; specialists' referrals; and prescriptions of PHC medical staff, with the corresponding pharmacy billing data, registered as anatomical, therapeutic, chemical (ATC) classification system codes [33]. Several reports have shown that SIDIAP data are useful for epidemiological research [34,35]. SIDIAP is listed under the European Network of Centres for Pharmacoepidemiology and Pharmacovigilance resources database [36].

The CMBD is a population-based registry that collects information on pathologies treated in the health centers of Catalonia [37] and includes ICD-10 codes [32]. This registry contains information provided by all Catalan health care centers on health care activity and morbidity. The CMBD-HA contains information on acute hospitalizations, with reasons and dates for hospital admission. The CMBD-UR reports activity in emergency departments.

The MHDA is a registry containing information on specific drugs that are dispensed in hospitals and reimbursed by the Catalan health system [38,39].

Sample Size

A feasibility count was requested from the SIDIAP database for the years 2012 and 2021. It was estimated that approximately 2.5 million UTIs were registered in the Catalan population during the study period.

Variables

Variables included in WP 1 and WP 2 include sociodemographic information; clinical variables and health conditions, with ICD-10 codes; tobacco and alcohol use; PHC laboratory test results; vaccination status (for influenza, pneumococcus, and COVID-19); prescriptions, with their corresponding pharmacy invoice data registered as ATC codes [33] in addition to prescriptions for MHDA drugs [38,39]; dates of sickness leaves,

XSL•FO
RenderX

visits, and referrals (to second- and third-level centers); sexual and reproductive health care; CMBD-HA hospital information; and CMBD-UR emergency department information (Multimedia Appendix 1).

Study End Points

Primary End Points

The primary end points of the first phase for WP 1 are the proportion of different types of UTI (uncomplicated UTIs, recurrent UTIs, and pyelonephritis), the percentage of first-line antibiotics used for different types of UTI according to the national guidelines [40,41], and the percentage of inappropriate prescriptions, with the type of antibiotic of these prescriptions. The primary end points for WP 2 are the percentage hospitalization rate and the proportion of UTIs with complications (ie, pyelonephritis, sepsis, pneumonia, and COVID-19). COVID-19 infection will be determined by ICD-10 codes, tests (ie, polymerase chain reaction tests, rapid antigen tests, and others), or both.

Secondary End Points

The secondary study endpoints are (1) types of UTI in women aged ≥18 years with the percentage of recurrent UTIs (defined as more than 2 UTIs in the last 6 months or more than 3 episodes in the last year); (2) types of UTI in men aged ≥18 years; (3) the percentage of urine cultures and laboratory tests ordered for the different types of UTI in both men and women; (4) the percentages of different types of antibiotics used in patients with UTIs, as well as dosage and duration of treatment; (5) the percentage of women with recurrent UTIs who were treated with suppressive therapy (ie, antibiotic treatment 3 times a week for 6 months or more) and the duration of the therapy; (6) the percentage of infectious complications, especially acute pyelonephritis and sepsis, in the 2 cohorts (ie, women with recurrent UTIs with suppressive therapy and women with recurrent UTIs without suppressive therapy but with UTIs treated punctually; (7) the percentage of pneumonia and COVID-19 infection in the 2 cohorts (ie, women with multiple antibiotic regimens for UTIs or suppressive therapy and women with UTIs treated punctually); and (8) the frequency of clinical variables of people affected by UTI who progress to acute pyelonephritis.

Statistical Analysis

Demographic and baseline characteristics of the participants will be reported as frequencies and percentages for categorical variables and means and standard deviation or median and interquartile range for continuous variables, as appropriate.

For WP 1, descriptive statistics will be reported for the results. For WP 2, a severity variable will be constructed that will include mortality and hospitalization, in addition to the presence of pneumonia in cases of COVID-19. Quantitative variables will be described as means and standard deviation, while categorical variables will be described as the proportion of exposed and unexposed individuals. Univariate tests will include the Student *t* test and the chi-square test, as appropriate. For the primary outcome, marginal structural models will be fitted to estimate causal effects by correcting for confounders. Inverse probability weights will be estimated as a function of propensity score using sociodemographic variables and clinical variables. The inverse probability weights will be used in the marginal structural model to estimate the risk ratio and confidence intervals for the prevalence of each outcome among individuals exposed to antibiotics versus those not exposed to antimicrobials. During the assessment of the correlation of prior antibiotic exposure with the different outcomes, patients will only be counted once and assigned to the worst outcome (with the severity of COVID-19 ranked in decreasing order as death, hospitalization, and pneumonia). The Wald test will be used to determine whether the adjusted risk ratios are significantly different from zero at a significance level of 5%.

Ethical Aspects and Data Confidentiality

The present study follows national and international regulations, including the Declaration of Helsinki Ethical Principles for Medical Research Involving Human Subjects, Good Research Practice principles and guidelines, and the *Real Decreto 957/2020, de 3 de noviembre*, which regulates observational studies of medicines for human use. The study protocol was approved by the Institut Universitari d'Investigació en Atenció Primària Jordi Gol Clinical Research Ethics Committee, the reference institution for research in primary health care of the ICS, on September 27, 2022. In accord with Spanish legislation on confidentiality and data protection (*Ley Orgánica 3/2018, de 6 de diciembre de 2018, de Protección de Datos Personales y garantía de los derechos digitales*), data included in SIDIAP are always pseudoanonymized. Thus, it is not necessary to obtain informed consent from the participants.

Results

We expect to describe the epidemiology of UTIs in Catalonia during the period from 2012 to 2021, including the characteristics of the population, diagnoses of UTI, the use of urine cultures or laboratory tests, and different antibiotics prescribed according to treatment guidelines for dose and duration. Furthermore, we will report the degree of adequacy of the prescribed treatments and the clinical evolution of the patients (ie, the rates of clinical resolution, recurrence, hospitalization, and complications, such as acute pyelonephritis, urosepsis, pneumonia, COVID-19, and death).

The first phase of the ITUCAT project is expected to be completed during the second half of 2023. Phase 2 will start after the data from phase 1 are obtained and used to create the predictive scale for acute pyelonephritis in patients with UTI; phase 2 is expected to be completed in 2024. Phase 3 will be carried out during the second half of 2023 and during 2024 to evaluate the degree of inadequacy in requests for urine cultures according to the clinical practice guidelines and establish the basis for a training intervention.

The results obtained will be presented according to the Reporting of Studies Conducted Using Observational Routinely Collected Health Data Statement for Pharmacoepidemiology (RECORD-PE) recommendations [42].

XSL•FO
RenderX

Discussion

We expect to find inadequate management in a high percentage of UTI cases, considering that on many occasions patients are treated with second- or third-line antibiotic therapies with a preference for the longest regimens. Likewise, the use of suppressive antibiotic therapy as a prophylaxis in cases of recurrent UTI is expected to vary in our study.

In addition, we aim to determine whether women with recurrent UTIs treated with antibiotic suppressive therapy have a higher incidence and severity of potentially serious future infections, with special attention to acute pyelonephritis, urosepsis, COVID-19, and pneumonia, in comparison to women who are treated with antibiotics only when they present with a UTI.

All the information obtained in this first phase will allow us to continue with the following WPs of the project. Furthermore, if we find the inappropriate use of antibiotics, we will work on the creation of proposals to promote the correct treatment of UTIs in our environment according to clinical guidelines [40,41]. In this way, we will promote responsible management of UTIs in PHC among health care personnel and patients. In addition, our study will provide valuable information for health care policy makers and national programs to optimize the use of antimicrobials.

Because this is an observational study based on data from administrative databases, it will not allow causality analysis. However, the results will be derived from health care carried out under conditions of routine clinical practice with data from electronic primary-care registries, including the SIDIAP, CMBD-HA, and CMBD-UR databases, which have proven to be valid and representative of the population in numerous previous studies [31,34,35]. Some limitations of these studies arose from underreporting of some variables and diagnoses that we will try to avoid with the use of the different databases. Another limitation of the databases is the lack of links between diagnoses and treatments. In order to deal with bias from this specific limitation, we plan to use proxy values available in the databases, such as dates of prescriptions and dates of diagnoses. An inherent limitation of observational studies is the presence of unmeasured confounding variables. A complete adjustment for all possible confounders would require detailed information on clinical parameters, lifestyles, socioeconomic conditions, use of over-the-counter medications, and personal circumstances, which is not routinely present in electronic health records, causing residual confounding bias. Nevertheless, this bias would affect all included populations equally. To minimize confounding, we will conduct sensitivity analyses and use external adjustments or specific statistical methods when appropriate [43]. We will also take this aspect into account in the scientific discussion of the results, as it is an inherent limitation of studies conducted with electronic health records.

Acknowledgments

This study obtained funding from a Strategic Research and Innovation Plan for Health (Pla estratègic de recerca i innovació en salut) 2022-2024 grant for the financing of research projects in the field of primary health care (file code SLT021/21/000022).

Data Availability

The data sets used and analyzed are available from the corresponding author on reasonable request.

Authors' Contributions

All authors designed the study and wrote the study protocol. SFG wrote the first version of the manuscript, which was reviewed and approved by all authors.

Conflicts of Interest

CL declares having received research grants from Abbott Diagnostics. The rest of authors have no conflicts of interest.

Abstract

Background: In total, 3.2% of American adults report using e-cigarettes every day or some days. The Vaping and Patterns of E-cigarette Use Research (VAPER) Study is a web-based longitudinal survey designed to observe patterns in device and liquid use that suggest the benefits and unintended consequences of potential e-cigarette regulations. The heterogeneity of the e-cigarette devices and liquids on the market, the customizability of the devices and liquids, and the lack of standardized reporting requirements result in unique measurement challenges. Furthermore, bots and survey takers who submit falsified responses are threats to data integrity that require mitigation strategies.

Objective: This paper aims to describe the protocols for 3 waves of the VAPER Study and discuss recruitment and data processing experiences and lessons learned, including the benefits and limitations of bot- and fraudulent survey taker–related strategies.

Methods: American adults (aged ≥21 years) who use e-cigarettes ≥5 days per week are recruited from up to 404 Craigslist catchment areas covering all 50 states. The questionnaire measures and skip logic are designed to accommodate marketplace heterogeneity and user customization (eg, different skip logic pathways for different device types and customizations). To reduce reliance on self-report data, we also require participants to submit a photo of their device. All data are collected using REDCap (Research Electronic Data Capture; Vanderbilt University). Incentives are US $10 Amazon gift codes delivered by mail to new participants and electronically to returning participants. Those lost to follow-up are replaced. Several strategies are applied to maximize the odds that participants who receive incentives are not bots and are likely to possess an e-cigarette (eg, required identity check and photo of a device).

Results: In total, 3 waves of data were collected between 2020 and 2021 (wave 1: n=1209; wave 2: n=1218; wave 3: n=1254). Retention from waves 1 to 2 was 51.94% (628/1209), and 37.55% (454/1209) of the wave 1 sample completed all 3 waves. These data were mostly generalizable to daily e-cigarette users in the United States, and poststratification weights were generated for future analyses. Our data offer a detailed examination of users' device features and specifications, liquid characteristics, and key behaviors, which can provide more insights into the benefits and unintended consequences of potential regulations.

Conclusions: Relative to existing e-cigarette cohort studies, this study methodology has some advantages, including efficient recruitment of a lower-prevalence population and collection of detailed data relevant to tobacco regulatory science (eg, device wattage). The web-based nature of the study requires several bot- and fraudulent survey taker–related risk-mitigation strategies, which can be time-intensive. When these risks are addressed, web-based cohort studies can be successful. We will continue to explore methods for maximizing recruitment efficiency, data quality, and participant retention in subsequent waves.

Introduction

Background

In the United States, 3.2% of adults, 7.6% of young adults [1], and 11.3% of high school students [2] use e-cigarettes (every day or some days for adults and use in the past 30 days for high school students), and the US Food and Drug Administration Center for Tobacco Products is interested in data-driven regulations that maximize public health benefits while minimizing unintended consequences [3].

Our team is conducting a web-based longitudinal survey to observe patterns that suggest the benefits and unintended consequences of three potential e-cigarette regulations: (1) limits on nicotine, (2) constraints on nicotine flux (ie, nicotine emitted over time) [4], and (3) reduction in flavor availability. Electronic nicotine delivery systems (ENDS) are e-cigarettes that heat a nicotine liquid into an aerosol that can be inhaled by a user, whereas electronic nonnicotine delivery systems (ENNDS) heat a nonnicotine-containing liquid (ENNDS are included in the study as ENDS users may become ENNDS users and vice versa). Both include a battery that powers a heating element, such as a metal coil, which is in contact with the liquid. Device size, shape, materials, features (eg, coil modifiability), and specifications (eg, battery voltage, coil resistance, and device wattage) vary considerably. The liquids are typically made of a propylene glycol and vegetable glycerin solution that contains flavorings and nicotine, a psychoactive and addictive drug [5].

Unlike cigarettes, which are all relatively similar in design, the heterogeneity of ENDS and ENNDS devices, settings, and liquid characteristics results in a highly customizable user experience. This heterogeneity and a lack of standardized reporting requirements for device specifications and liquid characteristics can lead to measurement challenges. For example, some manufacturers report liquid nicotine concentration as a percentage of the liquid solution, whereas others report it in milligrams per milliliter. These inconsistencies may partially explain why reporting liquid nicotine concentration accurately in surveys is challenging for some users [6,7]. In addition, liquid manufacturers sometimes inaccurately label nicotine concentration [8-10], and device manufacturers often do not publicize specifications such as device wattage, voltage, and resistance, thus creating additional challenges for researchers even after collecting the brand and model of a user's device. These data are critical for evaluating nicotine and toxicant emissions and delivery. For example, device wattage is a predictor of nicotine emissions and delivery to the blood [11,12].

Web-based survey methods also present challenges that must be addressed in both a preventive and ad hoc manner; such challenges include recruitment of lower-prevalence populations and navigating bots [13] and fraudulent survey takers [14], who primarily aim to deceive researchers for the purpose of receiving incentives. Nevertheless, web-based survey methods are an increasingly used avenue to recruit participants, collect data, and provide incentives across public health research domains, including ENDS and ENNDS research, and they may have several benefits over traditional methods, such as convenience for participants and researchers, scalability, reduced costs, and safety during extraordinary times such as the COVID-19 pandemic.

Studies that address these measurement and data integrity (eg, bots) challenges can offer a more detailed examination of frequent ENDS and ENNDS users' device features and specifications, liquid characteristics, and user behaviors while simultaneously benefiting from improved convenience, scalability, reduced costs, and safety. Moreover, through an improved understanding of the relationships among device type, features, specifications, liquid characteristics, and key user behaviors such as nicotine dependence, regulators may gain a more precise understanding of how regulating devices and liquids may positively or negatively affect users before implementing a regulation.

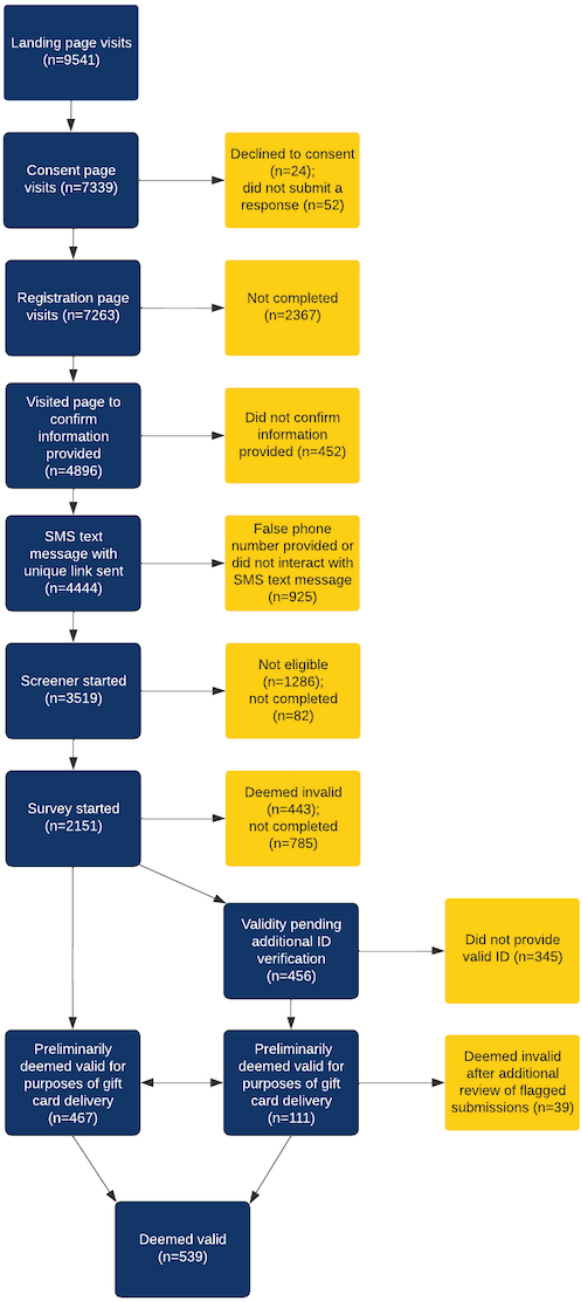
Objectives

Our aim is to describe the protocols for waves 1 to 3 of the Vaping and Patterns of E-cigarette Use Research (VAPER) Study, a web-based longitudinal cohort study of ENDS and ENNDS users (aged ≥21 years) who use devices ≥5 days per week and have a residential address in the United States. We also discuss our recruitment and data processing experiences and lessons learned, along with the benefits and limitations of implementing our strategies for mitigating measurement-, bot-, and fraudulent survey taker–related challenges.

Methods

Overview

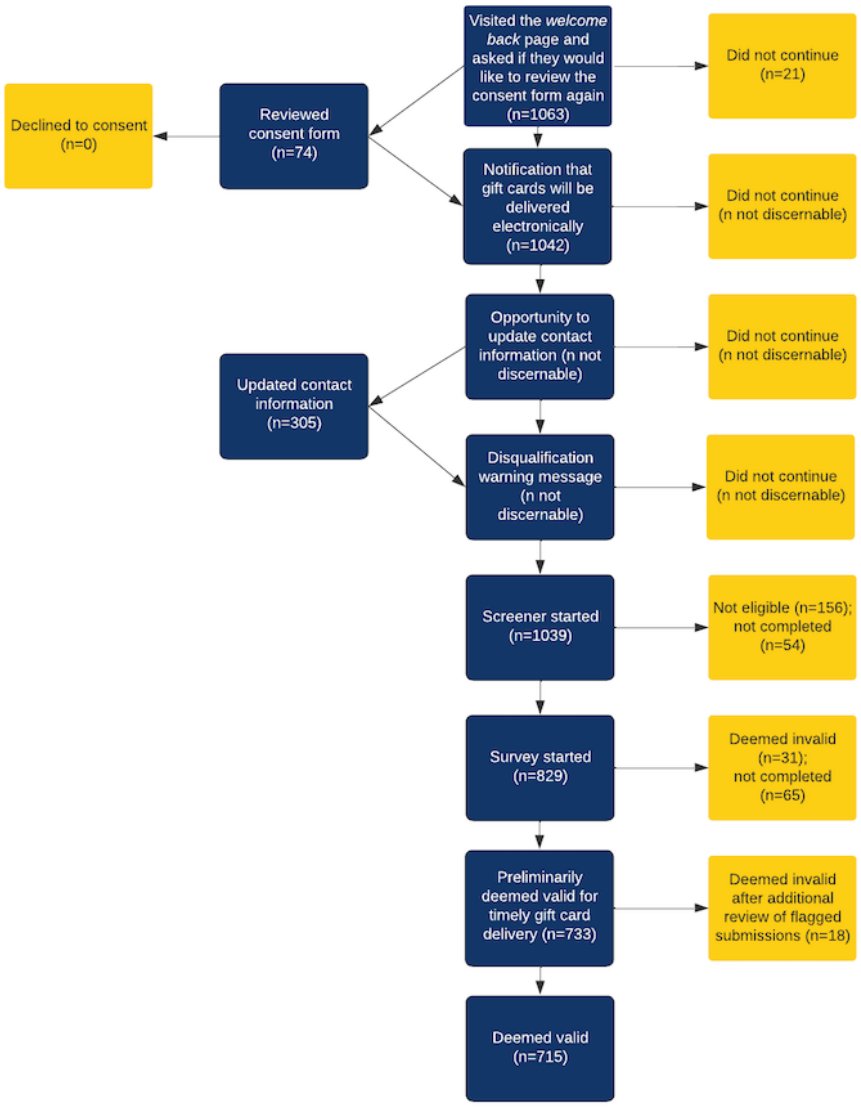
The protocols for waves 1 to 3 are similar. Key differences will be addressed; where none are discussed, similar protocols were followed in all waves and will also be followed in future waves. Additional technical details can be found in Multimedia Appendix 1. All data are collected using REDCap (Research Electronic Data Capture; Vanderbilt University), a free, secure, and robust data collection platform.



The VAPER Study is a cohort study conducted on the web, including participant recruitment, data collection, and incentive delivery to participants. A self-selection sampling method is used. Recruitment-related information for the baseline survey is posted on Craigslist Jobs and Gigs boards and directs potential participants to click a hyperlink to a study-specific landing page with a welcome message hosted on the Virginia Commonwealth University website (the web page is not accessible through other avenues unless the hyperlink is shared by participants). After

XSL•FO
RenderX

providing informed consent, participants complete a registration form requesting the following information: name, email address, mobile phone number, residential address, and date of birth. Participants then review the information they provided and complete a phone number authentication that contains a unique link to the REDCap screener and survey. Before starting the survey, all participants are reminded of actions that can result in their disqualification (also present in the consent form). Upon survey completion, identity verification, and review of submitted data, participants are mailed a US $10 Amazon gift code (Figure 1).



Participants who submit valid baseline surveys and indicate an interest in participating in additional surveys are invited to complete a follow-up survey in subsequent waves. Invitations are sent to their mobile phones and email addresses, and the links to the survey are tied to their previously established record ID number. Returning participants are greeted with a *welcome back* message and, before completing the screener, are provided with the opportunity to review the consent form again, are notified that they will receive their gift codes electronically, are asked to review and update their contact information (if necessary), and are again reminded of actions that can result in their disqualification (Figure 2).

Figure 1. Flow diagram of baseline survey participants from wave 3.

XSL•FO
RenderX

Figure 2. Flow diagram of follow-up survey participants from wave 3.

To replace those lost to follow-up, new participants are recruited to complete the baseline survey, resulting in 2 concurrent REDCap surveys per wave: one for baseline participants and another for follow-up participants. Therefore, a new baseline cohort is created in each wave, with all previously established cohorts taking a concurrent and identical follow-up survey (Table 1). The measures in the questionnaire evolve as changes in the marketplace are recognized, as new information is learned about the quality of the questions and response options, and as the VAPER Study team fields requests from the funders and colleagues working on related laboratory-based projects. This evolution creates a layer of complexity when analyzing data longitudinally but will not affect cross-sectional analyses. For longitudinal data analyses, steps are taken to ensure that the underlying questions and response options are comparable. More specifically, a data workbook is used to track variable names for each wave and survey (ie, baseline and follow-up surveys); whether edits have been made to the question or response option text; and if "yes," what those edits were. Manuscript authors can then determine whether their measures can be used across waves in consultation with our statistician and wider team.

Table 1. Surveys taken in each wave, by cohort.

	Wave 1: May 2020-October 2020	Wave 2: December 2020-April 2021	Wave 3: September 2021-December 2021
Cohort 1	Baseline	Follow-up	Follow-up
Cohort 2	N/A[a]	Baseline	Follow-up
Cohort 3	N/A	N/A	Baseline

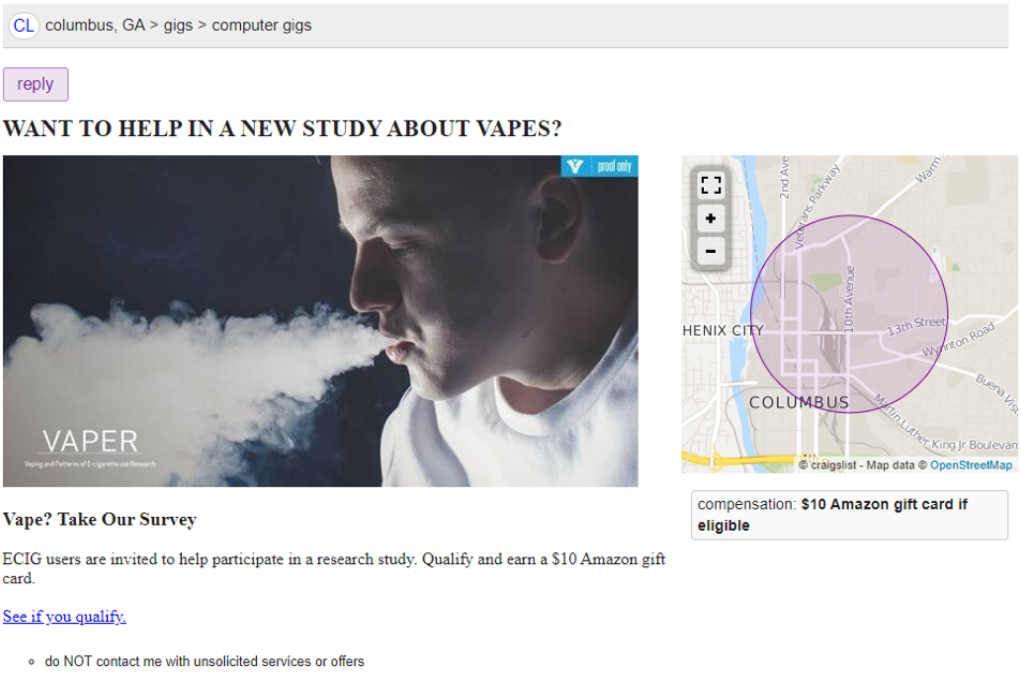
Sample

Participants are ENDS and ENNDS users who typically use e-cigarettes at least 5 days per week, are aged ≥21 years, and have a residential address in the United States. Adults are recruited for several reasons: (1) more adults (10.9 million) [15] than youth (2.2 million) [16] use ENDS and ENNDS; (2) school-based recruitment methodologies are slower, more expensive, and less scalable; and (3) most of our hypothesized relationships among devices, liquids, and user behaviors are expected to be present irrespective of age (eg, a negative correlation between device power and liquid nicotine concentration). The age of 21 years was chosen over 18 years because of institutional review board (IRB) guidance and state and federal legislation that raised the minimum age of purchase to 21 years. Users who use "At least five days per week" are recruited as we are primarily interested in within-person longitudinal data. Our rationale is that frequent ENDS and ENNDS users are more likely to continue using and remain in the sample compared with users using <5 days per week, thereby increasing the quality of the longitudinal data.



The intended sample size (N=900) was determined by assuming an effect size of 10% (for *t* tests to detect differences between 2 dependent means using a 2-tailed test), Cronbach α<.05, and power of 0.85. After adjusting for an anticipated loss to follow-up rate of 25%, we determined that a baseline sample of 1200 participants was required to ensure adequate power for the study duration.

Recruitment

Craigslist is used to recruit baseline survey participants. It has a high volume of website traffic, a user base interested in earning income, affordable rates for posting messages targeted to potential participants in the United States, and a track record of success in helping tobacco control [17] and other public health researchers [18] recruit participants. Craigslist postings include a photo and text indicating that we are recruiting ENDS and ENNDS users and will compensate participants with a US $10 Amazon gift code (Figure 3). Note that social media (ie, Facebook and Instagram) and vape shop customer recruitment were attempted early in wave 1 but, because of cost and efficiency reasons, were replaced by a Craigslist-focused strategy. Craigslist was used to recruit most of our wave 1 sample and to replace all participants lost to follow-up in waves 2 and 3.

The Craigslist postings are posted on the Jobs and Gigs boards in as many as 404 geographic locations per wave, including all 50 US states (Multimedia Appendix 1). Both boards were used in most geographic locations, but sometimes only 1 board was used. Geographic locations were selected based on population estimates of major US cities and states, with preference given to the most populous catchment areas (note that Craigslist regions can cover a single city, regions, or large geographic areas spanning entire states). To optimize recruitment efficiency, Craigslist postings are reposted at varying time intervals primarily based on the number of competing advertisers displacing our postings to a lower position on the page (eg, New York City boards need to be reposted 2 times per week, whereas others are reposted as infrequently as once per month). Other metrics are tracked and considered as well, including the fluctuating volume of clicks from different locations over the course of a survey wave (measured in real time using Google Analytics) and the number of participants completing the survey from each location (higher-yielding locations tend to be reposted more frequently).

Figure 3. An example Craigslist posting from wave 3.

XSL•FO
RenderX

Communication Strategy for Maximal Retention

To invite participants who previously submitted valid surveys to complete additional survey waves, our team sends 2 pairs of emails and SMS text messages per week for 2 weeks at the start of each wave. Afterward, 1 pair of emails and SMS text messages is sent per week for 6 weeks to all participants who have not yet completed the survey. The subject lines and message content of the reminders vary from week to week to attempt to appeal to different audiences. Note that, at the start of wave 2, tests were conducted to select the most effective communication content (eg, varied email subject lines) and frequency of communications (ie, 1 vs 2 pairs of emails and SMS text messages sent per week for 2 weeks, with each pair sent simultaneously). The tests were conducted using a small subset of the wave 1 sample (n=148), and we found no statistically significant differences in valid survey completion rates or the rates of opting out of SMS text messages, and the absolute number of SMS text message opt-outs was minimal (n=5).

Engagement Strategy

Loss to follow-up is common in longitudinal studies. To increase engagement and minimize loss to follow-up, our participants are sent an annual postcard indicating that they are eligible for a raffle. The annual raffle has 4 winners, with each receiving a US $100 Amazon gift code. Completing 2 surveys will earn participants 10 chances to win the raffle, and completing 3 surveys will earn them 50 chances.

Measures

Measures in the questionnaire are from or derived from those found in the PhenX Toolkit (RTI International; a web-based catalog of high-priority measures), validated measures, or measures used in large national surveys whenever possible and appropriate. We developed measures in all other instances. Randomization of questions and response options is not used; however, adaptive questioning to reduce the number and complexity of the questions is used (eg, questions are tailored based on self-reported device features). The number of questions per page is limited to 1 whenever possible; however, it is necessary to have more than 1 question per page when participants are asked to further specify information or in instances where the questions are easier to respond to in sequence (eg, grid-style questions). The number of pages varies widely based on the devices and liquids used and related behaviors. To ensure completeness, all participants must provide a response to continue to the next page (an error message is received when participants attempt to continue without completing all the questions). To mitigate data integrity issues, a back button is not used.

The usability and technical functionality of the questionnaire are rigorously tested by the study team before fielding the questionnaire in each wave. All permutations of skip logic and response option constraints are tested, and before the first wave, mock participants not familiar with the study completed the questionnaire and provided feedback on wording of the prompts, questions, response options, functionality of specific features (eg, photo upload), and overall user experience. Although these actions greatly mitigate technical issues and improve user experience, participants who complete the study during each wave often provide comments and suggestions that are incorporated as well.

To discern the impacts of potential regulations, outcome measures include current ENDS and ENNDS use (≥5 days per week), current combustible cigarette use (past 30 days), product switching (eg, devices, device settings, and liquid nicotine concentration and flavor), do-it-yourself flavor mixing (ie, mixing their own flavored solution typically by mixing a combination of propylene glycol, vegetable glycerin, nicotine, and flavorings), ENDS dependence, and respiratory symptoms. Psychosocial mediators include quitting intentions, perceived risk and severity, and outcome expectancies related to use experience. Moderators include sociodemographic factors, tobacco cigarette history, ENDS and ENNDS history, and reasons for use. Full details for select measures are available in the following sections; the full questionnaire is available on our study website [19].

ENDS and ENNDS use was assessed using the following question: “How many days in a typical week do you use an e-cigarette or vaping device to vape e-liquids with or without nicotine?” Response options included “I do not use an e-cigarette or vaping device to vape e-liquids with or without nicotine in a typical week,” “1 day,” “2 days,” “3 days,” “4 days,” “5 days,” “6 days,” and “7 days.”

Dependence is measured using the E-cigarette Dependence Scale. Participants receive the following prompt: “The following questions are about your E-CIGARETTE use only. Please respond to each question or statement by marking the most appropriate response.” The statements include “I find myself reaching for my e-cigarette without thinking about it,” “I drop everything to go out and buy e-cigarettes or e-juice,” “I vape more before going into a situation where vaping is not allowed,” and “When I haven’t been able to vape for a few hours, the craving gets intolerable.” Response options include “Almost Always,” “Often,” “Sometimes,” “Rarely,” and “Never.”

Quitting intentions are assessed using the following questions: “Are you planning to quit vaping” and “Are you planning to quit smoking cigarettes.” Response options include “Within the next month,” “Between 1-6 months from now,” “Sometime in the future, beyond 6 months,” and “Not planning to quit.” For cigarettes, only those who indicate that they have smoked ≥100 cigarettes in their lifetime and a cigarette in the past 30 days are asked the question.

The questions and skip logic are designed to accommodate marketplace heterogeneity and user customization. For example, there are different skip logic pathways for participants with disposable devices; disposable pod– or cartridge-based devices; and refillable pod–, cartridge-, or tank-based devices. These pathways allow our team to tailor the questionnaire to each participant’s situation and experiences with the expectation of creating a better user experience for the participants, higher retention, and higher-quality data. Another byproduct of this approach is that it allows for inquiry about the devices, liquids, and related behaviors that do not apply to all participants, such as the addition of extra nicotine to one’s liquid (often called

XSL•FO
RenderX

"nicotine boosters" or "nicotine shots"). Such behavior would only be applicable to participants who refill their device from a bottle of liquid. Please note that these device and liquid questions are not validated.

Device and Liquid Data Collection

Previous studies have suggested that self-report data alone may not be a viable strategy for capturing accurate device and liquid data [6,7]. To minimize reliance on these data, we require participants to submit valid photos of their most commonly used device, the current visual display screen (powered on) if available, and the most commonly used liquid for the device if available. Following a standard operating procedure, submitted photos are reviewed to identify the brand and model of the device. When the brand or model are not immediately apparent or found with the aid of a Google search, we use unique features, colors, and text on the device to conduct a Google image search. Upon identifying the brand and model, key variables are collected from manufacturer, academic, retailer, and review websites. YouTube product reviews are also helpful in understanding whether certain features are present when information is not readily available on the aforementioned websites (eg, adjustable airflow). To mitigate issues related to inconsistent reporting of device features and specifications and liquid characteristics across websites, data are collected preferentially from (1) manufacturer sites, (2) academic manuscripts, (3) retailer sites, (4) review sites, and (5) YouTube. Key variables collected for devices include wattage, voltage, resistance, coil modifiability, power modifiability, airflow adjustability, disposable versus reusable, and pod- or cartridge-based device versus tank-based device. Liquid variables include brand, flavor (primary and secondary), container size (mL), nicotine concentration (mg/mL), nicotine formulation (free base vs protonated), propylene glycol percentage, and vegetable glycerin percentage.

Missing Data

Missing data is a multifaceted issue. Participants may self-report not knowing the details of the products used and their related settings and specifications. Photos are also vulnerable to user error, with some participants not following instructions (eg, blurry images), resulting in unidentifiable device brands and models, visual display settings, and liquid characteristics. In addition, some web-based sources do not report all device features, specifications, and liquid characteristics.

We use several preventive strategies to mitigate these issues. First, by collecting device and liquid data via self-report and from photos and web-based sources and creating a combined variable that prioritizes photo and web-based data, we minimize missing data and reliance on participant expertise on the product details. Furthermore, participants are required to answer each question to advance and complete the questionnaire, resulting in minimal missing data for all questions without "Don't know" and "Prefer not to answer" response options (responses with identifying information were removed). Finally, for the collection of data from photo and web-based sources, participants are provided with instructions for submitting photos, and a comprehensive standard operating procedure is adhered to by the team to ensure that web-based data are reliably collected.

Despite these preventive efforts, missing data can still occur; therefore, we implement 3 additional post hoc strategies specific to device wattage, voltage, and coil resistance. The first strategy is to purchase the most prevalent devices in the sample with missing data for 2 or more of these device specifications, disassemble the devices, and directly measure the voltage and resistance using a multimeter when one or both values are missing. The second strategy is to use a power calculator (ie, a mathematical formula for calculating wattage, voltage, or resistance) when a single specification is missing. The third strategy is used when three conditions are met: (1) the device's range (eg, 0-80 W) is known, (2) the participant's current setting within the range is unknown (eg, the picture is blurry or there is no visual display), and (3) the setting is not self-reported by the participant. Under these conditions, we estimate the participant's setting by calculating the average midpoint for the device type (eg, the average refillable tank user used 35% of the allowable wattage range in wave 3). The average midpoint (eg, 35%) is then applied to the specific device's known range.

Data Integrity and Security

Rigorous measures are taken to prevent bots and fraudulent survey takers from subverting data integrity. All participants who register and complete the baseline survey provide identifying data and agree to participate in identity verification procedures. LexisNexis (RELX corporation), a third-party identity search engine, is used to verify identities before providing incentives. In instances where the LexisNexis database is not sufficient to identify participants, they are asked to provide a photo ID or utility bill that contains information confirming their identity.

Bot protections include a Completely Automated Public Turing test to tell Computers and Humans Apart (CAPTCHA), authentication of a mobile phone number, attention-checking questions, disabling the back button, and manual review of open-ended responses. The CAPTCHA is a well-known test that requests users to perform simple tasks that humans can accomplish easily but unsophisticated bots cannot. Authentication is used to confirm that phone numbers are real and to generate a new randomly generated survey link. By having 2 REDCap forms linked in this way, bots cannot easily generate new identities and immediately proceed to take the survey. Attention-checking questions not only help us identify participants quickly moving through the survey but also help identify unsophisticated bots who may be providing random answers to the questions. The back button is disabled to prevent participants who build bots from more easily learning the questionnaire and skip logic, thus making it more time-intensive to build a sophisticated bot capable of providing answers that closely mimic real users. The manual review of open-ended responses is particularly important as bots often use similar responses across multiple survey submissions. By screening the new survey submissions on a weekly basis for repeated phrases (particularly uncommon phrases), spelling, and formatting errors, we can more easily identify problematic cases and adjust the strategy as needed. However, the most sophisticated bots

XSL•FO
RenderX

may be capable of circumventing these procedures and may be indistinguishable from real users. These strategies are meant to mitigate the chances of having bot-related issues.

Fraudulent survey takers are participants who are savvy enough to enroll in and complete surveys for which they are not qualified. Similar to bots, they may also attempt to take a survey multiple times. By using identity checks, the risk that participants will take the survey multiple times is lower (note that they can use another person's identity); however, they may not be truthful about their e-cigarette use behavior. To further mitigate the risk of enrolling fraudulent survey takers, we use clear warnings against misuse, require participants to submit a photo of their most used device from the past week, review each photo to verify that it is valid (ie, instructions were followed), and mail incentives. Our warning statement is placed in the consent form and at the start of the surveys: "As a reminder, any perceived attempt to speed through the survey, take the survey more than once, or provide false or misleading information will result in your disqualification from the survey and forfeiture of any promised incentives." This provides us with maximum flexibility for determining who should not receive an incentive and be included in our final sample. Requiring that participants submit a photo of their most used device from the past week is essential to ensuring that they are in possession of a device and, thus, more likely to be ENDS or ENNDS users. Photo submissions of their most commonly used devices from the past week are rigorously reviewed for the following evidence: the objects featured in the photo are not ENDS or ENNDS devices, the photos are downloaded from the internet, the photos are staged in a store, the photos are identical or nearly identical to submissions by other unique IDs, and the photo-coded brand and model do not match the self-reported brand and model for 3 devices that were provided as examples in the self-report brand and model question; that is, "What is the brand AND model of the device (e.g., JUUL, Vaporesso Luxe, Voopoo Drag 2, etc.)?"

Other rigorous data quality checks are also performed before participants receive their incentives. The checks include identifying the use of non-English or non-Spanish alphabet characters in open-ended responses; verifying that a proper mailing address has been provided; confirming that participants do not submit more than 1 survey within or across survey waves; and verifying that more than the minimal number of questions have been answered (skip logic is such that this is highly improbable), completion time is >5 minutes, and 2 attention-checking questions are answered appropriately (both require correct responses).

Data security is ensured through the use of REDCap and Twilio. REDCap is a secure web application that is used to build web-based surveys and databases. It collects any type of data and is geared toward supporting data capture on a server for category-1 data (ie, confidential data). Access to files with identifying information is restricted to approved research team members, all of whom are trained in standards of research privacy and confidentiality and who have secure passwords required to sign onto the data server. When off-campus, virtual private network services are used to access the server. Twilio is a web service used to send a private survey link to respondents. Participants' phone numbers do not remain in Twilio's logs but are removed shortly after being completed, which is done for security and privacy concerns.

Incentives

The incentive for completing the 15-minute survey is a US $10 Amazon gift code. Once submissions are determined to be preliminarily valid after the initial data quality review and participants' identities are confirmed, incentives are mailed to the physical address provided by baseline survey participants and emailed to follow-up survey participants. The data quality check and identity verification are typically completed within 3 days of submission, and incentives are mailed on a weekly basis. Baseline survey participants are mailed their incentives as a form of delayed gratification to deter them from attempting to take the survey multiple times. Post office box addresses and other nonresidential mailboxes are not accepted to prevent multiple submissions. Occasionally, incentives are returned to the sender, indicating that a false address was provided, the participant moved, or a typo was present in the provided address. These record IDs are reviewed more closely for other data quality issues (eg, responses indicating that they were likely not ENDS or ENNDS users). If other survey data are found to be of low quality, the corresponding participants are dropped from the data set and not invited to future waves but are still eligible to receive their incentive for the wave in question. To facilitate the emailing of gift codes to follow-up participants, Rybbon (BHN Rewards), a digital gift code delivery service, is used.

Final Data Quality Checks

Once data cleaning procedures are completed after each survey wave, additional data quality checks are completed when preliminarily valid records are flagged. These include instances of photos with multiple devices or liquids present, poor photo quality, photos or survey responses with non–propylene glycol and vegetable glycerin solutions (eg, tetrahydrocannabinol or cannabidiol), age of first use occurring before ENDS and ENNDS were commercially available in the United States (baseline only), select examples of REDCap skip logic not working as intended (investigated by REDCap; the software bug remains unknown), and incentives being returned to the sender (as previously described). When at least one flag is identified, all the survey responses are reviewed for additional evidence of poor data quality. For example, additional evidence may include the self-reported device brand and model not matching the photo brand and model or self-reported liquid flavors not matching their respective photos. A scoring system is used to determine whether the issues found warrant exclusion from the current and future waves of data collection. All excluded participants still receive their incentive for the survey wave in question.

Ethics Approval

The IRB at the Virginia Commonwealth University (HM20015004) approved the study protocol. The Johns Hopkins Bloomberg School of Public Health IRB (9277) approved reliance on the Virginia Commonwealth University IRB.

Results

Recruitment and Retention

Funding for the VAPER Study began on September 1, 2018, and will conclude on August 31, 2023. Data collection for waves 1 to 3 was completed over 3 periods. Wave 1 was completed between May 18, 2020, and October 16, 2020 (n=1209); wave 2 was completed between December 10, 2020, and April 21, 2021 (n=1218); and wave 3 was completed between September 2, 2021, and November 18, 2021 (n=1254). Partially completed questionnaires are not analyzed.

Upon conclusion of wave 2, the retention rate of cohort 1 (baseline survey participants from wave 1; n=1209) was 51.94% (628/1209), and 5.29% (64/1209) of participants opted out of SMS text message reminders. For wave 3, a total of 37.55% (454/1209) of cohort 1 completed the survey, with 33.25% (402/1209) completing the wave 2 and 3 surveys (52/1209, 4.3% completed the survey for wave 3 but not for wave 2). A total of 7.03% (85/1209) of participants opted out of SMS text message reminders. Cohort 2 (baseline survey participants from wave 2; n=590) had a wave 3 retention rate of 44.2% (261/590), and 6.4% (38/590) of participants opted out of the SMS text message reminders.

Generalizability

For each wave, our wave 1 to 3 frequent users were largely generalizable to daily users of e-cigarettes in the United States (1185/1254, 94.5% of our wave 3 sample used ENDS or ENNDS 7 days per week; Table 2). There was no statistically significant difference between our wave 3 sample and the weighted 2019 Tobacco Use Supplement to the Current Population Survey data in terms of *age/gender/race* (P=.18) and *region* (P=.42). Compared with the Tobacco Use Supplement to the Current Population Survey, our wave 3 sample had a higher percentage of frequent ENDS or ENNDS users with an income of US <$60,000 (928/1225, 75.76% vs 804,024/1,537,547, 52.3%; P<.001). Applying poststratification weighting can help improve the representativeness of the data.

Table 2. A comparison of wave 3 and Tobacco Use Supplement to the Current Population Survey (TUS-CPS) 2019 frequencies for 3 weighting strategies.

	VAPER[a]—wave 3, n (%)	TUS-CPS 2019 (n=554)		
		Participants, n (%)	Weighted N (%)	SE of weighted frequency
Gender, age, and race (n=1233)[b]				
Men, <35 years, and non-White[c]	92 (7.5)	16 (2.9)	55,388 (3.6)	15,766

[b]Missing data: n=21.

[c]White includes single race White; non-White includes all other single races, including American Indian or Alaska Native, Asian or Asian American, Black or African American, Native Hawaiian or Pacific Islander, other, and multirace.

[d]Denotes a statistically significant difference between VAPER and TUS-CPS data at P<.001.

[e]Missing data: n=29.

Poststratification weighting normally requires the sample size of a subgroup to be >20. Thus, for the VAPER Study, creating 1 weight that covers all sociodemographic variables, including gender, age, race, income, and region, is not acceptable as the

XSL•FO
RenderX

cell sizes would be under the minimum threshold. Therefore, 3 separate weights are available: a gender, age, and race weight; an income weight; and a geographic region weight. The variables for the gender, age, and race weight are dichotomized as men and women, <35 years and ≥35 years, and White and non-White populations. For the annual income weight, data are dichotomized as US <$60,000 and US ≥$60,000. Finally, for the geographic region weight, data are categorized into "Northeast," "Midwest," "South," and "West." The specific poststratification weight used in the dissemination of the survey findings will be hypothesis-driven and based on whether the characteristics incorporated into the weight are expected to be correlated highly with the primary outcome of interest.

Planned Analyses

Analyses will be designed to observe patterns that suggest the benefits and unintended consequences of potential regulations. Our data offer a detailed examination of frequent ENDS and ENNDS users' device features and specifications, liquid characteristics, and behaviors. A better understanding of how devices and liquids relate to one another and may be associated with key behaviors such as nicotine dependence can provide regulators with a more precise understanding of how regulating features, specifications, and characteristics may positively or negatively affect users before implementing a regulation. We intend to examine these relationships for three potential regulations: (1) limits on nicotine, (2) constraints on nicotine flux (ie, nicotine emitted over time), and (3) reduction in flavor availability (Textbox 1).

Textbox 1. Hypotheses regarding the 3 potential regulations for electronic nicotine delivery systems (ENDS).

- Limits on nicotine
  - As of May 2016, the European Union limits nicotine concentration in liquids; the US Food and Drug Administration (FDA) may consider a similar action. Hypotheses will be informed by the latest available data at the time of analysis, but a priori, we hypothesize that device wattage will be correlated inversely with nicotine concentration and directly with the amount of liquid consumed and that, across concentration, more dependent ENDS users are using higher-power devices. Over time, users who switch to lower-concentration liquids will begin using higher-power devices. This pattern would highlight how limiting liquid nicotine concentration to control nicotine delivery may fail when higher-wattage devices are available.
- Constraints on nicotine flux
  - Nicotine flux is a function of device specifications and liquid characteristics (ie, power and nicotine concentration) and helps determine user nicotine exposure; it can be predicted mathematically, suggesting that a flux-based product regulatory standard is possible. We will investigate flux standards by studying device wattage, nicotine concentration, and user dependence. Again, hypotheses will be informed by the latest available data at the time, but a priori, we hypothesize that higher flux conditions (eg, greater wattage and nicotine concentration) will be associated with greater dependence, lower flux conditions will be associated with less dependence, and transitions from lower to high flux conditions will be accompanied by higher flux. This pattern highlights nicotine flux as a potential regulatory target.
- Reduction in flavor availability
  - The FDA began prioritizing the enforcement of premarket of ENDS products in 2021 [20,21]. This action has likely decreased the variety of liquid flavors sold. A priori, we hypothesize that this decrease may lead users to change their preferred flavor for their most commonly used device, change their device specifications, or change their behavior to maintain their nicotine delivery. Transition patterns will highlight how reducing flavor availability may affect behavior.

Our primary aims are to evaluate the 3 potential regulations; however, the relative novelty of our methods for collecting detailed device features and specifications and liquid characteristics along with a new practice of analyzing device and liquid pairings rather than analyzing them separately warrants additional supportive and foundational analyses, respectively. As such, our team has identified additional priorities, including but not limited to examining the percentage of agreement between self-reported responses and photo data collection of devices and liquids, mitigating the impact of bots and fraudulent survey takers, and identifying common combinations of device specifications and liquid characteristics (and transitions).

There is no one primary analytic approach; statistical tests will vary based on the research question, measures used, and cross-sectional versus longitudinal nature of the analysis. In general, for longitudinal analyses, generalized estimating equations will be used to account for the variable times between survey waves.

Discussion

The VAPER Study uses a web-based longitudinal cohort design to observe patterns that suggest the benefits and unintended consequences of 3 potential Food and Drug Administration regulations. A priori, we hypothesize that we will identify relationships among device features and specifications, liquid characteristics, and user behavior. A better understanding of these relationships, particularly longitudinally, may allow regulators to better understand how regulations positively or negatively affect user health.

Most population surveys about ENDS and ENNDS are unable to describe device features and specifications, liquid characteristics, and user behavior in a detailed manner because of measurement-related challenges such as a highly customizable user experience [22] and a lack of standardized reporting requirements for device features and specifications and liquid characteristics [9]. Consequently, surveys often oversimplify use. For instance, surveys sometimes presume that a single

XSL•FO
RenderX

device is used and request that participants indicate the device type, usually with predefined definitions that may not keep pace with market innovations (particularly salient for longitudinal surveys) [23,24] or terminology used by all participants [25]. Surveys that use such an approach also ignore the possibility that some users use multiple ENDS and ENNDS in varying amounts and that different device and liquid combinations (within and across device types) may affect nicotine and toxicant emissions and delivery [26]. Our study demonstrates potential solutions to these measurement challenges through survey questions that allow participants to describe their most commonly used device and most commonly used liquid for that device through the use of adaptive questions. In addition, we require valid photos of their most commonly used device and request photos of their most commonly used liquids for that device, thereby allowing our team to determine the device type, features, and specifications and liquid characteristics based on the photo and related website coded data independent of self-reported responses.

Web-based surveys have become increasingly common; however, reporting of contemporary methodologies to maximize data integrity and mitigate the impact of bots and fraudulent survey takers and best practices for de novo recruitment is lacking. Moreover, technology to evade basic survey protections has evolved since the Checklist for Reporting Results of Internet E-Surveys was developed in 2004, and the use of these technologies has become more common. For example, verifying that a sample does not contain duplicative IP addresses and use of "cookies" can be overcome through the use of virtual private network service providers that allow users easy access to hundreds of servers worldwide and the clearing of cookies (or use of another device), respectively. Our survey was able to address these challenges using a variety of strategies, such as identity verification.

Recruitment modalities beyond de novo recruitment were explored and given consideration for this study, including the use of existing panels. Although appropriate for other study designs and aims, existing panels were not considered a viable option for the VAPER Study. Existing panels at well-established research firms did not contain a sample large enough to recruit our population of interest (ie, ENDS and ENNDS users vaping ≥5 days per week). Mechanical Turk, a commonly used web-based panel, was considered as well but was also not large enough for our lower-prevalence population. Panels that aggregate participants from multiple panels are an option that might have yielded a large enough sample for wave 1; however, the recruitment methodologies are highly heterogeneous. In addition, they may not be large enough to replace those lost to follow-up in multiple waves. We were also advised by a company offering this aggregation service that high loss to follow-up rates should be expected; thus, panels that aggregate participants are not ideal for longitudinal studies.

Social media (eg, Facebook and Instagram) recruitment was attempted in consultation with a market research firm at the start of wave 1, but several challenges were encountered. Despite being an academic survey on ENDS and ENNDS use, our advertisements were repeatedly deleted by Facebook and Instagram for including images and text related to ENDS and ENNDS. Appealing these decisions became a regular and time-consuming phenomenon that was never resolved. Furthermore, the advertisements appeared to generate clicks, presumably by social media users interested in the survey; however, the number of advertisement clicks did not match the landing page traffic, and few valid surveys were submitted. Our approach to tracking landing page traffic was investigated for setup errors, and alternative back-end solutions were attempted, but no strategy improved our traffic. The high costs (US $280 per valid participant) combined with slow recruitment (approximately 5 valid participants per week) led us to switch to a Craigslist-focused recruitment strategy. Subsequently, wave 3 costs have decreased to US $10 per valid participant, and recruitment for the baseline survey has increased to approximately 53 valid participants per week.

Processing data and managing missing data are not without challenges. Coding photos and reviewing and abstracting manufacturer, retailer, and review site data are time-intensive and have practical limitations, including participants who do not follow photo submission instructions and inconsistent and incomplete device features and specifications available on the web. The resulting missing data present challenges, particularly given a lack of validated device and liquid questions and that some participants indicate that they do not know the details of their device features and specifications, settings, and liquid characteristics. Our solution is to implement comprehensive preventive and post hoc strategies that maximize the use of multiple data sources (ie, photos, self-report, and disassembled devices), tools (ie, multimeter), and formulas (ie, power calculator and an average midpoint calculation for each device type). The decisions were considered carefully based on the best available information; however, we cannot rule out the possibility that our underlying data sources, tools, or formulas are biased or inaccurate (eg, product packaging and labeling and manufacturer, academic, retailer, and review websites). Ultimately, we believe that the benefits of our approach outweigh the unknowns and are an opportunity to understand more deeply the interplay between devices, liquids, and user behavior as it pertains to regulations. Other strategies could be valuable, and our approach may change as better data sources emerge and more is learned about this topic.

The loss to follow-up rate is higher than initially presumed based on the expected loss to follow-up rates in more traditional cohort surveys. This presumption based on traditional cohort surveys was made after we were unable to find any web-based cohort surveys that reported their loss to follow-up rates during study design planning in 2019. The higher-than-expected rate is not readily explainable and is a matter of speculation. Our assumption is that it is owing to one or more of the following: (1) web-based cohort survey participants require larger incentives, (2) participants (and email providers) may believe that follow-up survey email and SMS text message invitations and reminders are spam, (3) participants may self-select out of the cohort survey if they no longer use e-cigarettes, and (4) participant commitment to web-based cohort surveys is lower given the lack of an in-person connection with the study team. We will attempt to lower the rate through several strategies. These include increasing the incentive to US $30 per participant,

XSL•FO
RenderX

sending postcards to participants to remind them of their involvement with the study and our annual raffle, creating a password-protected study website for participants that contains announcements and descriptive data for participants to review, and allowing follow-up participants who no longer use the devices ≥5 days per week to complete the survey or a shorter survey if they have not used the devices in the past 30 days.

Furthermore, our team is committed to improving the survey with each successive data collection wave. We will continue to monitor and adjust the details of our Craigslist strategy, such as the number of cities and boards used, as we learn more about the recruitment and cost-efficiency of "jobs" versus "gigs" postings and specific locations. We are also considering alterations to the raffles based on the frequency of waves completed and participant follow-up rates and are exploring additional engagement strategies to increase retention rates. Other options include birthday and holiday messages, a website containing updates on findings and survey-related announcements, and alternative incentive structures for follow-up survey participants. Moreover, participants are encouraged to provide us with feedback at the end of the survey: "We would like to continually improve this survey. If you have any comments or suggestions about this survey, please provide them here." Feedback is reviewed during each wave for isolated issues (eg, survey response corrections) and at the end of the survey wave for consistent feedback that may warrant improvements to the survey. For example, participants noted that our survey responses did not include options for wrapping one's own device coils and adding extra nicotine drops to liquids. We subsequently edited the response options and added a question to account for these behaviors.

Another key lesson learned was the importance of bot and fraudulent survey taker mitigation strategies. These comprehensive steps were taken in consultation with experts after an initial attempt in 2019 to recruit participants using social media advertisements failed. At the time, the VAPER Study allowed for anonymous survey participants, had minimal review of data before incentive delivery by email, and used fraud detection software *intended* to prevent multiple completions by each participant. Initially, recruitment began slowly (as expected) but accelerated quickly, raising substantial concerns that led us to halt data collection. Survey submissions (n=1624) were investigated for evidence of bots and fraudulent survey takers, and only 22.35% (363/1624) of the survey completions were assessed to be likely valid. We subsequently restarted recruitment in May 2020 (wave 1) and implemented the aforementioned risk-mitigation strategy. As a result of these steps and the transition to a Craigslist posting strategy, the recruitment pace stabilized, and data quality has appeared adequate. The final wave 1 sample does not include those from our failed attempt at recruitment and data collection in 2019.

The VAPER Study has demonstrated that web-based recruitment and data collection for cohort studies is a promising approach that may offer benefits to researchers and participants, including convenience, scalability, reduced costs, and safety during extraordinary times such as the COVID-19 pandemic. More specifically, this study design has allowed us to recruit a generalizable and nationwide sample relatively quickly and cheaply, recruit a lower-prevalence population successfully, and disseminate high-level findings to regulators quickly. To the best of our knowledge, no other tobacco policy research team is collecting such detailed data on the scale at which we are operating, which differentiates the value of these data from those of other studies. These data better position us to address questions about the relationships among devices, liquids, and user behavior that relate to the benefits and unintended consequences of possible regulations. However, strong risk-mitigation strategies are essential to ensure data quality [13,14], and steps such as identity verification and manual review of photo data quality before sending the incentive are time-intensive and have required a team of individuals at 2 universities. Other limitations include a limited sample size for specific questions (because of skip logic and rare behaviors), missing data resulting from inconsistent and incomplete device and liquid data available on the web, website-reported data on devices and liquids that may or may not correlate with laboratory-measured device specifications (eg, coil resistance) or liquid characteristics (eg, nicotine concentration), and participants unable to recall or who may be misinformed about their device features and specifications or liquid characteristics. Future plans include further optimizing our recruitment and data processing procedures and conducting 2 waves of data collection over the next 12-month period.

Acknowledgments

The research reported in this publication was supported by the National Institute on Drug Abuse and the Food and Drug Administration Center for Tobacco Products under award U54DA036105. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health or the Food and Drug Administration.

Data Availability

We intend to make deidentified data, codebooks, documentation, and research protocols available on a password-protected website by 2026 in accordance with the National Institutes of Health policy (notice: NOT-OD-03-032) released on February 26, 2003 [27], and IRB-approved protocols. Before or after the data are available on the aforementioned website, any investigator interested in collaboration or in using the data for their own work is invited to contact the corresponding author. They will be asked to submit a 1-page abstract of their proposed research, including purpose, analytical plan, and dissemination plans. An executive leadership committee will review these proposals and decide on each based on the individual merits (if a proposal is received after the end of the funding period, the principal investigator will review it). Review criteria and prioritization of projects include

XSL•FO
RenderX

the potential of the proposed work to advance public health; qualifications of the applicant; potential for publication; potential for future funding; and enhancement of the scientific, geographic, and demographic diversity of the Vaping and Patterns of E-cigarette Use Research Study research portfolio.

Conflicts of Interest

TE is a paid consultant in litigation against the tobacco industry and also the electronic cigarette industry and is named on a patent for a device that measures the puffing behavior of electronic cigarette users, on another patent application for a smartphone app that determines electronic cigarette device and liquid characteristics, and on a third patent application for a smoking cessation intervention.

Abstract

Background: Timely delivery of high-quality cancer care to all patients is barely achieved in South Africa and many other low- and middle-income countries, mainly due to poor care coordination and access to care services. After health care visits, many patients leave facilities confused about their diagnosis, prognosis, options for treatment, and the next steps in their care continuum. They often find the health care system disempowering and inaccessible, thereby making access to health care services inequitable, with the resultant outcome of increased cancer mortality rates.

Objective: The aim of this study is to propose a model for cancer care coordination interventions that can be used to guide and achieve coordinated access to lung cancer care in the selected public health care facilities in KwaZulu-Natal.

Methods: This study will be conducted through a grounded theory design and an activity-based costing approach that will include health care providers, patients, and their caregivers. The study participants will be purposively selected, and a nonprobability sample will be selected based on characteristics, experiences of the health care providers, and the objectives of the study. With the study's objectives in mind, communities in Durban and Pietermaritzburg were selected as study sites, for the study along with the 3 public health facilities that provide cancer diagnosis, treatment, and care in the province. The study involves a range of data collection techniques, namely, in-depth interviews, evidence synthesis reviews, and focus group discussions. A thematic and cost-benefit analysis will be used.

Results: This study receives support from the Multinational Lung Cancer Control Program. The study obtained ethics approval and gatekeeper permission from the University's Ethics Committee and the KwaZulu-Natal Provincial Department of Health, as it is being conducted in health facilities in KwaZulu-Natal province. As of January 2023, we had enrolled 50 participants, both health care providers and patients. Dissemination activities will involve community and stakeholder dissemination meetings, publications in peer-reviewed journals, and presentations at regional and international conferences.

Conclusions: This study will provide comprehensive data to inform and empower patients, professionals, policy architects, and related decision makers to manage and improve cancer care coordination. This unique intervention or model will address the multifactorial problem of cancer health disparities. If successful, this study will affect the design and implementation of coordination programs to promote optimal cancer care for underserved patients.

Introduction

Background Information

Cancer is increasingly becoming one of the leading public health problems globally [1-4]. The World Health Organization's projections indicate that global annual estimates will increase to 29.5 million new cancer cases and 16.5 million cancer-related deaths by the year 2040 [2,3,5]. Of concern is the fact that the current evidence demonstrates that survival from all cancers, including preventable lung cancer, is poor [2-10], and this is partly reflective of the poor access to coordinated cancer care. The public health challenges of the escalating cancer burden are more pronounced in low- and middle-income countries (LMICs) [9]. Patients with cancer in these countries are often diagnosed late (at stage 3 and 4) and the pathways of care are not clearly defined, thus delaying treatment initiation and leading to disproportionately high mortality rates and reduced quality of life when compared to their higher-income counterparts [5,9,11-13].

Medical care is error-prone even when it is delivered by a single provider; the opportunities for serious issues or difficulties escalate when multiple providers are involved [14-21]. Inherent care complexities for patients with lung cancer make these patients likely candidates for shared care between primary care providers, oncologists, and other specialties. A study investigating barriers impeding quality care coordination for patients with lung cancer in South Africa, from the perspectives of the health care providers, identified these challenges as contributing to adverse outcomes in lung cancer care [14]. Issues relating to access, timely delivery, and coordination of care ranked the highest in the priority list shared by health care providers [22]. These issues appeared to facilitate the rising numbers of cancer fatalities in South Africa [14]. Evidence from South Africa is consistent with what has been found in other countries [13,23-25], asserting that when a diagnosis is accurate and timely, a patient has an increased opportunity for a positive health outcome [26-37].

Despite the potential benefits of patient access to coordinated cancer care services [26-37], most countries in LMICs, such as South Africa, do not have systems for achieving this coordination. Specifically, lung cancer diagnosis has far-reaching and life-changing consequences for patients [14,16,20,36,38-42], with the disease likely to be at an advanced stage at the time of detection [14,16,43]. In South Africa, the structural configuration of the health systems compounds the challenges relating to providing quality and coordinated cancer care [44]. These challenges include socioeconomic factors, the unavailability of technical support for diagnosis and disease staging, the initiation of and lack of resources for treatment, and the poor availability of palliative care and other support services [14,16,20,21,44-48]. The current referral pathways for patients with cancer between the health care team and cancer services are either not structured or are poorly documented [13,14,47]. Patients with cancer often have limited familiarity with the multidisciplinary team involved and therefore lack the specific knowledge and resources needed to navigate the specialists and services involved in their clinical care. In turn, each team brings varying perspectives to the care of the same patient, whose true value can be achieved through proper communication. The interface between primary and specialty care for patients struggling with cancer offers a valuable opportunity to appreciate the challenges of delivering well-coordinated care.

To be comprehensive, cancer care must be coordinated between primary care providers and oncology specialists; however, achieving this has proven to be considerably challenging [14-21]. Understanding the strategies that can be used to achieve this coordination is necessary for better cancer care. However, attempts to improve care coordination can only be achieved through a properly and intentionally designed care coordination intervention strategy [49]. The high inconsistency of practices, the diversity of definitions, and the underlying concepts [49-52] increase the current difficulty to standardize, replicate, transpose, and assess care coordination, especially within the South African health system context. As such, the aim of this study is to propose a model for cancer care coordination interventions that can be used to guide and achieve coordinated access to lung cancer care in the selected public health care facilities in KwaZulu-Natal, South Africa.

Study Aim and Objectives

This study aims to propose a model for cancer care coordination interventions that can be used to guide and achieve coordinated access to lung cancer care in the selected public health care facilities in KwaZulu-Natal. This will be carried out in 4 phases. The specific objectives are as follows:

Phase 1: Assess the factors that affect access or delivery of coordinated lung cancer care

- To identify health system barriers and key pillars affecting access to a coordinated lung cancer care continuum.
- To conduct a needs assessment to lung cancer care necessary for achieving coordinated care.

Phase 2: Identify a model relative to cancer care coordination interventions

- To understand the scope of cancer care coordination interventions and services employed in low-and middle-income countries, in order to synthesize the existing evidence and identify the key model and its elements used to manage and improve cancer care coordination in these settings.
- To systematically analyze the available evidence on the identified model's characteristics, outcomes, and effectiveness across the cancer care continuum in low-and middle-income countries.

Phase 3: Identify key elements of the proposed model

- To explore what the primary functions of proposed model will be.
- To identify the roles and skill sets needed for proposing the key personnel required to implement the proposed model.
- To explore how the proposed model can be better integrated into the clinical care program.

Phase 4: Costing of the proposed intervention model

XSL•FO
RenderX

- To conduct a costing exercise in order to determine the feasibility of developing and implementing the proposed model.

Methods

Study Design

The study will use a mixture of the grounded theory (GT) approach and an activity-based costing (ABC) approach. The central principle of GT is that the researcher's theories about a topic are constructed based on their data [53]. It is appropriate when little is known about a phenomenon; the aim being to produce or construct an explanatory theory that uncovers a process inherent to the substantive area of inquiry [53-55]. GT sets out to discover or construct theory from data that has been systematically obtained and analyzed using comparative analysis. The study will predominantly be conducted through qualitative research methods, using participatory approaches. This is founded on the principles of active citizenry and constructivist theory, which views research participants as co-constructors of knowledge and not just passive subjects [56]. As a result, the study falls within the constructivism paradigm (interpretivist), as it aims to explore and understand the participants' experiences [57].

Described as "the most comprehensive qualitative research methodology available" [58], this approach is appropriate when research aims to explain a process where the concerns of those involved are central to its understanding and cannot be predetermined [55,58-60]. GT uses memoing or memos, which are ideas generated and documented through interacting with data to provide detailed records of the researchers' thoughts, feelings, and intuitive contemplations [54]. The theoretical sensitivity encompasses the entire research process; it is the ability to know when you identify a data segment that is important to your theory [54].

The ABC approach has 2 major elements: cost measures and performance measures. It is a methodology that measures the cost and performance of activities, resources, and cost objects [61]. Resources are assigned to activities, and then activities are assigned to cost objects based on their use. The basic concept of ABC is that activities consume resources to produce an output. It assists to identify activities in a project or organization and assigns the cost of each activity to all products and services according to the actual consumption by each [61]. This approach uses both financial and nonfinancial variables as bases for cost allocation. Today's health care system encompasses a wide variety of services. To manage them, it is important to determine the amount of resources that are consumed by each service. The complexity of widely varied service delivery systems can be readily managed with ABC, as its methodology is particularly suited to the complexities of health care service delivery [61].

Study Area

The study will be conducted in the province of KwaZulu-Natal. This province has the second-largest economy in the country [62]. The study will involve 2 cities, namely, Durban and Pietermaritzburg, which are within the KwaZulu-Natal province. KwaZulu-Natal has 1 metropolis and 10 districts. While Pietermaritzburg is the capital city of the province, Durban is the largest city in the province [63]. Durban and Pietermaritzburg have an estimated population of 3,120,282 and 750,845, respectively [64]. With the objectives of the study in mind, communities in Durban and Pietermaritzburg were selected as study sites, along with 3 health facilities that provide cancer diagnosis, treatment, and care in the province. In total, 3 of the communities are in Durban, and 2 are in Pietermaritzburg. These communities are Umlazi, Chatsworth, and South Durban Basin in Durban, and Imbali and Sobantu in Pietermaritzburg.

Study Settings

A geographical scoping and mapping of study clusters were done in each of the representative communities. In total, 40 out of 879 clusters were selected using probability proportional to population size sampling. Maps were used to identify the selected clusters along with their boundaries. This technical mapping exercise gave details of the location of the communities, population numbers, broad socioeconomic baseline characteristics of the communities, and resources available in the area, for example, clinics and hospitals, as well as other community social commons.

We selected both clinics and hospitals to ensure that the sampled data have implications for the full spectrum of cancer care providers. Furthermore, all public hospitals with oncology units in KwaZulu-Natal (Greys Hospital, Addington Hospital, and Inkosi Albert Luthuli Central Hospital) located in 2 cities will be recruited to participate in the study. These 3 participating health facilities were chosen on the basis that they are the only public hospitals offering oncology services in the province. Greys Hospital is located in Pietermaritzburg, whereas Inkosi Albert Luthuli Central Hospital and Addington Hospital are located in Durban.

Data Collection Process

Research staff will be concerned about participants' risks and also their risk of exposure during the collection of data. The study will be conducted in 4 phases.

Phase 1 will be through in-depth interviews (IDIs), determining the barriers and pillars affecting coordinated lung cancer care. Accomplishments and ongoing barriers to engagement in medical care identified in phase 1 will be prioritized and translated into service plans that will define the specific action steps in the proposed model. Throughout this phase, participants' demographic and clinical information will be collected.

Phase 2 will focus on identifying an intervention aimed at assisting patients in overcoming barriers to coordinated lung cancer care in KwaZulu-Natal. Based on phase 1 results, the models will be reviewed and modified to meet the needs identified in phase 1. The following will be key areas of focus for the strategy during the scale-up process. This phase will be conducted in two steps: (1) a scoping review to identify relevant models from the literature and all their components for coordinated care and (2) a systematic review of the identified or proposed care coordination model's effectiveness. The aim of this phase is to provide descriptions of a wide variety of care coordination interventions and thereafter propose an intervention

XSL•FO
RenderX

or model. The search strategy will include PubMed, Scopus, Google Scholar, and Web science databases using keywords such as “cancer care coordination,” “coordination of care,” or “coordinated care.”

Phase 3 will be through focus group discussion (FGD). The approach will facilitate awareness, understanding, and commitment to the optimal proposed cancer care coordination model among stakeholders and facilities involved. The goal is to identify key elements of the proposed model and obtain stakeholder support for coordinated referrals and linkage pathways for patients with cancer. This is anticipated to inform the development and implementation of a coordination model to improve lung cancer care.

Lastly, in phase 4, a costing exercise will be conducted in order to determine the feasibility of the development and implementation of the proposed model; this may be useful in the move to certify and establish the intervention. This phase will be achieved through ABC.

Data Collection Tools

For this study, an IDI and FGD guide will be used to address the study objectives. These were developed for this study; however, the FGD guide will be informed by the IDIs’ and phase 2 responses. Both the IDIs and FGDs will be facilitated by the lead investigator, who is experienced in qualitative research. Lastly, the costing exercise will be informed by findings from the IDIs, FGDs, and reviews. Table 1 provides study data collection methodology by phases.

Table 1. Summary of data collection methodology.

Tools and data source	Variables	Analysis plan
Phase 1: assess factors that affect coordinated access to lung cancer care (interviews)		

Patients and caregivers	• Description of their care, barriers, and how it was managed
	  • When the diagnosis was made
	  • How the diagnosis was confirmed
	  • Treatment initiation
	  • Reasons for not initiating treatment
	  • Time of treatment initiation
	• Understanding of “care coordination”
	• Suggestions to improve care coordination
		GT[a] approach analysis

Health care providers	• Description of what “care coordination” services involve • Outline of their roles in a patient’s “care coordination” • Essentials of “care coordination” • Weaknesses in “care coordination” processes • Suggestions to improve care coordination	GT approach analysis
Phase 2: identify model relative to cancer care coordination interventions		
Scoping review		
Scopus, PubMed, and Google Scholar	• Relevant models and all its components relevant for coordinated care	PRISMA[b] guide
Systematic review		
Scopus, PubMed, and Google Scholar	• Informed by the scoping review	PRISMA guide
Phase 3: identify key elements of proposed model (focus group discussion)		
Identified stakeholders and health care professionals to be involved in the designing of the proposed model	• What will be the primary functions of the proposed model? What will they fulfill? • Outline of their roles in a patient’s “care coordination” • What additional roles and skills set needed • How model can be integrated into the current clinical cancer care	Thematic analysis
Phase 4: costing of proposed intervention model (ABC[c] approach)		
Variables included in phases 1, 2, and 3	• Human resource costs for recruitment and hiring • Operational costs • Capital equipment costs • Model specific training costs	Costing analysis

[a]GT: grounded theory.

[b]PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

[c]ABC: activity-based costing.

XSL•FO
RenderX

Study Population

The study population will encompass patients, health care providers drawn from the participating health care facilities, including surgeons, radio-oncologists, medical oncologists, general practitioners, chemotherapy nurse practitioners, and social workers, all with a coordination activity for patients with cancer, and also the caregivers with whom they interact as part of their care activity. Caregivers will be proxies for patients who are unable or not in a condition to answer the questions and participate in the study. A proxy is a person authorized to act on behalf of someone else [65].

Inclusion and Exclusion Criteria

There are no exclusion criteria based on socioeconomic status, race, or sex, but patients with no lung cancer will be excluded. Textbox 1 summarizes inclusion and exclusion criteria for study participants by phases.

Textbox 1. Inclusion and exclusion criteria for study participants by phases.

Phase 1: patients with lung cancer (all stages), caregivers, and health professionals in lung cancer care

Inclusion criteria

- Patients diagnosed with lung cancer and are within the selected facilities
- Caregivers of patients who meet the inclusion criteria and are unable but willing to participate in the study
- Health professionals involved in the care and coordination of patients with cancer

Exclusion criteria

- Patients diagnosed with other diseases other than lung cancer
- Patients receiving care for lung cancer, but outside the selected facilities
- Caregivers of patients with lung cancer who do not meet the inclusion criteria
- Professionals who are not involved in the care of patients with cancer

Phase 2: systematic and scoping review

Inclusion criteria

- Studies presenting evidence published in low- and middle-income countries (LMICs)
- Studies presenting evidence on cancer care coordination
- Studies presenting evidence on coordination interventions or models
- Studies reported in English

Exclusion criteria

- Studies presenting evidence not published in LMICs
- Studies not presenting evidence on cancer care coordination
- Studies presenting evidence on coordination interventions or models
- Studies reported in English

Phase 3: identified stakeholders to be involved in the designing of the proposed model for coordination

Inclusion criteria

- Identified stakeholders to be involved in the designing of the proposed model for coordination
- Health professionals involved in the care activity of patients with cancer

Exclusion criteria

- Stakeholders with no coordination activity for patients with lung cancer
- Health professionals with no role in the care activity of patients with cancer

Phase 4: informed by phases 1, 2, and 3

Recruitment Procedure

Eligible patients will be identified during their visits or hospitalization in the participating facilities and will be informed about the study in a personal interview and with the help of written consent documents. A modified version of snowballing will be used to identify caregivers of patients not eligible to participate due to health conditions. Patients will be asked to invite their primary caregivers to participate in the study. Health care providers involved in cancer care (including surgeons,

XSL•FO
RenderX

radio-oncologists, medical oncologists, general practitioners, chemotherapy nurse practitioners, and cancer nurse coordinators) will be approached directly by the research team to participate in a focus group or interview. Eligible potential participants will be invited by email or telephone to participate in the study. The invitation letter will include a general introduction to the research topic and the study's aim and rationale. They will also be presented with information about their involvement, such as the anticipated length of the interview and where it would be conducted. General information about measures taken to guarantee confidentiality and informed consent will also be given.

Sampling Strategy

In-depth Interviews

Purposive sampling will be used to identify the participants relevant to address the research objectives [53-55,60]. Participants will be selected based on their characteristics, experiences, and the objectives of the study [66]. Concurrent data generation and analysis are fundamental to GT research design [67]. Hence, data generation, data coding, and analyses will be done iteratively. Theoretical sampling will begin with the codes and categories developed from the first data set. Theoretical sampling is used to identify and follow clues from the analysis, fill gaps, clarify uncertainties, check hunches, and test interpretations as the study progresses [67]. The selection of the study sample will be done per study site and according to the study phases and objectives.

Focus Group Discussions

The sample for FGDs will be purposive and will include individuals with characteristics of the overall population. Purposive sampling is often used when a researcher wants information-rich participants [6], in the case of FGD, a sub-sample of insightful participants from the phase 1 interviews will be invited for discussion. Each focus group will have a professional or stakeholder representing all levels of the health care systems.

Sample Size

For the IDIs, sampling saturation will be achieved when the same stories, themes, or codes and issues are emerging from the interviewees, and then a sufficient sample size will have been reached (saturation). We will take note of the importance of availability (limited number of health providers working within the oncological units), willingness, and the ability to communicate experiences and opinions in an articulate, expressive, and reflective manner. It is anticipated that data saturation will be reached at 25 interviews for each category (patients and professionals) of participants. For FGDs, and with support from the literature, the sample size will be between 7 and 12 participants to be effective [68].

Data Quality Assurance

Internal Validity

Bias can arise from the approach or instrument adopted for collecting or measuring data in a study [69]. Information bias, otherwise known as misclassification, is one of the most common sources of bias affecting health research's validity [63]. This bias will be minimized through the extensive training of the research assistants. The questionnaires will be validated and standardized during the training. To ensure the quality of the translation, an experienced translator competent in both English and isiZulu will translate the questionnaires, and a different person will perform the back-translation. The principal investigator will compare the original copy with the back-translation, and where necessary, adjustments will be made.

Measuring the Trustworthiness of the Qualitative Data

Credibility is defined as the confidence that can be placed in the truth value of the research findings, which is essential in establishing whether or not the research findings represent plausible information drawn from the participants' original data and is a correct interpretation of the participants' original views [70]. In this study, credibility will be ensured through the search for alternative themes developing from the data and the use of verbatim quotes when reporting the findings. In certain circumstances, where the translation will diminish the original meaning, isiZulu quotes may be retained with explanatory text. The researchers who conduct the IDIs with the key informants will receive advanced training on interviews and other qualitative research processes in order to ensure the collection of high-quality data. Analyst triangulation will be performed, whereby the principal investigator and the supervisors will analyze the transcripts independently and later discuss the analysis. According to Bitsch [71], dependability refers to "the stability of findings over time." Dependability will be ensured through a clear exposition of data collection and analysis methods and also through data source triangulation (with various key informants).

The study results will be based on the data generated through the thick description (ie, a rich and extensive set of details) of the phenomenon in order to enhance the transferability of the findings. The thick description will also include the context in which the study was carried out. Transferability, a concept that is comparable to generalizability in quantitative research, refers to the degree to which the results of qualitative research can be transferred to other settings with comparable contexts [71]. Confirmability will be ensured by keeping an audit trail, carrying out source and data triangulation, and also carrying out peer review or debriefing. Confirmability refers to the degree to which the results of an inquiry could be confirmed or corroborated by other researchers [72].

Data Analysis

Data analysis will follow a GT approach, a constant comparative analysis [54,73]. In GT-based analysis, the researcher generally analyzes the data by (1) finding repeating themes by thoroughly reviewing the data, (2) coding the emergent themes with keywords and phrases, (3) grouping the codes into concepts hierarchically, and then (4) categorizing the concepts through relationship identification [73-76]. Finally, the categories created through this process, and the links found between them, are used as the basis for the development of a new theory [74]. These steps facilitate an analysis process that allows the researcher to construct new theories instead of simply collecting

XSL•FO
RenderX

data to test how well an established theory applies to the social phenomena they are studying. Theoretical sampling joined with constant comparative analysis raises the conceptual levels of data analysis and directs ongoing data generation [54].

Results will be discussed until consensus between analysts is achieved. The construction process of these thematic categories and codes is both inductive and deductive because the development of themes and subthemes rests on both literature and emerging categories of empirical analysis [53-55,67,71,73,74,77,78]. Ongoing analysis and recruitment will be undertaken until saturation of themes is reached, which Hennink et al [79] refer to as code saturation. Interpretations of the findings will be supported by direct quotes from both FGDs and individual IDIs.

FGDs usually yield both qualitative and observational data where analyses can be demanding. For the discussion, thematic analysis, as the most common forms of analysis in qualitative research, will be used to analyze the data collected. It puts emphasis on, pinpoints, examines, and records patterns (or "themes") within the data [80]. Although the main source of data analysis is the recorded spoken language derived from the interview; nevertheless, reflection about the interview, the settings, and capturing the nonverbal communication expressed by the members of the groups would add a valuable dimension to the construction and analysis of data [81]. Prior to analysis, transcripts for each participant will be deidentified to ensure confidentiality and to limit analytical bias among researchers [82]. Qualitative data will be recorded, anonymously, integrally transcribed, and imported into the NVivo 12 software (QSR International), which will assist in the organization of the data during the analysis stage.

Ethics Approval

The study obtained ethics approval and gatekeeper permission from the University's Ethics Committee (Ref: BREC/00002153/2020) and the KwaZulu-Natal Provincial Department of Health (NHRD Ref: KZ_202010_030), as the study is to be conducted in health facilities in KwaZulu-Natal province. Written permission has been further sought from the concerned authorities and authorities from the different study sites to gain access to the facilities.

Risks

This study is anticipated to involve minimal risks. This means that the probability of harm or discomfort anticipated as a result of participation in the study is not greater than those ordinarily encountered in the daily lives of the participants. Adequate care will be taken to ensure the competence of the fieldworker for the study through continued educational sessions.

Potential Benefits

Participation in this research project will contribute to the improvement of collective medical, palliative, and public health knowledge that will enable the design of interventions to strengthen care coordination for patients with lung cancer while strengthening the cancer care program. The study will also provide strategic and scientific information on the implications of lung cancer during the access, diagnosis, referral, and treatment processes.

Informed Consent

Informed consent is sought in writing from every potential participant prior to participating in the study. Both the English and isiZulu versions of the participant information sheet will be appended to the protocol. The informed consent forms comprise 2 sections: the participant information sheet and the informed consent. These are shared with each potential participant a day or 2 before data collection to allow them time to read and process the documents. Measures are taken to ensure that the respect, dignity, and freedom of each participant are honored in the study. To guarantee the anonymity of each participant, the names of respondents, their addresses, or other identifying information will not be included in the transcripts, but a unique identification number will be used. Further, participants will be assured of the confidentiality of all their information. Their rights to refuse to participate and to opt out of the study at any time will be emphasized.

Results

This study receives support from the Multinational Lung Cancer Control Program, which is funded by Bristol-Myers Squibb Foundation. The support is granted for the lifespan of the study, from June 2020 to March 2023. The study obtained ethics approval and gatekeeper permission from the University's Ethics and KwaZulu-Natal Provincial Department of Health, as the study is being conducted in health facilities in KwaZulu-Natal province. As of January 2023, we enrolled 50 participants, both health care providers and patients. We started with data analysis of interviews with patients and their caregivers, saturation was reached at 21 interviews. We have concluded data collection and analysis of interviews with health care providers, and finalizing manuscript write-up. Once all the data are analyzed, the results will be consolidated into a coherent report for dissemination. In addition, manuscripts for all phases will be prepared for publication. A scoping review article emanating from results from phase 2 was published and is currently working on the next step which is a systematic review, assessing the effectiveness of the identified coordination model.

Discussion

Anticipated Findings

Cancer is a complex condition that often requires multiple interventions provided by a variety of health professionals within the health care continuum [14-21]. The identification of current obstacles has the potential to guide the development of a model to improve the quality of coordinated cancer health care. Care coordination strategies are of great interest as they have the potential to improve the quality of health care, effectiveness, and optimal patient health outcomes. Care coordination requires effective communication and consistent transfer of health information between the different levels of care [27,32,33,37,52,83-88]. There is adequate literature supporting the need for and benefit of care coordination for people affected by cancer [14,19,27,33,34,38,39,47,89-94]. Care coordination

XSL•FO
RenderX

is a set of activities needed to minimize the dangers of fragmentation [95], including the sharing of important clinical information by all health care providers involved with clear, shared expectations about their roles in the patient care process [49,51,52,95]. They also include efforts to keep patients and families informed and engaged throughout the care process. People with cancer are particularly at risk of receiving poorly organized and fragmented care due to the complex nature of the disease and its management [1,10,14,19,50,96-105]. Consequently, there is an increasing body of evidence on the potential of the patient navigation approach as a coordinated cancer care model for the effective improvement of access to health care services, especially for the poor, the uninsured, and other medically underserved populations [29,32,96,104-112]. The inclusion of patient navigation services in high-income countries is associated with improvements in access to timely diagnosis, treatment, and follow-up, among other quality indicators [11,85,112-115], something that is lacking in the LMICs [12]. In addition, evidence from global cancer agencies shows that improving access to clinical preventive services like cancer screening, linkage activities, and coordinated care among multiple providers not only minimizes delays and confusion about conflicting care plans but can also potentially reduce and prevent the disease [116].

There is a need to continuously review multilevel barriers (primary, secondary, and tertiary care) that threaten cancer care coordination across different settings and levels of clinical care to identify potential solutions for improving care. This study carries the promise of generating pertinent information for both policy makers and health care professionals. Decision makers will be provided with important information, concerning the proposed model designed with a costing exercise to determine the implementation viability. Once all the study phases are complete, the results will be consolidated into a coherent report for dissemination to key stakeholders and will also be presented in conferences and seminars. A technical report or policy brief is also anticipated from this study. A meeting of the relevant stakeholders will be organized, where the results will be presented and discussed. The thesis will be one of the outputs of this study, and this will be available in the University of KwaZulu-Natal library. The findings of the study will also be published in Department of Higher Education and Training accredited peer-reviewed journals.

The results of this study may be biased toward those patients who proactively seek or positively respond to diagnostic and treatment referrals by the health care professionals at the lower levels of care. Since the participating hospitals and the community-level study sites are located within the 2 major cities in KwaZulu-Natal, the profiles of patients may not be fully reflective of the geographical spread of the province. In addition, the global pandemic has presented a variety of challenges, including physical, emotional, financial, and much more, the effects of which are only beginning to be felt [117]. In our roles as researchers, these circumstances require us to be alert, innovative, and flexible in our approaches to collecting and disseminating data. The COVID-19 pandemic has disrupted the way that research is conducted [117] to the point that alternative ways of conducting research have become necessary. We hope to be able to come together virtually, collect and analyze data, rapidly generate knowledge, and disseminate it widely to improve the care of patients with cancer. Fortunately, the increased engagement of users on the internet and social media during the pandemic brings opportunities to engage in research through novel strategies and methods [118]. The results will be written up for publication in open-access, peer-reviewed journals for access by the scientific community, and abstracts will be presented at different conferences locally and internationally to encourage dissemination of the results. Shared information will be anonymized to ensure confidentiality.

Conclusions

This study will provide comprehensive data to inform and empower patients, professionals, policy architects, and related decision makers to manage and improve cancer care coordination. This unique intervention will be designed to address the multifactorial problem of cancer health disparities. If successful, this study will help inform the design and implementation of coordination programs in LMICs to promote optimal cancer care for underserved patients.

Acknowledgments

This work received support from the Bristol-Myers Squibb Foundation. The funders had no role in study design, the data collection and analysis, the decision to publish, or the preparation of the manuscript. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided a discount on the article processing fee (APF) for the publication of this article.

Authors' Contributions

BL, TG, and KH conceived the study protocol and its final design. BL drafted the manuscript, and all authors commented on and approved of the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: HIV incidence estimates are published each year for all Ending the HIV Epidemic (EHE) counties, but they are not stratified by the demographic variables highly associated with risk of infection. Regularly updated estimates of HIV incident diagnoses available at local levels are required to monitor the epidemic in the United States over time and could contribute to background incidence rate estimates for alternative clinical trial designs for new HIV prevention products.

Objective: We describe methods using existing, robust data sources within areas in the United States to reliably estimate longitudinal HIV incident diagnoses stratified by race and age categories among men who have sex with other men (MSM) eligible for pre-exposure prophylaxis (PrEP) but not taking it.

Methods: This is a secondary analysis of existing data sources to develop new estimates of incident HIV diagnoses in MSM. We reviewed past methods used to estimate incident diagnoses and explored opportunities to improve these estimates. We will use existing surveillance data sources and population sizes of HIV PrEP-eligible MSM estimated from population-based data sources (eg, US Census data and pharmaceutical prescription databases) to develop metropolitan statistical area–level estimates of new HIV diagnoses among PrEP-eligible MSM. Required parameters are number of new diagnoses among MSM, estimates of MSM with an indication for PrEP, and prevalent PrEP use including median duration of use; these parameters will be stratified by jurisdiction and age group or race or ethnicity. Preliminary outputs will be available in 2023, and updated estimates will be produced annually thereafter.

Results: Data to parameterize new HIV diagnoses among PrEP-eligible MSM are available with varying levels of public availability and timeliness. In early 2023, the most recent available data on new HIV diagnoses were from the 2020 HIV surveillance report, which reports 30,689 new HIV infections in 2020, and 24,724 of them occurred in an MSA with a population of ≥500,000. Updated estimates for PrEP coverage based on commercial pharmacy claims data through February 2023 will be generated. The rate of new HIV diagnoses among MSM can be estimated from new diagnoses within each demographic group (numerator) and the total person-time at risk of diagnosis for each group (denominator) by metropolitan statistical area and year. To estimate time at risk, the person-time of individuals on PrEP or person-time after incident HIV infection but before diagnosis should be removed from stratified population size estimates of the total number of person-years with indications for PrEP.

XSL•FO
RenderX

Conclusions: Reliable, serial, cross-sectional estimates for rates of new HIV diagnoses for MSM with PrEP indications can serve as benchmark community estimates of failures of HIV prevention and opportunities to improve services and will support public health epidemic monitoring and alternative clinical trial designs.

Introduction

There is an urgent need to develop additional options for HIV pre-exposure prophylaxis (PrEP) for men who have sex with men (MSM). MSM are disproportionately impacted by HIV in the United States and globally [1], and models in multiple countries have suggested that achieving high coverage of PrEP will be required to realize substantial reductions in HIV incidence [2-4]. The prevention value of PrEP has not been fully realized in the United States for several reasons [5]. First, levels of PrEP use in the United States are well below the levels of PrEP use that will be required to result in substantial reductions in HIV incidence [6]. Second, MSM are not monolithic, and future PrEP products should be developed to meet diverse prevention needs. For example, PrEP approaches that increase the flexibility of dosing regimens, minimize side effects, offer options for discretion, and offer multiple options that promote adherence and increase flexibility for men will help increase PrEP choices for diverse patient needs. Higher uptake, longer persistence, and higher adherence that can be realized through increased choices will increase the impact of PrEP on HIV incidence [2,7]. Third, although current levels of PrEP use are comparable in Black and White MSM [6], given the higher burden of new HIV infections that occur in Black MSM, equal use of PrEP is not equitable [8,9].

The US national Ending the HIV Epidemic (EHE) strategy is predicated on the need to concentrate resources for HIV prevention and treatment in a relatively small number of communities that are most highly affected by HIV. The plan identifies 57 priority jurisdictions that, together, account for 50% of new HIV infections in the United States [10]. Within these jurisdictions, there is considerable variability in HIV risk by behavioral risk, race or ethnicity, and age. Overall HIV risk varies across jurisdictions, but Black and Hispanic MSM have the highest HIV risk in nearly every geographic location [11]. To reach EHE goals for reductions in HIV incidence, effectiveness of prevention methods will need to be evaluated locally, and across key populations that vary by geography, age, and race or ethnicity. Currently, PrEP use relative to need is lower among Black versus white MSM, and this disparity may extend to, or even be exacerbated by, development of novel PrEP pharmaceutical products [6]. The availability of estimates of new HIV diagnoses over time—a proxy for HIV incidence—by geography, race, and age will help to monitor racial disparities in current and future PrEP use and demonstrate how improvements in adherence and the resulting effectiveness improve equity across populations.

We are now in a phase of increasing PrEP options beyond daily oral tablets and gluteal injections every 8 weeks [12-18]. Increased and equitable PrEP uptake will likely require the development of multiple formats for PrEP (eg, daily oral, event driven, monthly oral, and longer-acting injectable) that are congruent with users' lives, access to care, and preferences for prevention [19,20]. A more robust pipeline of PrEP products offers opportunities to reduce barriers for more people and increase effective PrEP use, as has been demonstrated in the contraceptive field [21]. However, there are clinical trial design challenges to sustaining the progress toward developing more modes for PrEP in populations with diverse needs and preferences.

Given the proven options for PrEP, the traditional trial design for new PrEP medications would be a noninferiority trial [22,23], such as the recently reported trials of combination emtricitabine and tenofovir alafenamide [15] and long-acting cabotegravir [24], designed to demonstrate that HIV incidence in those taking the experimental agent was not higher than incidence in those taking a proven PrEP option. These types of trial designs rely on enough incident infections within the trial population to demonstrate efficacy of the investigational agent. Demonstrating efficacy with these designs is becoming more challenging in the field of HIV prevention, where proven products are highly efficacious in clinical trial settings (with few incident infections), requiring impractically large sample sizes to achieve statistical power for noninferiority margins [25]. There is an argument that if multiple highly effective products are available such that traditional trials are not feasible, then there is no need for new products. However, this would ignore the ongoing HIV incidence outside of these highly controlled settings [26]. The significant ongoing unmet need for HIV prevention and the inequity it represents require us to develop methods that allow for rigorous efficacy and safety trial data for new HIV prevention methods.

Alternative trial designs for future HIV prevention products have been the topic of many recent meetings [27-29] and publications [25,30-33]. One of these alternative approaches is to compare the incidence in those receiving the investigational medication to the incidence in a counterfactual group (ie, a hypothetical contemporary group of persons with similar risk characteristics who would be eligible for the PrEP treatment, but who were not taking PrEP).

Ideally, a counterfactual group that would be used as a comparison group to evaluate the performance of a novel PrEP agent should reflect what the HIV incidence would have been

XSL•FO
RenderX

in a comparable group of PrEP-eligible MSM (ie, men who would be eligible for PrEP by the Centers for Disease Control and Prevention [CDC] clinical criteria, but who were not enrolled in the trial and were not taking PrEP outside of the trial). MSM who live in the study community, who would meet study eligibility criteria, and who could enroll in the trial but do not enroll constitute a potentially appropriate control group. The development of such a counterfactual control group, however, has important challenges. First, there is no enumerated registry of MSM who would have indications for PrEP. Second, unlike in a trial, where participants are regularly screened for HIV infection as an outcome, not all community-acquired cases of HIV infection will be diagnosed and documented. Third, the characteristics of men who do not enroll in the trial of the novel agent might be different in important ways from men who choose to enroll (eg, for understandable reasons such as mistrust of health research [34], Black and Hispanic people were historically less likely to enroll in HIV vaccine trials [35]).

Here, we propose a protocol to estimate the incident HIV diagnoses as a proxy of HIV incidence of HIV among PrEP-eligible MSM at the level of metropolitan statistical area (MSA). These estimates could represent a valuable source of data as a counterfactual reference group to evaluate the efficacy of PrEP in future trials of novel PrEP agents and would have other benefits to community planning and prevention efforts. To increase the rigor of this approach, we propose incorporating multiple population-based data sources, building on previously published methods [36] and incorporating methodologic improvements, including multiple stratifications of men by age and race to reflect important heterogeneities in HIV risks.

Methods

Modeling Equation

This surveillance study will be conducted using structured secondary data and will build upon the methodology outlined by Mera et al [36]. To estimate the new HIV diagnosis rate among MSM with PrEP indications, we will estimate the number of new diagnoses among this group (numerator) and the total person-time at risk of diagnosis for this group (denominator) by MSA and year. The approach is summarized by Equation 1 and described in detail below.

where *i* is demographic strata, *j* is MSA,*k* stands for year, *N* is number of new HIV diagnoses, *n* is number of new HIV diagnoses that are not in the MSM transmission category, *prepI* is *number of MSM with indication for PrEP*, *prepN* is *number of MSM PrEP users*, and *prepPT* stands for *average amount of time on PrEP my MSM in year k.*

Numerator Data Sources

The numerator represents the annual number of new HIV diagnoses among MSM with an indication for PrEP, by MSA and demographic strata, and will use data from the annual CDC HIV surveillance reports [37,38]; these data are available through CDC AtlasPlus [39]. The surveillance data sets have been published using consistent methods since 2008 and are the largest and most representative data sources for HIV diagnoses in the United States. The HIV surveillance report includes the number of new HIV diagnoses reported per year to the National HIV Surveillance System stratified by transmission category (ie, MSM, people who inject drugs, and heterosexual), race or ethnicity (ie, American Indian or Alaska Native, Asian, Black or African American, Hispanic or Latino, Native Hawaiian or Other Pacific Islander, White, Multiple races), age (10-year increments), and residence. Additionally, the HIV surveillance report includes stratification by MSA, as defined by the Office of Management and Budget. As described by Mera et al [36], a cumulative total of all new HIV diagnoses can be adjusted by subtracting all new HIV diagnoses that are attributed to a transmission category that are not in the MSM transmission category.

Denominator Data Sources

The denominator represents the total time at risk among MSM at risk of HIV acquisition. To estimate this for each stratum of interest, we will start with estimates of the number of adults that would be expected to have indications for PrEP [40] and remove person-time during which persons were on PrEP or acquired an incident HIV infection. Previous analysis of surveillance data has resulted in cross-sectional estimates of the number of adults in each HIV transmission risk category at the state level, who are then presumed to have an indication for PrEP [40]. To estimate the proportion of adults with a PrEP indication in each MSA by year, we will need to assume the proportion of persons with a PrEP indication is consistent within a jurisdiction and over time.

Person-Time Calculations

The amount of person-time among PrEP users can be estimated with data on the total number of PrEP users within each jurisdiction and year and data on the average length of time that users were on PrEP during the calendar year. Large, national prescription data sets include information on the number of patients who received a prescription of emtricitabine/tenofovir disoproxil fumarate or emtricitabine/tenofovir alafenamide and corresponding diagnostic codes. Using a validated algorithm [41], we can exclude prescriptions that were made for other known indications, such as HIV treatment, postexposure prophylaxis, and chronic hepatitis B management. We will estimate the number of prevalent PrEP users by tabulating the number of persons that had at least one day of prescribed PrEP in the respective calendar year. AIDSVu.org [42] applies this algorithm to data from Symphony Health to report estimates of the total number of current PrEP users within each county [6]. The estimates from each central county within an MSA can be summed to calculate the number of current PrEP users within the MSA. Additionally, we will assume that the rate of new HIV diagnoses is constant throughout the calendar year. With this assumption, we expect, on average, that the amount of time at risk among persons who experienced a new HIV infection during the calendar year was 6 months (ie, half of a year).

Ethical Approval

The proposed analyses will use deidentified and aggregated data sets; data about individuals are not provided in the data

XSL•FO
RenderX

sets. The Emory University IRB has determined that this project does not require institutional review board review because it is not research with "human subjects," nor is it a "clinical investigation" as defined in the federal regulations.

Results

In early 2023, the most recent available surveillance data on new HIV diagnoses were from the 2020 HIV surveillance report, which was published in May 2022 [11]. This report indicates there were 30,689 new HIV infections in 2020, and 24,724 of them occurred in an MSA with a population of ≥500,000. Additionally, this report presents the number of new reported HIV diagnoses by MSA. The number of new HIV diagnoses, stratified by transmission category, race or ethnicity, or age, is typically published in supplemental volumes to primary HIV surveillance report, and the most recent supplementary volume with these data reflects diagnoses that occurred in 2018 [11].

Smith et al [40] developed a methodology for estimating the number of adults with PrEP indications by race or ethnicity and transmission category within each state. The most recent application of this methodology yielded estimates that indicate 1.1 million adults (813,970 MSM, 258,080 heterosexually active adults, and 72,510 persons who inject drugs) had indications for PrEP use in 2015. The methodology and data sources for these estimates can be expanded and updated. Additionally, assuming the proportion of persons with a PrEP indication is consistent within a state allows for the calculation of the total number of persons within each MSA (by transmission category and race or ethnicity) that have a PrEP indication.

AIDSVu.org annually releases new estimates of the current number of PrEP users, stratified by US county [42]. The methods for the production of these data have been previously reported [43]. The most recent estimates reflect 2019 and are further stratified by age group. We will use the publicly available county-level estimates from AIDSVu, which are updated annually; we will also explore further analyses of commercial pharmacy claims data to further stratify PrEP users within counties by age and race or ethnicity. Race or ethnicity data will be obtained from the matching of commercial pharmacy claims data to commercial credit reporting data, as has been previously reported by the CDC [40]; these matches will be evaluated for completeness and for potential biases related to missing data. Additionally, line-listed data from commercial pharmacy claims will be used to calculate the average duration of use for each demographic group of interest, using methods previously reported using claims data from large national pharmacy claims [44]. Our previous methods were focused on daily oral PrEP dosing strategies; we will develop and validate algorithms for identifying injectable cabotegravir [24] from claims data, to include this new PrEP agent and delivery route, and will continue to address new PrEP agents or dosing schedules as new agents become available (eg, monthly oral PrEP) [16].

Discussion

Principal Findings

We present an analytic approach for estimating population-level HIV incident diagnoses among PrEP-eligible MSM by jurisdiction, age group, and race or ethnicity. The proposed methods rely entirely on existing data and largely on publicly available surveillance data. This method would, for the first time, facilitate counterfactual estimates for the evaluation of novel PrEP pharmaceutical products by important characteristics of person, time, and place. HIV infections among MSM are highly concentrated among groups characterized by geographic location, age, and race or ethnicity, making it critical to evaluate new prevention methods within risk strata. Ensuring access to effective HIV prevention among populations with the highest risks for infection will require a nuanced understanding of how effectiveness of novel methods may vary across the demographic characteristics that determine HIV risk.

Utility of New Data Produced

These estimates could be used in multiple ways to support alternative HIV prevention trial designs. They could serve as one estimate in building a background surrogate estimate for HIV incidence for an external control arm and could also be used in the context of noninferiority trials, the current standard for evaluating effectiveness of novel PrEP pharmaceutical products. These trials are costly and require large sample sizes to reach an adequate number of HIV infections among participants receiving prevention medications for comparison purposes. Dunn and Glidden [30] and Glidden et al [45] have proposed the ratio of averted infections in each trial arm as the summary measure for evaluating noninferiority of novel PrEP pharmaceutical products. This summary measure requires fewer assumptions about the noninferiority margin and a smaller sample size to evaluate noninferiority of the novel product than the commonly used ratio of HIV incidence in each trial arm. However, it requires an estimate of background HIV incidence for persons not taking either a proven PrEP product or the trial medication. Previously described approaches for estimating this counterfactual incidence parameter apply a Bayesian approach with estimates from historic research data on emtricitabine/tenofovir disoproxil fumarate effectiveness [32,45] or use the correlation between incidence of rectal gonorrhea and HIV to estimate the number of HIV infections that would have been observed in the absence of PrEP [46]. However, neither of these approaches makes use of population-based data, and they are therefore subject to bias to the extent that trial participants are dissimilar to persons among whom these assumptions are based.

The availability of estimates of PrEP incidence among PrEP-eligible MSM is also a critical building block to support the routine production of other data that will inform our understanding of the equitable use of PrEP and impact of PrEP. For example, we have described the PrEP-to-need ratio as an equity-based metric to depict the extent to which PrEP is used equitably by subpopulations (eg, Black and White MSM) [9]. These metrics have been calculated and reported at the state level [9], and the availability of data at the MSA level would

XSL•FO
RenderX

allow the calculation of these metrics at levels relevant to local health jurisdictions. Our plan to produce stratified estimates by age will also allow the characterization and modeling of PrEP needs and exploration of PrEP prioritization strategies to maximize the impacts of PrEP in local communities.

Enhancements to Existing Methods

The approach outlined here is based on previously published work by Mera et al [36], in which HIV diagnosis rates among PrEP-eligible individuals are estimated from 2012 to 2017. However, we propose several utility-added enhancements. First, use of the most current surveillance data will facilitate updated estimates for background HIV risk among PrEP-eligible MSM. Second, in addition to using updated surveillance data, the proposed method uses surveillance data that are stratified by age and race or ethnicity within jurisdictions. Stratification of key parameters in the surveillance data facilitates estimates specific to jurisdiction, age, and race or ethnicity. Third, previous estimates represent all PrEP-eligible individuals and assume adherence and persistence are constant across risk groups (eg, people who inject drugs, high-risk heterosexuals, and MSM). In reality, there may be important differences by risk group or age, and ignoring this heterogeneity might result in biased estimates of PrEP impact [47,48]. By focusing on MSM, who have the highest burden of HIV infection of all risk groups and the most unmet need for PrEP [9], our method will produce estimates that are directly informative to a trial counterfactual for MSM and to evaluating prevention needs of this important population. Last, we propose this method at the MSA level, but due to transparency of parameters used, it could be used at any geographic level for which needed data are available.

Limitations

Despite these improvements, these methods have several continuing challenges. First, while we propose to use the most updated surveillance data for input parameters, surveillance data are typically published with a 1-2–year delay. If implemented for noninferiority trials, adjustments to HIV diagnoses based on historical reporting delays might be needed [49]. We acknowledge that this might be challenging in the coming 6-8 years because of disruptions in HIV diagnoses and reporting during the COVID-19 pandemic [50]. Moreover, modeled estimates needed for this work that rely on surveillance data inputs, such as the proportion of HIV-negative MSM with PrEP indications, require additional time to compute and publish after surveillance estimates are made publicly available. Population-based estimates of background HIV incidence will therefore not be perfectly contemporaneous to trial periods, due to reliance on publicly available data. Second, population-level HIV risk among PrEP-eligible MSM may be higher or lower than MSM enrolled in PrEP trials. To the extent that there is differential risk between trial participants and the background population, estimates of effectiveness of novel PrEP products may be subject to selection bias. However, the risk of selection bias is diminished substantially in the context of population-level estimation specific to jurisdiction, risk group, as well as age and race or ethnicity groups. Possibly the greatest limitation of population-based methods to estimate HIV incidence is that, currently, only HIV diagnosis data, rather than incidence estimates, are available within levels of needed stratifications. Therefore, the assumption must be made that diagnoses are roughly equal to incidence in a given year, and that this is constant across geography, age, and race or ethnicity. As HIV surveillance methods continue to improve, it is likely that incidence estimates will be available at finer levels of geography and demographic characteristics. Third, we recognize that the proportion of MSM with PrEP indications might not be stable over time. We will monitor the proportion of MSM with PrEP indications over time by using data from the American Men's Internet Survey [6] and will adjust this parameter if the proportion of MSM with indications changes substantially over time. We will also conduct sensitivity analyses to this parameter in the first implementation of the protocol.

There are additional limitations and related assumptions that need to be considered to produce these estimates. For example, prescription data do not represent a full census of PrEP prescriptions, so PrEP use is underestimated in all MSAs and could be differentially underestimated. We assume that the average duration of PrEP use is the same for people who are and are not matched to race data; there are few data on PrEP persistence from observational studies stratified by race to inform the reasonableness of this assumption. We also assume that the proportion of MSM eligible for PrEP but not taking it is constant in MSAs over time and is consistent with state-level data. Most PrEP users in pharmacy data are men, and we assume that men on PrEP in pharmacy data are mostly MSM [43]. Prescription databases document the location of the provider who prescribed the medication, and not the patient; however, data suggest that people in urban areas usually reside 2-3 miles from their health care provider [51].

Public Health Impact and Conclusions

Updates and improvements to some parameters outlined here would further increase the utility of these estimates. In particular, estimates for the population size of MSM in the United States and the proportion of HIV-negative MSM with PrEP indications should be updated with current data, and novel methods are needed to incorporate uncertainty around these estimates. Previous estimates of HIV incidence among PrEP-eligible individuals did not incorporate uncertainty from data sources derived from population samples [36]. Building uncertainty estimates into these 2 parameters would facilitate computation of standard errors around HIV incidence estimates that incorporate uncertainty across multiple data sources.

Population-based data on estimated incident HIV diagnoses among PrEP-eligible MSM at the MSA level are critical public health resources. Developing estimates of incident HIV diagnoses among PrEP-eligible MSM will provide an important data resource for use by local health departments to benchmark progress in HIV prevention programs. The use of local, meaningful indicators of HIV incidence and trends in incidence supports the essential functions of public health [52]. We plan to produce periodic updates to the estimates and make them publicly available to researchers and health departments through AIDSVu.org [42], as we have done with other data resources such as estimates of PrEP prescriptions among populations at

XSL•FO
RenderX

the regional, state, and local geographic levels [9,43,53]. Estimates of incident HIV infections in PrEP-eligible MSM, in triangulation with other data sources, can inform assessments of local prevention coverage and opportunities.

Data Availability

Data used in the calculations will be available in aggregate form. Data on PrEP users is currently available through AIDSVu.org [54] for earlier years; updated public data sets will be posted as new data from this analysis are developed. Data on new HIV diagnoses will be taken from the CDC's AtlasPlus website [55]; these data are also publicly available.

Abstract

Background: Vaccine hesitancy is one of the many factors impeding efforts to control the COVID-19 pandemic. Exacerbated by the COVID-19 infodemic, misinformation has undermined public trust in vaccination, led to greater polarization, and resulted in a high social cost where close social relationships have experienced conflict or disagreements about the public health response.

Objective: The purpose of this paper is to describe the theory behind the development of a digital behavioral science intervention—*The Good Talk!*—designed to target vaccine-hesitant individuals through their close contacts (eg, family, friends, and colleagues) and to describe the methodology of a research study to evaluate its efficacy.

Methods: *The Good Talk!* uses an educational serious game approach to boost the skills and competences of vaccine advocates to have open conversations about COVID-19 with their close contacts who are vaccine hesitant. The game teaches vaccine advocates evidence-based open conversation skills to help them speak with individuals who have opposing points of view or who may ascribe to nonscientifically supported beliefs while retaining trust, identifying common ground, and fostering acceptance and respect of divergent views. The game is currently under development and will be available on the web, free to access for participants worldwide, and accompanied by a promotional campaign to recruit participants through social media channels. This protocol describes the methodology for a randomized controlled trial that will compare participants who play *The Good Talk!* game with a control group that plays the widely known noneducational game *Tetris*. The study will evaluate a participant's open conversation skills, self-efficacy, and behavioral intentions to have an open conversation with a vaccine-hesitant individual both before and after game play.

Results: Recruitment will commence in early 2023 and will cease once 450 participants complete the study (225 per group). The primary outcome is improvement in open conversation skills. Secondary outcomes are self-efficacy and behavioral intentions to have an open conversation with a vaccine-hesitant individual. Exploratory analyses will examine the effect of the game on implementation intentions as well as potential covariates or subgroup differences based on sociodemographic information or previous experiences with COVID-19 vaccination conversations.

XSL•FO
RenderX

Conclusions: The outcome of the project is to promote more open conversations regarding COVID-19 vaccination. We hope that our approach will encourage more governments and public health experts to engage in their mission to reach their citizens directly with digital health solutions and to consider such interventions as an important tool in infodemic management.

vaccine hesitancy; communication; serious game; conversation skills; self-efficacy; behavioral intentions; COVID-19

Introduction

Background

Vaccine hesitancy is one of the many factors impeding public health efforts to control the COVID-19 pandemic [1,2]. High vaccine uptake, especially in vulnerable and high-risk groups, is crucial to reduce severe disease hospitalization and death; however, vaccination rates differ markedly across countries (eg, 50% in Russia, 77% in Germany, and 91% in Singapore [3-5]). The World Health Organization (WHO) defines vaccine hesitancy as "a motivational state of being conflicted about, or opposed to, getting vaccinated; this includes intentions and willingness" [6], and it is a dynamic state that can evolve over the course of a pandemic. Reasons for vaccine hesitancy include a misunderstanding regarding COVID-19, a general mistrust of vaccination, safety and effectiveness concerns, concerns about the rapid development and testing of the vaccine, lack of awareness of the social benefits of vaccination, and logistical or opportunity-related factors [2,7-11]. These concerns have been exacerbated by the COVID-19 *infodemic*, in which "too much information including false or misleading information in digital and physical environments during a disease outbreak," can lead to confusion and loss of trust in health authorities and public health responses [12]. COVID-19 misinformation has not only undermined public trust in vaccination [13] but has also led to a high social cost where close social relationships have experienced conflict or disagreements about pandemic control efforts [14-16]. In response, the WHO and others have called for greater application of behavioral science interventions targeting behavioral change and to support individuals in dealing with the psychological burdens associated with pandemic prevention and response [17-19]. For instance, evidence-based interventions that can help strengthen the resilience of individuals and communities to misinformation and other factors affecting trust in information will be a valuable tool for infodemic management [20].

Objectives

The aim of this paper is to describe the theory behind the development of a new digital behavioral science intervention—*The Good Talk!*—designed to target vaccine-hesitant individuals through their close contacts (eg, family, friends, and colleagues) and to describe the methodology of a research study to evaluate its efficacy. *The Good Talk!* uses a serious game—a game that does not have "entertainment, enjoyment or fun as their primary purpose" [21]—to boost the competences of vaccine advocates to have open conversations regarding COVID-19 with their close contacts who are vaccine hesitant. Serious games have been used as educational tools to build skills, including teaching perspective taking to help students improve their open conversation skills [22] and inoculating people against misinformation (eg, the *Bad News* game [23]). Peer-led initiatives have been used to address mistrust in other domains, and communicating through relatable and trusted sources can lead to more acceptable and personal information exchanges, promoting prosocial behaviors when common identities are shared [1,19]. Furthermore, by focusing on boosting open conversation skills rather than addressing a specific cause of vaccine hesitancy, the approach has the potential to address a variety of reasons why an individual is vaccine hesitant [1,24] as well as build transferrable skills that can be applied across a variety of situations [25]. *The Good Talk!* is publicly available worldwide and will be evaluated in a preregistered randomized trial. Evaluating the impact of the intervention will be the subject of a future publication.

Vaccine Hesitancy, Polarization, and the Social Impacts of the COVID-19 Pandemic

In 2019, the WHO identified vaccine hesitancy as one of the 10 threats to public health [26]. Despite strong and sustained evidence of the efficacy of vaccinations, perceptions of the safety and effectiveness of some vaccines have varied over the past years [27,28], affecting vaccine uptake [29] and contributing to disease outbreaks [24]. The influence of vaccine hesitancy on public health efforts to manage disease outbreaks has been accentuated during the COVID-19 pandemic, in which vaccine uptake in some countries has been low or lagging despite high vaccine access [3,4,30,31]. Consequently, longer durations of public health and social measures to reduce COVID-19 transmission are required, resulting in a variety of economic, health, and social costs with substantial psychological burden on individuals and communities [19,32].

The social costs of vaccine hesitancy have also been fueled by the COVID-19 infodemic, in which an overabundance of information has made it more difficult for the public to differentiate between correct and misinformation. When the public's questions and concerns are left unanswered, information voids occur, which can lead to widespread false and misleading information. For instance, searches involving antivaccination rhetoric increased during the COVID-19 pandemic as people sought information about vaccine safety [33]. The infodemic has diluted trust in institutions, leading to confusion and disagreement about vaccination and safety measures [34,35], and has resulted in an increasingly polarized environment in which people avoid engaging with those who hold opposing or

XSL•FO
RenderX

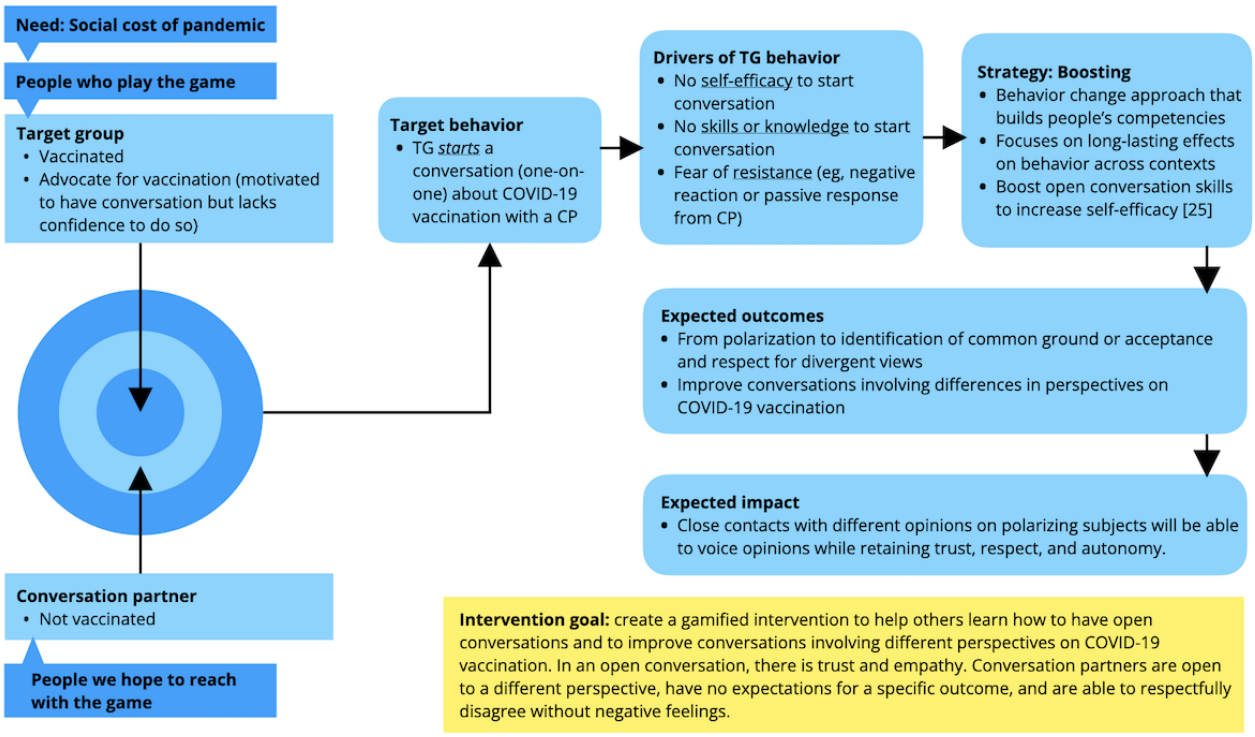
divergent views, negatively affecting interpersonal relationships [36].

For instance, 56% of participants in a nationwide UK-based study reported having arguments, feeling angry, or falling out with others because of discussions surrounding COVID-19 [16]. In addition, people report relationship strain, interpersonal conflict, and increased isolation associated with sharing differing opinions or information about COVID-19 with family members or friends or avoiding conversations altogether to prevent conflict [14,15]. Thus, interventions to help people develop skills to discuss potentially polarizing topics and maintain supportive relationships with those who hold different opinions are needed to reduce the negative social costs of the pandemic [15]. Furthermore, considering the evolving nature of COVID-19—both in terms of the emergence of new variants and cyclical gravity because of seasons—governments have imposed, lifted, and changed regulations frequently. As such, the topic of COVID-19 and vaccinations will hold relevance for many years to come [37].

Intervention Goal: Initiate One-on-One Open Conversations About COVID-19 Vaccination

We sought to develop an evidence-based behavioral science intervention that could address diverse drivers of vaccine hesitancy while also supporting individuals in managing the psychological burden of the COVID-19 pandemic. Vaccine hesitancy is context specific and falls along a dynamic continuum, with motivation toward vaccination existing on a spectrum of those who are fully, partially, or not yet vaccinated [6,38,39]. As such, one-size-fits-all public health communication strategies are unlikely to reach all such individuals and will require a tailored, targeted, and multifaceted approach [1,24].

Reviews of a broad range of intervention approaches for addressing vaccine hesitancy report a lack of evidence or mixed findings on the effectiveness of many interventions [6,40-42], with dialogue-based approaches being among the most effective strategies [40]. Dialogue-based approaches aim to facilitate and encourage open communication to understand a specific audience and their underlying concerns [40]. Open communication–based approaches have the potential to address the negative effects of the COVID-19 infodemic on polarization and interpersonal relationships. For instance, exposure to divergent views through interpersonal discussion can weaken the association between selective exposure—exposure to content and groups that reinforce one's opinions—and polarization [43]. Open communication is important for showing respect and empathy toward a communication partner, which can reduce defensiveness, increase receptiveness, and pave the way for open-minded conversations in which speakers are willing to share their views, consider new information, and potentially change their attitudes [44].



In addition, personalized communication can increase COVID-19 vaccine uptake, and these interventions are most effective when tailored to and delivered by a trusted peer or community member [6,42,45]. Advocating normative or prosocial behavior is more effective when a member of one's social network models the behavior and there is an expectation of social approval [19]. Social approval is important, as people have a strong need to belong [46] and people listen to others in their social environment [47]. Accordingly, vaccine-hesitant individuals may be more likely to listen to and trust their close ties, as public trust in health institutions among vaccine-hesitant individuals is exceedingly low [19,48], and peer-led initiatives have shown positive outcomes when addressing mistrust in other domains [1]. Peer-led initiatives capitalize on social networks to communicate and can influence social norms to promote behavior change [41]. Furthermore, communicating through trusted and relatable sources can facilitate more acceptable and personal information exchange [1].

Thus, the target group for the intervention is the close ties of vaccine-hesitant individuals who are vaccinated or are supportive of COVID-19 vaccination. For the purposes of this study, we refer to these individuals as *vaccine advocates*. As shown in the Theory of Change for the intervention (Figure 1), we aim to target vaccine advocates who are motivated to have a conversation about vaccination but lack the self-efficacy, skills, or knowledge to start a conversation or who fear resistance from their conversation partner. Motivation is an important driver of behavior change, and behavioral interventions are most effective when an individual is sufficiently motivated to learn new skills or competences [49,50]. In addition, targeting vaccine advocates increases the ecological validity and potential scope of the intervention, as they are likely to have more direct access and frequent encounters with vaccine hesitants and can reach broad and diverse audiences.

Accordingly, the goal of *The Good Talk!* intervention is to increase open conversations about COVID-19 vaccination by encouraging vaccine advocates to start a conversation with an individual they know or encounter who holds divergent or opposing views on vaccination or public health responses. We focus on *starting* an open conversation for several reasons. First, encouraging people to initiate a conversation is a first step to counter people's motivations to avoid conversations about difficult topics (eg, owing to conflict concerns) [51,52]. Second, starting an open conversation is a concrete behavior as opposed to the more ill-defined concept of *having* a conversation and does not focus on the outcome of the conversation as an indicator of success. Although open conversations are important for building trust over the longer term, they may not lead to immediate changes in vaccination behavior or in clearly identifiable positive or negative outcomes following each conversation instance [53]. Thus, the aim of the intervention is to develop a participant's competences, skills, and self-efficacy to approach rather than avoid conversations about COVID-19 vaccination. The intervention targets vaccine hesitancy indirectly by fostering more supportive interpersonal relationships between vaccine hesitants and vaccine advocates that encourage exposure to and consideration of divergent views. Ultimately, this should lead to continued exposure to divergent views between close ties and ongoing dialogue, which may eventually result in greater openness to the positions of others and remain open to evidence.

Applying Behavioral Science to Improve COVID-19 Vaccine Communication

We applied the theoretical framework of boosting to guide the development of our intervention. Boosting is an evidence-based behavioral science approach that focuses on building people's skills and competences rather than targeting a specific behavior [25,49]. The aim of boosting approaches is to foster people's existing skills and competences or to develop new ones, thus helping individuals build their skills, knowledge, and self-efficacy to shift their motivations and translate their intentions or preferences into behavior [25,49]. A core feature of boosts is that they preserve people's agency and enable them to exercise that agency to make their own choices [49]. Boosts are recommended for behavioral interventions where there is uncertainty or heterogeneity in people's goals, when generalizability and longevity of a behavior is desired, and boosts are most effective when people are motivated to acquire new skills or competences [49,54]. Accordingly, a boosting approach is well suited to the design of an intervention that seeks to develop open conversation skills that are generalizable and flexible to addressing diverse causes of vaccine hesitancy, and for interventions that enable individuals to make their own choices on how to apply the skills to achieve their interpersonal relationship goals.

The focus of boosting approaches on fostering competences aligns with the objectives and key drivers of the intervention target behavior. Competence in interpersonal communication skills is associated with positive conversational outcomes, such as personal conversational satisfaction and more positive evaluations from conversation partners [55,56]. Demonstrating open conversation skills also leads to reduced defensiveness, greater awareness of attitude contradictions, decreased attitude extremity, and more open mindedness in conversation partners [57-59]. Furthermore, interventions designed to teach open conversation skills (eg, high-quality listening) or simple receptive conversation strategies have been found to signal positive collaborative intentions and receptiveness to alternative views while reducing negative conversational outcomes, such as defensiveness or threat reactions [57,59].

Developing open conversation skills can also build confidence and self-efficacy in conversations [60,61], and perceptions of self-efficacy are associated with conversational satisfaction [55]. Boosts foster self-efficacy by helping people learn and apply skills and knowledge through the development of competencies, rather than by providing information per se [25]. For instance, rather than teaching universal skills (eg, declarative knowledge), boosts use techniques such as teaching procedural rules, simple heuristics, or trainings (eg, learning how to harness implementation intentions) that can be generalized across different contexts or environments. The approach is conceptually similar to the inoculation approach used in misinformation detection interventions (eg, the *Bad News* game [23]), in which participants are exposed to the *techniques* that underlie misinformation and encouraged to generate their own antibodies rather than learn passively through being shown examples of manipulative strategies [62]. Learning through feedback on the effectiveness of skills can help build self-efficacy and confidence in understanding where and when to apply the skills to achieve one's objectives [54].

Thus, our objective was to review the literature on open conversation skills to identify a set of simple strategies that could be integrated into a short behavioral intervention in the form of boosts. We aimed to design an intervention that would help individuals learn the effectiveness of these strategies on

XSL•FO
RenderX

conversational outcomes through guidance and feedback, thus fostering participants' self-efficacy in applying these strategies to initiate open conversations. In the following section, we will provide an overview of the evidence basis for the open conversation skills. The *Methods* section describes how we designed the intervention to provide participants with the opportunity to apply the strategies through an engaging and motivational serious game: *The Good Talk!*

Open Conversation Skills

Overview

We conducted a narrative review of a broad range of literature on communication approaches to identify evidence-based open conversation skills that can be designed as boosts within the intervention. To align with the goals, we searched for communication literature that focused on developing or fostering supportive relationships, promoting self-efficacy and empowerment, or on psychological or therapeutic approaches developed to support behavior change. Specifically, we explored literature on the topics presented in Textbox 1.

Textbox 1. Communication literature reviewed to develop open conversation boosts.

- Communication theories or frameworks to support behavior change (eg, motivational interviewing [7,63-65] and Self-Determination Theory [66-69])
- Core communication skills for fostering ongoing, supportive relationships (eg, building trust, empathy, and autonomy) [70-73]
- Literature on specific topics related to persuasive communication and listening skills [56-58,72] as well as strategies to increase receptiveness of divergent views and reduce psychological reactance (eg, conversational receptiveness) [59,74,75]
- Psychological strategies on how to handle negative reactions or outcomes (eg, mindfulness and intellectual humility) [76-78]
- Conversation guidelines or recommendations for health risk communications (eg, crisis communication) or on how to communicate about vaccinations [1,32,45,79-81]

From this literature, we identified 8 general open conversation skills that we categorized into 4 main communication objectives: to build trust and respect, be supportive, be receptive and demonstrate empathy, and practice acceptance. These objectives can be represented as a mnemonic for *The Good Talk!* acronym: gain trust, offer support, open up, and don't be sad if it doesn't work out. We provide a brief overview of each of the objectives and skills in the subsequent sections. More detailed descriptions of the open conversation skills and summaries of the supporting literature can be found in Table S1 in Multimedia Appendix 1 [7,56,58,59,63,65,66,69,72-76,79,82-87].

Gain Trust

The first objective focuses on building trust and rapport with the conversation partner to develop or maintain a supportive relationship or establish a partnership. The first of the 3 open conversation skills, *find mutual value*, aims to find points of agreement or shared value between conversation partners to create a sense of partnership, shared identity, or establish a common fate that one can connect or appeal to [69,79]. Finding points of agreement also signals receptiveness and positive collaborative intentions [59]. The second conversation skill, *respect autonomy*, aims to foster empowerment and self-efficacy in the conversation partner by treating them as responsible agents who have autonomy over their choices. Autonomy is considered a primary psychological need in Self-Determination Theory [66]. Further, emphasizing that one has and is responsible for their own choices reduces psychological reactance [69,75,82] and lowers feelings of defiance [83]. Fostering autonomy is a key recommendation in health risk and vaccine communication guides [53,79]. The third conversation skill, *don't lecture or persuade (don't be an expert)*, focuses on using language or strategies that avoid perceptions of authoritarian, coercive, or persuasive intent, which can lead to greater reactance to change communication [66,69,75,79,84]. For instance, using hedging (eg, use of "might" or "somewhat") to soften factual claims has been found to signal collaborative intentions [59].

Offer Support

Offering support during a conversational exchange can facilitate relationship building and serves to foster self-efficacy in the conversation partner. The first conversation skill is to *ask for perspective* by showing interest in another's viewpoint and expressing genuine appreciation for their concerns, feelings, or perspectives. Feeling understood and cared for by others is a primary psychological need according to Self-Determination Theory [66,69], and showing interest in another's view leads to more positive evaluations of the conversation partner and greater receptiveness perceptions [56]. Affirmation of a conversation partner's concerns is a component of motivational interviewing to promote self-efficacy and boost their confidence in taking action to make behavioral changes [7,63]. The second skill is to *affirm feelings/perspectives and acknowledge past efforts and successes* and is also a core component of motivational interviewing to support self-efficacy. It focuses on emphasizing the strengths, past successes, and efforts of the conversation partner and encouraging them to highlight their own strengths [7,63]. Applications of Self-Determination Theory to COVID-19 communication suggest that providing constructive feedback on how successful people have been in adhering to measures fosters a sense of competence and motivation to continue engaging in them [69].

Open Up

Two open conversation skills relate to the objective to open up. First, *asking open questions* aims to encourage individuals to use open (as opposed to closed) questions to gain insights and understanding and to allow their conversation partner to discuss their story. Open-ended questions are 1 of the 4 core

XSL•FO
RenderX

communication skills in motivational interviewing to help establish a mutually trusting and respectful relationship with a conversation partner [7,63] and a strategy to accommodate people's basic psychological need for relatedness in Self-Determination Theory [66,85]. Asking open questions is also an important active listening skill to enhance understanding and build relationships [73], and this communication skill is cited in numerous health risk communication guides [79,81]. Second, to *be resilient if the other* (conversation partner) *is right* promotes respect for divergent views (respectful disagreement) to foster open mindedness, shared identity, and more positive conversational exchanges [58,59,72]. At the same time, being willing to acknowledge and accept when a conversation partner is right or makes a valid argument demonstrates humility and openness to opposing views [76].

Don't Be Sad If It Doesn't Work Out

The final objective involves preparing the individual for a case in which their conversation will not necessarily lead to a positive outcome or observable behavior change [79]. The open conversation skill is to *accept negative outcomes* without judgment or negative evaluation of the situation or the conversation partner. Acceptance, nonjudgment, and nonreactivity are important for emotion regulation and for reducing strong negative emotions in mindfulness and acceptance and commitment therapy [70,78,86,88]. Accepting that the conversation may be one of several and leaving open the opportunity for future conversations can keep communication channels open and maintain ongoing relationships [79].

Intervention Delivery: Serious Game

We sought to deliver the intervention through a medium that had a strong evidence basis for promoting behavior change, was realistic and had strong ecological validity in terms of interpersonal communications during the COVID-19 pandemic, would motivate people to engage with the intervention, and could reach broad and diverse audiences. Gamified behavioral interventions have been found to promote positive behavior change across a variety of health-related areas, including asthma control, medication adherence, and diet [89], and were found to be more effective than inactive controls or nongamified interventions in improving physical activity behavior [90]. Games have also been used as educational tools across a variety of fields [91,92], such as teaching students role-playing and perspective taking to improve open conversation skills [22], and have been found to be effective at inoculating people against disinformation [93,94], specifically COVID-19 disinformation [95].

Serious games are games that do not have "entertainment, enjoyment or fun as their primary purpose" [21]. The learning benefits of serious games align with the goals of boosting interventions, in which the aim is to boost competences and in which motivation is key to intervention efficacy [49]. Serious games increase knowledge, build skills, and increase self-efficacy through design features within the game play that help players to select relevant information and integrate and organize the information with prior knowledge [96]. For instance, a first-person perspective can engage players in the learning experience, narrative and choice instill a sense of autonomy, interactions with game characters and personal reflection provoke empathy and relationship or community building, and mistakes and feedback processes can foster persistence [92,96]. Furthermore, serious games not only enhance motivation to learn but also have a strong motivational appeal [92,96].

Serious web-based games have the potential to reach a broad and diverse audience, can be accessed worldwide on mobile and desktop devices, and can be shared with others via web-based media. Edutainment mobile games aimed at educating remote or low-resource communities on issues such as agriculture and farming practices, health, livelihoods, and financial literacy have been disseminated in over 20 countries, with COVID-19–focused games reaching >2.7 million people across 11 countries in 2020 [97]. Furthermore, as social distancing and safety measures during COVID-19 have limited close interpersonal contact and people have increasingly turned to web-based communication to stay connected [98], mimicking widely used web-based communication applications (eg, using a messenger-type app) [99] has strong ecological validity [100]. Another goal of using this format was to facilitate adaptation, translation, and implementation into existing public health channels that may be fighting misinformation via chatbots (eg, WHO's Health Alert Services [101-103]), including in low-resource settings [104]. Therefore, we designed a serious game based on a messenger app to build self-efficacy and open conversation skills by mimicking real-world conversations between vaccine advocates and their close contacts. Further details on the specific design features of the serious game and how the open conversations skills were implemented are provided in the *Methods* section.

Overview of Intervention Hypotheses

In the previous sections, we have detailed the theoretical development of *The Good Talk!* intervention. Our next step is to conduct a research study to evaluate the efficacy of *The Good Talk!* serious game to improve people's skills and competences to have open conversations about COVID-19 with vaccine-hesitant individuals. In the following sections, we present a detailed research protocol describing the planned evaluation study to be conducted along with the implementation of the game. Once completed, the results of the evaluation study will be reported in a separate publication.

The efficacy of the intervention game will be evaluated in a preregistered randomized controlled trial. Specifically, we aim to answer the following research question: "How well does *The Good Talk!* game improve people's open conversation skills, perceptions of self-efficacy, and behavioral intentions to have open conversations with vaccine-hesitant individuals who are close contacts?" We will compare a group of participants who play the intervention game with a control group that will play the widely known noneducational game *Tetris*. *Tetris* was selected as the game for the control condition as it is in the public domain, and most people know how to play it without the need for practice or instruction. *Tetris* involves a similar amount of cognitive effort to play as the intervention game, it contains no content related to the study, and it has been used as

XSL•FO
RenderX

a control game to validate other digital game-based learning interventions [62,94,105]. *Tetris* is an inactive control group (receiving no educational material), which is an appropriate design for assessing the absolute efficacy of the intervention [106].

Our primary hypothesis is as follows:

- *Hypothesis 1: Relative to the control group, The Good Talk! game will result in a greater increase (boost) in participant's skills to have an open conversation with a vaccine-hesitant individual.*

We also hypothesize the following:

- *Hypothesis 2: Relative to the control group, The Good Talk! game will result in a greater increase in individual's feelings of self-efficacy to have an open conversation with a vaccine-hesitant individual.*
- *Hypothesis 3: Relative to the control group, The Good Talk! game will result in a greater increase in intentions to have an open conversation with a vaccine-hesitant individual.*

Methods

Participants and Recruitment

Participants will be recruited to play the game via video or push notifications promoting *The Good Talk!* game on social media platforms (eg, WHO chatbot channels) and advertised via other WHO informational campaigns. Recruitment will be open to all interested individuals worldwide but will be limited to English language speakers. Participants will self-subscribe to the study by accessing the WHO game information web page via the public link or when shared by members in their social network. On the game information page, participants will be asked if, in addition to playing the game, they would like to participate in the research element (a similar approach was used to recruit participants to research elements in other serious web-based games [93,95]). Participants who are not interested in participating in the study will be sent directly to play *The Good Talk!* game; otherwise, they will be asked to opt-in to the study after giving informed consent. Participation in the research element of the game will be restricted to individuals aged ≥18 years. Participation in the study is voluntary, and no remuneration will be offered to complete the study.

Previous studies evaluating the effect of similar serious games on the development of competences report small-to-medium effect sizes averaging around f=0.18 [95,100,105]. A power calculation with a small effect size (f=0.18), power of 0.90, and α=.05 for an analysis of covariance on posttest open conversation skills suggests a total sample size of n=327. We will aim to collect 450 responses (225 per condition) to account for potential technical issues or possible poor-quality data. Data collection will continue until the prespecified sample size for each condition is reached. Preregistration of this study can be found on the Open Science Framework [107].

The Good Talk! Game

The intervention game was developed in collaboration with the game design company "Tiltstudio," that has experience designing serious games including "Bad News," "Go Viral," and "Harmony Square," targeting misinformation, COVID-19 misinformation, and political misinformation tactics, respectively. The game was designed to simulate messenger-type conversations between participants and close contacts in their social network. Messenger-type technologies are dyadic, informationally rich, synchronous, and mimic interpersonal communication and are therefore better suited for establishing a sense of connection and generating empathy [19]. At the same time, they represent a realistic communication platform familiar to many users worldwide [99], which increases the ecological validity of the intervention [100]. The game design implements instructional techniques found in a meta-analysis to be effective at improving learning and motivation in serious games, such as feedback (providing feedback or guidance on whether an answer is correct), reflection (participants are asked to reflect on their responses), level of realism (the game uses basic and cartoon-like representations), and narrative elements [96,108].

The game consists of 5 chapters in which the participants have conversations with characters representing their close contacts. In the first chapter, participants are introduced to the objective of the game, that is, to have as many people attend an event that they are organizing and to earn points for the good talk skills. The participant is asked to select an avatar to represent themselves and can choose between 1 of 4 social events they would like to organize (eg, birthday party, dinner, dance party, or housewarming).

The remaining 4 chapters see the participants encounter characters within their close ties who are motivated by reactance (negative affective reaction when one feels personal freedoms are being threatened), skepticism (doubting knowledge or claims), and inertia (opposing change or action) when discussing COVID-19 measures for the social event. As the conversation develops, the player must select from ≥2 conversational responses that affect the participant's pathway toward the game objective and the points they earn on a Good Talk Meter. The Good Talk Meter increases with response choices that represent good open conversation skills and decreases for those that represent bad open conversation skills. In each chapter, participants are guided by a *Good Talk Guide* who offers advice and reinforces or educates participants about the strategies based on their selections. A brief description of the objective of each chapter is provided in Table 1, and a screenshot of the game interface is shown in Figure 2.

XSL•FO
RenderX

Table 1. Brief overview of the goal and open conversation skills for each chapter.

Chapter	Goal
Introduction	The participant is introduced to the objective of the game and asked to select an avatar and an event they would like to plan. An overview of *The Good Talk!* skills is provided to participants along with the definition of what it means to have an open conversation.
Gain trust	The participant converses with someone who is worried about their kids not being vaccinated and whose kids are skeptical about the government's use of COVID-19 antigen tests. The participant is encouraged to gain the trust of the conversation partner and, in turn, to encourage their partner to use open conversation skills to gain the trust of their children by expressing their concerns, finding mutual value, and supporting their kid's autonomy.
Offer support	In this chapter, the conversation partner mistrusts the seriousness of the pandemic, is skeptical about the evidence, and does not see a personal need to get vaccinated. The participant is encouraged to ask for the perspective of their conversation partner rather than argue, with the goal to understand their views and to continue the conversation. By acknowledging their partner's perspective and concerns, the participant is encouraged to find some common ground so that both feel comfortable attending the event.
Open up	The conversation partner is vaccinated but does not see a need to get the booster vaccination after reading some misinformation on the web and is reluctant to change their mind. The partner is overwhelmed by information and the impact of restrictions. By asking open questions, not being dismissive of their partner's feelings or concerns, and accepting their points while being respectful of divergent views, the goal is to help the partner overcome their inertia.
Don't be sad if it doesn't work out	In the final chapter, the participant encounters a conversation partner who is against vaccination, who mistrusts the government, and who continues to share fake news and misinformation rather than engage in an open conversation. Rather than argue, the participant is guided to not react negatively and to accept that the conversation will be unlikely to lead to a positive outcome.

Figure 2. Example of The Good Talk! game interface on a web browser.

Design

Participants who enter the game website and agree to participate in the research study will be randomized to the experimental or control group (between subjects) and complete both a pre- and postgame survey (within subjects). The experimental group will play *The Good Talk!* game, and the control group will play the noneducational game *Tetris*.

XSL•FO
RenderX

Outcome Measures

Prior Experience With COVID-19 Vaccination

Participants will be asked whether they have had or are currently supportive of people getting the COVID-19 vaccination, whether they currently know someone who is hesitant toward getting the COVID-19 vaccination (and if so, their relationship with this individual), and whether they have previously tried to have a conversation about COVID-19 vaccination with a vaccine-hesitant individual.

Self-efficacy

Participants will rate how confident they are to be able to start a conversation about COVID-19 vaccination with a vaccine-hesitant individual on a 7-point scale ranging from "not at all confident" to "very confident." The self-efficacy item will be asked in the pre- and poststudy surveys.

Behavioral Intention

Participants will be asked to indicate how likely it is that they will start an open conversation about COVID-19 vaccination with a vaccine-hesitant individual in the next 4 weeks on a 7-point scale ranging from "I will definitely not start a conversation" to "I will definitely start a conversation." Consistent with recommendations for assessing intentions, the measure uses a likelihood scale and defines a timeframe for the behavior [109,110]. The behavioral intention item will be asked in the pre- and poststudy surveys.

Implementation Intention

Following the behavioral intention item in the poststudy survey, participants will be asked to plan their intention. Implementation intentions refer to intentions to enact a preplanned behavior and can mentally simulate the process of implementing a goal, aiding goal striving [110-112]. Participants will be asked to indicate which vaccine-hesitant individual they plan to have an open conversation about COVID-19 vaccination with (eg, a family member, friend, coworker, or someone else or indicate that they have no plan to have an open conversation with a vaccine-hesitant individual), when they plan to have the conversation (eg, in the next ___ hours/days/months), and to specify what their starting sentence will be.

Open Conversation Skills

Participants will be provided with conversation snippets presented as messenger app messages and asked to rate each statement according to how good or bad they think the response is when having an open conversation on a 5-point scale ranging from "very bad" to "very good." Participants will rate 8 conversation snippets in the prestudy survey and a different set of 8 conversation snippets in the poststudy survey. Using parallel versions of pre- and postintervention tests in the evaluation of serious games reduces practice effects [106,113]. In each survey, there will be 1 conversation snippet for each of the 8 open conversation skills (Table 2). For each open conversation skill, one item will represent a bad response example and the other will represent a good response example. Good and bad response examples for a single open conversation skill will not appear in the same survey. The open conversation skill snippets were reviewed by experts in behavioral science interventions.

XSL•FO
RenderX

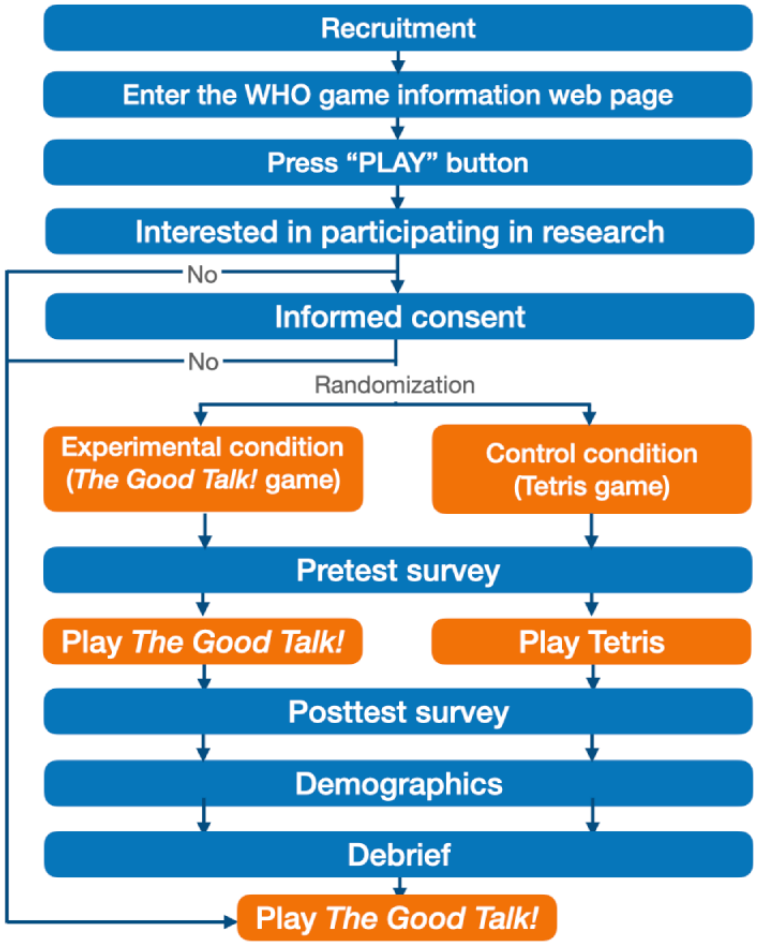
Table 2. Examples of good and bad open conversation skills included in the pre- and poststudy measure.

Objective and skill	Good response	Bad response
Build trust		
Find mutual value	• I am worried about the safety of the vaccine for my family. What if it made them sick?[a] • Response: I'm concerned about my family's health too and also feel responsible if something bad was to happen to them.	• Hey, so I'm unvaccinated but I'm still gonna go over to my friend's house who is really strict about people being vaccinated. • Response: Hmn, that's not something I would do. I would respect other's decisions.
Respect autonomy	• I can't believe the government is suggesting that everyone should get vaccinated. This is my health, my decision. • Response: The choice is yours and only you can make it. What would help you make your decision?	• These COVID regulations are ridiculous, next thing you know I'll have to wear a hazmat suit to go shopping.[a] • Response: You should respect other people's health and follow the regulations.
Don't lecture or persuade (don't be an expert)	• How can they even be sure the vaccine is safe if they made it so fast? It was rushed, who knows what steps they missed![a] • Response: I think it might have something to do with reducing all the red tape that helped speed things up but I'm not sure. Let's look into it together!	• I am concerned about the side-effects of the vaccine. I heard that they can get pretty bad. • Response: Have you looked at the data? I have, and the side-effects are minor. You should look into what can happen if you don't get the vaccine.
Offer support		
Ask for perspective	• My friend has a party but she says I need to be vaccinated to go, not sure how I feel about it? • Response: What makes you unsure?	• I don't believe getting a booster vaccine is really necessary.[a] • Response: It's interesting how you justify putting other people at risk.
Affirm feelings or perspective; acknowledge past efforts or successes	• I'm unsure about whether to take the vaccine, it seems dangerous.[a] • Response: It is good that you are critical and don't rush into things when you are unsure. Remember when you had to switch to that new medication and felt better when you looked into it more?	• Our neighbours were strict with the social distancing thing and one of them got it anyway. And they are both vaccinated! So I just don't see the point. • Response: That's not how to think about it. Just because they got it doesn't mean it's not worth you making any effort.
Open up		
Ask open questions	• For now, I don't want to get the vaccine. Just because everyone else has decided to get it, doesn't mean that I have to as well. • Response: If you were to consider getting the vaccine, what would change your mind?	• How would a mask even help against a virus?[a] • Response: Did you look at the evidence?
Be resilient if the other is right	• First we were told not to bother with masks, and then we were told to wear masks everywhere! These backflips don't help.[a] • Response: That's true, the changing recommendations about wearing masks did not help. It goes to show how uncertain things were at the beginning.	• I'm waiting, that's all. It takes time to make sure that the vaccine is safe for everyone. • Response: Yeah I've heard that point before but let's focus on why it is important that all healthy people should get vaccinated.
Don't be sad if it doesn't work out		
Accept negative outcomes (the conversation may not work out)	• It's clear that you and I are not on the same page about this. I have my reasons, you have yours. • Response: That's OK, thanks for helping me understand your reasons. It seems like it doesn't work out, so let's leave it there and maybe we can speak again next week?	• Look I just don't think we are ever going to agree on this.[a] • Response: You don't appreciate my views! But give me one more try and I bet I can change your mind on this one.

[a]Items included in the prestudy survey.

XSL•FO
RenderX

Demographic Questions



Participants will be asked to provide their age (in years) and indicate their gender, current level of English fluency, country of residence, and highest level of education obtained.

Procedure

Participants will first answer the questions regarding their support for COVID-19 vaccination and their past experience speaking with vaccine-hesitant individuals. Participants will then complete a pretest survey containing the 8 open communication skills items and the self-efficacy and behavioral intention items. The experimental group will then play *The Good Talk!* game, which will take approximately 10 minutes to complete. The control group will play *Tetris* for a similar amount of time.

Following the game, participants will respond to a posttest survey containing the open communication skills, self-efficacy, and behavioral intention questions. Participants will also complete the implementation intention questions and a short demographic survey. At completion of the study, participants will be thanked for their time and invited to share the study with their friends. Participants in the control group will be given the option to play *The Good Talk!*. Figure 3 presents the flowchart of the study design and procedure.

Figure 3. Flow diagram representing the study design and procedure. WHO: World Health Organization.

Ethics Approval

Ethics approval for the study has been submitted and is awaiting approval from the WHO Ethics Review Committee (application ID: CERC.0177).

Results

Recruitment and data collection are estimated to commence in early 2023. The efficacy of the study will be analyzed using an analysis of covariance with posttest open conversation skills as the dependent variable, controlling for pretest scores. Partially completed surveys will be included in statistical analysis whenever possible. As a sensitivity check, analyses will be repeated by excluding participants who complete the study less than 2 SDs below the median completion time as a data quality check.

The primary outcome is open conversation skills. The secondary outcomes are self-efficacy and behavioral intention items. Exploratory analyses will examine the effect of the game on implementation intentions as well as potential covariates or subgroup differences based on sociodemographic information or previous experiences with COVID-19 vaccination conversations.

XSL•FO
RenderX

Discussion

Expected Outcomes

We hypothesize that *The Good Talk!* game will lead to a greater increase in open conversation skills, self-efficacy, and intentions to initiate conversations about vaccination between vaccine advocates and their vaccine-hesitant close ties relative to the control game. We hope that the game will help people to talk to one another so that supportive relationships can be maintained, and over time, opportunities to share with consideration of divergent views may help combat some of the negative social costs of the pandemic. Furthermore, we hope that this study will highlight how serious games can be a promising forum for delivering evidence-based health behavior interventions to the public.

Strengths and Limitations

The Good Talk! game represents an evidence-based behavioral science application based on the theoretical framework of boosting that aims to boost people's skills and competences rather than target a specific cause of vaccine hesitancy. As such, this approach has the potential to build transferrable skills that can be applied across a variety of situations. Delivering the intervention via a worldwide, publicly available serious game means that it has the potential to reach a broad and diverse audience while using an ecologically valid medium that mimics real-world web-based communications.

Nevertheless, there are potential limitations to the insights that can be drawn from this study. First, as participants will access the study via a public link that is associated with the promotion of the game, it is not possible to blind participants completely from their assigned experimental condition. Although participants will be blinded to their assigned conditions at the initial pretest survey stage, it is not possible to avoid dropouts or potential self-selection to their assigned condition. To limit this effect, all participants will be told that both games are very important for the research and that everyone will get the opportunity to play *The Good Talk!* game. We will also collect data on the number of dropouts and partially complete and completed surveys per condition to evaluate their impact on study completion. Second, the game may attract a diverse set of participants from various backgrounds worldwide, including different levels of English proficiency, experience with COVID-19 vaccination, and social and political contexts. However, as the intention for the game intervention is to reach a broad and diverse audience and be applicable to individuals from a wide range of cultural, economic, and educational backgrounds, the evaluation will also contribute data on the effectiveness of the intervention in a real-world context.

Future Directions

We envisage that the positive results of the study can lead to concrete practical applications, for instance, as a valuable resource for health care professionals whose patients request advice on how to have vaccination conversations with those close to them. Furthermore, health care systems can refer to *The Good Talk!* game to boost the competencies of their patients to have open conversations about other difficult topics with their close contacts. More broadly, we hope that this study can motivate health care policies to consider serious games such as ours as an additional and efficacious method for promoting behavior change in public health communications.

Conclusions

The Good Talk! intervention represents an application of boosting theory to the field of behavior change for public health purposes. By describing the methods through which the intervention was designed, we hope to enable others to replicate and innovate our findings. We hope our approach will encourage more health ministers to engage in their mission to reach their citizens directly with digital health solutions and to consider such interventions as an important tool in infodemic management.

Acknowledgments

The authors acknowledge Tiltstudio, who was the vendor and recipient of funding to develop the game, and Lisa Menning for the helpful suggestions and comments on earlier versions of the manuscript. WHO does not endorse the brand or products of any technology platform mentioned in this paper, and any mentions are simply for clarification purposes. JAE, BY, SP, SB, DM, TN, and TDP are staff of the World Health Organization, and these authors alone are responsible for the views expressed in this publication, and they do not represent the views of their organizations.

Conflicts of Interest

None declared.

Abstract

Background: Postoperative patients who were previously engaged in the live musical intervention Meaningful Music in Healthcare reported significantly reduced perception of pain than patients without the intervention. This encouraging finding indicates a potential for postsurgical musical interventions to have a place in standard care as therapeutic pain relief. However, live music is logistically complex in hospital settings, and previous studies have reported the more cost-effective recorded music to serve as a similar pain-reducing function in postsurgical patients. Moreover, little is known about the potential underlying physiological mechanisms that may be responsible for the reduced pain perceived by patients after the live music intervention.

Objective: The primary objective is to see whether a live music intervention can significantly lower perceived postoperative pain compared to a recorded music intervention and do-nothing control. The secondary objective is to explore the neuroinflammatory underpinnings of postoperative pain and the potential role of a music intervention in mitigating neuroinflammation.

Methods: This intervention study will compare subjective postsurgical pain ratings among 3 groups: live music intervention, recorded music intervention, and standard care control. The design will take the form of an on-off nonrandomized controlled trial. Adult patients undergoing elective surgery will be invited to participate. The intervention is a daily music session of up to 30 minutes for a maximum of 5 days. The live music intervention group is visited by professional musicians once a day for 15 minutes and will be asked to interact. The recorded music active control intervention group receives 15 minutes of preselected music over headphones. The do-nothing group receives typical postsurgical care that does not include music.

Results: At study completion, we will have an empirical indication of whether live music or recorded music has a significant impact on postoperative perceived pain. We hypothesize that the live music intervention will have more impact than recorded music but that both will reduce the perceived pain more than care-as-usual. We will moreover have the preliminary evidence of the physiological underpinnings responsible for reducing the perceived pain during a music intervention, from which hypotheses for future research may be derived.

Conclusions: Live music can provide relief from pain experienced by patients recovering from surgery; however, it is not known to what degree live music improves the patients' pain experience than the logistically simpler alternative of recorded music. Upon completion, this study will be able to statistically compare live versus recorded music. This study will moreover be able to provide insight into the neurophysiological mechanisms involved in reduced pain perception as a result of postoperative music listening.

Introduction

In recent research, postoperative patients exposed to a live musical intervention reported significantly reduced perception of pain than patients without the intervention [1]. This encouraging finding indicates a potential for postsurgical musical interventions to have a place in standard care as therapeutic pain relief. However, live music is logistically complex in hospital settings, and previous studies have reported the more cost-effective *recorded* music to serve as a similar pain-reducing function in postsurgical patients [2,3]. Therefore, this study primarily aims to compare the effectiveness of postoperative live versus recorded music interventions in reducing patients' perception of postsurgical pain. In order to potentially expand this finding from subjective to objective metrics, secondary outcomes will explore whether subjective pain perception is statistically related to more objective metrics such as pain medication dosage or respiration rate [4].

Although previous findings showed a convincing influence of music intervention on postsurgical pain perception [1-3,5-7], the physiological mechanisms that could make this possible are not yet understood [8]. It has been reported that music modulates psychoneuroimmunology [9,10] such as lowering stress-induced cortisol [11] and enhancing neurogenesis [12]. While chronic or long-term postsurgical pain has established links to neuroinflammation [13,14], the possibility exists that immediate postsurgical pain—before it reaches a chronic state—may have links to neuroinflammation as well [15]. Thus, one possibility is that music is mitigating postsurgical neuroinflammation, which could in turn be affecting the immediate postsurgical pain.

Therefore, further secondary outcomes will explore behavioral indicators (postoperative cognitive decline or POCD and delirium) and biological markers (interleukin-6 [IL6], C-reactive protein [CRP], neutrophil gelatinase–associated lipocalin [NGAL], and translocator protein [TPSO]) with established neuroinflammatory underpinnings [16-20] to see whether the primary pain outcome has a statistical relationship to these neuroinflammatory-related metrics. The exploratory electroencephalogram (EEG) analyses will also be conducted to see whether either entropy [21], alpha power [22], or delta/alpha power ratio [23,24] can provide neuroinflammatory markers, which could correlate with postoperative pain outcomes. Finally, we will explore whether these neuroinflammatory markers seem to be mitigated by either the live music or active control intervention to explain the reduced pain reported by postsurgical patients in music intervention studies [2,20].

The primary objective is to see whether a live music intervention reduces pain perception compared to both recorded music active control and standard care control groups. The secondary objective is to explore the role of music in mitigating the neuroinflammatory response to surgery, for future hypothesis-directed research.

Methods

Study Design

The study will take place at the University Medical Center Groningen (UMCG), which has already hosted the Meaningful Music in Healthcare (MiMiC) live intervention [25]. The intervention study follows an on-off nonrandomized controlled trial (NCT) design [26]. The NCT is necessary for this particular intervention in practice because the live music intervention cannot easily be randomized to skip patients in the same ward without them hearing the music or seeing the musicians as they play for other patients and nurses.

In this NCT design, treatments and data collection will be conducted in 15 blocks over the course of 4 years. According to the 29-day treatment block, the three 5-day treatments (live music intervention, recorded music active control intervention, and standard care control) will be offered with a 7-day washout between treatments. The washout will minimize the number of participants whose hospital stay overlaps with another treatment. Based on the previous research (UMCG research register 201600541), we expect approximately 8 full data sets per 5-day treatment block.

Note that while the intended outcome of the music intervention is therapeutic (eg, experiencing reduced pain), the music intervention is conducted by conservatory-trained music practitioners but not by music therapists. Music therapists are licensed therapists who have a degree in music therapy including clinical training. The music practitioners in this study are primarily professional musicians who have taken 1 music-conservatory course and several internships to train them for clinical settings but they are not therapists.

Design procedures are chronologically displayed in Figure 1. Preoperative questionnaires will be collected to assess cognitive function (6-item cognitive assessment [6CIT]) [27,28] and musical background (excerpt from the Dutch Musical Background Questionnaire [DMBQ]) [29,30]. Postoperative data collection procedures per day of treatment include pain visual analog scale (VAS) ratings, heart rate (HR), and blood pressure measuring 4 times a day (before, directly after, 3-hour, and 6-hour postintervention). EEG electrodes will be applied once in the morning and 4 EEG recordings will be collected with VAS ratings, HR, and blood pressure (before, during, 3-hour, and 6-hour postintervention). A blood sample will be collected once daily and integrated with standard care as far as possible (eg, if blood is drawn as part of standard care, the sample will be collected from the same needle). A schedule of assessments may be found in Table 1. Daily dosage of pain medication as well as any incidence of delirium (delirium

XSL•FO
RenderX

observation screening scale [DOSS]) [31] or POCD will be collected.

Figure 1. Chronological walk-through of the design procedures. After entering the ward, subsequent steps repeat per each day of treatment. Blood sample, blood pressure, and heart rate are part of standard care measurements and will be incorporated with standard care whenever possible. 6CIT: 6-item cognitive assessment; DMBQ: Dutch Musical Background Questionnaire; fEEGrid: face electrode grid for electroencephalogram recordings; MiMiC: Meaningful Music in Healthcare; VAS: visual analog scale.

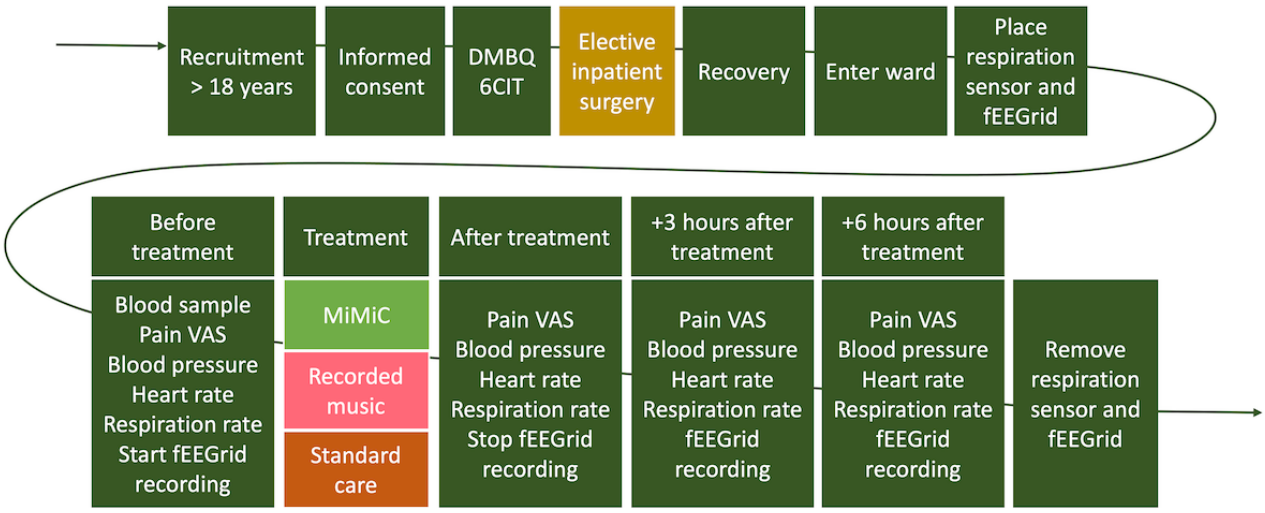

Table 1. Schedule of procedures.

Time	Procedures	Duration (minutes)
Preoperative	• Six-item cognitive assessment • Dutch Musical Background Questionnaire excerpt	7.5 and 4.5 (total 12)
Postoperative		
9 AM	• fEEGrid[a] preparation and placement • Respiration biosensor placement • Blood vial[b]	10
10:30 AM	• VAS[c] rating, HR[d], respiration rate, blood pressure, and start EEG[e] recording	5
10:40-11 AM	• MiMiC[f] or recorded music or no intervention • VAS rating, HR, respiration rate, blood pressure, and stop EEG recording	20
2 PM	• VAS rating, HR, respiration rate, blood pressure, and EEG recording	15
5 PM	• VAS rating, HR, respiration rate, blood pressure, and EEG recording	15
5:15 PM	• Remove fEEGrid and respiration biosensor	5
Total	• N/A[g]	70

[a]fEEGrid: face electrode grid for EEG recordings.

[b]The blood vial collection will be integrated into standard care as much as possible, thus, the time may not be 9 AM if other blood collection is at a different time.

[c]VAS: visual analog scale.

[d]HR: heart rate.

[e]EEG: electroencephalogram.

[f]MiMiC: Meaningful Music in Healthcare.

[g]N/A: not applicable.

Population (Base)

The study will include patients who have undergone elective surgery in the UMCG and are hospitalized for at least 1 day following surgery. All patients must be 18 years or older and able to make their own decisions. Patients must further be able to hear music with normal or corrected normal hearing (ie, a hearing aid).

XSL•FO
RenderX

Inclusion Criteria

In order to be eligible to participate in this study, a subject must meet all of the following criteria: (1) 18 years or older, (2) postsurgery hospitalization (all surgery types), (3) elective surgery, (4) able to hear music, (5) able to give informed consent, and (6) able to communicate.

Recruitment

Patients will be informed as soon as the date of hospital admission is set in the weeks that the study is planned. The patient will receive an information letter and informed consent from the provider or it will be sent to them by email. A member of the research team will contact the patients after a minimum of 24 hours for participation and answer possible questions. Patients will have up to the time of their surgery to decide, allowing for time to fill out the preoperative questionnaires. Consent can be withdrawn at any time at which point all data collection and treatment will stop.

Ethics Approval

This protocol has been approved by the Central Medical Ethics Committee of the UMCG (METc2021.359) and is registered with the Netherlands central commission of human research (CCMO-register number NL76900.042.21). The informed consent letter is written in plain, nonacademic Dutch with no medical jargon. Only pseudoanonymized (deidentified) data will be published. Patients participating in the study will receive a small token gift (such as a hand lotion or lip balm).

Study Parameters and End Points

Main Study Parameter and End Point

Subjective pain ratings are determined with a VAS rating (0-10) [1].

Secondary Study Parameters and End Points

The secondary study parameters (Table 2) and end points are as follows: (1) objective pain metric (volume of administered pain medication); (2) respiratory rate and tidal volume; (3) HR; (4) blood pressure; (5) neuroinflammation blood markers (IL6, NGAL, CRP, and serum TPSO); (6) behavioral indicators of neuroinflammation (delirium [31] and POCD incidence); and (7) EEG markers of neuroinflammation (alpha power, delta/alpha power ratio, and entropy).

Table 2. Secondary study parameters.

Outcome	Metric	Statistics
Objective pain measure	Pain medication dosage (ccs)	Chi-square test
Neuroinflammation, blood markers	IL6[a], NGAL[b], CRP[c], and serum TPSO[d]	*F* test (RM[e] ANOVA, pre-post)
Neuroinflammation, behavioral indication	Incidence delirium and incidence POCD[f]	*F* test (one-way ANOVA)
Neuroinflammation, EEG[g] indication	Alpha power, alpha/delta power, and entropy	*F* test (RM ANOVA same as primary)
Neuroinflammation, physiological	HR[h], respiration rate, and blood pressure	*F* test (RM ANOVA same as primary)

[a]IL6: interleukin-6.

[b]NGAL: neutrophil gelatinase–associated lipocalin.

[c]CRP: C-reactive protein.

[d]TPSO: translocator protein.

[e]RM: repeated measures.

[f]POCD: postoperative cognitive decline.

[g]EEG: electroencephalogram.

[h]HR: heart rate.

Other Study Parameters

Other study parameters used in this study are as follows: (1) comorbidities (Charlson comorbidity index) [32]; (2) complications (Clavien Dindo [33] and nurse-sensitive outcomes [34]); (3) postoperative days (T0=surgery); (4) surgery characteristics (invasiveness, etc) [20]; (5) musical background (excerpt from DMBQ) [30]; (6) age; and (7) presurgery cognitive testing [22] (eg, 6-item cognitive impairment score) [28].

Treatment Allocation

This study will take the form of an on-off NCT [26]. An on-off NCT takes into account real-world setting limitations of certain intervention types and allocates participant inclusion by alternation. The main reason for this is that MiMiC is a well-researched intervention, whose practical implementation is not suited for randomly selected participants to not participate. On the one hand, musicians will visit the nurses' station and play music in various rooms around the ward; thus, it is not possible to prevent participants who may be allocated non-MiMiC treatment from hearing the live music. On the other hand, a central tenet of the MiMiC intervention is inclusion and participation, thus "rejecting" patients who would want to participate in music they hear on the ward, on the basis of trial group allocation, goes against the spirit of the intervention.

In contrast, the NCT relies on the randomness of who is scheduled for surgery during a given intervention week but does not exclude any patient from the activity being conducted (listening to live or recorded music). Therefore, the treatment schedule (live music intervention, recorded music active control, and standard care control) will be predetermined months in advance, and the patients included will be offered whichever

XSL•FO
RenderX

treatment is occurring during their hospital stay. The patients will, however, be asked for their consent before they are informed which treatment will be offered during their surgery recovery. This will attempt to prevent patients who are initially biased for inclusion based on their affinity to music or not.

Study Procedures

After patients are recruited to the study, they will be allotted to the treatment occurring during the scheduled postoperative hospital stay. Noninvasive procedures include preoperative cognitive testing (6CIT), postoperative VAS pain ratings, HR, blood pressure, respiration rate, and EEG recording. Invasive procedures include obtaining blood samples, after which the serum will be analyzed in a laboratory for neuroinflammatory markers IL6, NGAL, CRP, and serum TPSO. An example schedule of procedures can be found in Table 1.

Primary End Point

The main end point, VAS pain ratings, requires patients to subjectively rate their pain on a plastic VAS where they move a tick mark to the desired location on a 0-10 scale [1].

Secondary End Points

The secondary end points, HR and blood pressure, will be collected from standard equipment on the ward at the time of obtaining VAS pain ratings.

Pulmonary Ventilation

Respiration rate and tidal volume have been linked to subjective pain experience in the literature [4]. Therefore, in order to see whether our pain findings extend from subjective to objective physiological measures, we will explore the association between these 2 objective metrics and subjective pain VAS ratings. A wearable biosensor that measures pulmonary ventilation metrics [35] will be placed on the chest of patients with an adhesive sticker and removed at the end of the day.

Blood Marker Analysis

One 10-ml vial of blood will be collected per day resulting in a maximum of 5 vials of blood over 5 days. The first sample must be taken before the first assigned intervention. Blood samples will be collected together with standard care insofar as possible. Serum extracted from blood samples will be processed by the Haemoscan lab and evaluated for the presence of 4 markers associated with neuroinflammation (IL6, NGAL, CRP, and serum TPSO; see “Introduction” section).

EEG Recordings

As opposed to typical electrode setup with, for example, a cap, the face electrode grids for EEG recording require minimal preparation of skin and are quickly applied. Each morning, the patient’s face will be cleaned and prepared with exfoliating gel, and electrodes will be applied with adhesive tape. The face electrode grid for EEG recordings will remain on the patient from morning until evening, spanning the first and last pain VAS ratings. Actual recordings will occur 4 times a day, in 15-minute increments, coinciding roughly with the times that pain VAS ratings are collected (before intervention, during intervention, 3-hour, and 6-hour postintervention). During the 15-minute EEG recording windows, the patients will be instructed to remain seated or lying doing a consistent activity of their choice, or otherwise as instructed during the assigned treatment.

Neuroinflammatory-Related Complications

After 30 days postsurgery, patient medical dossiers will be consulted, and any incidence of delirium and POCD will be recorded.

Other Parameters

A short, 6-item questionnaire [27,28] will be added to the standard preoperative intake in order to assess preoperative cognitive status, as well as a short questionnaire about the musical background (excerpt from the DMBQ) [29,30]. Both the cognitive status and the musical background will help to interpret the results. The preoperative cognitive status will serve as a baseline for postoperative cognitive status as well as alpha power in EEG recordings. The musical background will be assessed as a possible explanation for the success of the live or recorded music interventions. Other complications (classified according to Clavien-Dindo [33], nursing-sensitive outcomes such as dehydration and falling [34]) will be explored for changes in the music groups compared to care-as-usual to derive hypotheses for future studies.

Statistical Analysis

The primary outcomes of this study are VAS subject pain ratings. The *F* test is described immediately below. Statistics will be conducted with SPSS (IBM Corp) or equivalent software [36].

Primary Study Parameters

Pain ratings will be collected 4 times a day with a VAS. VAS mean and SD will be reported, and box plots, histograms as well as *P* values for Kolmogorov-Smirnov tests will be evaluated for normality of distribution. A univariate, one-way repeated measures (RM) ANOVA will be conducted with factors group (live music intervention, recorded music active control, and standard care control) by time points (1, 2, 3, 4). The α significance threshold will be .05. The result of interest is the significance of the training×time point interaction, that is, whether the course of the data across time points was altered by the training type. Data are planned with 4 time points; in case of up to 2 missing time points, data will be interpolated [37]. Cases with more than 2 missing time points will be excluded from the analysis. Alternatively, if the residuals of the ANOVA are not normally distributed, a similar Kruskal-Wallis one-way ANOVA will be conducted.

Secondary Study Parameters

For metrics that are collected on the same schedule as the VAS (EEG alpha power, delta/alpha power ratio, entropy metrics, HR, respiration rate, and blood pressure), the values per participant will be entered into the same *F* test described for the VAS ratings (as well as correlated with other baseline parameters as described in the “Other Parameters” section). For blood marker metrics that have 2 data collection points, a similar RM ANOVA will be conducted, but with 2 as opposed to 4 measures, and a significant interaction between treatment and time point would indicate whether treatment significantly

XSL•FO
RenderX

impacted the amount of the neuroinflammatory blood marker. Categorical incidence metrics (delirium and POCD) will be evaluated with a one-way ANOVA to determine whether treatment impacted these neuroinflammatory-related complications. Delirium and signs of delirium will be perceived using the DOSS. The DOSS is a screening instrument for delirium, consisting of 13 items, and will be filled by a registered nurse during hospital admission until discharge. Nurses have frequent contact with the patients and are in a good position to observe behavior changes 24 hours a day when patients are admitted. The DOSS is already part of a routine in the surgical wards and all registered nurses are already trained. Likewise, scalar pain medication dosage will be averaged over 24-hour periods per patient and entered into a chi-square test to determine whether the dosage was significantly different across the 3 treatment groups. As this is exploratory and serves to inform future hypothesis-directed testing, we will not correct for multiple comparisons.

Other Study Parameters

Posthoc analyses will be conducted to inform recommendations for participant grouping in future studies. Continuous baseline parameters (eg, age; see "Other Parameters" section for a full list) will be treated as covariates in an ANOVA in order to see whether the addition of these elements improves the model for each outcome. Similarly, categorical baseline parameters (eg, type of surgery) will be coded and entered as an additional factor (two-way RM ANOVA: treatment×baseline×time point) to see whether the additional factor can explain more variance than in the primary analysis model.

Power

The sample size was calculated using G*Power 3.1 [38], an industry-standard software. Below, we explain the parameters for an RM between-subjects univariate ANOVA as well as the final sample size. The calculation was based on the desired ability to detect a within-between interaction (intervention group×time point), with recommended internal settings from [39], which would effectively indicate whether the live music intervention altered the slope of outcome measurements compared to the recorded music or do-nothing control groups.

The effect size (partial η^2=0.051, converted to f=0.2318206) was determined from a retrospective RM ANOVA with published data [1].

- Alpha: As we have a single quantitative outcome measure, alpha may remain at the conventional .05 significance threshold.
- Power: Following recent recommendations to set power above the typical 0.8 to 0.9 and higher [40], the threshold was set at 0.9.
- Number of groups or measurements: The design calls for 3 groups, with 4 RM (see "Study Design" section; before treatment, after treatment, 3-hour, and 6-hour follow-up) for each participant.
- Nonsphericity correction: As mentioned earlier, retrospective analyses were conducted with the data published in [1]. The ANOVA conducted with that data passed the assumption of sphericity (*P*=.07); therefore, no correction (1) was entered in the G*Power calculation.
- Sample size: The sample size (n=327, Table 3) outputted from G*Power represents the total number of participants in a 3-group design required to achieve 0.9 power with an effect size of ~0.232-109 per group. Padding for a 10% dropout rate raises the per group n to 120, for a total N of 360.

Table 3. G*Power sample size calculation.

Parameters	Value
Input parameters	
Effect size *f*(*V*)	0.2318206
α err prob	.05
Power (1−β err prob)	0.9
Number of groups	3
Number of measurements	4
Nonsphericity correction ε	1
Output parameters	
Noncentrality parameter λ	17.5732385
Critical *F*	2.1078920
Numerator df	6.0000000
Denominator df	972
Total sample size	327 (109 per group)
Actual power	0.9007901

Results

The medical ethics committee of the UMCG approved the study in April 2022. This study began recruiting its participants in June 2022 and upon submission had recruited and collected data from 5 participants. Preliminary data analysis will commence once enough data have been collected to reach 0.8 power. Data collection is expected to be finished in 2026. The study results will be available within 1 year of completed data collection and shared in local, national, and international meetings within the medical, scientific, hospital administrative, and medical professional communities as well as the general public.

Discussion

Principal Findings

Previous studies have shown that postoperative pain management can be supplemented with music intervention. Yet, little is known about the benefits of live versus recorded music, or what physiological mechanisms may be mitigating pain perception as a response to listening to music. This NCT will compare the MiMiC live music intervention with listening to recorded music and care-as-usual. The primary objective is to see whether pain VAS ratings differ across the 3 conditions, and the secondary objective is to see whether postoperative neuroinflammation is reduced as a response to listening to music.

The strength of this study is the inclusion of preoperative assessments to establish some baseline characteristics of patients. First, the preoperative musical background questionnaire (selected items from [30]) assesses the estimated weekly hours of music listening as well as listening preferences for musical genre and whether or how the participant is musically trained. This provides us the opportunity to analyze how the extent of musical exposure may affect the primary outcome (pain VAS) of the intervention; depending on the strength of these findings, we may be able to even help inform future music interventions according to preoperative musical habits. Second, the preoperative cognitive assessment (6CIT) [28] serves as an important baseline for several secondary outcomes that may help to account for variability among the 3 intervention arms that otherwise might be attributed to the treatment. Specifically, the 6CIT will inform the interpretation of the postoperative cognitive status, and it may predict alpha power in EEG recording [22] that in turn may be linked to delirium [23,24]. If this proves to be the case, the preoperative cognitive status might be investigated in the future as a method to inform more at-risk patients who could especially benefit from supplementary nonpharmacological interventions [41] such as live or recorded music [42].

Limitations

While postoperative pain is common to most patients undergoing surgical intervention in hospital, other characteristics surrounding the surgery (eg, type of surgery, duration of surgery, and underlying medical need for surgery) are widely varied across patients. Thus, a limitation of the study is that we will have a heterogeneous patient group. Considering that reduced pain VAS among patients experiencing MiMiC live music intervention compared to care-as-usual was previously a robust finding in a heterogeneous patient group [1], we do not consider our primary outcome to be affected by this heterogeneity. However, secondary outcomes related to finding neurophysiological markers of inflammation, and whether they are influenced by a music intervention, might be greatly affected by this heterogeneity. Moreover, the short duration of the intervention may further limit proper interpretation of inflammatory biomarkers, since previous studies have found neuroinflammatory biomarkers readings to be informative to overall interpretation 5 to 14 days after a medical event [43,44]. We may therefore form posthoc groups with similar surgery types when evaluating secondary outcomes, which could inform future hypotheses for further, longer term clinical research on music interventions and postsurgical neuroinflammation.

Conclusions

Upon completing this study, we will contribute a systematic comparison of the effects of live versus recorded music on postoperative pain. This study can ultimately inform policy makers as to the benefits to patient pain outcomes when incorporating live versus recorded music in postoperative recovery settings.

Data Availability

When results from this trial are available, data sets will be deposited in a publicly available repository.

Conflicts of Interest

None declared.

Abstract

Background: Violence against paramedics has been described as a serious public health problem with the potential for significant physical and psychological harm, but the organizational culture within the profession encourages paramedics to consider violence as just "part of the job." Therefore, most incidents of violence are never formally documented. This limits the ability of researchers and policy makers to develop strategies that mitigate the risk and enhance paramedic safety.

Objective: Following the development and implementation of a novel, point-of-event violence reporting process in February 2021, our objectives are to (1) estimate the prevalence of violence and generate a descriptive profile for incidents of reported violence; (2) identify potentially high-risk service calls based on characteristics of calls that are generally known to the responding paramedics at the point of dispatch; and (3) explore underpinning themes, including intolerance based on gender, race, and sexual orientation, that contribute to incidents of violence.

Methods: Our work is situated in a single paramedic service in Ontario, Canada. Using a convergent parallel mixed methods approach, we will retrospectively review 2 years of quantitative and qualitative data gathered from the External Violence Incident Report (EVIR) system from February 1 2021 through February 28, 2023. The EVIR is a point-of-event reporting mechanism embedded in the electronic patient care record (ePCR) developed through an extensive stakeholder engagement process. When completing an ePCR, paramedics are prompted to file an EVIR if they experienced violence on the call. Our methods include using descriptive statistics to estimate the prevalence of violence and describe the characteristics of reported incidents (Objective 1), logistic regression modeling to identify high-risk service calls (Objective 2), and qualitative content analysis of incident report narratives to identify underpinning themes that contribute to violence (Objective 3).

Results: As of January 1, 2023, 377 paramedics—approximately 1 in 5 active-duty paramedics in the service—have filed a total of 975 violence reports. Early analysis suggests 40% of reports involved a physical assault on the reporting paramedic. Our team is continuing to collect data with more fulsome analyses beginning in March 2023. Our findings will provide much-needed epidemiological data on the prevalence of violence against paramedics in a single paramedic service, its contributing themes, and potential risk factors.

Conclusions: Our findings will contribute to a growing body of literature demonstrating that violence against paramedics is a complex problem that requires a nuanced understanding of its scope, risk factors, and contributing circumstances. Collectively, our research will inform larger, multisite prospective studies already in the planning stage and inform organizational strategies to mitigate the risk of harm from violence.

Introduction

Background

At the start of the COVID-19 pandemic, paramedics had some of the highest rates of posttraumatic stress injury (PTSI) among public safety personnel (PSP) in Canada. A recent cross-sectional survey of PSP in Canada found that 1 in 4 participating paramedics met the screening criteria for posttraumatic stress disorder (PTSD), 1 in 3 for major depressive disorder, and 1 in 3 for an anxiety disorder [1], with nearly half of the paramedics meeting the screening criteria for a current mental disorder [2]. Related research has also demonstrated high rates of exposure to trauma [3-5], disturbed sleep [6], adverse childhood experiences [7], chronic pain [2,8], and alarming rates of suicidality [9]—a situation that has since been described in research and policy as a "crisis in Canada" [10,11].

One dimension of the crisis that has received comparatively little attention is the exposure of paramedics to acts of intentional workplace violence. Although we know from previous research that situations involving threats to physical safety among PSP are associated with an increased risk of PTSI [3,5,12,13], the specific contribution of violence remains understudied. Part of the problem is that—in the absence of significant physical injuries—incidents of violence often go unreported. For example, in a 2014 survey of paramedics, over 75% disclosed having been subjected to workplace violence in the past calendar year. Despite these acts of violence negatively impacting their job satisfaction and home life, less than 20% of survey participants took any action to report the incidents to supervisors or the police [14]. This parallels a growing body of research internationally that indicates that violence against paramedics is a "serious public health problem" [15] that remains "vastly underreported" [16].

The organizational culture within the paramedic profession appears to contribute significantly to underreporting. In a qualitative study of paramedics in Ontario, Canada, we identified a complex interplay of organizational culture features in sustaining cultural norms that lead paramedics to downplay the significance of incidents and effectively position the ability for paramedics to "brush off" violent encounters as an expected professional competency [17]. Underreporting hinders the ability of researchers and policy makers alike to develop solutions to mitigate risk and enhance paramedic safety, as the scope of the problem, its contributing risk factors, and the potential harms remain poorly understood. Given the high rates of mental disorders among paramedics [1] and a growing hostility toward health care providers during the COVID-19 pandemic [18], the need for action has never been more apparent. Critical to intervening, however, is the need for robust epidemiological data to understand the problem more fully.

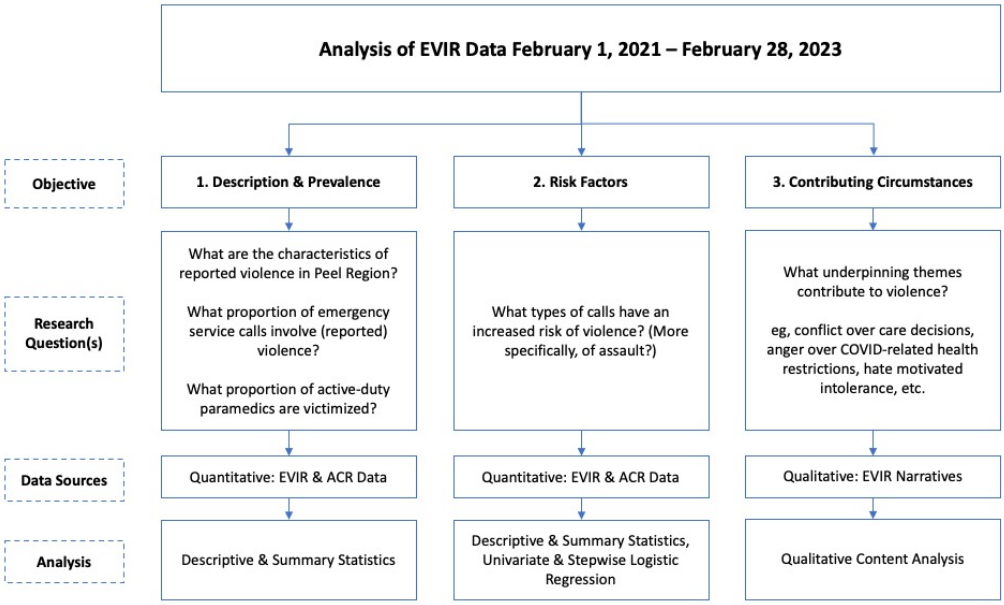
The EVIR Process

The External Violence Incident Report (EVIR) (Multimedia Appendix 1) is a novel, point-of-event reporting process embedded in the electronic patient care record (ePCR) in Peel Regional Paramedic Services (PRPS) in Ontario, Canada. Developed in 2020 through an extensive gap analysis, stakeholder consultation, and pilot testing process [19], the EVIR was launched in February 2021. When completing an ePCR after a 911 service call, paramedics in Peel Region are prompted to complete an EVIR if they experienced any form of verbal abuse, intimidating behavior, sexual harassment, or physical or sexual assault during the call. Using a series of drop-down menus and free-text narrative boxes, the EVIR gathers information about the type of violence, its source, and contributing circumstances in addition to administrative data (eg, time of day, call type, patient acuity, etc) that automatically populate from the corresponding ePCR. The goal of developing the EVIR was to produce a reporting process that minimized the administrative burden on the reporting paramedics by leveraging technological efficiencies (eg, by auto populating relevant fields) and minimize the amount of manual free-text entries or nonrelevant fields. The result is an accessible, user-friendly, and culturally accepted means of reporting violent incidents in real time.

Aim and Research Objectives

Following a year since the implementation of the EVIR, we aim to explore the prevalence of, risk factors for, and circumstances that contribute to incidents of reported violence against paramedics in Peel Region, Ontario, Canada. Using a convergent parallel mixed methods approach [20], our objectives are to (1) describe the prevalence and characteristics of violence against paramedics in the Peel Region; (2) explore features of 911 service calls associated with an increased risk of violence; and (3) qualitatively explore underpinning circumstances that contribute to incidents of violence, including harassment based on gender, race and related grounds, and sexual orientation.

Methods



Overview

This program of research is situated within a realist ontology [21] and uses a convergent parallel mixed methods approach [20] to broadly explore the prevalence, risk factors, and circumstances that contribute to incidents of violence against paramedics. We provide an overview of our methods blueprinted for each research objective in Figure 1. In brief, our approach includes calculating descriptive and summary statistics to characterize the prevalence and features of reported violence (Objectives 1 and 3) and logistic regression modeling to explore risk factors (Objective 2). To address Objective 3, we will use qualitative content analysis [22] within an interpretivist epistemology [23] to identify and define themes that contribute to incidents of reported violence. Data for the research will be

XSL•FO
RenderX

abstracted from completed EVIRs and other administrative data routinely gathered from ePCRs.

Figure 1. Overview of project objectives, research questions, data sources, and analysis plans. ACR: Ambulance Call Report; EVIR: External Violence Incident Report.

Ethical Considerations

Research ethics review for this program was submitted to the University of Toronto Research Ethics Board (REB protocol number 44162). All data used in the research will be scrubbed of direct identifiers (eg, patient or paramedic names, addresses of call locations, and call identification numbers). Anonymized alphanumeric participant identification codes will be substituted for paramedic names and the original linkages destroyed after deidentification. We will work to ensure that any potential combinations of indirect identifiers (particularly narrative descriptions of incidents) are presented in such a way as to reduce the risk of reidentification to the greatest degree reasonably possible.

There are 4 participant groups to whom consent requirements apply (Table 1). The EVIR has an embedded passive consent process wherein reporting paramedics (Group C) who do not want the information contained in the report used for research purposes can opt out by checking a box. During training on the EVIR, paramedics in the service were made aware that although the EVIR is not specifically intended as a research intervention per se, data from the EVIR may be subsequently used for research purposes in much the same way that health records are used retrospectively in medical research. Because of the sensitive nature of the data, we informed paramedics of the ability to indicate a preference (via the opt-out mechanism) for the future use of a specific report. This affords the paramedics the ability—at the time of reporting—to dissent to the future use of the report for subsequent research purposes.

Table 1. Participant groups included in the analysis.

Group	Violent incident	No violent incident
Patient	A	B
Paramedic	C	D

The Tri-Council Policy on the Ethical Conduct for Research Involving Human Participants [24] sets out specific criteria under which alterations to the consent process can be contemplated: (1) where the research involves no more than minimal risk to the participants, (2) the alteration to the consent requirements is unlikely to adversely affect the welfare of the participants, (3) it is impossible or impractical to conduct the research if prior consent of the participants is required, and (4) the precise nature and extent of the alteration to consent is defined. We will seek to waive the requirement for informed participant consent from patients (Groups A and B) on the grounds of minimal risk, necessity, and impracticality. Particularly for Group A, seeking prior consent from alleged perpetrators of violence would pose legitimate safety risks to the investigators. The information gathered from Group B is minimal and contains no direct or indirect risk of identification. Finally, no data are being collected directly from Group D, and we do not anticipate any risk of direct or indirect identification or harm to nonreporting paramedics.

Setting and Context

This research is situated in the Regional Municipality of Peel in Ontario, Canada. The PRPS is the publicly funded, sole provider of land ambulance paramedic services to this region, employing approximately 700 primary and advanced care paramedics (PCP/ACPs) [25]. Peel Region is divided geographically into 4 quadrants with 1 central paramedic headquarters facility per quadrant (called “divisions”).

XSL•FO
RenderX

Paramedics report for work at 1 of the 4 divisions and are then deployed to several smaller community stations strategically located in a "hub and spoke" model. Crew configurations include PCP-PCP, ACP-PCP, and solo responder (of either classification) models on emergency response units. PRPS responds to over 130,000 emergency calls per year, making it the second-largest paramedic service organization in the province in terms of staffing and caseload. Documentation standards mandate the completion of an Ambulance Call Report (ACR) for any service call for which paramedics arrive on the scene. In 2019, the service launched the External Violence Against Paramedics working group with the 2-fold mandate of gathering data to develop evidence-informed strategies to mitigate the risk of violence and enhance paramedic safety.

In 2020, 1 year before the implementation of the EVIR, the service recorded a total of 60 documented incidents of injury resulting from workplace violence, with the type of violence and the requirement for injury reporting left to the discretion of the affected paramedic and their supervisor. Following the development of the EVIR, the service released a new policy for staff that outlines the roles and responsibilities of paramedics and service leadership in identifying, intervening in, and reporting incidents of violence. Importantly, the new policy specified the types of violence to be captured as part of the reporting process with definitions drawn from a review of the literature and relevant occupational health and safety legislation (Table 2).

Table 2. Definitions of incident types in the External Violence Incident Report (EVIR)[a].

Type of violence	Definition
Verbal abuse	Offensive or hateful language; yelling or screaming with the intent of frightening the paramedic
Intimidation	Purposely threatening, following, or using gestures to offend or frighten the paramedic
Assault	Physical attack or attempt to attack; punching or kicking or using a weapon with the intent of causing bodily harm
Sexual harassment	Sexual propositioning or unwelcome sexual attention from a perpetrator. Humiliation, remarks, or offensive jokes with sexual overtones, suggestive looks, or physical gestures
Sexual assault	Indecent assault. Brushing, touching, or grabbing of genitals or breast area

[a]Adapted from Bigham et al [14] with language from the Ontario Occupational Health and Safety Act.

Objective 1: Prevalence and Characteristics

Research Questions

Objective 1 is concerned with answering the following research questions: (1) What proportion of 911 service calls involve exposure to reported violence? (2) What proportion of active-duty paramedics report experiencing violence? (3) What are the characteristics (eg, type and source of violence, location, time of day, etc) of incidents of reported violence?

Data Sources

A detailed accounting of the variables included in this study is provided in Multimedia Appendix 2. We will abstract the following administrative data from all ACRs completed during the study period: paramedic station of origin (division), paramedic level of care (eg, PCP/ACP), date, call received time, pick-up location code, dispatch priority, dispatch problem code, primary problem code, and return priority.

Where an EVIR is completed for a particular service call, we will additionally abstract the following fields from the violence report: report creator, incident type, source of violence, location of the incident, contributing circumstances (eg, alcohol intoxication, drug use, cognitive impairment), police present (yes/no), police response helpful (yes/no; narrative), and address hazard flag (communicated, created/extended).

The data will be assembled in Microsoft Excel (Microsoft Corp). An anonymized alphanumeric participant code will be substituted for the report creator's name by the data custodian.

Analyses

We will use descriptive and summary statistics to characterize the data, including means and medians with measures of dispersion for continuous data and counts and percentages for categorical data. Continuous variables will be plotted and assessed for normality, both visually and with skewness and kurtosis tests. We will then calculate the proportion of paramedics reporting exposure to violence and the average number of reports per paramedic. We will assess for group differences in reporting using 1-way ANOVA for continuous variables or chi-square for proportions, with significance set at $P<.05$. All analyses will be carried out in SPSS (version 28; IBM Corp).

Objective 2: Risk Factors

Research Questions

Objective 2 is concerned with answering the following research questions: (1) What characteristics of emergency calls are associated with an increased risk of reported violence? (2) Relatedly, what characteristics of emergency calls are associated with an increased risk of a violent encounter resulting in any form of assault?

The goal here is to assess the degree to which characteristics of emergency calls that are typically known to the responding paramedics before arrival at the scene can be used to identify service calls that have a higher risk of violence. This information can be used to develop risk mitigation strategies, such as coordinated responses with paramedic supervisors, police, or mobile crisis intervention teams.

XSL•FO
RenderX

Data Sources

Data for Objective 2 will be drawn from the ACR database and completed EVIRs with all the same data points listed in Objective 1.

Analyses

Our outcomes of interest are (1) whether an EVIR is filed for a particular service call ("EVIR"; yes/no) and (2) whether a service call results in a reported assault on a paramedic. Because paramedics can select multiple types of violence on the EVIR (eg, verbal abuse, assault, and intimidation), the assault outcome will require collapsing the incident type categories into a new output variable of ("Assault_Paramedic"; yes/no) that captures incidents that include combinations of violence that involve either physical or sexual assault.

Potential covariates in our analysis will include service call characteristics that are typically known to the responding paramedics at the point of dispatch. These include the day of the week, time of day, call/pick-up location (26 levels, eg, residence, street, restaurant/bar), dispatch problem code (55 levels, eg, unconscious, drug/alcohol overdose, dyspnea), patient sex (male/female/other), and patient age.

Paramedics in Peel Region normally work 12-hour day or night shifts with additional staff scheduled during "peak" demand periods (broadly, 10 AM to 10 PM). However, in our analysis, we will define 3 nonoverlapping 8-hour "buckets" adapted from paramedic shift scheduling: day (6 AM to 1:59 PM), afternoon (2 PM to 9:59 PM), and overnight (10 PM to 5:59 AM).

Given the large number of variables, our modeling approach involves several preliminary steps to whittle down the list of covariates to be included. We will first calculate frequencies by running cross tabulations for each variable with our outcomes of interest. Levels of variables (eg, pick-up location, dispatch problem code) with fewer than 10 observed events will be removed. Next, we will run univariate logistic regression analyses for each variable level in descending order of observed proportion. Variables that are significantly associated with each outcome at a threshold of $P<.10$ will be retained for the next stage of model construction.

Our interest in constructing multivariate logistic regression models is in the adjusted odds ratios (AORs) of the individual covariates rather than the predictive capacity of the model as a whole. We will construct our adjusted models using a forward step approach in declining order of significance (ie, starting with the smallest P values) with the condition that all included variables must retain a $P<.05$ with AORs whose confidence intervals do not include the null value. Finally, we will test for interactions between the pick-up location code and the dispatch problem code, constructing terms based on the significance of individual covariates in univariate modeling and introducing terms sequentially to the adjusted models for evaluation. Interaction terms that do not meet the significance threshold will be removed from the model.

The total number of included covariates will also necessarily be constrained by the observed event rate; consequently, we will not exceed an event-to-covariate ratio of less than 10:1.

Objective 3: Contributing Circumstances

Research Questions

Objective 3 is concerned with answering the following research questions: (1) What underpinning themes contribute to violence against paramedics? (2) Relatedly, what proportion of EVIRs involve harassment on grounds that are protected under the Ontario Human Rights Code (ie, gender, race/ethnicity, and sexual orientation)? (3) What is the potential contribution of conflict over COVID-19 health measures/restrictions to incidents of reported violence?

Data Sources

Each EVIR contains a space for the reporting paramedic to enter a narrative description in response to the "what happened?" prompt. During the rollout phase, paramedics were instructed to be detailed and specific in documenting the details of violent incidents and to include direct quotes where appropriate. We will abstract these free-text narratives for analysis.

Analyses

Approaching the data from an interpretivist epistemology [23,26], we will use qualitative content analysis [22,27] to answer each of our research questions. Qualitative content analysis is a technique for identifying themes in textual data using iterative, in vivo codes or the application of an a priori coding framework. As an analytical strategy, qualitative content analysis remains "close" to the surface of the data, avoiding the sort of deep inferences or abstractions that are germane to other qualitative methodologies (ie, grounded theory or ethnography). For Research Question 1, the incident narratives will be abstracted and imported into NVivo for Mac (QSR International) for analysis. We will inductively code the text using techniques described by Charmaz [28], with successive rounds of open [29] and then focused [30] coding to identify themes and then define categories based on conceptual similarity. This iterative approach will allow us to explore circumstances that underpin incidents of reported violence, such as conflict over patient care (eg, choice of hospital) that may escalate into violence.

For Research Question 2, we are guided by language in the Ontario Human Rights Code [31]. In brief, the law explains that all persons have the right to be free from discrimination and harassment based on 14 protected grounds. The code defines harassment as "engaging in a course of vexatious comment or conduct that is known or ought to be known to be unwelcome" [31]. The protected grounds include, among other things, age, disability, gender identity and expression, race and related grounds, and sexual orientation, with definitions for each derived from legislation and case law in Canada [31]. We are including 3 broad protected grounds in our analysis (Table 3), with the decision to exclude the remaining protected grounds because of the unreasonably high potential to identify study participants (eg, disability, age, citizenship, family status, marital status) or lack of plausibility (eg, record of criminal offenses, receipt of social assistance in housing).

XSL•FO
RenderX

Table 3. Included grounds with defining language drawn from the Ontario Human Rights Code.

Ground	Defining language
Gender identity and gender expression	Gender identity is each person's internal and individual experience of gender. Gender expression is how a person publicly presents their gender.
Race and related grounds	Race is a social construct that includes geographic, historical, political, economic, social, and cultural factors, as well as physical traits. The code also includes ancestry, ethnicity, religion, and place of origin in this category.
Sexual orientation	Sexual orientation covers the range of human sexuality from lesbian and gay to bisexual and heterosexual.

With respect to potentially vexatious words, we will reference the definitions for each word (eg, fuck, bitch, cunt, fag, cock, etc) provided in the *Urban Dictionary* as a sensitizing concept to aid in the determination of the word's potential to offend. The *Urban Dictionary* is a Wikipedia-style website that allows users to populate definitions for specific words based on contemporary usage in society [32].

To prepare the data, we will abstract the free-text incident narratives into a Microsoft Excel (Microsoft Corp) file for analysis. Drawing on the definitions for harassment and protected grounds provided in the code, we will use independent raters to assess the proportion of EVIRs that involve harassment on 1 or more protected grounds of interest. Specifically, we will recruit 2 research assistants with knowledge of the paramedic context and legal experience (ie, through university training or labor relations involvement) for this task. Following a period of rater calibration [27] with the research team, each rater will then independently evaluate each incident narrative to answer the following question: "Does the narrative suggest harassment on the basis of gender identity or expression, race and related grounds, or sexual orientation?" (Multimedia Appendix 3). We will calculate Cohen Kappa as a measure of interrater agreement, with a member of the research team resolving any areas of disagreement on a specific incident narrative.

Finally, for Research Question 3, we will examine the EVIR incident narratives for comments that refer to anger over COVID-19 health measures (ie, vaccination, masking, social distancing) that contribute to violent encounters. This might include, for example, hostile reactions in response to paramedics' requests that patients or bystanders at scenes wear a mask. Again, we will abstract the EVIR incident narratives into a Microsoft Excel (Microsoft Corp) sheet and have 2 independent raters review each narrative to answer the following question: "Does the narrative suggest violence on the basis of conflict over COVID-19 health measures?" Using a similar approach to Research Question 2, we will engage in a period of rater calibration followed by independent coding and then use Cohen Kappa to measure interrater agreement.

All personnel recruited to analyze qualitative data will be required to undergo online research ethics training made available for free by the Government of Canada and be instructed to treat the data as strictly confidential. Because the incident narratives may include detailed descriptions of specific incidents that may later be identifiable to persons with knowledge of the events, we will not report direct quotes and will use general language in describing examples to support relevant themes during publication.

Results

Although we originally planned to study a 1-year period, we have expanded our study window to include all violence reports filed between February 1, 2021 and February 28, 2023. As of January 1, 2023, a total of 975 EVIRs have been filed. The research program remains internally funded by the Region of Peel's paramedic services division, and our analysis will begin when the data collection window closes on February 28, 2023. We anticipate the publication of several manuscripts blueprinted for each research objective in late 2023 through early 2024

We anticipate being able to deliver a detailed accounting of the prevalence of reported incidents of violence in the study site, as a proportion of both the total number of service calls and the number of active-duty paramedics in the service. Second, will compile a list of service call characteristics that suggest an increased risk of any form of violence and for violence resulting in an assault on a paramedic. Finally, we will generate a qualitative description of themes that underpin documented incidents of violence, including the potential contribution of violence based on gender, race and related grounds, sexual orientation, and conflict over COVID-19 public health measures.

Discussion

Overview and Strengths

Despite a growing recognition of the potential for significant physical and psychological harm [15,33-38], there is very little epidemiological data describing violence against paramedics [35,39]. Aside from some reviews of occupational injury statistics [34,37,40-43], much of the research on the topic has used cross-sectional survey approaches that ask paramedics about exposure to violence during the past 12 months or throughout their careers [14-16,33,35,39,44-49]. Although informative in drawing attention to the issue and demonstrating that a concerning majority of paramedics have been subjected to violence, the work leaves several important questions unanswered. Without robust, event-level reporting data, it is difficult to ascertain the scope of the problem and potentially modifiable risk factors—both of which are needed in developing organizational strategies to mitigate the risks and enhance paramedic safety.

The challenge in gathering robust data about violence is that the organizational culture within the profession has contributed to underreporting. When surveyed, many paramedics describe violence as just "part of the job" [14,15,17]. As a result, only a minority of incidents are reported to paramedic supervisors or the police. Our own work on the topic has demonstrated a cycle

XSL•FO
RenderX

within which chronic exposure to violence, combined with its perceived inevitability and lack of consequences for perpetrators, serves to implicitly position the ability of paramedics to "brush off" violent encounters as an expected professional competency [17]. Breaking this cycle is an important step in understanding the scope of the problem. In that respect, our research has several strengths that will allow us to contribute meaningfully to this literature.

First, the reporting process was developed through an extensive stakeholder engagement and pilot testing process with the goal of promoting accessibility [19]. Embedding the EVIR within the patient care record gives us a streamlined, accessible, point-of-event reporting mechanism. This allows us to ask questions about the prevalence of violence as a proportion of both service calls and active-duty paramedics. We will also be able to generate a descriptive profile of the types of violence paramedics report, its sources, and contributing circumstances—an important first step to understanding the scope of the problem. Second, because the EVIRs are linked directly to ACRs, we will be able to evaluate the degree to which features of service calls that are generally known to the responding paramedics ahead of time (such as the nature of the problem) are associated with an increased risk of violence. This analysis can be used to develop strategies when responding to high-risk calls, such as coordinated response plans with police or mobile crisis teams. Third, qualitatively analyzing the free-text narratives potentially allows us to examine some of the root causes of violent encounters. It may be, for example, that violent encounters are precipitated by conflict over patient care, preferences, or psychosocial needs that can be better managed through improved policy or training. Relatedly, the degree to which paramedics are subjected to vitriol based on gender, race, or sexual orientation has not (to our knowledge) been previously studied and may be a novel contribution to the literature describing chronic stressors in paramedic work [50-52]. Examining the EVIR narratives for themes related to COVID-19 will generate modest empirical data in a local context on what media sources have been describing as a growing antipathy toward health care providers over public health measures, such as masking or vaccination mandates [18]. Finally, our analysis will enable refinements to the reporting mechanism itself. This can support both strengthened acceptance among the end users and scalability of the work to include other paramedic services in the province.

Limitations

We are placing some important boundaries on this research that need to be considered as limitations when interpreting our findings. First, we must acknowledge that all findings to be shared from this research are limited to reported incidents from a single study site. Although the development phase went to great lengths to address many of the organizational cultural barriers to reporting, we are mindful that the work is coming up against a very real and historically entrenched reluctance to report violent incidents. The degree of underreporting we will observe in our study is difficult to estimate. Both factors limit the generalizability of our findings. Second, we are gathering data about the incidents themselves but stopping short of evaluating the health consequences for the reporting paramedics in terms of physical injuries, lost time from work, or more nebulous psychosocial harms, such as burnout. Given the links between critical (or traumatic) stress and PTSI in the paramedic population, studying the impact on health and well-being will be an important next step in the research. Third, our statistical analyses will necessarily be constrained by the observed event rate, which is difficult to estimate ahead of time. Our evaluative time frame of 1 year following implementation is admittedly arbitrary, but it is reasonable from a feasibility perspective and aligns with the operational needs and priorities of the paramedic service.

Conclusion

Leveraging a novel, point-of-event reporting process, this study aims to describe the prevalence of violence against paramedics in the Peel Region, its risk factors, and underpinning themes. This research will broadly be used to develop evidence-informed risk mitigation strategies, support a wider-scale implementation of violence tracking, and contribute epidemiological data to what has been described as a "serious public health issue" [15].

Acknowledgments

This initiative is a collaboration between Peel Regional Paramedic Services (PRPS) and the University of Windsor, in Ontario, Canada. We wish to express our gratitude and appreciation to the members and leadership of PRPS, as well as the local executive committee of the Ontario Public Service Employees Union Local 277 for their support of this work.

Data Availability

Limited quantitative data from this study can be made available to interested parties upon request from the principal investigator. Note that this may require a formal data-sharing agreement.

Conflicts of Interest

JM is employed as an advanced care paramedic and researcher by the Peel Regional Paramedic Services.

Abstract

Background: Medical cannabinoids are controversial. Their use is comparatively rare, but it is rising. Since 2017, cannabinoids can be prescribed in Germany for a broader range of indications. Patient surveys on these drugs are hampered by the stigmatization of cannabinoids and their (still) low prevalence in medical contexts. Against this background, patients' willingness to provide information is limited. Moreover, it is logistically challenging to reach them with a survey. A thorough knowledge of currently ongoing therapies and their effects and side effects, however, is important for a more appropriate and effective use of cannabinoids in the future.

Objective: This study is an exploratory data collection using a representative sample. The main goal is to provide a detailed picture of the current use of medical cannabinoids in Germany. It is intended to identify subgroups that may benefit particularly well or poorly.

Methods: We are conducting a representative, anonymous, cross-sectional, one-time, web-based survey based on mixed methods in 3 German federal states. Health conditions under cannabinoid therapy and before are documented with validated, symptom-specific questionnaires. This allows an estimation of the effect sizes of these therapies. The selection of parameters and questionnaires was based on the results of independent qualitative interviews in advance. Representative samples of the hard-to-reach study population are obtained by cluster sampling via contracted physicians of the statutory health insurance companies.

Results: Recruitment was ongoing until the end of June 2022, with 256 enrolled participants. Validated questionnaires on pain, spasticity, anorexia or wasting, multiple sclerosis, nausea or vomiting, depression, and attention deficit hyperactivity disorder (ADHD) were selected. Symptom scores are being assessed for both current conditions under cannabinoid therapy and conditions prior to this therapy (in retrospect). Validated questionnaires are also used for treatment satisfaction and general quality of life. These are supplemented by existing diagnoses, a detailed medication history, any previous experiences with cannabis or illegal substances, experiences with the prescription process, and sociodemographic data. Based on the results of the previous qualitative interviews, questions were added regarding prior experience with relaxation methods and psychotherapy, personal opinions about cannabinoids, pre-existing or symptom-related psychological trauma, and different experiences with different cannabis-based therapies.

XSL•FO
RenderX

Conclusions: The exploratory mixed methods approach of this project is expected to provide valid and relevant data as a basis for future clinical research. The study design may be representative for a large proportion of outpatients treated with cannabinoids in the German federal states studied. It may have less bias toward social desirability and may provide valuable information in addition to existing studies. Due to the observational and cross-sectional nature of this study, various limitations apply. Causal relations cannot be drawn.

Introduction

Background

Cannabis plants contain a variety of active ingredients. More than 100 cannabinoid compounds have been identified [1]. The most relevant for medical applications are tetrahydrocannabinol and cannabidiol [2]. Many different pharmacologically active cannabis ingredients exist, especially terpenes and terpenoids, and the synergistic effects of different compounds are being discussed widely [2,3]. Nevertheless, pure tetrahydrocannabinol and cannabidiol drugs are also frequently used. After the discovery of the endocannabinoid system in the 1990s, interest in medical applications of cannabinoid drugs has been increasing [2,4]. At the same time, cannabinoids are still controversial in most countries, including Germany, despite changing legal frameworks in medicine and society [5].

Proponents of cannabinoid medications tout their benefits for a variety of conditions [2,6-8]. Cannabinoid drugs are already used in the fields of pain management for multiple sclerosis, chronic pain syndromes, and cancer-related pain. Currently, 73% of cannabinoid prescriptions in Germany are for pain [9]. Previous studies show a substantial improvement in 35.5% and a moderate improvement in 34.2% of patients treated [10]. Other common indications include spasticity in multiple sclerosis, nausea in patients with cancer, and specific mental health symptoms [11,12].

Feared side effects are psychosis, addiction, and physical intolerance reactions [13,14]. This includes dizziness, nausea, fatigue, euphoria, disorientation, confusion, loss of balance, and hallucinations [15]. The risk of side effects is higher for older adults due to their impaired metabolism and comorbidities, as well as their increased potential for drug-to-drug interactions [16]. Side effects also vary depending on the medication used.

Due to legislative changes in Germany in 2017, a wider range of cannabinoid medications can be prescribed medically [17]. By law, physicians who prescribe medical cannabinoids at the expense of statutory health insurance companies were required to participate in a mandatory monitoring study for each patient until 2022 [9]. Parameters included indication, effectiveness, drug, dosage, and quality of life. All were evaluated solely by the prescribing physicians. Patients with private health insurance and those who paid out of pocket were not monitored. Most of the scientific evidence on the current state of cannabinoid therapies in Germany stems from this source only. There is no representative data from direct patient surveys.

Considering the risks and benefits, as well as the ongoing social controversy, a more accurate mapping of the current use of medical cannabinoids in Germany is desirable. There is a need for precise differentiation according to the underlying illnesses, illness-related restrictions, and the resulting health and psychosocial consequences, involving patients and not only their physicians [18]. Such findings could be valuable for a more targeted use of medical cannabinoids and could help in the formulation of questions for future clinical research in this field.

Study Design and Goal

This is an anonymous, exploratory, cross-sectional, one-time, web-based survey using a mixed methods approach. All information is collected at the same point in time, past and current health status included. It aims to obtain representative, descriptive data on patients receiving outpatient treatment with medical cannabinoids in Germany and on their subjective treatment experiences. It is also intended to further explore the patient perspective of cannabis-based therapies and identify subgroups that may benefit particularly well or poorly.

Qualitative Preliminary Study

Between September 2020 and March 2021, after approval by the local ethics committee (8391_BO-K_2019), a qualitative survey was conducted at the Pain Clinic at Hanover Medical School, Germany. Upon written consent, 32 patients (15 women) with chronic pain who had taken cannabis-based medicines for at least 6 months were deliberately selected as a purposive sample, according to Moser and Korstjens [19]. Interviews took 16-88 minutes (on average, 35 minutes). These were semistructured interviews with no time limit. The interview guideline had been constructed according to Kallio et al [20]. It consisted of an introduction that explained the purpose of the interview as well as the process. This was intended to promote an open and trusting interview atmosphere. This was followed by open-ended questions about previous experiences with cannabis and the effects on different areas of life. The interviews were recorded and later transcribed. The data was analyzed according to Strauss et al (grounded theory) [21]. Data collection continued until qualitative saturation occurred, which means that no new knowledge could be generated by further collection of data [22].

XSL•FO
RenderX

All participants were interviewed by the same researcher (FF), who also transcribed and analyzed the interviews. In addition, 3 selected interviews were independently analyzed by 3 other researchers (MK, MF, and FIK). Results were reviewed and discussed by the entire research team to achieve higher intercoder reliability.

The findings on the patient perspective of cannabinoid therapy were used as an additional basis for selecting outcome parameters and corresponding validated questionnaires. However, the detailed presentation of the analysis of these qualitative interviews is beyond the scope of this study and will be presented elsewhere.

The results led to questions about previous experiences with relaxation techniques or psychotherapy, as these methods are considered standard treatment for some of the reported symptoms [23-26]. The findings also resulted in the decision to inquire about the personal opinion about cannabinoids, preexisting or symptom-related psychological trauma, and about varying experiences with different cannabis-based medications.

Methods

Setting, Recruitment, and Sampling

We are surveying patients who receive prescription cannabinoids. The original target size is 300 participants. A representative sample for the German federal states of Berlin, Brandenburg, and Lower Saxony is drawn in a stratified procedure (see the *Data Collection, Management, and Analysis* section for details).

The web-based survey is conducted anonymously using mobile website technology. It starts with patient-adapted questions analogous to those in the mandatory monitoring survey. Based on this, further detailed information on the respective underlying disease is collected. The previous course of the disease and previous therapy attempts are asked in detail. In addition, information on cannabis use throughout the life course is requested, as well as on attitudes and opinions toward cannabinoids prior to the first prescription, where these stemmed from, and to what extent they have changed since the ongoing cannabinoid prescription.

Sample Size

A total of 300 patients currently receiving cannabinoid therapy were to be included in this study (see Textbox 1). Based on the mandatory survey data, approximately 210 patients (69%) will likely experience pain symptoms [9]. Based on this assumption, a power analysis for this exploratory study indicates that using the standard parameters of α=0.05 and β=0.20 (corresponding to a power of 80%), *t* tests used for the pre-post comparisons among the 210 patients with pain symptoms can detect all large, medium, and even smaller effects with effect sizes of Cohen $d \geq 0.20$

Textbox 1. Eligibility criteria.

Inclusion criteria

- Being 18 years or older
- Ongoing therapy with medically prescribed cannabinoids or therapy with medically prescribed cannabinoids in the 12 months prior to survey participation
- Stable internet access
- Have sufficient German language skills, as well as cognitive and physical abilities, to participate in a web-based survey in German, lasting approximately 30 minutes
- Active, written web-based consent (see Multimedia Appendix 1)

Exclusion criteria

- Lack of active, written web-based consent

Outcome Parameters

Overview

The most common reasons for prescribing cannabinoids in Germany are known from the abovementioned mandatory survey. They are chronic pain (73%), spasticity (10%), anorexia or wasting (6%), multiple sclerosis (6%), nausea or vomiting (5%), depression (3%), and attention deficit hyperactivity disorder (ADHD; 1%) [9]. Accordingly, validated questionnaires on these conditions were selected for this survey. Symptom scores are being assessed for both current conditions under cannabinoid therapy and conditions prior to the cannabinoid therapy (in retrospect). Validated questionnaires are also used for treatment satisfaction (current and in retrospect) and for general quality of life (current and in retrospect). These are supplemented by existing diagnoses, a detailed medication history, any previous experiences with cannabis or illegal substances, experiences with the prescription process, and sociodemographic data. Modifications and additions were made based on the results of the qualitative interviews (see the *Qualitative Preliminary Study* section).

Treatment Satisfaction Questionnaire for Medication Version II

The Treatment Satisfaction Questionnaire for Medication (TSQM) version II is a general measure of patients' satisfaction with their medication [27]. It is viewed as a reliable and valid instrument consisting of 4 scales: side effects, effectiveness, convenience, and global satisfaction [27-29].

XSL•FO
RenderX

Patient-Reported Outcome Measurement Information Systems

The Patient-Reported Outcome Measurement Information Systems (PROMIS-29) represents an international standard for the evaluation of quality of life based on a patient report. This test consists of 29 questions about the domains of physical function, anxiety, depression, fatigue, sleep disturbance, the ability to participate in social roles and activities, pain interference, and pain intensity [30,31].

Face Pain Scale

The Face Pain Scale represents an intuitive and well-established way to assess pain. It has been validated for both children and adults in various contexts [32,33].

Multiple Sclerosis Spasticity Scale 88

Spasticity is assessed using the Multiple Sclerosis Spasticity Scale 88 [34]. Due to its considerable length, we decided to only include the 4 most clinically relevant subscales in the survey: muscle stiffness, muscle spasticity, walking, and physical movement.

Anorexia Nervosa Inventory for Self-Rating

For patients experiencing anorexia, we use the Anorexia Nervosa Inventory for Self-Rating which includes questions about figure consciousness, feeling of insufficiency, anancasm, adverse effect of meals, sexual anxieties, as well as bulimia [35].

Minimal Documentation System on Distressing Symptoms

The Minimal Documentation System on Distressing Symptoms (MIDOS^2) is a short questionnaire for non–anorexia-mediated weight loss and nausea or vomiting. This test inquires about a few symptoms associated with palliative care patients as well as their general condition and was validated for this patient group. Since the addressed items are not specific to palliative care, we expect MIDOS^2 to allow an adequate evaluation of the examined symptoms [36].

Hospital Anxiety and Depression Scale

For patients with depression, the Hospital Anxiety and Depression Scale is applied. This test, comprising 14 questions, is a very common, international instrument for quantifying anxiety or depression [37-39]. The Hospital Anxiety and Depression Scale can be used to track disease progression and response to psychotherapeutic and psychopharmacological interventions [40].

Adult ADHD Self-Report Scale

The Adult ADHD Self-Report Scale version 1.1 assesses ADHD and was originally developed in cooperation with the World Health Organization and the Workgroup on Adult ADHD. It consists of 2 parts, the first of which inquires about inattentiveness and the second of which evaluates hyperactivity and impulsivity [41,42].

Rights of Use of the Applied Questionnaires

The use of the validated questionnaires for academic purposes required the consent of the parties holding the copyright. For TSQM, PROMIS-29, and Multiple Sclerosis Spasticity Scale 88, licenses had to be obtained. The authors of the remaining questionnaires required proper referencing.

Data Collection, Management, and Analysis

A stratified random sample is collected via the prescribing contract physicians of the statutory health insurance companies. (88.1% of the German population has statutory health insurance [43]). All physicians with statutory health insurance contracts, medical specialist titles in anesthesiology, general medicine, neurology, and internal medicine, and who practice in the 3 federal states of Berlin, Brandenburg, and Lower Saxony are selected. According to the aforementioned mandatory monitoring survey, those 4 groups of specialists together account for 88% of prescriptions for cannabinoids in Germany [9].

Complete lists of these physicians are obtained by a formal request for academic research purposes from the corresponding medical councils at the federal state level. All physicians on those lists are contacted via email or, in the case of Lower Saxony, via fax (in Lower Saxony, email addresses could not be provided). In addition, physicians are contacted by telephone in random order and asked to invite their own patients who receive cannabinoid medication to partake in the survey, outpatient tertiary centers included. Randomization is done by random number values without duplicates using Microsoft Excel. In the event of unavailability, 3 attempts are made at different times. In the meantime, the next physicians on the list are called. This continues until the planned number of participants is reached.

Physicians who wish to forward study invitations to their patients send an email to the study secretariat requesting an appropriate number of anonymous study invitations. They can then forward the invitations either via email or as a printout to their patients. Each study invitation contains a unique participation code, which serves as the login code for the web-based survey. The study center never receives any personalized or pseudonymized patient data. In this way, a fully anonymous and representative survey is made possible. Both physicians and participants receive an incentive for participation. Physicians receive €50 (US $60) per patient of theirs who participates in the web-based survey as compensation for their time. Since it is known which physicians have received which codes to pass on to their patients, the compensation can be calculated. Information about which physician received which codes is strictly separated from the study data. The complete anonymity of the study participants is thus preserved. On the last page of the web-based survey, patients are shown an impersonalized voucher code worth €15 (US $18) for books from a German bookstore.

The web-based survey is conducted using LimeSurvey (version 5.1.10; Carsten Schmitz) running on a dedicated and secure local server at Charité—Universitätsmedizin Berlin. Entries made by the individual subjects are checked for plausibility and completeness, where possible. Possibly missing data will be imputed using the Multiple Imputation by Chained Equations algorithm [44]. Clearly implausible or very incomplete entries (>50% missing data) will be excluded from the analysis.

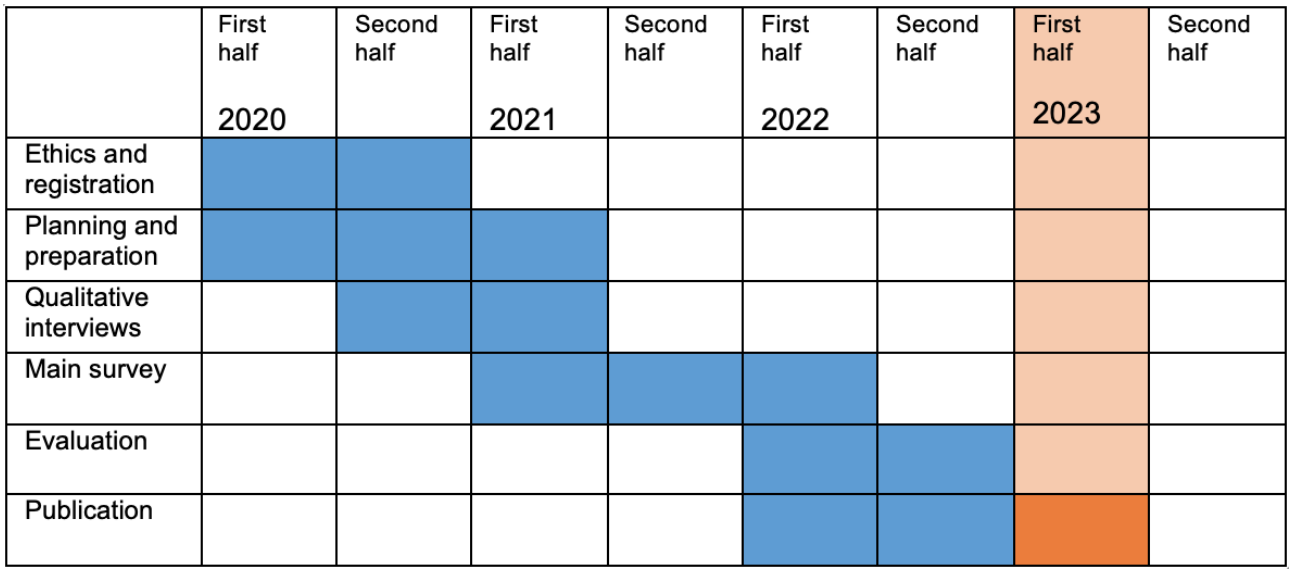
XSL•FO
RenderX

Data from this exploratory cross-sectional study will be evaluated primarily using descriptive statistics. Parametrical figures will be provided, as well as risk and odds ratios for selected questions. Scores for all questionnaires are obtained twice from the participants in the same session. They are first instructed to answer the questionnaires based on their current state, and then on what they remember their state being like prior to the commencement of the cannabinoid therapy. Individual *t* tests will be applied to assess, on a strictly exploratory level, whether within-group changes constitute a substantial improvement. This assessment will rely on both significance levels and effect sizes (Cohen *d*). As there is no control group, findings will be interpreted with due precaution. Furthermore, as a sensitivity analysis, the results for the main tests for pain (numeric analog scale), treatment satisfaction (TSQM), and quality of life (World Health Organization-5 Well-Being Index) will be tested for confounders by extending the *t* test to ANOVA and analysis of covariance models. The authors are very aware of the limited informative value of a pre-post assessment as part of a one-time survey in an observational study design, especially with regard to causal attributions.

The data is stored at the Charité—Universitätsmedizin Berlin for 10 years before being deleted. Only the responsible staff of the study center has access. There is continuous monitoring of enrollment during the survey phase. This is necessary to reach the planned number of participants. If necessary, slow recruitment can be compensated for by contacting more physicians on the phone (this is in addition to contacting all physicians via email or fax). Phone calls are carried out by the responsible study physician, trained study nurses, and trained student assistants. Additional student assistants are available if speeding up recruitment is required. Monitoring of enrollment status is performed by the responsible study team. No data monitoring committee is required because this is a noninterventional observational study. No interim analysis of the data is planned.

Ethics Approval

The ethics committee of the Charité—Universitätsmedizin Berlin gave its approval to obtain, process, and analyze the data and to publish the results (German Clinical Trials Register DRKS00023344; ethics number EA1/327/20). All participants provided their informed written web-based consent to participate in the study. The study is conducted in accordance with the Declaration of Helsinki in its currently valid version, the guidelines of the International Conference on Harmonization of Good Clinical Practice, and the applicable German laws.



Patient and Public Involvement

Patients are not involved in the design, implementation, reporting, or dissemination plans of our research. Yet, they are a key element in the choice of parameters via qualitative interviews. All parameters in the survey are patient-reported parameters.

Timeline

The timeline of this study is presented in Figure 1.

Figure 1. Timeline.

Results

Recruitment was ongoing until the end of June 2022. A total of 11,744 physicians were contacted to invite their patients who receive cannabinoid medication to participate in the study (Berlin, n=1700; Brandenburg, n=2041; Lower Saxony, n=8003). At the time of submission, 256 participants had been enrolled. The COVID-19 pandemic markedly slowed down participant enrollment. Many physicians did not have the capacity to forward the study invitation to their patients as they had to cope with unusually high numbers of patients, sick leave among their own staff, and other extra duties. We were frequently told that while there was interest in principle in supporting the study, the pandemic conditions at the time did not allow for activities outside of regular patient care. Due to slow recruitment, the survey was later expanded to the federal state of Brandenburg (amendment approved by the ethics committee on January 20, 2022.) Here, all physicians were contacted once by email. Direct calling in random order could

XSL•FO
RenderX

not be carried out in Brandenburg before the study was terminated. Recruitment was terminated as no further funding was available to extend the recruitment period. Results will be published in summer 2023.

Discussion

Principal Findings

We are conducting a one-time cross-sectional web-based survey of a cohort of patients receiving prescription cannabinoids in Germany. In addition, based on the results of a qualitative preliminary study, a clinically relevant selection of parameters was made for the study presented here. In addition to data on quality of life, psychological parameters (including anxiety and depression), and social participation over the course of cannabinoid treatment, we included questions on previous experiences with psychotherapy and relaxation procedures. We also included screening questions for trauma to detect differences in prevalence compared to the general population. While in the preceding qualitative interviews the effects of different cannabis-based preparations and doses were reported very differently (eg, from positive to negative by the same patient), we included questions on the cannabis-based preparations used and their respective perceived effects in their exact time course. This might help identify favorable dose ranges for different diagnoses and age groups based on patient experiences. The use of symptom-specific standardized questionnaires will also allow us to estimate effect sizes of cannabinoid therapies, while bearing in mind all present limitations within the scope of this study design. This survey collects detailed information on the patients' underlying diseases, previous treatment attempts, and individual attitudes toward cannabis.

A strength of this study is its sample of a rather hard-to-reach study population in Germany and Europe using a representative approach. Cannabis consumption is stigmatized in parts of German society [45]. The use of medical cannabinoids is also still rare in Germany (approximately 27,000 patients in a total population of 83.2 million) [9]. This study may represent up to 77.5% of total cannabinoid prescriptions in Germany. The proportion of the total population of outpatients who receive cannabinoid medications in Germany, which is depicted in this study, has been estimated as follows: proportion of all patients with statutory health insurance (who are accordingly treated by physicians licensed by the statutory health insurance) multiplied by the proportion of these patients who are treated by the specialist groups involved in this study, 88.1% (73.3 million/83.2 million) [43] × 88% (8809/10010) [9] = 77.5%. In comparison, the mandatory monitoring survey was able to generate 9000 complete records out of at least 27,000 reported prescriptions (33.3%) [9]. Our intention is to supplement the existing data with a sample that significantly adds to it by involving the patient perspective.

The study design also provides a substantial reduction in social desirability bias due to the full anonymity of participants. The existing mandatory monitoring survey is directed at prescribing physicians who may have an interest in justifying their own therapeutic approach. When patients are surveyed by their prescribing physicians, they too may be biased by social desirability.

In contrast, social desirability bias is potentially lower in this study since it is anonymous. It is also more independent from prescribing physicians, as they merely forward the invitation, and patients fill out the questionnaire without the doctor's presence at home. Lastly, the mixed method approach of this design is intended to provide especially valid and relevant data.

Nonetheless, there are several factors that may influence the answers in the questionnaires, like the doctor-patient relationship and the high patient compliance required for detailed data entry. The study's major limitations also include a risk of selection bias. The web-based survey will most likely underrepresent or not represent certain patient groups, such as patients who are very old or very sick and are not able to participate in a web-based survey. These represent a relevant proportion of the total prescriptions for cannabis-based medicines in Germany. Wasting (and anorexia) and nausea in patients with cancer are among the most common reasons for prescribing, at 6% (641/10.010) and 5% (511/10.010), respectively [9]. The results of this study will only be transferable to them to a limited extent.

There is a considerable risk of recall bias. We try to capture a large amount of information in a cross-sectional survey. Some pieces of information may relate to long-past events. Attempts are made to mitigate this by indicating in both the study invitation and the virtual login area that it may take up to an hour to complete the web-based survey. Participants are also asked to have all available medical records ready and to complete the questionnaire in a quiet place. Nevertheless, the validity of the results will, of course, not be comparable to those of a prospective study.

There is no absolute control over whether individuals completing the web-based survey are actually patients who receive cannabinoid medication. Invitations and login codes can theoretically be given to third parties to receive an incentive (a €15 (US $18) voucher code for books). We assume an extremely low rate of abusive participation but cannot completely exclude it, making it a minor limitation to the validity of this study.

Up until now, about half of the randomly selected doctors could be successfully called on the phone and were asked to invite patients to participate. All doctors did receive an invitation by either email (Berlin and Brandenburg) or fax (Lower Saxony). This creates a risk for systematic bias in the sample.

It is quite certain that the groups of specialists included in the study were affected by the COVID-19 pandemic to varying degrees. Thus, for example, a higher workload in general medicine could lead to an underrepresentation of patients treated there. Medical practices that were particularly affected by the pandemic were significantly less likely to invite patients to participate in the study, and vice versa. This is understandable, as they did not have time to attend to matters beyond regular patient care. For this reason, a risk of sample bias remains.

The qualitative interviews of the independently performed previous study were held, recorded, transcribed, and analyzed by a single researcher. Only 3 out of 32 interviews were interpreted independently by other researchers for intercoder

XSL•FO
RenderX

reliability. The large number of interviews conducted until theoretical saturation was reached may reflect the individual diversity of cannabinoid therapies and how they are experienced. It could also be an indication of methodological uncertainties in conducting the qualitative interviews. However, coding and results were discussed among the entire research team, including 2 experienced qualitative researchers. There was unanimity regarding the data and its interpretation.

Finally, it must be said that all the usual restrictions apply with regard to the interpretability of data in the context of cross-sectional, observational studies. Accordingly, the results must then be discussed with all due restraint and contextualized in a reflective manner.

Conclusions

This study may contribute to a more comprehensive picture of experiences with medical cannabinoids from the perspective of patients with various diseases. Additional understanding of the risks and benefits of cannabinoid therapies may contribute to more appropriate use of these drugs and less societal stigma.

Acknowledgments

The study is funded by Vayamed GmbH, Jägerstr. 28-31, 10117 Berlin, Germany. Vayamed GmbH was not involved in the planning, design, conduct, analysis, and publication of this investigator-initiated study and will not have special or privileged access to study data at any stage. Special thanks to Nadine Sylvester, Miriam Rösner, Gunda Loibl, Daniel Itzlroither, Arnab Chakrabarty, and Carsten Schütz, without whom this study would not have been possible. We would also like to extend a heartfelt thank you to all participants and their supporting physicians.

Data Availability

In accordance with the granted ethics approval, the study data will not be made publicly available to protect participant data. The data sets can be requested from the corresponding author upon justified request.

Authors' Contributions

JMF, MK, and CSK conceived the study together. JMF, MK, and CSK developed the study design. JMF and F-IK analyzed the survey data. FF conducted and evaluated the qualitative interviews. JMF, F-IK, MK, and FF evaluated qualitative interviews for validation. JMF, MK, FF, and CSK conducted the survey. MK, AM, and CSK managed the resources. The curation of the data was done by JMF, F-IK, and LSZ. JMF and FF wrote the first draft of the manuscript. All authors participated actively in reviewing and editing the draft. JMF, MK, AM, and CSK supervised the project. JMF, MK, AM, and CSK were responsible for the project administration. CSK solicited funding for the project.

Conflicts of Interest

The study is funded by the pharmaceutical company Vayamed. Vayamed GmbH is not involved in the planning, design, conduct, analysis, and publication of this investigator-initiated study and will not have special or privileged access to study data at any stage. The study is entirely conducted by an established public research department at Charité—Universitätsmedizin Berlin. Financial dependencies with the funder do not exist. MK has received speaker honoraria from the Federal Association of Pharmaceutical Cannabinoid Companies Demecan, EVER Pharma, Grunenthal, Hormosan, IUVO Therapeutics, Lilly, the Medical Service of the Health Insurance Funds, Novartis, Stadapharm, Teva, and Tilray. He has received consultancy fees from Almirall. He has received expert opinion fees from several local and social courts. He is member of the ad hoc commission cannabis in medicine of the German Pain Society and the Science Network Cannabinoids in Medicine (Wissenschaftsnetzwerk Cannabinoide in der Medizin). CSK has received consultancy and speaker fees from Pedanios GmbH and Deutsches Institut für Medizinalcannabis more than 3 years ago. He is part of the Science Network Cannabinoids in Medicine (Wissenschaftsnetzwerk Cannabinoide in der Medizin). No further conflicts of interest related to this manuscript were declared.

Abstract

Background: Pre-exposure prophylaxis (PrEP) is a highly effective biomedical prevention intervention and a major strategy for reducing the HIV burden in the United States. However, PrEP provision and uptake remain lower than estimated needs, and in ways that may exacerbate HIV disparities among Black adolescent girls and young women in the southern United States. Data suggest that gaps in provider knowledge of HIV epidemiology and PrEP and skills assessing sexual health practices are important barriers to provision and uptake, with limited evidence-based interventions to address these gaps.

Objective: This paper describes the "PrEP-Pro" intervention, a multicomponent intervention to train and support family medicine (FM) trainees to promote PrEP for adolescent girls and young women in Alabama.

Methods: The PrEP-Pro intervention comprises 3 main components guided by the Capability-Opportunity-Motivation-Behavior (COM-B) model for behavioral change and the Consolidated Framework for Implementation Research (CFIR): (1) provider HIV epidemiology and PrEP education, (2) sexual history taking, and (3) PrEP Champions. In phase 1, we will work with community advisory boards (providers and clients) and then conduct focus groups with FM trainees to adapt content to train FM residents on HIV epidemiology and PrEP and develop implementation strategies, including provider-facing tools and client-facing educational materials. In phase 2, we will pretest and then pilot-test the initially adapted PrEP-Pro intervention with FM trainees. FM trainees will complete baseline, 3-, and 6-month questionnaires post PrEP-Pro intervention. We will also conduct in-depth interviews (IDIs) with FM pilot participants, adolescent girls and young women who accessed care after the PrEP-Pro pilot, and key

XSL•FO
RenderX

stakeholders. The primary outcomes are PrEP-Pro acceptability and feasibility, which would be assessed using validated instruments at months 3 (among pretest participants) and 6 (among pilot participants). Secondary outcomes will also be assessed, including PrEP knowledge, sexual history-taking attitudes and practices, PrEP prescriptions among adolescent girls and young women encounters, and sexually transmitted infections (STIs) and HIV testing among adolescent girls and young women encounters in 6 months.

Results: Study results will be disseminated to practices, state health officials, and other key stakeholders to solicit feedback on implementation opportunities and challenges to inform a hybrid effectiveness implementation trial. Our results will also be presented at local and national conferences and submitted to peer-reviewed journals.

Conclusions: As PrEP grows, there is a pressing need to train FM providers and develop appropriate, contextually relevant tools to support PrEP implementation. The PrEP-Pro intervention is a multicomponent intervention to train FM residents across Alabama on sexual history-taking, PrEP provision for adolescent girls and young women, and supporting practice-based PrEP Champions. The PrEP-Pro intervention is anticipated to increase PrEP prescriptions for adolescent girls and young women and expand comprehensive sexual and reproductive health care for adolescent girls and young women in rural and urban Alabama.

Introduction

In the United States, Black adolescent girls and young women are disproportionately affected by HIV compared to their White and Hispanic counterparts [1]. In 2019, Black adolescent girls and young women accounted for 54% of the approximately 36,801 new HIV diagnoses among women, despite representing just 13% of the female population [2]. Further estimates suggest that Black adolescent girls and young women are at disproportionately higher risk of HIV in the south than in other regions, where they account for 67% of new HIV diagnoses among women [3,4], with a growing number among those living in rural areas [4-6].

Pre-exposure prophylaxis (PrEP) is a highly effective biomedical prevention intervention and is an important strategy for ending the HIV epidemic in the United States. [7-9]. In 2012, the US Food and Drug Administration approved the first PrEP agent, a fixed oral combination of tenofovir disoproxil fumarate/emtricitabine for use in adults [10,11], and later broadened the approval to include adolescents in 2018 [12]. Most recently, in 2021, the Food and Drug Administration approved a long-acting injectable formulation, cabotegravir, as PrEP for adults and adolescents with vaginal or anal exposure to HIV [13].

Despite advances in biomedical PrEP therapeutics to reduce HIV incidence and increase patient autonomy, PrEP uptake remains low compared to estimated needs and in ways that may exacerbate disparities in HIV incidence [14,15]. In a cross-sectional study of 429 adolescents (aged 15-21 years) accessing preventive care in an urban adolescent primary care center in Alabama, almost half were PrEP-eligible, yet none were prescribed PrEP [16]. National data also suggest low PrEP prescription among adolescents and young women, as well as PrEP inequities by race and geographical location [14,17]. In 2019, only approximately 10% of women aged 16 years and older with indications for PrEP received a PrEP prescription [17]. Additionally, PrEP prescriptions among those with indications for PrEP were lowest among adolescents and young adults aged 16-24 years (16%) compared to adults aged 35-44 years (28%), and among Black individuals (8%) compared to White individuals (63%) [17]. Sullivan and colleagues [14] in a recent study using commercial pharmacy data to count PrEP users from 2012-2021 found the lowest PrEP use in the South compared to other US regions, and the lowest PrEP access in relation to the needs among the Black compared to the White individuals.

Multilevel barriers to PrEP provision and uptake include client-level barriers (such as low PrEP awareness, mistrust of the health care system, and PrEP-associated stigma) [18-21], health care system–level barriers (such as knowledge gaps and comfort among providers, unconscious bias, and racism) [22-24], and structural-level barriers (such as costs, reimbursement, and lack of health insurance) [24-26]. More specifically, in the South, PrEP provision and uptake have been limited by geographical factors—living in rural areas with limited access to PrEP providers [7], provider and health care system factors, including PrEP knowledge [27], provider sexual assessment skills [27], perceived provider racism [28], PrEP stigma [28,29], and health care capacity, among many other factors [7,30,31]. Thus, training providers in taking a sexual history and PrEP clinical care may be a successful strategy to increase PrEP use among Black adolescent girls and young women in the South [31-34].

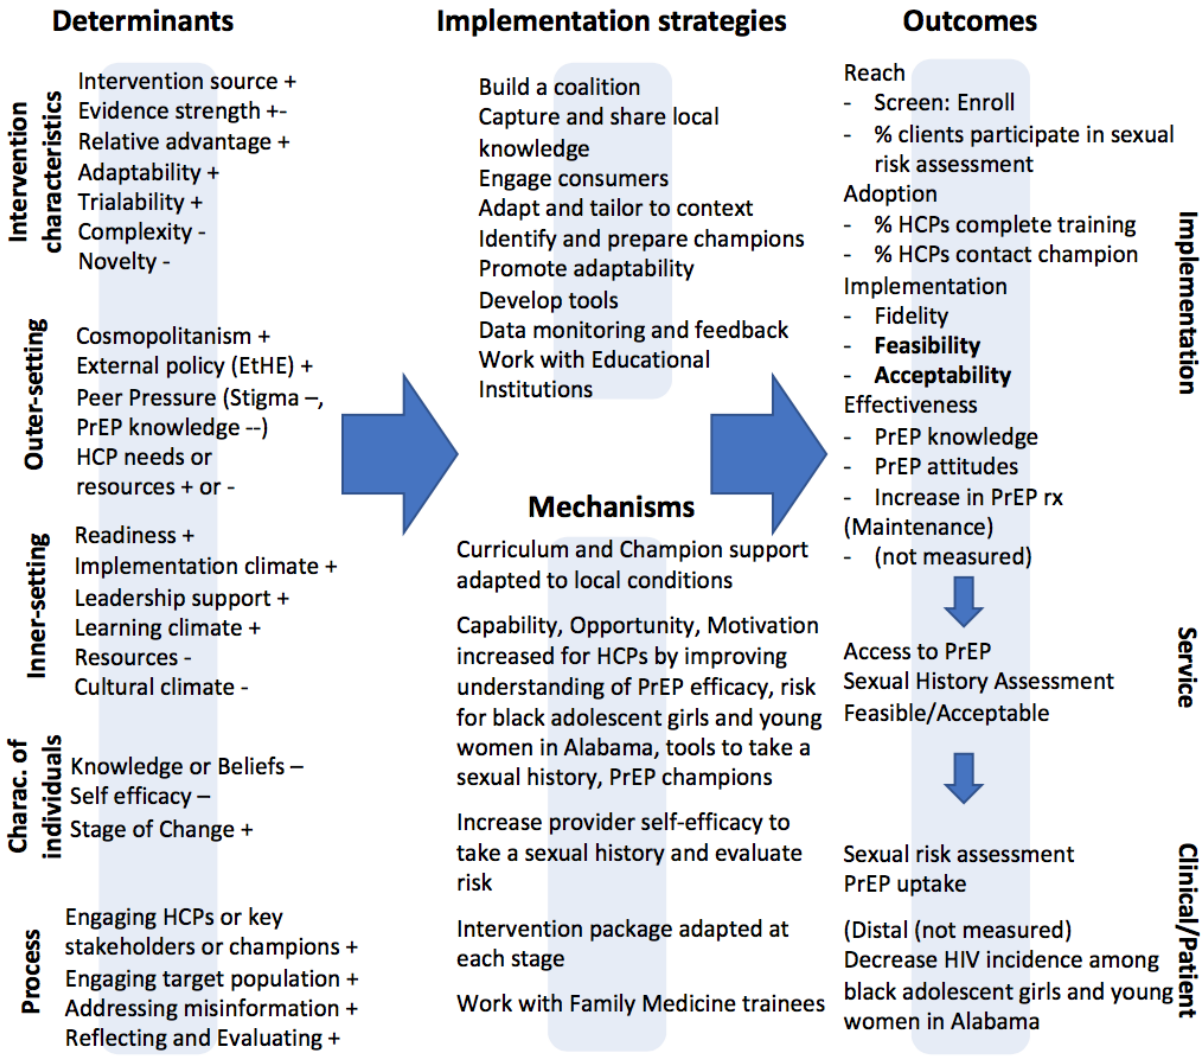
Among health care providers (HCPs), family medicine (FM) practitioners have tremendous reach in rural communities and provide crucial preventive care for underserved populations [35]. They also provide transitional care as children advance into late adolescence, which often coincides with the onset of sexual activity [36-38]. In predominantly rural states like Alabama with high HIV incidence in rural communities, FM practitioners are a critical workforce to engage in HIV prevention methods like PrEP. Building the HIV workforce

XSL•FO
RenderX

capacity is also responsive to the Ending the HIV Epidemic (EHE) national goals to improve our epidemic and decrease current inequities [39].

This paper outlines a protocol to develop and pilot a multicomponent intervention to train and support FM trainees to promote PrEP for adolescent girls and young women in Alabama. Our primary aims are to (1) adapt content to train FM trainees on HIV epidemiology and PrEP; (2) take a gender-neutral sexual history, and support "PrEP Champions," (ie, FM trainees committed to promoting PrEP within the clinic); (3) pretest and pilot test the initially adapted intervention; and (4) conduct a formative evaluation to explore determinants of implementation. This proposed intervention provides an opportunity to expand comprehensive sexual and reproductive health care for adolescent girls and young women and train providers in HIV prevention.

Methods



Study Design and Setting

We are conducting an implementation science mixed methods study to develop and pilot test a multicomponent intervention—PrEP-Pro—for FM trainees in urban and rural Alabama to promote PrEP education, counseling, and prescription to Black adolescent girls and young women in Alabama. We chose to work with FM practitioners who provide comprehensive health care services across the lifespan, including adolescent girls and young women, and dominate the rural workforce [35]. In addition, we opted to work with trainees as provider behavior change may be more effective when integrated into the formative stages of training [40,41]. The FM program partners include trainees and providers from 4 programs across the state of Alabama, including programs based in rural and urban areas.

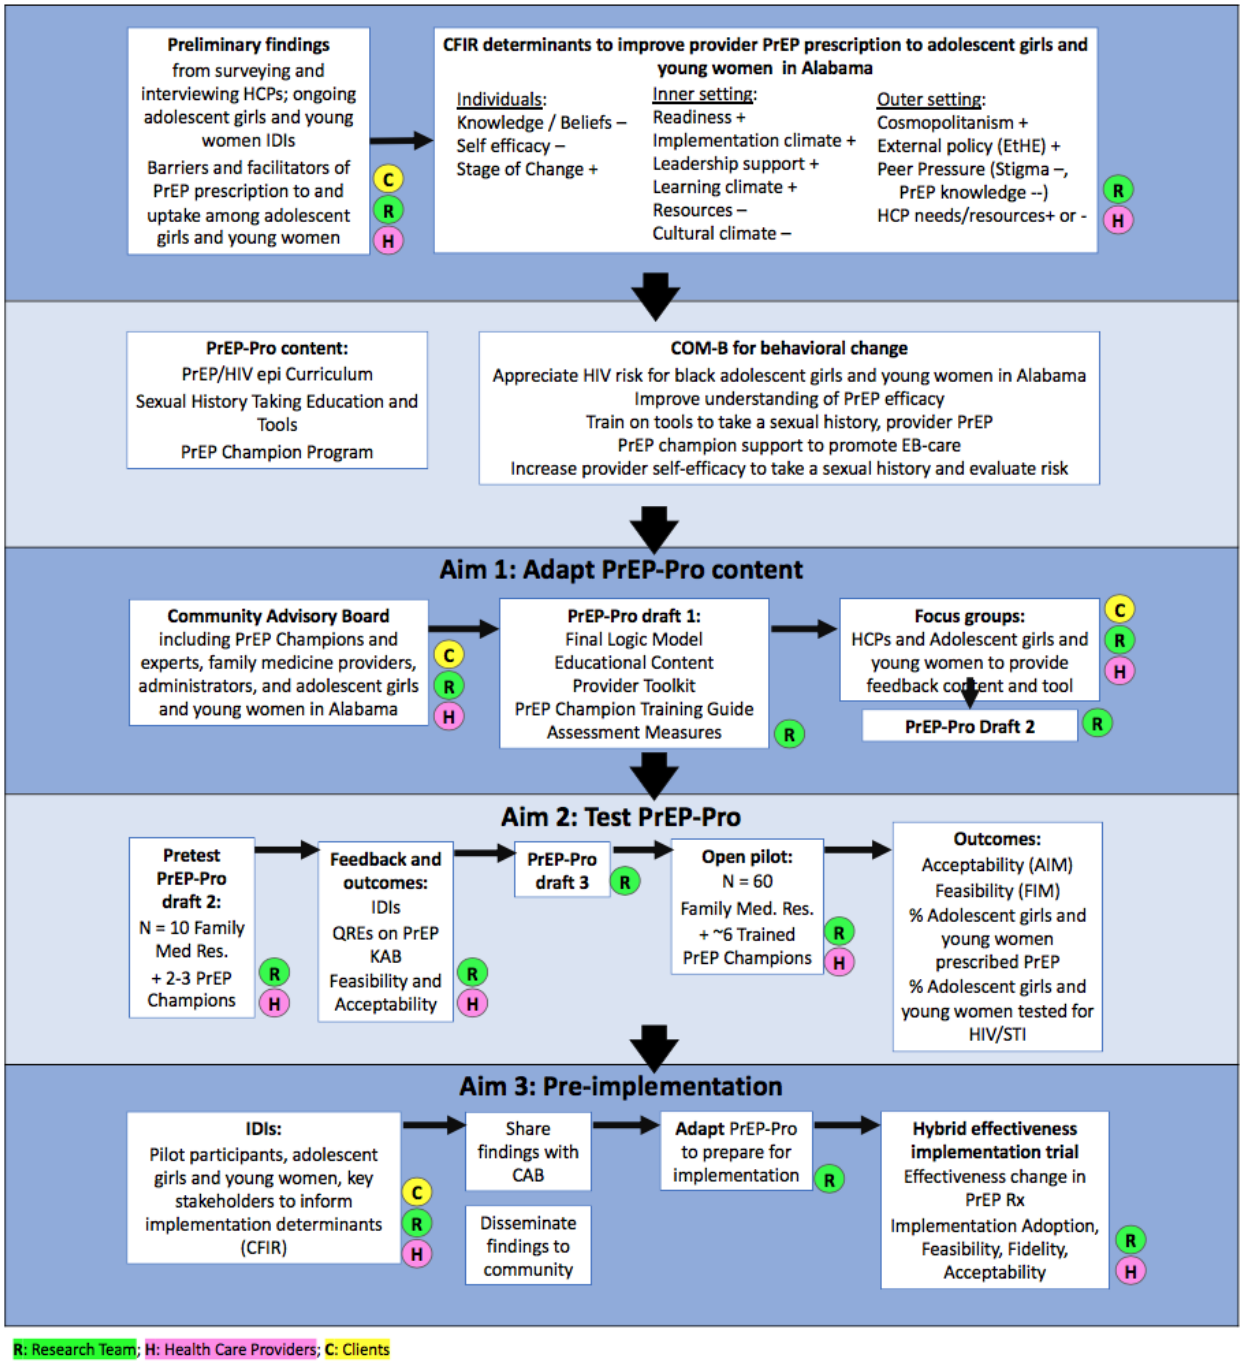
The PrEP-Pro intervention is theoretically informed by the Capability-Opportunity-Motivation-Behavior (COM-B) model for behavioral change [42] and the Consolidated Framework for Implementation Research (CFIR) [43]. The COM-B model for behavioral change proposes 3 components to any behavior [42]. Capability (C) refers to how capable providers feel about performing a behavior. For example, FM residents must be able to efficiently take a sexual history from adolescents to assess risk. Opportunity (O) refers to the social and physical opportunity to engage in the behavior. FM residents need support (eg, PrEP Champions) to navigate health insurance, privacy issues, and community stigma to offer PrEP. Motivation (M) refers to the desire to carry out the behavior in the face of other competing interests and may be addressed by helping FM residents understand the effectiveness of PrEP or by engaging PrEP Champions to motivate FM residents to prescribe PrEP. Our PrEP-Pro intervention addresses each component of the COM-B model to facilitate the increase of PrEP prescriptions to Black adolescent girls and young women. We also apply CFIR to consider multiple determinants required to increase PrEP prescriptions to Black adolescent girls and young women. CFIR is an implementation science determinant framework widely used to guide the systematic assessment of multilevel contextual factors that affect implementation and includes 5 domains, 48 constructs, and 19 subconstructs [43,44]. The 5 domains are (1) intervention characteristics or innovation (ie, the product or the "thing" being implemented), (2) inner setting (ie, setting where the innovation is being carried out), (3) outer setting (ie, setting where the inner setting exists), (4) individuals (ie, roles and responsibilities of individuals), and (5) implementation process (ie, various activities carried out to implement the innovation) [44]. For example, the individual-level determinants at the provider level that may influence PrEP prescription include knowledge and beliefs around PrEP and conducting a sexual history or risk assessment, and self-efficacy as identified in our studies and also supported by prior literature [21,22,24,31,45]. The inner setting determinants include readiness for change, ease of access to knowledge and information about sexual history taking and PrEP, and leadership engagement within FM training programs to innovate and provide research opportunities for residents. The outer setting determinants include state-level EHE impetus and PrEP products in the pipeline. Therefore, guided by CFIR, we will draft and further explore and understand more granularly the implementation determinants of PrEP-Pro intervention to inform a future hybrid effectiveness/implementation trial (Figure 1).

XSL•FO
RenderX

Figure 1. Implementation Research Logic Model (PrEP-Pro). The symbols "+" and "-" serve to indicate the "valence" of the determinants, or whether we anticipate the determinant will be a facilitator (+), a stronger facilitator (++), a barrier (-), a stronger barrier (—), or have a mixed impact *(+/-) on the implementation of the intervention. HCP: health care provider; PrEP: pre-exposure prophylaxis.

PrEP-Pro Multicomponent Intervention

The PrEP-Pro intervention consists of 3 main components. Tailored training in HIV epidemiology and PrEP basics, sexual history taking, and support practice–based PrEP Champions will be provided. We will first adapt and develop the PrEP-Pro intervention and then conduct a pilot test. To guide the systematic development of our intervention, implementation, and evaluation, we will use intervention mapping (IM) techniques [46,47].



Phase 1: Development of the Multicomponent Intervention

Overview

In phase 1, we will develop a multicomponent intervention, PrEP-Pro intervention (Figure 2). This includes the adaptation of content to train on HIV epidemiology and PrEP and the development of implementation strategies including provider-facing tools and client-facing educational materials. We plan to make the content developed compatible with the Project Extension for Community Healthcare Outcomes to optimize dissemination opportunities [48]. Project Extension for Community Healthcare Outcomes is a disease management approach using case-based web-based learning to increase knowledge among providers and standardize best practices for the screening, care, and treatment of a disease [49,50].

XSL•FO
RenderX

Figure 2. PrEP-Pro study flow and aims. AIM: Acceptability of Intervention Measure; CAB: community advisory board; CFIR: Consolidated Framework for Implementation Research; FIM: Feasibility of Intervention Measure; HCP: health care provider; IDI: in-depth interview; PrEP: pre-exposure prophylaxis; PrEP KAB: pre-exposure prophylaxis knowledge, attitudes, and behavior; QRE: questionnaire; STI: sexually transmitted infection.

Anticipated Adaptations

We plan to make adaptations or develop new content in the following areas: (1) epidemiology of HIV risk for Black adolescent girls and young women in Alabama; (2) PrEP indications for adolescent girls and young women; (3) PrEP knowledge, attitudes, and behavior (KAB) tool; (4) sexual history taking with focus on adolescent girls and young women needs and nuances in how to ask questions to this age group; (5) sexual history screening tool for adolescent girls and young women including strategies to optimize sexual behavior screening for adolescent girls and young women; and (6) PrEP champion toolkit.

Adaptation Process

Review of Existing Literature

To adapt content, the research team reviewed existing literature and web-based databases to identify relevant and more recent content on sexual history taking [51-54], HIV epidemiology [55-57], PrEP curriculum [58-61], local resources and tools for PrEP Champions, as well as relevant instruments to assess PrEP knowledge, attitudes, and beliefs [62,63]. The lead authors of publications were contacted through email to request additional materials discussed in their publications which are not accessible digitally.

XSL•FO
RenderX

Review With the Scientific Advisory Board (SAB)

The research team worked with a broader scientific investigative team inclusive of expertise in adolescent health, medical education, FM training, and HIV prevention or PrEP care to solicit input and review materials and data gathered from the review of existing literature.

Community Engagement With the Community Advisory Board (CAB)

Drawing on the principles of cocreation [64,65], we developed 2 CABs, 1 group (N=7) comprising FM representatives from rural and urban settings, including FM trainees, administrators, and advocates, and a second group (N=4) comprising Black adolescent girls and young women. The CABs were convened separately due to the different roles, expertise, and comfort level in sharing. CAB members were identified and recruited based on recommendations from our scientific team and our collaborating FM programs. CAB members meet remotely for 1 hour every month to review and reach a consensus on the content of the curriculum and tools that address adolescent tenets, tools to measure PrEP knowledge, as well as provide input on optimal strategies to train FM residents and promote or offer PrEP. This process is ongoing, and details on the iterations made to the content of the curriculum and tools will be published in a subsequent paper. In addition to working with the CAB to adapt content, we also plan to work with the CAB throughout the study to help with the interpretation of results and dissemination of study findings.

Focus Group Discussions (FGDs) With FM Providers (Trainees)

Two FGDs comprising FM trainees will be conducted (December 2022-January 2023) to seek feedback on the draft PrEP-Pro content and a newly developed PrEP KAB tool. Provider participant eligibility criteria include (1) being a licensed HCP (MD, DO) trainee, (2) providing medical care to adolescent girls and young women in Alabama, (3) working in a clinic setting where at least 20% of the population is Black, and (4) being able or willing to provide informed consent. Participants will complete a brief questionnaire outlining sociodemographic and clinic practice characteristics. During the FGD, the facilitator will present the initial adapted PrEP-Pro intervention (including the initial draft of the PrEP-Pro content, badges, flow charts, and tools) iteratively to the 2 groups of 4-6 FM trainees. FGDs will be conducted virtually or in an enclosed private location and will last for approximately 60 to 90 minutes. Trained interviewers will facilitate all FGDs, including probing, asking open-ended questions, ensuring nonjudgmentalism, and using grounded theory. FGDs will be digitally recorded and transcribed. All FGD participants will be reimbursed US $50 for their time.

Phase 2: Testing the Initially Adapted PrEP-Pro Intervention

Overview

Using peer champions to improve provider knowledge and quality of care is an evidence-based implementation strategy [66]. Studies describe the presence of change champions within clinical practices as essential facilitators of quality improvement [67], and such champions can play an essential role in communication, marketing, education, skill-building, and assessment [68]. Provider champions are agents of change [69], empowering their peer providers within their practice to engage in innovations, practice new skills, and implement new care strategies with more ease and confidence.

The primary aim of phase 2 is to pretest and pilot-test the initially adapted PrEP-Pro intervention with FM trainees in Alabama (Figure 2). We will pretest the intervention by training 2 FM trainees as PrEP champions with the initially drafted curriculum, who will then deliver the draft curriculum and ongoing support to 8-12 FM trainees (from at least 1 urban and 1 rural setting). In addition to receiving additional training and support, PrEP champions will have access to PrEP consultants and experts.

The pretest phase will allow us to optimize the PrEP-Pro intervention (refine the number and length of sessions, educational material content, and other details that will be key to maximizing acceptability, feasibility, and impact). Thereafter, an open pilot trial of the PrEP-Pro intervention will be conducted by training an additional 6 FM trainees to serve as PrEP Champions and enrolling 60 unique FM trainees from rural and urban settings into the study.

Training PrEP Champions can thus support entire practices to sustain the provision of evidence-based care, navigate medical assistance programs and insurance coverage and troubleshoot new challenges [70].

PrEP-Pro Champion Training Workshop

PrEP Champions will complete an estimated 4 hours of training over 3 sessions using the PrEP Champion training tools. PrEP Champions will receive more comprehensive detailed training on HIV epidemiology and how to remain updated with the latest data, how to use the adapted sexual history-taking tool, PrEP efficacy, and indications. They will also be supported by an established PrEP Champion on our team to train on and role play, prescribing requirements, nuances to prescribing and fielding questions from adolescents, PrEP adherence support, medical assistance program navigation, and effective curriculum delivery to peers. An education expert member of the scientific team will coach PrEP Champions in effective curriculum delivery. PrEP Champions will also be trained to troubleshoot challenges that may arise and will be encouraged to set up a "community of practice" within their group for check-ins regarding challenges and solutions (eg, through a monthly call or WhatsApp or GroupMe chat). PrEP Champions will also log their time and provider contacts through a web-based app (eg, toggl.com, myhours.com, or text the project coordinator) over 3 months (pretest) and 6 months (pilot). To optimize PrEP-Pro intervention fidelity, PrEP Champions will complete standardized training and use structured protocols. Early training sessions will be monitored. Subsequently, a subset of sessions (at least one additional session per champion) will be audio-recorded and reviewed by the investigators, and a checklist will be developed for a protocol adherence. This will allow for real-time feedback and minimize drift in the approach [71]. After the initial training, PrEP Champions will complete

XSL•FO
RenderX

an evaluation to assess HIV epidemiology, PrEP knowledge, and the acceptability and feasibility of training curricula.

Provider PrEP Education

Other FM trainees will receive 2 hours of case-based real-time sessions with a videoconference hosted by a local PrEP Champion including a 1-hour session on PrEP prescription and a 1-hour session on sexual history taking.

Participants and Eligibility Criteria

Participants will be identified and purposefully selected through FM partner program directors and faculty. The project coordinator will work with site leadership to generate a list and contact details for all practicing FM trainees at the study sites. A random-order list of eligible FM trainees stratified by gender, race, training site, year of training, and age quartiles will be generated. FM trainees will be approached by the project coordinator (via email, phone, or in person) and invited to participate in the pilot program. Reasons for declining will be recorded. Eligibility for PrEP Champions, pretest, and pilot participants will include (1) a licensed HCP (MD, DO) trainee, (2) providing medical care to adolescent girls and young women in Alabama, (3) working in a clinic where at least 20% of the population is Black, and (4) being able or willing to provide informed consent. The aim is to ensure that trainees feel free from coercion by including at least 1 trainee in our CAB. All language within the recruitment materials and consent forms will be explicit that participation in this study is not mandatory nor impacts trainee clinical obligations, clinical evaluations, or standing within the residency program. Participants will be reimbursed for their time.

Primary Outcomes

The primary outcomes to be assessed per our original protocol are PrEP-Pro acceptability and feasibility (Table 1). However, as we engage our CAB and SAB continually and iteratively, these outcomes are subject to evolve based on feedback.

Table 1. Primary and secondary outcomes.

Outcomes and measures	Source of data
Primary outcomes	
• Acceptability of Intervention Measure (AIM): 4 items, 5-point Likert scale • Intervention Appropriateness Measure (IAM): 4 items, 5-point Likert scale • Evidence-Based Practice Attitude Scale (EPAS-15): 15 items, 5-point Likert scale • Feasibility of Intervention Measure: 4 items, 5-point Likert scale • Number screened, eligible, and enrolled • Number or proportion who completes all planned training modules • Number or proportion who contact the PrEP[a] Champion at least once after training	Quantitative data (Survey/Process measures)
• PrEP-Pro Feasibility • PrEP-Pro Acceptability • Willingness to prescribe PrEP	Qualitative data (IDIs[b])
Secondary outcomes	
• PrEP knowledge • HIV epidemiology knowledge • Sexual history taking beliefs and attitudes • Willingness to prescribe PrEP	Quantitative data (Survey)
• Sexual history taking practices • HIV and STI[c] tests or adolescent girls and young women encounters • PrEP prescriptions or adolescent girls and young women encounters	Quantitative data (EMR[d])

[a]PrEP: pre-exposure prophylaxis.

[b]IDI: in-depth interview.

[c]STI: sexually transmitted infection.

[d]EMR: electronic medical record.

PrEP-Pro Acceptability

This will be assessed using three validated instruments: (1) Acceptability of Intervention Measure (AIM), a 4-item instrument with 5-point Likert scale response options [72], (2) Intervention Appropriateness Measure, a 4-item instrument with 5-point Likert scale response options [72], and (3) Evidence-Based Practice Attitude Scale, a 15-item instrument with 5-point Likert scale response options [73].

PrEP-Pro Feasibility

This will be assessed using the Feasibility of Intervention Measure, a 4-item instrument with 5-point Likert scale response options [72]. Additionally, to assess PrEP-Pro feasibility, the number of residents screened, eligible, and enrolled, the time to complete training, the number of participants who complete training, and the number of participants who contact PrEP champions at least once in the quarter after the training (as reported by each PrEP Champion via study logs) will also be described.

XSL•FO
RenderX

To assess these outcomes, FM trainees will complete questionnaires at 0, 3, and 6 months post PrEP-Pro training. Enrolled FM trainees (PrEP Champions, providers who pretest PrEP-Pro, and pilot participants) will complete a baseline questionnaire to capture sociodemographic data (age, race, gender, years of practice, and client volume), PrEP KAB practices, and experiences with PrEP provision. PrEP Champions and providers that pretest PrEP-Pro will complete a posttraining or intervention questionnaire within 3 months of training or 6 months of training for pilot participants. Questionnaires will be completed in REDCap by the participants via a secure link sent to their computer, phone, or other electronic devices.

Secondary Outcomes

Other outcomes will also be assessed including PrEP knowledge, sexual history taking attitudes and practices [74], PrEP prescriptions at adolescent girls and young women encounters, and sexually transmitted infection (STI) and HIV testing at adolescent girls and young women encounters (Table 1). We aim to explore how to optimize PrEP-Pro to maximize acceptability, feasibility, and impact including barriers and facilitators to PrEP-Pro initially adapted intervention.

To assess these secondary outcomes, data will be extracted from electronic medical records at baseline, 3 months, and 6 months after enrollment to provide data on the number of PrEP prescriptions to adolescent girls and young women, HIV testing, and STI testing among adolescent girls and young women in the 6 months before or after PrEP-Pro training. Additionally, IDIs will be conducted with PrEP Champions and pretest participants within 3 months of scheduled training completion. Interview guides will be developed using our conceptual frameworks, a recent review of literature, and input from study team members and the CAB and will focus on challenges, successes, barriers, and facilitators to PrEP prescription to adolescent girls and young women and feasibility, acceptability, anticipated impacts of the draft PrEP-Pro intervention. To plan for the implementation of PrEP-Pro as an intervention strategy to promote PrEP prescription, IDIs will be conducted with 25 pilot participants, 25 adolescent girls and young women who accessed care after the PrEP-Pro pilot, and ~12 other key stakeholders (eg, administrators and support staff) to explore anticipated determinants of implementation based on CFIR [43,75]. PrEP Champions will inform process-level domains, PrEP-Pro pilot providers and adolescent girls and young women will inform individual-level domains, and key stakeholders will inform outer-setting domains. PrEP-Pro will be updated based on any interval innovations in PrEP implementation science and present the findings to the CAB and consultants to seek feedback on implementation determinants. Interviews will be conducted remotely or in an enclosed private location and will last for approximately 45 to 60 minutes. All interviews will be digitally recorded and transcribed.

Sample Size Justification

The plan to pretest PrEP-Pro with 12 providers is consistent with recommendations for pretesting from IM literature [76] and our pretesting sample in prior intervention development. For this pilot study, the importance of sample size lies in establishing acceptability and feasibility and the precision of estimated changes in PrEP prescriptions. There will be a recruitment of 60 FM trainees throughout Alabama. With our sample, we can estimate this measure with a 95% margin of error of 0.26 SD, where SD is the observed standard deviation of the Feasibility of Intervention Measure or AIM score. For example, if we observe an SD of 5, the 95% CI would be ±1.3. Similarly, the margin of error for the change in average PrEP prescriptions 6 months before to 6 months after the intervention is ±0.26 SD.

Ethical Considerations

Ethical approval for phase 1 of the study to assemble a CAB and conduct FGDs was approved by the Institutional Review Board (IRB) at the University of Alabama at Birmingham, Alabama (IRB-300008567). Written informed consent will be obtained from all FGD participants prior to their participation in the study. Both FGD participants and CAB members are compensated US $50 for their time (eg, an hour-long CAB meeting or an hour-long FGD). A separate ethics approval will be obtained from the institutional review board prior to commencing phase 2 of the study. All data will be kept confidential and stored in password-protected software with encryption. Only deidentified data will be reported.

Data Analysis

FGD Analysis

FGDs will be audio recorded, transcribed, and initially analyzed using a structured template and memo-based approach with subsequent transcription and coding [77]. This template approach will consist of team members reviewing the recordings of the FGD, making notes of important themes and responses, and then summarizing the interview content. Using this method, the research team will be able to quickly discuss and apply key data points to the implementation strategy design, and later, a more in-depth analysis of the transcribed discussions will be conducted using content analysis [78,79].

IDI Analysis

IDIs will be audio recorded, transcribed, and analyzed more in-depth using the content analysis approach [78,79].

Two investigators will independently review transcripts to generate an overarching thematic framework for data interpretation. Initial themes will be identified based on the initial readings of a subset of transcripts and guided by our theories or conceptual frameworks (COM-B and CFIR). Themes will be discussed among the scientific team, transcripts will be reread, and themes will be refined based on further review of the transcripts until saturation is achieved. Final themes including major themes and subthemes will be developed. A codebook will be developed with a detailed description of major themes and subthemes. The investigators will compare their thematic frameworks for consistency, and any discrepancies will be discussed until there is agreement on the thematic framework. Using multiple coders also enhances the validity of the analysis [80]. Kappa statistics will be computed to measure agreement between coders (interrater reliability test). Data will be reexamined, messages will be extracted and

XSL•FO
RenderX

highlighted, and the ongoing discussion between coders will allow for further theorizing and interconnections between research questions, coding categories, and raw data (108). Emerging themes will be explored with the CAB and the SAB to enhance the validity of the findings. We will also compare data findings with results from our quantitative data and external review of the literature for consistency. NVivo (QSR International) software will be used to organize data and facilitate analyses.

Statistical Analysis

Descriptive statistics will be calculated to characterize acceptability and feasibility measures collected 3 months (PrEP champions and pretest participants) and 6 months (pilot participants) after enrollment. All scores will be summarized using appropriate descriptive statistics. The number of participants screened, eligible, and enrolled; the proportion of participants who complete all planned training modules; and the proportion of participants who contact the PrEP Champion at least once in the quarter after training will be described. We will also describe the data and compare pre- and post-PrEP prescription or tests per adolescent girls and young women visit with nonparametric measures. Agreement between pre– and post–PrEP-Pro tests for categorical measures will be assessed using the McNemar test bivariate and using multiple logistic regression of post–PrEP-Pro outcomes adjusting for pre–PrEP-Pro measures and covariates. Covariates in adjusted models will include individual providers (such as age and race) and selected setting variables (such as client demographics, number of clients seen per day, and environment toward PrEP). Poisson regressions will determine associations between post–PrEP-Pro count measures (such as the number of PrEP prescriptions) and pre–PrEP-Pro counts, both unadjusted and covariate-adjusted. Similarly, for continuous outcomes (such as percent of adolescent girls and young women with PrEP prescription), Wilcoxon signed rank tests and linear models of post–PrEP-Pro measures would be used. We will examine missing data, but as our primary outcomes are feasibility or acceptability in which missing data (no response) is informative, no adjustments will be made.

Results

Study results will be presented to the CAB members and disseminated to practices, state health officials, and other key stakeholders to solicit feedback on implementation opportunities and challenges to inform a hybrid effectiveness implementation trial. The results of this study will also be presented at local and national conference meetings and submitted to peer-reviewed journals for publication.

Discussion

Principal Findings

This protocol paper describes a research study to develop and pilot a theoretically driven multicomponent intervention, PrEP-Pro, to train and support FM trainees across Alabama on HIV epidemiology, sexual history taking, and PrEP provision for adolescent girls and young women. Although PrEP is a highly effective biomedical intervention that can reduce HIV incidence among adolescent girls and young women, uptake remains low among adolescent girls and young women populations due to several multilevel factors [8,14]. In Alabama, which has been identified in the EHE strategy for the United States as a geographic hot spot due to high rural incidence, almost half of new HIV infections occur in those aged 13-29 years [57]. As PrEP options expand, there is an urgent need for appropriate, contextually relevant training tools to support PrEP implementation. It is anticipated that the PrEP-Pro intervention will result in an increase in PrEP prescriptions for adolescent girls and young women and an expansion of comprehensive sexual and reproductive health care for adolescent girls and young women in rural and urban Alabama.

To our knowledge, this is the first provider intervention that seeks to promote PrEP prescription among adolescent girls and young women in the South. Working with FM trainees is an innovative approach to promoting PrEP provision among clinicians who work with adolescents in rural communities across the United States [35,81]. Adapting PrEP-Pro to trainees provides an opportunity to modify clinician behavior at an early stage of training and help seed the rural health workforce with effective HIV prevention advocates and providers. Combining education specialists in theory-based IM with community engagement allows us to adapt interventions with greater content retention and implementation.

Despite our proposed novel intervention, we acknowledge several limitations. Many PrEP uptake barriers in Alabama are structural, including structural racism, a lack of comprehensive education in school settings, costs to access repeated HIV or STI testing, transportation, and a lack of Medicaid expansion [7,25,26]. While our study aims to target provider-level barriers, delivering multilevel interventions to address client, provider, and structural-level barriers would be ideal. However, structural issues are addressed in other projects our group supports [82-84]. Another limitation is that our study focuses primarily on adolescent girls and young women, and our outcomes will assess PrEP prescriptions for adolescent girls and young women, such that our study findings may not be generalizable to all populations. However, we have developed our PrEP-Pro content and intervention so that FM trainees can support and prescribe PrEP to all populations. Additionally, our PrEP-Pro intervention provides content mainly on tenofovir disoproxil fumarate/emtricitabine PrEP agents, with some content on newer PrEP products (injectable PrEP). Further, there is the possibility of selection bias in those who choose to become PrEP Champions or engage in the pretest and pilot. Lastly, as this is a pilot study, there will be a lack of data to assess long-term changes in outcomes. Future prospective cohort studies with longer periods to assess implementation outcomes and effectiveness outcomes among adolescent girls and young women populations may be warranted.

Conclusions

In conclusion, this study applies implementation and health services research science to adapt strategies to increase provider PrEP prescribing to adolescent girls and young women in the southern United States. As PrEP options expand, there is a

XSL•FO
RenderX

pressing need to train FM practitioners and develop appropriate, contextually relevant training tools to support PrEP implementation. Study findings on the acceptability and feasibility of our PrEP-Pro intervention will help to inform a future hybrid effectiveness-implementation trial.

Acknowledgments

The authors acknowledge and greatly appreciate our CAB members for their time, support, and feedback on this project. This work is supported by funding from the National Institute of Mental Health/NIH/DHHS (R34MH128044).

Data Availability

Deidentified quantitative data sets generated during the study will be uploaded into a data-sharing site to be determined by the research team when the data are cleaned and analyzed. Due to the small sample size and difficulties in redacting qualitative data collected from a small group (FM providers from select programs in a small state), qualitative data with providers will not be shared.

Authors' Contributions

LTM and LE are the principal investigators of the study. OOI drafted the protocol. SVH, BH, DK, DML, MEC, NVW, RGL, and TS contributed to the study design. SVH, MEC, NVM, LE, and LTM read and revised the draft. All authors are involved in the study implementation. All authors approved the final manuscript.

Conflicts of Interest

MEC has received research support (grants to the institution) from Gilead Sciences and Viiv Healthcare, has served on advisory boards for Roche Diagnostics Corporation and Viiv Healthcare, and has received personal fees for educational events from Vindico Medical Education, Practice Point Communications, and Prime Education. LTM has received research support (grants to the institution) from Gilead Sciences.

Abstract

Background: Despite enormous clinical improvements, due to better management strategies and the availability of biologicals, immune-mediated inflammatory diseases (IMIDs) still have a significant impact on patients' lives. To further reduce disease burden, provider- as well as patient-reported outcomes (PROs) should be taken into account during treatment and follow-up. Web-based collection of these outcomes generates valuable repeated measurements, which could be used (1) in daily clinical practice for patient-centered care, including shared decision-making; (2) for research purposes; and (3) as an essential step toward the implementation of value-based health care (VBHC). Our ultimate goal is that our health care delivery system is completely aligned with the principles of VBHC. For aforementioned reasons, we implemented the IMID registry.

Objective: The IMID registry is a digital system for routine outcome measurement that mainly includes PROs to improve care for patients with IMIDs.

Methods: The IMID registry is a longitudinal observational prospective cohort study within the departments of rheumatology, gastroenterology, dermatology, immunology, clinical pharmacy, and outpatient pharmacy of the Erasmus MC, the Netherlands. Patients with the following diseases are eligible for inclusion: inflammatory arthritis, inflammatory bowel disease, atopic dermatitis, psoriasis, uveitis, Behçet disease, sarcoidosis, and systemic vasculitis. Generic and disease-specific (patient-reported) outcomes, including adherence to medication, side effects, quality of life, work productivity, disease damage, and activity, are collected from patients and providers at fixed intervals before and during outpatient clinic visits. Data are collected and visualized through a data capture system, which is linked directly to the patients' electronic health record, which not only facilitates a more holistic care approach, but also helps with shared decision-making.

Results: The IMID registry is an ongoing cohort with no end date. Inclusion started in April 2018. From start until September 2022, a total of 1417 patients have been included from the participating departments. The mean age at inclusion was 46 (SD 16) years, and 56% of the patient population is female. The average percentage of filled out questionnaires at baseline is 84%, which

XSL•FO
RenderX

drops to 72% after 1 year of follow-up. This decline may be due to the fact that the outcomes are not always discussed during the outpatient clinic visit or because the questionnaires were sometimes forgotten to set out. The registry is also used for research purposes and 92% of the patients with IMIDs gave informed consent to use their data for that.

Conclusions: The IMID registry is a web-based digital system that collects provider- and PROs. The collected outcomes are used to improve care for the individual patient with an IMID and facilitate shared decision-making, and they are also used for research purposes. The measurement of these outcomes is an essential step toward the implementation of VBHC.

Introduction

Background

Immune-mediated inflammatory diseases (IMIDs) represent a group of chronic conditions that share common pathophysiological pathways that cause acute or chronic inflammation [1,2]. Any organ system can be affected, resulting in a broad variety of conditions including inflammatory arthritis (IA), inflammatory bowel disease (IBD), cutaneous inflammatory conditions, and several immunologic disorders [1,2].

Many IMIDs are treated with immunosuppressive medication, such as biologicals and disease-modifying antirheumatic drugs [1-9]. Over the years, the innovation of management approaches and the development of new treatment options have led to significant improvement in clinical outcomes [1]. However, IMIDs still have a large impact on patients' lives, including lower quality of life, more disability, and productivity loss [10-12]. Moreover, treatment is also often associated with medication-related adverse events [1,13]. Therefore, we should not only focus on clinical outcomes, such as disease activity measures, but also on outcomes that are relevant for the individual patient.

These "patient-reported outcomes" (PROs) cover topics, such as fatigue, pain, treatment satisfaction, and quality of life, without interpretation by a health care provider [14]. They are measured with PRO measures that mostly consist of validated questionnaires. The measurement of PROs in daily practice has several potential benefits as they could (1) improve care for the individual patient, (2) provide real-world data for research purposes, and (3) serve as a valuable part in the shift toward value-based health care (VBHC).

As PROs provide insight in disease burden and its treatment from a patient's perspective, they could be complementary to conventional clinical measures that are normally used during outpatient clinic visits. The use of PROs in daily practice helps both the physician and patient in preparing the consultation, but also facilitates the prioritization of topics that need to be addressed, resulting in a more efficient and problem-focused consultation [15]. The health care provider may also have the opportunity to tailor the treatment to the patients' needs and recognize problems that might otherwise be overlooked [15]. Moreover, visualizing PROs over time makes it easier for both patient and physician to monitor progress or deterioration of outcomes [15]. Lastly, measuring and reviewing PROs together with the patients could contribute to shared decision-making [16,17]. All these advantages contribute to a more patient-centered care approach.

Data generated within registries can also be used for research purposes. These real-world data are very valuable because they, among others, show us the community effectiveness [18]. Community effectiveness studies often show less benefit than efficacy studies or randomized controlled trials. Community effectiveness is determined by the following variables: efficacy, access (coverage), diagnostic certainty, upholding management guidelines by the treating physician, and patient compliance [18]. Furthermore, the organization and delivery of care may differ between medical specialists who treat IMIDs. For example, current rheumatoid arthritis guidelines do not have a laboratory monitoring program for tumor necrosis factor inhibitors, but the European psoriasis vulgaris guideline has one [19-21]. Another example is the use of therapeutic drug monitoring for tumor necrosis factor inhibitors in daily practice, which is more common in IBDs compared to rheumatic diseases [22,23]. The ability to use these data gives us the opportunity to better understand not only the differences between the organization and delivery of care, but also the differences or similarities in clinical outcomes as well as PROs between IMIDs. These data might help us improve the care of the individual patient through direct implementation of our research findings.

Finally, routine outcome measurements could be the first step toward the implementation of VBHC. VBHC aims to improve care by focusing on value instead of volume [24]. Value is defined as gained health divided by resources spent [24]. Gained health includes clinical outcomes as well as PROs and is therefore broader than we are currently used to [25,26]. As IMIDs are chronic conditions with fluctuating disease activity, longitudinal measurement of outcomes is necessary to evaluate the sustainability of health, incidence of complications, and side effects [25].

Implementation of longitudinal outcome measurement is currently upcoming. This is challenging because both health care providers and patients may find it time-consuming or

XSL•FO
RenderX

impractical [27]. Therefore, there should be a practical way for physicians and patients to report and access these data, which could be through a web-based system. Electronic distribution of surveys before and during outpatient clinic visits has several benefits [28]: (1) patients can fill them out at home, (2) it streamlines the data-entry process, and (3) it allows for computer adaptive testing to reduce user burden. It also allows for easy data visualization and linkage with the electronic health record (EHR) for easy access by the health care providers.

The IMID registry was developed to implement digital routine outcome measurements in daily practice (1) to improve individual patient care, including shared decision-making, (2) for research purposes, and (3) as a first step toward the implementation of VBHC in patients with an IMID.

Objectives of the IMID Registry

The objectives of the IMID registry include (1) improving patient care on an individual level through a patient-centered care approach, including shared decision-making; (2) collecting real-world data for research purposes, including evaluating community effectiveness; and (3) implementing VBHC for patients with IMIDs, for which—in our opinion—collection of patient- and provider-reported outcomes is a fundamental component.

Methods

Study Design

The IMID registry is a single-center prospective cohort within the Erasmus MC in Rotterdam, the Netherlands. Patients are recruited from the departments of rheumatology, immunology, gastroenterology, and dermatology. A steering committee was also formed and included representatives of all participating departments. All representatives were involved in the design of the registry and selection of outcome measures. The cohort combines provider-reported outcomes and PROs. On request, clinical and administrative data can be exported from the EHR and pharmacy database. These data may include disease activity measures, the number of outpatient clinic visits in a certain time period, laboratory results, and medication, including administration and dosage.

Patients

All adult patients diagnosed with one of the following conditions are eligible: IA (rheumatoid arthritis, psoriatic arthritis, juvenile idiopathic arthritis, and spondyloarthritis), atopic dermatitis, psoriasis, IBD (Crohn disease and ulcerative colitis), uveitis, Behçet disease, sarcoidosis, or systemic vasculitis. Patients are excluded if they have insufficient knowledge of the Dutch language or are unable to fill out web-based questionnaires. Health care providers of each department ask eligible patients for informed consent, after which patients are included in their specific trajectory of the registry, which is based on the diagnosis that is made by the treating physician.

Outcome Measures

For IBD and IA, the questionnaires were aligned with the corresponding International Consortium for Health Outcomes Measurement (ICHOM) outcome sets to make sure that all recommended questionnaires were included in the registry [29,30]. Generic and disease-specific outcomes that are used for each diagnosis include disease activity, disease damage as a result of active disease or complications (eg, changes in anatomy, physiology, pathology, or function), disease-specific and generic quality of life, treatment satisfaction, side effects, medication adherence, beliefs about medication, work productivity, disability, fatigue, and substance use. If available, validated questionnaires are used to measure these PROs. To reduce patient burden, the shortest versions of the questionnaires are used. See Table 1 for overarching outcomes and Table 2 for disease-specific outcomes. These outcomes can be linked to data from the EHR, such as medication, health care use, and disease duration.

Generic Outcomes

Patient- and Physician-Reported Side Effects

Because health care providers might underreport side effects, both patients and physicians are asked about the occurrence of side effects [66]. If any side effects occur, respondents are asked to clarify the time of onset, severity, and if there are any persisting side effects after medication dosage was changed or stopped. The physician is asked to clarify if medication is switched or if additional medication (eg, antibiotics) is needed.

Beliefs About Medication

The Beliefs About Medicine Questionnaire has been validated for assessing medication beliefs in patients with somatic chronic illnesses and consists of a specific and general section [31,32]. For this cohort, we only use the "specific" section that measures patient beliefs about the necessity of prescribed medication to treat their disease and their concerns about potential adverse events of taking the medication. All questions are rated on a 5-point Likert scale. Higher scores indicate stronger beliefs about necessity of their medication or concerns.

Medication Adherence

The 5-item Medication Adherence Report Scale is used to assess nonadherence to medication using a 5-point Likert scale [33]. It addresses nonadherence in a nonjudgmental way, encourages patients to answer truthfully and avoid socially desirable answers. Higher scores indicate higher levels of self-reported adherence.

Treatment Satisfaction

Patients are asked to indicate their feeling of satisfaction with the effect of their current treatment on disease activity on a visual analog scale (VAS) from 0 to 100. Higher scores indicate higher treatment satisfaction.

Fatigue

This questionnaire asks patients to rate their fatigue level in the last 7 days using a numeric rating scale of 1 to 10. A higher score corresponds with more fatigue experienced.

(Health-Related) Quality of Life

(Health-related) quality of life is measured with 2 different questionnaires: the 5-level EQ-5D and the Patient-Reported Outcomes Measurement Information System (PROMIS-10) [34-37]. The 5-level EQ-5D is used to measure utility scores based on the Dutch reference values and consists of 5 questions representing 5 dimensions of health, namely, mobility, self-care, daily activities, pain and discomfort, and anxiety and depression [34,35,67]. Each dimension can be scored on a 5-point Likert scale. Higher scores indicate more reported problems in the stated health dimension. The sixth question consists of a VAS general health.

The PROMIS-10 measures general health-related quality of life using 10 questions on physical, mental, and social health, pain, fatigue, and overall perceived quality of life [36,37]. Answers are given using a 5-point Likert scale or a VAS from 0 to 10. Outcomes are summarized into a summary score for global physical health and global mental health with accompanying *t* scores that compare the patients' health to the general population.

Work Productivity

The Work Productivity and Activity Impairment questionnaire [41] measures sick leave or unemployment (absenteeism) and work impairment due to the disease (presenteeism) during the past 7 days. The questionnaire contains 6 questions regarding the effect of disease on work and productivity.

Other Questionnaires

Over the years, some of the used questionnaires have changed or have been adapted based on feedback from health care providers and patients. These questionnaires are shown in Tables 1 and 2.

Disease-Specific Outcome Measures

For each disease (group), disease-specific outcome measures were chosen. They cover outcomes about disease activity and damage, quality of life, functional ability, side effects, and productivity loss. These outcome measures along with their accompanying questionnaires are shown in Table 2.

Patient and Public Involvement

Patients were not involved in the design of the registry, but our patient participation panel and included IMID registry patients will be regularly asked to evaluate the questionnaire system,

XSL•FO
RenderX

including the number and relevance of the questionnaires. The registry will be optimized based on their feedback.

Data Collection

To limit user burden, the questionnaires are divided over different time points. At baseline and 2 weeks before the outpatient clinic visits, an invitation to fill out new questionnaires is sent to the patient by email. The health care providers fill out the surveys during or right after the consultation. After 1 year, the questionnaires are filled out yearly. However, an exception is made for patients with IA, IBD, and atopic dermatitis, because they are asked to fill out questionnaires before each outpatient clinic visit or at fixed intervals, which were added on request of the participating departments. Surveys are filled out using a web-based questionnaire form (LimeSurvey) [68]. The questionnaires are managed by a data capture system (GemsTracker) [69], which is integrated in the EHR.

Data Visualization

Data are accessible through a web-based form, which is linked to the EHR. PRO scores are shown in the same manner as, for example, laboratory results and are also directly accessible through the EHR and visualized in graphs over time. For IA and atopic dermatitis, a dashboard has been developed, which allows visualization of several outcome measures over time in a comprehensive manner.

Training and Monitoring of the Implementation Process

Group trainings were given at the participating departments on the usage of the registry and how to access the data from the EHR. During the implementation phase, health care providers were supported during their consultations on the use of the data and how to discuss and interpret the PRO outcomes with the patients, including shared decision-making. Every 3 months, the IMID steering group comes together to discuss the progress of the registry, and every month multidisciplinary (scientific) meetings are held for all participating health care providers.

Ethics Approval

The IMID registry is a quality of care improvement initiative. Therefore, written informed consent is not mandatory for this purpose. Patients are asked by their health care provider to participate and give oral informed consent. In the web-based questionnaire form, they can opt-in for the use of their pseudonymized data for future scientific research. The Medical Ethics Committee of the Erasmus MC deemed the study to not be subject to Dutch law (WMO; Medical Research Involving Human Subjects Act) and provided a waiver (MEC-2018-1075).

Results

The IMID registry is an ongoing cohort with no end date. Inclusion started in April 2018. Until September 2022, a total of 1417 patients have been included in the registry. The included patients belong to the dermatology (n=477, 34%), immunology (n=153, 11%), gastroenterology (n=327, 23%), and rheumatology (n=460, 32%) departments.

The mean age at inclusion was 46 (SD 16) years, and 56% of the included patients are female. In Table 3, the demographics and baseline response rates are given, stratified for medical specialty. A total of 84% of patients filled out their questionnaires at baseline, which declined to 72% after 1 year of follow-up. In addition, a total of 92% of patients gave written informed consent for usage of their pseudonymized data for research purposes.

Table 3. Demographics and baseline response rate stratified for medical specialty.

Medical specialty	Response rate,[a] n (%)	Age (years), mean (95% CI)	Sex (female), %
Dermatology[b] (N=477)	378 (79)	41 (39-42)	43
Immunology[c] (N=153)	126 (82)	50 (47-52)	58
Gastroenterology[d] (N=327)	314 (96)	46 (44-47)	53
Rheumatology[e] (N=460)	415 (90)	49 (47-51)	68

[a]Percentage of patients who filled in the patient satisfaction questionnaire at baseline.

[b]Atopic dermatitis, psoriasis, and unclassified dermatologic diseases.

[c]Uveitis, Behçet disease, sarcoidosis, and systemic vasculitis.

[d]Crohn disease and ulcerative colitis.

[e]Rheumatoid arthritis, psoriatic arthritis, juvenile idiopathic arthritis, and spondyloarthritis.

Discussion

The IMID registry is a web-based system linked to the EHR that collects provider-reported outcomes and PROs. These outcomes are not only used to improve care for the individual patient with IMIDs including facilitation of shared decision-making, but they are also used for research purposes. Moreover, routine outcome measurements are an essential component in the implementation of VBHC. The registry has been used by the departments of rheumatology, gastroenterology, dermatology, and immunology, since 2018. Over the years, the outcome sets have been improved and adapted based on feedback from health care providers, patients, and current scientific insights. During the first 4 years, more than 1400 patients were included, which represents a broad uptake from all participating departments.

Previous publications have shown that patients with IMIDs may cope with lower quality of life, more disability, increased

XSL•FO
RenderX

fatigue, pain, and productivity loss, but they also have more psychiatric comorbidity and medication-related adverse events [1,10-13,70]. The questionnaires were chosen to cover all aforementioned topics in a comprehensive manner to best reflect our overall health status of patients with IMIDs, but we also included the domains that matter most to our patients.

We chose to use generic questionnaires for several types of IMIDs, since these diseases may share common problems and patients may suffer from overlapping conditions within the IMID spectrum [1]. These diseases also share treatment strategies that may cause similar adverse events [1-9,13]. Generic questionnaires about these topics may lead to (1) evaluation of outcomes across patients with different conditions, (2) feedback from a larger patient-panel, and (3) improvements through the steering group's broad perspective.

Although the IMID registry has improved over the years, the cohort has some limitations. First, patients did not participate in the design of this registry. Currently, the IMID registry has been evaluated by 42% (n=467) of the patients that filled out a questionnaire in the past year. The survey included questions on the use of the system and length and content of the questionnaires. They also provided feedback on which topics they would like to discuss during consultations. The registry was adjusted based on their feedback. A couple of examples are rephrasing of some questions to make them more understandable, lowering the number of questionnaires before each visit, and changing the user interface to make them accessible for phone or tablet users. These evaluation rounds will be planned regularly.

The generalizability of the registry might be limited due to selection bias. Not all treating physicians use the registry during their outpatient clinic visits, and also not all patients are included or fill out their questionnaires. This could be due to the fact that patients cannot read or understand Dutch, have problems using a digital system, or the fact that the PROs are not discussed during consultation. Moreover, only patients who need specialized care are treated at the Erasmus MC. Finally, patients who tend to avoid care may cause nonresponse or selection bias. Although most of the included patients filled out their questionnaires at baseline, this percentage declines during follow-up. This is partly due to patients not filling out the questionnaires, but also on occasion, the questionnaire were not sent to the patient before the follow-up visit. In the near future, we hope to address these limitations by automatic inclusion of patients, giving them the opportunity to fill out questionnaires in the waiting room as well as by providing validated questionnaires in different languages. Providing more information about the use of the data, automatic distribution of questionnaires, as well as providing feedback about the filled out questionnaires during every consultation could also increase the response rate during follow-up.

We will also keep improving the IMID registry to optimize its relevance and feasibility. Currently, data are collected and visualized using a separate data collection tool, which is linked to the EHR. In the future, we will incorporate data collection directly into the EHR, as well as making it possible for the patient to visualize the data in a mobile app. Although routine outcome measurements are—in our opinion—a fundamental component in the implementation of VBHC, we hope to incorporate more VBHC principles in the future, as well as collaborating with other hospitals in the region, which has already been established for IBD and will soon be established for rheumatology [71].

In conclusion, the IMID registry provides a web-based outcome measurement system, which could facilitate the principles of VBHC, improve care on an individual patient level, and provide real-world data for research purposes.

Protocol

Evaluation of the Effectiveness of a Whole-System Intervention to Increase the Physical Activity of Children Aged 5 to 11 Years (Join Us: Move Play, JU:MP): Protocol for a Quasiexperimental Trial

Abstract

Background: Daily physical activity is vital for the health and development of children. However, many children are inactive. Previous attempts to achieve sustained increases in daily physical activity in children have been ineffective. Join Us: Move Play (JU:MP) is a whole-system, complex, community-based intervention aiming to increase the physical activity levels of children aged 7 to 11 years who live in areas of Bradford, England, which are multicultural and have high levels of deprivation.

Objective: The purpose of this quasiexperimental controlled trial is to assess whether the JU:MP program increases primary school children's physical activity.

Methods: The study has a 2-arm, quasiexperimental, nonblinded, nonequivalent group design and will be conducted with primary school children aged 5 to 11 years at 3 timepoints, including baseline (before intervention), 24 months (during intervention), and 36 months (after intervention). Children attending primary schools within the intervention area will be invited to participate. Children attending similar schools within similar neighborhoods based on school and community census demographics (deprivation, free school meals, and ethnicity) outside of the JU:MP geographical area will be invited to participate in the control condition. At each timepoint, consenting participants will wear an accelerometer for 7 consecutive days (24 hours a day) to measure the primary outcome (average daily moderate-to-vigorous physical activity). Multivariable mixed effects linear regression will be applied to estimate differences in the primary outcome between the 2 arms at 24 months and 36 months on an intention-to-treat basis. The secondary outcome analysis will explore changes in socioemotional well-being (teacher reported), quality of life (parental/carer reported), and other contextual factors (parents/carer reported), as well as segments of the day activity, sleep, sedentary screen time, frequency of places to be active, parent practices (nondirective support and autonomy support), social cohesion, and neighborhood walking/exercise environment.

Results: Recruitment occurred from July 2021 to March 2022, and baseline data were collected from September 2021 to March 2022. As of March 2022 (end of baseline data collection), a total of 1454 children from 37 schools (17 intervention schools and 20 control schools) have been recruited. The first follow-up data collection will occur from September 2023 to March 2024, and the second and final follow-up data collection will occur from September 2024 to March 2025. Data analysis has not begun, and the final results will be published in December 2025.

Conclusions: This article describes the protocol for a quasiexperimental controlled trial examining a novel whole-system intervention.

Introduction

Background

Daily physical activity, particularly of moderate-to-vigorous intensity, is very beneficial for the physical, emotional, and social development of young people [1,2], and is preventive for the early onset of diseases and disorders [3-5]. This importance is enhanced when considering physical activity behaviors tracked through childhood into adulthood [6-9]. All 4 nations of the United Kingdom, along with the World Health Organization, recommend that children aged 5 to 18 years should engage in moderate-to-vigorous–intensity physical activity for an average of 60 minutes a day [10]. Since the publication of government guidance, evidence has shown that engaging in daily light-intensity physical activity [11] or increasing daily moderate-to-vigorous activity by an average of 10 minutes a day [12] can be beneficial for children and young people.

Worryingly, levels of inactivity are high across the globe [13,14]. Much effort has been made to combat levels of inactivity among young people [15,16], but previous interventions have been generally unsuccessful, especially in the medium to longer term [16,17]. The reasons for the lack of success so far include poor study design, poor methodology, and not considering the full complexity of physical activity, which is a behavior with much variance and heterogeneity across different groups and populations [16,17]. Previous interventions have only generally been discrete, simple, and 1-dimensional [16,17], although it has been over 3 decades since McLeroy et al [18] proposed that health promotion interventions and policies should consider every aspect of society from the social to physical environment, to individual personal traits. This socioecological perspective theorizes that change in such a complex behavior is not likely to occur just through individual motivation and desire alone, but instead through influencing every aspect of the socioecological model and wider system of society, to seek and promote more human movement. The challenge to decrease physical inactivity among all members of society, particularly children and young people, is only going to be addressed if future interventions and programs have a *systems thinking philosophy* and fully embrace the whole socioecological model within intervention and program planning and implementation [19]. The International Society of Physical Activity and Health supports this perspective with the publication of "Eight investments that work for physical activity," which advocates whole-system change across 8 domains, including schools, communities, travel, urban design, health care, workplaces, mass media, and sports and recreation [20].

In response to the growing realization of a need for whole-system approaches to physical activity, Sport England (a nondepartmental public body, which is the largest funder of physical activity and sport programs in England) funded 12 local delivery pilots over a 5-year period (2019-2024), to design and implement a whole-system place-based approach to reduce physical inactivity and health inequalities. All of the selected pilot areas are characterized by high levels of deprivation, but target different populations (eg, older people and whole communities), with the Join Us: Move Play (JU:MP) program being delivered in Northern areas of the City of Bradford, targeting children and young people aged 5 to 14 years. Bradford is the 7th largest metropolitan district in England and is home to more than half a million people. A quarter of Bradford's population is under the age of 16 years, making Bradford the "youngest" city in the United Kingdom [21,22]. Bradford is a culturally rich and ethnically diverse city with over 40% of children and young people being of South Asian heritage [23]. However, Bradford (city area) falls in the most deprived quintile of the index of multiple deprivation (IMD), with 60% of the population living in the poorest 20% of wards in England and with 24% of children living in poverty [21,22]. Given the high childhood population in Bradford and given that there is an inverse association between physical activity levels and age during childhood [24], successfully increasing physical activity for the child population in Bradford could have far reaching public health positives for the city in the future. For this reason, the JU:MP program is focused on increasing physical activity in the 27,000 children and young people aged 5 to 14 years and their families living in the area. This article details a protocol for the effectiveness evaluation of the JU:MP program and is part of a wider evaluation plan (including process evaluation – development, implementation, and evaluation), details of which have been described previously [25].

Aims and Objectives

The aim of this quasiexperimental trial is to explore whether JU:MP is effective at increasing physical activity among children aged 5 to 11 years. The specific research objectives are as follows:

1. Determine the effectiveness of JU:MP to increase device-measured (accelerometry) mean average daily moderate-to-vigorous physical activity among children aged 5 to 11 years 24 months and 36 months after the implementation of a whole-system community intervention.
2. Determine the effectiveness of JU:MP to improve secondary outcomes among children aged 5 to 11 years 24 months and 36 months after the implementation of a whole-system community intervention. The secondary outcomes are as follows: (1) mean average daily, weekday, and weekend day sedentary time (device measured [accelerometry]); (2) mean average daily, weekday, and weekend day light physical activity (device measured [accelerometry]); (3) weight status and body fat level (waist circumference and

XSL•FO
RenderX

BMI); (4) socioemotional well-being, including prosocial behavior, emotional problems, behavioral problems, peer problems, and hyperactivity/inattention (teacher reported); and (5) children's quality of life (parental reported).

3. Undertake exploratory subgroup analysis (ie, neighborhood level and school level) investigating the change in the primary and secondary outcomes.
4. Investigate the potential meditating effects of changes in contextual factors (JU:MP is seeking to change; parental reported): (1) home physical activity, (2) school time physical activity, (3) children's sedentary screen time behaviors, (4) active travel and street physical activity, (5) parent practices (nondirective support and autonomy support), (6) neighborhood social cohesion, (7) neighborhood walking/exercise environment, (8) religious setting physical activity, (9) physical activity during sports and recreation, and (10) park/green space physical activity.

Methods

Intervention: JU:MP Program

A more comprehensive description of the JU:MP program can be found in the report by Hall et al [25]; a brief summary is contained herein.

The JU:MP program (Figure 1 outlines the SPIRIT [Standard Protocol Items: Recommendations for Interventional Trials] schedule [trial design and timescales]) is a whole-system, complex, community-based intervention that was originally developed in 2018 with underlying themes, a framework (settings, tools, and principles), and a theory of change being informed by community consultations, community priority setting workshops, data from the Born in Bradford research program [26-28], international peer-reviewed evidence [29,30], and the socioecological model [18,31]. After a period of development and piloting (2019-2020), the JU:MP program model was developed (Figure 2) [25]. The JU:MP program includes 15 interacting work streams, which include a focus on, for example, embedding physical activity in policy, parks and green spaces, communications and social marketing, and organizations including schools and faith settings. The program is being implemented within 8 distinct geographic "neighborhoods" within the Bradford local delivery pilot area (see Multimedia Appendix 1 for a map of the local delivery pilot neighborhoods). Neighborhood boundaries were based on having an area of green space with potential for development, at least 4 to 5 primary schools, and an active community organization. This hyper-local scale of whole-system delivery aims to foster genuine collaborative working and build strong sustainable relationships. Using an asset-based community development approach, JU:MP facilitates the development of an action group within each neighborhood, including key organizational partners, community members, and families. To allow the program to meet local needs and facilitate longer-term behavior change, the action group is responsible for designing and implementing change at the local level. Initially, the neighborhood approach was operationalized within 3 "pioneer neighborhoods" (2019-2021) to pilot and develop the program. Subsequently, the program will be delivered in the 5 remaining neighborhoods (2021-2024) to cover the whole local delivery pilot area. The remaining 5 neighborhoods are further broken down into those that are directly facilitated by the JU:MP team (n=3) and those whose delivery will be externally commissioned (n=2). Differences between implementation models are to permit examination of how JU:MP could be implemented differently in the future in different communities. The process evaluation outlined by Hall et al [25] will explore such differences; for the purposes of the trial described in this protocol, only effectiveness will be examined in the directly facilitated neighborhoods. The reason for this is a mixture of research capacity and a focus on the effectiveness of the fully developed JU:MP program.

Figure 3. Join Us: Move Play (JU:MP) program neighborhood, quasiexperimental, nonequivalent group trial. EQ-5D-Y: EuroQol 5-dimension youth version; PedsQL: Pediatric Quality of Life Inventory.

Setting

The research will be situated within primary schools located across the Northern English County of West Yorkshire. Recruitment and data collection are taking place through primary schools as they are located within JU:MP neighborhoods, and children tend to live in close proximity to the school they attend. Primary schools allow access to a large number of children as potential participants, and previous research has shown that it is feasible and acceptable to conduct physical activity trials through primary schools [32].

Identification of Neighborhoods

The JU:MP program is operating in 8 distinct neighborhoods. The 3 neighborhoods eligible for participation in this effectiveness trial are the 3 direct-delivery neighborhoods of JU:MP. Control neighborhoods will be based on local authority wards (local areas with elected officials representing the local area) and be in the county of West Yorkshire in order to ensure that neighborhoods would be politically and geographically similar to the JU:MP neighborhoods. Other neighborhoods/wards in Bradford have been excluded due to potential intervention contamination. Control neighborhoods

XSL•FO
RenderX

must ideally have similar characteristics to the JU:MP neighborhoods to maximize internal validity. The process of identifying control neighborhoods will include pooling state-funded primary school census data [33], which are released from schools annually, for every ward in West Yorkshire and then calculating the median/mean of (1) the value of the school postcode-derived IMD (IMD 2019) [34]; (2) the proportion of children eligible for state-funded free school meals (school population measure of deprivation); and (3) the proportions of the 2 predominant ethnic groups in the 3 JU:MP areas (White British and South Asian heritage [combining Pakistani heritage, Bangladesh, Indian, and other South Asian ethnic groups]). Ward areas deemed to be suitable control areas must have no more than 1 IMD decile median difference than a JU:MP neighborhood and no more than 10% difference in the proportion of children eligible for free school meals, and the predominant ethnic group (majority or large minority) must be the same as that in a JU:MP neighborhood with ideally no more than 15% difference.

Recruitment of Schools

Once the neighborhoods are selected, government-funded primary schools located in the JU:MP and control neighborhoods will be invited to participate in the research. The number of control schools recruited will be dependent on the recruitment of intervention schools in the neighborhoods to the study. Private and designated special schools have been excluded from this study. Identified schools will be contacted via standardized emails and follow-up phone calls (48 hours later) to request and arrange an in-person/virtual meeting to discuss the study and school-level consent. The primary schools in the JU:MP neighborhoods will be part of the JU:MP program and will receive whatever benefits may be derived from participating in the program. The primary schools within the control areas will not be offered access to the JU:MP program and must agree in principle not to commit to any whole-system school physical activity research in the next 3 years. To incentivize such a commitment, each of the primary schools in the control areas will be offered a total of £600 (US $727), with the caveat that this should not be spent on physical activity provision (physical education, active travel, after school clubs, etc) for the duration of the 3-year study. The £600 (US $727) payment will be split into 3 instalments of £200 (US $242) to be paid after the competition of each of the 3 study data collections (baseline, 24-month follow-up, and 36-month follow-up). If the school agrees to participate in the study, arrangements will be made to begin recruiting children.

Recruitment of Children

All children in years 1, 2, and 3 (ages 5-8 years) at recruited schools will be invited to participate. Members of the research team will agree with school leadership on how best to speak and discuss about the study with all children in the school, but this will likely involve a researcher speaking to each class individually or the year groups collectively during a school assembly. Children will be provided with printed study information sheets and consent forms to take home for their parents/carers. The research team will ensure all forms are distributed to each class teacher and forms are sent home with children in book bags or school planners/diaries so that parents/carers can make an informed decision about whether their children can participate in the study. To ensure parents/carers have an opportunity to discuss the study with the research team, a time and day when they can attend a presentation and a question-and-answer session (within the school or virtually) will be arranged within a week of the information sheets and consent forms being issued. The research team will also seek to agree on times and days when researchers can be present in the school playground before and after school (pick up and drop off time). Short videos will also be produced, which will explain the study, and schools will be asked to distribute links of the videos (ie, YouTube) to parents. For children to participate, their parents/carers must provide informed consent. On the day of data collection, 2 members of the research team will discuss the study with each child and obtain verbal assent. For children with special educational needs/disabilities and those who do not have the capacity to provide assent, the research team will instead seek assent from a school staff member familiar to the child, with the child present. All children participating will receive a gift “goodie bag” worth an estimated £2 (US $2.42), which will include nonphysical activity–related items such as a book, stickers, and other similar items. The goodie bag will be given to each child at each data collection timepoint (baseline, 24 months, and 36 months).

Materials

Primary Outcome Assessment: Accelerometry

The primary outcome assessment of this study will involve waist-worn accelerometry. At each timepoint, researchers will support children to fit an accelerometer (ActiGraph) worn on a belt around the child’s waist, just above the right hip. Children will receive a demonstration by a member of the research team, showing them how to fit the accelerometer. Children will be asked to wear the accelerometer for 7 consecutive days (24 hours a day; only to be removed for showering, bathing, and swimming). Children will be told that if it is uncomfortable to sleep in, they can remove it for sleep and wear it when they wake-up. ActiGraph data will be analyzed using ActiLife v6 (ActiGraph) and downloaded in 60-second epoch files. Sleep will be removed using validated sleep period–detection algorithms [35,36] (requiring 60-second epochs for this process) to produce sleep start and sleep end times. To ensure consistency with the chosen calibration of cut points and therefore increase validity [37], data will be reprocessed using 15-second epoch data in order to correspond with Evenson cut points [38] to classify time spent being sedentary, in light physical activity, and in moderate-to-vigorous physical activity. Sleep time will be removed by treating the sleep start and end times as sleep diaries within ActiLife. Nonwear time will be defined as 20 minutes of consecutive zeros and will be removed from the data. A valid day for inclusion in the analysis will be a minimum of 600 minutes, and children with at least 3 days of wear time, including at least 1 weekend day of data, will be included in the analysis. This wear-time criterion has been calculated using local Bradford data and has an estimated intraclass correlation of 0.75 [26].

XSL•FO
RenderX

Child Demographics and Anthropometric Data

After the receipt of parental/carer consent, researchers will request school-stored demographic data, such as date of birth, unique pupil number (linked to health records), biological sex, ethnicity, home postcode (for IMD calculation), child's disability or special educational needs, and receipt of government-funded free school meals, from participating schools. The immediate request is to ensure the research team can plan provisions for any children with any additional needs during testing. On the first day of data collection, the research team will ask schools to provide the most recent attendance records and educational attainment data, and a copy of the class timetable for 2 weeks starting from the date of data collection (for accelerometry data collection). Anthropometric measurements will include weight, height, BMI, and waist circumference; all will be measured by trained researchers within the school setting. Weight will be assessed barefoot and in light clothing using a digital scale (eg, Tanita body composition analyzer SC-240MA III). Height will be measured unshod, with the head placed in the correct position, on a Seca 213 stadiometer (graduation=1 mm). BMI will be calculated and converted to a BMI percentile and z-score based on UK reference data [39]. Waist circumference will be measured using a Seca 201 tape (graduation=1 mm).

Children's Socioemotional Well-being (Teacher Rated)

In order to measure children's socioemotional well-being, class teachers of the recruited children will be asked to complete an assessment of the child's behavior and socioemotional development using the strengths and difficulties questionnaire (SDQ) [40]. The SDQ is a short questionnaire (25 items) on positive attributes of the child as well as difficulties. The items are grouped into the following 5 subscales: "prosocial behavior" (ie, being helpful), "emotional problems" (ie, unhappiness), "behavioral problems" (ie, conduct problems), "peer problems" (ie, friendless), and "hyperactivity/inattention" (ie, restless). The SDQ teacher version has been found to have acceptable validity for evaluating psychosocial functioning in children [41].

Physical Activity, Sedentary Behavior, Sleep, and Quality of Life (Parent/Carer Rated)

On the day of data collection, children will be given a questionnaire to give to their parents/carers, which takes an estimated 20 minutes to complete. Parents/carers will complete this questionnaire at all 3 timepoints. Parents/carers will be asked to complete the questionnaire about their children's life, rather than asking the children themselves, due to the young age of the children at baseline (5-8 years), which limits questionnaire comprehension and increases the risk of social desirability bias. The purpose of collecting such questionnaire data is to attempt to understand potential mediating factors of children's accelerometer-measured physical activity. The content aligns with key components of JU:MP. This questionnaire has been piloted with groups of parents/carers living in West Yorkshire and has been deemed acceptable. The questionnaire comprises 6 sections. The first section relates to personal information of the children, including their name, school class, teacher's name, age, and relationship with the person completing the questionnaire. The second section is the youth activity profile (YAP) [42], which is a published child-answered questionnaire. However, for this trial, parents/carers will be required to complete the questionnaire (due to the young age of the children), which entails reporting the frequency and duration of physical activities engaged in through segments of a usual day (ie, before school, break time at school, lunch at school, and after school). The YAP is also used to estimate sedentary behaviors of the children while watching television, playing video games, using a mobile phone, and using a computer/tablet during the previous 7 days. The third section asks parents/carers to report the normal time their children go to bed and wake-up on weekdays and weekend days, in order to calculate average sleep time [43]. The fourth section asks questions about where the children are physically active and has 3 parts. In the first part, parents are asked to indicate places their children engage in physical activity for more than 10 minutes, and how many days their children have visited the place in the previous 7 days. The places are prespecified and include inside the home, garden/yard, street/streets around the home, organized sport or physical activity, swimming pool/leisure center, community center, religious setting (ie, madrassa, church, or temple), and any other places. The second part asks questions for those of the Muslim faith, and focuses on whether and how often their children have attended a mosque or madrassa in the last 7 days, what time they arrived and left, and whether they actively travelled to and from the mosque or madrassa. These questions were included because the neighborhoods of the JU:MP program have large proportions of Muslim families whose children may attend a mosque or madrassa weekly [27]. The third part includes questions regarding children's frequency of being active in parks and green spaces (ie, public gardens and playfields). The fifth section of the questionnaire comprises a series of questions asking parents/carers to consider their own parenting practices when it comes to physical activity (autonomy promotion and nondirective support), and how they themselves consider their own neighborhood (neighborhood social cohesion) and the walking/exercise environment characteristics of their neighborhood. These questions are taken from 2 validated questionnaires [44,45]. In the sixth section of the questionnaire, parents/carers will be asked to answer questions regarding their children's quality of life, which comes from the parent-reported version of the EQ-5D-Y (EuroQol 5-dimension youth version) [46-48] and PedsQL (Pediatric Quality of Life Inventory) [49].

Sample Size and Power Analysis

A sample size calculation was performed using Stata V.16 (StataCorp), with the function "power two means cluster," factored in 6 clusters (3 intervention neighborhoods and 3 control neighborhoods), and a 5% 2-sided alpha, as well as an assumed control average daily value of moderate-to-vigorous physical activity of 53.7 minutes, a SD of 19.7, and an intracluster correlation (ICC) value of 0.007, which was conservatively rounded up to 0.01. As the JU:MP project is a neighborhood/community-level intervention and no previous studies using accelerometry as an outcome assessment among children or young people could be identified, the values of average daily moderate-to-vigorous physical activity, SD, and ICC were derived from an unpublished pilot study (sample size n=564; 3 neighborhoods; 12 primary schools). The missingness

XSL•FO
RenderX

of data was conservatively factored into the sample size calculation by assuming 30% accelerometer noncompliance at baseline, followed by further 50% loss of data (30% accelerometer noncompliance and 20% attrition) at both the 24-month and 36-month follow-ups. The parameters outlined led to a minimum recommended sample of 1200 children (600 per condition, 200 per neighborhood, and 32 per school) for adequate power (80%) to detect a change of at least 10 minutes in the primary outcome of average daily minutes of moderate-to-vigorous physical activity at both the 24-month and 36-month follow-ups.

Data Analysis

Data will be entered electronically with a double data entry protocol using REDCAP software. Data will be kept on a secure file storage system, which will also be password protected. Data will be anonymized by the assignment of a unique identification number (study ID) to each participant. The primary comparative analysis (objective 1) will be performed on an intention-to-treat basis, including all participants recruited and without imputation for missing data. Multivariable mixed effects linear regression will be used to estimate differences in the primary outcome (accelerometer-assessed mean daily minutes of moderate-to-vigorous physical activity) between the intervention and control groups. Demographic variables of gender and ethnicity will be treated as random effect variables, and baseline moderate-to-vigorous physical activity, age, accelerometer wear time, BMI z-score, school, neighborhood, and condition will be treated as fixed effect variables. Similar analyses will be repeated for secondary outcomes (objective 2). A sensitivity analysis, using a suitable imputation method, will be conducted to assess the effect of missing data. *P* values and 95% CIs will be calculated. A small number of prespecified subgroup analyses will be carried out to evaluate whether the intervention is differentially effective in different subgroups, such as by neighborhood and school (objective 3). The trial is not powered to detect effectiveness in subgroups, and this analysis will be treated as exploratory, presented using CIs, and interpreted with caution. Mediation analysis using structural equation modeling will be applied to look at whether any intervention effect is mediated by potential determinants (objective 4), including (1) home physical activity, (2) school physical activity, (3) children's sedentary screen time behaviors, (4) travel and street physical activity, (5) parent practices (nondirective support and autonomy support), (6) neighborhood social cohesion, (7) neighborhood walking/exercise environment, (8) religious setting physical activity, (9) physical activity during sports and recreation, and (10) park/green space physical activity, which the JU:MP program could have impacted based on the complexity of the program. Multimedia Appendix 2, Multimedia Appendix 3, and Multimedia Appendix 4 present 3 directed acyclic graphs that show the simple mediating pathways to be examined, the potential causal pathways between meditating variables, and the potential casual pathways between confounders (sex, ethnicity, age, socioeconomic status, and weight status), respectively.

Ethical Considerations

This study and all processes were given ethical approval by the University of Bradford Research Ethics Committee (Humanities, Social, and Health Sciences Research Ethics Panel; reference: E891). Informed consent will be sought from schools and parents. Children (participants) will also be asked to provide assent at every data collection timepoint. Schools in the control condition will be paid £600 (US $727) overall (£200 [US $242] for every data collection [baseline, 24-month follow-up, and 36-month follow-up]), and children will be given a "goodie bag" (includes books, stationery, and stickers) worth £2 (US $2.42) as a thank you each time they complete data collection. All data collected will be deidentified and anonymized by using ID numbers and storing all data on secure National Health Service servers, and only the principal investigator and senior researcher will have access to confidential information. All questionnaire data will be double data entered into secure databases created within RedCap.

Results

This study has been registered at ISRCTN (ISRCTN14332797). Recruitment occurred from July 2021 to March 2022, and baseline data collection occurred from September 2021 to March 2022. As of March 2022 (end of baseline data collection), a total of 1454 children from 37 schools (17 intervention schools and 20 control schools) have been recruited. The first follow-up data collection will occur from September 2023 to March 2024, and the second and final follow-up data collection will occur from September 2024 to March 2025. Data analysis has not begun, and the final results will be published in December 2025.

Discussion

This paper describes the protocol for a quasiexperimental, nonblinded, nonequivalent group design trial of the JU:MP program, a complex, community, whole-system children's physical activity intervention. The research outlined in this protocol seeks to explore whether the JU:MP program is effective at increasing the physical activity levels of children aged 5 to 11 years. The recruitment of this trial and baseline data collection have been completed, with 1454 children from 37 schools (17 intervention schools and 20 control schools) being recruited. This number indicates overrecruitment according to the power-calculated target of 600 children per condition (N=1200) and puts the future of this trial in good stead for follow-ups at 24 and 36 months.

Many children and young people do not engage in enough physical activity, with those from ethnic minority backgrounds and economically deprived backgrounds being at greater risk for inactivity and related ill-health. Previous attempts to change children's physical activity have largely been unsuccessful [15,16]. Moves to more complex interventions using the socioecological model and whole-system approach have increased public health, especially with regard to obesity and physical activity [19,25]. Effectiveness research of whole-system approaches for obesity has been mixed and unclear [50,51]; however, no known effectiveness evaluation has occurred for a whole-system children's physical activity intervention. The

XSL•FO
RenderX

JU:MP program is a complex long-term whole-system intervention (≥2 years) in economically deprived neighborhoods with high proportions of people from ethnic minority groups. The planned and ongoing trial is one of the largest trials ever conducted with an accelerometry outcome measure, which if successful (recruitment and retention rates meet power calculations) will contribute to wider academic public health research by being able to assess the effectiveness of a whole-system approach, which is only currently theorized to be able to change the health of large populations. This effectiveness research is part of a wider body of research with complex process evaluations occurring simultaneously in order to fully examine the full complexity of a whole-system intervention and produce different types of knowledge about a phenomenon that can be combined to further advance knowledge [25,52]

As with all research, there are limitations with the proposed work detailed in this protocol. Namely, the quasiexperimental design of the work naturally has an increased risk of bias when compared with a randomized controlled trial, which is the gold standard way to detect the effects of programs and interventions [53]. However, a randomized controlled trial would not have been feasible for the JU:MP project due to the growing and developing nature of the program in preselected areas of Bradford [25]. Thus, we decided to seek to reduce the risk of bias with matching of neighborhoods based on key descriptive statistics. Another limitation of this work is the reliance on parental/carer and teacher proxy reports, which reduces the validation and reliability of the measures being taken. The reliance on proxy measures is due to the young age of the participants who will not have the capacity to accurately complete questionnaires on key health behaviors (screen time, modes of physical activity, and sleep) and secondary health outcomes such as quality of life and emotional well-being. However, the use of accelerometry as an outcome assessment overcomes the capacity issue of younger children and provides a more objective tool to measure the complex behavior of physical activity.

Many attempts have been made by researchers, practitioners, and policy makers to address children's physical inactivity. However, previous attempts have been unsuccessful in both intervention design and the application of complex evaluations. Lack of success leads to children's physical activity levels stagnating or worsening, increasing the risk of ill-health and negatively impacting the growth and development of young people. Sport England, the largest funder of sports and physical activity in England, has invested significant funds in 12 geographical areas in England to increase physical activity through a place-based whole-system approach. Methodologically rigorous and high-quality research is required to examine what works, why, for whom, and in what context, in order to understand the potential of whole-system approaches for increasing children's physical activity, and whether and how they can be replicated [25]. Research evaluating one of the geographical areas (the JU:MP project in the City of Bradford) seeks to achieve this endeavor. This protocol outlines the effectiveness part of the evaluation.

Acknowledgments

We are grateful for the funding provided by Sport England to implement and evaluate the program. The authors wish to thank the JU:MP team and wider stakeholders, including colleagues within Born in Bradford and ActEarly, including Dr Brian Kelly, for their inputs in developing the trial design. This work was also supported by the UK Prevention Research Partnership (MR/S037527/1), which is funded by the British Heart Foundation, Cancer Research UK, Chief Scientist Office of the Scottish Government Health and Social Care Directorates, Engineering and Physical Sciences Research Council, Economic and Social Research Council, Health and Social Care Research and Development Division (Welsh Government), Medical Research Council, National Institute for Health Research, Natural Environment Research Council, Public Health Agency (Northern Ireland), The Health Foundation, and Wellcome.

Data Availability

This is not applicable at present as this is a protocol article. However, future and final data sets will be available from the corresponding author and a Born in Bradford (BiB) executive on reasonable request. Scientists are encouraged and able to use BiB data, which are available through a system of managed open access. The steps below describe how to apply for access to BiB data.

Before you contact BiB, please make sure you have read our guidance for collaborators. Our BiB executive reviews proposals on a monthly basis, and we will endeavor to respond to your request as soon as possible. You can find out about the different data sets available. If you are unsure if we have the data that you need, please contact a member of the BiB team. Once you have formulated your request, please complete the "Expression of Interest" form available and send it to borninbradford@bthft.nhs.uk. If your request is approved, we will ask you to sign a collaboration agreement, and if your request involves biological samples, we will ask you to complete a material transfer agreement.

Conflicts of Interest

None declared.

Abstract

Background: On the national level, nutritional monitoring requires the assessment of reliable representative dietary intake data. To achieve this, standardized tools need to be developed, validated, and kept up-to-date with recent developments in food products and the nutritional behavior of the population. Recently, the human intestinal microbiome has been identified as an essential mediator between nutrition and host health. Despite growing interest in this connection, only a few associations between the microbiome, nutrition, and health have been clearly established. Available studies paint an inconsistent picture, partly due to a lack of standardization.

Objective: First, we aim to verify if food consumption, as well as energy and nutrient intake of the German population, can be recorded validly by means of the dietary recall software GloboDiet, which will be applied in the German National Nutrition Monitoring. Second, we aim to obtain high-quality data using standard methods on the microbiome, combined with dietary intake data and additional fecal sample material, and to also assess the functional activity of the microbiome by measuring microbial metabolites.

Methods: Healthy female and male participants aged between 18 and 79 years were recruited. Anthropometric measurements included body height and weight, BMI, and bioelectrical impedance analysis. For validation of the GloboDiet software, current food consumption was assessed with a 24-hour recall. Nitrogen and potassium concentrations were measured from 24-hour urine collections to enable comparison with the intake of protein and potassium estimated by the GloboDiet software. Physical activity was measured over at least 24 hours using a wearable accelerometer to validate the estimated energy intake. Stool samples were collected in duplicate for a single time point and used for DNA isolation and subsequent amplification and sequencing of the 16S rRNA gene to determine microbiome composition. For the identification of associations between nutrition and the microbiome, the habitual diet was determined using a food frequency questionnaire covering 30 days.

Results: In total, 117 participants met the inclusion criteria. The study population was equally distributed between the sexes and 3 age groups (18-39, 40-59, and 60-79 years). Stool samples accompanying habitual diet data (30-day food frequency questionnaire) are available for 106 participants. Current diet data and 24-hour urine samples for the validation of GloboDiet are available for 109 participants, of which 82 cases also include physical activity data.

Conclusions: We completed the recruitment and sample collection of the ErNst study with a high degree of standardization. Samples and data will be used to validate the GloboDiet software for the German National Nutrition Monitoring and to compare microbiome composition and nutritional patterns.

Introduction

Within the last decade, there has been a huge increase in research in the field of the human microbiome, leading to a new body of knowledge in this area. It is now well established that the human intestinal microbiome is an essential mediator in the interplay between diet and host physiology. Initiatives like the HDHL-INTIMIC Knowledge Platform on Food, Diet, Intestinal Microbiomics, and Human Health [1] were founded to collect and extend this knowledge by fostering multidisciplinary projects.

Many associations between diet and the microbiome have been described, for example, correlations of the long-term diet with differences in gut microbiota composition and functions [2-7]. However, until now, only a small part of gut microbiota variation has been attributed to nutrition [8]. The usual dietary pattern has a strong influence on microbiota composition, as has been shown for plant-rich diets such as the Mediterranean diet, vegetarian or vegan habits, and the abundance of *Prevotella* species [9-12]. It is important to understand how nutrition impacts microbiota, as a disturbance in the latter (dysbiosis) has been associated with many diseases, including diet-related diseases such as obesity and type 2 diabetes. Many studies have been performed on such specific topics, but the results are often inconsistent or even contradictory [13-15]. Such a variety of results can be partially explained by differences in the study population, but also by a lack of standardization of methods, including sample preparation, technology, and bioinformatic analysis [16-18].

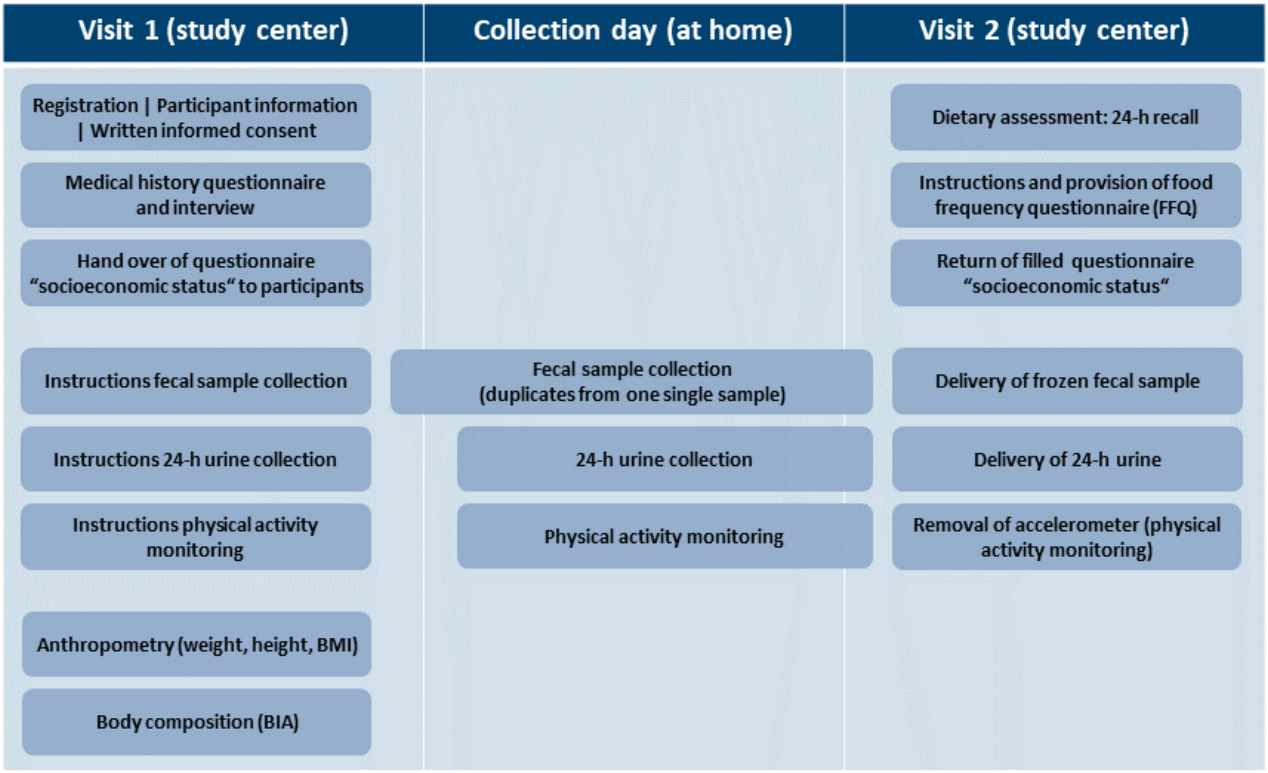
Besides the importance of standard methods to determine the microbiome composition, the assessment of reliable representative dietary intake data also requires standardized and validated tools that are up-to-date with recent developments in food products and the nutritional behavior of the population. In Germany, the Max Rubner-Institut (MRI) is responsible for the national nutrition monitoring of the adult population and has so far conducted the second German National Nutrition Survey [19] and the longitudinal study NEMONIT [20]. National nutrition monitoring serves to assess food consumption, nutritional status, and nutritional behavior of the general population and specific population groups. In addition, trends in the nutritional behavior of the population can be monitored. The data are used to update national food-based dietary guidelines, to perform risk assessment by food consumption of the population toward chemical substances in food items, and to serve as decision support for national and European statutory rules. Sound and representative data on nutrition are, therefore, essential for policy-making, answering scientific questions, providing information on the population, and making national and international comparisons.

In this context, the European Food Safety Authority (EFSA) developed methodological guidelines for data assessment in national food consumption surveys [21,22]. Accordingly, 24-hour recalls should be applied to national nutrition monitoring as a dietary assessment method for the adult population. The software GloboDiet (previously EPIC-Soft; International Agency for Research on Cancer), developed as a software platform for a standardized, structured interview, fulfills the EFSA recommendations and thereby provides data with the required detail and quality for national nutrition monitoring [23,24]. In some countries across the European Union, GloboDiet is used for the assessment of representative detailed food consumption data [25,26]. GloboDiet was adapted for the German food market. For example, new foods available on the food market were added and obsolete foods were deleted. In addition, adjustments were made to the description and quantification of the foods in accordance with the abovementioned objectives of the German National Nutrition Monitoring. The standard units to assess the consumed quantity of different food items were updated, and the descriptions of the foods were adjusted to enable analyses of the consumption of ultraprocessed foods.

The ErNst (“Erfassung der Energie- und Nährstoffzufuhr”; English “assessment of energy- and nutrient intake”) study was conceived to address two independent objectives: (1) to verify whether food consumption, as well as energy and nutrient intake of the German population, can be recorded validly by means of the current version of the dietary recall software GloboDiet for the German National Nutrition Monitoring and (2) to obtain biosamples and high-quality data for an exploratory assessment of associations between dietary intake, microbiome composition, and microbial metabolites (as a proxy for functional activity of the microbiome). The purpose of this manuscript is to provide a comprehensive description of the study protocol and the methods used for the collection of biosamples and dietary intake data, combined with an overview of the number of samples and data points that will be available for further analysis.

Methods

Study Design and Setting



The ErNst study was designed as a cross-sectional observational study and performed at the Division of Human Studies of the Department of Physiology and Biochemistry of Nutrition at the MRI, Karlsruhe, Germany, between October and December 2018. On day 1, all volunteers visited the study center for registration, further instructions, application of the accelerometer

XSL•FO
RenderX

device, and initial measurements (visit 1, Figure 1). Furthermore, participants were informed about the study procedures and gave their written consent (see also Ethics Approval). Either on the first or second day after the initial visit, participants collected stool and 24-hour urine samples at home (collection day) and brought them on the second visit to the study center the day after (visit 2). Questionnaires and interviews on nutritional intake were also completed on this day.

During visits 1 and 2, the participants underwent a series of standardized examinations described in detail below. For all interviews, examinations, measurements, sample collection, sample preparation, and storage, standard operating procedures were developed and tested for feasibility. Interviewers and examiners had been extensively trained and supervised during data collection.

Figure 1. Overview of the ErNst (Erfassung der Energie- und Nährstoffzufuhr) study days. Collection day was either on the first or second day after visit 1. Visit 2 followed immediately the day after collection day. BIA: bioelectrical impedance analysis.

Participants

Female and male volunteers aged 18-79 years without any known or apparent acute or chronic illnesses or diseases were eligible to participate. Detailed inclusion and exclusion criteria are listed in Textbox 1. Health status questionnaires were used to assess medical history, including potential confounding variables like the use of antibiotics within the last 12 months and smoking status.

Recruitment procedures included direct communication with previous study participants and MRI employees and their families, the use of flyers and other information materials provided to institutions in and around Karlsruhe, information about the study on MRI's homepage, and word of mouth. Initially, 230 interested persons contacted the study center (Figure 2). Those who passed an initial telephone interview (done with a checklist) were scheduled for their first study visit (n=133). Reasons for the exclusion of interested persons are also given in Figure 2. Participants included in the study were asked to complete a questionnaire regarding their marital status, partner relationship status, household size (the number of people living in the household, including children), net monthly household income, school education (highest school-leaving qualification), and occupational qualification.

Since the software GloboDiet shall be validated for the German National Nutrition Monitoring of the adult population, we recruited the participants of the ErNst study according to 3 preselected age groups (18-39, 40-59, and 60-79 years). The proportion of men and women in the respective age groups was equal, as was the total number of participants in each of the 3 groups.

XSL•FO

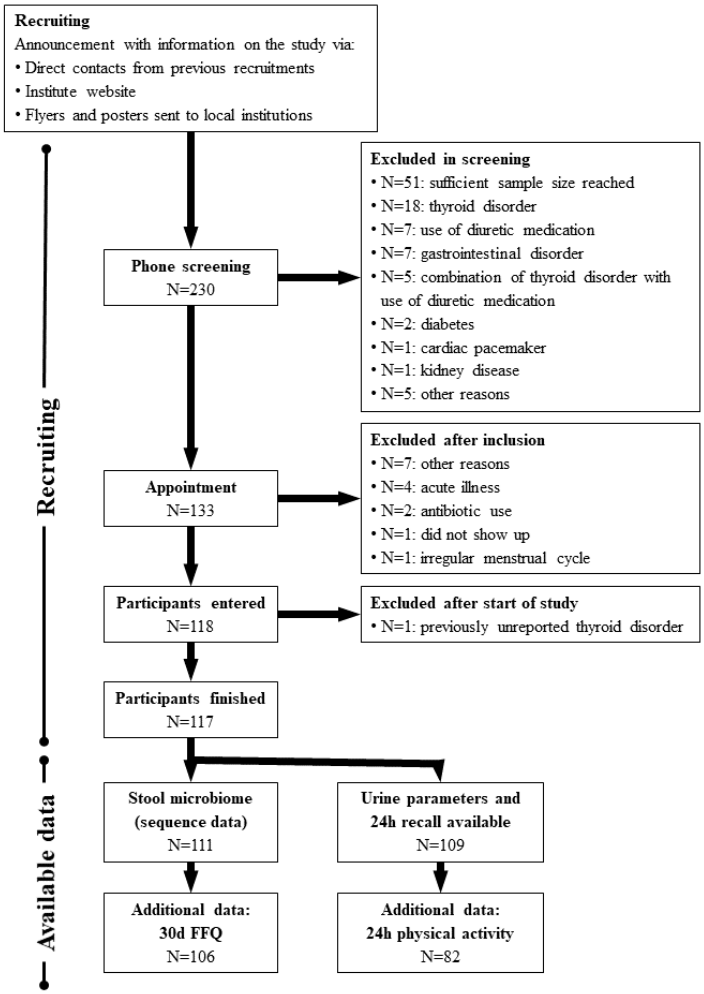
Textbox 1. Criteria for inclusion and exclusion.

Inclusion criteria



- Healthy female or male
- Able to complete all planned examinations, interviews, and questionnaires
- Written consent to participate voluntarily in the study
- Aged between 18 and 79 years

Exclusion criteria

- Pregnant or breastfeeding
- Diabetes mellitus
- Renal disease
- Use of diuretics
- Hyper- or hypothyreosis
- Currently on diet to reduce weight
- Technical implants (such as pacemaker)
- Amputation of arms or legs
- Diseases and treatments leading to malabsorption of energy and nutrients
- Blood donation within last 4 weeks
- Insufficient German language to complete interviews
- Use of antibiotics within last 12 months
- Tumors requiring therapy
- Acute or chronic infectious disease
- Abuse of drugs or alcohol
- Likely failure to comply with study conditions
- Persons who are kept in an institution by court or official order
- Failure or unwillingness to provide written consent of participation

XSL•FO
RenderX

Figure 2. Flowchart describing the recruitment process and available data points of the ErNst (Erfassung der Energie- und Nährstoffzufuhr) study. The bifurcation of the available data separates long-term and short-term (current) data points. FFQ: food frequency questionnaire.

Anthropometric Measurements and Assessment of Body Composition

Anthropometric data were assessed using standard methods. Participants were asked not to eat or drink for 4-5 hours before the examination.

Body weight was measured to the nearest 0.05 kg in light clothing without shoes, and height was measured to the nearest 0.1 cm using the seca 285 measurement station (seca). Both parameters were used to calculate the respective BMI (kg/m²).

Bioelectrical impedance analysis (BIA) was used to assess body composition with the measurement device Nutriguard-MS (Data Input GmbH) using multifrequency technology (5.50-100 kHz; 0.8 mA). The analysis was conducted with NutriPlus software (version 5.3.0; Data Input GmbH).

Assessment of Physical Activity and Calculation of Total Energy Expenditure

The activity energy expenditure (AEE) was determined using accelerometers (ActiHeart from CamNtech) for at least 24 hours. Here, the heart rate was recorded together with the acceleration data, so that activities that took place in a sitting position and where the subject itself experienced little acceleration (eg, cycling) could also be adequately depicted. The software used for programming and reading out the acquired data was the ActiHeart software (version 4.0.131; CamNtech).

Resting metabolic rate (RMR) was calculated according to the formula of Müller et al [27] and considered fat-free mass as well as fat mass and the age of the participants.

Dietary-induced thermogenesis (DIT) accounts for about 10% of the energy content of the consumed food [28-30]. Total energy expenditure (TEE) was calculated using the following formula: TEE (kcal) = RMR (kcal) + AEE (kcal) + DIT (kcal)

Assessment of Current Food Consumption by Applying the Software GloboDiet (24-Hour Recall) and Calculation of Energy and Nutrient Intake

During the second visit to the study center, the food consumption of the participants was assessed face-to-face by trained interviewers using the software GloboDiet. The software was adapted to the current German food market and modified for use in the German National Nutrition Monitoring of the adult population. The structure and standardization procedures of GloboDiet have been described in detail elsewhere [24]. For the 24-hour recall, participants were asked in detail about their food and beverage consumption, as well as the use of dietary supplements on the previous day. Corresponding to a first so-called quick list of the consumed foods and beverages in

XSL•FO
RenderX

chronological order of the meals, the reported food items were further described by facets and descriptors (eg, the applied preparation method, the preservation method, the flavor, and the fat content). Consumed quantities were assessed with a picture book, household measurements, as well as standard units. Interviews were conducted on Mondays, Wednesdays, and Thursdays, leading to results of food consumption on Sundays, Tuesdays, and Wednesdays, representing a balanced coverage of weekdays and weekends, which was intended regarding the validation of the GloboDiet software.

Based on the assessed food consumption, energy and nutrient intake were calculated using data from the German Nutrient Database version 3.02 [31].

Acquisition of Habitual Diet (30-Day Food Frequency Questionnaire)

The 48-item food frequency questionnaire (FFQ) that was used in this study is an adapted version of the validated 53-item FFQ applied in the German Health Examination Survey for Adults 2008-2011 [32]. The ErNst FFQ, therefore, includes questions on the frequency and amount of food groups consumed during the past 4 weeks. The questionnaire was given and explained to the participants on their second visit to the study center, with the request to complete it at home and return it. Frequencies for the consumption of food items were asked according to prespecified categories: never, once a month, 2-3 times a month, 1-2 times a week, 3-4 times a week, 5-6 times a week, 1 time per day, 2 times per day, 3 times per day, 4-5 times per day, and more than 5 times per day. Furthermore, participants had to report the portion sizes of the food items consumed in predefined answering categories. Portion sizes were based on common household measures such as a cup, a glass, a tablespoon, and so on, and, where applicable or necessary, supported by pictures to aid participants in estimating their usual intake. Habitual nutrient intake was calculated using the German Nutrient Database version 3.02 [31].

24-Hour Urine Collection

The 24-hour collection of urine by the study participants took place the day before the 24-hour dietary recall (visit 2). The study participants were provided with 2 urine collection containers (volume 2 liters, Sarstedt AG & Co) and were asked to store the urine at home in the refrigerator or in a cool bag with prechilled thermal packs to keep the collected urine permanently cool. This cool bag was also used to ensure the chilled transport of the urine collection until delivery to the study center. Urine collection was performed according to a standard protocol. On the first visit to the study center, participants were instructed by a study nurse and were given a protocol with written instructions and documentation. Subjects were interviewed about any difficulties during 24-hour urine collection on the second visit day (delivery of 24-hour urine). Urine samples were excluded from the analysis in case of collection errors, for example, if the collection time was interrupted, incomplete, or less than 20 hours, or if the first-morning urine was not discarded as described in the standard protocol.

Creatinine was analyzed as a reference value for potential urinary analytes using a method modified from Slot [33] and Heinegård and Tiderström [33,34] with the Urinary Creatinine Detection Kit from Arbor Assays (Ann Arbor) according to the manufacturer's protocol. The creatinine excretion in urine was also used to estimate the completeness of the urine collection. Creatinine is formed during the breakdown of creatine or creatine phosphate. This occurs almost exclusively in muscle tissue; therefore creatinine excretion in the urine is related to muscle mass or fat-free body mass. Since creatinine excretion in urine is subject to intraindividual fluctuations and depends on the creatine or creatinine content of food [35], it is only suitable for a rough estimate of the completeness of the 24-hour urine collection.

Stool Sampling and Storage

Study participants were provided with a prepacked stool collection kit ("Easy Sampler," GP Medical Devices A/S) and received precise oral instructions and a written manual for the sampling procedure. Each participant collected 2 independent, approximately nut-sized samples from the same stool. Samples were frozen at –20 °C immediately after collection, delivered frozen to the study center, and then stored at –80 °C until aliquoting. After all the samples were collected, multiple aliquots of 200 mg and 500 mg were kept at –80 °C until further analysis. One aliquot per sample was immediately transferred to and frozen in NucleoSpin Bead Tubes Type A (Macherey-Nagel GmbH & Co) for DNA extraction (see Microbiome Analysis).

Analysis of Biomarkers in Urine

Overview

The validation of the German GloboDiet version will use an approach with nitrogen and potassium urinary excretion as biochemical markers for protein, as well as potassium intake [36,37]. Nitrogen and potassium excretion were chosen because errors are likely to be independent between the measurements of biomarkers and dietary intake [38,39].

Nitrogen Content

Total urinary nitrogen was quantified by the Kjeldahl method using automated digestion and distillation units (Digestion Unit K-35, KjelFlex K360, Büchi). Concentrated sulfuric acid and Hg- and Se-free Kjeldahl catalyst tablets (Merck) were used for digestion. Titration was done with 0.05 M sulfuric acid. Individual urine volumes and an assumed specific gravity of urine of 1.020 g/mL were used to convert the nitrogen content into grams of nitrogen per 24 hours. The reference range for the specific gravity of urine is between 1.010 and 1.030 g/mL. The Karlsruhe Metabolomics and Nutrition (KarMeN) cohort [40] was used as the reference population.

Sodium and Potassium Content

Sodium and potassium measurements were performed in an accredited clinical laboratory (MVZ Labor PD Dr Volkmann and colleagues) using ion-sensitive electrodes.

In order to obtain the excreted urinary sodium and potassium amount per day, the respective concentrations (mmol/L) were

XSL•FO
RenderX

converted into g/d while taking the volume of urine and the respective molar masses into account.

Osmolality

Osmolality in urine was measured using the freezing point osmometer, Advanced Osmometer Modell 2020 (Advanced Instruments LLC), and values were expressed in mOsm/kg. These values can be used as reference values for potential urinary analytes to be measured in the future.

Analysis of Stool Samples (Intestinal Microbiome)

Single aliquots of the 2 independent stool samples collected from each subject were used for DNA extraction using the NucleoSpin DNA Stool Kit (Macherey-Nagel). The 200 mg of stool, previously transferred to the bead tubes, were incubated with 850 µL lysis buffer at 70 °C for 5 minutes. A bead beating step was included using a FastPrep 24 machine (MP Biomedicals) at 6.0 m/s for 40 seconds, followed by washing and elution according to the kit's standard protocol. The purity and concentration of the extracted DNA were checked on a NanoDrop microvolume photometric device. The variable region V4 of the prokaryotic 16S rRNA gene was amplified in a single polymerase chain reaction (PCR) step with dual indexing primers as described by Kozich et al [41] with a modification to increase sensitivity toward Archaea [42] (Multimedia Appendix 1). Phusion Hot Start II DNA Polymerase (Thermo Fischer Scientific) was used in a 25 µL reaction mix with 1 ng template DNA, 0.5 µM of each PCR primer (forward and reverse), 0.2 mM dNTP mix, 0.25 µL enzyme, and 5 µL 5x HF buffer. The PCR program included initial denaturation for 2 minutes at 98 °C, 25 cycles of 30 seconds at 98 °C, 10 seconds at 55 °C, and 15 seconds at 72 °C, followed by terminal elongation for 5 minutes at 72 °C. PCR products were purified using magnetic beads (Mag-Bind RXNPure Plus, Omega) and their concentration was measured using a Quantus Fluorometer (Promega) with the QuantiFluor One dsDNA System (Promega), according to the manufacturer's recommendation. The PCR products were pooled at an equimolar concentration in 2 independent libraries that were subsequently sequenced on the Illumina MiSeq platform using a MiSeq Reaction Kit v3 with 2 × 301 cycles at a final concentration of 8 pM, adding 20 mol% of PhiX DNA.

Sample Size Calculation

The sample size was based on the validation of the 24-hour recalls using the difference between energy expenditure (EE) and energy intake (EI) as the end point. The statistical power for a paired *t* test of the hypotheses H_0: EI – EE = 0, H_1: EI – EE ≠ 0 was calculated by the Leibniz Institute for the Social Sciences (GESIS) in Mannheim, Germany. Statistical parameters were estimated using data from a study by Biltoft-Jensen et al [43], as this study used comparable methods for the estimation of EE and nutrient excretion. For an effect size d = (EE – EI)/SD (EE – EI), significance level α=.05, and group sizes of 50 female and 50 male participants, the statistical power was calculated to be >0.998. To prevent an age bias, the group sizes were distributed evenly to the 3 age groups, that is, recruiting at least 17 participants per sex and age group.

The second aim of the study, the analysis of microbiome composition and its association with nutrition, is exploratory and not hypothesis-driven. Therefore, no additional power or sample size calculations were required for this part of the study.

Ethics Approval

The study has been performed in accordance with the Declaration of Helsinki. It was approved by the Ethics Committee of the State Medical Chamber of Baden-Württemberg (EK LÄK BW; F-2018-055) in October 2018 and registered at the German Clinical Trials Register (DRKS00015216). All participants were informed in detail about the purpose of the study, examination procedures, measurements, and potential risks involved. Participants signed their consent to the procedures and the analysis of pseudonymized data, including their potential use for research related to nutrition and health. Privacy and confidentiality of personal data are guaranteed by following the regulations of the State Medical Chamber and the EU General Data Protection Regulation. Pseudonymization was achieved by assigning randomized subject identifiers. All participants received €50 (US $56.50) in compensation upon inclusion in the study.

Results

Recruitment of potential participants involved an initial telephone screening of 230 people who were interested in participating, of whom 133 were selected based on exclusion criteria (Figure 2). After their assignment to the study, 16 subjects had to be excluded for various reasons (Figure 2). Overall, a total of 117 participants completed the 2 visits to the study center (Table 1, Multimedia Appendix 2).

For 109 participants (57 women and 52 men), food consumption and nutrient intake data, assessed by a face-to-face 24-hour dietary recall, are available. The participants were equally distributed among the age groups (18-39 years of age: 36; 40-59 years of age: 35; 60-79 years of age: 38). Urine samples collected during a 24-hour period were provided and suited for analysis in 109 cases (nitrogen and osmolality measurements failed in 2 cases that could not be validly reproduced).

ActiHeart records were not complete in 27 cases, mostly because of the detachment of the device or similar technical problems that resulted in measurements shorter than the required 24 hours. Physical activity data were obtained for 82 of the 109 participants for which urine and current food consumption data were collected.

Nearly all participants provided the requested stool samples, but a few reported irregularities during sampling (eg, potential contamination with toilet water) that led to the exclusion of the samples from further analyses. A final available number of 111 stool samples, each consisting of 2 replicates, were attained.

FFQs were completed by 106 participants (53 women and 53 men) who also provided valid stool samples, equally distributed over the age groups (18-39 years of age: n=37; 40-59 years of age: n=31; and 60-79 years of age: n=38).

Discussion

Principal Findings

Within the study, 117 participants completed the recruitment. After the subtraction of some errors in sample collection and measurements, 106 stool samples are available with corresponding data on common nutrition (30-day FFQ). In addition, 109 face-to-face 24-hour recalls were conducted (data on current nutrition), with corresponding urine samples and measured urine parameters. For 82 of these data sets, additional data on physical activity have been collected.

The 2 main aims of the study were to collect samples and data for (1) validating the dietary recall software GloboDiet and (2) for studying the association between diet and the intestinal microbiome. The 117 participants who successfully completed the study were equally distributed with respect to sex and age groups. However, the fraction of participants with a BMI above 25 kg/m² was lower in the study (females: 18/61, 29.5%, males: 27/56, 48.2%) than observed in the official representative statistics of the German population in 2017 (females: 43.1%, males: 62.1%, data set 12211-9018 in the Genesis database [44]). In addition, the average level of education is high in the study population. Therefore, the study population could be somewhat biased toward a healthier lifestyle, including nutrition and activity, than would be expected in the general population.

For the validation of the updated GloboDiet version, protein and potassium intake determined with the software will be compared with the excretion of protein and potassium in the 24-hour urine collection. In addition, EI calculated from the 24-hour recall will be compared to TEE and RMR. To estimate the validity of the current GloboDiet version, different methods will be applied, like the Wilcoxon-signed rank test to test if the differences between nutrient excretion and nutrient intake, as well as TEE and EI, are different from zero, Spearman rank correlation coefficients to assess the strength of the correlations, as well as Bland-Altman plots [45,46]. Bland-Altman diagrams are suitable for visualizing measurement differences. In addition, participants will be grouped into tertiles to assess the agreement in ranking participants regarding nutrient intake and excretion, as well as EI and TEE. Furthermore, for EI, cutoff values according to Goldberg et al [47] and Black [48] will be calculated for group levels as well as for individuals.

With the samples collected in this study, we plan to further analyze the association between habitual diet and gut microbiota. The microbiota analysis will include single parameters (alpha-diversity and abundance of single taxa), which will be compared with specific food groups or nutrient intakes to identify biologically significant associations. More complex data, like beta diversity of the microbiome and dietary patterns, will be compared by means of ordinations or group categories like enterotype and dietary pattern (using both a priori and a posteriori approaches, such as principal component and principal coordinate analysis, reduced rank regression, or dietary indices). Thereby, we also aim at identifying which level of dietary data yields potential explanations for the observed microbiota variations (eg, dietary pattern, food group, or nutrient level). As a similar composition of the gut microbiota can lead to different activities and functions of this complex and versatile ecosystem within the host, it is important to look not only at the present bacteria but also at the metabolites they produce. Therefore, the fecal content of short-chain fatty acids and bile

XSL•FO
RenderX

acids will also be determined. Correlation analyses between nutrition parameters and these functional indicators of microbial activity will further enhance the obtained information on associations between the microbiome and nutrition.

Besides the 2 primary aims of the study, the set of valuable samples and data offers opportunities for further analyses. The availability of 24-hour urine samples with corresponding information on nutrient intake, for example, enables the search for biomarkers associated with specific foods or food constituents. This data can be further enhanced or validated using data from the KarMeN study that was previously performed at the MRI [40].

Limitations

The study population was not recruited representatively. Therefore, the average BMI of study participants was lower than generally observed in the German population, indicating a potential bias toward healthier nutrition and lifestyles among the participants. With regard to recruitment, the focus was based on the sample size of the study population needed for the validation of the 24-hour recalls. A total of 50 women and 50 men provided sufficient statistical power for the planned analyses. However, the number of participants was comparatively low for the analysis of the microbiome, limiting the resolution to identify fewer common associations, for example, between nutrition and microbial features. Microbiome analysis based on 16S-rRNA genes is limited to identifying taxonomic composition, but available samples offer opportunities to measure metabolite concentrations or sequence the metagenomes to enable deeper insights.

A further limitation is that TEE was not measured using a doubly labeled water technique. This method has been shown to provide an accurate measure of the TEE [49-51]. At the time when the study was conducted, the use of doubly labeled water was not possible due to time and cost constraints.

Comparison With Prior Work

During the KarMeN study, the metabolomes of blood and urine samples from 301 participants were analyzed, enabling the identification of biomarkers for dietary intake [40]. In comparison, while lacking blood samples, ErNst includes urine samples that are available for metabolomics and adds the opportunity to measure the intestinal microbiome and metabolome using the collected stool samples.

Conclusions

We completed the recruitment and collection of samples and data for the ErNst study with a high degree of standardization. This enables the validation of the GloboDiet software, which will be used in the German National Nutrition Monitoring. In addition, microbiome composition and nutritional patterns will be compared to investigate functional associations and potential biomarkers.

Acknowledgments

We gratefully acknowledge the excellent assistance of Martina Broßart, Tanja Gadau, Eva Hoch, Susanne Jonatzke, Ulrike Rossi, and Ute Stadler-Prayle during recruiting, preparations, care of volunteers, sample management, and analyses. Selina Chabauty and Rebecca Seeger for microbial DNA isolation and amplification; Lilia Wiest, Melanie Huch, and Dominic Stoll for Illumina MiSeq sequencing; Iris Schwald for excellent assistance in planning and assessing the FFQs; Julia Geerlings, Anne Hirchenhein, Sigrun Pape, and Katrin Pfeiffer for participant interviews and 24-hour recalls; Diana Bunzel and Sepp Dieterich for nitrogen analytics; and Judith Lauvai for language editing.

Data Availability

In accordance with the informed consent of the ErNst (Erfassung der Energie- und Nährstoffzufuhr) participants, pseudonymized study data could be provided to external researchers upon request for cooperation or data-use purposes. In this case, a cooperation or data-use agreement must be concluded in advance. The use of ErNst study data is therefore possible with a detailed prior justification of its scientific purpose and after agreement with the MRI. However, informed consent would, in general, allow the publication of a publicly available data set of anonymized study data, which is also planned in the future.

Raw sequence data have already been deposited in the European Nucleotide Archive [52] under the accession number PRJEB51875. The study was included in the collection of human observational studies in the context of the INTIMIC Knowledge Platform [53], and study metadata were deposited on the project's metadata server, Mica [54]. Further data will be published later with the results of the ongoing analyses and could be shared earlier upon a reasonable request.

Abstract

Background: The International Council of Nurses' 2021 code of ethics mandates nurses to provide evidence-informed care to patients. Globally, using research evidence has led to improvement in nursing and midwifery practice, according to the World Health Organization. A study in Ghana found that 25.3% (n=40) of nurses and midwives use research in clinical care. Research utilization (RU) increases therapeutic effectiveness, improves health outcomes, and enhances the personal and professional development of clinicians. However, it is uncertain the extent to which nurses and midwives are prepared, skilled, and supported to utilize research in clinical care in Ghana.

Objective: This study aims to develop a conceptual framework that can facilitate RU among clinical nurses and midwives in Ghanaian health facilities.

Methods: This will be a cross-sectional study with a concurrent mixed methods approach. It will be conducted in 6 hospitals and 4 nursing educational institutions in Kumasi, Ghana. The study has 4 objectives which will be executed in 3 phases. Phase 1 follows a quantitative approach to describe the knowledge, attitudes, and practices of clinical nurses and midwives on the use of research in their practice. Using a web-based survey, 400 nurses and midwives working in 6 health facilities will be recruited. Data analysis will be conducted using SPSS, with statistical significance set at .05. Qualitative methodology, using focus group discussions with clinical nurses and midwives, will be conducted to identify the factors influencing their RU. In phase 2, focus group discussions will be used to examine and describe how nurse educators in 4 nursing and midwifery educational institutions prepare nurses and midwives for RU during their education. Views of nurse managers on the RU in Ghanaian health care facilities will be explored in the second section of this phase through one-on-one interviews. Inductive thematic analysis will be used to analyze the qualitative data, and Lincoln and Guba's principles of trustworthiness will be applied. In phase 3, the stages of model development proposed by Chinn and Kramer; and Walker and Avant will be used to triangulate findings from all objectives and formulate a conceptual framework.

Results: Data collection started in December 2022. Publication of the results will begin in April 2023.

Conclusions: RU in clinical practice has become an acceptable practice in nursing and midwifery. It is critical that nursing and midwifery professionals in sub-Saharan Africa shift their practice to embrace the global movement. This proposed conceptual framework will empower nurses and midwives to improve their practice of RU.

Introduction

The 2021 code of ethics of the International Council of Nurses mandates that nurses across the globe should provide evidence-informed health care to patients [1]. This requires the use of research in practice. Consequently, according to the World Health Organization, using research evidence has led to improvement in nursing and midwifery practice globally [2]. Using research evidence is a component of evidence-based practice (EBP), which is a great means for nurses and midwives to meet the changing health needs of the society [3,4]. EBP is a systematic approach to problem-solving for health care providers [5] which is characterized by using the best research evidence that is currently available, clinical expertise, and patient values for clinical decision-making to provide consistent and best possible care to patients [6,7]. The transition to EBP not only increases therapeutic effectiveness and improves health outcomes but also enhances the personal and professional development of clinicians [4]. Research utilization (RU) is vital to the successful implementation of EBP [4].

RU is defined as the process of analyzing, disseminating, and implementing research-produced knowledge to influence or improve current nursing practice [8,9]. This can be achieved through nurses' critical appraisal of research [10]. According to the World Health Organization, globally, nursing and midwifery services have been enhanced due to implementation of research evidence, which highlighted the significant role of nurses in patient care, especially for decision makers [2].

Globally, the use of research in nursing practice has been found to have enormous benefits for both providers and recipients of care [11]. The benefits extend to the public who receive care, the nurses and midwives who provide the care, and the health care system in which the health care is provided [12,13]. Nursing care that is based on the best available research evidence is vital to resolving problems in the clinical setting, improving patient outcomes, decreasing trial and error in nursing care, increasing nurses' confidence in decision-making, and supporting professional development [14-17]. RU contributes to the science of nursing through the introduction of innovation to practice [15]. RU is critical in evidence-based nursing practice because it can save time and money by improving the quality of patient care through cost reduction and effective treatment [18]. It provides a more solid foundation for health care investment decisions and collaboration for capacity development [4]. In the nursing profession, research has been a vital means of developing new knowledge [2]. The benefits of RU in clinical nursing and midwifery practice cannot be realized if it is not implemented.

In Ghana, most of the studies that have been conducted on nurses and research have focused on EBP [14,19-21] with only 1 study [22] focusing on RU. The latter looked at the barriers to RU, given the scarcity of data on the knowledge, attitudes, and practices of RU by nurses and midwives in Ghana. There is methodological limitation in most of the studies on EBP and the RU study in Ghana because they used 1 methodology (either quantitative or qualitative). In addition, the findings of the studies on EBP cannot be used as RU because they are not the same and there are variations in their meanings. This has led to limited published studies in the literature on RU in Ghana.

In addition, there is an urgent need for formal training of nurses and midwives on how to utilize research evidence in their practice. However, there have not been any studies focusing on how nurses are prepared to implement RU in Ghana. This has led to a dearth of information on how well RU is incorporated in both the undergraduate and postgraduate curriculum and the extent to which they are prepared to implement RU after their training. Moreover, leadership plays a key role in the implementation of programs that ensure improved clinical care, which includes RU [23]. Nurse managers have been found to be influential on their staff in translating research evidence into action [24]. This creates a need to identify the views of nurse managers in Ghana on RU and how they can or have been influencing its practice in their health facilities.

Globally, research evidence use in nursing practice has become imperative due to increasing knowledge and technology [25]. Using research evidence in clinical care has not been fully achieved in nursing practice due to the inability of nurses to translate research into practice [26]. This has been confirmed by studies in Singapore [27], Brazil [28], Malaysia [29], South Africa [30], Ethiopia [31], Kenya [11] and Ghana [22]. This inability of nurses to translate research into practice has reflected on their use of research, as studies show Nigeria uses 17% of research [32]. In Kenya, 20.6% of nurses have participated in work-related research and half of them (10.3%) have ever implemented research evidence in practice [11]. In Ethiopia, poor RU was also found [33] and in Ghana, 25.3% research use was found [22]. This shows that if nurses are provided with guidance, research use will be improved.

Further, due to the enormous benefits of RU and the interplay of factors that influence its implementation, evidence suggests that the recurring problem of implementing research in clinical nursing practice can be resolved by offering a framework to guide the implementation of evidence in practice [11,18,22,34,35]. This study aims to establish such a framework to guide RU in clinical nursing and midwifery practice. This study seeks to explore RU by Ghanaian clinical nurses and midwives in hospital settings to develop a conceptual framework to guide RU in clinical nursing and midwifery practice. This will be achieved through the following objectives: (1) describe the knowledge, attitudes, and practices of clinical nurses and midwives toward the use of research in clinical practice in Ghana; (2) identify the factors (barriers or facilitators) that influence the use of research by nurses and midwives in clinical practice; (3) explore the preparation of nurses and midwives to implement RU in Ghana by nurse educators in nursing institutions; (4) explore the views of nurse managers on the implementation of RU in their facilities; and (5) develop a conceptual framework to guide nurses and midwives to utilize research in Ghanaian health facilities to improve the implementation of EBP in Ghana.

XSL•FO
RenderX

Methods

Study Design

The study will be cross-sectional, using a concurrent mixed method approach. The quantitative methodology will be used to identify the knowledge, attitudes, and practices of RU among the nurses. Concurrently, the researcher will collect qualitative data to explore the barriers to and facilitators of RU, the preparation of nurses and midwives, and the views of nurse managers on RU in health facilities. This will ensure synergy of the results to help in the development of a conceptual framework to facilitate RU in Ghanaian health facilities. This study will be implemented in 3 phases, chronologically. Quantitative data will be collected and analyzed independently, as well as the qualitative data. The results will then be interpreted and triangulated to inform the development of the conceptual framework of RU.

Study Setting

The study will be conducted in health care facilities and nursing and midwifery educational institutions within Kumasi city, in the Ashanti region of Ghana. The study sites are 6 health facilities and 4 nursing educational institutions, depending on the study phase and objective. Specifically, the health facilities are 1 teaching hospital, 1 quasi-health facility, and 4 Ghana Health Service facilities. The facilities were selected for the study because each represents an agency of the Ministry of Health in Ghana, which regulates their activities. The educational institutions are 2 degree-awarding universities and 2 diploma-awarding training colleges. The institutions were selected based on ownership, that is, private or public, and the level of education—diploma or bachelor's degree. This is to ascertain whether there are variations in the preparation of nurses and midwives based on the ownership and level of training.

Phase 1

This phase will be divided into 2 sections based on the specific objectives to be achieved. The study sites for this phase are 6 health facilities.

Phase 1: Objective 1

Overview

The goal of the first part is to describe the knowledge, attitudes, and practices of clinical nurses and midwives regarding the use of research in clinical practice in Ghana. The quantitative research methodology will be used to achieve this objective.

Population and Sampling

Nurses and midwives who work in the clinical units of the health facilities with a minimum educational qualification of a diploma in nursing or midwifery and who have worked for not less than 2 years post qualification will be included in the study. Nurses and midwives who will be on leave at the time of data collection or are working on a part-time basis will be excluded. A sample size of 400 was calculated using Taro Yamane's formula for calculating sample size and a 10% dropout rate. Multistage sampling, including proportionate and systematic sampling methods with a sampling interval of 9, will be used to achieve the target sample size in each health facility.

Data Collection

All the data for this PhD study will be collected by the primary investigator (LBO), who is also trained in qualitative and quantitative research methods. For this study phase, data will be collected using an adapted Evidence-Based Practice Questionnaire created by Upton and Upton [27], as permitted by the original authors. Knowledge or skills, attitudes, and practice are the 3 subscales of the tool, which are measured using a 5-point Likert scale, where 1=very poor, strongly disagree, or never, and 5=excellent, strongly agree, and always. In its original form, the overall Cronbach α is .87. Since this study focused only on RU, some questions were modified to focus on retrieving and implementing current research evidence in clinical practice. The modifications were based on RU literature and Rogers' theory of diffusion of innovation, which guides the overall study. The Cronbach α for the modified tool is .84. Data collection will be done using a web-based survey after obtaining the consent of participants.

Quantitative Data Analysis

Quantitative data will be analyzed using SPSS (version 25.0; IBM Corp) and Stata (version 16; StataCorp). Exploratory data analysis will be carried out for the sociodemographic characteristics of the respondents. Inferential statistics will be used to ascertain the association between demographics and knowledge, attitudes, and practice levels. The chi-square test for independence and its alternative the Fisher exact test will be used to examine the association between categorical variables, while the nonparametric signed rank test will be used to examine the difference in the participants' knowledge scores, and the Pearson and Spearman correlation coefficients will measure the degree of agreement between the scores. Structural equation model and factor analysis will be adopted to assess the effect of demographic characteristics (gender, educational level, age, and number of years of clinical practice) on RU in practice. Statistical significance will be established at *P* value of .05.

Validity and Reliability of Quantitative Data

To test the validity of the modified data collection tool, face validity was established by sending the questionnaire to 5 expert nurses and midwives who have a bachelor's degree and work in the clinical area. Their inputs were used to modify the questionnaire. Pretesting was then carried out with 40 nurses and midwives, representing 10% of the sample size, who work in 2 health facilities located within the study area but not included in the study, using a web-based survey. Results of the pretest and inputs from the study supervisors as well as consultant statistician were used to modify the questionnaire. Cronbach α was calculated for the tool after modification to ensure reliability thereof. The overall Cronbach α factor for the tool was .8438, which is acceptable.

Phase 1: Objective 2

The second objective of phase 1 will be to identify barriers and facilitators influencing RU by nurses and midwives in clinical practice. Qualitative methodology, specifically focus group discussions (FGDs) that will be held via Zoom for each facility, will be used to achieve this objective. The population will be

XSL•FO
RenderX

the same as those who participated in objective 1 with 6-8 participants per group as suggested by Busetto et al [36] and Ochieng et al [37]. A note will be placed on the survey to request respondents who are interested in participating in the FGD to add their phone numbers. Those who provide their phone numbers will be contacted and asked to sign the consent form. An interview guide with 2 sections, exploring barriers to and the facilitators of RU will be used to direct and facilitate the discussions. Each FGD will last between 60 and 90 minutes as recommended [37-39] and based on the exhaustion of questions on guide and responses from participants. Data collection and analysis will be done simultaneously, and collection will be stopped when data saturation is achieved.

Phase 2

Overview

The study in this phase will be used to achieve objectives 3 and 4. It will take place in 2 settings with 2 populations as follows: nurse managers in the selected health facilities used in phase 1 and nurse educators in 4 nursing and midwifery educational institutions.

Phase 2: Objective 3

Overview

The objective here is to explore and describe nurse educators' preparation of nurses and midwives toward RU in nursing and midwifery educational institutions. The phase 2 study sites will be the 4 nursing educational institutions stated earlier.

Sampling and Data Collection

The study will purposively sample nurse educators who have not less than 2 years of teaching experience and teach core nursing courses like pediatric nursing, medical and surgical nursing, neonatal nursing, public health nursing, and puerperium in the selected institutions. FGDs via Zoom will be held under the direction of an interview guide. The guide has 3 broad, open-ended questions to lead the discussions, with an emphasis on how the nurse educators prepare the nursing and midwifery students for RU, the challenges students experience in RU after nursing education, and the strategies that nurse educators could use to enhance RU in clinical practice. The number of participants per group, the duration of discussions, and the number of discussion sessions will be same as phase 1, objective 2.

Phase 2: Objective 4

Overview

The second part of phase 2 is aimed at exploring the views of nurse managers on the RU in health facilities using qualitative methodology.

Sampling and Data Collection

Nurse managers in the 6 health facilities used in phase 1 will be engaged in a face-to-face key informant interview through purposive sampling. The interviews will be guided by a semistructured interview guide to solicit the nurse managers' views on RU in their various health facilities. Data collection and thematic analysis will be done simultaneously and terminated when data saturation is reached.

Qualitative Data Analysis

Data will be thematically analyzed using Braun and Clarke's thematic analysis process [28]. The recorded data will be transcribed. Codes will be generated in a systematic fashion across the entire data set and will be collated into themes and subthemes to generate a thematic "map" of the analysis.

Trustworthiness

A total of 2 researchers will analyze the data independently and hold coding meetings until they reach intercoder agreement. Themes which emerge will be discussed with a group of participants to achieve member checking, thereby ensuring credibility. Also, method triangulation where the use of FGDs and individual interviews for data collection will be done so that the limitations of each method is counterbalanced whiles their strengths are projected [40]. Again, data from multiple sources like nurse managers, nurse educators, and clinical nurses and midwives will be used to enhance the credibility of the study [40,41]. Transferability will be achieved by providing a thick description of the research context and clear methodology to enhance potential for replication of the study. Verbatim transcriptions and use of quotations from collected data in reporting the study will ensure confirmability [40].

Phase 3: Objective 5

This phase aims to develop a conceptual framework to facilitate RU by clinical nurses and midwives in Ghana. Findings from phases 1 and 2 will be triangulated and used to develop the conceptual framework. Data triangulation which uses data from multiple sources [41] will be performed in this study. This will be guided by Rogers' theory of diffusion of innovation and the 4 stages of model development proposed by Chinn and Kramer (2008) and Walker and Avant (2005), ie, concept development, statement development, model description, and model evaluation.

Ethical Approval

The study has been approved by the Health Research and Ethics Committee of North-West University in South Africa (NWU-00070-22-A1), the Ghana Health Service Ethics Review Committee (GHS-ERC 003/07/22), the Komfo Anokye Teaching Hospital Institutional Review Board in Kumasi (KATH IRB/AP/152/22), and the Committee on Human Research, Publication, and Ethics of the School of Medicine and Dentistry at the Kwame Nkrumah University of Science and Technology in Kumasi, Ghana (CHRPE/AP/762/22).

Results

Data collection started in December 2022. It is envisaged that the results from phase 1 will unveil the knowledge, attitudes, and practices of clinical nurses and midwives regarding the use of research as well as factors influencing research use by nurses and midwives in clinical practice in Ghana. Phase 2 will identify the views of nurse managers on RU in nursing practice in their facilities and how nurse educators prepared student nurses and midwives to utilize research. Once all the findings from different

XSL•FO
RenderX

groups of participants have been analyzed, we expect that the conceptual framework will be developed.

Discussion

Overview

Globally, RU is of utmost importance in health care and therefore cannot be downplayed [10-12]. A systematic review identified that most studies conducted on RU in nursing practice used the quantitative method and were conducted in Sweden, the United States, and the United Kingdom [42] with a dearth of literature on RU in Ghana. This study will unveil the activities of nurses and midwives in implementing research in their clinical practice. Also, the factors influencing clinical nurses' and midwives' RU will be unearthed. This will lead to minimizing the barriers and enhancing the facilitators to promote RU. Moreover, assessing the nurse managers' views on RU will bring out how leadership in nursing influences RU in their various facilities. The study will identify how nurses are prepared for RU while they are in nursing school. This will guide the scope of the framework that will be developed. A systematic review of studies on barriers to RU in nursing practice from 2002 to 2021 by Jabonete and Roxas (2022) found that almost all studies on barriers to RU used the Barriers scale through a quantitative methodology. The review found that the Barriers scale is outmoded and therefore research on the barriers to RU requires a more robust approach to identify the challenges to nurses RU [42]. This study will use the qualitative methodology to identify the barriers to RU. The use of mixed methods will enable triangulation of findings, observation of the divergence and convergence of findings, and elimination of possible biases. This will also assist the researchers to examine the interplay of factors at the individual (clinical nurses and midwives), group (nurse educators), and organizational (nurse managers) levels [29]. Inclusion of nurse educators, managers, and clinical nurses and midwives as participants in the study contributes to the coproduction of knowledge and increases the chances of the acceptability and utilization of the framework. Nurses will use research if there is guidance on translating research into practice [31]. Consequently, several frameworks have been developed for RU [43]. However, few frameworks have been extensively used, in part because the dynamic processes and players involved are varied and context-specific but also because some frameworks offer little "how-to" guidance for implementation [44-46]. For an RU framework to be accepted for use, it must be contextually appropriate and suit the needs of countries with similar developmental classifications [45]. In the Ghanaian context, this is one of the first studies which focuses on RU. The conceptual framework that is developed will guide nurses and midwives on the implementation of RU in clinical care, guide the managers on how best they can support RU, and guide nurse educators on teaching of RU.

Expected Clinical Impacts

The outcome of this study will have clinical, scientific, and socioeconomic impacts as it aims to produce a conceptual framework that will guide nursing and midwifery practice. The use of this framework will enhance the scientific practice of nursing and midwifery by enhancing evidence-based nursing care through the introduction of innovation to practice. Clinically, the outcome of this study, which is the development of the RU framework, when implemented, will improve patient outcomes by implementing tried and tested treatment modalities that will guide nurses and midwives' decision-making and support their professional development. Socioeconomically, the implementation of the RU conceptual framework that will be developed at the end of this study will save time and money by improving the quality of patient care through cost reduction and effective treatment.

Limitations

The study should be considered with the limitation that the study will not validate the conceptual framework that will be developed since it is beyond the scope of this study. However, we believe that the strong theoretical underpinning, the methodology, and the population used in the study, as well as the triangulation of the results of the study that will be used to develop the conceptual framework, will make the framework a must-use approach in clinical practice to enhance nurses and midwives RU. We again believe that future studies will be conducted to validate and pilot the use of the conceptual framework.

Conclusions

RU in clinical practice has become an acceptable practice in nursing and midwifery. It is critical that nursing and midwifery professionals in sub-Saharan Africa shift their practice to embrace the global movement. This proposed conceptual framework will empower nurses and midwives to improve their practice of RU.

Acknowledgments

The authors would like to acknowledge Professor Atinuke Olusola Adebanji and the Laboratory for Interdisciplinary Statistical Analysis at Kwame Nkrumah University of Science and Technology in Kumasi, Ghana for providing statistical consultation for this protocol.

Authors' Contributions

LBO conceptualized this study and wrote the initial draft of the manuscript. This is a proposed doctoral dissertation in fulfillment of the requirements for the award of a PhD in Nursing Science in the Quality Nursing and Midwifery (NuMIQ) Research Focus Area of the Faculty of Health Sciences of North-West University. NS and IST are supervisors of the doctoral research project of LBO; they helped in the conceptualization and design of the study, including reviewing and revising of the approved protocol and this manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Some children and adolescents suffer from late effects of a SARS-CoV-2 infection despite a frequently mild course of the disease. Nevertheless, extensive care for post–COVID-19 condition, also known as post–COVID-19 syndrome, in children and young people is not yet available. A comprehensive care network, Post-COVID Kids Bavaria (PoCo), for children and adolescents with post–COVID-19 condition has been set up as a model project in Bavaria, Germany.

Objective: The aim of this study is to evaluate the health care services provided within this network structure of care for children and adolescents with post–COVID-19 condition in a pre-post study design.

Methods: We have already recruited 117 children and adolescents aged up to 17 years with post–COVID-19 condition who were diagnosed and treated in 16 participating outpatient clinics. Health care use, treatment satisfaction, patient-reported outcomes related to health-related quality of life (the primary endpoint), fatigue, postexertional malaise, and mental health are being assessed at different time points (at baseline and after 4 weeks, 3 months, and 6 months) using routine data, interviews, and self-report questionnaires.

Results: The study recruitment process ran from April 2022 until December 2022. Interim analyses will be carried out. A full analysis of the data will be conducted after follow-up assessment is completed, and the results will be published.

Conclusions: The results will contribute to the evaluation of therapeutic services provided for post–COVID-19 condition in children and adolescents, and avenues for optimizing care may be identified.

Introduction

Background

COVID-19, caused by the novel coronavirus SARS-CoV-2, is considered a multi-organ disease with varying symptom patterns [1]. Frequently occurring characteristics are fever, cough, headache, myalgia, or fatigue and in some cases, intestinal symptoms [2,3]. Research has focused on the treatment of acute COVID-19 cases, which mainly occur among elderly patients and people with preexisting comorbidities like diabetes or cardiovascular disease [4-6]. These persons belong to a risk group among whom a more severe form of the infection can also occur [7].

Children and adolescents are less affected by severe forms of the infection and usually have a mild course of disease [8,9]. Nonetheless, some of them still suffer from long-term consequences of the infection, referred to as "long COVID," post–COVID-19 syndrome (PCS) or post–COVID-19 condition (PCC) [10], which not only affect risk groups, but also people with a milder form of COVID-19 or even asymptomatic SARS-CoV-2 infection [11-13]. Those persistent clinical symptoms vary considerably but can be very restricting for the individual [10].

Currently, there is no clear and uniform definition of PCC [14]. According to the National Institute for Health and Care Excellence, 3 different phases of an infection with SARS-CoV-2 should be distinguished [10]. An acute COVID-19 infection is classified by signs and symptoms that can last up to 4 weeks. The next phase is between 4 and 12 weeks and is termed ongoing symptomatic COVID-19. If signs and symptoms last longer than 12 weeks, are consistent with SARS-CoV-2 infection, and cannot be explained by any other diagnosis, this is called PCC. The commonly used term "long COVID" includes ongoing symptomatic COVID-19 and PCC [10]. According to the World Health Organization (WHO), the following definition is used [15]:

> *Post COVID-19 condition occurs in individuals with a history of probable or confirmed SARS CoV-2 infection, usually 3 months from the onset of COVID-19 with symptoms that last for at least 2 months and cannot be explained by an alternative diagnosis.... Symptoms may be new onset following initial recovery from an acute COVID-19 episode or persist from the initial illness. Symptoms may also fluctuate or relapse over time. A separate definition may be applicable for children.*

Most recently, a modified Delphi consensus was used to suggest a first research definition of PCC in children and adolescents that complements the clinical case definition in adults proposed by the WHO [16]:

> *Post-COVID-19 condition occurs in young people with a history of confirmed SARS-CoV-2 infection, with at least one persisting physical symptom for a minimum duration of 12 weeks after initial testing that cannot be explained by an alternative diagnosis. The symptoms have an impact on everyday functioning, may continue or develop after COVID infection, and may fluctuate or relapse over time. The positive COVID-19 test referred to in this definition can be a lateral flow antigen test, a PCR test or an antibody test.*

Frequently reported long-term symptoms in children and adolescents after COVID-19 are fatigue, headache, sleep disturbance, concentration difficulties, abdominal pain, muscle and joint pain, cough, chest pain, loss of appetite or weight, disturbed smell or anosmia, and rash [11,12]. This symptom pattern appears similar to the one seen in adults [11,17]. Another symptom of PCC in children and adolescents is Kawasaki-like hyperinflammation, also known as multisystem inflammatory syndrome in children associated with COVID-2019 (MIS-C) or pediatric inflammatory multisystem syndrome temporally associated with SARS-CoV-2 (PIMS-TS) [11,18]. Patients with this condition have persistent fever and high levels of inflammation in which several organs are affected [19,20]. In addition, acute SARS-CoV-2 infection can cause myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) [21,22]. The main symptoms of this complex, severe disease are fatigue and exercise intolerance with symptoms worsening after minimal exertion, which is referred to as postexertional malaise (PEM) [23,24]. In general, data on PCC in children and adolescents is still scarce [25,26].

The prevalence of PCC has been estimated at 0.8% to 13% in pediatric studies with uninfected controls [12,27,28]. The Follow CoKiBa study in Regensburg, Germany, found mild, long-lasting symptoms in 10% of children and adolescents aged up to 14 years who had a previous SARS-CoV-2 infection and severe, long-lasting symptoms in at least 3% of those who were affected with a mild, acute form of COVID-19 [29].

Due to the complexity of its symptoms, the diagnosis and treatment of PCC is time-consuming and often difficult [10]. In addition, children and adolescents can be affected by pandemic-related mental disorders [30,31], and differential diagnosis for these disorders and PCC is difficult [32]. Therapy should be carried out depending on a comprehensive differential diagnosis and the patient's symptoms. However, no data or recommendations on how to provide treatment are yet available [1,33].

There is an urgent need to create a comprehensive care network for children and adolescents with PCC. Models and structures of care are needed that enable interdisciplinary, somatic, and psychological diagnostics with subsequent comprehensive therapy. In Bavaria, Germany, such a network of physicians and specialized outpatient clinics, named Post-COVID Kids Bavaria (PoCo), has been established to provide specific care for young patients with PCC, including a specialized Post-COVID Fatigue Centre (PCFC). This should ensure that those who are affected receive appropriate care as close to home and with as little stress as possible. To the best of our knowledge, no other studies have been published that focus on the evaluation of health care services for children and adolescents with PCC.

XSL•FO
RenderX

Aim of the Study and Hypotheses

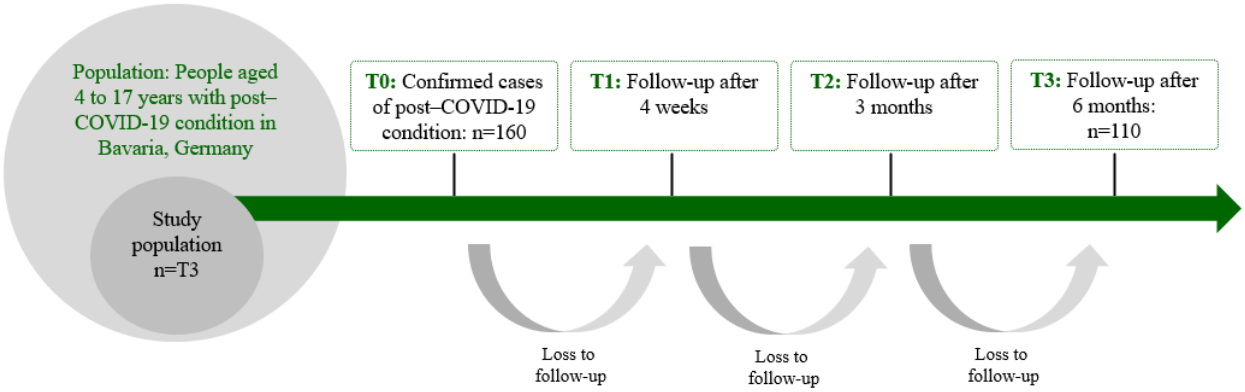
The overarching aims of this study are to describe care pathways in the context of PCC in children and adolescents and to evaluate the effects of health care services from the perspective of affected children and adolescents within and outside the PoCo network.

We hypothesize that the health care being provided within the PoCo network is improving the subjective health status of young patients with PCC. Table 1 describes the specific objectives and hypotheses of the study.

Table 1. Objectives and hypotheses of the study.

Objectives	Hypotheses
Documentation of care pathways, including care structures used and therapeutic measures prescribed, with regard to post–COVID-19 condition.	Patients will have many contacts with the health care system within and outside the Post-COVID Kids Bavaria (PoCo) network.
Evaluation of the effects of therapeutic programs.	The patients' health status and quality of life will improve over time.
Evaluation of satisfaction with different care structures and therapeutic programs.	The patients will be mostly satisfied with care for post–COVID-19 condition and will use the different care structures.

Methods



Study Design

This study is taking place within the PoCo network, which follows long-term conditions after COVID-19 in children and adolescents. The aim of the PoCo network is to provide optimal care for children and adolescents affected by PCC. This involves pediatricians and general practitioners (GPs) in private practice, as well as 16 specialized pediatric outpatient clinics all over Bavaria, including one with focus on the treatment of ME/CFS (PCFC). Thus, the network comprises ambulatory and stationary health care institutions throughout Bavaria. Statewide provision of care is ensured by trained, practicing physicians and supplemented by telemedical services.

Patients with severe forms of PCC are cared for in special outpatient clinics. If post-COVID ME/CFS is suspected, patients are treated in or together with the PCFC in Munich. Patients with severe limitations, such as pain, sleep disorders, cognitive problems, or orthostatic intolerance are cared for as inpatients in the pediatric rehabilitation center in Berchtesgaden or in the pediatric pain clinic in Garmisch-Partenkirchen. The latter has expertise in treating children with ME/CFS.

This study is dedicated to health-services research within the PoCo network. It has a longitudinal design (Figure 1). Patients were included in the study after the (suspected) diagnosis of PCC by participating special outpatient clinics. If patients had been treated before, a retrospective assessment of diagnoses and treatments was performed. Patients are assessed at baseline (ie, inclusion in the study; T0), after 4 weeks (T1), after 3 months (T2), and after 6 months (T3) using routine data, interviews, and questionnaires. The primary outcome is subjective health status after 6 months, measured by the visual analogue scale (VAS) of the EQ-5D [34].

Figure 1. Planned study sample and measurement points.

Sample and Recruitment

Study Sites

Pediatricians or GPs in private practice in the PoCo network all over Bavaria recruited patients and referred them to the participating outpatient clinics, where they were included in the study. Patients could also be included directly via the special outpatient clinic without having been referred by a pediatrician or GP.

Patients

Male and female patients aged 4 to 17 years were included in this study if they had a positive test for SARS-CoV-2 and showed clinically evident PCC symptoms or had a COVID-19 infection in the family environment in combination with PCC-typical symptoms. Textbox 1 shows the inclusion and exclusion criteria.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Children and adolescents, male and female, aged 4 to 17 years
- Proficient German language skills
- Evident clinical abnormalities or symptoms of post–COVID-19 condition with one or both of the following (at least 4 weeks earlier):
  - A positive test for SARS-CoV-2, including any or all of the following: a polymerase chain reaction test, antigen test, and SARS-COV-2 antibodies
  - A verified SARS-CoV-2 infection in the family environment
- Current treatment at one of the participating outpatient clinics
- Written consent of the parents and the patient (depending on age)

Exclusion criteria

- Age <4 years or >17 years
- Nonproficient German language skills
- No positive test for SARS-CoV-2 or confirmed infection in the patient's family
- No current treatment at one of the outpatient clinics
- No written consent

Sample Size and Patient Flow

Based on the primary outcome (subjective health status, measured with the VAS), a sample size calculation was performed. Under the assumption of an effect size d=0.35, a significance level α=.05, and power β=.80, the calculated sample size was n=55. However, we assumed that there would be some patients who declined participation in the study, even after inclusion, or dropped out. Therefore, we planned to include 80 patients who were treated within the PoCo network. Patients included and cared for in the PCFC will be evaluated separately. The same assumptions for sample size and dropout were made for these patients, resulting in the inclusion of an additional 80 patients. Thus, the result of the sample size calculation was n=160.

Measurements

Table 2 provides an overview of the variables that are measured for answering the research questions.

A detailed list of all variables is presented in Multimedia Appendix 1 [10,16,34-38].

XSL•FO
RenderX

Table 2. Overview of variables, constructs and scores, and measurement instruments.

Domains and variables/constructs	Scores, instruments, and data sources	Time point
Sociodemographic characteristics		T0
Patient's age, gender, current education/health care facility and health insurance status, family household size, other children living in the household, place of residence, parents' migration status, level of education and vocational education	Proxy questionnaire, hospital information system	
General medical characteristics		T0
Height, weight, current medication, chronic conditions and diseases	Hospital information system	
Medical characteristics relating to COVID-19 and its treatment		T0
History of SARS-CoV-2 infection, symptom patterns, use of ambulatory and stationary health care, comorbidities, treatment and medication of comorbidities, COVID-19 vaccination status	Hospital information system	
Characteristics of health care use		T1, T2, T3
Visits to physicians and therapists, recommended and used treatment, usefulness of treatment, recommended and used medication or supplements, visits to special outpatient clinic, length of stay and frequency of visits at special outpatient clinic, use of telemedicine, inpatient admission, days of absence from school or work due to illness, counselling on school attendance	Proxy questionnaire via telephone interview, hospital information system	
Patient-reported experience measures		T1, T2, T3
Treatment satisfaction	Proxy questionnaire via telephone interview	
Patient-reported outcome measures		T0, T1, T2, T3
Health-related quality of life	EQ-5D-Y [34], visual analogue scale [34]	
Fatigue	Patient-Reported Outcomes Measurement Information System (PROMIS) Pediatric Short Form version 2.0–Fatigue 10a [36]	
Postexertional malaise	DePaul Symptom Questionnaire Focusing on Post-exertional Malaise (DSQ-PEM) [37]	
Mental health	Strength and Difficulties Questionnaire (SDQ) [38], proxy questionnaire (age ≥12 years: self-reported questionnaire)	

Sociodemographic Characteristics

Sociodemographic information about the patients and their families characterizing the sample was obtained with a paper-based questionnaire (described in the Data Sources and Data Collection sections) handed out at baseline. These variables included patients' age, gender, level of education and health insurance, family household size, other children living in the household, place of residence, migration status, and parents' level of education and vocational education.

General Medical Characteristics

General medical information was also asked for at baseline, to obtain an overview of the patient's general state of health. Patients' height, weight, current medication used, and chronic conditions and diseases were assessed with routine data and questionnaires.

Medical Characteristics Relating to COVID-19 and Its Treatment

Different parameters relating to COVID-19 were recorded at baseline: history of SARS-CoV-2 infection, symptom patterns, use of ambulatory and stationary health care, comorbidities, treatment and medication against comorbidities, and COVID-19 vaccination. The information was obtained from routine data and questionnaires.

Characteristics of Health Care Use

To evaluate use of health care services within and outside the PoCo network, the following variables are recorded at T1, T2, and T3 by means of a telephone interview with the parents: visits to physicians and therapists, recommended and used treatment, usefulness of treatment, recommended and used medication or supplements, days of absence from school or work due to illness, visits to a special outpatient clinic, length of stay and frequency of visits at the special outpatient clinic, use of telemedicine, inpatient admission, and counselling on

XSL•FO
RenderX

school attendance. Telemedicine includes structured correspondence of pediatricians and GPs with specialists via the post-COVID–specific PädExpert PraxisApp before admission to a hospital, as well as follow-up visits by phone, email, or video conference.

Patient-Reported Experience Measures

Information on patient experience is captured by the variable "treatment satisfaction." Data is collected via telephone interviews at the measurement timepoints T1, T2, and T3.

Patient-Reported Outcome Measures

The primary outcome is the VAS, scored on a scale from 0 to 100, of the EQ-5D-Y. Remaining questions of the EQ-5D-Y are answered on a 3-point Likert scale [34]. Secondary outcomes are fatigue and PEM. Fatigue is assessed with the PROMIS Pediatric Short Form version 2.0–Fatigue 10a questionnaire. The questionnaire comprises 10 items, which are answered on a 5-point Likert scale [36]. A total score is calculated by building the sum of the individual item scores, with higher scores indicating greater fatigue [39]. The DePaul Symptom Questionnaire Focusing on PEM (DSQ-PEM) provides information on the presence of PEM by asking about the frequency and severity of different symptoms [37]. Further, the emotional problems scale of the Strength and Difficulties Questionnaire (SDQ) is used to examine mental health. Items are answered on a 3-point Likert scale. By summing up the individual item scores, a total score is determined that indicates whether a patient shows abnormalities for mental problems, with higher scores implying higher risk for abnormalities [38]. Patient-reported outcome measures (PROMs) are assessed at all measurement points with proxy questionnaires for children aged 4 to 11 years and self-report questionnaires for adolescents aged 12 years and older. Only adolescents aged 12 years and older provide information about fatigue.

Data Sources and Data Collection

Data are derived from various sources. Characteristics relating to COVID-19 and its treatment, as well as general medical characteristics, were obtained from the hospital information system by health care providers and entered into an electronic database (DB), Qnome (Maganamed). Sociodemographic characteristics were assessed via paper questionnaires. These questionnaires were already filled out at baseline by the parents of the patients. Characteristics of health care use are measured via telephone interviews at different time points (Table 2). These questions are also answered by the parents. Some sociodemographic characteristics and characteristics of health care use were assessed via routine data from the hospital information system. PROMs are obtained via paper questionnaires at all time points from the participants themselves or from their parents if they are younger than 12 years. All questionnaires are sent to the study participants by mail. Completed paper questionnaires are manually entered into the electronic DB using the individual IDs of the participants.

Data Management and Quality Assurance

Qnome is used for electronic data collection and data management. The study participants were assigned to the Qnome DB after their parents (and, depending on age, the participants themselves) had confirmed their written consent to participate in the study. Within this overarching DB, however, separate DBs were set up for the individual data sources and types, which are stored separately from each other. A distinction is made between the DB of the trust center (TC) for personal data, the clinical DB for clinical data (including routine data) and the health-services research DB for health-services research data. The data of the study participants were pseudonymized and provided with different IDs: for the clinical data, the clinical data ID (C-ID) and for the health-services research data, the health-services research ID (H-ID). Each participant was assigned a randomly generated pseudonymized C-ID and H-ID. The C-ID was communicated to the attending physicians, who performed a structured clinical examination as part of patient care and documented and store all findings in the clinical DB with this C-ID. The H-ID is only used by the health services research team for their data. The TC is responsible for the provision of the different IDs and the linking to the personal data.

For the data collection for the health-services research (Figure 2), contact data are forwarded by the TC with the corresponding H-ID to the health-services research team. For this purpose, a list of persons to be contacted is compiled weekly and transmitted to the health services research team. The transmission of the personal data for contacting is carried out via Citrix ShareFile (Citrix), an internet-based platform for data transmission that is detached from the study DBs. The data are stored on the local server of the Barmherzige Brüder Hospital Regensburg for a short period of time. At the designated follow-up time points, the health-services research team contacts the person with custody to conduct the interview or to fill in the questionnaire. By means of the H-ID, the answers to the interview conducted by the health-services research team can be entered into the health-services research DB. After successful contact, the weekly list with the contact data and IDs will be destroyed.

When data assessment is complete, data sets will be prepared that do not contain the names or contact details of the study participants (Figure 3).

XSL•FO

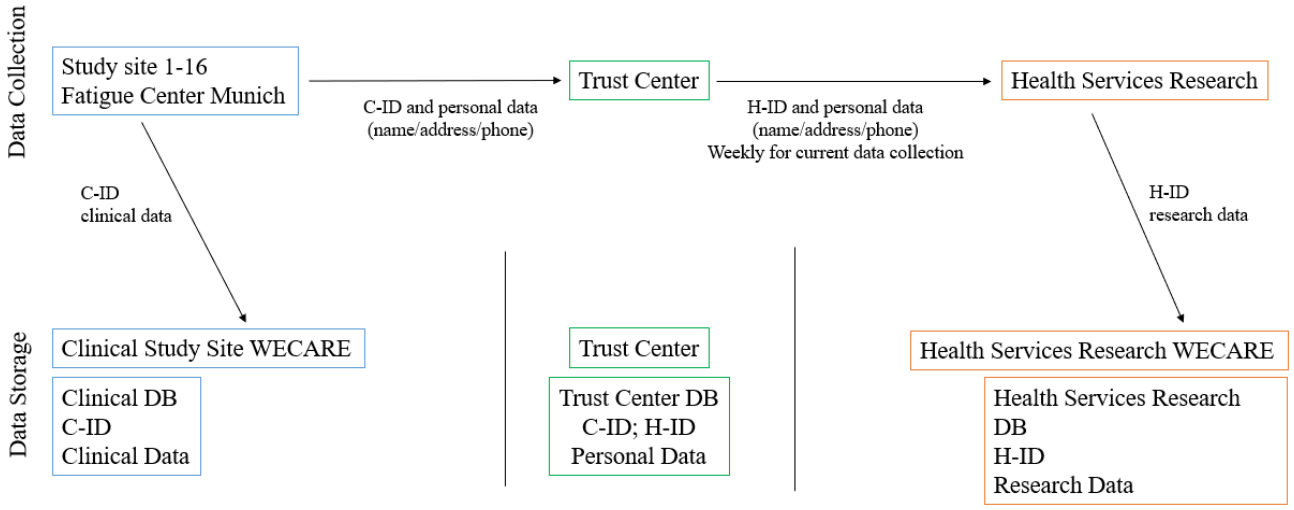

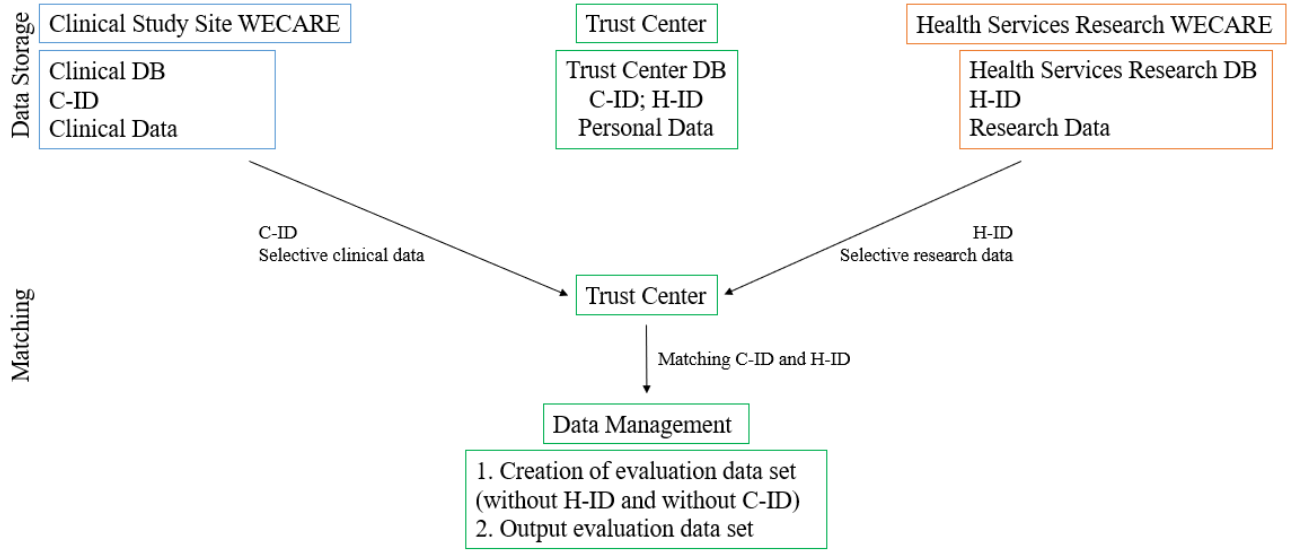

Figure 3. Data storage and matching (only for joint evaluation, if necessary). C-ID: clinical data ID; H-ID: health services research ID; DB: database; WECARE: Research and Development Campus Regensburg.

Statistical Analysis

Plausibility checks of the data are performed continuously during data collection and before data analysis. Patients who drop out during the course of the study will be compared to patients who stay in the study by comparing their general characteristics, such as age, education, and migration background, at baseline. When information is missing in the questionnaire, queries are sent to participants. Descriptive statistics will be used to analyze patient characteristics and to describe care pathways, diagnoses, and treatments. Parents' education will be transformed to categories according to the Comparative Analysis of Social Mobility in Industrial Nations (CASMIN) classification, and the children's BMI will be calculated using their height and weight [40]. Additionally, PROMs will be analyzed for each measurement point using descriptive statistics.

Therapeutic programs will be analyzed using a pre-post study design. The Wilcoxon signed-rank test for matched samples will be used, as outcome data (eg, VAS) are not assumed to be normally distributed. VAS scores at baseline and after 6 months will be compared in order to detect significant improvement after therapeutic interventions. A difference of 10 points on the scale indicates a clinically relevant change. Analyses of the minimal important difference (MID) for PCC in children and adolescents are not available. This assumption of 10 points was derived pragmatically. Half an SD is taken as the MID for quality-of-life measures [41]. A study on acutely ill children, chronically ill children, and children from the general population found a mean VAS score of 77.1 (SD 21.3) [42]. The value 10 is slightly less than half of 21.3. Studies in older people show lower SDs (eg, 18.5) [43]. Therefore, a minimal clinically important difference of 10 seems to be a pragmatic determination. All analyses will be carried out using SPSS (version 28; IBM Corp) and R (version 4.1.1; R Foundation for Statistical Computing).

Ethics and Consent

The study received original approval on November 29, 2021, and approval of an amendment on March 10, 2022, from the ethics committee of the University of Regensburg (21-2691-101). The study received original approval on April 7, 2022, and approval of an amendment on April 26, 2022, from the ethics committee of the medical faculty of the Technical University Munich (2022-103 S-SR). All data collected will be pseudonymized. Written informed consent was obtained from all study participants at baseline, from their parents, and, depending on their age, from the participants themselves. Participation in the study is voluntary, and participants were reassured that they are free to withdraw from the study at any time without consequences.

Results

The recruitment process for the study ran from April 2022 to December 2022. Unfortunately, only 117 children and youth were included in the study. The planned sample size could not be reached within the period scheduled for recruitment. Interim analyses will be carried out and a full analysis of the data will be conducted after follow-up assessment is completed. The results will be published.

Discussion

The PoCo network aims to improve the care of young patients with PCC by providing comprehensive, multimodal, and intersectoral health services in Bavaria. The main focus is to ensure that comprehensive differential diagnosis is made and that subsequent patient-specific therapy is provided whenever indicated. The established network facilitates access to health services. Using a longitudinal study design, we will be able to evaluate the health care services provided within the PoCo network using outcomes assessed from the patient's perspective. To this end, we use extensively evaluated and widely used tools [37,44-46]. It is assumed that health-related quality of life, fatigue, PEM, and mental health will improve over time in children and adolescents participating in this study.

In addition, this study will improve our knowledge about medical characteristics relating to COVID-19 and its treatment as well as health services and treatments used by young patients with PCC. Risk groups can be identified that are particularly affected by the long-term effects of SARS-CoV-2, including patients with ME/CFS. The prospective evaluation of health care services for children and adolescents with PCC brings some challenges, including consideration of the heterogeneous symptoms of PCC and the complexity of therapeutic measures. In addition, the different age groups make it difficult to identify outcome measures suitable for all participants, and severely affected patients may have problems completing the self-reported instruments due to fatigue or exertion intolerance. Moreover, as in many longitudinal studies, patients might drop out of the study early on, due, for example, to the presumed improvement of symptoms through the care provided in the network. We acknowledge that the study is a single-group study and lacks a control group. We will therefore not be able to study the effects of the health services provided in the PoCo network in comparison to usual care or the improvement in health status caused by natural recovery over time. Also, we will not be able to investigate the effects of the different treatment strategies used in the PoCo network in a comparative manner. Nevertheless, this study will contribute to the evaluation of the health care services provided in the PoCo network in response to the needs of those children and adolescents who suffer from prolonged sequelae after COVID-19.

Acknowledgments

We thank all the families for their participation in the study and all members of the participating outpatient clinics for their support in the recruitment of patients. UB has received a Post COVID Kids Bavaria research grant from the Bavarian government.

Conflicts of Interest

None declared.

Abstract

XSL•FO
RenderX

Background: Core outcome sets (COSs) are important and necessary as they help standardize reporting in research studies. Cranioplasty following traumatic brain injury (TBI) or stroke is becoming increasingly common, leading to an ever-growing clinical and research interest, especially regarding the optimal material, cost-effectiveness, and timing of cranioplasty concerning neurological recovery and complications. Consequently, heterogeneous reporting of outcomes from such diverse studies has led to limited meta-analysis ability and an ongoing risk of outcome reporting bias. This study aims to define a standardized COS for reporting in all future TBI and stroke cranioplasty studies.

Objective: This study has four aims: (1) undertake a systematic review to collate the most current outcome measures used within the cranioplasty literature; (2) undertake a qualitative study to understand better the views of clinicians, patients' relatives, and allied health professionals regarding clinical outcomes following cranioplasty; (3) undertake a Delphi survey as part of the process of gaining consensus for the COS; and (4) finalize consensus through a consensus meeting resulting in the COS.

Methods: An international steering committee has been formed to guide the development of the COS. In addition, recommendations from other clinical initiatives such as COMET (Core Outcomes and Effectiveness Trials) and OMERACT (Outcome Measures in Rheumatology) have been adhered to. Phase 1 is data collection through a systematic review and qualitative study. Phase 2 is the COS development through a Delphi survey and consensus meetings with consensus definitions decided and agreed upon before the Delphi survey begins to avoid bias.

Results: Phase 1 started at the end of 2019, following ethical approval in December 2019, and the project completion date is planned for the end of 2022 or beginning of 2023.

Conclusions: This study should result in a consensus on a COS for cranioplasty, following TBI or stroke, to help standardize outcome reporting for future studies, which can be applied to future research and clinical services, help align future studies, build an increased understanding of cranioplasty and its impact on a patient’s function and recovery, and help standardize the evidence base.

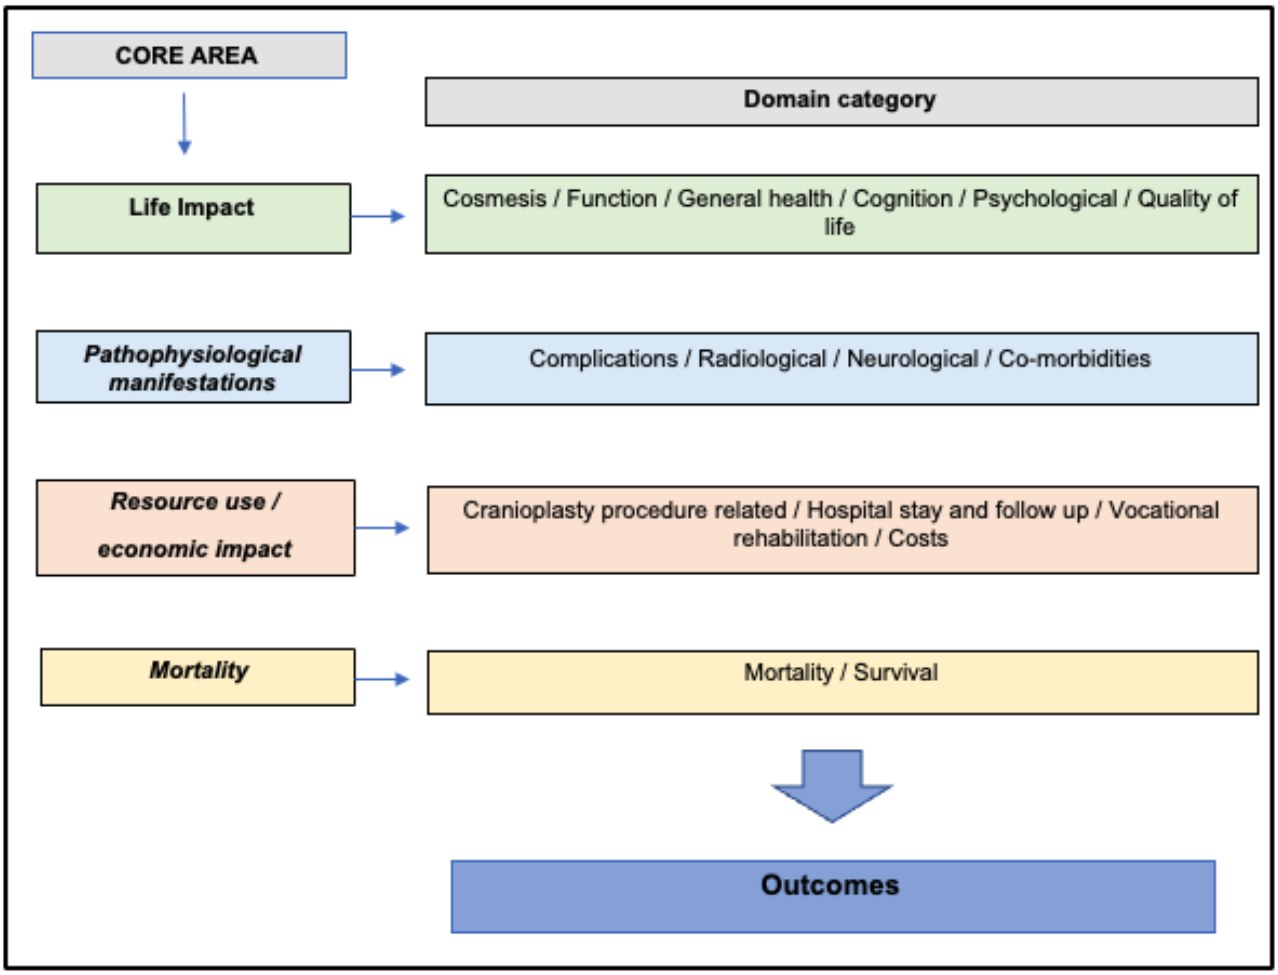
Introduction

Background

Several randomized trials [1,2] have shown that decompressive craniectomy, which is a surgical procedure in which a large section of the skull is removed to accommodate brain swelling, can be helpful in the management of patients with substantial brain swelling and raised intracranial pressure after a traumatic brain injury (TBI) or stroke. Patients who survive usually have their skull reconstructed a few months later through an operation termed cranioplasty. Cranioplasty not only restores skull integrity, providing a degree of mechanical protection to the brain, but can also improve neurological function [3]. However, there are various interesting and unanswered clinical questions around cranioplasty, including complication rates, neurological recovery and outcomes, and the influence timing has on these [4], material choice, and overall cost-effectiveness. As a result, there are many studies published in the literature exploring these themes [3,5,6]. This has led to variability of the terminology used and heterogeneity of outcomes and outcome measures used. These aspects pose substantial barriers to establishing an evidence-based approach to clinical care and research for cranioplasty. Nevertheless, the development of common data elements (CDEs) and core outcome sets (COSs) is becoming increasingly common to overcome such obstacles.



The importance of high-quality, evidence-based clinical practice is known to all, as without reliable, cost-effective interventions and treatments, clinicians' decision-making can become compromised. A core outcome set (COS) is defined as “an agreed standardized set of outcomes that should be measured and reported, as a minimum, in all clinical studies and trials in specific areas of health or health care” [7]. They are a strategy to help as they result in predefined, consensus-derived outcomes that should be reported on in any given condition. This can improve the quality of evidence by allowing studies to be combined for systematic reviews, meta-analyses, and clinical guidelines [8]. The concept was first developed in the early 1990s with the OMERACT (Outcome Measures in Rheumatology) group, which started by creating a COS for rheumatoid arthritis trials and now has a widely used methodological framework on which to identify and validate such sets [9]. Over the past 10 years, further initiatives, including the COMET (Core Outcome Measures in Effectiveness Trials) and the International Consortium for Health Outcomes Measurement, have also produced frameworks as a base for the development of a COS in a specified disease or health condition.

Conceptual models have been developed for studying health, diseases, and outcomes, but not all are appropriate for direct use in COS development [10]. The OMERACT initiative overcame this issue by broadening the scope of one of these frameworks, the International Classification of Functioning, Disability, and Health, by incorporating the Wilson and Cleary [11] model of health-related quality of life and thus developing what is now in its second iteration: the OMERACT Filter 2.0 [12], which is widely used as a framework primarily for COS development and has “4 core areas” broadly representing

XSL•FO
RenderX

important categories of outcomes measurable in clinical trials (Figure 1). The core areas are "life impact," "resource use and economic impact," "pathophysiological manifestations," and "death." The core areas are defined, with domains of the specified health-related condition grouped within one of the core areas. For example, the life-impact core area can include domains from both the International Classification of Functioning, Disability, and Health and health-related quality-of-life frameworks. Resource use and economic impact should have domains describing the economic impact of the health condition for an individual and society and specific resource use. Finally, the pathological manifestation's core area is to assess whether the effect of the intervention targets the pathophysiology of the health condition explicitly. It is recommended that at least one domain from each core area is included in the COS [12].

Figure 1. Cranioplasty outcome domains and associated core area categorization using the OMERACT (Outcome Measures in Rheumatology) 2.0 filter.

Study Aims and Objectives

Aim

The aim is to develop a COS for cranioplasty research following TBI or stroke by defining a standardized and agreed set of outcomes that should be reported as a minimum [13] while adhering to the COS-STAD (Core Outcomes Set-Standards for Development) recommendations [14] for COS development (Textboxes 1 and 2).

XSL•FO
RenderX

Textbox 1. Cranioplasty core outcome set scope.

Health condition

- Patients who have undergone a decompressive craniectomy secondary to a traumatic brain injury or stroke await a cranioplasty

Population

- Adult patients older than 16 years

Health intervention

- Cranioplasty

Context

- The core outcome set will be used in future cranioplasty clinical studies and clinical trials to inform clinical decision-making

Textbox 2. Study protocol definitions, adapted from the OMERACT (Outcome Measures in Rheumatology) filter 2.0.

Health

- A state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.

Health condition

- A situation of impaired health.

Health intervention

- An activity performed by, for, with, or on behalf of a client(s) whose purpose is to improve individual or population health, alter or diagnose the course of a health condition, or improve functioning.

Core area

- An aspect of health or a health condition needs to be measured to assess a health intervention's effects appropriately.

Domain

- Component of core area: a concept to be measured, a further specification of an aspect of health, categorized within a core area.

Outcome

- Any identified result in a domain arising from exposure to a causal factor or a health intervention.

Measurement instrument

- A tool to measure the quality or quantity of a variable in a domain or a contextual factor. The tool can be a single question, a questionnaire, a score obtained through physical examination, a laboratory measurement, or a score obtained through observation of an image.

Outcome measurement instrument

- A measurement instrument was chosen to assess the outcome.

Core domain set

- For studies of health interventions, the minimum set of Domains and Subdomains is necessary to cover all Core Areas adequately, that is, sufficiently measure all relevant concepts of a specific health condition within a specified setting.

Core outcome measurement set

- The minimum set of outcome measurement instruments must be administered in each intervention study of a particular health condition within a specified setting to adequately cover a corresponding Core Domain Set.

Scope

- The set of factors describes the studies and circumstances to which the core outcome measurement set will apply.

Contextual factor

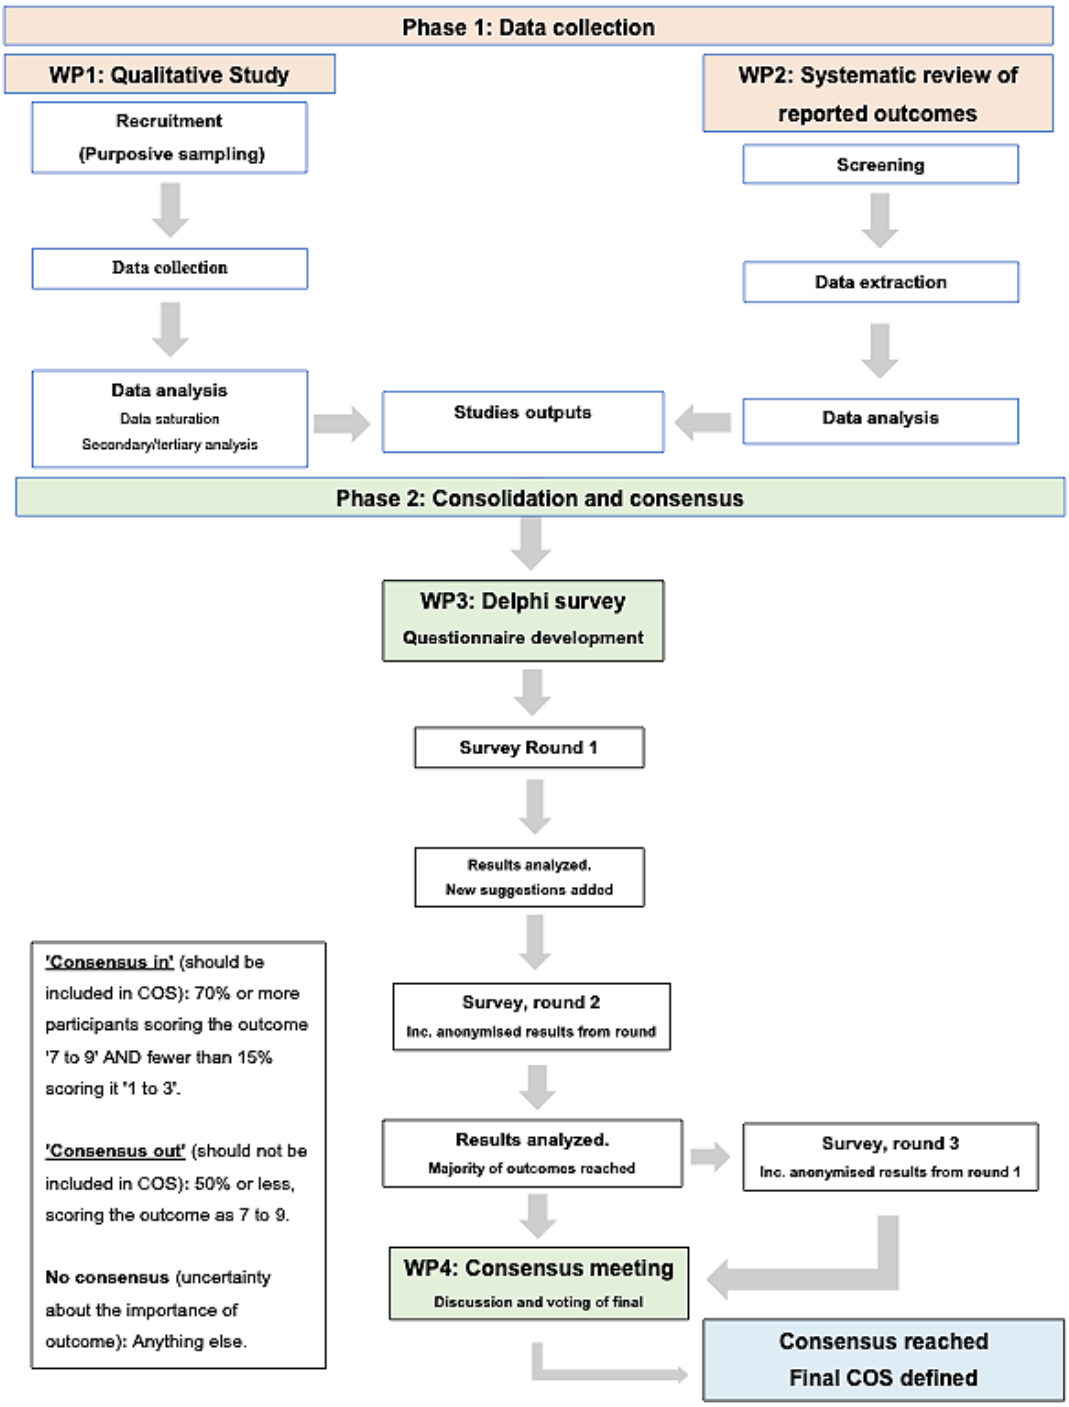
- A variable that is not an outcome of the study must be recognized (and measured) to understand the results.

XSL•FO
RenderX

Objectives

This study has 4 objectives:

- Undertake a systematic review to collate the most current outcome measures used within the cranioplasty literature
- Undertake a qualitative study to understand better the views of clinicians, patients' relatives, and allied health professionals regarding clinical outcomes following cranioplasty
- Undertake a Delphi survey as part of the process of gaining consensus for the COS
- Finalize consensus through a consensus meeting resulting in the COS



Study Design

This is a mixed methods study and will be divided into 2 main phases (Figure 2):

- Phase 1 (information gathering):
  - WP1: systematic review
  - WP2: a qualitative study producing a comprehensive list of outcome domains relating to the cranioplasty pathway
- Phase 2 (consolidation and consensus):
  - WP3: Delphi study
  - WP4: consensus meeting and finalization of COS

XSL•FO
RenderX

Figure 2. Study Flowchart. COS: Core Outcome Set.

Stakeholder Involvement

Advocates from multiple stakeholder groups were a part of the COS development [13,15] by COS methodologists. Adhering to this, the COAST study has 4 stakeholder groups:

1. Patients and/or relatives: people who have had or are awaiting a cranioplasty or their relatives
2. Surgeons: experts who perform cranioplasty in their clinical practice
3. Physicians (nonsurgeons) and intensivists: physicians who care for and treat patients awaiting or having had a cranioplasty
4. Nurses, allied health professionals, and researchers: professionals who treat and help rehabilitate those patients who have had or are awaiting a cranioplasty or have a research interest

These 4 stakeholder groups represent the key personnel in the acute and long-term management and rehabilitation of patients who have undergone or will undergo a cranioplasty. The groups will provide a wealth of experience and views from all aspects of the patient's care pathway.

COS Development Team

An international steering committee has been formed to oversee the development of the COS. The committee represents a broad

XSL•FO
RenderX

range of disciplines and regions of the world, all with clinical interest in and involvement with cranioplasty from a research perspective. A project team oversees the COS development process' day-to-day management, which includes 3 steering committee members and a coordinator. In addition, the project team will establish the methodology and address the key aspects of the project. Key definitions and concepts used to develop this COS have stemmed from the OMERACT initiative (Textbox 2).

Methods

Phase 1: Information Gathering

WP1: Systematic Review

Which outcome domains are used within the published literature for patients undergoing a cranioplasty following TBI or stroke and their recovery and rehabilitation?

Participants/population

Participants should be adult patients aged >16 years who have undergone a decompressive craniectomy.

Intervention

The intervention being studied will be cranioplasty.

Identification of Studies

A search of three databases (PubMed, Embase, and Web of Science) from 1990 to the present analysis will be undertaken to identify either prospective cohort studies with >10 cranioplasty patients or retrospective cohort studies with >20 cranioplasty patients, and two reviewers (AMCL and HM) will independently assess the abstracts of the studies resulting from the search.

Eligibility of Studies

Two reviewers (ACL and HM) will independently review the full texts of the screened abstracts, with any disagreements for inclusion being resolved through discussion. If required, a third reviewer (AK) will be consulted.

Data Extraction

Data will be extracted independently by two reviewers (AMCL and HM). The data will then be reviewed to ensure all outcomes have been identified and no unresolved issues arise. Any disagreements will be resolved through discussion with a third reviewer (AK) available for consultation if required.

Outcomes

The included studies' outcomes will be categorized into domains under one of the four core areas of the OMERACT 2.0 filter framework [12]. Outcomes will be classified as primary when explicitly identified by the study authors, and all other outcomes will be classified as secondary. Each core area and subsequent domain evaluation of the number and frequency of the different outcomes will be analyzed.

WP2: Stakeholder Consultation—A Qualitative Study

To ensure a comprehensive list of outcomes, a qualitative study involving participants in the 4 stakeholder groups will be run, exploring cranioplasty experiences and services and discussing which outcomes are essential to the individual or group. These will then be combined with the outcomes from WP1 to develop the Delphi survey questionnaire.

The qualitative study will include both interviews and focus groups. Participants will be sampled purposively, and the sample size will be guided by data saturation, with 25 and 40 participants across the stakeholder groups likely to be required to reach saturation. A thematic analysis [16] will be used using deductive and inductive coding to analyze known topics of interest and generate new information as the study proceeds. Disconfirming evidence and outlying data will be searched to enhance the reliability and rigor of the analysis process and findings [17]. Data will be compared across and within groups. Qualitative data analysis software (ATLAS.ti) [18] will facilitate data management and analysis.

Phase 2: Consolidation and Consensus

WP3: Delphi Survey

The survey will be online using the Delphi Manager software developed by COMET at the University of Liverpool. Participants will be asked to register and assign themselves to one of the four stakeholder groups. Registration will be implied consent.

Questionnaire Development

This will be drawn from outcomes collated in phase 1 (WP1 and 2) and reviewed and signed off by the steering committee before use.

Recruitment and Sample Size

This will involve centrally coordinating with phase 1 participants invited to participate in further recruitment by post, email, or in person. Participants will also be advised of the importance of completing the Delphi survey, and email reminders will be generated as required to help with compliance.

There are no specific guidelines for the optimal number of participants in a Delphi survey, with previous COS studies having reported 140-150 participants in total [19,20]. Therefore, a pragmatic approach will be taken with the number of participants recruited for each stakeholder group. No new recruitment will occur after the completion of round 1.

Rounds and Scoring

The survey is an iterative process, with a minimum of two rounds but occasionally requiring a third or fourth. All participants score all outcomes using a 9-point Likert scale [21] (Table 1). There will be an "unable to score" option, allowing participants to abstain from scoring a particular outcome if they feel they do not have the expertise to do so; this has been demonstrated to work well in previous COS development projects [22]. A comments box will accompany each outcome to allow feedback as required.

Between rounds, scores are analyzed, summarized, and fed back to all participants in a histogram displaying the distribution of the scores of each outcome, with their scores highlighted. In addition, if there are any descriptive comments for a particular outcome, these will be summarized and presented.

XSL•FO
RenderX

Table 1. Likert scoring scale.

Likert scale	Outcome
1-3	Limited importance
4-6	Important but not critical
7-9	Critical
Unable to score	N/A[a]

[a]N/A: not applicable.

All outcomes from round 1 will be carried forward to round 2, with any additional recommended outcomes also included in round 2. Participants who completed round 1 in the time allocated will be asked to participate in round 2. Each participant will be shown all the outcomes and scores, the number of respondents, the distribution of respondents' scores, and their scores from round 1. The participant will then be asked to rescore each outcome measure with the feedback from round 1 but categorized by stakeholder group. Brookes et al [21] have shown that this feedback method may improve overall agreement in scoring because it enables reflection based on expert views in other groups. Following round 2, no new outcome measures will be considered, and the consensus definition (see WP4) will be applied.

The steering committee will be informed of scores and analysis between rounds, with any issues or conflicts being addressed.

WP4: Consensus Definition and Meeting

Consensus Definition

In line with a previously proposed definition by Williamson et al [13], our consensus definition has been discussed and agreed upon by the steering committee and will be applied in round 2 of the Delphi study.

- "Consensus in" (should be included in COS): 70% or more participants scoring the outcome "7 to 9" AND fewer than 15% scoring it "1 to 3"
- "Consensus out" (should not be included in COS): 50% or less, scoring the outcome as 7 to 9
- No consensus (uncertainty about the importance of outcome): Anything else

The consensus criterion needs to be met for each outcome across the 4 stakeholder groups separately for inclusion or exclusion in the final COS; otherwise, the outcome will be classed as "no consensus" and taken forward for discussion.

The results of the Delphi survey will be discussed at a "final consensus meeting" involving invited participants from the 4 stakeholder groups. Outcomes categorized as "consensus in" across the stakeholder groups during the Delphi will be included in the final COS, and those outcomes categorized as "consensus out" will be excluded. Other outcomes that either have no consensus or partial in or out consensus across the stakeholder groups will be discussed within the consensus meeting, including a round of voting on all debated outcomes. If a final COS cannot be decided by the end of this consensus meeting, further consensus meetings may need to be planned to reach the final consensus.

Ethics Approval

Ethical approval has been granted from the HRA Wales REC 7 committee for phase 1 and phase 2 of the COS study (19/WA/0314). Written consent is required for all face-to-face interviews or focus groups. Verbal recorded consent from health professionals being interviewed over the telephone is acceptable. Participants in the Delphi survey must register online, and implied consent would be assumed if this process is completed.

Safety Considerations

Due to the study type and voluntary nature of the survey, with the ability to withdraw participation at any time, there are no perceived risks to participants.

Follow-up

There is no follow-up as part of this study.

Data Management and Statistical Analysis

Descriptive statistics will display score distribution within stakeholder groups between Delphi rounds. In addition, an analysis of attrition bias will be undertaken.

Quality Assurance

All data will be stored securely, and all individuals accessing any of the data will comply with the requirements of the Data Protection Act 2018 and adhere to the General Data Protection Regulation (GDPR) and its statements regarding the collection, storage, processing, and disclosure of any personal information.

Expected Outcomes of the Study

This research will help standardize outcome definition, collection, measurement, analysis, and interpretation in subsequent studies for cranioplasty. In addition, the output will provide the platform for future patient-reported core outcome measures for use in cranioplasty clinical trials.

Project Management

There is an international steering committee overseeing the study and a working group meeting regularly and reporting to the steering committee.

Results

This study commenced in December 2019. Phase 1 has been completed, and phase 2 started in Spring 2022, with completion due at the end of 2022/beginning of 2023. The study length will be 3-4 years in total. In phase 2, each round of the Delphi will be 3-4 weeks in length, with a 3-week analysis period in-between rounds. The consensus meetings will then be held

XSL•FO
RenderX

before a final consensus meeting with the key stakeholder groups to finalize the COS.

Discussion

This COS aims to standardize cranioplasty-specific outcomes that would then be recommended for future use across research and clinical practice. Categorizing outcomes into domains under one of the four core areas of the OMERACT 2.0 filter framework [12] will hopefully ensure a broad and patient-focused range of relevant outcomes. Cranioplasty needs to be viewed in context with the underlying brain injury. Therefore, the outcomes for this COS will be specific to the impact cranioplasty has on patients rather than an extension of outcomes of the underlying brain injury. There is overlap, but cranioplasty-specific outcomes will hopefully improve the understanding of the impact of cranioplasty on the trajectory of recovery for patients following brain injury.

We know of no published COS for cranioplasty following decompressive craniectomy for TBI or stroke. The COS is being developed with key stakeholder groups using a robust, standardized, and transparent methodology. This iterative process focuses on ensuring a clear, nonbias pathway for developing the cranioplasty COS, all detailed in this protocol. The continuing involvement of key stakeholder groups provides the relevance of this research to all groups involved and, hopefully, makes it accepted as helpful research in the future.

Acknowledgments

This project has been funded by the Division of Academic Neurosurgery, University of Cambridge.

Data Availability

Data sharing does not apply to this article as no data sets were generated or analyzed as this is a protocol.

Conflicts of Interest

The authors have no personal, financial, or institutional interest in any drugs, materials, or devices described in this article. PH is supported by the NIHR (Senior Investigator Award, Cambridge BRC) and the Royal College of Surgeons of England.

Abstract

Background: Mass vaccination of the global population against the novel COVID-19 outbreak posed multiple challenges, including effectively administering millions of doses in a short period of time while ensuring public safety and accessibility. The government of Dubai launched a mass campaign in December 2020 to vaccinate all its citizens and residents, targeting the population aged >18 years against COVID-19. The vaccination campaign involved a transformation of multiple commercial spaces into mass vaccination centers across the city of Dubai, the largest of which was the Dubai One Central (DOC) vaccination center. It was operational between January 17, 2021, and 27 January 27, 2022.

Objective: The multiphase research study aims to empirically explore the opinions of multiple health care stakeholders, elicit the key success factors that can influence the effective delivery of emergency health care services such as a COVID-19 mass vaccination center, and explore how these factors relate to one another.

Methods: To understand more about the operations of the DOC vaccination center, the study follows a multiphase design divided into 2 phases. The study is being conducted by the Institute for Excellence in Health Professions Education at Mohammed Bin Rashid University of Medicine and Health Sciences between December 2021 and January 2023. To elicit the key success factors that contributed to the vaccination campaign administered at DOC, the research team conducted 30 semistructured interviews (SSIs) with a sample of staff and volunteers who worked at the DOC vaccination center. Stratified random sampling was used to select the participants, and the interview cohort included representatives from the management team, team leaders, the administration and registration team, vaccinators, and volunteers. A total of 103 people were invited to take part in the research study, and 30 agreed to participate in the SSIs. To validate the participation of various stakeholders, phase 2 will analytically investigate one's subjectivity through Q-methodology and empirically investigate the opinions obtained from the research participants during phase 1.

Results: As of July 2022, 30 SSIs were conducted with the research participants.

Conclusions: The study will provide a comprehensive 2-phase approach to obtaining the key success factors that can influence the delivery of high-quality health care services such as emergency services launched during a global pandemic. The study's findings will be translated into key factors that could support designing future health care services utilizing evidence-based practice. In line with future plans, a study will use data, collected through the DOC vaccination center, to develop a simulation model outlining the process of the customer journey and center workflow.

Introduction

Improving Health Care Services

Health care providers are continuously looking to innovate the design and delivery of health care services as it is essential to provide the highest level of patient and public health care [1]. In general, health care systems that can also include the design of health care services are deemed complicated since multiple parties are typically involved, such as health care experts, patients, indirect caregivers, governmental entities, political representatives, and the community [2]. The relationships between these diverse stakeholder groups may impact the planning and delivery of high-quality patient care [2]. Furthermore, Mosadeghrad [3] identified 5 specific features that are needed to provide high-quality health care, including environment, empathy, efficiency, effectiveness, and efficacy.

Gaining insight into the nature of the stakeholder's interactions and individual perspectives is valuable to consistently enhance the quality of care, ensuring that these 5 topics are also incorporated within health care design [2,3]. These insights can be integrated into a process known as design thinking, which is described as a systematic approach to executing progressive ideas through understanding the patients' and stakeholders' needs [1]. Studies have demonstrated the benefit of applying design thinking to the health care industry to meet patient needs and provide new services covering areas such as digital innovation, medical devices, new patient experiences, and upgraded hospital and clinic environments [1].

Critical Success Factors in Health Care

Another aspect of improving health care services is applying service-oriented architecture (SOA), which was found to reduce costs, improve patient care quality, and incorporate the organization's legacy system with updated IT infrastructure to be better aligned with the organization's principles and targets [4]. In addition, SOA encompasses the concept of reusability and focuses on streamlining processes within an integrated health care system [4].

Research surrounding the implementation of SOA in health care has identified critical success factors (CSFs) that can influence this process and are considered valuable for its success. Koumaditis et al [4] developed a proposed CSFs model comprising of 21 factors that can be used as a framework for the successful implementation of SOA in health care and the design of effective services. The factors were categorized into 5 groups consisting of managerial, operational, strategic, IT infrastructure, and organizational topics. The theory of proposing the CSFs model can support health care practitioners and researchers in classifying the importance of each CSF and its impact within each category. The significance of creating an integrated health information system is noted to reduce medical errors, improve medical data, and enhance governance and decision-making [4].

Health Care Services in Emergency Situations

During the COVID-19 pandemic, one of the health care services that needed to be immediately deployed was the creation of emergency vaccination centers to support the vaccination strategy [5,6]. When discussing the feasibility of introducing vaccine centers, multiple factors are considered, including the structure of the local health care system, infrastructural strength, and monitoring the success of the vaccination campaign [7]. Mass vaccination of the global population posed multiple challenges, including the effective administration of millions of doses in a short period of time while ensuring it can be safely and widely accessible to everyone [8].

The typical method to improve the effectiveness of mass vaccination during health emergencies or a global pandemic is the development of emergency points, also known as points of dispensing (PODs) [6]. PODs are physical locations that provide medical services such as vaccines to large populations in a short time frame. They differ from typical medical facilities as their primary purpose is to fairly provide medical supplies on a large scale [6]. Mass vaccination centers (MVCs) or PODs are commonly placed in nontraditional spaces or short-term sites such as converting parking lots or larger indoor areas due to the exceptional circumstances of the situation [8].

COVID-19 Management in Dubai

The novel COVID-19 outbreak was first declared a global pandemic by the World Health Organization on March 11, 2020 [9]. Due to the virus's fast-spreading nature, the pandemic began to globally disrupt daily life and compelled countries to announce extended periods of nationwide lockdowns and impose travel restrictions to curb the spread of the virus [10]. The United Arab Emirates (UAE) was no exception and began a partial lockdown campaign on March 22, 2020 [11]. Regaining any level of normalcy hinged on understanding a suitable way to manage symptoms from COVID-19 infection, the discovery of a possible treatment, and more importantly, the administration of effective vaccines [8,9]. The second half of 2020 carried promising news with the discovery and the initiation of mass production of several vaccines, initiated by the World Health Organization as part of their global effort to manage the pandemic [8,9]. Looking more closely at the UAE, the response protocols set by the National Emergency, Crisis, and Disaster Management Authority included large-scale testing, monitoring

XSL•FO
RenderX

outbreak cases, creating emergency field hospitals, global cooperation, and the deployment of vaccination campaigns [12].

The government of Dubai, for example, launched a mass campaign to vaccinate all its citizens and residents who met the criteria in December 2020, also targeting the population aged >18 years. The collaborating authorities managing the launch of this campaign involved the Dubai Health Authority and Dubai's COVID-19 Command and Control Center. The expertise throughout the collective teams complemented each other; the Dubai Health Authority placed a medical guideline for the administration of the vaccines and shared updated protocols, whereas Dubai's COVID-19 Command and Control Center developed a strategy to open and manage multiple vaccination centers across the city. The implementation of this program stretched the resources of various governmental agencies to swiftly achieve and create accessible public vaccination PODs. It included transforming commercial spaces into dedicated vaccination centers, the largest of which was the Dubai One Central (DOC) vaccination center. This was the first vaccination center opened in Dubai and was operational between January 17, 2021, and January 27, 2022.

DOC Vaccination Center

The empty commercial spaces at DOC were swiftly transformed and equipped to become a fully functioning vaccination center in just 72 hours. Figure 1 shows one of the waiting halls in DOC. The transformation involved multiple streams of action, such as the placement of all necessary medical equipment, planning for the ultra-cold supply chain of vaccine vials and their storage, recruiting the required staff, as well as the mapping out of the customer journey and flow of people in and out of the center.

As a result, the team at the center administered 1,476,776 Pfizer-BioNTech vaccine doses (complete appointments) against the infection of COVID-19 in one year (367 operational days). They are considered as complete appointments once the customer completes the entire process of registering for and receiving a COVID-19 vaccine dose, whether it is the first, second, or third dose. The DOC vaccination center received between 147,836 and 211,859 customers per month during the peak operational times (May 2021 to September 2021), vaccinating between an average of 5280 and 7062 customers per day. Notably, the original capacity of the center was designed to hold a total of 4000 customers per day; however, through various operational improvements, the center was able to receive and vaccinate over 10,000 people per day.

Figure 1. Preregistration waiting area of the vaccination center in Dubai One Central.

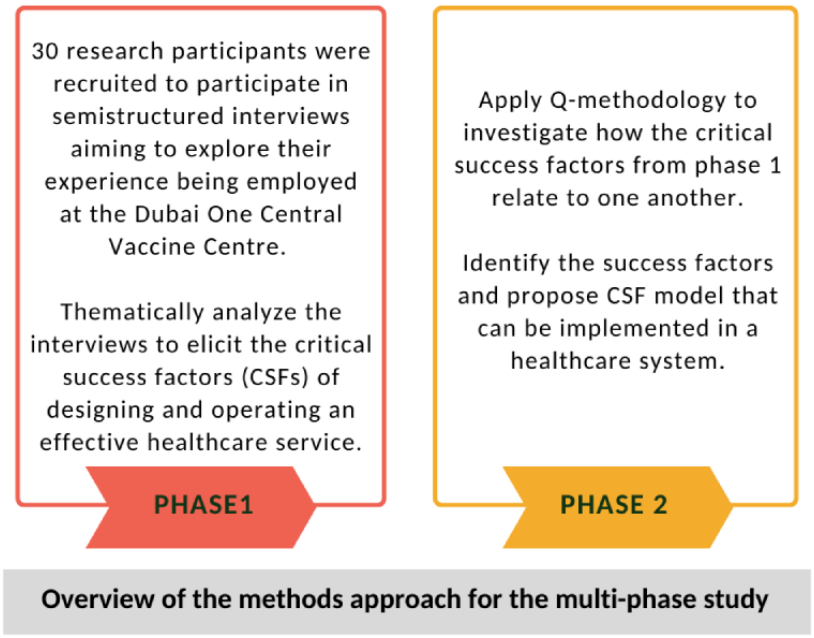
Aim and Research Questions

Our review of the literature identified multiple studies that discussed the importance of exploring the patient's perspective when designing an optimized model to deliver a more efficient health care service [1,13,14]. To ensure that we are considering a more comprehensive perspective, our study aims to empirically explore the opinion of multiple health care stakeholders and elicit the key success factors influencing the delivery of quality care at the DOC vaccination center.

Through a comprehensive research design, the following 3 research questions will be addressed:

1. What key success factors can influence the delivery of a health care service during a public health emergency, such as a vaccination center?
2. How do these CSFs relate to one another?
3. To what extent do these CSFs impact the delivery of health care services?

Methods



Study Design

The study is being conducted by the Institute for Excellence in Health Professions Education at Mohammed Bin Rashid University of Medicine and Health Sciences, located in Dubai,

XSL•FO
RenderX

UAE, between December 2021 and January 2023. To better understand the CSFs of the DOC vaccination campaign, this study follows a multiphase design divided into 2 phases, as illustrated in Figure 2. This 2-step approach aims to investigate the key success factors that supported the design and delivery of a health care service implemented as part of nationwide efforts to combat a global pandemic. It further aims at documenting the efforts and exploring the operations of the first COVID-19 vaccination center opened in Dubai, the DOC vaccination center.

Figure 2. Overview of the methods approach for the multiphase study.

Phase 1: Conducting Semistructured Interviews

A qualitative design was applied to fulfill the study's aim and answer the first research question. Individual semistructured interviews (SSIs) were conducted via Microsoft Teams with a sample of staff and volunteers (n=30) working at the DOC vaccination center. The staff and volunteers of DOC were considered key contributors to the design and execution of the vaccination program. A total of 103 people were invited to participate in the research study, and 30 people agreed to participate in the SSIs.

Stratified random sampling was used to select the participants. The interview cohort included representatives from team leaders, the management team, the administration and registration team, vaccinators, and volunteers. The composition of the participants' roles is included in Multimedia Appendix 1. The inclusion criteria to participate in the study's interview phase included participants aged 18-70 years, who could fluently communicate in Arabic or English, and who worked for a minimum of 3 months at the DOC vaccination center. Based on previous research, a target of at least 30 participants is needed for the sample size to reach thematic saturation and were selected based on their experience at DOC and criteria eligibility [15].

The study's cohort was recruited via email or phone invitation. Before the start of any interview, the research participants were asked to sign a consent form that outlined their rights as a research participant and complete a questionnaire that collected general sociodemographic data before the start of the interview, which can be found in Multimedia Appendices 2 and 3. The approximate duration of the interviews was scheduled for 60 minutes.

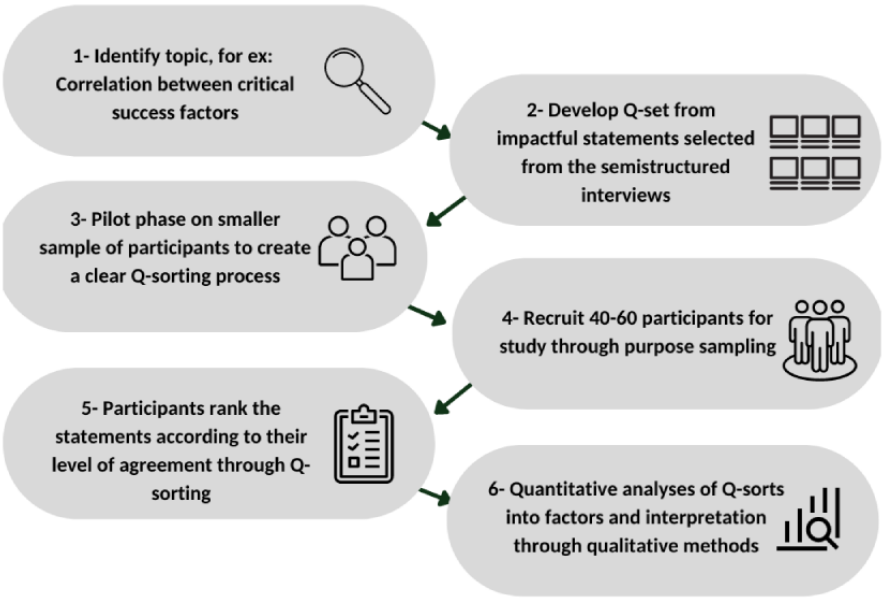
The interview protocol was developed to capture the study's objectives and included 2 main elements: the opening statement by the interviewer and the interview script, including a set of questions acting as a guide during the discussion (Multimedia Appendix 4). The opening statement introduces the researcher, the interview's intention, how the interview result will be utilized, consent to the interview, confidentiality of the interviewee's identity, and options to withdraw at any stage of the process [16]. Before finalizing both versions of the interview guide, a pilot round of SSIs was performed with a sample participant group (n=8). It comprised experts who led the same roles as outlined in Multimedia Appendix 1. The process led to the interview protocol being revised twice after the pilot phase. In addition to testing the interview guide, if the opening statement and flow of questions were understood, the researcher practiced probing to extract key insights and expand on certain topics where needed. The interview guide was then translated to Arabic (Multimedia Appendix 5) to accommodate the language preferences of almost half (14/30, 47%) of the participants. The Arabic language SSI guide was revised by an independent reviewer and later back-translated by another translator to ensure it matched the copy of the English SSI guide.

Finally, the interviews were recorded through Microsoft Teams for documentation purposes, which later assisted with the transcription process. The SSIs conducted in English (n=16) were outsourced to be transcribed using the verbatim method and then revised by a researcher on the project. The Arabic interviews were also transcribed verbatim, translated to English,

XSL•FO
RenderX

and then independently revised by a researcher. Finally, the content is currently in the process of being thematically analyzed using MAXQDA 2020 (VERBI Software) [17]. The thought process behind the thematic analysis is to use the topics outlined in the interview guide (Multimedia Appendix 4) as the main themes. During the coding process, subthemes are intended to emerge, which will shape the list of key success factors considered as the driving force behind operations of the vaccine center. Each of the themes and subthemes were assigned a number, and any mention of a specific theme (success factor) across all 30 interviews will be tabulated and categorized, as viewed by the research participants. The thematic analysis will be conducted by a researcher and reviewed by 2 independent reviewers. If discrepancies are found among the answers, they will be referred to the lead investigator for a final decision.

Phase 2: Applying Q-Methodology



Combining qualitative and quantitative techniques, the Q-methodology aims to investigate one's subjectivity [1] analytically and will be applied to empirically investigate the opinions obtained from the research participants during phase 1. The entire process of the Q-methodology is illustrated in Figure 3 and is summarized across 6 stages. In addition, this technique has illustrated that it is suitable for use when various health care stakeholders are involved (Multimedia Appendix 1) [1].

To answer the second research question, a topic will be identified for the Q-methodology to examine how the identified success factors from phase 1 relate to one another. The "Q-set" will be developed based on the most common and impactful answers selected from the thematic analysis of the SSIs. This "Q-set" will be shared with a smaller sample group (n=10), and they will be asked to rank each of the statements based on purposefully defined criteria such as perceived importance [1]. After gathering feedback from the participants in the pilot phase, the content will be modified if needed and shared with a larger cohort (n=40 to 60) [1]. The inclusion criteria to participate in this phase of the study includes participants aged 18-70 years, who can fluently communicate in English or Arabic, and who worked for a minimum of 3 months at any of the vaccination centers in Dubai.

The next step is data collection and will include "Q-sorting," where each research participant ranks the statements in the "Q-set," following the same scale set in the pilot phase. After purpose sampling, a collection of the ranked statement by an individual, known as the "Q-sort," will be statistically analyzed using the inverted factor analysis methods [1]. During the "Q-sorting" stage, individuals will be asked postsorting questions about their experience participating in the research and their knowledge of the topic at hand, which could lead to additional qualitative insights [1].

Finally, the CSFs that may impact the delivery of health care services will be identified after discovering the relation between the factors. These CSFs will be mapped and categorized following the proposed model by Koumaditis et al [4].

Figure 3. Stages of the Q-Methodology to study the participants' perceptions collected from phase 1. Image inspired by the stages of Q-methodology from Churruca et al [2] which is published under Creative Commons Attribution 4.0 International License [18].

Ethics Approval

The Dubai Scientific Research Ethics Committee approved the study in November 2021 (DSREC-11/2021_04).

Informed Consent and Data Security

The research population included members directly involved in developing and implementing the COVID-19 vaccination campaign in Dubai and at the DOC vaccination center. All participants signed a consent form before the interview and were notified of the study's purpose in written and verbal communication. The identity of all participants will remain anonymous during the submission of the results for phases 1 and 2 of the study. All study data will be kept on a secure, password-protected computer accessible only to the research team (principal investigator and research assistant).

XSL•FO
RenderX

Results

To fulfill the first research question, as of July 2022, 30 SSIs were conducted with the research participants outlined in Multimedia Appendix 1. On average, each interview lasted 45 minutes and ranged between 25 and 84 minutes.

Discussion

Expected Findings

The results from the project's first phase are expected to elicit the critical success factors, enablers, and barriers of the design and operation of the COVID-19 vaccination center at DOC.

Results from the project's second phase will highlight how the success factors identified in phase 1 will relate to each other, answering the study's second research question. Additionally, the expected results from the analysis will feature patterns of similarities and differences from the Q-sets. Finally, and to answer the third research question, we will identify the extent of these success factors' impact on the delivery of health care services.

Strengths of the Study

The SSIs were conducted to explore people's perceptions about the DOC vaccination center and elicit the key success factors surrounding its design and implementation. Another strength of the research study is the number and quality of interviews completed. The researchers organized 30 interviews—the recommended number of SSIs that need to be completed to provide meaningful results for a research study [15]. The group of interviewees included employees and volunteers from diverse professional backgrounds. The varying roles each of the interviewees held at the vaccination center (refer to Multimedia Appendix 1) provided the study with richer and diverse insights [19]. Furthermore, the open-ended question format of the SSIs allowed the participants to focus on each topic in detail and share varied responses based on their individual experiences [20]. This approach helps reduce the risk of bias relating to the researcher's preconceptions about the themes, as this style of data collection allows the use of follow-up probes throughout the discussion as directed by the participant [20].

In addition to completing the SSIs, the Q-methodology will focus on allowing participants to express their opinions about the subject while reducing former expectations and possible biases introduced by the researcher. It is also known as a people-centric approach that can provide a deeper view on the matter and is beneficial when studying complex health care topics [1]. This method is not commonly found in health care research and can potentially be a valuable tool [1].

The result of our research can help bridge a noted gap in the literature [4] as we explore each of the CSFs independently, their relation to each other and the health care service, as well as develop a CSFs model that can be applied to any level within a health care organization or service to improve the quality of patient care and organization of data [4]. Combined with the implementation of SOA, there is a real opportunity to achieve interoperability and flexibility to update medical processes in line with new regulations and improve decision-making [4]. According to research in this area, developing SOA culture and governance from the leadership are seen as a driving force for resisting change and successful execution [4].

It is noted that there is limited information in the medical literature on the systematic process of creating MVCs. Although mass vaccination campaigns have been mentioned as a general component for managing communicable diseases since the 1970s during the spread of H1N1 influenza, there is a lack of clear criteria to defining an MVC, such as pertaining to the number of doses and/or number of people served in a day [8]. For example, in the spring of 2021, Euro Disney Paris was transformed into an MVC with the capability of serving 1000 doses/day, whereas in Italian cities, they were able to vaccinate over 4000 people in one day [8]. Global health experts are executing their own strategies and procedures to administer the COVID-19 vaccines as the concept has more prominently emerged within the last 2 and a half years [8].

Comparison to Other Works

Studies surrounding the development of MVCs specific to the COVID-19 pandemic are still considerably low [8,21]. They are typically found to focus on documenting the MVC process, analyzing the vaccination system, and understanding people's perceptions about the COVID-19 vaccine [20,22]. However, the outcome from these studies is not usually connected to the enhancement of more general health care services and improving patient care. For example, Brambilla et al [21] studied the process surrounding mass vaccination. They outlined the method of developing a scalable and replicable MVC model in Lombardy, Italy, which can be adapted and created in non–health care locations, whereas Andrade et al [22] focused their research on investigating the UAE's population's motivation to receive the vaccine and its correlation to their level of understanding, acceptance, and conspiracy beliefs related to the vaccine. Another example of a recently published study illustrated the application of Lean tools to develop an MVC and investigated its effectiveness and whether this approach increases the efficiency of mass vaccination sites [23].

Since MVCs for COVID-19 are believed to be the first mass vaccination effort in the present era [8], it is considered integral to document the process of creating a high-volume MVC such as the DOC vaccination center and the collaborative efforts to safely administer over 1.4 million doses in the span of one year to everyone that required it. In addition to documenting these efforts, this study also aims to connect the results from understanding the key success factors of implementing an MVC to its potential impact on the delivery of health care services and improving patient care.

Knowledge generated from this study conducted in the Gulf Cooperation Council and the Middle East region will contribute to a more accurate global representation of the success factors, as we aim to empirically explore the opinion of multiple health care stakeholders and elicit the key success factors influencing the delivery of a health care service during a public health emergency, such as a vaccination center.

RenderX

Limitations of the Study

Due to restrictions imposed because of the COVID-19 pandemic, the SSIs were completed remotely, via the videoconferencing platform Microsoft Teams. This was often considered a challenge as there were technical difficulties while the interviews were taking place such as unreliable internet connection. Utilizing an online platform to collect data may have impacted the quality of recordings, which in turn may have affected the quality of the transcriptions. Additionally, attempting to schedule at least 30 interviews in a short time frame before the center's closure proved difficult to plan around the employee's schedules, and the interview schedule was continuously delayed. The SSIs were conducted with a sample of DOC vaccination center's staff and volunteers before the closure of the center by 2 months and were completed shortly afterward. Therefore, the time between data collection and the closure of the DOC vaccination center may have contributed to recall bias as the interviewees were asked to recollect events from the past. Finally, due to the workload of the front-line workers at the DOC vaccination center, pandemic fatigue may have also been a factor that could have influenced their responses in the interviews.

Future Work

Future research will leverage the data collected to contribute to the medical informatics field, specifically with the aims to explore approaches that can effectively analyze big data, include predictive analytics, and optimize decision-making [24]. In line with the future plans, a study will use data, collected through the DOC vaccination center, to develop a simulation model outlining the process of the customer journey and center workflow.

The simulation model will focus on capturing the data at 3 significant milestones, including when the center reached a daily capacity of administering 1000 doses, 4000 doses, and 10,000 doses to customers. This will showcase the center during various operational phases and the improvements that took place during each stage and identify areas that needed more enhancements to increase operational efficiency. Simulation modeling has been identified as a smart tool that offers the prospect of testing various scenarios using a cost-effective approach, obtaining solutions for obstacles during certain health care service phases, comprehensively visualizing the process [8].

This analytical phase of the study will focus on the operational aspect of designing a health care service and how it can assist with the decision-making process through an optimized health care service model [24]. In a way, the pandemic accelerated the growth of designing and delivering a high-capacity vaccination center. Therefore, it is recommended that the next phase of planning for health care services is to focus on operational efficiency, its link to patient satisfaction, high-quality care, and the need to apply a standard operating procedure across various processes and facilities [4].

Conclusion

The study provides a comprehensive 2-phase approach to eliciting the CSFs that can influence the delivery of high-quality health care services such as emergency services launched during a global pandemic. The findings from the study will be translated into key factors that could be optimized and applied when designing future health care services, utilizing evidence-based practice. Additionally, the results from the study conducted in the Middle East region will contribute to a more globally accurate representation of CSFs. Finally, the future work from this research study will explore methods to analyze data collected from the DOC vaccination center, include predictive analytics, and optimize decision-making.

Acknowledgments

This research was supported in part by the Al Jalila Foundation and is funded by a Pfizer Independent Medical Education Grant (number 69872363). However, the funding body was not involved in the study's design, data collection, or analysis.

Abstract

Background: Previous research has suggested that care home interactions need significant improvements, especially those between staff and residents with dementia. Reasons for the lack of interactions are staff time pressures and residents' language impairments. Although residents may experience reduced language abilities, they can continue to communicate through other forms, including nonverbal communication and music. Person Attuned Musical Interactions (PAMI) is a staff training tool that provides staff with music therapy skill-sharing to promote high-quality interactions between staff and residents using nonverbal communication and music. The tool was originally developed in Denmark. To ensure that the tool is appropriate for UK care homes, a team of researchers in the United Kingdom have modified and culturally adapted the tool.

Objective: This study aims to investigate the appropriateness of the adapted and modified manual for UK care homes and to explore the impact of PAMI on residents with dementia and care staff.

Methods: The project consists of 2 phases, a qualitative field-testing study and a mixed methods evaluation study, which have been developed following the Medical Research Council's guidelines for complex interventions. Care staff and residents with dementia will be recruited from care homes in Lincolnshire, where the care staff will be trained in the PAMI intervention before implementing the intervention in their daily routines. Fortnightly reflective sessions will be provided throughout the phases to provide supervision and monitoring. The qualitative methods include interviews, reflective session transcripts, diary entries, and resident experience questionnaires. The quantitative outcome measures are residents' music engagement, staff's dementia competence, residents' quality of life, and staff burden. The resident's music engagement will be administered at 9 fortnightly time points. Staff's dementia competence, resident's quality of life, and staff burden will be administered at preintervention and postintervention time points.

Results: The study has been funded by The Music Therapy Charity as part of a PhD studentship. The study began recruiting in September 2021. The research team aims to publish the results of the first phase in July to September 2023 and those of the second phase in October to December 2023.

Conclusions: This study will be the first to investigate the modified version of PAMI. Therefore, it will provide feedback on the appropriateness of the manual for UK care homes. The PAMI intervention has the potential to offer high-quality music intervention training to a larger population of care homes who may currently be restricted by finances, the availability of time, and a lack of training opportunities.

Introduction

Care Homes and Residents With Dementia

People reside in care homes for several reasons, including old age, health conditions, and disability, but generally, care home residents require substantial help and support to complete activities of daily living, including personal care, and to access leisure activities. In the United Kingdom, between 408,371 and 490,326 individuals live in approximately 17,079 care homes [1,2]. Approximately 70% of the residents in care homes have a diagnosis of dementia [3]. Dementia is an umbrella term for a range of progressive conditions characterized by a slow deterioration in brain function, including memory, language, decision-making, and judgment [4-6]. Individuals with dementia can experience a range of symptoms because of the deterioration, including disorientation, anxiety, depression, apathy, agitation, restlessness, hallucinations, mobility issues, and personality changes, which can affect an individual's ability to complete daily tasks and live independently.

Care Home Communication

The care and assistance staff provide to residents compel the need for a strong relationship based on trust, respect, and understanding [7,8]. Care staff should aim to provide person-centered care and interactions to tailor care to the resident's needs, preferences, impairments, and abilities [9-11]. Staff should consider the individual as a whole person who is treated with respect and dignity. Person-centered care can be inconsistent among staff and care homes. During a 6-hour observation period, Willemse et al [12] reported, on average, 1.5 meaningful interactions, with one-third of participants experiencing zero meaningful interaction during the observation. Care home interactions are not only infrequent but can also be short, be fragmented, sometimes consist of "Elder speak," and be task orientated in nature [13,14]. "Elder speak" refers to interactions characterized by simplistic vocabulary and grammar, shortened sentences, slow speech, elevated pitch, and inappropriate use of endearments [14-16]. "Elder speak" has been compared with interaction techniques typically used with babies and leaves individuals feeling patronized. The frequency and quality of interactions generally correlate with the severity of the individual's dementia and impairments, including limited verbal language [14,17]. Understaffing and time pressures have been suggested to explain the limited interactions in some care homes and result in prioritizing physical care and safety over meaningful activities and interactions [18]. However, meaningful activities and interactions are equally essential to ensure that the resident's psychological, social, and emotional needs are met; the resident's identity remains; and dementia symptoms are managed. Therefore, interventions and staff training targeting interactions and meaningful activities in care homes without increasing staff time or burden are vital.

Music in Dementia Care

Although individuals can experience reduced verbal language, involvement in interactions can continue through nonverbal communication and other alternative communication styles [17,19,20]. However, as they are untraditional and less familiar to individuals, staff can miss or misinterpret more ambiguous and subtle communication cues [20].

Music, consisting of both verbal and nonverbal elements, has been highlighted as a potential alternative communication form accessible to individuals with dementia. Although language processing significantly deteriorates as dementia progress, music processing seems to remain intact, potentially owing to music processing requiring nearly all brain areas [21-23]. Music is an inclusive and adaptable tool not limited by age, culture, or health conditions and has been evidenced as a multibeneficial tool for various health conditions, including dementia [24,25]. Music in dementia care has the potential to improve well-being, alertness, anxiety, depression, agitation, and activity disturbance [26-28]. When care staff facilitate music activities, research has reported improvements in quality of life, job satisfaction, communication skills, stress, and burden [29]. Typically, music can be categorized into 2 intervention types: music therapy, facilitated by specialist music therapists [30]; and music activities, facilitated by care staff, family members, volunteers, and musicians. Both have highlighted the benefits of incorporating the intervention into dementia care. The most appropriate intervention depends on the aims of the intervention, symptoms, residents' preferences, and care home factors such as time and finances.

In the United Kingdom, music therapists are limited, with only 200 to 250 individuals working in the dementia field [30], resulting in the intervention being restricted to a limited number of individuals. In addition, care home finances can restrict care homes from employing music therapists. Research highlights that music therapy benefits generally only remain during and immediately after the session [31]. Therefore, to maintain the benefits, regular daily doses of music interventions should be provided in care homes, which may not be plausible with music therapy. Music activities have more flexibility and can be provided by anyone, making them a more viable option for long-term use in a larger proportion of care homes. When music activities are of high quality and implemented successfully, they can provide similar benefits to music therapy [32-36]. However, the implementation of care home music activities is currently minimal. In 2017, only 5% of care homes provided good quality arts and music interventions [37]. The lack of staff time knowledge, resources, and training may explain the lack of

XSL•FO
RenderX

music interventions in UK care homes [38-40]. The lack of available time has been highlighted as a potential barrier to staff interactions and music interventions. However, a series of studies investigating music therapeutic care (MTC) demonstrated the plausibility of incorporating music into personal care tasks [32,41-45]. Because music was incorporated into other tasks, staff did not have to spend additional time or bear additional burden; instead, the intervention improved task efficiency. However, the issue remains that low-quality music activities implemented unsuccessfully can be ineffective and even harmful to residents with dementia [46].

Music Therapy Skill-Sharing

Music therapy skill-sharing provided by music therapists has been suggested as a solution to improve the implementation of high-quality music interventions facilitated by staff in care homes. Music therapists share their skills and knowledge of music therapy, allowing staff to incorporate indirect music therapy practices into their routines [46]. As previously highlighted, staff and family members may lack knowledge and experience in music interventions. Inappropriate or lack of space and support for staff to reflect on how to be with the individual and focus solely on the content can lead to a loss in benefits [40,46,47]. Currently, music therapy skill-sharing only occurs in care homes with employed music therapists. A structured manual developed from evidence-based practices that train staff in the type of music skills and how facilitators should deliver skills would enable music therapist knowledge to be shared with and accessible to a larger population of care homes.

Person Attuned Musical Interactions Manual

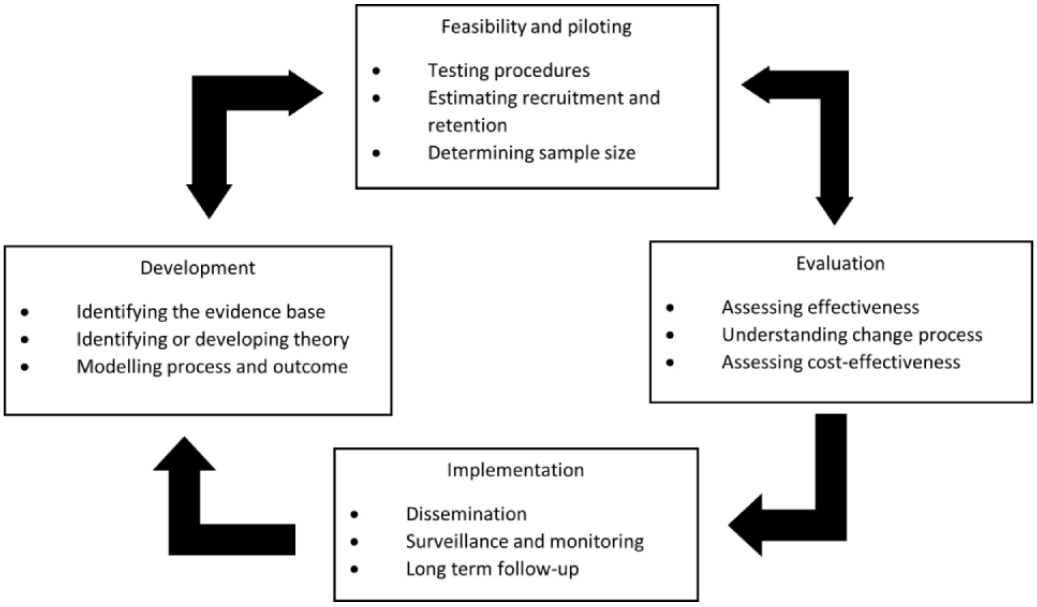
Person Attuned Musical Interactions (PAMI) is a structured staff training tool developed based on previous research that provides staff with music therapy skill-sharing training. The tool was initially created by a team of music therapist researchers at Aalborg University, Denmark [48], which aimed to promote 2-way attuned music interactions between care staff and residents with dementia. In the intervention, the PAMI research team train music therapists, who then go into care homes to train staff. The training provided to care staff consists of 3 elements: group theory and reflective training, group practical supervision, and individual practical supervision. In the group theory and reflective training, staff gain insight into the theory behind PAMI, complete reflective exercises, and learn about the PAMI skills. The group and individual supervision sessions involve the music therapists working with the care staff on the care home floor to assess and guide staff on the PAMI skills by observing them using the skills with residents. All the elements of the PAMI training are completed in person. On the basis of cultural adaptation intervention research [49,50]. A modified version of PAMI was developed by a team of researchers at the University of Nottingham to ensure that PAMI was culturally appropriate for UK care homes (Waters, B, Orrell, M, and McDermott, O, unpublished data, March 2023).

The researchers followed 2 cultural adaptation frameworks, the Barrera and Castro [51] framework and the Formative Method for Adapting Psychotherapy [52], to guide the development process. The first author's thesis reports the manual development process and the differences between the Danish and Modified version of PAMI (Waters, B, unpublished data, March 2023). Both frameworks advise that once adapted, the newly adapted intervention should be reviewed with stakeholders to test its appropriateness and obtain preliminary results.

Aims

The aims of this study are as follows:

1. To investigate the suitability, manual layout, and clinical relevance of the PAMI-Modified (PAMI-M) manual
2. To investigate the cultural adaptation appropriateness of the PAMI-M manual
3. To identify changes in staff's and residents' behavior and mood after using the PAMI-M manual
4. To identify staff's views on using the PAMI intervention within their care home
5. To investigate the factors influencing the implementation of PAMI in UK care homes



Methods

Medical Research Council Guidelines

The research team identified PAMI as a complex intervention; therefore, the Medical Research Council (MRC) guidelines have been followed for this study. Complex interventions refer to interventions consisting of several interacting components. Interventions may be complex for several reasons, including the number and difficulties of behaviors of those receiving the treatment, the requirements of the facilitator, the number and variability of outcomes, the degree of flexibility, tailoring of the intervention, and the number of groups targeted. The MRC created a framework for researching complex interventions to aid researchers in designing, running, and reporting complex interventions [53]. The framework consists of 4 phases (Figure 1): development, feasibility and piloting, evaluation, and implementation. This protocol focuses on the development phase and begins to explore the feasibility and piloting phase.

XSL•FO
RenderX

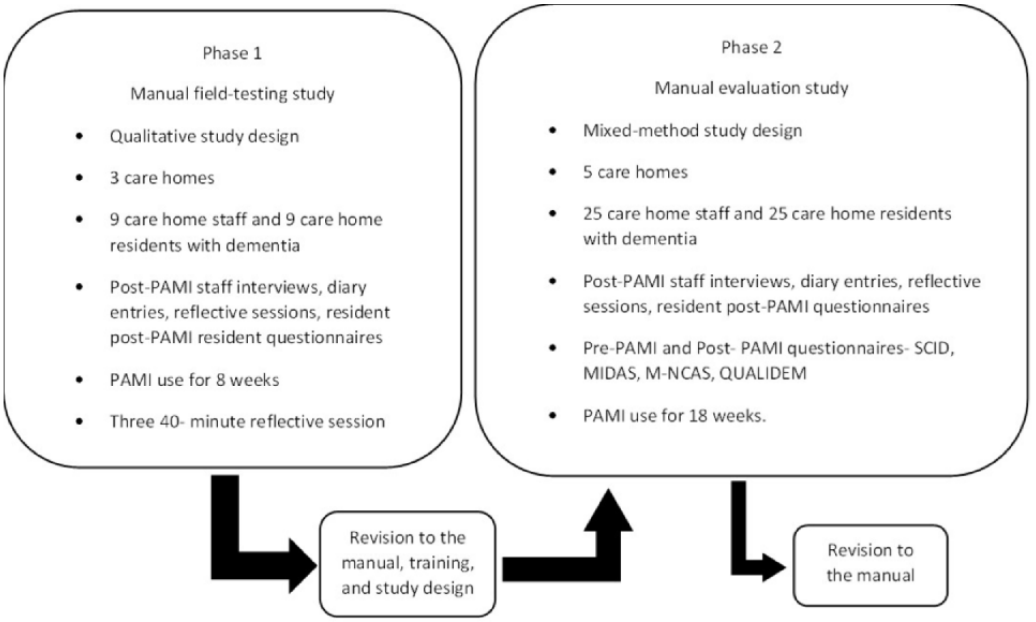


Figure 1. Medical Research Council complex intervention framework.

Study Overview

Two phases will be conducted to investigate the aims, which follow the stages of the MRC guidelines and cultural adaptation frameworks. A field-testing qualitative study will review the culturally adapted manual with its intended stakeholders to ensure appropriateness. Data will be collected on the factors influencing the implementation of the intervention and stakeholders' (care staff and residents) experience with PAMI, including changes in behavior and mood and care staff's views on using the intervention. The data collected in the first phase will aid adaptations to the manual in preparation for the second phase. The second phase is a mixed method study that will continue reviewing the culturally adapted manual with its intended stakeholders. In addition, the study will collect preliminary data on the impact of PAMI on staff and residents to begin investigating the feasibility and piloting stage of the MRC guidelines. The data collected in the second phase will aid final manual revisions and be used to develop future studies to continue exploring the feasibility and piloting stage of the MRC guidelines. Figure 2 displays the study overview.

Figure 2. Study overview consisting of 2 phases and 2 revisions stages. The study overview was developed based on the Medical Research Council guidelines for complex interventions and culturally adapting intervention frameworks. MIDAS: Music in Dementia Assessment Scale; M-NCAS: Modified Nursing Care Assessment Scale; PAMI-M: Person Attuned Musical Interactions-Modified; SCIDS: Staff Competence in Dementia scale.

Ethics Approval

The 2 phases received ethics approval from the London-Harrow Research Ethics Committee on June 29, 2021 (reference number 21/LO/0283). Amendments to the study were approved by the London-Harrow Research Ethics Committee on March 22, 2022.

National Health Service Trust Partnership

A partnership with the Lincolnshire Partnership National Health Service (NHS) Foundation Trust was created early in the manual development process, which will assist with running the studies in care homes. As part of the partnership, PAMI will be advertised through the trust's Enabling Research in Care Homes (ENRICH) organization. ENRICH is a national organization developed by the National Institute for Health Research (NIHR) to support care home staff, care home residents, residents' families, and researchers to implement research into care homes more smoothly, accessibly, and effectively.

The Lincolnshire trust developed a pilot in-reach scheme in 2020 to improve the accessibility of care home research within Lincolnshire. The partnership between the research team and Lincolnshire NHS trust has led to an in-reach practitioner (RF) joining the team. The in-reach practitioner will liaise between the researchers and care homes with whom they already have a rapport. This rapport means that the in-reach practitioner is already aware of care homes potentially interested in the PAMI research, reducing the time needed for introductions, providing a recognizable face, and thus reducing anxiety among potential participants. The in-reach practitioner will support the researchers in setting up and running the study. The role involves introducing the study to care homes, recruiting participants, distributing documents, assessing capacity, obtaining consent, introducing the care homes to the research team, collecting documents, and being an in-person contact for the research team. When designing the study, the research team was uncertain about the possibility of the researchers attending the care homes owing to the COVID-19 pandemic; however, the in-reach practitioner is an NHS role, allowing them to continue attending care homes throughout the studies. The care homes involved in the in-reach pilot scheme belong to ENRICH and were invited to join the scheme.

Recruitment

Care homes will be recruited first through the in-reach scheme or advertisement through the Lincolnshire ENRICH. Once the care homes are recruited, 2 participant types will be recruited: care staff and residents with dementia. The researchers will contact care home managers and introduce the team to interested individuals. A management introductory letter will introduce the study and provide the potential benefits to the residents, care staff, and care home. The introductory letter will also inform managers of the required time commitment from themselves, the staff, and the residents to ensure that their care home can commit the required time. The welcome pack also contains introductory letters for the care staff, residents, and residents' families. The care home managers will be asked to distribute the welcome letters to the staff and residents. Care staff will be recruited first before residents to enable the staff to communicate the study to the residents. As the researchers cannot access residents' care plans, the researchers require care staff to distribute the information sheets to eligible individuals. Interested individuals can contact the researchers using the provided contact details or inform the in-reach practitioner when she attends the care home of their wish to participate. Information sheets and consent forms will be provided to interested individuals, with them given a week to consider their participation. The in-reach practitioner will organize visits with the care homes during recruitment to discuss the study and answer questions. Once care staff and residents are recruited, the residents will be paired with the participating care staff they have the most direct contact with daily.

Informed Consent

Written informed consent will be collected from all participants at the start. There are different information sheets for staff and residents. A dementia-friendly version of the resident information sheet is available for residents who may struggle to comprehend the formal participation sheet. If individuals wish to participate, a consent meeting is organized, where they can review the documents with the in-reach practitioner and sign the consent form. The consent meeting can be completed either in person at the participating care home or remotely via Microsoft Teams (Microsoft Corp). During the meeting, potential participants are given time to ask any questions or concerns. Once the consent forms are signed, 1 copy is given to the participant, and the research team keeps 1 copy. A third copy is kept in the resident's care file when resident participants consent. Consent is an ongoing process; therefore, the research team will continue checking participants' consent. Some resident participants may be unable to consent verbally; therefore, the researchers will work with the care home to determine the most appropriate form of communication for each resident.

Researching Adults Who Lack Capacity

The studies involve participants who may lack capacity owing to their dementia diagnosis. The Mental Capacity Act 2005 [54] will be followed to determine participants' capacity to consent. All research team members have previously worked in care homes, where their role required the understanding of the lack of capacity. All members have also completed training in informed consent with adults lacking capacity. With assistance from the care homes, the in-reach practitioner will assess the resident's capacity to consent during the consent meeting, which involves assessing whether the resident understands the study and what is required of them and ensuring that they understand the consent form and can follow the instructions to sign the form. A consultee, who is a family member, a friend, or an appointed power of attorney, will be appointed for residents who are deemed to lack capacity. Once a consultee is appointed, they will be provided with an invitation letter, a consultee information form, and a consultee declaration form, with time to consider their relative's (the term relative is used to also refers to those who's consultee is a friend or power of attorney) participation in the study before a consultee meeting is organized. The consultee meeting can take place in person or remotely via Microsoft Teams. During the consultee meeting, the consultee will be asked to sign the declaration form if they wish their relative to take part in the study. Staff and consultees can use the dementia-friendly information sheet to discuss with residents their participation in the study. For residents who are deemed to lack capacity to consent, on top of their consultee's declaration to participate, assent will be obtained to ensure that they agree to partake. Assent will be collected to allow residents to remain involved in the decision process when not legally able

XSL•FO
RenderX

to consent. The most appropriate communication form for residents will be used to obtain assent. Researchers will ensure that residents continue to consent throughout the study, using their choose communication form. For residents unable to verbally assent, staff and researchers will assess residents' behavior for signs of wishing to withdraw or distress throughout the study.

Dementia is a progressive condition; therefore, some resident participants could lose capacity during the study. The researchers will review the resident's capacity throughout. If a resident is deemed to lose the capacity to consent during the study, a consultee will be appointed and asked to complete the consultee declaration form to allow the resident to continue the study.

Withdrawal

Care staff participants will be reminded at the start of each reflective session that their participation and their resident's participation are voluntary, and they can withdraw at any time without providing a reason. Participants will also be reminded that withdrawal from the study will not affect the care they receive as a resident or their employment as staff. During the reflective sessions, care staff will be asked to report any PAMI issues and whether residents have displayed signs of distress or wish to withdraw. In-between reflective sessions, participants can contact the researchers via email or telephone. All study activities will cease immediately if a participant withdraws, and no further data will be collected. However, the data that have already been collected will be used in the final analysis. As participants partake in the study as dyads, both participants will be withdrawn from the study. The only exception is if only the staff interview remains and the resident withdraws; in this case, the staff member can complete the interview but will only be able to report on their experience of the training. Withdrawn participants will not be replaced.

Setting

The 2 phases will be conducted in Lincolnshire care homes caring for individuals with dementia. The care homes can be private, voluntary, NHS or council owned and provide either residential, nursing, or both types of care. All care homes must meet the eligibility criteria.

The care home eligibility criteria are as follows: they should have received a score of "Needs improvements" or "good" on their most recent Care Quality Commission report and have adequate Wi-Fi for staff to be able to attend the PAMI training and reflective session.

The in-reach practitioner will review care homes' eligibility to determine to whom to introduce the study. The care homes in the in-reach pilot are all part of the ENRICH group, which promotes and supports care homes with research.

Remote Delivery

When designing the study, the UK COVID-19 guidelines restricted researchers from attending care homes. As a result, several study elements have been converted to take place remotely. The training, reflective sessions, and interviews will be completed remotely using a conference call platform. Microsoft Teams was selected because of its ease of use; it allows up to 250 individuals to join a call; it allows for screen sharing; it is not time limited; it can record sessions; and it is encrypted, making it safer. The NHS Transformation Directorate Department, formally known as NHS user experience, confirmed in 2020 that Microsoft Teams is safe to use in health care [55,56]. A Microsoft Teams channel will be created for each care home where the training session, reflective sessions, and interview meetings are scheduled. A Microsoft Teams information sheet has been created, providing information on joining Microsoft Teams channels and meetings. The information sheet will also be provided to consultees who complete their consultee advice meeting remotely. For ease and consistency, the research team decided to continue running the studies remotely when the UK COVID-19 guidelines were lifted.

Intervention

The PAMI intervention can be split into 3 elements: the paper copy of the PAMI manual, the initial training session, and fortnightly reflective sessions.

Manual

The PAMI manual consists of theory, reflective exercises, examples, and practical skills. The manual can be sectioned into 6 categories: interactions and music, the voice, framing, balancing, connecting, and practical tips and resources. Colored boxes have been used to separate the different elements to make it easier for staff to locate information. Staff are required to bring the paper manual to the initial PAMI training, as the reflective exercises in the manual are completed during the training.

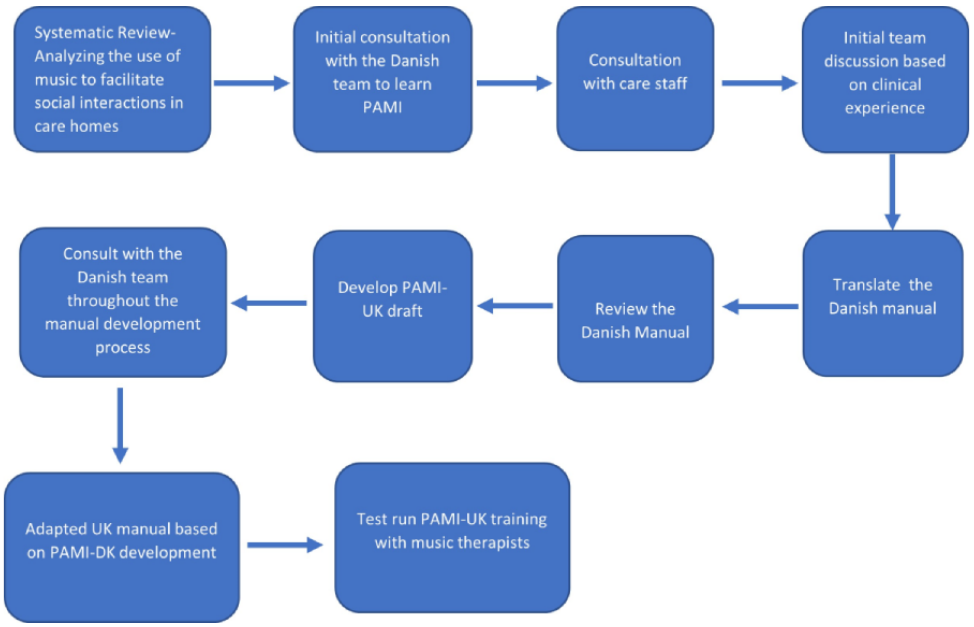
The first section, interactions and music as communication, provides staff with theory on interacting with individuals with dementia. PAMI aims to be able to train all staff regardless their level of experience and training; therefore, this section provides the foundations of interactions in dementia care to ensure that everyone is at the same level before exploring the PAMI skills. This section also starts to explore using music therapeutically and the research highlighting the benefits of music for individuals with dementia. The second section begins to explore the voice as a musical element. The section reflects on when and how staff use their voice currently. The music parameters of the voice, including pitch, rhythm, tone, and volume, are explored in relation to the staff's roles. Framing explores adapting the care home environment to create security and predictability. This section introduces the skills of using music as a cue for tasks and sound environments. Balancing explores recognizing and adapting residents' arousal states using music, the voice, and the body when residents experience agitation or apathy. Staff also gain skills to recognize their arousal state and regulate it to ensure that their emotions are not impacting their interactions with residents. Connecting explores using meaningful music to connect and create relationships. Staff explore reminiscence and music therapy skills such as attunement, validation, and holding. The connecting section introduces the PAMI music care plan, providing residents with a tailored music plan that staff can use to implement music successfully. The final section provides practical tips to improve the implementation of the intervention.

XSL•FO
RenderX

Training Session

The primary researcher (BW) will facilitate the training sessions with assistance from a music therapist (BS). BW is a nonmusic therapist with a background in psychology and has worked as a care home well-being therapist. BW was the researcher who developed the modified PAMI manual as part of her PhD. (Waters, B, unpublished data, March 2023). The PhD student was selected by the research team as the most suitable candidate for the role, and her experience complemented the rest of the team's expertise and knowledge. The primary researcher worked with the original Danish team and the principal investigator, who is also a music therapist, to ensure that the training covered all the appropriate areas of music therapy. Before the delivery of the training to any care homes, the primary facilitators ran the training with 2 music therapists, the principal investigator, and second PAMI facilitator, who provided feedback on the content and delivery of the training. The feedback was used to make final changes to intervention before its use in the study. A 3-hour group interactive webinar will be delivered via Microsoft Teams at the study's beginning. The training is organized at the convenience of the care homes and care staff. The training session follows the manual layout, with staff completing the reflective exercises in the manual during the session. Different learning elements have been used, including written text, pictures, talking, interactive activities, videos, and the music therapist experience, to make the training accessible to many learning styles. During the session, staff are provided with examples for implementing the skills and theories into practice. As PAMI's central ethos is person centered, what, when, and how frequent skills are used are at the staff's discretion. Staff are instructed to use PAMI in relation to their resident's needs, impairments, and preferences. However, they are advised to use PAMI regularly on every shift.

Reflective Sessions



BS, a music therapist on the researcher team, will facilitate the reflective sessions with assistance from the primary researcher. The sessions will be conducted once a fortnight for 40 minutes via Microsoft Teams. The sessions hold two purposes: (1) to get staff to reflect on their practices and their experience implementing PAMI and (2) to collect data on using PAMI in care homes. Unlike the training, which has more structure, the reflective sessions are less formal, with sessions guided by the care staff. Three reflective sessions are more structured, each focusing on one of the specific PAMI elements to ensure that staff have understood each element and attempted to implement the skills in the care home. A reflective session outline has been developed by BS to guide the sessions and provides potential questions that the facilitator may wish to ask to prompt discussion.

Intervention Development

The research team completed a multistage process to culturally translate and adapt the Danish PAMI intervention for UK care homes (Figure 3). Throughout the process, the research team liaised with the Danish PAMI team to ensure that any adaptation and modification remained consistent with the PAMI ethos. The research team also incorporated public and patient involvement throughout the development stage to ensure that the intervention was appropriate and suitable for the intended setting and audience. A detailed manual development process is discussed in the primary author's thesis (Waters, B, Orrell, M, and McDermott, O, unpublished data, March 2023).

During the manual development process, several changes were highlighted to make the intervention more culturally appropriate for UK care homes Table 1.

Figure 3. The manual development process for culturally translating and modifying the Person Attuned Musical Interactions (PAMI) intervention for UK care homes. PAMI: Person Attuned Musical Interactions.

[b]PAMI-M: Person Attuned Musical Interactions Modified.

Phase 1: Manual Field-testing Study

Overview

Phase 1 aims to review the culturally adapted manual with the intended stakeholders (care staff and residents with dementia). The study will explore the adapted manuals' suitability, layout, clinical relevance, and culturally adapted appropriateness. Data will also be collected on the factors influencing the implementation of PAMI to determine optimal use, use behavior, and the experience of staff and residents. The data collected in phase 1 will aid revisions to the manual and study design.

Phase 1 is a qualitative field-testing study consisting of interviews, reflective session transcripts, diary entries, and residents' postintervention questionnaires.

Participants

The study will recruit 9 care staff and 9 residents from 3 Lincolnshire care homes. Each staff member will be paired with a participating resident from their care home. Care staff and residents are required to meet the eligibility criteria.

The care staff inclusion criteria are as follows:

- Should be aged >18 years
- Should have the capacity to consent in accordance with the Mental Capacity Act 2005
- Should be permanently employed at the participating care home
- Should have been employed for at least 6 months with plans to remain working at the care home for the study duration (to ensure that staff are familiar with the residents)
- Should work a minimum of 2 shifts a week to ensure sufficient time to implement PAMI into routines
- Should have the ability to read, write, and communicate fluently in English
- Although any member of staff who has direct daily contact with residents can use PAMI, for this study, only staff who assist with activities of daily living or activity staff are eligible
- Should not be currently taking part in any other psychosocial interventions

The care staff exclusion criteria are as follows:

- Staff who are not an employee of the participating care home (eg, agency staff and external health care professionals)
- Members of staff who do not have sufficient direct contact with residents daily (eg, catering or housekeeping)

XSL•FO
RenderX

The resident inclusion criteria are as follows:

- Should be aged >18 years (no upper age limit)
- Should have a diagnosis of dementia as described by the International Classification of Diseases, 11th Revision
- Should have the capacity to consent in accordance with the Mental Health Capacity Act 2005 or have a consultee who could advise on the individual's wishes if the individual is deemed to lack capacity
- Should have lived at the participating care home for at least 6 months with plans to remain residing at the care home for the duration of the study (to ensure that residents are settled and familiar with the staff)
- Should have sufficient hearing or use hearing aids
- Should have regular interactions with a participating staff member; this will be the staff member they are paired with
- Should not be currently taking part in any other psychosocial intervention research

The resident exclusion criterion is as follows: residents who are residing at the care home on respite or short-term stay.

Procedure

The study will run for approximately 10 weeks in each care home, with PAMI being implemented for 8 weeks. The in-reach practitioner will advertise the study to care homes in the in-reach scheme. The manager of eligible care homes will receive the PAMI welcome pack containing welcome letters for staff and residents, which they will be asked to distribute. Interested staff and residents can express their interest via email or to the in-reach practitioner when she attends the care home, after which they will be provided with a participant information sheet and consent form. A consultee will be appointed and provided with information sheets and declaration forms for residents deemed to lack capacity. Consent or consultee declaration forms will be signed for each participant before the start of the study. Once participants have been recruited, staff and residents will be paired into dyads.

At the beginning of the study, staff will receive a paper copy of the PAMI manual, staff and resident demographic questionnaires, a diary entry form, and the Dementia Severity Rating Scale (DSRS) and be asked to complete the questionnaires before the training. A dementia-friendly demographic questionnaire is also provided to assist residents who may struggle with the demographic questionnaire. Each care home is sent a care home demographic questionnaire to complete. The researchers will work with the care home and staff to organize a convenient time to complete the training. After the training, staff will implement PAMI in routines for 8 weeks. Staff are instructed to use the skills in relation to their resident's needs, impairments, and preferences; therefore, the skills used and frequency of use will vary among staff. However, staff are advised to use PAMI regularly on each shift. Staff are asked to complete the diary form each time they use PAMI with their resident. Once a fortnight, staff will attend a 40-minute reflective session via Microsoft Teams. The facilitators will monitor the study procedure during each reflective session to ensure that no issues or distress have occurred and that both staff and residents are happy to continue. Staff will complete a total of 3 reflective sessions. After the 8 weeks, staff will be invited to a semistructured interview to discuss their experience. The interview will be completed via Microsoft Teams and last approximately 30 minutes. A postintervention resident questionnaire will be sent to staff to complete with their resident if the resident has the ability to communicate their experience. Each care home will receive a participation certificate, and staff members will receive a certificate for completing the PAMI training. At the end of the study, the researcher team will meet to discuss the feedback from participants on the intervention and manual development. Once the team has decided on the required changes, the primary researcher will make revisions to the PAMI manual. The team will also discuss any changes needed to the study design for phase 2; after changes are made, the study will be resubmitted to the ethics committee for approval.

Phase 2: Manual Evaluation Study

Overview

The data collected in the manual evaluation study will aid final manual revisions and aid preparations for future studies. This phase aims to continue to review the culturally adapted manual with the intended stakeholders (care staff and residents with dementia). In addition, preliminary data will be collected on the impact of PAMI on residents and care staff. This phase will be the early stages of the feasibility and piloting stage of the MRC guidelines.

Phase 2 is a mixed methods exploratory study consisting of interviews, reflective session transcripts, diary entries, resident postintervention questionnaire, and pre-post outcome questionnaires.

Participants

The study will recruit 25 care staff and 25 residents from 5 Lincolnshire care homes. The care homes will be different from those recruited in the first phase. Each staff member will be paired with a participating resident from their care home. Care staff and residents will be required to meet the eligibility criteria. The same eligibility criteria as those used in phase 1 will be used.

Procedure

The study will run for approximately 20 weeks in each care home, with PAMI being implemented for 18 weeks. The recruitment procedure will remain the same as that in phase 1.

At the beginning of the study, staff will receive a paper copy of the PAMI manual, care staff and resident demographic questionnaires, a diary entry form, and the DSRS [57]. A dementia-friendly demographic questionnaire will also be provided to assist residents who may struggle with the demographic questionnaire. Staff will also receive the baseline questionnaires, including the Music in Dementia Assessment Scale (MIDAS) [58], Staff Competence in Dementia scale (SCIDS) [59], QUALIDEM [60], and Modified Nursing Care Assessment Scale (M-NCAS) [61]. Additionally, 8 MIDAS and 8 reflective session prompt sheets will be included in the pack, which staff will require for each reflective session. Staff will be asked to complete the questionnaires before training except for the MIDAS, which staff will be asked to bring to the training.

XSL•FO
RenderX

Each care home will be sent a care home demographic questionnaire to complete.

The researchers will work with the care homes and staff to organize a convenient time to complete the training. At the end of the training, staff will be asked to complete the preintervention MIDAS form. The facilitators will then explain that staff should complete 1 reflective session prompt sheet each fortnight before attending the next session and bring the subsequent MIDAS to the session. After the training, staff will implement PAMI in routines for 18 weeks. Staff will be asked to complete the diary form each time they use PAMI with their resident. Once a fortnight, staff will attend a 40-minute reflective session via Microsoft Teams. The facilitators will monitor the study procedure during the session to ensure that there are no issues or distress and that both staff and residents are happy to continue. Staff will complete a total of 8 reflective sessions. During each session, the staff will be asked to complete 1 MIDAS and to use their reflective session prompt sheet to set a goal for the coming fortnight. After 18 weeks, the postintervention questionnaires, the SCIDS [59], M-NCAS [61], and QUALIDEM [60], will be sent to staff to be completed again. At the end of the study, staff will be invited to a semistructured interview to discuss their experience. The interview will be completed via Microsoft Teams and last approximately 30 minutes. A postintervention resident questionnaire will be sent to staff to complete with their resident if the resident has the ability to communicate their experience. Each care home will receive a participation certificate, and staff members will receive a certificate for completing the PAMI training.

Data Collection

Data is collected in several ways across the 2 phases. The qualitative data collection methods are the same in both phases. The preintervention and postintervention quantitative questionnaires will be collected only during the manual evaluation phase .

Demographic Questionnaires

Staff will be required to complete resident and staff demographic questionnaires. Staff should work with their resident to complete the resident version. Resident's involvement will be dependent on their impairments and communication abilities. A dementia-friendly questionnaire has been created to allow residents to have more involvement in the research without their impairments hindering participation. However, staff may need to complete the resident questionnaire. The staff questionnaire collects the following details: age, gender, nationality, length of time at the care home, length of time in dementia care, and views on music in dementia care. The residents' questionnaire collects the following details: age, gender, nationality, length of time at the care home, communication ability, and interest in music.

Participating care homes will complete a demographic questionnaire on the care home. The care home questionnaire collects the following details: care home type, resident type, number of residents in the care home, staff to resident ratio, the current availability of music and activities in the care home, and the availability of Wi-Fi and technology. The question about the availability of Wi-Fi and technology is to ensure that care homes have adequate accessibility for the staff to access the web-based training.

Staff members will complete the DSRS [57] for their residents to determine dementia severity. The DSRS is an informant-based multiple-choice assessment tool. The scale consists of 11 items covering a range of functions impacted by dementia. The areas covered in the DSRS are memory, language, recognition of family members, orientation to time, orientation to place, ability to make decisions, social and community activities, home activities and responsibilities, cleanliness, eating, control of urination and bowels, and ability to get from place to place. A score of 0 to 18 indicates normal to mild dementia, a score of 19 to 36 indicates moderate dementia, and a score of 37 to 54 indicates severe dementia. The DSRS has been calculated to have high internal consistency, high concurrent validity, and high test-retest and high interrater reliability, with carers rating similar to trained clinicians and nonmedical professionals [57]. The DSRS was selected because it is easy to use, can be completed without a researcher, and has high validity and reliability.

Diary Entries

Staff will keep a diary throughout the study to document their use of PAMI and thoughts. The primary researcher produced the diary forms. The paper and pencil method was selected over a more technology-based method to ensure that all staff could complete the diary entries during their shift, as the paper and pencil method does not rely upon regular access to a computer, a phone, or other devices. It is also suggested as one of the easiest diary methods; therefore, little instructions are required on it at the beginning of the study [62]. This study will use an event-contingent diary format where staff document every time PAMI interactions occur during the study. The use of diary entries in the PAMI studies allows the researchers to examine the regular use of PAMI in care homes. Data are collected on the time and date of interaction, interaction length time, which PAMI section the interaction corresponded to, what the interaction entailed, the resident's reaction, PAMI's impact on the interaction, and space for notes. The diary entry form has been kept simple and made such that it is quick to complete, with an entry taking participants only a few minutes, to improve the completion rate.

Reflective Sessions

Although the reflective sessions contribute to part of the PAMI training, they are also a form of data collection. The reflective sessions aim to collect qualitative data on the staff's experience implementing PAMI in care homes and the impact of PAMI on residents and staff. The reflective sessions are semistructured, with the staff's experience guiding sessions; therefore, there is no prior expectation of collecting specific information. However, in general, information on the staff's experience of using the skills, issues concerning the implementation of the intervention, the usability of the manual, and issues with specific skills and case anecdotes of specific interactions will be collected. At the beginning of each reflective session, staff will be asked for permission to audio record the session.

XSL•FO
RenderX

Interviews

Staff will be invited to attend an interview at the end of the study to discuss their experience with PAMI. The interviews will follow a semistructured format with a topic guide, but interviewers will ask additional questions based on participants' responses. Either BW or BS will facilitate the interviews via Microsoft Teams. At the beginning, participants will be asked to provide permission to audio record the interview. Staff will be reminded to use participants' identity codes when discussing specific residents. However, any information identifying the care home, staff, or residents will be removed and anonymized at the transcribing level. Although face-to-face interviews are considered the gold standard of interview data collection methods [58], all interviews will be completed remotely owing to the uncertainty of COVID-19 restrictions when designing the study. Using a videoconference call to conduct the interviews was selected, as this allows for the closest simulation of an in-person interview [63]. It has also been suggested that when in-person interviews are unavailable, video interviews can create a closer bond between the interviewer and interviewee [63].

Quantitative Outcome Measures

A modified version of the MIDAS [58] was selected to measure residents' music engagement. Typically, the measure is proxy reported, completed by care staff and the music therapist before the beginning of music therapy and then again after the music therapy session to examine the change observed during the session. In the PAMI study, the MIDAS is still proxy reported. However, it will be completed only by care staff at 9 time points at fortnightly intervals, first in training and then at each reflective session. The measure uses a Visual Analogue Scale (VAS) without anchor points, with each VAS consisting of a 100-mm line. Staff will be asked to rate the individual based on their current stage of life; therefore, "highest" means the optimal level that the individual can achieve at that stage of their life. Each VAS has a maximum score of 100, and the MIDAS has an overall maximum score of 500. The MIDAS form consists of 5 VAS on interest, response, imitation, involvement, and enjoyment; a checklist question on major reactions; and any comments or questions. This measure was selected for the PAMI study, as it collects observational data on music engagement using proxy reporting methods, making it suitable for participants with moderate to advanced dementia. Studies investigating the psychometric properties of the MIDAS reported high internal consistency between the 5 VAS items, acceptable test-retest reliability, acceptable concurrent validity, and high construct validity.

The QUALIDEM [60] was selected to measure residents' quality of life. The QUALIDEM is a dementia-specific proxy rating scale for measuring the quality of life. The scale has been designed to be suitable for use in care homes. The QUALIDEM is completed before and after intervention, with 18 weeks between the 2 points. It is a 37-item multidimensional scale that consists of 9 homogeneous subscales. Each question has a 4-point scoring system ranging from 0 to 3. The scores on the subscales are calculated by adding up the item scores. The higher the score, the better the quality of life that the individual is expected to have for that quality of life domain. The QULIDEM was selected because it measures the emotional and social domains and investigates the care relationship and coping with the nursing home environment, a domain not investigated in other scales. The QUALIDEM has been reported to have moderate interrater reliability; moderate internal structure; and high convergent, discriminate, and concurrent validity [60].

The SCIDS [59] was selected to measure care staff's competence before and after PAMI. The scale can investigate the effects of training on staff and how these relate to care behavior and the residents' quality of life. The SCIDS is a professional caregiver's self-report measure comprising 17 items categorized into 4 subscales: professionalism, sustaining personhood, building relationships, and care challenges. Each question has a 4-point answer scale ranging from 1 to 4. Overall scores range from 17 to 68, with a higher score indicating a higher level of sense of competence. The SCIDS has been reported to have good internal consistency and substantial to moderate test-retest reliability.

The M-NCAS [61] was selected to measure staff burden before and after PAMI. The M-NCAS not only measures behavior but also addresses other aspects of nursing, including staff's perception of the meaningfulness of residents' lives and residents' gratefulness for care. The M-NCAS is a self-reporting staff measure consisting of 32 items. Each item has 2 domains: one explores the occurrence and intensity of the behavior, whereas the other explores the staff's rating of the difficulty of coping with the behavior. Each domain is scored on a 4-point scale. A lower score on both domains indicates a lower score of staff burden. The M-NCAS has been reported to have excellent to good internal consistency and reliability and moderate construct validity.

Analysis

Demographic Statistics

Data collected from the resident, staff, and care home demographic questionnaires and residents' DSRS scores will be entered into SPSS Statistics (IBM Corp). The mean and SD will be created for the demographic data.

Quantitative Outcome Measures

The data collected from the MIDAS, SCIDS, QUALIDEM, and M-NCAS will be imported into IBM SPSS Statistics. Two-tailed *t* tests will be conducted from the questionnaire data to determine a change before and after PAMI.

Qualitative Data

Transcribing

Before analyzing the reflective sessions and interviews, audio recordings will be transcribed. The University of Nottingham Automatic Transcribing Service will be used for the first transcribing stage. The service is secure, meets General Data Protection Regulation guidelines, and has an accuracy rate of 70% to 99% [64]. For recordings to be transcribed using the service, they needed to be in the format Mono MP3. The software Audacity (The Audacity Team) will be used to convert the recordings into the appropriate format [65]. Two reviewers will independently review the transcripts to determine accuracy.

XSL•FO
RenderX

During transcribing, the names and personal information identifying the residents, staff, or care homes will be removed.

Thematic Analysis

NVivo (QSR International) will be used to analyze the transcripts [66]. Due to its flexibility, the researchers will use thematic analysis to analyze the qualitative data. Thematic analysis entails identifying, analyzing, and reporting themes within the chosen set of data [67]. A theoretical approach will be taken, where themes will be generated based on the research aims and questions set at the beginning of the study. Braun and Clark's [67] 6 steps for thematic analysis will be followed.

Braun and Clark's [67] 6 steps are as follows: familiarizing yourself with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing the report.

The 2 PAMI facilitators who conduct the interviews will also transcribe and conduct the thematic analysis, allowing the researchers to immerse themselves in the data from the beginning. The reviewers will independently generate codes before they are combined and analyzed for inter-reviewer reliability. The 2 reviewers will discuss the generated codes and resolve discrepancies. The reviewers will then independently cluster relatable codes to generate themes before they work together through discussions to develop one set of themes representing the data. Once the 2 reviewers agree, the set of themes will be shared with the research team for feedback.

The qualitative and quantitative data will not be combined in the analysis. The quantitative data are for exploring preliminary statistical findings and testing the appropriateness of the outcome measures for future studies, whereas the qualitative data are for exploring the participants' experience of using PAMI and reviewing the culturally adapted appropriateness of the manual.

Results

This project was funded by The Music Therapy Charity in October 2019 as part of a PhD studentship. The study's first phase began recruitment in September 2021 and continued until January 2022. A total of 8 care staff and 8 residents were recruited, with 5 dyads completing the study. The data have been analyzed that will be used in the primary researcher's thesis (Waters, B, Orrell, M, and McDermott, O, unpublished data, March 2023) and several papers in peer-reviewed journals. The research team aims to publish the results from the first phase in July to September 2023.

The second phase began recruitment in April 2022 and continued until December 2022. Overall, 20 care staff and 19 residents were recruited with 11 dyads completing the study. The researchers are currently in the stage of analyzing the data that will be used in the primary researcher's thesis (Waters, B, Orrell, M, and McDermott, O, unpublished data, March 2023) and published in peer-reviewed journals. The research team aims to publish the results from the second phase in October to December 2023.

Dissemination will also occur through conferences. Participating care homes will receive a summary of the results. A summary will be provided to the Lincolnshire NHS trust, which they can use to disseminate the results.

Discussion

Anticipated Findings

This study will be the first to investigate the modified PAMI-M. Therefore, the data collected in phases 1 and 2 will provide feedback on the appropriateness of the modified manual for care staff working in UK care homes. The data collected will aid final manual revisions. Due to COVID-19, the intervention was converted from an in-person training tool to an intervention delivered remotely. Therefore, this study will provide a greater understanding of the plausibility of providing PAMI remotely. The study investigates the implementation of PAMI in a real-life setting, highlighting potential barriers and allowing the researchers to adapt the intervention to accommodate.

Previous research has highlighted that implementing meaningful interactions and staff-led music interventions in care homes are challenging because of limited staff time, limited resources, and the lack of knowledge [68,69]. Music therapy skill-sharing can provide staff with music therapy skills to implement in routines without them having to spend additional time or bear additional burden [46,70]. Implementing music interventions in other care tasks can improve task efficiency and reduce staff time. Music therapy skill-sharing is only accessible to a few care homes owing to music therapists' availability and finances. A music therapy skills-sharing manual such as PAMI will make the intervention accessible to a larger population of care homes. Implementing PAMI in care homes in Denmark has begun and is displaying positive results [48]. This study will investigate whether the modified version of PAMI can benefit residents, care staff, and care homes in the United Kingdom.

Strength and Limitations

The main strength is the remote element. The remote-based conversion of PAMI has allowed the researchers to continue developing the intervention during the pandemic when there were uncertain COVID-19 regulations. Even as the regulations are dropped, care homes are still battling with care home lockdowns when outbreaks occur; and remote training will allow staff to continue training during these periods. Thinking long term, converting PAMI to remote training would make the intervention more accessible to a wider population of care homes, as the facilitators would not be limited by geographic distance or location. Although the remote element of PAMI is its main strength, it is also the main limitation. All study elements will occur via email and Microsoft Teams; therefore, data collection and implementation will rely on self-report. It will be challenging for the researchers to determine whether staff are using PAMI and are successfully implementing the skills.

Conclusions

The study will be the first to investigate the modified PAMI. The study will provide feedback on the appropriateness of the manual and explore participants' experience of using a modified

XSL•FO
RenderX

version of PAMI. PAMI has the potential to offer music therapy skill-sharing training to a larger proportion of care homes, ensuring that high-quality appropriate music interventions are provided to residents in care homes where music therapy may be inaccessible. The intervention aims to promote 2-way attuned musical interactions between staff and residents with dementia through musical skills and nonverbal communication and has the potential to benefit residents, staff, and the overall care home.

Acknowledgments

This study is funded by The Music Therapy Charity. The authors thanks Rachael Fothergill, an in-reach practitioner at the Lincolnshire NHS Partnership Trust who is involved with the setting up and running of the study. The authors also thank Brigette Schneible, who is the music therapist in the study and was involved with the manual development.

Data Availability

Data sharing is not applicable to this study as no data sets were generated or analyzed during the study.

Authors' Contributions

BW is an early career researcher under the supervision of OM and MO, who are both senior researchers. BW, OM, and MO are responsible for designing the study. BW took the lead in developing the study materials and intervention with support from OM. BW is responsible for promoting the study, recruiting the participants, running the intervention, and collecting data. OM and MO will provide guidance and support throughout the study.

Conflicts of Interest

None declared.

Abstract

Background: Permanent supportive housing (PSH) is an evidence-based practice to address homelessness that is implemented using 2 distinct approaches. The first approach is place-based PSH (PB-PSH), or single-site housing placement, in which an entire building with on-site services is designated for people experiencing homelessness. The second approach is scatter-site PSH (SS-PSH), which uses apartments rented from a private landlord while providing mobile case management services.

Objective: This paper describes the protocols for a mixed methods comparative effectiveness study of 2 distinct approaches to implementing PSH and the patient-centered quality of life, health care use, and health behaviors that reduce COVID-19 risk.

Methods: People experiencing homelessness who are placed in either PB-PSH or SS-PSH completed 6 monthly surveys after move-in using smartphones provided by the study team. A subsample of participants completed 3 qualitative interviews at baseline, 3 months, and 6 months that included photo elicitation interviewing. Two stakeholder advisory groups, including one featuring people with lived experience of homelessness, helped guide study decisions and interpretations of findings.

Results: Study recruitment was supposed to occur over 6 months starting in January 2021 but was extended due to delays in recruitment. These delays included COVID-19 delays (eg, recruitment sites shut down due to outbreaks and study team members testing positive) and delays that may have been indirectly related to the COVID-19 pandemic, including high staff turnover or recruitment sites having competing priorities. In end-July 2022, in total, 641 people experiencing homelessness had been referred

XSL•FO
RenderX

from 26 partnering recruitment sites, and 563 people experiencing homelessness had enrolled in the study and completed a baseline demographic survey. Of the 563 participants in the study, 452 had recently moved into the housing when they enrolled, with 272 placed in PB-PSH and 180 placed in SS-PSH. Another 111 participants were approved but are still waiting for housing placement. To date, 49 participants have been lost to follow-up, and 12% of phones (70 of the initial 563 distributed) were reported lost by participants.

Conclusions: Recruitment during the pandemic, while successful, was challenging given that in-person contact was not permitted at times either by program sites or the research institutions during COVID-19 surges and high community transmission, which particularly affected homelessness programs in Los Angeles County. To overcome recruitment challenges, flexible strategies were used, which included extending the recruitment period and the distribution of cell phones with paid data plans. Given current recruitment numbers and retention rates that are over 90%, the study will be able to address a gap in the literature by considering the comparative effectiveness of PB-PSH versus SS-PSH on patient-centered quality of life, health care use, and health behaviors that reduce COVID-19 risk, which can influence future public health approaches to homelessness and infectious diseases.

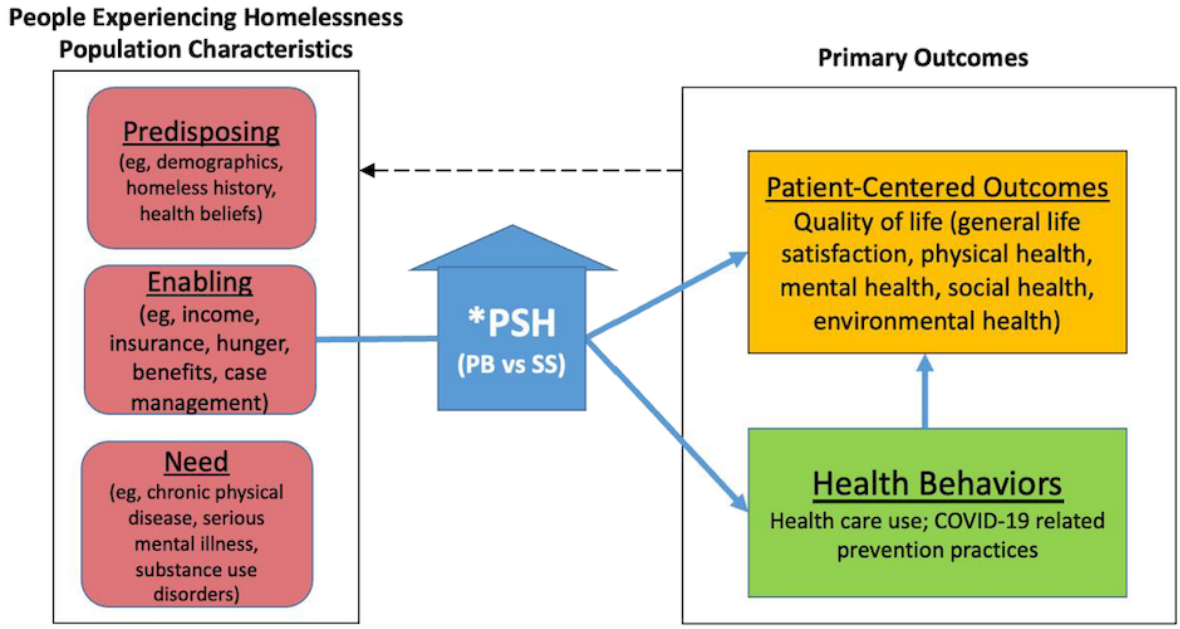
Introduction

The COVID-19 pandemic has made housing and health care for people experiencing homelessness an important priority for the health care and public health systems in the United States. Due to this population's preexisting vulnerabilities [1-3] and difficulties in maintaining social distance and hygiene, researchers predicted at the outset of the COVID-19 pandemic that, without intervention, people experiencing homelessness would experience a 2-4 times higher risk of COVID-19 complications and fatality than the general population [4]. As a result of these concerns, more than US $2 billion from the US federal government's Coronavirus Aid, Relief, and Economic Security Act was aimed at protecting people experiencing homelessness by reducing shelter densities and placing people in more secure housing options.

Permanent supportive housing (PSH)—programs that provide immediate access to independent living situations coupled with support services—represent one of the most studied and effective approaches for serving highly vulnerable people experiencing homelessness [5]. Numerous studies have demonstrated PSH's effectiveness in improving housing retention, quality of life, and HIV outcomes. Nevertheless, a 2018 report by the National Academy of Medicine of the National Academies of Sciences noted the need for more research on PSH to establish what would constitute "housing-sensitive [health] conditions"—conditions whose transmissibility, course, and medical management are particularly influenced by homelessness and housing placement [5]. Two years after this report, COVID-19 and rapid policy decisions to address homelessness and expand housing during the pandemic offered a rare opportunity to address this gap in knowledge and advance research on housing as a social determinant of health.

This paper describes the protocols for the Person-Centered Housing Options, Outcomes, Services, and Environment (PCHOOSE) study, which examined the comparative effectiveness of 2 distinct approaches to implementing PSH. The first approach is place-based PSH (PB-PSH), or single-site housing placement, in which an entire building with on-site services is designated for people experiencing homelessness. The second approach is scatter-site PSH (SS-PSH), which uses apartments rented from a private landlord while providing mobile case management services. The limited research related to the comparative effectiveness of PB-PSH versus SS-PSH has been mixed. A meta-analysis of 8 studies with more than 3000 participants found 84% of people experiencing homelessness with mental disorders preferred SS-PSH [6], despite greater feelings of social isolation than those in PB-PSH. This is supported by qualitative research that has found people experiencing homelessness dislike the rules and limited privacy of PB-PSH [6-8]. Other studies have suggested PB-PSH may provide more supportive services [9] and may be more effective than SS-PSH in improving disability severity, community integration, and recovery [10]. Individuals with substance use disorders, those living with HIV, veterans, and women may also benefit more from PB-PSH programs than other populations because of the strong sense of community and mutual support they offer [11]. The PCHOOSE study intended to add to this literature by considering the comparative effectiveness of PB-PSH versus SS-PSH on patient-centered quality of life, health care use, and health behaviors that reduce COVID-19 risk.

Methods



Setting and Conceptual Model

The PCHOOSE study is situated in Los Angeles County, California, which has the nation's largest unsheltered homeless population [12]. Los Angeles County also represents the country's largest natural experiment in housing interventions to protect people experiencing homelessness [13] due to a major taxpayer-funded US $1.2 billion homelessness initiative passed

XSL•FO
RenderX

in 2016 that resulted in the opening of thousands of new PSH units in Los Angeles County during the pandemic [14]. The study followed a diverse sample of people experiencing homelessness placed in either PB-PSH or SS-PSH for 6 months; barriers and facilitators that may affect PSH implementation during the pandemic and its aftermath were also investigated. The study was guided by the Gelberg-Anderson behavioral model for vulnerable populations [15], which involves examining predisposing, enabling, and need factors that contribute to health behaviors and patient-centered outcomes (see Figure 1). PSH is positioned as a key enabling factor for people experiencing homelessness with the hypothesis that PSH type (ie, PB or SS) will affect THE quality of life (general life satisfaction; physical, mental, social, and environmental health, including housing and neighborhood characteristics) and health behaviors, including health care use (eg, receipt of health care, mental health care, and social supports) and COVID-19–related prevention practices. We also expected that changes to our primary outcomes would affect the predisposing, enabling, and need characteristics of the people experiencing homelessness population over time.

Figure 1. Gelberg-Anderson behavioral model for vulnerable populations (modified for PSH and COVID-19). PB: place-based; PSH: permanent supportive housing; SS: scatter-site.

In describing the protocols of the PCHOOSE study, this paper also highlights the challenges of conducting research with this vulnerable population in the United States during the highly dynamic COVID-19 pandemic. This includes steps taken to protect the research team, people experiencing homelessness participants, and PSH staff members, as well as the need to change survey instruments to reflect an evolving understanding of the COVID-19 virus, public health mitigation policies, and personal protective practices.

Design Overview

This study leveraged Los Angeles County's ongoing efforts to provide PSH to people experiencing homelessness during the COVID-19 pandemic using a mixed methods, prospective longitudinal design. We recruited people moving into PSH and provided them with smartphones with paid data plans to stay connected with the study for a 6-month period. All study participants were recruited through organizations that provide housing, supportive services, or both. Although PB-PSH is clearly defined in the homelessness services system, SS-PSH could have been officially categorized as a PSH program or a rapid rehousing program. Although rapid rehousing programs are typically short-term housing programs with time-limited and tailored assistance programs, during the pandemic, Los Angeles County expanded the use of rapid rehousing programs coupled with supportive services to quickly provide access to housing. Thus, for this study, we considered anyone receiving rapid rehousing assistance to be SS-PSH if they also received support services, and examined whether those receiving rapid rehousing differ in terms of demographics, health status, or homelessness histories.

For the study's quantitative arm, participants completed a baseline survey followed by 5 monthly follow-up surveys once in housing. For the qualitative arm, we recruited a purposive subsample of people experiencing homelessness from both PB-PSH and SS-PSH who participated in 3 semistructured interviews; the first was an in-depth interview when they initially moved into PSH, followed by 2 follow-up interviews conducted 3 and 6 months later. Focus groups with housing providers from the affiliated housing agencies were also conducted. Study protocols for each study component are described separately in more detail.

To ensure that the study addressed questions important to people experiencing homelessness, providers, and policy makers and that the data were correctly interpreted, we also established 2

XSL•FO
RenderX

stakeholder advisory boards (SABs). The first advisory board is a lived experience group (LEG), which consists of 11 individuals who have personally experienced homelessness. The LEG meets quarterly and uses its lived experience, knowledge of what is important to people experiencing homelessness, and perspectives on how people experiencing homelessness may respond to study questions to inform recruitment strategies, interpretation of study findings, and dissemination efforts. The study's second advisory board is a SAB, which consists of 15 providers, administrators, policy makers, and researchers with expertise in homelessness and housing programs in Los Angeles County. Due to concerns about meeting in person during the pandemic, all LEG and SAB meetings have been conducted remotely via Zoom.

Ethics Approval

This human subjects' research has been performed in accordance with the Declaration of Helsinki and approved by the University of Southern California's Institutional Review Board (UP-20-01081) with a reliance agreement in place with the University of California, Los Angeles. All human subject participants provided informed consent via electronic signature. As described in more detail below, participants could receive up to US $105 in gift cards for participating in the quantitative survey component of the study and US $150 in gift cards for participating in the qualitative component of the study.

Recruitment of Study Participants

People experiencing homelessness were eligible to participate in the study if they were 18 years or older, had been approved for PSH, could be interviewed in English or Spanish, and were willing to provide informed consent. Enrollment included people experiencing homelessness who had been approved for PSH in Los Angeles County and had either been housed in the past 2 weeks or were expected to be placed in housing in 30 days. PSH placement is determined through a county-run coordinated entry system that identifies clients' needs and matches them with available housing options. Because the system typically assigns individuals approved for PSH to specific nonprofit, community-based agencies that are ultimately charged with securing housing and supportive services, recruitment was conducted through 26 agencies. The study began recruitment in January 2021 amid a significant surge in the COVID-19 pandemic in Los Angeles County. Therefore, in-person recruitment was not a viable option and instead depended on the case managers at each program, who were already interacting with people experiencing homelessness as part of the housing placement process. The study team relied on these agencies to inform anyone approved for PSH (or rapid rehousing who would be receiving supportive services) about the study. Study staff members then coordinated a meeting with the eligible people experiencing homelessness interested in the study via phone or Zoom to complete the enrollment process. Although this process remained largely intact throughout the recruitment period, in-person recruitment occasionally occurred when COVID-19 rates were low and visitors were allowed at program sites.

Recruitment for the qualitative portion of the study involved 2 sources. The qualitative people experiencing homelessness sample was selected from those who enrolled in the quantitative portion of the study. A subsample of study participants (N=40; 20 from each PSH model type) was selected for interviews using maximum variation sampling [16] based on demographic and health characteristics (ie, Black or African American people, women, individuals with chronic disease, individuals with serious mental illness, individuals with substance use disorders or individuals aged 60 years or older), and they separately consented to participate in qualitative interviews. The provider sample (N=48; 24 from each PSH model type) was selected from housing providers who worked at agencies that were study recruitment sites. Sites were asked to identify staff members who would be willing to participate in a focus group; staff members were asked to provide verbal consent at the outset of the focus group.

Enrollment and Quantitative Data Collection Procedures

To enroll, an agency staff member initiated the referral process for people experiencing homelessness by contacting the research recruitment team via phone, email, or text. A research recruitment team member then followed up to schedule an appointment with the potential participant to complete a screening to ensure eligibility, review the consent form, and answer any questions related to the study protocols. Case managers then distributed study phones that had been shipped to the recruitment site. Participants received a Samsung A01 Core smartphone with an unlimited data and calling plan, which allowed them to provide electronic informed consent and complete a self-administered questionnaire sent via text message. Participants were enrolled in the study once they provided informed consent by completing a web-based form that assessed study comprehension and documented their electronic signature.

Initially, participants completed a 20-minute survey upon enrollment in the study to capture basic demographic and historical information about their housing and health. Baseline outcome measures were then administered in a follow-up survey approximately 1 day later to help reduce the burden involved in completing a lengthy questionnaire at the time of enrollment. Participants received a US $15 electronic gift card incentive for completing the baseline outcome measure survey. Participants who enrolled in the study prior to moving into a housing unit were asked to complete a second baseline outcome measures survey once they moved in and received another US $15 electronic gift card incentive. After moving into PSH and completing the demographic and baseline surveys, participants received 5 monthly follow-up surveys and received a US $15 electronic gift card incentive for each completed survey. Participants could also complete surveys over the phone if they preferred to speak with a surveyor rather than self-administer the survey. Electronic gift cards were sent to an email address provided by the participant. The survey links were all sent via text message. The study team, in consultation with the LEG, opted to allow "prefer not to answer" as a response option for all historical and monthly survey questions to reduce any frustration among those who were not sure how to answer and minimize the possibility that some questions could be triggering given high rates of past trauma.

XSL•FO
RenderX

Quantitative Measures

Patient-centered quality-of-life outcomes in this study were based on the World Health Organization's definition of health as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" [17]. Table 1 describes the study's constructs and measures, with the exception of COVID-19–related outcomes, which are discussed in more detail subsequently.

Table 1. Study constructs and measures.

Construct	Variables and instruments
Patients experiencing homelessness population characteristics: covariates measured at baseline only [18]	
Predisposing	Demographics (ie, age, gender, marital status, and veteran status); health beliefs (ie, knowledge of disease and health services attitudes); social structure (ie, race and ethnicity, education, employment, religion, trauma, and homelessness history); systems involvement history (eg, foster care, criminal justice, and trauma); housing preference
Enabling	Income, insurance, benefits, case management, food insecurity, and social support
Need	Chronic physical disease, serious mental illness, and substance use disorder; baseline measures for physical and mental health status as noted in outcomes
Patient-centered outcomes: quality of life including physical, mental, social, and environment health, and measured monthly	
Life satisfaction	NIH[a] Toolbox Item Bank v2.0 General Life Satisfaction (10 items, self-rated life satisfaction) [19]
Physical health	PROMIS[b] Global Health Scale Version 1.2 (PROMIS; 2 items, self-rated physical health and activities) [19]
Mental health	PROMIS (2 items, self-rated mental health, frequency bothered by symptoms) [19]
Social health	PROMIS (1 item, self-rated satisfaction with social activities and relationships) [19]
Environmental health	Housing retention and Housing Environment Scale (4 items, residential satisfaction; 12 items, neighborhood quality and safety) [20]
Health behaviors: measured monthly	
Substance use	Collaborating Consortium of Cohorts Producing NIDA[c] Opportunities survey (12 items) [21]
Health care use	COVID-19– and non-COVID-19–related past-180-day use of physical, mental, substance use, social services, and PSH[d] support; medication adherence; ambulatory and emergency department visits and hospitalizations; barriers to care

[a]NIH: National Institutes of Health.

[c]NIDA: National Institute on Drug Abuse.

[d]PSH: permanent supportive housing.

COVID-19–Related Outcomes

Given that the study project period began in October 2020, with initial recruitment starting in January 2021, our initial survey questions focused on COVID-19–related protective health behaviors that were salient at the time—namely, social distancing and handwashing. As science and the pandemic evolved, questions about COVID-19 testing and vaccines were introduced as key protective health behaviors. For COVID-19 testing on the monthly surveys, we first asked whether participants had been tested in the past 30 days and, if so, the outcome of the test. For anyone who had not been tested in the past 30 days, we asked about barriers to testing (ie, "Did you want to get tested for coronavirus [COVID-19] in the past 30 days but were unable to?"). For those who replied affirmatively, possible reasons for not getting tested included: I didn't know how to make an appointment to be tested; I didn't know where to go; I don't think that I can afford the cost of the test; I didn't have time to get tested; I am unable to travel to a testing location; I am worried about bad things happening to me or my family if I get tested (including discrimination, government policies, or social stigma).

For vaccination status, questions evolved over time. When the study began and there was only 1 approved vaccine that was not readily available, participants were asked if they "have been offered the COVID-19 vaccine?" with branch logic based on whether they said they had received the vaccine or would receive it if offered. If participants responded "no" to having received the vaccine after being offered it or to a hypothetical offer, they were prompted about the reasons for not receiving the vaccine to better understand their hesitancy. Six months into data collection, when multiple approved vaccines were more readily available, the survey was revised to first ask if a participant had received the vaccine rather than if it had been offered. Questions about the type of vaccine (brand) and the number of doses received were also added to the monthly surveys. In June 2022, the survey was revised a final time to ask new questions about receipt of COVID-19 booster vaccines using the following three uniform questions: (1) "How many doses of the COVID-19 vaccine have you received (including booster shots)? Please indicate the brand of each dose you received and the month and date when you received it"; (2) "To the best of your knowledge, have you received all COVID-19 doses or boosters that you're eligible for?"; and (3) "In the future, how likely are you to receive another dose or booster of the COVID-19 vaccine if it's

XSL•FO
RenderX

recommended?" Participants who had already completed the study and not been asked these questions were recontacted.

Qualitative Interview Procedures

Each member of the qualitative people experiencing homelessness sample was asked to complete 3 semistructured qualitative interviews. The first interview, conducted over the telephone and audio recorded, focused on questions concerning participants' (1) prehousing homelessness experiences; (2) experience obtaining PSH; (3) health, social services, and social experiences prior to and after obtaining PSH; and (4) management of COVID-19–related safety and concerns. These interviews lasted approximately 30-60 minutes each. The second and third interviews were conducted 3 and 6 months after the baseline interviews and used photo elicitation interviewing (PEI), a method that uses photographs taken by participants to guide interviews [22]. This method enhances the depth of each interview and increases the capacity to identify potential topics of interest that were not part of the study's original data collection plan. PEI is also an effective tool for building rapport, gaining access to participants' lived experiences, and relieving the strain of direct, extended verbal questioning, which can be particularly taxing for participants with cognitive or mental disabilities [23-25]. All client PEI interviews were conducted over the phone and lasted approximately 45 minutes. Each interview was recorded and transcribed for analysis, and participants received a US $50 gift card incentive of their choice (Visa, Amazon, or Target) after each interview.

PEI Methods

Participants were asked to use their study-issued cellphones to take photos that represent their daily lives and experiences in their housing placement for a 2-week period. There was no limit on the number of photos they could take, though they were asked to avoid taking any identifiable photos of any individuals to protect privacy. Participants were then asked to choose 5-10 of the photos that best captured their recent experiences and email or text them to the study coordinator, who then provided them to the interviewer. At the outset of each interview, interviewers asked participants to choose whichever photo they wanted to discuss first. For this photo and subsequent images, participants were asked first to describe each photo and then elaborate on how it reflects their recent experiences related to housing, health, service use, COVID-19 protection, safety, resources, relationships, personal growth, and daily functioning. Participants were also asked to come up with a title or theme that collectively described the photos they discussed, if there was anything they wanted to take a photo of but could or could not, and why, and any recommendations for improvements in services for others experiencing homelessness based on the photos. If any participant did not feel comfortable using the phone camera, they were offered the alternative of taking "mental snapshots," in which they made a list of 5-10 things they wished to discuss and shared this list with their interviewer. For the second PEI at the 6-month follow-up, participants were asked to go through the same procedures. However, during this PEI, participants were asked to focus on how things changed for them across the different domains and compare their photos from the 2 PEIs.

Focus Groups

Provider group interviews concentrated on learning provider perspectives on the difference between PB-PSH and SS-PSH, the strengths and weaknesses of each model in improving outcomes for people experiencing homelessness, and the impacts of the COVID-19 pandemic on PSH service delivery. Each focus group met for approximately 60 minutes and was conducted either in person or via Zoom, depending on the housing agency's preference. As with the client interviews, staff focus groups were recorded and transcribed for analysis, and participants received a US $50 gift card incentive of their choice (Visa, Amazon, or Target).

Quantitative Analysis

The statistical analysis will rely on bivariate and multivariate regression analysis to examine the relationship between PSH (SS-PSH vs PB-PSH) and quality of life and COVID-19–related health behaviors. For outcomes, we will use a pre-post design that treats Month 1 as the baseline and Month 6 as the endline and compares pre-post changes for SS-PSH and PB-PSH. For outcomes sensitive to monthly trajectory variation, we will use fixed-effects and random-effects models of monthly outcomes that test for interaction between the PSH model and months of exposure to each PSH type. These models will be informed by an analysis of baseline variation between SS-PSH and PB-PSH clients. We expect variations in the level of baseline morbidity. Thus, we will use both multivariate models that account for baseline differences and propensity score matching models that establish an area of common support for SS-PSH and PB-PSH comparisons. We will use calendar-month controls to account for historic changes in the ecology of health behavior, particularly in relation to rising and falling rates of COVID-19. We will also address the potential need for multilevel or mixed-effects models to account for potentially shared experiences by housing and service providers. Additional models will test for differences in housing outcomes by race, ethnicity, sex, and gender via interaction effects and stratified models. Further analysis will entail the use of a path modeling framework to understand the pathways leading from PSH types to outcomes of interest. Due to the decision to include "prefer not to answer" as an option for all questions, all analyses will account for the frequent use of this response option. In cases where "prefer not to answer" is a common or meaningful response option, such as regarding partisan political affiliation or experiences of trauma, we will include it as a response option. In cases where "prefer not to answer" appears to reflect a random nonresponse pattern, we will treat the value as missing, use multiple imputations to maintain sample size, and conduct robustness checks comparing the imputed and raw samples.

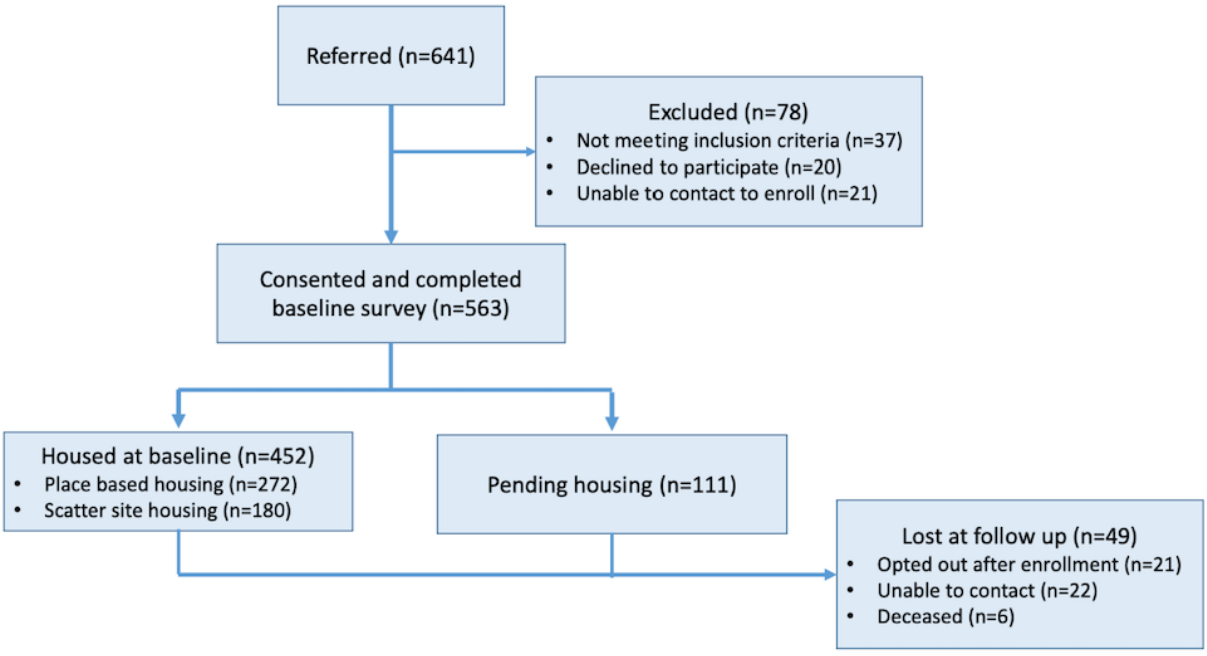
Qualitative Data Analysis and Integration

Client semistructured interview and focus group transcripts have been imported into Dedoose [26] for analysis. Analysis was conducted using template analysis, with thematic codes defined in relation to the study questions (eg, housing process and experiences, COVID-19 experiences, and posthousing experiences), and inductively through coding the transcripts [27]. Individual team members cocoded the transcripts and discussed the codes iteratively, including collapsing, expanding,

XSL•FO
RenderX

and combining codes, until consensus was reached on the codebook. Any discrepancies in codes and excerpts were discussed in team meetings and resolved in discussion with the qualitative team leaders [27]. After initial cocoding, team members coded the remainder of the transcripts using Dedoose.

PEIs will be analyzed using 2 approaches—one for the interview text and one for the photographs. Interview text will be analyzed using template analysis as previously described. Photographs are analyzed through a process of initial categorization by theme, referencing interview texts to ensure proper interpretation, and group discussion to develop an initial visual code book. Members of the team will cocode photos from 5 interviews to test the codebook's utility and identify codes that needed further definition or clarity. Once the codebook is established, each photo will be coded independently by 2 researchers, who discussed discrepancies until they reached a consensus on all interpretations of images [22].



Mixed Methods Analysis

As appropriate, qualitative and quantitative data will be merged to achieve several functions. First, merged data will be used to identify convergences—areas where qualitative data confirm quantitative findings, and vice versa. Second, the research team will use qualitative data complementarily to provide depth and understanding to the findings that emerge from quantitative analyses. Third, qualitative data will be used to explain and expand on findings from quantitative data. The researchers will note areas where one data source generates insights but the other does not [28].

Results

Study recruitment was supposed to occur over 6 months starting in January 2021 but was extended due to delays in recruitment. These delays included COVID-19 delays (eg, recruitment sites shut down due to outbreaks and study team members testing positive) and delays that may have been indirectly related to the COVID-19 pandemic, including high staff turnover or recruitment sites having competing priorities. Given these delays, data collection and analysis are expected to be completed in 2023. As depicted in the consort diagram (see Figure 2), at the end of recruitment in July 2022, a total of 641 people experiencing homelessness had been referred from 26 partnering recruitment sites, and 563 people experiencing homelessness had enrolled in the study and completed a baseline demographic survey. Of the 641 referrals, 37 were not eligible to participate due to not meeting the criteria, 20 declined to participate, and our recruitment team could not reach 21 to complete enrollment. Of the 563 participants in the study, 452 had recently moved into the housing when they enrolled, with 272 placed in PB-PSH and 180 placed in SS-PSH. Another 111 participants were approved but are still waiting for housing placement. To date, 49 participants have been lost at follow-up, with 21 opting out of the study, 22 who could not be reached, and 6 participants who died.

Figure 2. Consort enrollment diagram. PSH: permanent supportive housing.

To date, 12% of phones (70 of the initial 563 distributed) have been reported lost by participants. Of those who reported losing their phone, we lost contact with 22 participants; 28 completed the study using a replacement phone provided by the study or an alternative phone number. Redemption of electronic gift card incentives has been high. To protect respondent privacy, gift card redemption data was not linked to respondents at the personal level, but we analyzed aggregate and monthly redemption rates for all completed surveys. Among all gift cards issued, 82% were redeemed. This figure likely reflects an underestimate of overall redemption rates because the denominator double-counts individuals who were reissued a second card after failing to redeem the first. Redemption rates improved during the study, from 75% in month 1 to 86% in

XSL•FO
RenderX

month 5. Because redemption data were not linked at the person level, it was impossible to discern whether redemption affected retention or response rates.

Discussion

Principal Findings

This paper presents the protocols from the PCHOOSE study, a mixed methods prospective longitudinal study designed to examine the comparative effectiveness of PB-PSH and SS-PSH in promoting COVID-19 protective behaviors among people experiencing homelessness. To date, the study has successfully recruited 563 participants in the study, with 452 of those participants moving into housing (272 placed in PB-PSH and 180 in SS-PSH). Another 111 participants are still waiting for housing placement. As noted, however, recruitment during the pandemic was challenging given that in-person contact was not permitted at times either by program sites or the research institutions during COVID-19 surges and high community transmission, which particularly affected homelessness programs in Los Angeles County.

To overcome recruitment challenges, flexible strategies were used that included extending the recruitment period and the distribution of cell phones with paid data plans. Although this was a viable approach to recruitment and data collection, thus far, 12% of phones have been lost. It is not clear to what extent study recruitment rates would have been different without distributing phones given the high rates of phone ownership in this population, although maintaining consistent phone service is challenging [29]. Given current recruitment numbers and retention rates that are over 90% (only 49 have been lost to follow-up), the study will be able to address a gap in the literature by considering the comparative effectiveness of PB-PSH versus SS-PSH on patient-centered quality of life, health care use, and health behaviors that reduce COVID-19 risk.

Limitations

This study is unique in that it represents a large-scale study that started in the first year of the COVID-19 pandemic to better understand how housing programs serve as a social determinant of health for people experiencing homelessness [5]. Given this context, the study required ongoing changes to the survey instrument due to COVID-19–related outcomes, vaccine implementation, and community mitigation strategies that continued to change throughout the study period. Changing study instruments will pose challenges for analysis and also highlight the need to consider how period effects may drive changes in participant response as opposed to the time in housing that was originally planned. Other potential challenges may include discrepancies between qualitative and quantitative reporting, data richness due to qualitative phone interviews instead of in-person interviews, missing or inaccurate vaccine data, and participants failing to report on health risk behaviors such as drug use, receiving the vaccination, or other risky behaviors due to stigma. These issues will be examined and reported on after the study. We also note that this study represents a natural experiment and that people experiencing homelessness were not randomized to PSH type; further, participants were referred to the study through a case manager, which may introduce additional selection bias. Examining baseline characteristics will help determine whether there are selection differences between the 2 groups that will need to be adjusted during analyses.

Conclusions

The PCHOOSE study protocols demonstrate that recruitment of people experiencing homelessness is possible during a global pandemic but that significant flexibility is required to conduct research with an underresourced population during major historical events, such as the COVID-19 pandemic, which reflects a period where scientific knowledge and public policies evolved rapidly. At a minimum, information gained from this project can provide insights into how people experiencing homelessness navigated the pandemic, but we may also better understand the contextual factors that contribute to COVID-19 being a housing-sensitive condition. Given that few studies have compared PB-PSH and SS-PSH, let alone amid a global health concern such as COVID-19, this study will be able to address a gap in the literature regarding how different models of PSH can affect the patient-centered quality of life, health care use, and health behaviors that reduce COVID-19 risk, which can influence future public health approaches to homelessness and infectious diseases.

Acknowledgments

We would like to thank our recruitment sites, advisory board members, and study participants. Funding for this study was provided by the Patient-Centered Outcomes Research Institute (COVID-2020C2-10933). Dr Patanwala was supported by the United States Veterans Administration (VA) Office of Academic Affiliations through the VA National Clinician Scholars Advanced Fellowship; the contents do not represent the views of the US Department of Veteran Affairs or the United States Government.

Data Availability

All data from this research will be made available in a public data repository (TBD), as is contractually required by the funding organization.

Abstract

Background: Overuse of antibiotics contributes to antimicrobial resistance (AMR) and is a growing threat to human health worldwide. Previous work suggests a link between antimicrobial use in poultry and human AMR extraintestinal pathogenic *Escherichia coli* (E coli) urinary tract infections (UTIs). However, few US-based studies exist, and none have comprehensively assessed both foodborne and environmental pathways using advanced molecular and spatial epidemiologic methods in a quasi-experimental design. Recently, California enacted Senate Bill 27 (SB27), which changed previous policy to require a veterinarian's prescription for the use of antibiotic drugs, and which banned antibiotic use for disease prevention in livestock. This provided an opportunity to evaluate whether SB27 will result in a reduction in antimicrobial-resistant infections in humans.

Objective: We describe in detail the methods implemented to achieve the overarching objective of this study to evaluate the impact of SB27 on downstream antibiotic resistance rates in human UTIs.

Methods: A summary of the overall approach and the partnerships between Columbia University, George Washington University (GWU), Johns Hopkins Bloomberg School of Public Health, Kaiser Permanente Southern California (KPSC) Research and Evaluation, the Natural Resources Defense Council, Sanger Institute at Stanford University, Sutter Health Center for Health Systems Research, the University of Cambridge, and the University of Oxford is presented. The collection, quality control testing, and shipment of retail meat and clinical samples are described. Retail meat (chicken, beef, turkey, and pork) was purchased from stores throughout Southern California from 2017 to 2021. After processing at KPSC, it was shipped to GWU for testing. From 2016 to 2021, after clinical specimens were processed for routine clinical purposes and immediately before discarding, those with isolated colonies of *E coli*, *Campylobacter*, and *Salmonella* from KPSC members were collected and processed to be shipped for testing at GWU. Detailed methods of the isolation and testing as well as the whole-genome sequencing of the meat and clinical samples at GWU are described. KPSC electronic health record data were used to track UTI cases and AMR patterns among the

XSL•FO
RenderX

cultured specimens. Similarly, Sutter Health electronic health record data were used to track UTI cases in its Northern California patient population.

Results: From 2017 to 2021, overall, 12,616 retail meat samples were purchased from 472 unique stores across Southern California. In addition, 31,643 positive clinical cultures were collected from KPSC members during the same study period.

Conclusions: Here, we presented data collection methods for the study, which was conducted to evaluate the impact of SB27 on downstream antibiotic resistance rates in human UTI. To date, it is one of the largest studies of its kind to be conducted. The data collected during this study will be used as the foundation for future analyses specific to the various objectives of this large body of work.

KEYWORDS

AMR; antimicrobial resistance; E coli; Escherichia coli; urinary tract infection; UTI

Introduction

Worldwide, antibiotics are used to prevent and treat bacterial infections in both humans and animals. However, routine and inappropriate uses of antibiotics have contributed to antimicrobial resistance (AMR), which is a major challenge to human health worldwide [1]. In the United States, industrial food animal production drives antibiotic consumption through both therapeutic and prevention uses in animals [2]. The majority of medically important antibiotics are sold for use in livestock, with tetracyclines accounting for 66% of these antibiotics [3,4]. This livestock use may result in antimicrobial-resistant infections in humans. Prior work [5,6] has suggested a link between antibiotic use in poultry and antimicrobial-resistant extraintestinal pathogenic *Escherichia coli (E coli)* urinary tract infections (UTIs) in humans [7-11]. This suggests the potential for use of antibiotics in food-producing animals to be important to address to help curb AMR.

California has a large livestock industry and is one of the leading US producers of beef cattle, broiler chickens, and turkey [12,13]. It is also the most populous US state, with a human population larger than the Netherlands, Denmark, and Sweden combined (countries that lead the European Union science and policy on AMR in livestock [14,15]). In an effort to reduce AMR and related human infections, on January 1, 2018, California enacted Senate Bill 27 (SB27), which changed previous policy to require a veterinarian's prescription for the use of antibiotic drugs, and banned antibiotic uses for disease prevention in livestock [16]. A similar policy was enacted in the European Union in 2006, which led to reductions in antibiotic use and AMR [14,17-20]. SB27 was the first such legislation in the United States and provided a natural experiment with which to investigate whether a ban on antimicrobials used for disease prevention in livestock was associated with a decrease in antimicrobial-resistant *E coli* in retail meat and among UTI cases in humans.

Here, we describe the methods of a study that was a collaborative effort among Columbia University, George Washington University (GWU), Johns Hopkins Bloomberg School of Public Health (JHU), Kaiser Permanente Southern California (KPSC) Research and Evaluation, the Natural Resources Defense Council, Sanger Institute at Stanford University, Sutter Health Center for Health Systems Research, University of Cambridge, and the University of Oxford. Specifically, we describe the methods used to investigate whether the passage and implementation of SB27 were associated with a decrease in AMR among retail meat products in California and among *E coli* UTI at KPSC and Sutter. We simultaneously collected chicken, beef, turkey, and pork retail meat samples from across Southern California and clinical isolates from KPSC between 2017 and 2021. We also leveraged KPSC electronic health record (EHR) data to track UTI cases and AMR patterns among the cultured specimens. Similarly, Sutter Health EHR data were used to track UTI cases in its Northern California patient population. Whole-genome sequencing (WGS) was also performed by GWU on confirmed *E coli*, *Salmonella*, and *Campylobacter* isolates from retail meat and clinical samples.

Taken together, the aims of the study were to characterize and compare AMR phenotypes, genes, and *E coli* populations isolated from retail chicken and human clinical samples; to quantify changes in AMR phenotypes, genes, and *E coli* populations from retail chicken and human clinical samples before and after SB27 implementation; and to define the spatial relationship between livestock operations and patients with an antimicrobial-resistant *E coli* UTI. Under SB27, California was the first US state to ban nontherapeutic uses of antibiotics in livestock. At the time of this writing, this was the first population-based study in the United States to rigorously measure the association between AMR profiles of *E coli* isolated from chicken retail meat and human clinical samples during the implementation of a statewide policy meant to reduce antibiotic use. This descriptive assessment builds on a small number of early publications [16,21-24] to provide a common foundation for future analyses specific to the various objectives of this large body of work.

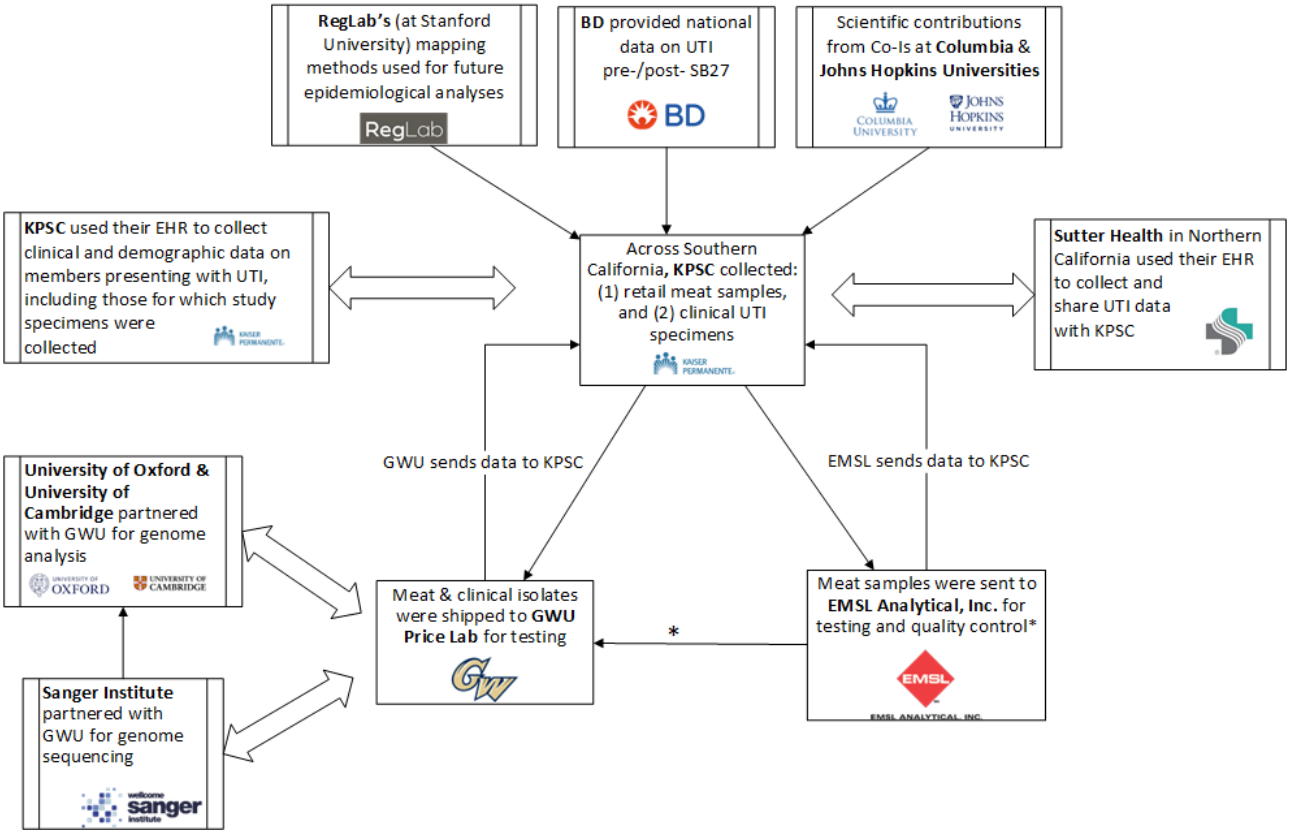
Methods

Partnerships and Summary of Approach

Meat and Human Clinical AMR Data

A prospective study design was used over the study period (2016-2021) to collect information on AMR in retail meat and human infections. Retail meat was purchased in Southern

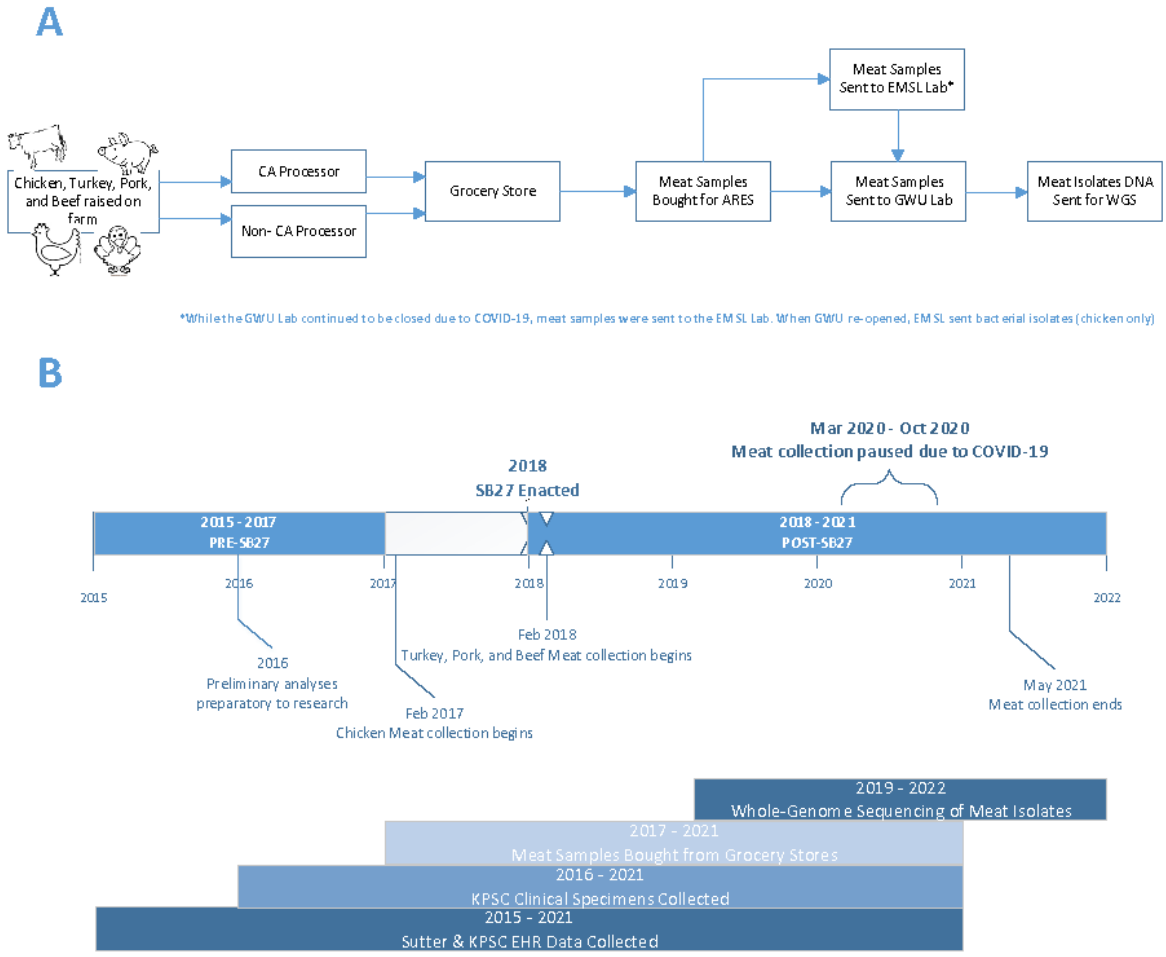
XSL•FO
RenderX



California and human infection data came from KPSC in Southern California and Sutter Health in Northern California. Each week, retail meat (chicken, turkey, beef, and pork) was purchased from stores across Southern California. Clinical and demographic data for members presenting with a UTI were extracted from the KPSC EHR along with ancillary information on *E coli* isolated from urine specimens. Study data were also obtained for KPSC members with *Salmonella* and *Campylobacter* isolated from stool samples. Each week all isolated *Salmonella* and *Campylobacter* and a subset of the isolated *E coli*, based on convenience sampling (samples processed across multiple shifts from Bacteriology), were collected from KPSC laboratories for additional analysis. Similarly, in Northern California, Sutter Health's EHR data were used to extract clinical and demographic data for patients who presented with a UTI; however, no clinical samples were collected from Sutter Health. The purchased meat and the subset of clinical isolates from KPSC were shipped to GWU (Price Laboratory). GWU isolated bacteria from the meat and conducted antimicrobial susceptibility testing of *E coli*, *Salmonella*, and *Campylobacter* from meat (Table S2 in Multimedia Appendix 1). Additionally, human isolates from KPSC were sent to GWU for further susceptibility testing to augment EHR resistance profiles with microbials that were not tested by the KPSC clinical laboratory.

Additional Partnerships

The study involved several additional key partnerships to conduct laboratory analyses, supply supplemental clinical data, identify livestock operation locations, and describe SB27 implementation. The Sanger Institute, the University of Oxford, and the University of Cambridge partnered with GWU on the WGS data management, genome assembly, quality control analysis, and sequence type assignment of select samples. The RegLab at Stanford University [25] developed a methodology to map animal production sites using satellite imagery and will be utilized in future spatial epidemiologic analyses to assess whether proximity to animal production sites increases the risk for AMR UTI; Beckton, Dickinson, and Company provided national data on UTI for a manuscript on UTI pre- and post-SB27; and KPSC used a local laboratory in Pasadena (EMSL Analytical, Inc [EMSL]) for quality control of meat testing. Finally, JHU partnered with the study team to (1) conduct parallel analyses of microbial recovery and AMR from the National AMR Monitoring System within and beyond California [26], and (2) undertake a qualitative study of food-animal producers and related agricultural stakeholders within and beyond California to describe attitudes, knowledge, beliefs, and practices around antimicrobial uses in food animal production, including in the context of SB27 [21].



The partnerships are summarized in Figure 1. Timelines for EHR data, meat collection, and clinical sample collection activities are summarized in Figure 2.

Figure 1. Study partnerships flowchart. Meat collection paused due to the pandemic. Once we resumed meat collection during lockdown, samples were sent to EMSL only as GWU was closed. Retail Meat Samples

Collection and Shipment

Meat sample collection occurred from 2017 to 2021 (Figure 2B) in regions where KPSC facilities were located (from Bakersfield to San Diego). To ensure that the retail meat-sampling approach maximized the diversity of geography and meat processor facilities, from March through July 2017, we performed several inventory surveys of hundreds of stores to collect data on availability and attributes (eg, regulated label claims like United States Department of Agriculture [USDA]–certified organic or raised without antibiotics [if neither, then classified as "no restrictions"], and if processed in California or non-California) of meat. Research associates (RAs) surveyed stores across Southern California (Los Angeles, Inland Empire, and San Diego areas), taking photos of retail meat package labels and gathering all USDA Establishment (meat processor) code. Establishment codes are used to identify the facility in which the retail meats are processed [27]. These codes include p-codes used for poultry (chicken and turkey) and m-codes used for pork and beef. Surveys were repeated yearly to ensure ongoing representation of USDA establishment codes available for purchase in the retail establishments in our target region. The survey data informed the development of weekly shopping routes for retail meat collection, each of which included a list of designated stores and meat types to purchase. There were 53 different routes, each with assigned stores. The Los Angeles region was divided into 8 sections with 42 routes, the Inland Empire region had 6 routes, and the San Diego region had 5 routes. A Google Maps (Multimedia Appendix 2) account was used to document and save the routes.

The RAs followed prespecified criteria for retail meat purchasing. They were instructed to purchase smaller packages, valued under US $10 and weighing less than 2 lbs, when possible. Larger packages were permitted when no smaller packages existed for the brand or establishment code combination of interest. Only raw meat that had not undergone any secondary processing was purchased. Expiration or sell-by dates were to be at least 3 days after the date of purchase and the longest expiration period was to be purchased when possible. The RAs traveled with labels, cooler, ice packs, temperature gauge, assigned shopping list, Ziploc bags, paper towels, gloves, and insulated shopping bags. They also used a prepaid debit card to monitor the study budget.

After meat was purchased, a study ID was assigned. The shopping date was written on the ID label and placed close to the printed price label. Two pictures of the meat with the label (one of the whole package and the other, a close-up of the

XSL•FO
RenderX

establishment code and label) were taken. A third photo was taken if the establishment code was not easily visible in the close-up photo. Sealed retail meat packages were then placed into a Ziploc bag with a paper towel. Retail meat packages were transported to the KPSC research facility, the same day of purchase, in a cooler, equipped with a thermometer, where the meat was kept cool, but never frozen; temperature logs were also kept.

Following transport to the research facility, retail meat packages were placed in a study refrigerator. Photos were uploaded by the RA into the secure study folder and saved per instructions in the standard operating procedures (SOPs). All meat-related data and photos were also entered into the study tracking database; a list of the variables in the tracking database is provided in Multimedia Appendix 3. This database was only accessible to approved study staff and saved in a secure KPSC network study folder. Tracking ensured the correct amounts of retail meat were purchased, shipments were sent on time every Tuesday to be received by GWU no later than Friday, and for other general tracking needs. The study tracking database was created using Microsoft Access and maintained by a data manager. The data manager was also responsible for all troubleshooting and for updating the database as needed. The database stored data on meat samples, tracked clinical samples, and shipping data.

Each meat sample was individually placed in a second Ziploc bag with a paper towel to prevent any leaks or cross-contamination. The paper towel was placed on the backside of the meat package to maintain the visibility of the ID labels. The individually packaged, double-bagged samples were placed into a study cooler. Ice packs wrapped in insulation were placed on the bottom of the cooler, followed by a double layer of meat samples. This was repeated until the cooler was full (approximately 3-4 rows of meat samples per cooler), and ice packs were added as the top layer. The temperature was monitored in all the study coolers.

Each cooler had a “Research Purposes Only” label attached on the outside, and a KPSC business card on the inside. The cooler was securely sealed before shipment through FedEx overnight “First Priority” to the GWU laboratory. If a FedEx pick-up could not be scheduled from the KPSC research facility, the designated RA would drop off the shipment at the nearest FedEx location. All shipment related details were tracked in the study tracking database.

During meat purchasing, transferring, and shipping, Occupational Safety and Health Administration (OSHA) standards and guidelines were followed by all study staff. All RAs were cross-trained in meat collection, tracking, safety, and shipping. RA meetings were used to help address or resolve study issues or concerns. Participants in these meetings included the study team, project coordinator or project manager (PM), and GWU (as needed).

Quality Control Testing

KPSC used EMSL, a laboratory located in Pasadena, which performs bacterial testing of meat, for quality control of the study retail meat samples. Each week, approximately 5-10 samples were randomly provided to EMSL for quality control. EMSL used their own SOPs adapted to align with SOPs developed by GWU.

The COVID-19 Pandemic

In March 2020, the study was paused through the middle of October 2020 due to the COVID-19 pandemic as staff was required to work from home. After the study resumed, EMSL became the primary laboratory as the GWU laboratory continued to be closed to in-person work. During April-May 2021, the GWU laboratory resumed on-site work and all retail meat isolates, including any samples tested by EMSL during the closure were sent to GWU for processing and testing.

Clinical Samples

Collection and Shipment

After clinical specimens were processed for routine clinical purposes and immediately before discarding, clinical specimens in the form of agar plates with isolation colonies of *E coli*, *Campylobacter,* and *Salmonella* from KPSC members were collected from Regional KPSC labs on a weekly basis from 2016 to 2021.

Under aseptic conditions, *E coli* was isolated by KPSC study laboratory technicians from 100 mm Blood Agar- Trypticase soy agar II MacConkey/ChomAGAR Biplates into Biobank tubes (Microbank tubes with beads, Pro-Lab Diagnostics) under a vented CLASS II hood. *Campylobacter* was isolated from *Campylobacter* blood agar plates and placed into Biobank tubes. *Salmonella* was isolated from Trypticase soy agar slants and placed into Biobank tubes. All Biobank tubes were labeled with custom −80 °C-resistant study labels and were stored frozen at −80 °C before shipping. All samples were maintained in the freezer and temperature logs were checked weekly to ensure no temperature deviations occurred. Samples were shipped through FedEx Priority Overnight First Delivery to GWU for testing. Before shipping samples to GWU, a GPS temperature monitoring probe was used to confirm the temperatures were acceptable for transport. In addition, through our study database, we were able to accurately track all samples and their location.

All clinical sample data were tracked in the study database that also maintained the retail meat sample data. Laboratory RAs entered the patient medical record number, sample type, accession number, study ID, and other variables outlined in Multimedia Appendix 4. Study IDs were used to maintain the privacy and security of the protected health information of the patient and their sample. This database was also used to generate on-demand reports of the number of samples collected and the demographic characteristics of the patients from whom the clinical samples were collected.

Testing of Meat and Clinical Samples at GWU

Isolation and Testing

To isolate bacterial species of interest from meat, 200±25 g of each retail meat specimen was aseptically transferred to a stomacher bag and 250±25 g of the appropriate enrichment broth was added. The bags were placed on a stomacher rack, briefly agitated on a benchtop shaker, then placed in an

XSL•FO
RenderX

incubator. Species-specific selective and screening media were inoculated from the enrichment broth cultures, and several rounds of single-colony isolation were performed to obtain pure isolates of *E coli*, *Salmonella*, and *Campylobacter*. The species of each isolate was confirmed by quantitative polymerase chain reaction. *E coli* was isolated from all 4 meat types; *Salmonella* was isolated from chicken, turkey, and pork; and *Campylobacter* was isolated from chicken. Species-specific enrichment and isolation methods for each bacterial species are further detailed in Multimedia Appendix 1.

The "Antibiotic Susceptibility Testing" section in Multimedia Appendix 1 describes both types of tests conducted at GWU (Kirby-Bauer and Minimum Inhibitory Concentration [MIC]) to test *E coli*, *Salmonella* spp, and *Campylobacter* spp isolates for susceptibility to a panel of antibiotics. The Kirby-Bauer disc test was conducted on all meat isolates, as well as for the subset of human clinical isolates. MIC tests were conducted on a subset of both meat and human clinical isolates to augment K-B disc testing. Specifically, MIC testing by the broth microdilution method was conducted for antibiotics to which >5% of *E coli* or *Salmonella* isolates from any source were resistant.

Most of the susceptibility data for *E coli* from clinical isolates came from testing conducted as part of routine clinical microbiology protocols at KPSC; MIC data were obtained with the Beckton, Dickinson, and Company Phoenix method. During GWU's COVID-19 closure, when EMSL conducted testing of some meat samples, similar procedures and protocols were followed.

Preparation of Samples for WGS and Sequencing Procedures

DNA for genomic analysis was extracted from a subsample of the confirmed meat and clinical sample-derived *E coli*, *Salmonella* spp, and *Campylobacter* spp isolates using the PureLink Pro 96 Genomic DNA Purification Kit (Invitrogen). WGS was performed on the NovaSeq platform with a read length of 150 bp. Assemblies for downstream analyses were generated from raw sequencing data, and quality control of the sequencing run was performed by checking the quality of the trimmed sequencing reads. Multilocus sequence typing was performed for *E coli* using the Achtman scheme [28,29] and population structure was inferred using fastbaps. A midpoint-rooted species tree was built under a GTR+GAMMA substitution model. Additional detail on methods for WGS data processing and analysis is available in Multimedia Appendix 1.

EHR Data

KPSC and Sutter Health integrated health care systems have wide coverage areas, high completeness of data, racial, ethnic, and socioeconomic diversity among their members or patients, longitudinal health care usage information, and research infrastructure [30,31]. Both systems use Epic for their EHR data, allowing the synthesis of information across the 2 systems. Data were aggregated across both networks to identify UTI cases presenting for clinical care across California populations, thereby increasing the representation and generalizability of the results.

KPSC provides comprehensive care to more than 4.7 million members across 15 medical centers and 235 medical offices in Southern California. KPSC uses KP HealthConnect (an Epic system) as its EHR to capture all aspects of members' clinical care, encounters and communications, and administrative and demographic data. HealthConnect links all patient care information including primary and specialist care, outpatient surgery, laboratory services, radiology, pharmacy, patient-level demographic, and membership data and billing. The system links facilities across the region and provides members, physicians, and other authorized health care providers with online access to clinical information.

In Northern California, Sutter Health, a not-for-profit organization, provides care to more than 3 million patients across 22 counties, including rural, urban, and suburban communities. Like KPSC, Sutter Health uses a comprehensive Epic EHR system allowing researchers to access detailed clinical data, including physician orders and free text clinical notes, as well as the standard ambulatory, hospital, laboratory, and pharmacy data.

Researchers from KPSC and Sutter Health partnered to develop reproducible programing code to construct standardized data sets from the EHR representing episodes of UTI from 2015 to 2022. This collaboration included monthly meetings to discuss data extractions, share code, and monitor data quality. Early publications on trends in UTI and risk factors for UTI, including low socioeconomic status and ambient temperature, have been conducted on these data sets [22-24].

All analyses were conducted using SAS Enterprise Guide 8.2 (SAS Institute) at KPSC, and R at Sutter Health.

Training

All study staff were trained on study procedures by the PM. The PM had OSHA certification and trained staff on how to safely handle meat samples during the collection and shipment. SOPs were drafted to ensure consistency and accuracy in specimen collection, and a Project Management Plan was developed to ensure that all study milestones were met on time.

Ethics Approval

No patient recruitment or patient contact occurred as part of this study, and all study data will be limited [32]. Both health systems use an opt-out research participation system where members or patients can opt out of their health data being used for research. If they do not opt out, their data become available for research following institutional review board (IRB) approval and Health Insurance Portability and Accountability Act (HIPAA) compliance.

The study was approved by the Kaiser Permanente Southern California (KPSC) IRB (IRB #11284); GWU and JHU ceded review to the KPSC IRB. A waiver for the use of protected health information and of informed consent was approved for this study by the KPSC IRB. The study was also approved by the Sutter Health IRB (IRBNet #1063246) with a waiver of HIPAA authorization and informed consent. No IRB was required from the remaining collaborating sites as no data were collected at those sites.

Results

Retail Meat Samples

Overall, retail meat samples were purchased from 472 unique stores. Between 2017 and 2021, chicken retail meat samples were purchased from 285 unique stores (Table 1). Starting in 2018, the study initiated the purchase of retail turkey, pork, and beef meat samples from 266, 267, and 253 stores, respectively (Table 1). Multimedia Appendix 2 shows the map of the stores throughout the Southern California region.

A total of 12,616 retail meat samples were collected from the 472 stores from 2017 to 2021 (Table 2). Of these, 6084 were chicken, 2701 were turkey, 2486 were beef, and 1345 were pork.

Table 1. Unique stores visited for retail chicken, turkey, pork, and beef meat purchases (2017-2021).

Table 3 further details the retail chicken, turkey, pork, and beef samples collected from 2017 to 2021 by the state of processing (California and non-California) and by regulated label (USDA-certified organic, raised without antibiotics, and no restrictions). Among the retail chicken, pork, and beef samples bought, more came from a California processor than a non-California one. For the chicken, 1529 USDA-certified organic samples were identified. For the beef, 605 samples were identified as organic. Furthermore, for the pork, none of the samples were organic. Conversely, for turkey, non-California samples were more prevalent, with 441 being organic.

[h]Total: n=2486, processed in California: n=1589, and processed outside of California: n=859 (for the latter 2, missing establishment codes (n): Beef: 38).

Clinical Samples

A total of 31,643 positive clinical cultures were collected from KPSC members from 2017 through 2021 (Table 4). Of these, 28,647 tested positive for *E coli*, 1681 for *Campylobacter*, and 1315 for *Salmonella*.

XSL•FO
RenderX

Overall, the mean age of KPSC members with a positive clinical specimen was 49.3 (SD 23.1) years (Table 5). This group was also primarily female (85.7%, 27,104/31,643) and Hispanic (44.1%, 13,945/31,643).

Table 4. Clinical specimens of Kaiser Permanente Southern California (KPSC) members collected (2017-2021; N=31,643).

Discussion

We present data collection methods for the study which was conducted to help fill a gap in the literature by evaluating the impact of SB27 on downstream antibiotic resistance rates in human UTIs. To date, it is one of the largest studies of its kind to evaluate the relationship between antibiotic use in livestock production and AMR profiles in retail meat and humans before and after the implementation of a statewide policy meant to reduce antibiotic use in the livestock sector.

The study concurrently sampled retail meat (chicken, turkey, beef, and pork) and clinical specimens at regular time intervals. The study team cultured and isolated *E coli*, *Salmonella*, and *Campylobacter* from retail meat, and clinical specimens were processed by clinical laboratory staff at KPSC to isolate bacteria of interest. WGS was performed on a subset of *E coli* isolates, and all *Salmonella* and *Campylobacter* isolates. This study used expansive EHR data, before (2015-2017) and after (2018-2021) SB27 enactment, from KPSC and Sutter Health, 2 large and well-established health systems. Overall, 12,616 samples of meat were collected from more than 400 retail stores in Southern California. From 31,643 clinical specimens, 28,647 *E coli*, 1315 *Salmonella*, and 1681 *Campylobacter* isolates were collected. Our large study sample size thus allows us to support emerging evidence of the connection between AMR in livestock and human *E coli* UTI [33,34]. This study had complementary methodological components requiring different measurement techniques and areas of expertise, including laboratory-based methods, geospatial modeling, market-basket research design and techniques, incorporation of publicly available data sets, and use of secondary EHR data for population health research. Moving forward, the study data will be used for further analysis and manuscripts that address the project's various primary and

XSL•FO
RenderX

secondary aims, as well as complementary work and secondary data analyses through various partnerships.

The study had strengths and limitations. It successfully collected retail meat, clinical microbiological specimens, and data over a 5-year period. Early in the study, there were no readily available data to help identify Concentrated Animal Feeding Operation locations. As a result, we sought out and partnered with Stanford University to classify Concentrated Animal Feeding Operation locations. To set up the study, huge, concerted logistical planning across various divisions had to be implemented. The coordination of laboratory leadership at KPSC to integrate research into the clinical flow had to occur, as well as hiring a large RA team to cover the large Southern California area needed to collect the meat samples. The RAs also had to ensure all the meat samples bought were kept at reasonable temperatures from purchase to delivery to GWU where they could properly be tested. The shipments themselves were an undertaking as they tended to be bulky and heavy, and they needed their temperatures constantly monitored. Additionally, we worked with the EMSL laboratory to mirror the main laboratory (GWU) procedures, to act as a quality control laboratory for the meat samples. Though the RA team covered many grocery stores throughout Southern California, we did not collect data on which products were more likely to be purchased by KPSC members. However, we strategically selected a representative sample of grocery stores to overlap with the geographic distribution of KPSC facilities and members. The study was also successful in gaining access to the clinical samples, and in being able to collect a large quantity for the study. A further limitation was the lack of routine testing for tetracycline for clinical UTI samples at KPSC. As a solution, we shipped all study samples to GWU for tetracycline susceptibility testing. Lastly, the COVID-19 pandemic impacted data collection, as testing laboratories were closed for several months, and meat purchasing was suspended for a short period due to safety concerns of field staff. However, data collection resumed in mid-October 2020 with additional pandemic procedures in place, such as the addition of personal protective equipment and other safety precautions.

This methods paper describes the processes of collecting, processing, and shipping meat and clinical samples, and can be used as a guide for any subsequent, similar research. The analyses implemented and subsequent results will provide the evidence necessary to evaluate the effectiveness of SB27 and will be detailed in forthcoming publications.

The authors would like to acknowledge the following Cambridge University contributors: Julian Parkhill, Antonis Dimopoulos, and Caitlin Collins; the following University of Oxford contributors: David Aanensen and Julio Diaz Caballero; the following Columbia University contributor: Kara Rudolph; the following George Washington University contributors: Daniel Park, Maliha Aziz, Yashan Wang, Kaeley Bush, Ann Nyaboe, Benjamin Keaton, Katherine Thompson, Katherine Huillca-Jara, Morganne Halpin, Lauren Schneider, Hanna-Grace Rabanes, Erika Roloff, Caitlin Flouton, Isabelle Wal, Michael Hughes, Fariha Bablu, Precious Williams, Qi Hu, Ariana Campos, Amari Manigault, You Lian Weiner, Jonathan He, Remy Hilsabeck, Kelsey Roach, Alexis Carson, Grace Rahman, Jonny Phan, Emilee Benos, Megan Pater, Kristan Boutte, Arianna Perez, Blair Cabunoc, Alexis Pracar, Francesca Cetta, Bianca Punger, Myles Rogers, Speline Irakoze, Shubha Kapuganti, Liam Ruddy, Janet Kyi, Sam Ruth, Sharee Lopez, Alex Sadzewicz, Christina Maldonado, Pascale Schmidt, Felicity Nelson, Niyati Shah, Kelly O'Connor, Naga Betrapally, Melody Fung, Jacob Wittbrodt, Adina Dingankar, and Meaghen Murphy; the following Johns Hopkins University contributors: Sean Stapleton, Gabriel Innes, Raychel Santo, and Sara Lupolt; the following Kaiser Permanente Southern California leadership: Louie Farnacio, Jonathan Gullett, and Darryl Palmer-Toy; Vahe Khanlian, Paulette Medina, Gustavo Saenz, Jaecer-Jeffrey Elago, Onie Bueno, Sienna Mendoza, Grace Rabot, and Cynthia Aye; the following Kaiser Permanente Southern California contributors: Peggy Hung, Sean Anand, Julie Stern, Cathy Ngo, Nooreen Khan, Jonathan Arguello, Cindy Agus, Raul Calderon, Rossy Perez, Karlesse Clayton, Brittany Brown, Amanda Mancilla, Leann May, Michael Aragones, Stephanie May Juson Agpalo, Dwayne Agpalo, Laura Dilanchian, Mitchell Tran, Fariba Kianmajd, Mitchell Ian Bomben, and Elmer Ayala; and the following Sutter Health contributor: Alex Scott.

The authors would also like to thank the patients of Kaiser Permanente Southern California and Sutter Health for their partnership with us to improve their health. Their information, collected through our electronic health record systems, leads to findings that help us improve care for our patients and can be shared with the larger community.

The study comprised of the Antimicrobial Resistant *E coli* before and after California Senate Bill 27 (ARES), Maximizing the Knowledge Gained from California Senate Bill 27 (MAX SB27), and Johns Hopkins Fisher Center Discovery Program studies. The ARES R01 study was funded by the National Institutes of Health (NIH grant 5R01AI130066-05); the MAX study was funded by the Wellcome Trust (Reference 211493/Z/18/Z; award no. 18-1030952970); and the Fisher study was funded by the Johns Hopkins Sherrilyn and Ken Fisher Center for Environmental Infectious Diseases Discovery Program (grant 010NAC2017). This study was also funded by KPSC internal funding.

Data Availability

Anonymized data that support the findings of this study may be made available from the investigative team in the following conditions: (1) agreement to collaborate with the study team on all publications, (2) provision of external funding for administrative

XSL•FO
RenderX

and investigator time necessary for this collaboration, (3) demonstration that the external investigative team is qualified and has documented evidence of training for human subjects protections, and (4) agreement to abide by the terms outlined in data use agreements between institutions.

Authors' Contributions

JAC, KN, LBP, VQ, MFD, CML, AP, KJB, and SYT contributed to the concept and design. AF, MEP, HST, and SYT were responsible for drafting of the manuscript. JAC, KN, LBP, VQ, LDC, MFD, RW, VH, JHK, CML, AP, SR, KJB, and SBS were involved in critical revision of the manuscript. LDC, RW, VH, SR, and SBS were responsible for statistical and data support. All authors reviewed and approved the final draft.

Conflicts of Interest

AF received research support from Pfizer, Moderna, Gilead, and GlaxoSmithKline unrelated to this study. KJB received research support from Dynavax, GlaxoSmithKline, Moderna, and Pfizer unrelated to this study. SYT received funding from Pfizer paid directly to institution for work unrelated to this study.

Abstract

Background: The traumatic brain injury (TBI) Intensive Evaluation and Treatment Program (IETP) is an innovative modality for delivering evidence-based treatments in a residential, inpatient format to special operational forces service members and veterans with mild TBI. IETPs provide bundled evidence-based assessment, treatment, referral, and case management in concordance with the existing guidelines for mild TBI and commonly co-occurring comorbidities. To date, there has been no formal characterization or evaluation of the IETP to understand the determinants of implementation across the system of care. The goal of our partnered evaluation initiative (PEI) with an operational partner, the Physical Medicine and Rehabilitation National Program Office, is to facilitate the full implementation of the IETP across all 5 Veterans Health Administration TBI–Centers of Excellence (TBI-COE) and to inform minimum standards while supporting the unique characteristics of each site.

Objective: This IETP partnered evaluation will describe each of the 5 TBI-COE IETP services and state of implementation to identify opportunities for adaptation and scale, characterize the relationship between patient characteristics and clinical services received, evaluate the outcomes for participants in the IETP, and inform ongoing implementation and knowledge translation efforts to support IETP expansion. In alignment with the goals of the protocol, ineffective treatment components will be targeted for deimplementation.

Methods: A 3-year concurrent mixed methods evaluation using a participatory approach in collaboration with the operational partner and TBI-COE site leadership will be conducted. Qualitative observations, semistructured focus groups, and interviewing methods will be used to describe IETP, stakeholder experiences and needs, and suggestions for IETP implementation. Quantitative methods will include primary data collection from patients in the IETP at each site to characterize long-term outcomes and patient satisfaction with treatment and secondary data collection to quantitatively characterize patient-level and care system–level data. Finally, data sets will be triangulated to share data findings with partners to inform ongoing implementation efforts.

Results: Data collection began in December 2021 and is currently ongoing. The results and deliverables will inform IETP characterization, evaluation, implementation, and knowledge translation.

Conclusions: The results of this evaluation seek to provide an understanding of the determinants affecting the implementation of IETPs. Service member, staff, and stakeholder insights will inform the state of implementation at each site, and quantitative measures will provide options for standardized outcome measures. This evaluation is expected to inform national Physical

Medicine and Rehabilitation Office policies and processes and knowledge translation efforts to improve and expand the IETP. Future work may include cost evaluations and rigorous research, such as randomized controlled trials.

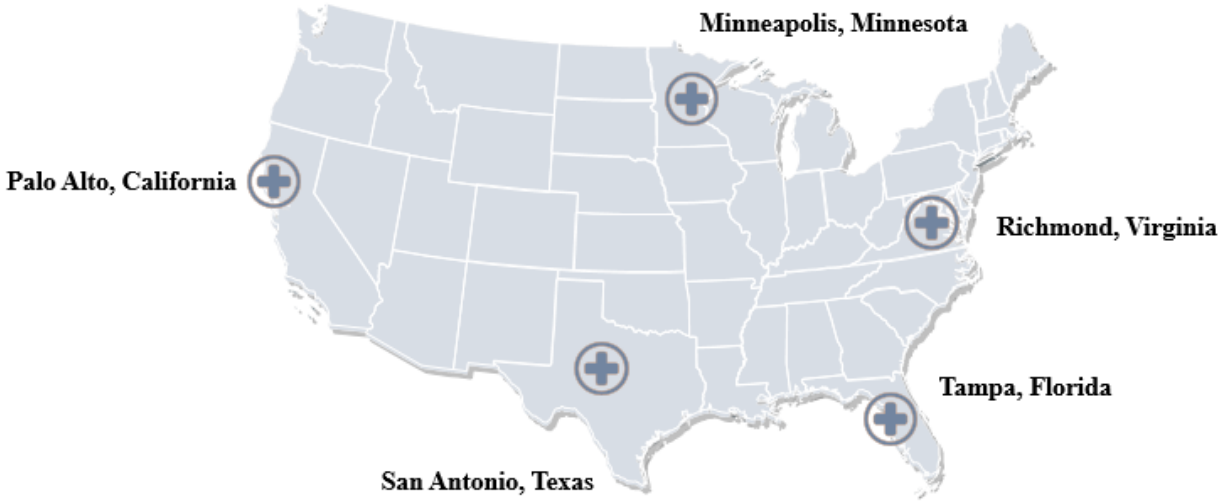
Introduction

Background



Record numbers of service members with traumatic brain injury (TBI) have flooded the Veterans Affairs (VA) and the Department of Defense (DoD) during the past 2 decades. Since 2000, a total of 430,720 service members have been diagnosed with TBI, and the majority (82.4%) have been diagnosed with mild TBI [1]. Service members consist of conventional forces and special operational forces (SOF). SOF service members undergo extensive training and experience increased risk exposure owing to deployment and job hazards [2]. Sequalae from mild TBI may co-occur with at least 1 of the following: posttraumatic stress disorder (PTSD), chronic pain, and visual and balance disturbances. In particular, the SOF population has a unique presentation of TBI sequala [3]. Interdisciplinary TBI rehabilitation, particularly for the SOF population, is intended to enhance functioning, reduce disability, and improve quality of life. To meet the demand for rehabilitation services required by SOF service members and veterans with TBI, the Veterans Health Administration (VHA) Physical Medicine and Rehabilitation (PM&R) National Program Office developed 5 specialty TBI–Centers of Excellence (TBI-COE) to provide a coordinated approach for comprehensive TBI rehabilitation (Figure 1). The TBI-COE sites are located at VA hospitals in Minneapolis, Minnesota; Palo Alto, California; Richmond, Virginia; San Antonio, Texas; and Tampa, Florida.

To date, there has been no formal characterization or evaluation of the TBI Intensive Evaluation and Treatment Program (IETP) to understand the implementation determinants or formalize core program components across the system of care. This limits the ability of VA to make evidence-based decisions for policy and planning to meet the long-term needs of this patient cohort. To expand the capacity for innovation in delivering guideline-concordant care, the PM&R National Program Office, our operational partner, is supporting a partnered evaluation to implement the effective components of this modality across VHA.

IETP Partnered Evaluation Goal and Aims

The goal of our partnered evaluation initiative (PEI) is to facilitate the full implementation of the IETP across all 5 VHA TBI-COE sites and to inform minimum standards while supporting the unique characteristics of each site. The aims of this partnered evaluation are as follows: (1) describe IETP services and state of implementation of these services in each of the 5 sites to identify opportunities for adaptation and scale—the findings will identify IETP core aspects and determinants of implementation; (2) characterize the relationship between patient characteristics, clinical services received, and outcomes for participants in the IETP across multiple outcome domains, including trajectories of recovery; and (3) evaluate the clinical impact of IETP components and deliver a final report to include deliverables that support IETP implementation playbook content development (Figure 2). The completion of these aims will promote effective IETP practices across this polytrauma system of care. The development and dissemination of product deliverables from the evaluation will support IETP implementation and continued evaluation over time.

Figure 2. Intensive Evaluation and Treatment Program (IETP) partnered evaluation aims. TBI: traumatic brain injury.

TBI IETP—Innovative Modalities of Care

Innovative modalities of care improve access to evidence-based care for mild TBI. Innovative models of care have been developed within the polytrauma system of care, which includes 5 specialty TBI-COE that provide comprehensive rehabilitation services for veterans and service members with TBI. The TBI IETP is an innovation that has yielded high consumer demand across locations. The IETP delivers evidence-based care in a residential, inpatient format. The IETP provides bundled evidence-based assessment, treatment, referral, and case management in concordance with the existing guidelines for mild TBI and commonly co-occurring comorbidities (refer to the IETP characterization table in Multimedia Appendix 1 [4-23]). Indeed, the residential format has grown out of necessity to address the unique needs of the SOF population in a compressed, timely manner ideally suited for abbreviated inpatient treatment stays. A recent study by Dismuke-Greer et al [24] highlighted higher annual outpatient use and cost over protracted time intervals for veterans with mild TBI compared with non-TBI controls, highlighting extended intervals and delayed access to evidence-based care. Proponents of IETP emphasize its improved access to evidence-based care, including TBI-adapted treatment of mental health conditions previously published [25,26].

Responsiveness and Alignment With Goals: Quality Enhancement Research Initiative Implementation Roadmap

Overview

In response to this evaluation, engagement with partners and alignment with network director goals will guide implementation across the Quality Enhancement Research Initiative (QUERI) Implementation Roadmap. In response to the special solicitation for a PEI with VHA PM&R, the Characterization, Evaluation, and Implementation of Innovative TBI IETPs will evaluate the ongoing implementation of the IETP at all 5 TBI-COE sites to identify the effective and ineffective components. The project will align with the QUERI Implementation Roadmap, a functional framework for evaluating and contextualizing the implementation of IETP [27]. QUERI Implementation Roadmap elements provide a framework for planning, implementing, and sustaining programs—from reaching audiences to establishing effectiveness, promoting adoption and implementation, and ultimately sustaining maintenance over time. The partner priorities aligned with the roadmap of the framework are summarized in Table 1. Partner goals and challenges will be addressed across the study aims.

XSL•FO
RenderX

Table 1. Integration of the Quality Enhancement Research Initiative Implementation Roadmap conceptual model with partner-identified goals, challenges, and partnered evaluation initiative (PEI) solutions.

Aims and partner goals	Partner-identified challenge	PEI solution
Pre-PEI		
Identify and align needs and goals	Work with a team that understands needs and goals from the TBI[a] and implementation perspective	Ongoing communication and meetings to understand needs and identify priorities
Engage stakeholders	Prior push to implement not successful	Site representatives recruited to facilitate a bottom-up pull and buy-in from local staff. Input on study design and findings were sought from a stakeholder panel including veterans, service members, VA[b] and DoD[c] administrators, and clinicians
Develop measures and data	Program evaluation data are not standardized and readily accessible	Site representatives recruited to facilitate engagement of stakeholders for data collection. Meetings with PM&R[d] partners and various stakeholders to identify and prioritize outcomes
Data to knowledge (preimplementation stage)		
Aim 1: characterize consumer demand	IETP[e] value from referrals within VA and DoD is unknown	Use of qualitative data collection with patients treated across fully and partially implemented sites
Aims 1-2: fully characterize the innovation (IETP)	IETP is a black box with poor characterization to duplicate and sustain across systems	Use of qualitative interview technique and quantitative analyses of administrative data sets to identify effective practice core elements and adaptation options
Aim 2: determine early and late outcomes from IETP	Outcome monitoring has not been the focus of the existing programs	Leverage existing data (eg, IETP data) and collect prospective outcome data to identify measures of success and establish baseline performance at the fully implemented site
Knowledge to implementation (implementation stage)		
Aim 1: characterize the degree of implementation	IETP innovations have occurred asynchronously with variation of implementation	Qualitative data collection with a purposive sample of clinicians at each site to understand the degree of implementation, inform selection, and tailor implementation to each site
Aim 3: disseminate and promote IETP implementation	Continued funding for TBI rehabilitation services in a competitive fiscal environment across the VA organizational hierarchy	Use participatory approach to (1) promote a bottom-up pull for "IETP evidence-based" practices, (2) disseminate implementation content, and (3) gather feedback for each site. Leverage existing reporting structures to summarize findings for reports to Congress including VA and DoD administrators, and clinicians for uptake and sustainment
Performance to data (sustainment; post-PEI)		
Implement IETP	Funding mechanism and timeline insufficient to achieve all partner goals	Will develop future proposals to evaluate the uptake of IETP, evaluate the ongoing implementation, and inform continuous learning

[a]TBI: traumatic brain injury.

[b]VA: Veterans Affairs.

[c]DoD: Department of Defense.

[d]PM&R: Physical Medicine and Rehabilitation.

[e]IETP: Intensive Evaluation and Treatment Program.

Preimplementation Stage: Data to Knowledge

Aim 1 qualitative methods will fully characterize the successful IETP model and the perceived value of IETP components. We will leverage existing data resources and prospective data collection to evaluate program outcomes prioritized by our operational partner and other stakeholders, including service members and veterans with mild TBI (aim 2). Findings from the first 2 study aims will be used to develop the foundation for the implementation of effective components and the deimplementation of ineffective components in aim 3.

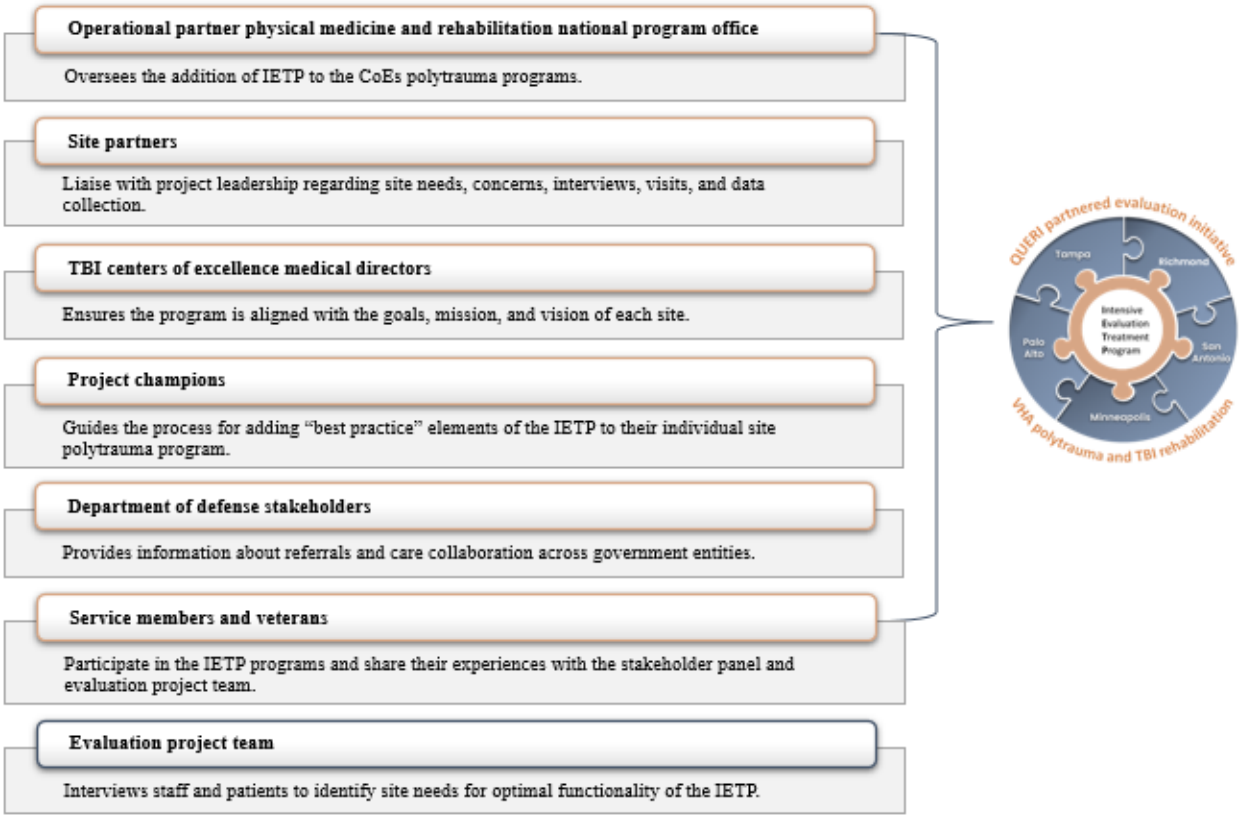
Implementation Stage: Knowledge to Implementation

A participatory approach with IETP stakeholders will be used to develop implementation content that outlines "IETP evidence-based" practices. This effort will involve clinical and administrative IETP stakeholders across study sites as well as a formal stakeholder panel to inform and review a blueprint for implementation.

Sustainment: Performance to Data

Future work will address implementation, deimplementation, and their effects on the system and patient outcomes. Table 1 provides an overview of the timing and conduct of the 3 aims.

XSL•FO
RenderX



Methods

Partnerships, Research Team, and Relevant Experience

The multiple principal investigators (MPIs) have developed an interdisciplinary team to conduct this mixed methods partnered evaluation with PM&R leadership, informing the development of a stakeholder agenda that is reflected in the aims and deliverables.

The PEI engages a stakeholder panel representing multiple stakeholders in IETP from each study site as well as PM&R leadership (Figure 3). The primary goals of the stakeholder panel are to represent operational and clinical perspectives, collaborate on data collection tool development, facilitate site engagement, and identify preferred implementation strategies. Weekly meetings in years 1 through 3 will be held to gather stakeholder input on the study methodology, interpretation of findings, and deliverables.

Figure 3. Intensive Evaluation and Treatment Program (IETP) partnered evaluation collaborative roles. COE: Center of Excellence; QUERI: Quality Enhancement Research Initiative; TBI: traumatic brain injury; VHA: Veterans Health Administration.

Ethical Considerations

The project protocol was reviewed by James A. Haley Veterans' Hospital Research and Development Committee and deemed *nonresearch*, and no informed consent was necessary. Participants' identities are confidential, and deidentified data are stored behind VA firewalls. No compensation will be provided to the participants for this program evaluation project. All methods are performed in accordance with the relevant guidelines and regulations. All staff interviews were approved by the VA national union. Patients' interviews were reviewed by the QUERI administration and were exempt from Code of Federal Regulations Part 1320.3, as the project will evaluate the direct treatment currently provided.

Aim 1

Overview

We will use qualitative methods to describe and characterize IETP to support implementation efforts across all 5 TBI-COE. In alignment with the QUERI Implementation Roadmap, this project will coconstruct a meaningful theoretical context for identifying and describing the implementation of each IETP using the Consolidated Framework for Implementation Research (CFIR) [28,29]. In addition, project leadership will use an implementation evaluation process conducted in a *sister* project, Optimizing Rehabilitation Interventions (ORION) for Cognition Following Complex Traumatic Brain Injury funded by the DoD (W81XWH-19-1-0615), which will maximize the efficiency of this effort and promote interoperability and knowledge translation between VA and DoD. The PEI team will use this implementation evaluation process to present and review the content in initial development in Tampa. Subsequently, the materials will be used and further developed in an iterative fashion at the other IETP sites. The aim 1 deliverable is a characterization of the IETP, IETP Care Implementation Elements Inventory, and IETP Logic Model. The inventory and logic model will be iteratively developed and used to assess the implementation at TBI-COE sites.

XSL•FO
RenderX

Sampling and Sample Size

We will collaborate with site partners to recruit a purposive sample of key informants and IETP team members, including a physician, nurse, and therapist, to attend focus groups at each of the 5 sites. As conceptual saturation is the goal, we will recruit the minimum sample necessary to represent the types of professional disciplines to compare experiences. We will also conduct interviews with a purposive sample of DoD IETP stakeholders involved in the referral and coordination of IETP, based on key informant referrals and feedback from our stakeholder panel. As part of a comprehensive evaluation, we will also conduct telephone interviews with service members and veterans from each site who previously participated in IETP, and contact information will be obtained from the data collected for aim 2. Participants will be purposively selected among those in the top and bottom quartiles of the Mayo-Portland Adaptability Inventory (MPAI; patient outcome across all 5 sites) at program discharge [30]. The MPAI reflects the outcomes prioritized by the operational partner. In qualitative projects, sample and size rely on the population characteristics and the quality and richness of information obtained [14,15]. Recruitment efforts will oversample women and minority individuals to ensure that their perspectives are represented in the data. Qualitative recruitment and sampling for aim 1 are presented in Table 2.

Table 2. Aim 1 qualitative recruitment.

Data collection activity	Participants	Site sample size:total sample size
Key informant interviews	Clinical team from IETP[a]	1:5
Focus groups	Physician, nurse, therapist, etc	15:75
Interviews	DoD[b] IETP stakeholders	15:75
Telephone interviews	Service members who previously received IETP	12:60
Demographic questionnaire	Physician, nurse, therapist, etc	15:75
Follow-up interviews	Subsample of key informant and focus group participants	15:75
Site visit observation	IETP representatives, leadership, and clinicians	N/A[c]

[a]IETP: Intensive Evaluation and Treatment Program.

[b]DoD: Department of Defense.

[c]N/A: not applicable.

Measures and Data Collection Procedures

We will use site visit observations, key informant interviews, focus group, and follow-up interviews to complete aim 1. We will also refine the fidelity checklist as part of aim 1 data collection (Multimedia Appendix 2). Data collection tools will include veteran and focus group demographic questionnaires (Multimedia Appendix 3), interview and focus group scripts, and a site observation guide and comparison checklist.

Initial Interviews

Qualitative researchers will conduct key informant initial interviews remotely with the program or medical director at each site. These participants will be purposively identified and confirmed by the operational partner. Informants will provide an overarching introduction to each site and the site's implementation efforts and then provide key referrals to recruit other team members for focus group interviews (Multimedia Appendix 4). Key informant interviews will be audio recorded and transcribed verbatim. Researchers will take field notes to capture nuances potentially missed by audio recordings and will facilitate preliminary data analyses when transcription is completed. All data will be stored on a secure VHA server with restricted access. The key informant will also facilitate the analysis of local program outcome data to help recruit local participants in the IETP eligible for telephone interviews.

Site Observation

A team of 2 qualitative researchers will travel to each site for site visits. Two-day site visits will comprise (1) a facility tour, (2) presentations from and discussions with program representatives, and (3) meetings with leadership and identified local stakeholders. The qualitative team will take field notes and photos with permission and collect site-specific artifacts. These items will be saved on a secure VHA server with restricted access and uploaded into ATLAS.ti 22 Windows software for organization, coding, and analysis. These partnering activities will be critical for developing relationships with site staff and setting the stage for subsequent aim 3 activities. Site observation guides will be used to assess sites qualitatively, and the checklist will be used in tandem to assess fidelity across sites (Multimedia Appendix 5).

Focus Groups

Focus groups, coordinated with the clinical partners to reduce interference with patient care, will be conducted using web conferencing technology to collect data from clinicians about their site's IETP. Participants will receive an email before the focus group, which will include interview questions. Each focus group will be facilitated by 1 qualitative researcher with a team of evaluation staff to take notes, manage any technological issues, and observe the chat box for any questions or comments. The focus groups will be audio recorded with permission. Information collected during focus groups will address IETP logic, program content, operationalization, and other relevant

XSL•FO
RenderX

implementation factors (Multimedia Appendix 6) and will be stored on a secure VHA server with restricted access and uploaded to ATLAS.ti 22 Windows software for organization, coding, and analysis.

Follow-up Interviews

Follow-up interviews will be conducted by phone: (1) key informant follow-ups will be conducted to share data summaries, IETP checklists, and draft content and to assess validity and usefulness and (2) focus group member follow-up interviews will be conducted with a subsample of focus group participants to account for differences in knowledge and perspective by role, providing broad perspectives and accounting for potential power differentials. Individual interviews will ensure that team members have an opportunity to address personal perspectives, discuss issues that may not arise in focus groups, explore emergent themes, and review data summaries and content (Multimedia Appendix 7). Follow-up interviews will be conducted via web conferencing and will be audio recorded. Recordings will be transcribed verbatim. Researchers will take field notes to capture nuances potentially missed by audio recordings and facilitate preliminary data analyses when transcription is completed. All data will be stored on a secure VHA server with restricted access.

Veteran and Service Member Interviews

Interviews with service members and veterans who participated in IETP will be conducted at each site to describe patient experiences with IETP (Multimedia Appendix 8). These interviews will be audio recorded and transcribed verbatim. Researchers will take field notes to capture nuances potentially missed by audio recordings and facilitate preliminary data analyses when transcription is completed. All data will be stored on a secure VHA server with restricted access.

DoD IETP Stakeholder Perspectives

DoD IETP stakeholders will share their perspectives on IETP as consumers to assess the value of VA IETP services from a DoD perspective and obtain their perspectives of important outcomes and their perceptions of the projected trajectory for the continued patient need for IETP services (Multimedia Appendix 9). As with the other qualitative data collection methods, the interviews will be completed using web conferencing and will be audio recorded. Recordings will be transcribed verbatim. Researchers will take field notes to capture nuances potentially missed by audio recordings and facilitate preliminary data analyses when transcription is completed. All data will be stored on a secure VHA server with restricted access.

IETP Data Collection Content

In our project start-up, we are developing a preliminary IETP characterization table based on guidelines and subject matter expertise (refer to the preliminary summary in Multimedia Appendix 1). In tandem, using clinical team expertise and literature on evidence-based implementation strategies that are relevant to the IETP clinical components reviewed in the IETP characterization table, the process of implementation to date will be represented as a CFIR-based implementation research logic model (IRLM) [31]. The IRLM will use data on inputs, activities, and outcomes to specify the relationships among determinants of implementation, implementation strategies, and the mechanistic links between strategies and outcomes relevant to the following: (1) inputs—program referral patterns, characteristics of IETP patients, staffing and skills required to deliver the program, facilities, resources needed to deliver the program, and other program inputs evident in the literature review; (2) activities—set of therapeutic activities that comprise the program, characterized as core or peripheral and as individual or group interventions, along with the programmatic meetings and staff training that are necessary to deliver the program; and (3) outcomes—immediate and long-term outcomes that define program success [32]. The IRLM, contextualized by CFIR constructs, will be triangulated and analyzed as part of aim 1 and iteratively revised to reflect the clinical relevance for each site. The team will also refer to the validated inventory of implementation strategies in the development process by Powell et al [33]. The IRLM template is provided in Multimedia Appendix 10 [31].

Elicitation of IETP Contents and Operationalization

We will interview respondents to identify the inputs, activities, and outcomes that define the IETP. We will refer to the IETP characterization table to elicit inputs on convergence and divergence between their experience and the guidelines. The preliminary IETP characterization table will be used as a plausibility check for these initial interviews to evaluate, for instance, whether the elicited program inputs, activities, and outcomes are concordant with the published literature and whether the suggested links between program activities and outcomes are plausible. The analysis will be conducted within the context of CFIR to ensure strategic alignment with the implementation recommendations. The elicitation of program inputs, activities, and outcomes will be expedited by comparing similar products developed in the ORION project. ORION project library elements that correspond to IETP inputs, activities, and outcomes will be shared with the interviewees as examples. This process will support the iterative development of the IETP Care Implementation Elements Inventory. Multimedia Appendix 11 provides an example from the ORION project.

Data Analysis

Qualitative data collection and analysis will occur concurrently. Insights from the data analysis will be used to iteratively guide data collection. The evaluation team will work together to develop an a priori code book based on the 2009 CFIR constructs, as each interview guide is also based on the 2009 CFIR constructs. Transcripts, artifacts, and observation notes will be uploaded to ATLAS.ti 22 Windows software to organize and code data. Analysis methods will be used to identify domains related to data for specific data types, such as key informant interviews and focus groups [34]. Participant comments will be organized to develop codes and merged to develop categories. Categories will be compared, and relationships will be identified. Data samples will be extracted and coded by 2 project team members and evaluated for interrater reliability and credibility. The data sets for each site will be compared to determine the commonalities and

XSL•FO
RenderX

differences between sites. The evaluation team will conduct a matrix analysis to analyze across-site domains and taxonomies [35]. Descriptive and comparative matrices will identify the patterns of regularities and inconsistencies and identify the relevant and representative components by site to support strategy development. Once cases and comparative matrices are developed, follow-up interviews will be reviewed by the stakeholder panel to verify the findings and provide additional input and clarification.

Aim 2

Aim 2 will use the existing data to identify IETP participants; types of care received; and long-term outcomes, including postdischarge needs and trajectories, of IETP. The models will be reviewed with clinical partners throughout, with the final analytic output delivered at the end of year 2.

Measures and Data Collection Procedures

Data from each IETP participant will be obtained from site leads beginning with Tampa (2015 to present; n=approximately 350). We will obtain identifiers that allow linkage to VA and DoD health system data and create a study crosswalk database behind the VA firewall that includes the encrypted identifier, a study ID, and contact information for interview and survey administration. We will obtain intake and discharge measures from each IETP site. We will assess IETP fidelity based on the IETP characterization table (Multimedia Appendix 1) using a checklist (Multimedia Appendix 2) and chart abstraction focusing on the admission note, admission IETP care plan, discharge TBI care plan, and discharge summary, which are highly accurate in describing the reasons for seeking treatment, baseline status, the type of treatment recommended, the type of treatment received, and outcomes on discharge (Multimedia Appendix 12).

We will also link these IETP data to VA and DoD health system data, as we have done previously [36], to obtain information on physical and mental health, medications, and military demographic data before and after IETP. As approximately 90% (225/250) of participants in the IETP are active duty at the time of treatment with the goal of returning to full duty and operational partner priority outcomes include return to duty or employment, the use of VHA data (eg, Patient Health Questionnaire-9 [PHQ-9] and PTSD checklist-5) is not a feasible approach to long-term outcomes. Therefore, we will conduct a survey using a VA-approved web-based survey software for participants of IETP (2015-2022; approximately 500) using a Modified Dillman Method, which we used in prior VA studies (Multimedia Appendix 13) [37-40]. We will begin a survey of earlier IETP graduates in the first year of the study and send surveys to new graduates 6-9 months post study completion. The final outcome measures included in the survey will be developed in collaboration with stakeholders. The current list of stakeholder-identified measures that are evaluated at intake and discharge include the PHQ-9, PTSD checklist-5, MPAI, and the Neurobehavioral Symptom Inventory.

We will also use VA and DoD health system data to describe health system outcomes such as use, new diagnoses, and adverse outcomes, which will, together with data baseline, discharge, fidelity, and discharge outcomes, be used to develop trajectories of recovery.

Characterize IETP Participants

We will begin characterization with the Tampa site (n=approximately 350) and Richmond site (n=approximately 150), followed by other sites. We will use VA and DoD health system data to characterize preadmission military and sociodemographic characteristics, TBI-related diagnoses (eg, PTSD, pain, and sleep), and medication use (eg, opioids, antidepressants, and sedative hypnotics). We will add data from TBI history and symptom inventories administered at IETP admission to develop mild TBI phenotypes [36,41,42]. This allows the characterization of participants in the IETP and the identification of groups that are likely to have similar courses of care.

Data Analysis

After calculating descriptive statistics (proportions and quantiles for discrete variables and means and SDs for continuous variables) of VHA and DoD intake measures before IETP admission, we will fit a latent variable mixture model, a multivariate statistical technique used to classify individuals into interpretable categories based on a set of measurements (described in the *Measures and Data Collection Procedures* section) [36,42-49]. Similar to cluster analyses, the latent variable mixture model is an exploratory technique to identify underlying constructs associated with multiple variables, in our case, the underlying comorbidity phenotypes. On the basis of prior work, we expect 2 to 3 groups each with n=approximately 100-200 participants [36]. Health system data identifying the treatment provided are not likely to have missing data owing to the professional responsibility to document. Each visit requires a primary diagnosis for care, which will lead to data available at each visit; therefore, we expect little to no missing data.

Identify Treatment Received During IETP

Consistent with prior studies [50-52], we will create an abstraction tool in collaboration with IETP clinicians and aim 1 data. Using the crosswalk database, we will conduct chart abstraction for IETP focusing on the initial assessment, TBI care plan, processes and amount of care received, discharge assessment, and TBI care plan. After finalizing the procedures and appropriate training, team members will independently review 10 charts and then meet to identify inconsistencies, errors, or disagreements and resolve any by consensus. This will continue until there is 90% agreement on all items abstracted, to ensure abstraction fidelity. The areas of uncertainty will be discussed with IETP clinicians. These data will be merged with IETP data, VA and DoD analytic file data, and survey data for the outcome analyses.

We will identify what happens during the IETP stay using descriptive statistics for the overall cohort, stratified by phenotypes from the measures listed in the *Measures and Data Collection Procedures* section. We expect that different types of care will be provided to individuals with different prior comorbidities and clinical presentations. We will apply Pearson chi-square test to assess the association between

XSL•FO
RenderX

recommendations for admission TBI care plan and TBI phenotype.

Identify Components of IETP Associated With Sustainment and Improvement Trajectories

Outcomes currently identified by operational and clinical stakeholders that are collected at all sites (Tables 3 and 4) will be included in the survey to develop longitudinal outcome trajectories. On the basis of stakeholder feedback, we will also measure and describe community reintegration, employment, retention in the military where relevant, compliance to discharge from the TBI care plan, reasons for difficulty in care plan compliance, and unmet rehabilitation needs. Per operational partners' request, we will also use VHA and DoD data to identify use relevant to discharge (eg, TBI care plan within primary, mental health, specialty care, or emergency care).

We will use Bayesian network analysis to generate a directed acyclic graph, which probabilistically describes the trajectory of symptoms, care, and outcomes for IETP participants. This network will enable us to explore the contribution of the baseline phenotype to the decision to use a particular treatment course and the contribution of those treatments to the participants' resulting outcome measures [53]. Using a hill-climbing algorithm scored with the Bayesian information criterion, we will establish directional connections between nodes, called edges, and evaluate the robustness of the edges using bootstrapped samples of the data. We will a priori exclude any implausible directed edges (eg, IETP care cannot lead to precare symptoms). The resulting directed network will have edges between the levels: (1) phenotypes, (2) treatment, and (3) outcomes, while disallowing connections that go from levels 2 to 1 or 3 to 2 or 1. We can allow edges between nodes within the treatment level of the network to better understand the interactions between treatments and to assess how the treatments individually and in combination probabilistically affect patient outcomes. By fitting this model, we can isolate the most probable trajectories between TBI phenotypes and treatments and then determine which treatments have a higher probability of positive long-term outcomes. To gain an understanding of the treatment courses on outcomes, we will present a graphical display of the nodes and edges, the conditional probabilities calculated between nodes that estimate the probability of long-term outcomes given the participants' IETP components and comorbidity phenotypes, and the robustness measures from bootstrapping.

Table 3. Proposed measures for developing trajectory outcomes.

Measure	Baseline	Discharge	Survey	Construct
Mayo-Portland Adaptability Inventory	✓	✓	✓	Ability, adjustment, and participation
Patient Health Questionnaire-9	✓	✓	✓	Depression
PTSD[a] checklist-5	✓	✓	✓	PTSD
Neurobehavioral Symptom Inventory	✓	✓	✓	Postconcussion symptoms

[a]PTSD: posttraumatic stress disorder.

Table 4. Proposed measures for developing trajectory outcomes.

Health system data	Prebaseline	During IETP[a]	After IETP	Construct
Diagnoses	✓	✓	✓	History and emergence of physical or psychiatric comorbidity
Health care use	✓	✓	✓	Type of care received
Medications and procedures	✓	✓	✓	Type of pharmacological or nonpharmacological care

[a]IETP: Intensive Evaluation and Treatment Program.

Power and Missing Data

The analyses in this aim take an exploratory approach to establishing phenotypes with latent variable mixture models and isolating common trajectories based on Bayesian networks. As such, we do not have a targeted hypothesis with which to power this analysis for minimum detectable effect sizes but rather a model selection approach using the Bayesian information criterion. With 500 participants, we expect that our sample size will be well above the number of nodes in the Bayesian network, which will allow for an accurate estimation of the conditional probabilities in the network [54,55].

We will assess the risk of bias owing to missing data by looking at patterns of missing measurements at each phase of the patients' trajectories, although we expect most missingness to be postdischarge. Reasons for missing measurements will be tabulated with a focus on differentiating missed measurements for logistical reasons from dropouts or intermittent missingness potentially related to the condition of the patient. If >10% (25/250) of the patients have missing outcome measurements for any of the follow-up measures or if the comparisons of baseline characteristics between patients with missing and nonmissing measurements indicate considerable imbalances, rather than only looking at complete cases, we will apply the structural expectation-maximization algorithm, an imputation method that directly processes data with missing values while fitting the Bayesian network [56]. This method incorporates baseline and follow-up factors beyond the variable being analyzed to account for the dependence of missing data on other factors. TBI history is a primary piece of data required for admission to the program. It is unlikely that any data will be

XSL•FO
RenderX

missing for TBI history. However, if >20% (>50/250) of the sample has missing data related to TBI history, the study should be stopped.

Aim 3

Overview

In aim 3, aim 1 and aim 2 data will be triangulated to develop a final report to support IETP full implementation at sites. The primary deliverable for aim 3 is a final report that will include the IETP characterization table, IETP Care Implementation Elements Inventory, IRLM, patient experience data summaries, implementation checklists, educational content, and templates. A concluding presentation will be delivered, and consultation on findings integration will be provided for each site. In year 3, we will conduct site visits and presentations with each program to present the developed content and consult with each site to individualize and prioritize how content can be tailored at each site to facilitate full IETP implementation, including the deimplementation of ineffective care.

Measures and Data Collection Procedures

For the purposes of this PEI, the final report will be delivered to operational partners as both (1) a tool that can be used at sites to strategize the implementation of effective IETP practices and deimplementation of low-value care and (2) a resource that will include education about research implementation to support knowledge translation.

The team will develop a product grid to propose and prioritize implementation content with the stakeholder panel. Prioritized products and content from the product grid will be developed and packaged into a comprehensive report. Although the team will leverage previous projects to expedite the PEI efforts, the products will be unique to this evaluation. The final report content will be developed iteratively, and components will be reviewed with participants throughout the PEI to ensure quality control and fidelity of the developed content. In addition, the team and stakeholder panel will attend a meeting in year 3 to review and validate the IETP content. The engagement of other key stakeholder groups will be determined based on data collected in aims 1 and 2. Potential groups include consultation specialists in sleep and pain, rehabilitation disciplines, and program administrators.

Characterizing the core components of IETP as a fully implemented program will inform subsequent staged implementation efforts across sites by establishing means for monitoring the fidelity, timing, and teaching of programs over time. Products will not be designed to clone IETP across sites but will rather support site-to-site harmonization and implementation, sustainment, or enhancement of key components. Although we have established a strategic plan for acquiring data to inform product development, to be stakeholder driven, we contend that to fully identify aim 3 activities before aim 1 and aim 2 data collection would be premature. Identifying implementation efforts, including best practices, facilitators, barriers, strengths, and challenges, will be a solid approach to developing tailored implementation content.

Results

Funding and start-up activities for the evaluation began in April 2021, and the evaluation officially began in October 2021. Data collection is underway at all 5 sites and is expected to continue through May of 2025. Key informant and staff focus groups have been completed at 4 of 5 sites; the fifth site was launched in April of 2023. DoD and patient interviews are underway at all 5 sites, with one site observation to be conducted. Data analyses are underway. The anticipated evaluation results will be disseminated by 2024 and thereafter.

Discussion

Principal Findings

The goal of this evaluation protocol is to facilitate the full implementation of IETP at all VA TBI-COE sites and to inform minimum standards while supporting the unique characteristics of each site. In alignment with the goals of the proposal, ineffective treatment components will be targeted for deimplementation. The findings of this mixed methods evaluation effort will allow the characterization, evaluation, and implementation of IETP across the VA polytrauma system to improve the standardization and fidelity of care for SOF service members and veterans with mild TBI and co-occurring conditions, while preserving the unique facets of the individual program sites.

Potential Limitations

The proposed PEI does not address implementation sustainment and cost. Implementation and cost evaluation elements are beyond the scope of this 3-year PEI; however, the proposed aims are foundational efforts that will facilitate a cost and sustainment evaluation after the proposed PEI. A “rigorous” design (eg, step wedge, randomized controlled trial) is not proposed. Our proposed mixed methods design is aligned with the preimplementation emphasis of operational requests and needs. There is a potential lack of clinician or administrator participation in aim 1. We partnered with coinvestigators at each study site to support recruitment. We will meet with them during “training time” or “clinical team meetings” to maximize their availability and convenience to participate. We will offer individual interviews (by phone or in person) to maximize participation for those unable to participate in the focus groups. We will conduct meetings in person or by phone to meet their preferences, particularly through individual interviews. All patients will be interviewed by phone. The time frame is compressed for study activities. For aim 1, we will conduct simultaneous site visits and rapid iterative analysis as data are collected and analyzed. Transcription turnaround time is minimized using an internal transcription service with an established protocol with the Tampa team. For aim 2, we will leverage existing data sets (i.e, IETP, TBI model systems, VA, and DoD data sets) and include site leads as experts in those data sets to facilitate timely analyses. A potential pitfall of aim 2 is the lack of participation in long-term outcome surveys; we will address this with an introductory letter from PM&R describing the importance of the study, as well as individualized follow-up strategies that have been effectively used by the team

XSL•FO
RenderX

in previous projects. For aim 3, final report content development will begin at the onset of the PEI, supported throughout aims 1 and 2, relying on protocols and templates used in other projects. We will use an iterative design process that will support the development and validation of the content with the PEI stakeholder panel. There is no comparison group for this treatment modality. The operational partner did not want to prioritize this comparison and felt this would be better suited in subsequent proposals.

Management Plan and Timeline

This team initiated a comprehensive approach with operational partners to ensure timely deliverables. Operational partners have described their expectations and anticipated deliverables; as such, they informed and approved the proposed evaluation and activities. The proposed aims represent distinct deliverables as a result from each aim, which are to be delivered within the established project timeline (Multimedia Appendix 14). In addition to deliverables, the PEI team will provide operations with quarterly reports to include current tasks; progress; recruitment, data collection, and analysis benchmarks; PEI barriers and solutions; product development; and lessons learned.

Communication and Collaboration

This team has established effective communication and collaboration across sites to allow visual and audio access and secure shared folder and drive access. We will use 4 primary means of project management and communication to complete the study within the projected timeline. First, we conduct weekly meetings, attended via web-based platform by the team from the primary site, including MPIs, coinvestigators, and project managers, to address day-to-day activities. The MPIs also conduct weekly meetings with their operational partners. Second, at the onset of the study, the PEI team, site leads, and operational partners will attend a virtual kick-off meeting. At this kick-off, we will attend to start-up issues and collaborate with operational partners to confirm and refine needs and anticipated deliverables. As a result of this kick-off meeting, the team will initiate a Memorandum of Understanding outlining specific deliverables. The Memorandum of Understanding is a standard agreement between operational partners and research teams to establish expectations and performance outcomes relevant to project aims. Third, the team, including the stakeholder panel, will attend quarterly meetings with relevant agenda topics to address evaluation activities, benchmarks, project issues, and subsequent implementation efforts. We propose quarterly meetings with PEI team members and operations partners to facilitate ongoing data reports, operational updates, immediate reporting and resolution of any PEI barriers and concerns, and presentation of deliverables. This ongoing communication will facilitate any changes or operations-prompted amendments to the PEI, as warranted by operational partners. In this case, MPIs will consult with operations and reconceptualize project activities and deliverables as needed. As needed, updates will be made on the weekly meeting calls and email correspondence. Updates will be summarized in quarterly reports to the operational partners.

Conclusions

This PEI will examine the implementation of the IETP across 5 sites and characterize program participants, core components, and unique site adaptions. Components that are associated with improved participant outcome trajectories will be identified. This information will be the foundation for the future implementation of effective IETP components and deimplementation of ineffective components. Future work may include cost evaluations and rigorous research such as randomized controlled trials.

Acknowledgments

This work was funded by the Veterans Health Administration Health Services Research and Development Partnered Evaluation Center (PEC 21-129) through the Quality Enhancement Research Initiative. This protocol is the result of work supported with resources and the use of facilities and personnel at the James A. Haley Veterans' Hospital and Clinics. Abstract

Background: Knowledge about the causal factors leading to falls is still limited, and fall prevention interventions urgently need to be more effective to limit the otherwise increasing burden caused by falls in older people. To identify individual fall risk, it is important to understand the complex interplay of fall-related factors. Although fall events are common, they are seldom observed, and fall reports are often biased. Due to the rapid development of wearable inertial sensors, an objective approach to capture fall events and the corresponding circumstances is provided.

Objective: The aim of this work is to operationalize a prototypical dynamic fall risk model regarding 4 ecologically valid real-world scenarios (opening a door, slipping, tripping, and usage of public transportation). We hypothesize that individual fall risk is associated with an interplay of intrinsic risk factors, activity, and environmental factors that can be estimated by using data measured within a laboratory simulation setting.

Methods: We will recruit 30 community-dwelling people aged 60 years or older. To identify several fall-related intrinsic fall risk factors, appropriate clinical assessments will be selected. The experimental setup is adaptable so that the level of fall risk for each activity and each environmental factor is adjustable. By different levels of difficulty, the effect on the risk of falling will be investigated. An 8-camera motion tracking system will be used to record absolute body motions and limits of stability. All laboratory experiments will also be recorded by inertial sensors (L5, dominant leg) and video camera. Logistic regression analyses will be used to model the association between risk factors and falls. Continuous fall risk will be modeled by generalized linear regression models using margin of stability as outcome parameter.

Results: The results of this project will prove the concept and establish methods to further use the dynamic fall risk model. Recruitment and measurement initially began in October 2020 but were halted because of the COVID-19 pandemic. Recruitment and measurements recommenced in October 2022, and by February 2023, a total of 25 of the planned 30 subjects have been measured.

Conclusions: In the field of fall prevention, a more precise fall risk model will have a significant impact on research leading to more effective prevention approaches. Given the described burden related to falls and the high prevalence, considerable improvements in fall prevention will have a significant impact on individual quality of life and also on society in general by reducing institutionalization and health care costs. The setup will enable the analysis of fall events and their circumstances

XSL•FO
RenderX

ecologically valid in a laboratory setting and thereby will provide important information to estimate the individual instantaneous fall risk.

Introduction

Falls are the most prominent cause of death due to injuries in older persons [1]. Falls are also a common event leading to serious physical consequences such as fractures as well as reduced quality of life, loss of independence, and institutionalization in nursing homes. In total, 1 in 3 community-dwelling people aged 65 years or older fall at least once a year, and half of them fall multiple times [2,3]. Falls are one of the leading health conditions associated with disability in populations aged 60 years and older [4]. Therefore, research on falls and fall-related aspects has been intensified in the past years.

The current Cochrane Review on fall prevention in community-dwelling older people lists several effective exercise programs [5]. However, there is limited impact at the population level with the risk of falls being reduced between 13% for balance and functional exercises and 22% for multiple types of exercises including resistance training. Tai Chi reduced the fall risk by 20%. Even less effective are interventions in residential aged care [6], where the effect of exercise on risk of falling makes little or even no difference. These numbers clearly show the need for further improvements in fall prevention programs. The limited effectiveness might be due to lacking task-specific exercises required to prevent falls. Perturbation training is a task-specific intervention with the aim to improve a person's reactive balance control under safe laboratory conditions [7]. Recent perturbation studies showed a significant reduction of falls among healthy older adults as well as patients with Parkinson disease and stroke [8]. Furthermore, clinically relevant reductions of fall incidence were shown in frail older adults. It appears that treadmill-based approaches, which enable multiple types and directions of perturbations, might be the most practical method and might be of the most benefit. Although recent studies showed the feasibility of perturbation-based training, conclusions related to the optimal perturbation number and type are difficult to make. Another promising task-specific approach is gait adaptability training [9]. During gait adaptability training, participants respond to environmental challenges by making quick and appropriate voluntary adjustments of gait patterns. A systematic review and meta-analysis by Nørgaard et al [9] showed a reduction of 42% in fall rate, and the proportion of fallers could be reduced by 43% in older adults. These results are in accordance with the results of perturbation-based interventions. It is likely that even more efficient strategies could be informed by a more comprehensive understanding of the causal pathways of falling and fall risk.

Analyses of fall risk factors suggest that we do not fully understand their complex interplay and factors triggering fall events. Meta-analyses identified about 30 fall risk factors for falls in community-dwelling older adults [10]. These include fall history, balance, and gait problems. The published fall risk models are unsatisfying considering the externally validated predictive accuracy. A systematic evaluation of 4 fall prediction tools in residential care showed that each model was unsuitable due to poor precision [11]. Sensitivity and specificity ranged from 0.50 to 0.80 and 0.32 to 0.80, respectively. The web-based FRAT-up (Fall Risk Assessment Tool) fall prediction tool, developed for community-dwelling older people, has an area under the curve of 0.65 and showed heterogeneity in results from different cohorts [12]. The performance of these fall risk models in individuals has been moderate at best and is therefore not sufficient to guide clinical practice and health policy.

With the rapid development of eHealth devices including body-worn sensor technology, small wearable and unobtrusive devices are now available; this can provide objective measures of physical activity, kinematics of human movement [13], and falls during everyday life [14]. Additionally, it is possible to examine environmental factors such as stairs, weather conditions, or indoor or outdoor environments using combinations of monitoring systems. Adding these measurements such as gait intensity and gait complexity to clinical risk factors improves the area under the curve for fall prediction from 0.68 to 0.82 [15]. However, the most important risk factor still remains the history of a prior fall. Other recent studies using information and computer technology to predict falls showed similar results. Internal and external validity is not yet firmly established as some models have been developed and validated on the same samples; thus, replication is required [16,17]. Furthermore, most of the above information and computer technology studies have limitations. They have used fall history, clinical fall risk assessment, or both to define fall risk, instead of the gold standard measure, which remains the prospective fall ascertainment [18].

Even if it is possible to replicate the results, there is still a large number of falls that are not predicted. Furthermore, a rarely discussed aspect in fall risk estimation is the time frame of prediction in which the event of interest occurs. A simple distinction between fallers and nonfallers is insufficient as most people will fall if the period of observation is long enough. The time window of prediction in most studies is 1 year based on the follow-up duration of the prospective fall recording. However, the question remains whether this follow-up period is sufficient or which period is necessary to cover a relevant fall risk. This question is also relevant in terms of feasibility for a

clinical trial. Furthermore, the necessary duration may also depend on whether a fall is more likely due to a chronic disease or if a fall is merely due to random unpredictable circumstances. For effective and acceptable fall prevention measures on an individual level, much shorter prediction windows may be needed. In this context, an intervention that is able to directly test fall risk by exposing participant to hazardous ecologically valid situations would be conceivable.

Rubenstein and Josephson [19] drafted a conceptual model, which includes intrinsic risk factors, extrinsic risk factors, and precipitating causes. Klenk et al [20] further developed this concept by structuring the components and adding the dynamic nature of fall risk and thereby suggested a modified model, which includes intrinsic risk factors and the exposure. The model considers that fall risk factors may change over time due to individual and temporary exposure to hazardous situations, environmental factors, and unexpected events. Furthermore, different activities pose different levels of hazard, for example, it is riskier to run than to walk.

The complex interplay of different factors results in an individual instantaneous fall risk. If a person with impaired balance walks over slippery ground, the risk of falling is increased compared to a person with balance impairment who walks fast on dry ground.

The impact of one or more activities undertaken at the same time varies depending on cognitive capacity and environmental conditions. For instance, walking on an uneven surface while talking may result in a fall, whereas talking and walking on a smooth surface may not. Similarly, an unexpected event, such as a perturbation, or a visual startle may disrupt an otherwise simple maneuver. We posit that all mentioned components of risk do not simply sum linearly to a total, but the way they could be combined is likely to be complex. Components change over time, and the impact of the components could be additive, multiplicative, or weighted. A fall event occurs when the interplay of intrinsic risk factors and exposures reaches a threshold.

To operationalize the different components of the dynamic fall risk model, real-world fall events with detailed information about the fall events are necessary. Although falls are common, it is challenging to capture real-world fall signals due to the limited recording capacities of sensor devices. However, the Fall Repository for the Design of Smart and Self-adaptive Environments Prolonging Independent Living (FARSEEING) consortium, funded by the 7th EU Framework Program for Research, started to collect an ample data set of real-world falls by a preplanned collaboration of many research groups. Within the European FARSEEING project, a database of more than 200 validated real-world falls of older people measured by body-worn sensor technology was compiled [21]. First results in the field of fall detection show the potential to bridge existing knowledge gaps [22,23]. The fall events, collected in the FARSEEING database, provide the possibility to obtain knowledge concerning ecologically valid real-world fall scenarios, activities that were performed immediately before the fall as well as environmental factors.

However, most sensor devices are not able to provide information about context and environmental conditions as well as intrinsic fall risk factors triggering a fall event. The information available so far is not sufficient. A promising approach to add missing information is the re-enactment of known fall events. Connell and Wolf [24] previously proposed the method to validate subjective fall reports. Participants were interviewed and asked to re-enact in detail (if they felt comfortable) all activities, body movements, body part placements, and interactions with the environment at the location of the incident to obtain more precise information. Re-enactment is suitable in order to improve simulation protocols and produce more realistic fall simulations [25]. However, to further improve simulation settings and gain more knowledge, controllable and repeatable conditions are needed, which also realistically correspond to everyday situations. For certain everyday situations, these criteria can be met within a laboratory setting. This approach allows intrinsic risk factors as well as instantaneous dynamic risks (eg, activities and environmental conditions) and their complex interplay to be investigated in a controlled condition in realistically re-enacted everyday situations and thereby to provide a more comprehensive understanding of the causal mechanisms of falling and fall risk.

Therefore, we developed a setup to provide an experimental environment to simulate and measure selected paradigms under different conditions and adjustable factors in order to find individual fall thresholds. In this paper, we describe an experimental laboratory setting based on 4 ecologically valid real-world scenarios and the planned pilot study that will provide the data to operationalize a first simplified dynamic fall risk model.

Methods

Study Design

This study has an experimental design to analyze the interplay between intrinsic fall risk factors and exposure to hazardous environmental conditions and activity. All participants will obtain extensive clinical and quantitative assessment as well as perform the study protocol to evaluate the effect of different conditions on the individual fall risk in accordance with the study protocol at the Robert-Bosch-Hospital, Stuttgart.

Eligibility Criteria

German-speaking, community-dwelling, healthy as well as prefrail people aged 60 years or older will be recruited. Exclusion criteria are current diagnosis of a serious neurological or sensory disease; uncorrected visual difficulties; dizziness; uncontrolled or serious cardiovascular, metabolic, or psychiatric disorders; cognitive restriction and manifest daily relevant dementia; contraindications for perturbations, including osteoporosis, joint replacement, joint stiffening, severe spinal disease, or recent fracture as well as people who are unable to walk at least 5 minutes freely.

Recruitment

Participants (N=30) will be recruited from an existing pool of subjects who have already participated in studies and have given their written consent to participate in further studies. To obtain

XSL•FO
RenderX

sufficiently meaningful results, see if the experimental setup needs adaption, and test the feasibility within this pilot study, sample size is sufficiently high and chosen pragmatically but not estimated [26]. Overall, 20 subjects will be used for the development of the prototypical fall risk model, and 10 subjects will be used for validation. Ideally, half of the subjects would be considered prefrail, but prefrail subjects may drop out during the experiment or will not participate at all. Participants will be contacted via telephone and informed about the study and the procedure if they are interested.

Clinical Assessments

To identify several fall-related intrinsic fall risk factors relevant to the model development and describe the cohort, appropriate clinical assessments were selected. The estimated total duration of clinical assessments and the trial protocol will be 120 minutes. Clinical assessments will be carried out for all participants before the experimental protocol. All assessments will be performed by trained assessors.

Clinical data like sex, age, body weight (BW), physical activity as well as medical history will be assessed. Furthermore, general state of health and comorbidity will be assessed using the Functional Comorbidity Index [27].

Occurrence of falls during the last 12 months will be inquired. For the assessment of fall-related self-efficacy, the Short Form of the Falls Efficacy Scale-International will be used. This scale has been shown to be highly related to previous and subsequent falling [28].

Physical performance will be assessed by the Short Physical Performance Battery [29] and the Timed Up-and-Go Test [30]. People who need >12 seconds for the Timed Up-and-Go test will be classified as individuals at a higher risk of falling [31]. Regarding the cutoff value of 12 seconds, we followed Jansen et al [31], who lowered the threshold of 13.5 seconds originally defined by Barry et al [32]. Additional gait analysis will be conducted for habitual and fast walking speed. Furthermore, gait analysis will be performed under dual-task conditions (fast gait speed and counting backward minus 7 beginning with 100). Cognitive condition will be examined using the Trail-Making-Test [33]. Assessment measurements are listed in Textbox 1.

Textbox 1. Listing of demographic and medical data as well as assessments.

Sociodemography

- Age and gender

Medical information

- Height, weight, BMI, comorbidities, occurrence of fatigue, and weight loss

Physical activity status

- Questionnaire: physical activity during the last 2 weeks
- Fall history and fall-related injuries in the past 12 months

Fear of falling

- Short Falls Efficacy Scale International [28]

Motor function

- Short Physical Performance Battery [29]
- Timed Up-and-Go [30]
- Gait performance (usual or fast pace, dual-task condition)

Cognitive status

- Trail-Making-Test [33]

Experimental Setup

Overview

All participants will perform the same protocol. The fall simulation experiments will collect the data needed to develop the simplified mathematical dynamic fall risk model. Ideally, the activities performed should not give the impression of a simulation for the subjects. They should behave as they would naturally, and our objective is to provoke a reaction that ideally cannot be consciously influenced by the individual. Due to safety reasons and to avoid injuries, participants will wear a safety harness that prevents any contact of the body with the ground except the feet. The safety system is adjusted accordingly. Also, the treadmill can be stopped immediately at any time by the trained study assistant who is always standing next to the treadmill at an emergency stop button during the measurements. The test protocol will comprise a series of the selected activities without and in combination with mediating environmental factors. The experimental setup has to be adaptable meaning that it is possible to adjust the level of fall risk for each activity and each environmental factor. The level of difficulty will be stepwise increased for each participant. The registration of more than 30% of the BW on a load cell attached

XSL•FO
RenderX

to the safety harness will be used to define a fall event [34]. Several prototypical examples of everyday fall scenarios have been recorded in the FARSEEING database [21]. Based on this data, we will consider four prototypical scenarios, which are common and relevant from a public health perspective: (1) falling during walking backward while opening the door, (2) falling due to slippery surface, (3) falling due to a trip over an obstacle, and (4) falling in a bus while the bus is starting.

An experimental setup for each selected scenario will be established in the laboratory. The 4 selected fall scenarios and their implementation in the laboratory are shown in Figure 1.

Figure 1. Illustration of the 4 selected everyday fall-related scenarios and their implementation in the laboratory. (A) Opening a door, (B) slippery surface, (C) tripping over an obstacle, and (D) usage of public transportation.

Opening a Door

In front of the participant is a custom-built wooden door–like frame. Participants will be instructed to open the door. Following this baseline measurement, the participants will be repeatedly asked to open the door with additional activities and environmental factors: opening the door as fast as possible, carrying a laundry basket, balancing a ball on a scoop, and opening a rough-running door. The laundry basket will be represented by a wooden frame with handles to cause less occlusion (Figure 2). To simulate a rough running door, the door will be equipped with a neodymium magnet that increases the resistance when opening.

XSL•FO
RenderX

Figure 2. Equipment for additional tasks: carrying a wooden frame that represents a laundry basket, carrying a backpack, balancing a ball on a scoop, and playing with a memory buzzer.

Slippery Surface

Within this scenario, participants will wear shoe covers while walking over an aluminum di-bond plate, so that there will be reduced ground friction. To make it harder to maintain balance, the following factors will be stepwise added and combined: walking as fast as possible, balancing a ball on a scoop, usage of a memory buzzer to increase cognitive load (Figure 2), walking up and down the inclined (5%) treadmill (h/p/cosmos venus; length 200 cm, width 75 cm, h/p/cosmos sports medical GmbH).

Tripping Over an Obstacle

Two retaining plates will be attached to the participants' heels with a custom-built fixation. At first, the participants will walk on the treadmill with self-selected gait speed in order to get used to the treadmill. After habituation, a neodymium magnet will be stuck to the retaining plate at the participants' heels (magnetic adhesive force=41 kg). The magnet will be connected to inelastic cords and will ensure that the blockage of the leg can be broken by detaching the magnet when swinging the affected leg forward. The 2 inelastic cords will be attached behind the treadmill, which will be shortened or lengthened with low resistance by a coil spring while the participant is walking. The continuous length variation of the cords can be interrupted at the push of a button. When pushing the button at the end of the stance phase, the subsequent swing phase is perturbed. In random time intervals, the participants' feet will be blocked for a very short moment until the button is released or the magnet is detached from the retaining plate in order to perturb the swing phase but enable continuous walking afterward without stopping or limping. The series of perturbations will be determined in advance and will be unknown to the participants. Additional factors will be carrying a laundry basket, playing with the memory buzzer, and increasing the self-selected gait speed by 33%.

Usage of Public Transportation

To simulate the starting of a bus, participants will stand on the resting treadmill, and suddenly the treadmill belt will be accelerated. By means of the coscom interface protocol coscom v4, acceleration values and duration as well as target speed can be accessed. A custom application is written in Python for this purpose. Each participant will start with several forward and medio-lateral right perturbations with lower intensity to become familiar with the perturbations and choose an individual standing position that is not allowed to be changed during the experiments. The selected position shall correspond to the position that the participants would also choose on a bus. Concerning forward perturbations, the treadmill will be accelerated for 1 second and thereby will reach a maximum acceleration of 1.61 m/s^2. Participants will stand against the running direction of the treadmill belt. Concerning sideward perturbations, the treadmill will accelerate for 0.75 seconds and will reach a maximum acceleration of 1.51 m/s^2. To realize sideward perturbations, the participants will stand crosswise to the running direction of the treadmill belt. In Stuttgart, Germany, Lindemann et al [35] measured the incident-type acceleration from standing extreme values of acceleration of 3.37 m/s^2 in buses. Therefore, the maximal possible acceleration values within this study will be lower compared to the real-life ones, but due to safety conditions and technical limitations, no higher acceleration will be realizable. Acceleration from resting state and stopping to standing of the treadmill belt depends on length of the treadmill. The entire acceleration and deceleration process has to result in a movement of the treadmill belt less than 2 m. By doing so, the subjects will not fall off the treadmill in case

XSL•FO
RenderX

they would not do any recovery steps. After baseline measurement, which represents the participants' reaction to the perturbation without an additional factor, one or more additional factors will be combined. The additional factors for this fall scenario will be hearing bus-related noise, wearing a backpack, and playing with the memory buzzer. The backpack will be loaded with 10% of the subject's BW and will be carried symmetrically. Sahli et al [36] demonstrated that carrying a backpack loaded with 10% BW seems to alter balance of adolescents with mild idiopathic scoliosis.

Measurement Instruments

An 8-camera VICON T10 system (Vicon Motion Systems Ltd UK) will be used to record absolute body motions and limits of stability using the Plug-in-Gait full-body marker model. The VICON motion tracking system is able to measure a person's movement and duration very precisely.

To record further parameters, we will use 2 wearable sensors (Blue Trident inertial measurement unit, Vicon Motion Systems Ltd UK) with a combined triaxial accelerometer (sampling rate 1125 Hz; range ±16 g) and triaxial gyroscope (frequency 1125 Hz; range ±2000°/s). The sensors will be fixed with a custom-built elastic belt. Two synchronized Blue Trident inertial measurement units (Vicon Motion Systems Ltd UK) will be connected to the system. One will be attached to the lower back at L5 position, and the other one will be attached to the dominant leg at ankle height. To validate the results from the body-worn sensors, all laboratory experiments in this project will also be recorded by a video camera (Basler pilot piA640-210gc).

Participants' Safety and Adverse Events

All study participants will receive instructions for safe performance (shoes and safety harness) and will be asked to perform all paradigms as long as they feel comfortable. During the laboratory experiments, the participants will be protected from falling by a safety harness. Serious adverse events related or potentially related to the study participation will be reported to the responsible ethic review board.

Ethics Approval

The study will be conducted according to Good Clinical Practice and in accordance with the principles of the Declaration of Helsinki 1964 and all subsequent revisions. All procedures are approved by the local ethics committee (University of Tübingen, 245/2018BO2). All participants will have to give their written informed consent and will be insured. All project staff is bound by confidentiality. The results of the data collection in written form are subsequently digitized for evaluation. All data are pseudonymized. If a subject withdraws his or her consent, the corresponding data will be deleted immediately.

Outcome Measure and Data Analysis

Primary outcome will be the number of falls experienced by the participants during the experiment. Furthermore, the concept of margin of stability (MoS) will be used as a continuous measure to quantify the risk of falling [37]. MoS indicates the distance between the base of support of a person and the extrapolated center of mass in static and dynamic conditions.

As previously described, sociodemographic and medical information, physical activity status, fear of falling as well as motor function will be assessed and subsequently included as factors in the dynamic fall risk model.

The estimation of a person's individual fall risk will be based on the collected data. In the first step, logistic regression analyses will be used to model the association among activity characteristics, environmental fall risk factors, and falls. The optimal model for each scenario will be selected by receiver operating characteristic analyses. In the second step, continuous fall risk will be modeled by generalized linear regression models using MoS as outcome parameter. Nonlinear associations and interactions will be tested and modeled, if necessary.

Participants who will drop out or incomplete data will be included as long as the data set for at least 1 scenario is complete. It is planned to use the data sets of 20 subjects for model development, the other 10 data sets will be used for validation.

Results

This study was initially designed to begin recruitment in July 2020 after ethics approval has been received. First, measurements took place in October 2020, but not all subjects could be measured as planned because of the COVID-19 pandemic. Due to access restrictions in hospitals and difficulties in recruitment as a result of a lack of willingness in the target group to participate in the study, further measurements were not conducted until October 2022. In the meantime, the already recorded data were processed and prepared for subsequent analyses. Up to February 2023, a total of 25 of the planned 30 subjects have been measured. The submission of the manuscript including complete results is expected by August 2023.

Discussion

Principal Findings

Older people fall frequently with serious consequences, including injury and hospitalization. However, the knowledge about the causal factors leading to falls is still limited, and fall prevention interventions need to be more effective to limit the otherwise increasing burden caused by falls in older people. Therefore, the aim of this project is to operationalize a dynamic fall risk model by focusing on the time period close to the fall event where all domains of the dynamic fall risk model cumulate. This will help to further understand the complex interplay triggering a fall event.

To the best of our knowledge, this planned study is the first approach to assess the complex interplay of intrinsic risk factors and environment and activity exposure under controlled but realistic experimental conditions. We will consider 4 prototypical scenarios that are common and relevant from a public health perspective. The model-based assessment of fall risk under (simulated) real-life conditions in a safe environment will enable the systematic analysis of the complex relationship between fall risk factors. Based on the planned analysis of the MoS, even small perturbations that will not immediately lead to a fall show an effect on a person's dynamic stability. Such

XSL•FO
RenderX

an in-laboratory fall simulation environment might also serve as an outcome parameter for intervention studies. A rarely discussed aspect in fall risk estimation is the required time window of prediction in which the fall event occurs. A simple distinction between fallers and nonfallers is not sufficient as most people will fall if the period of observation is long enough. The time frame of prediction in most studies is 1 year. However, the question remains whether this follow-up period is sufficient or which period is necessary to cover a relevant fall risk. For effective and acceptable fall prevention measures on an individual level, much shorter prediction windows may be needed. This would reduce costs and speed up the development of new fall prevention measures. In this context, an intervention that is able to directly test fall risk by exposing participant to hazardous ecologically valid situations would be conceivable.

Limitations

Nevertheless, this study has some limitations. First, the sample size will be relatively small. However, the subjects will be tested extensively with a standardized protocol. This setting will allow the extraction of relevant information and the development of the dynamic fall risk model. Although the laboratory setting will approach natural conditions, it will remain artificial insofar that subjects will partially walk on a treadmill in a sparse environment. Furthermore, the subjects will be aware of the objective of the study: reaching the fall threshold by creating a situation that becomes stepwise more challenging. In contrast, falls are a sudden and mostly unexpected event during everyday life, and normally, a person would not anticipate a falling situation. Another aspect is the acceleration of the treadmill belt. To simulate the starting of a bus, the treadmill will accelerate with a maximum of 1.61 m/s^2 due to safety reasons and technical limitation. Lindemann et al [35] measured extreme values of acceleration of 3.37 m/s^2 in buses. Therefore, the maximal possible acceleration is lower compared to the real-life ones. However, we believe that this setup will allow analysis of the association of environmental as well as intrinsic factors and activity exposure and thereby will lead to a better understanding of the complex interplay triggering fall events in individuals.

Conclusions

The results of the described study have the potential to expand knowledge regarding the complex interplay between environmental conditions, activities, and intrinsic fall risk factors triggering a fall event. The operationalization of the described prototypical dynamic fall risk model will enable the estimation of an individual fall risk and thereby improve several fields of fall prevention.

Abstract

Background: Tobacco smoking is highly prevalent among persons with serious mental illness (SMI) and is the largest contributor to premature mortality in this population. Evidence-based smoking cessation therapy with medications and behavioral counseling is effective for persons with SMI, but few receive this treatment. Mental health providers have extensive experience working with clients with SMI and frequent treatment contacts, making them well positioned to deliver smoking cessation treatment. However, few mental health providers feel adequately trained to deliver this treatment, and many providers believe that smokers with SMI are not interested in quitting or have concerns about the safety of smoking cessation pharmacotherapy, despite substantial evidence to the contrary.

Objective: We present the protocol for the pilot "IMPACT" (Implementing Action for Tobacco Smoking Cessation Treatment) study, which aims to pilot test a multicomponent implementation intervention to increase the delivery of evidence-based tobacco smoking cessation treatment in community mental health clinics.

Methods: We are using a prepost observational design to examine the effects of an implementation intervention designed to improve mental health providers' delivery of the following four evidence-based practices related to smoking cessation treatment: (1) assessment of smoking status, (2) assessment of willingness to quit, (3) behavioral counseling, and (4) pharmacotherapy prescribing. To overcome key barriers related to providers' knowledge and self-efficacy of smoking cessation treatment, the study will leverage implementation strategies including (1) real-time and web-based training for mental health providers about evidence-based smoking cessation treatment and motivational interviewing, including an avatar practice module; (2) a tobacco smoking treatment protocol; (3) expert consultation; (4) coaching; and (5) organizational strategy meetings. We will use surveys and in-depth interviews to assess the implementation intervention's effects on providers' knowledge and self-efficacy, the mechanisms of change targeted by the intervention, as well as providers' perceptions of the acceptability, appropriateness, and feasibility of both the evidence-based practices and implementation strategies. We will use data on care delivery to assess providers' implementation of evidence-based smoking cessation practices.

Results: The IMPACT study is being conducted at 5 clinic sites. More than 50 providers have been enrolled, exceeding our recruitment target. The study is ongoing.

XSL•FO
RenderX

Conclusions: In order for persons with SMI to realize the benefits of smoking cessation treatment, it is important for clinicians to implement evidence-based practices successfully. This pilot study will result in a set of training modules, implementation tools, and resources for clinicians working in community mental health clinics to address tobacco smoking with their clients. Introduction

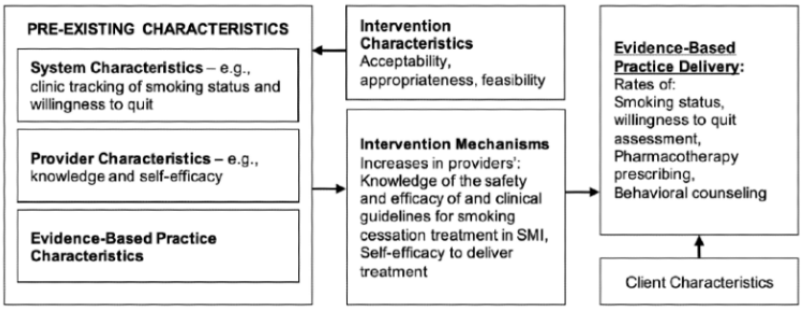
Tobacco smoking is the largest contributor to premature mortality among persons with serious mental illness (SMI) [1-4]. An estimated 53% of US adults with SMI smoke tobacco [5], compared to 14% of US adults overall [6]. In general, US smoking rates have declined dramatically over the past 50 years, but smoking has persisted at consistently high rates among those with SMI [7,8], even though the majority of persons with SMI who smoke would like to quit [9]. Pharmacotherapy combined with behavioral counseling is effective and safe for people with SMI [10-13] and increases abstinence rates by up to 7 times over behavioral counseling alone [11,14].

The provision of effective, evidence-based smoking cessation treatment could substantially reduce the premature mortality experienced by people with SMI; however, few in this group receive evidence-based treatment [15-20]. In a large Maryland behavioral health system, less than 5% of persons with schizophrenia who smoke are prescribed evidence-based smoking cessation pharmacotherapy [8]. Limited available research shows similarly low rates of smoking cessation pharmacotherapy as well as behavioral smoking cessation counseling [21] delivery to the individuals with SMI who smoke in other states [15,18].

As many people with SMI receive the majority of their health care from the specialty mental health sector [22-24] and tobacco smoking is not typically a target behavior in mental health settings [21,22], it is critical to prepare mental health providers to deliver evidence-based smoking cessation treatment. Achieving this goal will require addressing knowledge and self-efficacy barriers among clinicians, including skepticism that people with SMI want to quit smoking, misperceptions about cessation treatment efficacy and safety for this group, and low self-efficacy to deliver evidence-based smoking cessation treatment for clients with SMI [15,25-28]. Mental health providers may also perceive smoking cessation treatment as outside their scope of practice [15,25-28]. Clinic-level barriers to treatment, such as lack of systems for assessing smoking status and interest in quitting among clients with SMI, may also need to be addressed [25,26]. Despite these known barriers, few published studies have evaluated implementation strategies to increase mental health providers' delivery of evidence-based smoking cessation pharmacotherapy and counseling for people with SMI [29].



This protocol describes a pilot study of an implementation intervention of evidence-based smoking cessation treatment in community mental health clinics. We developed and are testing an implementation intervention designed to improve mental health providers' knowledge, self-efficacy, and delivery of evidence-based smoking cessation treatment. The shorthand name for the study is "IMPACT" (Implementing Action for Tobacco Smoking Cessation Treatment).

Methods

Conceptual Framework

Our study is grounded in Gurses et al's [30] model of interdisciplinary factors which promote clinicians' compliance with evidence-based guidelines. As shown in Figure 1, the model posits the importance of preexisting characteristics of the system (eg, tools and technologies and physical environment), providers (eg, knowledge and attitudes), and guideline characteristics (eg, relative advantage and complexity). These factors affect the implementation intervention characteristics (ie, how and when a practice is implemented) and mechanisms that, in turn, affect the delivery of evidence-based practices.

Figure 1. Gurses' interdisciplinary conceptual framework of clinician's compliance with evidence-based guidelines [30].

XSL•FO
RenderX

Pilot Study Design

This is a prepost study examining the effects of a 12-month implementation intervention on providers' knowledge and self-efficacy and the mechanisms through which the implementation intervention is designed to improve the delivery of evidence-based smoking cessation treatment. We will also evaluate the effects of the implementation intervention on the delivery of evidence-based practices for smoking cessation. In addition, we will analyze measures of providers' perceptions of the acceptability, feasibility, and appropriateness of the implementation strategies and the IMPACT evidence-based practices.

Setting and Sample

The study is conducted in 5 community mental health clinics, all of which serve persons with SMI. Provider participants are employees of the community mental health organizations, including leaders and mental health clinicians (prescribers, including psychiatrists, nurse practitioners, and primary care physicians, therapists, and other clinicians, including licensed counselors, psychologists, social workers, and nurses). Data will also be analyzed from the clients served by the clinics around their receipt of the evidence-based practices. The research was approved by the Johns Hopkins University School of Medicine Institutional Review Board (IRB) (#IRB00231836).

Evidence-Based Practices

The intervention includes the following four evidence-based practices for smoking cessation that are based on consensus guidelines, recommendations for persons with SMI, and recent clinical trials [10,11,13,31-33]:

1. Assessment of smoking status involves asking adult clinic clients if they currently smoke tobacco and, if they respond yes, further assessing the severity of tobacco dependence [34].
2. Assessment of willingness to quit uses stage-of-change questions [34]. In this project, we classify those endorsing setting a quit date within 12 weeks as ready for active cessation treatment [35]. We targeted willingness to quit within 12 weeks rather than the standard 30 days in order to include motivational enhancement strategies for those not ready to commit to a quit date within 1 month and to give adequate time to complete behavioral counseling and achieve smoking cessation for those interested in quitting [36].
3. The focus of the behavioral counseling will vary depending on clients' willingness to quit. For clients who are not interested in quitting within 12 weeks, behavioral counseling entails an immediate, brief session (<10 minutes) using motivational interviewing techniques to explore the pros and cons of smoking, elicit client concerns about their smoking, and identify potential benefits of quitting [37]. The provider will also discuss the resources available to help the client if they decide to work toward quitting, including the benefits of using smoking cessation medications. Those clients who express a willingness to quit will be referred for ongoing smoking cessation behavioral counseling [36] and smoking cessation pharmacotherapy. The counseling sessions, which can occur remotely or in person, are cognitively tailored for those with SMI and address standard topics (eg, identifying personal reasons to quit, addressing smoking triggers, coping with nicotine withdrawal, and preparing for the quit date) [38]. Clients who do not quit are encouraged to continue counseling if they are interested in making a future quit attempt. When a client quits, counseling then focuses on relapse prevention, including refusal skills, responding to permission-giving beliefs, and developing personalized relapse prevention plans.
4. The fourth evidence-based practice is pharmacotherapy prescribing, in which a prescribing physician or nurse practitioner meets with clients undergoing smoking cessation behavioral counseling to encourage use of 1 of the following 3 Food and Drug Administration (FDA)–approved treatments: varenicline with or without nicotine replacement therapy (NRT), bupropion SR with or without NRT, or NRT alone [34]. When NRT is used, combination NRT (transdermal patch + lozenge or gum) is recommended. Medication choice is made by the prescriber in a collaborative discussion with the client, taking into account factors such as differential effectiveness, potential side effects, and clinical profile (eg, seizure history). Therapists and prescribers regularly share care of clients and will communicate about smoking cessation plans. Medication may continue for 1 year or longer as relapse rates are high without ongoing pharmacotherapy, particularly for those with SMI [10]. Those not willing to quit within 12 weeks will be offered, and if interested, referred for, a 1-month trial of varenicline to increase their readiness to quit [39]. The goal is that all clients who smoke should be offered treatment with a first-line smoking cessation pharmacotherapy, preferentially varenicline or combination NRT [40].

Implementation Strategies

Overview

To improve mental health providers' knowledge, self-efficacy, and delivery of evidence-based practices, the study will employ the following five implementation strategies: (1) training on evidence-based smoking cessation treatment, including an innovative web-based avatar module for motivational interviewing practice; (2) a tobacco smoking treatment protocol; (3) expert consultation for prescribers and therapists; (4) coaching; and (5) organizational strategy meetings (OSMs). A more detailed description of each component is outlined below.

Training

Trainings are conducted by study staff. All provider participants in the IMPACT project complete 1 hour of prerecorded web-based training modules. Then, therapists and prescribers use a video conferencing platform to participate in real-time training on delivering smoking cessation behavioral counseling, prescribing smoking cessation pharmacotherapy, and using motivational interviewing counseling skills when having conversations with clients about their smoking. Trainings are housed in a web-based management system that enables tracking

XSL•FO
RenderX

of provider participation as well as continuing education credit. The training outline is shown in Textbox 1.

The real-time motivational interviewing training is supplemented with a web-based avatar practice module developed in partnership with Kognito [41,42]. The module includes a 15-minute didactic component during which clinicians are reminded about motivational interviewing techniques that can be used to guide clients with SMI toward health behavior changes and a 15-minute conversation simulation during which providers assume the role of a provider avatar and use motivational interviewing to discuss smoking cessation with a client avatar. A web-based avatar with simulated conversations enables the learner to use and receive immediate feedback about how different responses in a clinical encounter affect a conversation with a patient in which smoking cessation is discussed. The avatar is appealing and can be accessed at the convenience of the learner. Clinicians are encouraged to use the platform once per month throughout the intervention.

Textbox 1. Outline of provider training.

Prescribers (psychiatrists and nurse practitioners):

- Online training modules (1 hour)
  - Module 1: Why IMPACT (Implementing Action for Tobacco Smoking Cessation Treatment)?
  - Module 2: Evidence-based treatment for smoking cessation for persons with serious mental illness (SMI)
  - Module 3: Assessing smoking status willingness to quit
  - Module 4: Pharmacotherapy for smoking cessation
- Real-time trainings (in person or videoconferencing platform) (2 hours)
  - Training 1 (1 hour): Facilitating smoking cessation conversations
  - Training 2 (1 hour): Motivational interviewing approach to smoking cessation pharmacotherapy
- Online motivational interviewing avatar (recommended monthly 15-minute practice sessions)

Therapists (psychologists, social workers, counselors):

- Online training modules (1 hour)
  - Module 1: Why IMPACT?
  - Module 2: Evidence-based treatment for smoking cessation for persons with SMI
  - Module 3: Assessing smoking status willingness to quit
  - Module 4: Pharmacotherapy for smoking cessation
- Real-time trainings (in person or zoom) (4 hours)
  - Training 1 (2 hours): Facilitating smoking cessation conversations and an overview of behavioral counseling
  - Training 2 (2 hours): Motivational interviewing approach to smoking cessation behavioral counseling
- Online motivational interviewing avatar (recommended monthly 15-minute practice sessions)

Tobacco Smoking Treatment Protocol

The research team developed a tobacco smoking treatment protocol to assist clinicians in delivering evidence-based smoking cessation treatment. This protocol includes a resource guide that provides an overview of the IMPACT program and will help clinicians navigate their work on the project. Clients who report being current smokers (ie, have smoked a tobacco product in the past 7 days) are assessed for their willingness to quit. Based on client responses to the tobacco smoking status and willingness-to-quit assessment, instructions help clinicians facilitate brief smoking cessation conversations; all clients interested in quitting will be offered treatment. Clinicians are provided manuals for delivering smoking cessation behavioral counseling sessions and prescribing pharmacotherapy.

The smoking cessation behavioral counseling manual includes the outline for 13 session topics that can be delivered flexibly based on the client's current smoking status and the provider's judgment about what would be most helpful (see Table 1). A smoking cessation session may be "standalone" or part of a regularly scheduled therapy session and is designed to be 10-15 minutes in duration. Each session is expected to include an assessment of the client's past week's average cigarettes smoked per day, current smoking status and review of quit attempts since the previous visit, new session content, and collaborative identification of a smoking-related behavioral goal to focus on until the next therapy session.

XSL•FO

Table 1. Topics of behavioral counseling sessions.

Session	Topic[a]
1	Introduction: positives and negatives of smoking
2	Health effects of smoking and benefits of quitting
3	Smoking cessation pharmacotherapy to help you quit
4	Barriers to quitting and the 4 D's
5	Identifying triggers and high-risk situations
6	Smoking cessation medication adherence and coping with side effects
7	Planning for the quit day
8	Withdrawal symptoms and coping with withdrawal symptoms
9	Quit day follow-up
10	Developing a "Stay Quit" plan
11	Permission-giving beliefs and how to respond to them without smoking
12	Dealing with slips
13	Coping with symptoms of SMI[b] and staying strong

[a]Order and selection of topics to be made by therapists based on their clinical judgment and on the smoking status of the client.

[b]SMI: serious mental illness.

Expert Consultation

Expert consultation is available for prescribers and therapists to discuss issues and ask questions related to smoking cessation pharmacotherapy and behavioral counseling. Study team members who are experts in smoking cessation pharmacotherapy and behavioral counseling are available during the 12-month intervention to conduct as-needed phone or email consultation with clinicians.

Coaching

Coaching is available for therapists and prescribers to discuss specific client cases, develop smoking cessation behavioral counseling skills, and answer questions about prescribing smoking cessation pharmacotherapy. The coaching sessions, which will be offered monthly through a videoconferencing platform, will focus on skill development, overcoming barriers to providing evidence-based smoking cessation treatment, and additional training as requested. To increase participation, we aim to incorporate coaching sessions into regularly scheduled clinic meetings but will schedule individual coaching sessions as needed. The expectation is that providers attend at least one session per quarter.

Framework of OSMs

OSMs are designed to improve engagement in practice change. These meetings will occur monthly and consist of a 2-to-3–member clinic leadership team, including providers and staff leaders. OSMs will be a chance for the study team to work with the clinic to identify successful organizational-level processes, share implementation data, provide feedback, and problem-solve to overcome identified barriers to program delivery.

Data Collection

Data will be obtained from several sources, including provider surveys, provider interviews, web-based data collection regarding provider participation in training, and client data from the electronic medical record. Providers will be surveyed either by email with instructions and a link to the study assessments in the REDCap software or by paper-and-pencil, depending on-site preference; these assessments will be administered at baseline and at 12 months. Table 2 presents a summary of data collection and measures. Assessments will include measures of providers' knowledge about smoking cessation, self-efficacy about delivering smoking cessation treatment, motivation to deliver evidence-based practices, and beliefs about and confidence in using motivational interviewing. The surveys will also assess providers' views of the acceptability, appropriateness, and feasibility of the intervention and of the implementation strategies, implementation climate of the organization, and providers' social network ties within the organization. A convenience sample of providers and clinic leaders also will be interviewed at baseline and 12 months to elicit their perceptions of the intervention, implementation barriers and facilitators, and the implementation strategies used to overcome barriers.

XSL•FO
RenderX

Table 2. Study data collection.

Measure	Description	Participants	Timing
Provider interviews	• Semistructured interviews using a standard protocol that will elicit providers' perceptions of barriers to smoking cessation treatment and implementation strategies to overcome barriers.	Selected providers, clinic director	Baseline, 12 months
Demographic characteristics	• Age, gender, race or ethnicity, length of time at program, role in program, years at clinic, work hours, previous motivational interviewing training	All providers, clinic leaders	Baseline
Knowledge of evidence-based smoking cessation treatment	• A 16-item scale developed by our team to assess knowledge	All providers	Baseline, 12 months
Self-efficacy	• To deliver evidence-based smoking cessation treatment, adapted version of Compeau and Higgins' task-focused self-efficacy scale [43]	All providers	Baseline, 12 months
Implementation climate	• A measure of the degree to which an organization supports evidence-based practice implementation [44]	All providers, selected clinic leaders	Baseline
Acceptability, appropriateness, and feasibility of the intervention implementation strategies	• Measured with a brief 4-item practice instrument (AIM[a], IAM[b], FIM[c]) [45]	All providers, selected clinic leaders	Baseline, 12 months
Acceptability, appropriateness, and feasibility of the evidence-based practice	• Measured with a brief 4-item practice instrument (AIM, IAM, FIM) [45]	All providers, selected clinic leaders	Baseline, 12 months
Clinic social network	• A 4-question survey used to collect data about social networks	All providers, selected clinic leaders	Baseline, 6, 12 months
Motivation measures	• Assessment of degree of agreement or disagreement with statements that deal with aspects of the intervention to improve use of evidence-based smoking cessation treatment	All providers	Baseline, 12 months
Beliefs about the Motivational Interviewing Questionnaire	• A 7-question survey assessing the extent to which each person agrees with statements about motivational interviewing.	All providers	Baseline, 12 months
Importance and confidence of using motivational interviewing	• A 6-question survey assessing the importance and confidence each person has to deliver motivational interviewing.	All providers	Baseline, 3, 6, 12 months
Avatar motivational interviewing performance measurements	• From use of motivational interviewing techniques in simulated web-based conversations	All providers	Baseline, 12 months
Motivational Interviewing Treatment Integrity Tool	• Validated tool used to measure fidelity to motivational interviewing from Standardized Actor Interviews	All providers	Baseline, 12 months
Fidelity to behavioral smoking cessation counseling	• Standardized Actor Interviews will be conducted to assess fidelity to smoking cessation behavioral counseling sessions	All providers	Baseline, 12 months
Guideline-concordant smoking cessation treatment	• Smoking status assessment rates • Willingness-to-quit assessment rates • Prescription of smoking cessation medication rates • Behavioral counseling rates	All clinic clients	Baseline through 12 months

[a]AIM: Acceptability of Intervention Measure.

[b]IAM: Intervention Appropriateness Measure.

[c]FIM: Feasibility of Intervention Measure.

Data on providers' competency using motivational interviewing skills will be obtained from scheduled avatar-simulated conversations and from standardized actor phone interviews, which will occur at baseline and 12 months at a minimum. Standardized client scenarios will be provided to actors that reflect the kind of situations community mental health clinicians would likely encounter with clients who smoke; this method has demonstrated predictive validity in terms of providers' performance with actual clients [46]. The research team will access data from the electronic medical record (EMR) system or site-specific documentation procedures to assess providers' uptake of the evidence-based practices (eg, percentage of clinic visits where a smoking assessment is documented) and

XSL•FO
RenderX

client-level data (eg, demographics and primary mental health diagnosis).

Measures

The *primary outcomes* are changes in providers' knowledge about and self-efficacy to deliver evidence-based smoking cessation treatment from baseline to 12 months.

Secondary outcomes include change in the delivery of the recommended four evidence-based practices: (1) assessment of smoking status for all adult clinic clients (with quarterly follow-up assessments for smokers not yet willing to quit), (2) assessment of willingness to quit for smokers, (3) receipt of behavioral counseling for those willing to quit within 12 weeks, and (4) receipt of pharmacotherapy for those willing to quit within 12 weeks and referral for pharmacotherapy for those not willing to quit in this time frame. These outcomes will be measured by clinic documentation during client visits (in the EMR or site-specific documentation) and assessed at baseline and throughout the implementation period. When available, baseline documentation will include data from 3-6 months prior to project implementation. Additional secondary measures are changes in the acceptability, appropriateness, and feasibility of the intervention implementation strategies and of the evidence-based practices as assessed through the survey instrument.

To assess motivational interviewing skills, we will use the Motivational Interviewing Treatment Integrity coding system [47]. We will code random 20-minute segments of audio-recorded interactions with standardized client actors. The same interviews will be used to assess fidelity to the components of an IMPACT evidence-based smoking cessation counseling session.

Perceived barriers and facilitators on the part of clinic providers and leaders will be assessed based on qualitative interviews with individual providers before the start of the implementation intervention and at 12 months, and also with information obtained in monthly OSMs. We will also collect data about providers' and clients as shown in Table 2 including age, gender, race or ethnicity, and for providers, years worked at the clinic, and for clients, primary mental health diagnosis.

Data Analysis

We will conduct 2 main analyses. First, we will use survey data to assess the effects of the implementation intervention (baseline and 12 months) on providers' knowledge and self-efficacy, the mechanisms through which the implementation intervention is designed to improve the delivery of evidence-based smoking cessation treatment, using a generalized linear mixed effects modeling approach. The model will include a binary variable representing the prepost time points, fixed effects for the 5 study sites, and provider demographic characteristics. Second, we will evaluate the effects of the intervention (baseline and 12 months) on the implementation of evidence-based practices using a multilevel modeling approach. We will also assess the potential moderating effects of the implementation climate by adding appropriate interaction terms to the main models. We will use descriptive statistics to characterize staff perceptions of the acceptability, feasibility, and appropriateness of the implementation intervention strategies and the IMPACT evidence-based practices. Interview transcripts will be analyzed in MAXQDA (VERBI GmbH), using inductive coding to identify key themes. Survey analysis will be done using Stata 14 (StataCorp LLC) or SAS software (SAS Institute).

Ethical Considerations

The study was approved by the Johns Hopkins University School of Medicine IRB on January 14, 2021 (IRB number 00231836). Community mental health leaders and clinical staff will be appropriately recruited and informed of the study by the study team, with a waiver of documentation of informed consent. Patient data will be obtained per an approved waiver of consent. These waivers were approved by the IRB.

Each participant will be assigned a unique study ID number for data collection. Interview data will be audio recorded and transcribed by an approved vendor. Names will be removed from transcripts. Standardized actor interview will be stored on a secure network and participants identified by study number only. Study data will not be presented in such a way that identity can be inferred. Mental health leader and staff study participants will be paid US $50 for completing each interview and US $25 for each standardized actor interview as applicable. They will be paid up to a maximum total of US $60 for completing surveys at 4 time points.

Results

The study is underway at 5 clinic sites. More than 50 providers have been enrolled, exceeding our recruitment target. The study is ongoing. We anticipate that results will be reported in 2023 or 2024.

Discussion

Overview

Tobacco smoking is the leading cause of preventable mortality among persons with SMI and contributes to the reduced lifespan up to 25 years for persons in this population [1]. Evidence-based treatments for smoking cessation are available, safe, and efficacious for persons with SMI; however, few persons with SMI receive these treatments [38].

In order to realize the intended benefits of smoking cessation treatment for persons with SMI, it is important that mental health programs implement evidence-based practices. Current barriers faced by clinicians include not having the knowledge or confidence to deliver smoking cessation treatments, as well as misconceptions about the safety of smoking cessation medications and client interest in quitting [25-28]. There are also barriers at the organizational level; community mental health centers may not have standard systems for screening, monitoring, or treating tobacco smoking. In addition, the complexity of the evidence-based treatment, that is, the combination of behavioral counseling and pharmacotherapy, often delivered by different clinicians, contributes to the challenges of implementation [48]. In this pilot study, we will strive to address these barriers through the use of implementation strategies, including training about evidence-based smoking

XSL•FO
RenderX

cessation treatment and motivational interviewing, a tobacco smoking treatment protocol, expert consultation, coaching, and OSMs.

Strengths and Limitations

While evidence-based smoking cessation treatments are not provided routinely in mental health clinics, where people with SMI receive the majority of their health care, these settings provide opportunities for the delivery of these recommended practices. We have specifically designed the training materials for providers in the community mental health center setting and have tailored the counseling manual for delivery to persons with SMI. We also worked with the sites' leadership to embed smoking cessation processes of care into the EMR and current workflow to increase clinician uptake. Using data from the EMR can provide an objective measure of smoking cessation evidence-based practices that are being implemented, enabling us to highlight areas of success and problem-solve barriers. At the completion of this study, we will have training modules, implementation tools, and resources for the delivery of smoking cessation treatment in community mental health centers. In order to address barriers to the implementation of these evidence-based practices, we are using a range of strategies, including asynchronous trainings and novel avatar simulations, to improve motivational interviewing counseling skills. We will collect data about the acceptability, appropriateness, and feasibility of both the evidence-based practices and implementation strategies that will inform future implementation efforts and planning for a randomized controlled trial.

In terms of limitations, our implementation intervention is effortful and multifaceted and may require additional supports to be carried out at other community mental health centers. The COVID-19 pandemic has created further challenges. As a result of pandemic-related restrictions, the study team had to adapt the implementation strategies to be delivered remotely rather than in-person, which, while being efficient to deliver, can make it more challenging to engage clinicians. Clinicians also had to adapt the counseling sessions to be delivered remotely if needed, which can be an added barrier for those less comfortable with technology. We also recognize that it may be difficult for providers to prioritize smoking cessation given other time-sensitive client concerns, such as those related to acute psychiatric symptoms and mental health crises [49]. Clinician challenges in delivering smoking cessation treatment may be exacerbated by staff shortages, which have occurred in many community mental health clinics during the pandemic and which have led to increased caseloads and other agency-related pressures. More generally, there are difficulties changing the culture in mental health organizations, many of which have been permissive about tobacco smoking in the past, in order to facilitate more active promotion and delivery of smoking cessation treatments [15]. Finally, our prepost design does not allow us to make causal inferences about the effects of our implementation strategies on outcomes.

Conclusion

The IMPACT study will provide evidence about the use of implementation strategies to increase providers' knowledge, self-efficacy, and delivery of the evidence-based practices for smoking cessation treatment for persons with SMI in community mental health center settings.

Acknowledgments

This work is supported by 5P50MH115842, Center to Accelerate Translation of Interventions to Decrease Premature Mortality in SMI (G Daumit, principal investigator).

Data Availability

The data sets generated and analyzed during this study will be available from the corresponding author on reasonable request with appropriate institutional review board approval and data use agreement.

Authors' Contributions

GLD, EMM, FD, AEE, and CC conceived the design of the study. NYW participated in the analytic and statistical analysis plans. AD, SG, and CTY contributed to the design of the intervention. BE, JVG, and EM directed data collection. FD, SG, EM, and CTY drafted the original version of the manuscript. All authors edited and approved the final manuscript.

Conflicts of Interest

CC and AEE received consulting from Charles River Analytics. The authors have no further interests to declare.

Abstract

Background: Indigenous peoples live across all continents, representing approximately 90 nations and cultures and 476 million people. There have long been clear statements about the rights of Indigenous peoples to self-determine services, policies, and resource allocations that affect our lives, particularly via the United Nations Declaration on the Rights of Indigenous Peoples. An area for urgent improvement is curricula that train the predominantly non-Indigenous health workforce about their responsibilities and that offer practical strategies to use when engaging with Indigenous peoples and issues.

Objective: The Bunya Project is designed to advance Indigenous community-led teaching and evaluation of the embeddedness of strategies to achieve an Indigenous Graduate Attribute in Australia. The project centers the relationships with Aboriginal community services to lead education design relating to Indigenous peoples. The project aims to articulate community recommendations for university education in allied health in the usable format of digital stories to create culturally informed andragogy, curriculum, and assessment measures for use in teaching. It also aims to understand the impact of this work on student attitudes and knowledge about Indigenous peoples' allied health needs.

Methods: Multilayered project governance was established, along with a 2-stage process using mixed methods participatory action research and critical reflection, using the reflective cycle by Gibbs. The first stage, *preparing the soil*, used community engagement, drew on lived experience, encouraged critical self-reflection, embodied reciprocity, and demanded working collectively. The second stage, *planting the seed*, requires more critical self-reflection, the development of community data through interviews and focus group discussions, the development of resources with an academic working group and community participants, the implementation of those resources with student feedback, the analysis of the feedback from students and community members, and reflection.

Results: The protocol for the first stage, *preparing the soil*, is complete. The results of the first stage are the relationships built and the trust earned and gained, and it has resulted in the development of the *planting the seed protocol*. As of February 2023, we have recruited 24 participants. We will analyze data shortly and expect to publish the results in 2024.

Conclusions: The readiness of non-Indigenous staff to engage with Indigenous communities has not been ascertained by Universities Australia, nor can it be assured. Staff preparation and skills to support the curriculum, create a safe learning environment, and develop teaching and learning strategies to guide academics to recognize that how students learn is as important as the content students learn. This learning has broad implications and benefits for staff and students within their professional practice and for lifelong learning.

Introduction

Overview

There are 476 million Indigenous peoples worldwide, who belong to the world's oldest continuing cultures and who have the right to self-determine health services to meet needs [1]. Health services are built upon and use the services of a predominantly tertiary-educated workforce. However, university health education contains little about Indigenous rights or knowledge [2]. Although immersion in cultural settings is recommended to stimulate transformation in knowledge and skills, current health curricula in Australia offer little toward this [3]. With few Indigenous staff at universities, responsibility lies with non-Indigenous staff, who are often underconfident in selecting and conveying information about Indigenous peoples [3]. Partnerships with Indigenous health organizations as experts in cultural models of care are essential; however, there are few examples in the literature to guide this [3]. An area for urgent improvement is curricula that train the predominantly non-Indigenous health workforce about their responsibilities and practical strategies they must use when engaging with Indigenous peoples and issues.

The Bunya Project is part of a participatory action research (PAR) project that aims to develop the skills and capabilities of academic staff to understand the principles and processes required to develop and embed Indigenous perspectives into the health care curriculum, ultimately influencing systemic change within the health care workforce.

This paper outlines a process for Indigenous community participation, showing how it is possible and important in developing culturally respectful engaging resources for students learning at university, across disciplines. The Bunya Project models processes and protocols for working with Indigenous peoples and community organizations that honor diverse Indigenous peoples' knowledge with authenticity, humility, and reciprocity, as per cultural and ethical protocols. This paper contributes to the narrative as to how and why universities should partner with Indigenous communities and organizations; the value of the Bunya Project lies not only in sharing important knowledge held by Indigenous community organizations and members but also in demonstrating how to bring community into university life. This Bunya Project protocol may be useful for Indigenous peoples around the world, to adapt to local circumstances in partnership with community organizations and local teaching institutions.

The Bunya Project protocol outlined in this paper provides the principles and strategic knowledge used by a university education health faculty in Australia, driven by the Indigenous health team. The early stages of the protocol describe what could be called the "pre-research" stage—much of this preliminary work is taken for granted by the authors as "proper ways" or a respectful process, knowledge of which is gained through lived experiences and social expectations in a community context. However, what is obvious to us may not be obvious to non-Indigenous academics. Therefore, this paper outlines the principles and processes required to implement this protocol, based on the authors' insider knowledge and lived experience as Indigenous peoples.

The Bunya Project is inspired by the tall Bunya tree of eastern Australia—*Araucaria bidwillii*—which grows slowly and, through its development, produces large pinecones that separate into edible nuts for current generations to be nourished by. It also spreads seeds for future generations to cultivate and grow. This Bunya Project provides a long-term, intergenerational, and unifying process for the voices of Indigenous peoples to be heard and shared in the allied health curriculum.

Background

Aboriginal and Torres Strait Islander peoples are the Indigenous populations of the continent referred to as Australia. Aboriginal peoples are heterogenous, with >250 different language groups [4], each with their own protocols and ceremonies. The Torres Strait Islands comprise 5 island clusters, consisting of 38 inhabited islands and 113 islands in total. The islands lie between the tip of Queensland on the Australian continent and Papua New Guinea. Acknowledging this diversity is foundational to understanding and approaching teaching and learning within Indigenous contexts.

Government Policy Context

In Australia, all national and state-based policies indicate that Aboriginal and Torres Strait Islander peoples have the right to cultures being at the center of decisions made, with full participation in decision-making [5,6] and its evaluation [7]. However, many of those currently in decision-making positions have had little education or support in understanding Australia's history, cultures, or rights [8]. There are limited representative mechanisms for Aboriginal and Torres Strait Islander peoples to formally be included in decision-making, as there is an inherent power imbalance [9,10]. Those agreements made between governments and peak Aboriginal and Torres Strait Islander organizational bodies often have little resourcing and no evaluation, which limits both their ability to act and accountability [11].

University Responsibilities and Realities

Current university education curricula produce graduates who often enter positions of power relevant to Indigenous peoples' realization of rights. However, their education is severely lacking and does not produce graduates who are sufficiently well developed to bring about the types of urgent health system or health workforce changes needed to influence the drastic improvements required [3,12]. This is a common issue for Indigenous peoples globally [13].

The embedding of Indigenous peoples' perspectives into mainstream university curriculum has been named for at least 2 decades in Australia [14,15] but only recently have structures been put in place by some universities [16,17] that help produce conditions for clear, evaluable actions. The peak body for

XSL•FO
RenderX

Australian universities, Universities Australia, produced a strategy for 2017 to 2020 [18] and an Indigenous strategy for 2022 to 2025 [19], both of which make leadership statements but have not been wholly evaluated or updated for future developments.

Nonetheless, most Australian universities have committed to embedding Indigenous perspectives into their curriculum [20] and are seeking Indigenous peoples' leadership [21]. A specific strategy has been introduction of an "Indigenous Graduate Attribute" (IGA), a statement of attainment that is expected of all graduates in relation to Indigenous peoples [22]. In the health context, the IGA aims to improve graduates' knowledge about Indigenous peoples and issues and, where possible, provide experiences with Indigenous peoples, with the expectation that this will improve professional practice [23] and, ultimately, improve health outcomes for Indigenous peoples.

Unfortunately, there are few examples for universities about how to achieve the IGA. Universities have rarely met Indigenous staff targets [24], meaning that non-Indigenous people are largely responsible for developing and delivering curricula about Indigenous peoples and for driving the implementation and evaluation of the IGA. Perhaps in some recognition of this, Universities Australia recommends that tertiary institutions "build robust, respectful and collaborative partnerships between themselves and the Aboriginal and Torres Strait Islander communities that they serve" [14]. There are few practical strategies, scaffolding, or implementation guidance for university staff to create Indigenous community collaborations.

As an example of uninformed curriculum content, information about Indigenous peoples' health and well-being often begins with a focus on the most easily available information in the public domain—the Australian Government's Closing the Gap framework [25]. This framework has been designed to highlight inequity—the gap in processes and outcomes that Indigenous Australian peoples experience across many life domains compared with others in Australia [26]. In so doing, Closing the Gap powerfully reinforces negative stereotypes and assumptions about Indigenous Australian peoples, with no focus on strengths, local cultures, or worldviews about health. In the curriculum and in the classroom, this perpetuates stereotypes with a deficit lens [27] that is neither community driven nor reflective, entrenching in students' minds the notion that Indigenous peoples do not have the expertise to enhance mainstream learning or contribute to developing their professional practice in providing health care.

The holistic collectivist notion of Indigenous Australian peoples' health has much to offer to Western biomedicine in recognizing the whole person and their context: "Not just the physical wellbeing of an individual but refers to the social, emotional and cultural wellbeing of the whole community in which each individual is able to achieve their full potential as a human being, thereby bringing about the total wellbeing of their community. It is a whole-of-life view and includes the cyclical concept of life-death-life" [28].

To health educators who are versed in Western biomedicine, this holistic health concept seems complex and "too hard" [29]. Statistics used to measure and teach about health reinforce a power imbalance and dominance of the medical model [30]. With skilled, confident, and supported staff, more complex underlying contextual and environmental factors in health, including ongoing processes of colonization, systemic bias, and racism, are minimized [31]. Furthermore, the focus on Indigenous peoples' ill-health does nothing to challenge students to understand the influence of their own cultural lens [32] or the future risks of continuing to render invisible and devalue Indigenous models of health care.

Challenges in Allied Health Education

Allied health care professions are recognizably underdeveloped, particularly in relation to Indigenous peoples' ways of knowing, being, and doing in the curriculum and clinical practice [3]. Allied health education has a long history of excluding Indigenous knowledge [3,33]. The Indigenous allied health workforce and student cohorts are small; there is an assumption that more Indigenous allied health practitioners and students are required, but there is little critical thought in supporting Indigenous holistic health care and how that might shape the future health workforce [34]. There are clear gaps in research about allied health care needs of Indigenous peoples, and there is no attention to minority populations of Indigenous peoples such as those in prisons and those with disability or multiple, compounding issues. This limits the scope of exemplars available to inform curriculum. These gaps persist despite allied health professional education having specific accreditation requirements, often specific to the discipline and with mandatory renewal [35]. Furthermore, for example, the Australian Physiotherapy Council has strengthened its accreditation requirements to achieve more Indigenous student enrollments and include cultural safety in the curriculum [36], reinforced by changes to the National Safety and Quality Health Service Standards [37]. The Indigenous Allied Health Association provides some resources to guide health professionals and support students [38]; however, the implementation and use of available resources vary across institutions [39].

Expertise About Indigenous Health Does Not Lie in Universities

Statements implicating universities in perpetuating the disadvantage of Indigenous peoples' experience have recently been met with mixed responses in Australia, including denial and confusion [39,40]. The cultural load that Indigenous Australian staff experience in mainstream organizations—the additional expectations on Indigenous staff to fulfill tasks in accordance with position descriptions and educate others about Indigenous cultures [41]—is beginning to be aired. However, the experience of the relatively small number of Indigenous staff at universities is seldom acknowledged—having to both cope with stereotypes and exclusion of Indigenous knowledge and having to rectify the curriculum to meet accreditation while being understaffed [42]. University employment is not sustainable for Indigenous staff without the support of Indigenous community—personally or to help shape curriculum. Expertise about Indigenous health does not lie in universities. It is in the Indigenous community, which generally has few university graduates but has valuable expertise, cultural

XSL•FO
RenderX

protocols, and appropriate positioning to identify and discuss key issues affecting their community and successful solutions.

Expertise of Indigenous Communities and Organizations

In contrast, mounting evidence exists for the success of Aboriginal community–controlled health organizations. The networked organizations (>140) across Australia have demonstrated leadership since the 1970s in effective and efficient holistic health care [43]. They address the social determinants of health [31] and recognize their successes emanating from continued cultural connections within Indigenous communities [44]. They carry across generations the Indigenous knowledge that has "multiple and interconnected discourses, social practices and knowledge technologies" [45] and they showcase Indigenous voices that carry within them the shared and lived experience of families and communities, beyond individuals [46]. Aboriginal community–controlled health organizations are now one of the largest workforces of Indigenous Australian peoples [47]; they demonstrate many strengths in models of care, staff, support, retention, and career progression [48] and are important leaders for any new curriculum development.

Project Context

Bunya has been designed as a central strategy for a university faculty (the University of Technology Sydney [UTS] Faculty of Health) and a graduate health school (the UTS Graduate School of Health) to support students to achieve IGA and to deliver curriculum for students embarking on a career in allied health care, specifically pharmacy, physiotherapy, clinical psychology, orthoptics, genetic counseling, and speech pathology. Bunya explores both how curriculum development processes can include Indigenous communities and Indigenous community members' experiences of allied health care.

The idea of seeking to connect a university health faculty with Indigenous communities to develop curriculum and to research the process and outcomes is very well supported by Australia's peak body for health and medical research, the National Health and Medical Research Council (NHMRC). The NHMRC guidelines, *Ethical conduct in research with Aboriginal and Torres Strait Islander Peoples and communities* and *Keeping research on track II*, were developed to promote health, prevent harm, and encourage best practice [49,50]. The NHMRC has also developed these specific guiding principles for conducting studies with Aboriginal and Torres Strait Islander peoples [49,50]. Historically, studies conducted in Aboriginal and Torres Strait Islander communities were extremely negative [50]. Previous studies conducted in Indigenous communities were, in some cases, physically barbaric [51]. Studies were designed to disempower, oppress, and silence Aboriginal and Torres Strait Islander peoples [52]. It is only in recent years that studies have been designed to be of benefit to Aboriginal and Torres Strait Islander peoples [53]. Aboriginal and Torres Strait Islander peoples are described as the most overresearched population in the world [54]. Processes have been put in place by governing research bodies such as the NHMRC and the Aboriginal Health and Medical Research Council of New South Wales. Both guidelines, *Ethical conduct in research with Aboriginal and Torres Strait Islander Peoples and communities* and *Keeping research on track II* [49,50], have been instrumental in the design and development of the Bunya Project and this protocol.

We have divided the Bunya Project into 2 stages—preparing the soil and planting the seed. Owing to the nature of PAR, it is impossible to separate protocols and learnings as clearly as in papers describing other forms of research, such as a clinical trial. The learnings from the *preparing the soil* stage influence the protocol developed in the *planting the seed* stage. As such, this paper will present some of the findings from the first stage, and a subsequent paper will elucidate them more clearly. The paper was written at the time of the transition from the first stage to the second stage.

Theoretical Frameworks

We have taken a PAR approach [55]. PAR is a qualitative research methodology that relies on the participation of the researcher and the participants to collaboratively gather and interpret data and findings throughout the project. The process of PAR is flexible and responsive to be able to adapt to the direction of the project, rather than being dictated or set from the beginning. PAR is a recognized Indigenous research methodology [56] designed to center and amplify Indigenous voices and self-determination [57], which is an underpinning value of the Bunya Project. PAR reduces power inequity and helps to ensure reciprocity.

PAR also reflects the authors' lived experiences of working with the community and as educators in the university context.

PAR prioritizes researchers and participants forming partnerships to identify issues of local importance and determine ways to understand the issues and strategies for action [58,59]. Furthermore, PAR methodology is used to understand complexities and influence change [55]. This resonates with the research team, given that Indigenous peoples have always implemented participatory principles within community governance through collective consultation and collective action [57]. PAR celebrates the complexity related to multiple contexts, including unique community settings and university education settings [60], with the ability to be agile to adapt to changing settings, participants, and ways of understanding [60].

In developing and articulating the preliminary process and protocol, the reflective cycle principles by Gibbs [61] were applied in a critical self-reflection context. The reflective framework principles by Gibbs also guided the authors to unpack informal conversations within the community engagement process, ensuring that the community remained central to the process and principles articulated [62]. Therefore, no data have been collected from student participants or will be reported here from external research associated with the Bunya Project. This paper presents critical reflection data from the research team to inform the project and its stakeholders. In evaluating Bunya, these are the foundational aspects required to build and replicate the project.

XSL•FO
RenderX

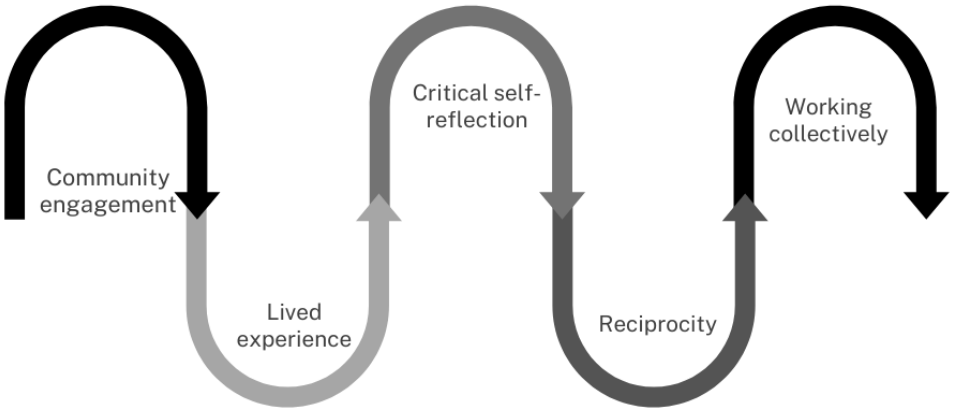
Methods

Ethics Approval

The Bunya Project has been designed in accordance with NHMRC ethics guidelines regarding studies being conducted with Aboriginal and Torres Strait Islander peoples [49,50].

The Bunya Project has been approved by both the University of Technology Sydney Human Research Ethics Committee (ETH18-2618) and the Aboriginal Health and Medical Research Council of New South Wales Human Research Ethics Committee (1451/18).

Preparing the Soil



Overview

To develop the Bunya Project and method, the authors took into account cultural ways of working, along with community protocols and expectations. Overall, 5 steps were necessary to "prepare the soil" for the Bunya Project process. The five steps are as follows:

1. Community engagement—developing relationships to ensure that the project is of benefit to the community and responsive to the community objectives
2. Lived experience—humility in recognizing the influence of our own lived experience on our worldviews and interactions
3. Critical self-reflection—about our own perspectives and the influence these perspectives and experiences have on the formulation of ideas, conduct, and expectations
4. Reciprocity—which ensures that the benefit is mutual and the communities are meeting their objectives, not what the researcher thinks is of benefit to them
5. Working collectively—which creates the space for all participants to belong and feel empowered as an important part of the team, process, and outcomes achieved

Figure 1 shows these steps but note that they are fluid and may be repeated in part or whole throughout the process.

Figure 1. Preparing the soil in the Bunya Project.

Community Engagement

We identified four priority groups to engage with:

1. Indigenous community organizations
2. Indigenous community members and health care service users
3. University staff
4. University students

Invitations for group 1, Indigenous community organizations, to participate in the Bunya Project were circulated through networks and social media to encourage self-nomination. The research team visited community organizations and attended community events, circulating information and responding to queries. In total, 6 organizations signed up as Bunya Project collaborators. During the COVID-19 pandemic, this was reduced to 5 owing to travel distance restrictions and then to 4 because 1 organization ceased operating. A formal agreement was negotiated with each organization about their participation, including supporting curriculum development, assisting with the recruitment of Indigenous individuals who are willing to participate in data collection, and providing mentoring and peer support during the Bunya Project.

The Indigenous community organizations invited community members and health care service users (group-2 participants) to participate either directly or through social media. Information about the Bunya Project was circulated within each organization. Participants then self-nominated to participate. Participation includes interviews to collect data pertaining to insight into their own health care needs and strengths within their community influencing educational opportunities for allied health education. A total of 24 Indigenous community members and health care users were recruited to be interviewed.

Group-3 participants, university staff, were recruited through self-nomination.

University students (group-4 participants) will be invited to participate in the Bunya Project via the unit coordinator or class tutors. Participation is voluntary. Students who self-nominate will be required to complete premethod and postmethod surveys; we are aiming to survey most participants (n=169, 75.1%), with the total being 225 students.

The Bunya Project encourages connectedness wherever possible among project participant groups.

XSL•FO
RenderX

Lived Experience

Lived experience recognizes the cultural, spiritual, physical, emotional, and mental experiences; circumstances; beliefs; and worldviews of a person, including the well-being of the individual, family, or community. A lived experience recognizes the ongoing impact of colonization experienced by Aboriginal and Torres Strait Islander individuals, families, and communities. Lived experience also recognizes specific events that have an impact on the social, emotional, and cultural well-being of Aboriginal and Torres Strait Islander peoples [63]. Lived experience as an Aboriginal person is complex, with many layers; is difficult to define but understood and recognized within the community and shared commonality; and does not need to be defined but is reflected through respecting protocols within the community [64]. Lived experience is an extremely valuable teaching tool, as students connect with shared lived experiences and the opportunity to learn from experiences that differ from their own. Lived experience also ensures that the teaching is authentic and relevant in a real-world context [65].

Critical Self-reflection

Critical self-reflection resulted in the identification of clear guiding principles for the conduct of the project. These guiding principles also reflect general cultural expectations when working with community and Indigenous knowledge. These principles are a guide for consideration in best practices for community engagement and leadership in teaching and learning and Indigenous research cultural protocols. As an Indigenous peoples–led research team, we cannot differentiate cultural protocols from research protocols; Indigenous culture informs knowledge production and the use of knowledge in research and practice.

Reciprocity

The research team actively participates in the Indigenous community organizations' business, supporting initiatives and events; contributing to committees; contributing skills, knowledge, and expertise; and providing access to university resources and networks.

The project continues to progress with mutual understanding of and agreement on key activities.

Working Collectively

Although the leadership of the Bunya Project rests with the Indigenous health academic unit within the faculty, the leadership has a clear desire to work collectively. The heads of each of the 6 postgraduate health disciplines were invited to nominate a staff member to join an academic working group fondly termed "the Bunya Nuts." These representatives provide discipline-specific expertise and guide curriculum development to ensure academic rigor and alignment with the curriculum that is already established.

The Bunya Nuts developed the terms of reference collectively; members are responsible for liaising within their discipline, inviting feedback, distributing community-developed video teaching resources, and facilitating student survey participation.

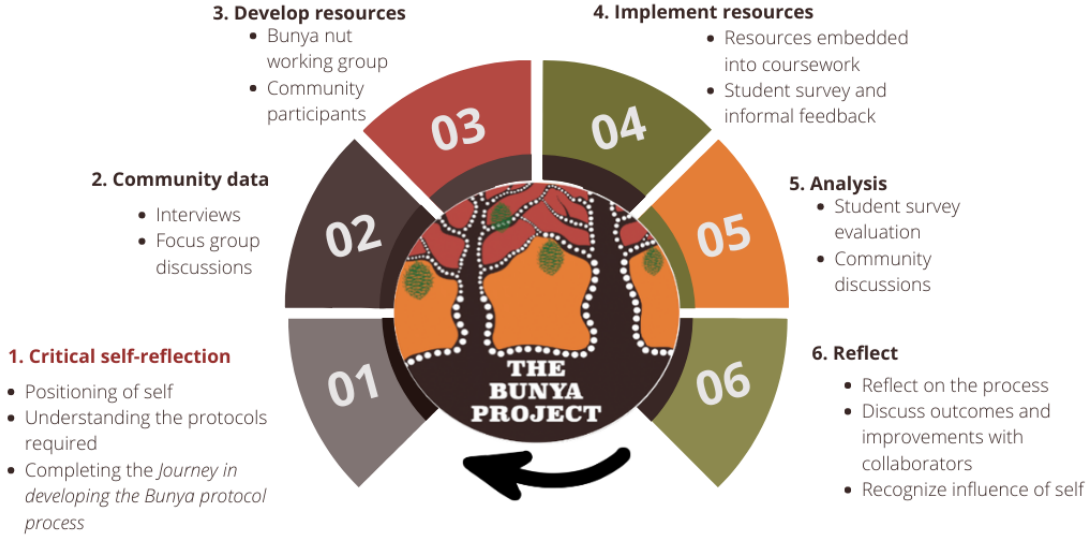
Objectives

The Bunya Nuts also selected the following objectives for its mixed methods PAR project:

1. Develop relationships with Aboriginal community services to support the project and understand community recommendations for university education in allied health
2. Conduct interviews and collect digital stories from Aboriginal and Torres Strait Islander peoples, to understand "what are their experiences, perspectives, knowledges and aspirations for their own health and wellbeing and in relation to allied healthcare?"
3. Create culturally informed andragogy, curriculum, and assessment measures for use among teaching staff and students
4. Implement an evaluation framework to understand the effects on student attitudes and knowledge about Indigenous peoples' allied health needs and aspirations and the authenticity, relevance, and accessibility of the curriculum for staff
5. Continue to develop culturally informed teaching and learning strategies

Results

Planting the Seed



Overview

This section discusses the results of the "preparing the soil" process of the Bunya Project. The "preparing the soil" process resulted in key insights for the "planting the seed" stage including how future data are to be collected and the process and methodology for replication within the reader's own context.

As outlined in this paper, the Bunya Project uses PAR cycles to gather information, develop curriculum, use it, and evaluate it from multiple perspectives. As a PAR project, the "planting the seed" stage of Bunya itself has 6 stages, each stage influencing the next in a continuous cycle, as illustrated in Figure 2.

XSL•FO
RenderX

Figure 2. Planting the seed—Bunya Project protocol phases.

The "planting the seed" process begins with critical self-reflection positioning by those guiding the project, their bias and influence, and ensuring that they have undertaken deliberate preparation to uphold the authenticity of the project. Phase 1 also incorporates the process in "preparing the soil" illustrated in Figure 1 previously. This involves recognizing their position, influence, and power and identifying the strategies and protocols required to privilege Indigenous voices and leadership and honor local protocols and expectations. Following this is community engagement and data collection; the data collected in each phase influence the following phases. Community data generate the content for the development and embedding of resources, and the resources activate thinking for the collaborative analysis of the survey and discussion. This is followed by a collaborative reflection about the process, improvements, and adjustments, and the cycle then commences again, with critical self-reflection of the person guiding the project.

As Figure 2 shows, Bunya is a PAR project because the overall community participation is central to all elements of the project. Phase 2 involves qualitative data collection, and phase 3 involves filming and editing the new teaching and learning resources and planning where in the curriculum they will be most effectively used, in collaboration with Bunya Nuts and community participants. Phase 4 involves using the resources and collecting a baseline survey from students and staff, and phase 5 involves the follow-up survey to help understand change and analysis of data. Phase 6 involves reflection with Bunya Nuts and community participants. PAR defines Bunya because it relies on community engagement throughout [55,58,61,66].

Critical Self-reflection

Critical self-reflection is again consciously used in the "planting the seed" stage of the Bunya Project, using the reflective cycle by Gibbs [61] to understand the experience, identify thoughts and feelings through the process, and recognize the importance of continuous improvement and the role of the researcher in modeling those processes as best practice. Undertaking this process at this point in the protocol provides the opportunity to highlight areas that may need to be revisited or unpacked further, in collaboration with the community involved.

Community Data

Focus Groups Discussions

In the future, focus group discussions will be conducted with Indigenous organization representatives. Focus group discussions encourage knowledge-producing dialogue in a group context. They allow the researcher to be part of the discussion [67]. This aligns with Indigenous ways of yarning and kapati, which encourages Indigenous peoples to talk freely about their experiences, thoughts, and ideas [68]. Furthermore, focus group discussions allow for broad discussion and framing and focusing questions and concepts to inform subsequent research phases, in this case, to inform semistructured interviews.

Focus group discussions will be semistructured, with guiding questions developed by the Bunya Nuts, and will be 30 to 60 minutes in duration.

The groups will have approximately 6 participants. Topics will range from health care knowledge and experiences to identifying needs and strengths within their community to influence the educational opportunities for tertiary education.

The focus group discussions will be audio recorded with written consent from all participants. Focus group participants will receive light refreshments in reciprocity of their time. All data collected during the focus groups will be deidentified.

Interviews

Interviews are designed to occur as a social interaction while sharing a cup of tea, known as kapati time, and create a safe space that facilitates yarning and storytelling [68]. Interviews stimulate knowledge sharing through storytelling and yarning [69]; storytelling is an important way of sharing information in Aboriginal and Torres Strait Islander cultures [67]. The interview structure will follow a line of questioning arising from the Bunya Nuts and the focus group discussions; however, this structure is intertwined with the informality of conversation and storytelling about experiences pertaining to the question.

XSL•FO
RenderX

The interviews will be video recorded, with individual consent obtained from each participant before participation. Videos—digital stories—are a way of clearly displaying that the individual holds ownership over their knowledge, culture, and experiences and tells their story themselves, rather than having someone interpret their experience. Videos will then be edited for use, and written final approval will be obtained from the participant before the videos are implemented as internal teaching resources. Videos remain as the property of the participant and are not permitted to be changed or altered in any way unless additional consent is sought from the participant. The 24 interview participants will receive a gift card worth Aus $20 (US $13.23) as compensation for their participation.

Overall, 6 interviews will be conducted at each of the 4 locations.

Premethod and Postmethod Surveys for Staff and Students

The survey chosen to be used for the Bunya Project was designed as a university-wide instrument by the Centre for the Advancement of Indigenous Knowledges [8]. It measures students' attitudes, knowledge, and learning experiences pertaining to Indigenous ways of knowing, being, and doing. The premethod and postmethod survey measures whether the teaching and learning resources and strategies influenced change in staff and students' attitudes.

The survey assessment framework is based on 5 overarching themes that are aimed to critically engage with teaching and learning content related to the university's IGA. The overarching themes are as follows:

1. Knowledge
2. Critical reflectivity
3. Indigenous voice
4. Indigenous community engagement
5. Applied Indigenous knowledge [70]

The students will be provided with the survey through the survey platform. The Bunya Nuts representative for the discipline will upload the link to the learning management system for the subject. The link will be accompanied by an announcement to encourage student participation. The survey will remain open for at least 3 weeks, and students will be encouraged to complete it.

Develop Resources

The development of the resources begins with the Bunya Nuts working group to identify topics within the curriculum for each discipline. These topics will be discussed in focus group discussions with Aboriginal community–controlled health services, identifying the specific learning or information that the group determines as important for the students to know, understand, and apply within their professional practice. On the basis of the results of the discussions, one-on-one interviews will be conducted and video or audio recorded (according to participant preference). The interview questions and topics will be directly linked to the outcome of the focus group discussion, ensuring Indigenous self-determination throughout the process. The clips will be edited into short clips and reviewed by the participants to ensure that the message remained as intended.

Implement Resources

The resources developed will be made available to the school teaching staff within the various disciplines. The resources will be uploaded to the learning management system. Staff will be invited by the project team to access the resources. The project team will have control over who can access the resources and analytics to track where the resources are implemented within the learning management system, to ensure that the resources are only implemented in accordance with the ethical guidelines. The teaching staff will copy the resources into various points within their subjects to ensure that an Indigenous voice is present. The implementation of the resources will be accompanied by support processes outside this project, including teaching principles, an andragogy framework, and professional development opportunities for the staff. The project team recognizes the importance of not only what is taught (the content) but also how it is taught (the andragogy).

Analysis

The analysis of the data will be undertaken by the research team, in collaboration with the community partners and the Bunya Nuts. The andragogy framework guides the analysis, centering Indigenous knowledge and learning methodology within the context of adult education. Specific analysis will be conducted for each data set—the focus group discussions, interviews, and surveys.

Interviews will be transcribed and entered into NVivo (QSR International) [71] to be coded, with themes arising from the data. Codes will be compared, condensed, and organized into high-level themes to be communicated [72]. Focus group discussions will be managed similar to interviews, with the inclusion of group analysis [73]. Drafts and ideas about the data will be shared with the participating community organizations for their feedback. Furthermore, the qualitative interviews will be transformed and edited into digital stories, to be given to each participant and produce teaching resources for the disciplines. We will also draw on facilitator's written notes made during the focus group discussions.

The Centre for the Advancement of Indigenous Knowledges' processes for the analysis of data will be followed. The results of the validated survey will be analyzed to measure the impact of the authentic community-controlled teaching resources on the staff and students' attitudes, knowledge, and learning experiences in relation to Indigenous perspectives within their professional learnings. The quantitative data will be carefully cleaned, with frequencies identified using SPSS [74] to identify overall patterns, including across the 5 basic themes the instrument focuses on. Other basic statistical data analysis will occur including averages and partial correlation for associations with student outcomes.

Drafts and initial thoughts will again be shared with the community organizations to provide feedback regarding the progress and impact of the resources developed. The community guidance will influence modifications in the teaching resources for future implementation, beyond the scope of this project.

XSL•FO
RenderX

Current Status

The protocol for the first stage, *preparing the soil*, is complete. The results of the first stage are the relationships built and the trust earned and gained, and it has resulted in the development of the *planting the seed protocol*. As of February 2023, we have recruited 24 participants. We will analyze data shortly and expect to publish the results in 2024.

Discussion

Summary

Through the "preparing the soil" stage of the PAR, the "planting the seed" Bunya Project protocol emerged, as depicted in Figure 2. This represents key findings, the importance of critical self-reflections in Indigenous health education and PAR, the importance of holding space in curriculum development and design to privilege Indigenous voices through the engagement of community data, collective development of resources, implementing resources in a culturally safe learning space, the analysis of the learning content and process, and reflection to ensure continuous improvement of the process and educators.

PAR is an empowering methodology that privileges local knowledge and lived experiences throughout every facet of the project [56,57]—the direction, implementation, analyses, and outcome. The Indigenous perspectives embedded within the curriculum are based on establishing relationships with the local community that are reciprocal and collaborative with Indigenous leadership and the university through the Bunya Nuts academic working group. The collaboration between the Bunya Nuts and the community is instrumental in the creation of new knowledge as this collaboration develops the capacity of both parties learning from each other through action [57,60,69]. The collective action involves creating videos and resources that honor and reflect the intended meaning and context from community to academia and from academia to community. This action extends to influence change in allied health care through educating and building a culturally responsive workforce. Bunya's andragogic framework is designed to reinforce the content, collaboration, and leadership of the community as the authoritative voice and knowledge holders [67].

This study encourages universities to develop partnerships with Indigenous community organizations in curriculum development. Establishing and maintaining authentic partnerships with Indigenous community organizations is important for the development of the future workforce and provides essential knowledge and skills for all graduates. Academic staff and institutions must move past an "othering" mindset, including the notion that developing relationships with Indigenous community organizations and including Indigenous perspectives in the curriculum is the sole responsibility of Indigenous academic staff. The reality is that Indigenous staff numbers in universities are low, globally. Embedding Indigenous perspectives into the curriculum is the responsibility and privilege of all the academic staff. It is not possible to create a checklist or a descriptive "how to" guide, as teaching and learning must be grounded and relevant to the local context. This paper outlines the guiding principles developed from the lived experience and reflectivity of the authors as community members and educators.

In Australia, government policy and legislative requirements have been introduced to ensure that curricula and workplaces implement training and professional development opportunities for students and staff, so that they can develop and apply knowledge and skills that create conditions for cultural safety and culturally responsive health care. Authentic partnerships with community organizations are an obvious place to start. Students can then commence their career with a strong foundation by understanding how to work authentically with Indigenous organizations and peoples. This paper outlines how to approach and achieve this outcome.

As this paper also shows, partnerships require reciprocal benefit and authenticity, creating the opportunity for universities to positively and authentically work with Indigenous community organizations to share knowledge skills and resources that will benefit not only the university and the students but also the community organizations and their staff and clients.

Comparisons With Previous Studies

The Bunya Project protocol unifies elements identified by past studies to form a comprehensive approach to embedding Indigenous perspectives within higher education with community engagement and leaders, andragogical framework, staff accountability, and student evaluation.

The growing momentum to include Indigenous perspectives into higher education and preparing graduates to work effectively with Indigenous populations is positive. However, current implementation processes in Australia lack accountability [63], evidence, and evaluation [8].

It has also been identified that Indigenous peoples cannot be solely responsible for all learning and teaching in academia. Indigenous and non-Indigenous academic staff must work together to implement the curriculum, using culturally safe [75] and relevant teaching and learning strategies [68,76,77]. This extends to the professional context whereby previous studies identified the importance of Aboriginal health workers and mainstream allied health workers working together within their professional context [75].

In accordance with United Nations Declaration on the Rights of Indigenous Peoples, Indigenous peoples have the right to self-determine health care and education [78]; therefore, they must be leaders in designing and informing curriculum, ensuring that learning is *with* Indigenous peoples and not *about* Indigenous peoples. This is demonstrated in various ways through previous studies, by applying and building on knowledge and experience with Indigenous peoples [79] to inform curriculum, through local Indigenous ways of knowing and learning in the classroom, and through community-engaged learning.

Previous studies in the area have identified the importance of the local context, of working with a single community—this does not reflect the diversity within Indigenous populations in Australia. The Bunya Project protocol extends this to include leadership from a diversity of communities.

XSL•FO
RenderX

The Bunya Project protocol also challenges educators to push past the concept of pedagogy to ensure that teaching and learning are receptive to the adult learner [80].

Transformational learning is central to this space and was identified throughout previous studies [32]. The San'yas Indigenous Cultural Safety Training in Canada is implemented as an educational intervention to promote transformational change in health systems, policies, and practice [81]. The Bunya Project protocol incorporates and builds on the importance of transformational learning and recognizing the position of self by all involved, including community participants, academic staff, and students.

Limitations

COVID-19 affected the project, as lockdowns restrict interactions. Even during times of eased restrictions, communities were very cautious to engage owing to the risk posed by COVID-19 and have cancelled events or adapted to web-based events. However, the pandemic provided another opportunity to highlight Indigenous excellence as the overall response to the pandemic, including public health messaging and responses, and the rapid adaptability to web-based connectedness has been exemplary.

The Bunya Project was developed in 1 university and 6 communities, which does not reflect the diversity of Aboriginal peoples or Indigenous peoples globally.

Conclusions

This study reinforces the necessity for universities to be active in engaging with Indigenous communities to influence education content and, consequently, outcomes. It is not the responsibility of the few Indigenous staff to champion this; the implication is that the majority must authentically engage with the community and privilege their leadership and expertise within teaching and learning design, delivery, and evaluation.

The value and implication of the Bunya Project lies in its demonstration of how universities resource staff to engage with community organizations and members within the university setting. If working well with Indigenous peoples requires the readiness of non-Indigenous staff and students, universities need to provide staff with cultural capability training, facilitating opportunities to learn. This Bunya Project protocol and its "preparing the soil" and "planting the seeds" stages model a process for best practice and authentic engagement that creates space, respect, and recognition of the value and privilege to learn from Indigenous leadership and expertise.

PAR of the Bunya Project is working to evolve university education through the quality delivery of an IGA that prepares students to be informed professionals throughout their careers and to contribute to creating conditions for Indigenous peoples to experience cultural safety; this is a lifelong learning journey. The intended learnings from the Bunya Project are expected to extend beyond university through continuing personal and professional development and application throughout the individual's career.

Acknowledgments

The authors thank Dr Mark Ragg of Ragg & Co for the contribution to the development of the protocol. The study received funding from the University of Technology Sydney Graduate School of Health seed grant program.

Abstract

Background: Hepatocellular cancer (HCC) is associated with high mortality, and early diagnosis leads to better survival. Patients with cirrhosis, especially due to nonalcoholic fatty liver disease and viral hepatitis, are at higher risk of developing HCC and form the main screening group. The current screening methods for HCC (6-monthly screening with serum alpha fetoprotein and ultrasound liver) have low sensitivity; hence, there is a need for better screening markers for HCC.

Objective: Our study, TENDENCY, aims to validate the novel screening markers (methylated *septin 9*, urinary volatile organic compounds, and urinary peptides) for HCC diagnosis and study these noninvasive biomarkers in liver disease.

Methods: This is a multicenter, nested case-control study, which involves comparing the plasma levels of methylated *septin 9* between confirmed HCC cases and patients with cirrhosis (control group). It also includes the comparison of urine samples for the detection of HCC-specific volatile organic compounds and peptides. Based on the findings of a pilot study carried out at University Hospital Coventry & Warwickshire, we estimated our sample size to be 308 (n=88, 29% patients with HCC; n=220, 71% patients with cirrhosis). Urine and plasma samples will be collected from all participants and will be frozen at –80 °C until the end of recruitment. Gas chromatography–mass spectrometry will be used for urinary volatile organic compounds detection, and capillary electrophoresis–mass spectrometry will be used for urinary peptide identification. Real-time polymerase chain reaction will be used for the qualitative detection of plasma methylated *septin 9*. The study will be monitored by the Research and Development department at University Hospital Coventry & Warwickshire.

Results: The recruitment stage was completed in March 2023. The TENDENCY study is currently in the analysis stage, which is expected to finish by November 2023.

Conclusions: There is lack of effective screening tests for hepatocellular cancer despite higher mortality rates. The application of more sensitive plasma and urinary biomarkers for hepatocellular cancer screening in clinical practice will allow us to detect the disease at earlier stages and hence, overall, improve HCC outcomes.

Introduction

Background

Hepatocellular cancer (HCC) has been the sixth most common cancer worldwide and the third most frequent cause of cancer-related deaths around the world in 2020 [1]. There has been a significant increase in the incidence of HCC in the United Kingdom and worldwide. Cirrhosis is the most potent risk factor for HCC and hence constitutes the major screening group for HCC globally. Cirrhosis can be caused by chronic viral hepatitis (B and C), chronic alcohol abuse, inherited metabolic diseases such as genetic haemochromatosis, or in some cases alpha-1-antitrypsin deficiency. The acquired metabolic disorder, nonalcoholic fatty liver disease (NAFLD), has also emerged as an important risk factor. NAFLD is a manifestation of the metabolic syndrome and is associated with type 2 diabetes mellitus and obesity. NAFLD affects around 20% to 30% of the adult population. Growing evidence suggests an increased HCC incidence in patients with NAFLD, and it will become the leading cause of HCC in the developed world [2,3].

The current screening strategy for HCC in the United Kingdom in established cirrhotic and high-risk groups is 6-month (twice a year) ultrasound surveillance scans and serum alpha fetoprotein (AFP) measurement. However, there are significant limitations associated with this approach. The sensitivity of AFP for HCC detection is only 60%, and the specificity is 87.7%. Previously, any attempts to increase the cutoff to increase the specificity had resulted in a lower sensitivity [4]. In fact, previous large-scale trials had shown that up to half of patients with primary liver cancer are AFP negative [5]. Hence, it is far from ideal as a screening test for HCC surveillance. Ultrasound liver is very much operator dependent, and again, the sensitivity remains modest around 63% for an early-stage HCC case [6].

There is always a significant risk of missing early-stage HCC or late diagnosis of HCC due to the poor sensitivity of the current screening modalities. Unfortunately, the late diagnosis of HCC is associated with overall poor outcomes, with a median survival of around 6 to 20 months post diagnosis [7]. Early diagnosis can be associated with curative options, including surgical resection, liver transplantation, and radiofrequency ablation. However, the chances of the earlier diagnosis rely mostly on better screening.

Current methods used to diagnose cirrhosis and NAFL have limitations. Transient elastography (TE) and enhanced liver fibrosis tests are used to check the presence of fibrosis, with TE also giving estimations of fatty changes in liver. However, they both have limitations, with enhanced liver fibrosis being a proprietary test [8] at a high cost (and with data coming from observational studies), and TE being operator dependent and nonconclusive in patients with a high BMI [9]. Hence, better noninvasive diagnostic tests are required for NAFLD and cirrhosis diagnosis and HCC screening.

Potential New Screening Markers for HCC and Liver Disease for Further Evaluation in TENDENCY

Methylated Septin 9

Studies on colorectal cancer have identified that methylation of the *septin 9* gene occurs during carcinogenesis and is released into the plasma, which leads to the development of blood-based *septin 9* gene methylation assays [10]. A study of 304 HCC tissue samples showed that methylated *septin 9(mSEPT9)* is a significant epi-driver gene in liver carcinogenesis [11]. He et al [12] conducted a case control study (64 patients with HCC, 44 patients with liver cirrhosis, and 298 healthy individuals) and demonstrated an overall plasma *mSEPT9* sensitivity of 76.7% for the detection of HCC. However, further work is required to validate these findings in screening a high-risk cohort [12].

Li et al [13] showed plasma *mSEPT9* to have a sensitivity of 82% and a specificity of 96% for HCC detection in a similar study carried out in Beijing (including 104 patients with HCC, 95 patients at risk of the disease, and 174 healthy controls).

A proof-of-concept study done as part of the TENDENCY study at University Hospital Coventry & Warwickshire (UHCW) with 141 participants (including 39 HCC cases) showed *mSEPT9* to have a sensitivity of 89% and a specificity of 81% (in comparison to an AFP sensitivity of 50% and a specificity of 97%) [14]. Thus, *mSEPT*9 has a far better sensitivity than AFP. However, in order to prove its applicability over the screening population, we require validation in a larger cohort of HCC cases against a control group of patients with cirrhosis (which is the major screening group in clinical practice).

Volatile Organic Compounds

Volatile organic compounds (VOCs) are endogenous and exogenous compounds with a lower boiling point and high vapor pressure. Endogenous VOCs are predominantly produced as a result of fermentation of nonstarchy polysaccharides and fibers in gut. These compounds then permeate the bowel wall and enter the portal circulation. Liver then plays further role in the metabolism of these compounds via various enzymes. The end products are subsequently excreted in various body secretions [15]. In addition, several volatile organic compounds are produced in liver as a result of complex metabolic processes (including lipid peroxidation, dextrose metabolism, and pathways involving cytochrome P450 enzymes). Any disruption in these metabolic pathways and possible oxidative stress can lead to fluctuations in the levels of relevant VOCs [16]. This fact has formed the basis for further studies involving the identification of various VOCs as possible biomarkers for liver diseases.

XSL•FO
RenderX

The UHCW research group conducted a pilot study that provides proof of concept for further research into the role of VOCs in NAFLD. The aim of the study was to determine whether urinary VOCs could distinguish between various stages of fatty liver disease (NAFLD, nonalcoholic steatohepatitis [NASH], and NASH-C) and controls. The results suggested that urinary VOCs can help distinguish between NASH and NAFLD [17].

The analysis of urinary VOCs has a potential role in the screening of HCC. VOCs can be both released and metabolized by HCC cells. A pilot study at UHCW (as part of the TENDENCY project) has used gas chromatography–ion mobility spectrometry and gas chromatography–time-of-flight mass spectrometry to identify significant VOCs associated with HCC and liver fibrosis. The gas chromatography–Ion mass spectrometry data separated patients with HCC from the patients with fibrosis with an area under the receiver operating characteristic curve of 0.97. Seven compounds were identified to be provisionally associated with HCC from the gas chromatography–time-of-flight mass spectrometry data set. The compounds included 4-methyl-2,4-bis (p-hydroxyphenyl)pent-1-ene (2TMS derivative), 2-butanone, 2-hexanone, benzene, 1-ethyl-2-methyl-, 3-butene-1,2-diol, 1-(2-furanyl)-, bicyclo (4.1.0) heptane, 3,7,7-trimethyl-, [1S-(1a,3β,6a)]-, and sulpiride. However, the sample size was small, with 20 HCC and 38 non-HCC cases, and as a result, quantification was not possible [18] (Table 1).

Table 1. Volatile organic compound (VOCs) as potential hepatocellular cancer (HCC) biomarkers [18].

VOC identified during GC-TOF-MS[a]	Change in HCC
4-Methyl-2,4-bis(p-hydroxyphenyl)pent-1-ene,2TMS derivative	Lower
2-Butanone	Higher
2-Hexanone	Lower
Benzene, 1-ethyl-2-methyl-	Lower
3-Butene-1,2-diol, 1-(2-furanyl)-	Lower
Bicyclo[4.1.0]heptane, 3,7,7-trimethyl-, [1S-(1a,3ß,6a)]-	Lower
Sulpiride	Lower

[a]GC-TOF-MS: gas chromatography–time-of-flight mass spectrometry.

Urinary Peptides

Significant alterations in protein expression occur during carcinogenesis. These altered proteins then play an important role in tumor cells proliferation via the modification of signaling and other cellular metabolic pathways. Further characterization of protein alterations has shown a specific association for certain malignancies [19]. Hence, studies are being conducted to evaluate the role of these altered proteins as possible cancer biomarkers.

Several proteomics studies involving capillary electrophoresis coupled to mass-spectrometry (CE-MS) have demonstrated a good diagnostic potential of urinary peptide biomarkers [20]. A pilot study (joint collaboration of the United Kingdom and Germany) has shown that peptides specific to HCC can be identified by urinary CE-MS analysis. This study successfully identified a set of 31 urinary peptides showing an overall sensitivity of 79.5% for HCC. Further validation studies are required on a larger cohort of HCC urine samples [21].

Aims and Objectives

The aim of this study is to investigate the metabolic function in patients with liver disease and to identify the biomarkers in liver disease.

Primary Objectives

Our primary aim was to study the metabolome of patients with cirrhosis, NAFLD, and HCC to identify novel noninvasive diagnostic biomarkers.

Secondary Objectives

We also aimed to achieve the following:

1. Characterize the urinary VOC biological signatures to identify specific chemicals that can be used as biomarkers in HCC.
2. Identify a specific urinary protein biomarker in HCC via CE-MS.
3. Study blood for nuclear markers and compounds that can be used as diagnostic tests in HCC.

Methods

Overview

This is a multicenter case-control study comparing patients with HCC to patients with cirrhosis. Participants in the United Kingdom will be recruited from UHCW, Russells Hall Hospital, New Cross Hospital, and Royal Stoke University Hospital. These hospitals cover the majority of West Midlands and North Midlands in the United Kingdom, providing comprehensive liver services. In addition, participants will also be recruited from Pakistan Kidney and Liver Institute and Research Center.

The participants in this study will require one visit only. Following posting the participant information sheet and a phone call, the participant will be given an option of either attending a specified research clinic or meeting after a routine clinic appointment arranged for their care in UHCW. Urine and blood samples for the study will be collected during that appointment.

For recruitment, we will be identifying positive HCC cases through HCC multidisciplinary team meetings as per the

XSL•FO
RenderX

international guidelines (inclusion criteria will include radiological or histological confirmation) [2,22]. We will recruit our control group of patients with cirrhosis (inclusion criteria comprises radiological or clinical confirmation) via our cirrhotic follow-up clinics.

Patients under the age of 18 years or pregnant or those unable to give consent will be excluded from the study.

Written informed consent will be taken by a member of the research team. Before taking consent, the patient will be given adequate time to read the participant information sheet and will be given the opportunity to ask any questions they may have. Baseline data (as mentioned in Table 2) will be collected upon the recruitment of the participants prior to the collection of samples. Participant flowsheet throughout the study can be seen in Textbox 1.

Table 2. Schedule of events.

Taking blood sample		X	
Taking urine sample		X	X
Collecting relevant clinical data done as part of the standard clinical care		X	

Textbox 1. Participant flowsheet throughout the study.

- Patient screened
- Confirmed patient diagnosis and eligibility
- Postinvitation letter and relevant participant information sheet
- Phone call to confirm if interested in participating
- Patient attends routine appointment or attends dedicated research clinic
- Patient approached by member of research team on the day of recruitment
- Informed consent taken
- Blood and urine sample taken
- If patient was unable to provide urine sample on the day, an option to send it via post will be provided.

Sample Size Calculation

Definitive sample size calculations are difficult as the technologies used are novel with little available literature for comparison. However, we have estimated our sample size based on the preliminary findings of the TENDENCY pilot study conducted from 2019 to 2021.The pilot study conducted at UHCW (as part of TENDENCY) showed the sensitivity and specificity of *mSEPT9* as 89% and 81%, respectively, for detecting HCC in patients with cirrhosis [14]. Based on that, we have estimated our required total sample size using the method used by Buderer [23] to be N=308, with 88 (29%) patients with HCC and 220 (71%) patients with cirrhosis (considering a 10% dropout rate for HCC). The prevalence has been ascertained using cumulative 5-year incidence of HCC as 30% in certain groups of cirrhotic patients [24].

ME = half the 95% CI =0.05

Total sample size = n/prevalence

Storage and Analysis of Samples

After collection, urine specimens will be frozen at –80 °C in the tissue bank for later analysis. Prior to analysis, they will be left to thaw in a laboratory fridge overnight and aliquoted into appropriate sample bottles.

XSL•FO
RenderX

Urinary Volatile Organic Compounds

The detection of the urinary VOCs will consist of sample concentration with a sample containment system, transfer of the VOCs from the air sample to the analytical device with an odor-sampling system, and detection and identification of each VOC with proprietary instrument for analysis. Gas chromatography–Ion mass spectrometry will identify different VOCs. The data generated will then be digitized and processed by computer software and subjected to principal-components analysis to ascertain whether there are differences between the different urine samples.

Urinary Proteomic Analysis

For the proteomic analysis, urine samples will be processed using the CE-MS to help identify proteins specifically linked to HCC. The principal stages involved in the process would include the removal of large molecular proteins, CE-MS analysis, CE-MS data processing, and support vector machine processing and classification.

Plasma Analysis for Methylated Septin 9

Blood samples will be centrifuged at 5000 revolutions per minute for 15 minutes, and at least 1 milliliter plasma will then be decanted in a separate aliquot. The plasma samples will then be frozen at –80 °C until the end of recruitment.

Plasma samples will then be analyzed using real-time polymerase chain reaction with a fluorescent hydrolysis probe for the methylation-specific detection of the *septin 9* DNA target (*mSEPT9*); this automated real-time polymerase chain reaction test is aimed at a qualitative detection.

Study Overview

UHCW is the sponsor for the study and provides indemnity for the study. An authorized representative of the sponsor has approved the final version of this protocol with respect to the study design, conduct, data analysis, interpretation, as well as plans for the publication and dissemination of the results.

Monitoring, Audit, and Inspection

The study will be monitored by the Research & Development department at UHCW as representatives of the sponsor to ensure that the study is being conducted as per protocol, adhering to Research Governance and Good Clinical Practice. The approach to and extent of monitoring will be specified in a study monitoring plan determined by the risk assessment undertaken prior to the start of the study.

Ethics Approval

TENDENCY has been approved by Northeast-York Ethics Committee (aproval number: 19/NE/0213). The Integrated Research Application System (IRAS) number for the study is 260179, and the National Institute for Health and Care Research (NIHR) portfolio ID is 42438. All the investigators will be granted authorship in the final study reports.

Data Protection and Patient Confidentiality

This study will comply with the current data protection regulations, and regular checks and monitoring will be undertaken by the UHCW Research & Development department, National Health Services to ensure compliance. Participants will be assigned a unique identifier upon enrollment into the study to allow link anonymization of patient-identifiable data. Access to patient-identifiable data will be restricted to members of the study coordination team, and electronic data will be stored on password-protected, encrypted drives.

Results

The recruitment stage was completed in March 2023. The TENDENCY study is currently in the analysis stage, which is expected to finish by November 2023. The results from TENDENCY will be published in medical journals and will be of specific interest to clinicians managing chronic liver disease. The results may form the basis for a possible change in the screening pathways for cirrhosis, NAFL disease, and hepatocellular cancer.

Discussion

The lack of more sensitive screening tests for HCC has prompted a search for the novel biomarkers. The noninvasive blood tests and urine tests can serve as an easier and more effective method of the close surveillance of patients at a high risk for liver disease. The findings of the TENDENCY study will provide a basis of formulating better pathways for HCC screening. This is the first large-scale UK multicenter study that incorporates both urinary and plasma biomarker testing for HCC screening. The findings from this study can provide a basis for the development of assays incorporating a combination of biomarkers for enhanced early-stage HCC detection.

Based on the findings of the study, the next step will be to study the plasma *mSEPT9* in posttreatment cohorts to study its prognostic value.

The application of more sensitive plasma and urinary biomarkers for hepatocellular screening in clinical practice could allow us to detect HCC at earlier stages and overall improve the outcomes.

Acknowledgments

We are very grateful to our hepatology colleagues Dr Esther Unitt and Dr Victoria Gordon (University Hospital Coventry & Warwickshire) and Dr Sarah Townsend (New Cross Hospital) for their support. Funding for this study is provided by the Medical Life Sciences Research Fund. The design and management of this study are entirely independent of the funder.

Abstract

Background: Data regarding the kinetics of anti–SARS-CoV-2 antibodies and information about post–COVID-19 condition (colloquially known as “long COVID”) in children are scarce, especially in low-income countries. Even though cases of COVID-19 in children are less prevalent than adults, post–COVID-19 condition cases in children are high and have a burden that may impact their growth and development. There are other features of antibody kinetics in connection with SARS-CoV-2 infection that are yet unknown as of this writing, especially in children following infection. Furthermore, the long-term results, risk factors, and underlying pathophysiology are still uncertain. To better understand post–COVID-19 condition in children, it is necessary to further investigate the impact of clinically significant factors such multisystem inflammatory syndrome and disease severity among hospitalized survivors through their SARS-CoV-2 antibody response.

Objective: We aim to analyze anti–receptor-binding domain SARS-CoV-2 immunoglobulin G antibodies over time and characterize the signs and symptoms of post–COVID-19 condition in pediatric patients at the time of diagnosis and at 2 weeks and 1, 3, and 6 months following infection.

Methods: This is a longitudinal observational study in Indonesia. Pediatric patients diagnosed with COVID-19 by positive molecular assay using nasopharyngeal swab will be tested for anti–SARS-CoV-2 antibodies using the Roche Elecsys Anti-SARS-CoV-2 S assay at the time of diagnosis and at 2 weeks and 1, 3, and 6 months following infection. Antibody titer data will be reported as means and SDs. The respondents’ signs and symptoms will be observed up to 6 months after the onset of infection, including the vaccination event, reinfection, rehospitalization, and mortality. The clinical features will be reported as frequencies and percentages.

Results: Participant enrollment began in February 2022. As of September 30, 2022, a total of 58 patients were enrolled. After data collection, results are expected to be analyzed in August 2023.

Conclusions: This study will allow us to know the kinetics of anti–receptor-binding domain SARS-CoV-2 immunoglobulin G antibodies and data regarding post–COVID-19 condition up to 6 months following infection in the Indonesian pediatric population. Furthermore, this study has the potential to serve as a foundation for government decisions about vaccination programs and prevention measures.

Introduction

COVID-19 is a pneumonia caused by the novel SARS-CoV-2 virus. It was first identified in Wuhan, China, in December 2019; it then spread rapidly across the globe and became an international public health emergency [1,2]. In March 2020, the World Health Organization (WHO) declared COVID-19 a pandemic [2]. SARS-CoV-2 is transmitted directly (droplet or person-to-person transmission through coughing, sneezing, or talking) and indirectly (contaminated objects and airborne) [1].

Data compiled by the WHO in 2021 showed that cases in children younger than 5 years from December 30, 2019, to September 13, 2021, were 1.8% of the world's cases [3]. Meanwhile, cases of COVID-19 at the age of 5-14 years were 6.3% of the world's cases. Older children (15-24 years) had more cases, which accounted for 14.5% of the world's total cases. The American Academy of Pediatrics in 2022 stated that the total number of cases in children were 18.5% of the total COVID-19 cases in the world [4]. In Indonesia, there were 77,254 children who were positive for COVID-19 until December 21, 2020, accounting for 11.5% of all positive cases in Indonesia [5].

To date, there are many aspects that remain unknown about the antibody kinetics related to SARS-CoV-2 infection, especially in children. Understanding the kinetics of humoral response in the pediatric population could help to develop more effective vaccination programs in children [6,7].

The spike protein of SARS-CoV-2 contains a receptor-binding domain (RBD) that mediates the entry into human cells by binding to the angiotensin-converting enzyme 2 (ACE-2) receptor [8]. A positive correlation between anti-RBD immunoglobulin G (IgG) antibody levels and neutralizing antibodies has been described [9]. However, data on children are still inconsistent. Some studies described a persistence in neutralizing antibodies over a period of up to 8 months and reported that younger children have a higher titer compared to older siblings or adults [10,11]. In contrast, another study described higher anti–spike protein IgG antibody levels at younger ages, without high levels of neutralizing activity [12].

Around 15% to 24% of children with COVID-19 are asymptomatic. The symptoms of COVID-19 that most often appear in children are fever and cough [13]. Some respiratory symptoms that rarely appear in children include nasal congestion, sore throat, and dyspnea [14]. Other symptoms, such as headache, fatigue or myalgia, diarrhea, and vomiting, only occur in less than 10% to 20% of children [13].

Generally, the symptoms appear for approximately 6 days in children aged 5-17 years. Some of these symptoms can appear longer, whereas 4.4% of symptoms persist up to 4 weeks and 1.8% of symptoms are still present up to 8 weeks [15]. "Long COVID," "post-COVID syndrome," or "post-acute sequel of SARS-CoV-2 (PASC)" are terms that are often used to describe symptoms that persist around 4-12 weeks after being infected [16]. Other literature defines post–COVID-19 condition as new symptoms that appear and persist about 8 weeks after being infected with SARS-CoV-2 [17]. The prevalence of post–COVID-19 condition in children is different in each study, ranging from 4% to 66% [18]. The most common symptoms of post–COVID-19 condition are cognitive difficulties, headache, fatigue, fever, myalgia, cough, dyspnea, abdominal pain, diarrhea, and anosmia or altered sense of smell [16]. Different symptoms and severity are associated with different immune responses. Many aspects of the immune response in children are still unclear due to limited research in this population [12]. Accordingly, in this study, we aim to examine anti-RBD IgG antibodies over time and characterize the signs and symptoms of post–COVID-19 condition in pediatric patients at the time of diagnosis and at 2 weeks and 1, 3, and 6 months following infection.

Methods

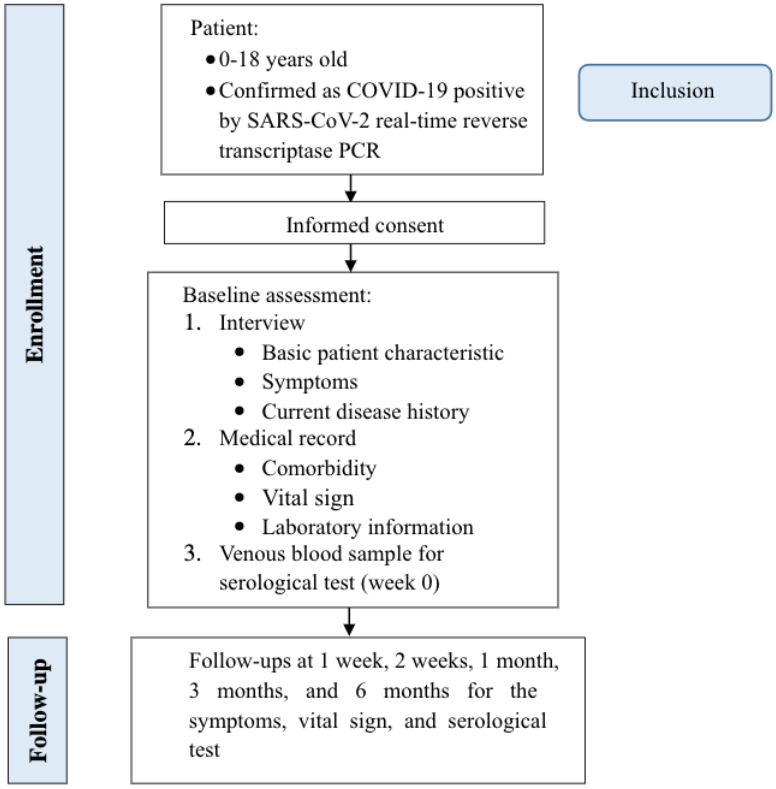
Study Design

This study is a single-center, longitudinal observational study. Pediatric patients diagnosed with COVID-19 confirmed by molecular assay using nasopharyngeal swab will be recruited. The patients will be tested at the time of diagnosis and at 2 weeks and 1, 3, and 6 months after diagnosis to observe the kinetics of anti–SARS-CoV-2 antibodies. The Roche Elecsys Anti-SARS-CoV-2 S assay will be used to quantify the immunoglobulin M (IgM)/IgG–spike protein–RBD titer. We will also observe the signs and symptoms of the patients up to 6 months after infection to identify the sequelae of the post–COVID-19 condition cases.

Study Setting

The study is being conducted in Dr Sardjito General Hospital, Sleman District, Yogyakarta Province, Indonesia. This is a tertiary referral hospital for Yogyakarta, Southern Central Java, and Eastern Indonesia regions.

Sample Size



Samples were obtained by the total sampling method. We included all pediatric patients who met the inclusion criteria from February to April 2022.

Participants

Patients will be observed prospectively after a confirmed diagnosis of COVID-19 in isolation wards at Dr Sardjito General Hospital. The inclusion criteria for this study are all patients aged 0-18 years who are confirmed as COVID-19 positive by SARS-CoV-2 real-time reverse transcriptase polymerase chain reaction (RT-PCR) with their legal guardian's agreement to participate (Figure 1). There are no exclusion criteria for this study.

XSL•FO
RenderX

Figure 1. Study flowchart of inclusion criteria and data collection. PCR: polymerase chain reaction.

Data Collection

Patient data will be retrieved from their medical records, which will include: (1) basic patient characteristic such as date of birth, sex, age, address, and referral case; (2) current disease history (symptoms, travel history, contact history in past 14 days, COVID-19 vaccination status, history of treatment in previous health facilities, and laboratory and imaging examination in previous health facilities); (3) comorbidity (diabetes; cancer; hypertension; obesity; heart disease; chronic obstructive pulmonary disease; chronic liver disease; chronic kidney disease; autoimmune disease; HIV; other infectious comorbidities such as hepatitis B and C, malaria, and dengue; and other immunodeficiencies such as long term steroid use and pelvic inflammatory disease); (4) vital signs and anthropometric parameters; (5) laboratory information (SARS-CoV-2 RT-PCR of the nasopharyngeal or oropharyngeal swab; complete blood count; electrolyte; blood glucose; ferritin; C-reactive protein; procalcitonin; lactate dehydrogenase; liver transaminases; serum blood urine nitrogen and creatinine; prothrombin time and activated partial thromboplastin time; D-dimer; lactate; blood gas analysis; cerebrospinal liquor examination; blood culture; broncho-alveolar liquid culture; and chest X-ray, computerized tomography scan, magnetic resonance imaging, or other imaging examination); and (6) clinical management data (drugs, intravenous fluid, supplements, oxygenation, blood transfusion, ventilator support, and other intensive care support).

Venous blood samples for serological tests will be drawn as a baseline when the diagnosis is made. Further serial blood samples will be collected at 2 weeks and 1, 3, and 6 months after the diagnosis (Figure 1). Samples will be collected in the clinical pathology laboratory. The data of any resolution or persistence of symptoms, such as fever, cough, runny nose, dyspnea, sore throat, seizure, cephalgia, malaise, nausea, vomitus, diarrhea, abdominal pain, myalgia, the loss of taste, the loss of smell, and dermatological disorder, in addition to patients' vital signs, travel history, contact history, compliance with health protocols, any possible COVID-19 reinfection, COVID-19 vaccination status, therapy, and blood test result, will be recorded in each subsequent monitoring time point. A flowchart of the inclusion criteria and data collection of this study is shown in Figure 1.

Blood Samples Collection and Storage

Samples will be collected in a vacutainer and sent to the pathology clinic laboratory for testing. The protocol is to proceed to centrifugation at 4000 rpm for 10 minutes. The samples will be uniquely coded and stored at –80 °C until use.

The Roche Elecsys Anti-SARS-CoV-2 S Assay

The Roche Elecsys Anti-SARS-CoV-2 S assay is an immunoassay for the in vitro quantitative determination of total antibodies to the SARS-CoV-2 spike protein RBD in human serum and plasma. The test is intended as an aid to assess the adaptive humoral immune response, including neutralizing antibodies to the SARS-CoV-2 spike protein after natural infection with SARS-CoV-2 or in vaccine recipients. The assay is run on a Cobas e 411 analyzer, which utilizes an electrochemiluminescence immunoassay with the double-antigen sandwich principle. Calibration and quality control will always be performed before running the samples. The values obtained should fall within the defined limits. The analyzer automatically calculates the analyte concentration of each sample in U/mL with value ≥0.80 U/mL as a cut-off for positive anti–SARS-CoV-2 spike protein [19].

XSL•FO
RenderX

Data Management Plan

All data are collected in an application-based data collection tool. Data will be stored on self-managed servers and only can be accessed by authorized research personnel.

Data and Statistical Analyses

We will observe the kinetics of antibody response to the RBD of the spike protein of SARS-CoV-2 and the persistent signs and symptoms up to 6 months after the onset of infection.

Antibody titer data will be reported as means and SDs at baseline (when the diagnosis is made) and each monitoring time point (2 weeks and 1, 3, and 6 months after diagnosis).

The acute infection symptoms and post–COVID-19 follow-up clinical features will be reported in frequencies and percentages. The comparison of patient groups stratified by disease severity and RBD antibody will be analyzed and presented by graphs at the 1, 3, and 6-month follow-up time points.

Ethics Approval

This study was reviewed and approved by the Medical and Health Research Ethics Committee, Faculty of Medicine, Public Health, and Nursing, Universitas Gadjah Mada (KE/FK/1288/EC/2021). The legal guardian of all participants will be provided with an information sheet detailing the aim and rationale for the research; inclusion and exclusion criteria; what will happen if they agree to take part; any risks of taking part in the study; the clarification of the process for ensuring anonymity and confidentiality, including any limits to confidentiality; what information will be held about them and who will have access to it; possible benefits; and plans for project report. All the legal guardians of the participants will then be required to sign the informed consent form before participating in the study. Additionally, all participants' identifiable data will first be anonymized. The identifiable and anonymized data will be stored in separate secure cloud-based databases before being transferred to the Research Data Store. Finally, each participant will be compensated Rp 50.000,00 (US $3.37) at each monitoring time point.

Results

Participant enrollment started in February and was extended to April 2022. The data collection was conducted up to 6 months following the last participant enrolled. As of September 30, 2022, a total of 58 patients were enrolled. After data collection, results are expected to be analyzed in August 2023.

Discussion

Expected Findings

This study aims to observe the kinetics of anti–SARS-CoV-2 antibodies and post–COVID-19 condition in children, up to 6 months after SARS-CoV-2 infection. SARS-CoV-2 consists of 4 main structural proteins, namely small envelope glycoprotein, membrane glycoprotein, nucleocapsid protein, and spike glycoprotein. The spike glycoprotein is divided into 2 subunits, S1 and S2. The S1 subunit includes RBDs that mediate viral binding to host cells via the ACE-2 receptor. Antibodies formed against the RBD on the S1 subunit have the potential to neutralize SARS-CoV-2 by preventing the binding of the virus' ACE-2 receptor and endocytosis [20].

It takes 18 days from RT-PCR positivity to seropositivity (ie, antibody detection) [21]. Antibodies are detectable by the end of the first week in most patients, but progression can take weeks in patients with subclinical or mild infections. SARS-CoV-2 antibodies can be used to detect the presence of COVID-19 infection 1-3 weeks after the disease onset. In the acute phase, IgM peaks around 2-5 weeks following disease onset and then declines in 3-5 weeks before being undetectable. The immunoglobulin A anti-S1 antibodies decreased 1 month after diagnosis and remained detectable thereafter. The IgG peaks later, around 3-7 weeks following disease onset, and then persists for at least 6-8 weeks. Survivors with more severe symptoms show a stronger antibody response than asymptomatic and symptomatic survivors, in which IgM, IgG, and immunoglobulin A were found at higher titers and last longer in the body [22].

Post–COVID-19 condition is a condition where the symptoms of COVID-19 persist for a few weeks or months after SARS-CoV-2 infection [23]. Symptom usually persist around 4-12 weeks after being infected with COVID-19 [16,24]. The common symptoms are fever, fatigue, dyspnea, and myalgia [25]. Other symptoms that are present include chest pain, paresthesia, headache, hair loss, anosmia-ageusia or parosmia/anosmia, gastrointestinal symptoms, dizziness, weight loss of more than 5% of body weight, arthralgia, tremor, cough, palpitations, tiredness, difficulty concentrating, and increased need for sleep [25,26].

Older age and the presence of allergies are associated with higher risk of persistent symptoms after being infected with COVID-19. Those aged 6-18 years have a 3 times higher risk of persistent symptoms compared to children aged <2 years [27]. Children with allergies have a 2-3 times higher risk of persistent symptoms [27,28]. Patients with preexisting neurological comorbidities are also associated with persistent symptoms and have a 4 times higher risk of persistent symptoms after COVID-19 infection [28].

Research related to SARS-CoV-2 antibody kinetics in children is limited, and studies concerning the post–COVID-19 condition cases are scarce. It is important to conduct more research to determine children's antibody response to SARS-CoV-2 infection and post–COVID-19 condition symptoms as the basis for patient management and forthcoming policy formulation.

This study will have recruitment and retention obstacles because it is difficult to get parental consent for serial blood sampling for children. This study will observe the development of post–COVID-19 condition symptoms and the kinetics of the COVID-19 antibodies for up to 6 months, making compliance from respondents and their families particularly important.

Conclusions

At the completion of this study, we will be able to learn more about the dynamics of anti-RBD SARS-CoV-2 IgG antibodies and gain valuable information concerning post–COVID-19 condition in children in Indonesia for up to 6 months following

XSL•FO

infection. Additionally, this research may serve as a foundation for government decisions about vaccination programs and prevention measures.

Acknowledgments

This research is fully funded by the Dr Sardjito General Hospital (grant HK.02.03/XI.2/42760/2021). We also acknowledge Inggar Armytasari and the other staff of Dr Sardjito General Hospital for the support. The funders had no role in the data collection, data analysis, writing of the manuscript, or in the decision to publish the manuscript.

Abstract

Background: Research indicates that risky play benefits children's risk assessment and risk management skills and offers several positive health effects such as resilience, social skills, physical activity, well-being, and involvement. There are also indications that the lack of risky play and autonomy increases the likelihood of anxiety. Despite its well-documented importance, and the willingness of children to engage in risky play, this type of play is increasingly restricted. Assessing long-term effects of risky play has been problematic because of ethical issues with conducting studies designed to allow or encourage children to take physical risks with the potential of injury.

Objective: The Virtual Risk Management project aims to examine children's development of risk management skills through risky play. To accomplish this, the project aims to use and validate newly developed and ethically appropriate data collection tools such as virtual reality, eye tracking, and motion capturing, and to provide insight into how children assess and handle risk situations and how children's past risky play experiences are associated with their risk management.

Methods: We will recruit 500 children aged 7-10 years and their parents from primary schools in Norway. Children's risk management will be measured through data concerning their risk assessment, risk willingness, and risk handling when completing a number of tasks in 3 categories of virtual reality scenarios: street crossing, river crossing, and playing on playground equipment. The children will move around physically in a large space while conducting the tasks and wear 17 motion-capturing sensors that will measure their movements to analyze motor skills. We will also collect data on children's perceived motor competence and their sensation-seeking personality. To obtain data on children's risk experiences, parents will complete questionnaires on their parental style and risk tolerance, as well as information about the child's practical risk experience.

Results: Four schools have been recruited to participate in data collection. The recruitment of children and parents for this study started in December 2022, and as of April 2023, a total of 433 parents have consented for their children to participate.

XSL•FO
RenderX

Conclusions: The Virtual Risk Management project will increase our understanding of how children's characteristics, upbringing, and previous experiences influence their learning and ability to handle challenges. Through development and use of cutting-edge technology and previously developed measures to describe aspects of the children's past experiences, this project addresses crucial topics related to children's health and development. Such knowledge may guide pedagogical questions and the development of educational, injury prevention, and other health-related interventions, and reveal essential areas for focus in future studies. It may also impact how risk is addressed in crucial societal institutions such as the family, early childhood education, and schools.

Introduction

Background

How children learn to handle risk and avoid injuries is poorly understood by researchers. Injuries remain the leading cause of child death and a leading cause of hospitalization in high-income nations despite widespread prevention efforts. Among the leading mechanisms of injury are motor vehicle crashes (being a passenger in a car) [1] and falls (eg, from high playground equipment) [2]. Drowning, pedestrian, and cycling injuries also represent threats of serious injury and death [3]. Improved car safety has resulted in significant improvements in injury rates, but injury prevention efforts must be multifaceted, addressing the physical environment and individual risk factors [4]. One novel and promising approach to child injury prevention may be through improving children's own ability to assess risk. In this regard, *play* appears to be an ideal context for children's learning, as the pretend or nonliteral aspect allows the players to test out risky behavior, situations, or actions without the severe consequences of real life. *Risky play* has therefore emerged as a topic of interest for researchers, parents, teachers, policy makers, authorities, and others working with children over the last 20 years. A growing body of research investigates various aspects of risk-taking, including playful activities, and indicates that the concept reflects a basic aspect of human life.

The link between childhood risky play experiences and subsequent ability to cope with hazards of everyday life warrants investigation. A common definition of risky play is "thrilling and exciting forms of physical play that involve uncertainty and a risk of physical injury" [5]. Through observations and interviews with children and early childhood education and care (ECEC) staff, Kleppe et al [6] and Sandseter et al [7,8] identified eight categories of risky play: (1) play with great heights, (2) play with high speed, (3) play with dangerous tools, (4) play near dangerous elements, (5) rough-and-tumble play, (6) play where children go exploring alone, (7) play with impact, and (8) vicarious risk.

Qualitative studies suggest that children develop skills and learn to cope with risk through risky play that translates to real life and is retained for a lifetime [9-14]. Engagement in risk-taking activities leads to brain development, for example, and enhances the ability of 18- to 19-year-olds to predict outcomes, supporting the hypothesis that children and youth will learn risk assessment through risk experiences [15,16]. Moreover, there are indications that risky play in early childhood has a positive impact on the development of children's own risk management skills [11,17]. Researchers also suggest that the ability to handle risk is a favorable evolutionary trait [18] and that outdoor risky play offers several positive health effects for children such as resilience, social skills, physical activity, well-being, and involvement [19,20]. In addition, there are indications that the lack of risky play and autonomy increases the likelihood of anxiety, both in childhood [21-24] and subsequently in adolescence and adulthood [18,25-29].

Children's affective, cognitive, perceptual, and motor systems are all involved in children's behavior and activities in an integrated manner. Children's motor competence, including their capacity to execute fundamental motor skills as well as their perceived motor competence, therefore, impacts and is most likely reciprocally impacted by healthy risk-taking. Possessing high perceived or actual motor competence allows children to engage in different interactions with risky environments and tasks compared with children who possess lower perceived or actual motor competence because perception and action are intertwined processes occurring between the individual, the task, and the environment [30,31].

Despite its well-documented importance and the willingness of children to engage in risky play [5,6,32,33], there are indications that this type of play is increasingly restricted [34-37]. ECEC institutions restrict risky play because they fear being sued in case of child injury and they receive pressure from the insurance industry to avoid any injuries [32,35,36,38,39]. Moreover, parents restrict children from playing outdoors because they are concerned about traffic accidents [39-43], that children could be injured or kidnapped, or because they fear rainy or cold weather [39]. When children are prohibited from risky play through overprotection, there may be negative effects on their development.

The downward trend in children's opportunities for risk-taking in play [44,45] may also have wider negative consequences. First, an increased focus on safety has resulted not only in greater restrictions on children's movement but also less challenging and engaging play environments [35-37,46-50]. Second, there is concern that lack of play opportunities may

XSL•FO
RenderX

result in negative long-term consequences such as reduced well-being and excessive or unhealthy risk-taking (eg, through risky substance use or sexual behavior).

As evidence accumulates concerning the benefits of risky play, both researchers and policy makers have begun to recognize the limitations of our current knowledge. Most existing data are based on descriptive studies and fail to offer rigorous data to address potential causal relationships between risky play and benefits to children's health, development, and learning. The field hypothesizes that engagement in risky play in childhood may reduce the likelihood of subsequent anxiety, faulty decision-making, and excessive risk-taking later in life. However, those hypotheses are generally based on data from small samples and frequently lack the rigor of longitudinal designs, randomization, and control groups.

One reason for the sparsity of rigorous data is that the hypotheses are difficult to test empirically. There are obvious ethical issues with conducting studies designed to allow or encourage children to take physical risks with the potential of injury. There are also ethical barriers to restricting children from playing freely or to randomly assigning some children to play freely and others not. Thus, assessing the long-term effects of play choices is problematic. Creative methodologies such as Kretch and Adolph's [51] and Adolph and Kretch's [52] experiments with the visual cliff (ie, allowing children to cross narrow bridges without the real possibility of falling) or Morgan et al's [53] laboratory-based activity room to assess behavior should be further developed, perhaps leveraging virtual reality (VR) technology [54,55] as a promising methodology. However, transferability of results from laboratory or other controlled environments to real-life contexts poses a potentially inappropriate leap [56]. There is a need to continue to develop VR, augmented reality, and other technologies to simulate real-life settings and strengthen ecological validity of research methods. Using VR or augmented reality enables researchers to test situations that would be too dangerous to investigate in real life. Adding measurements of bodily movement and eye-tracking equipment, mostly absent in the field, would contribute detailed data on children's reactions to stimuli in their environments. Understanding connections between risk experiences and risk management is central to understanding how risky play affects overall health and development.

In the Virtual Risk Management—Exploring Effects of Childhood Risk Experiences through Innovative Methods (ViRMa) project, risk is defined as future uncertainties that can entail negative or positive outcomes [44]. Further, risk is seen as both objective and subjective [57,58]. *Objective* risk refers to an estimation of the probability of an adverse event and of the expected harm or loss. The ways in which objective factors are experienced as risky depend on the individuals and are referred to as *subjective risk*. Both personality and temperament traits as well as cognition [59-62] and previous experience [57,63] affect an individual's subjective risk experiences and decisions. Risk decisions can be interpreted as representing a balance between an individual's propensity to take risks, the potential rewards of risk-taking, the perceived *danger* in the situation, and *previous experience* with injuries or losses [57].

In the ViRMa project, we aim to explore risks that are relevant to children's everyday life and that they can at least partly control themselves. These are risks where children's dynamic choices and actions matter. To capture this and to develop scientific measures, we have developed a conceptual framework (in process to be published in a theoretical paper) to describe the dynamic process through which children manage risks, a framework that captures how the child acts in an environment with potential for risk and where their risk willingness (ie, the emotional drive to seek and take risk, overlapping conceptually with sensation seeking and risk seeking), risk assessments (ie, the cognitive process of evaluating risk throughout a risk situation), and risk handling (the behavioral or motor process of managing a risk) can be observed through their actions and behaviors. Overall, children's dynamic risk management therefore represents the outcome of a defined task or the observable outcome of whether they fail or succeed in the risk situation.

Study Objectives

The aim of the overall ViRMa project is to develop, test, and validate ethically appropriate, technologically innovative, and easy-to-use methods to explore the relationship between children's risk experiences through play and daily activities and their risk management skills. We introduce methods that to our knowledge did not exist before ViRMa. Thus, the project focuses especially on method development and exploration concerning whether the methods are useful and valid to measure the relationships of interest.

This paper describes the protocol of the third stage in the ViRMa project. Stages 1 and 2 had the following aims: (1) develop VR, eye-tracking, and motion-capturing tools and software, plus psychometric scales and additional data collection methods to provide insight into how children assess and handle risk situations using ethical study designs; (2) conduct a small-scale pilot study to test the feasibility of the research methods, particularly the developed VR scenarios, the eye-tracking technology, and the motion capture system.

In the presently reported final stage, the tools and methods developed in stages 1 and 2 will be used for large-scale data collection. The aim of stage 3 is twofold: (1) establish measures for children's risk management, suggestively split into risk willingness, risk assessment, and risk handling through the VR, eye-tracking, and motion-capturing data, as well as validating the questionnaires to a Norwegian context, and (2) explore how children's past risk experiences through play and daily activities (collected through parent questionnaires) are associated with their risk management.

In this trial, we are measuring associations between behaviors in VR with demographics as a first step to validate the methods and explore relationships between children's risk experiences, their motor skills, and their risk management skills. If we succeed with the stage 3 ViRMa project, the long-term goal for the project group is to further develop a large-scale project with children and parents from different countries and cultural contexts, preferably with longitudinal data collection. This would enable both comparative analysis across cultures and longitudinal data on how children's motor skills and risk

XSL•FO
RenderX

management skills develop over time in accordance with their opportunities for risk experiences.

Methods

Study Design

This study is a quantitative cross-sectional study of children's risk management in VR scenarios, measuring their risk willingness, risk assessment skills, and risk handling skills as well as their motor skills. Cross-sectional data on children's self-perceived motor skills and sensation seeking personality will also be collected. In addition, the study has a retrospective component that gathers extensive data from parents' questionnaires concerning the children's background experiences: parenting styles, parental risk tolerance, and children's practical risk experience from childhood. Analyses will explore associations between cross-sectional data and retrospective data.

Participants and Eligibility Criteria

We aim to recruit 500 children (50% girls and 50% boys) in second to fourth grade (7- to 10-year-old). This age group was chosen because we want to not only explore risk management skills among children as early in child development as possible but also consider practical matters such as the appropriate age to use current generations of VR goggles given their large size, weight, and functionality. VR technology develops rapidly, and studies involving even younger children would be an aim in the future. Further, children aged 7 to 10 years are likely familiar with navigating traffic and nature environments, while also remaining interested in exploring a playground, which reflects the tasks in the VR scenarios in this study. This is also an age group when children are more likely to behave independently and outside adult supervision, creating greater injury risk.

We aim to recruit children from both urban and rural primary schools in Norway because children in rural areas usually spend more time playing and being active in nature environments than children living in urban areas. The pilot study demonstrated that VR is a popular data collection method among children. To avoid excluding any children from a particular setting, we will select 4 primary schools from different parts of Norway and invite all children in the relevant age range at each school to participate. Inclusion criteria are as follows:

- Between the ages of 7 and 10 years (grades 2, 3, and 4 in Norwegian schools)
- Informed consent obtained from parents to participate
- Assent obtained from the child to participate.

We will contact selected schools through the principal and ask if they are willing to participate. If they agree, parents will then be contacted through the school's web-based information system, with information about the project and an electronic consent form provided. Children whose parents provide consent will then be placed on a participant list and names will be replaced with a random code. Children will also be asked for assent to participate, and if they decline, their name and code will be deleted.

Parents (both mothers and fathers) of children will be invited to complete the web-based survey.

Data Collection and Measures

VR

VR technology encompasses computer technology enabled by, in this case, head-mounted displays (goggles) in which one experiences and physically moves around in scenarios that closely represent real life. Participants will be fully immersed in the virtual environment, providing visual and auditory stimuli to create illusive feelings of physically existing in that environment [64]. VR technology is an innovative and successful strategy for training and research on health and safety behavior among both adults [64,65] and children, with a large body of child research focused on street-crossing [54,55,66,67] and bicycling tasks [68,69]. In this study, we use VR technology (HTC Vive Pro Eye VR headset), with 4 SteamVR 2.0 Base Stations defining a VR area of 6 × 7 m for free movement, to test how children manage different kinds of risk situations.

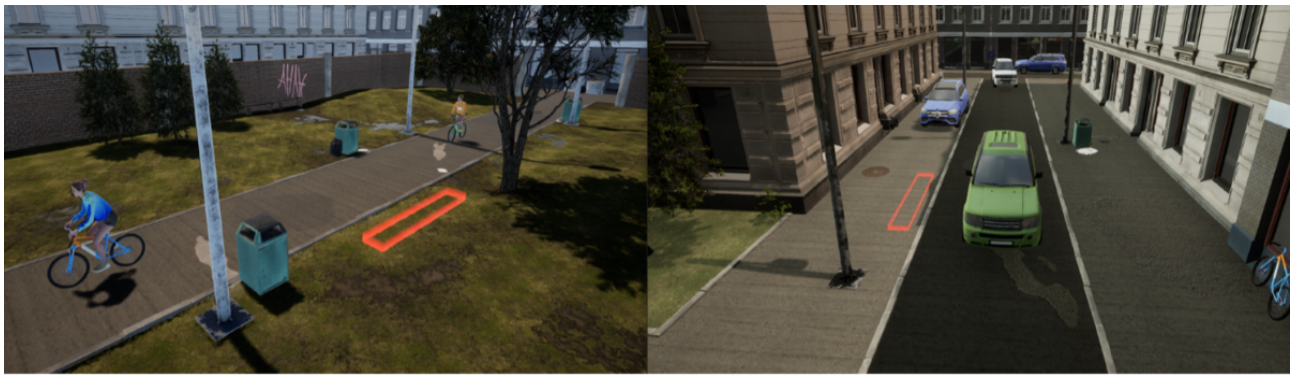
On the basis of research into common causes of injury among children [1-3], we developed three categories of VR risk scenarios: (1) street crossing, (2) crossing a river, and (3) Balancing on high playground equipment. All scenarios include various tasks with increasing levels of difficulty and risk.

The VR scenarios were developed through collaboration between the research group and a VR design company (Nordic Neurotech AS) from September 2021 to March 2022. The aim was to create fully immersive scenarios in a virtual world where children performed risky tasks and judged the experience to be as similar to reality as possible. The veracity of the VR scenarios is strengthened through realistic sounds integrated in the VR goggle headphones (eg, city sounds, car sounds, birdsongs, and sounds of running water). In all VR scenarios, children receive the same prerecorded messages before each task, telling them what to do (eg, "Cross the river without falling down").

The VR software provides data output in the form of a text file (.txt), with one line for each recorded hertz. Within each line, the position of the headset and the 5 Vive trackers are provided using the x, y, and z coordinates. Data on the headset and tracker's rotation are also available in the data set. Similarly, the position of every simulated moving object (cars and bicycles) is represented with coordinates. Quantitative data from this text file are obtained through MATLAB analysis.

Street Crossing

The street crossing scenario consists of 2 urban traffic environments. In both environments, children are exposed to 3 different tasks with varying levels of risk, with risk level varied by manipulating harm severity and probability of being hit [70,71]. The lowest risk scenario involves bicycles and the highest involves both cars and bicycles. Probability risk is adjusted through traffic density and speed and by including traffic from 1 direction versus 2 directions. The first environment represents a bicycle pathway and includes buildings, trees, and grass surfaces (Figure 1, left side). The second environment replicates a busy urban street with buildings, sidewalks, and parked cars (Figure 1, right side); it



XSL•FO
RenderX

includes a cars-only task as well as tasks with both cars and bicycles. In all cases, the child's goal is to cross the path or street without getting struck by a car or bicycle. All street-crossing scenarios incorporate realistic sounds from the urban environment (the sound of cars, bikes, people, etc).

If the child is hit by a bike or car, a new trial on that same task is provided. If the child is hit a second time, the VR continues to the next task. The time to complete tasks in the street-crossing scenario will vary across children because they will be free to take the time they need, both to assess the situation before acting and to perform the crossing. Pilot research found that children spent on average 3 minutes to complete the street-crossing tasks (Figure 1, left and right side).

Quantitative data points that will be obtained from the street-crossing tasks include measures related to the child's risk assessment (eg, time used to assess the environment before crossing the street and fixation on vehicles before crossing the street), risk willingness (eg, distance to vehicles when starting to cross the street), risk handling (eg, speed of crossing, running, acceleration, and deceleration), and risk management outcomes (eg, number of times the child was hit or almost hit by vehicles).

Figure 1. Screenshots of the virtual bicycle pathway environment and the virtual street environment. The red square represents the point where children are asked to move to.

River Crossing

The river-crossing scenario presents a rural environment with a flowing river. Children complete 7 tasks, each with the goal of crossing the river without falling into the water. Five of the tasks involve balancing on planks to cross the river, whereas in the other 2 tasks children must step or jump between elevated stones to cross. Similar to the street-crossing scenario, the 7 river-crossing tasks vary in risk, based on harm severity and probability of failure [70,71]. Harm severity risk levels are manipulated by the speed and depth of the river and the presence of rocks in the water. Probability risk is adjusted by the width (between 8 and 38 cm) of the balance planks and the placement of stepping stones (ie, how close or far they are from each other). In all river-crossing scenarios, children hear sounds from a rural nature environment (eg, the sound of running water, wind, and birds).

If the child falls into the water, a new trial on that same task is provided. If the child falls a second time, the VR continues to the next task. The time required to complete the river-crossing scenario tasks will vary between children because they are free to take the time they need, both to assess the situation before acting and to perform the crossing. Pilot research found that children spent on average 3 minutes to complete the river-crossing tasks (Figure 2).

Quantitative data points that will be obtained in the river-crossing tasks include measures related to the child's risk assessment (eg, time used to assess the environment before crossing the river), risk willingness (eg, opting out of the task, jumping between rocks, and choosing the narrow plank), risk handling (eg, speed of crossing, keeping both feet on the ground while balancing, acceleration, and deceleration), and risk management outcomes (eg, number of times the child falls into the river).

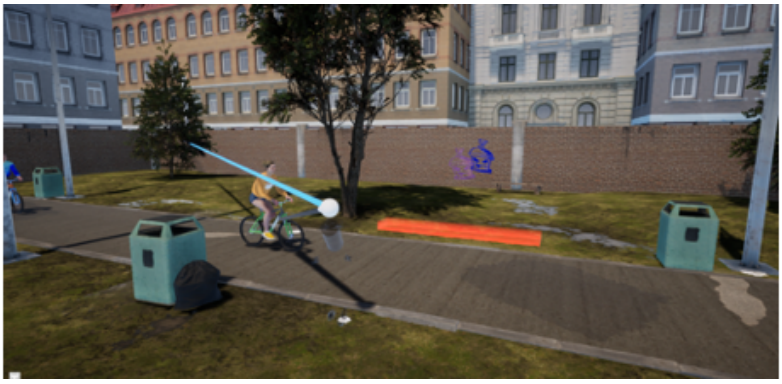
Figure 2. Screenshots of the river crossing scenario, one of the plank tasks and one of the stepping stones task.

XSL•FO
RenderX

Playground

The playground scenario presents a balancing play structure in an urban playground environment. Unlike the first 2 scenarios, where children perceive a fixed and objective task to cross the street or river, in the playground scenario, children are free to move and play as they like, without fixed objectives or goals. The virtual balancing structure comprises a complex pattern of balance beams of varying widths, vertical pillars of varying diameters, and 4 different height zones above the ground surface. Similar to the first 2 scenarios, variation in harm severity and probability of failure occur within the playground scenario. Probability risk varies by the difficulty of the play areas (ie, a child could choose to balance on the narrowest beams or jump out to one of the pillars), whereas harm severity varies by the height zones children choose to explore. In the study, children are provided 3 minutes to explore the playground before the scenario automatically ends. If a child falls off the playground equipment, he or she will enter the starting point of the playground task and have the opportunity to further play and explore during the remaining time in the 3-minute period. The sounds of an urban environment (eg, cars, bikes, or people) are emitted through the headphones (Figure 3).

Figure 3. Screen shot of the playground scenario.



Quantitative data points that will be obtained during the playground task include measures related to the child's risk assessment (eg, time used before starting to balance on a beam), risk willingness (eg, stepping out on pillars, jumping over gaps, and time spent in high-risk zones), risk handling (eg, speed of balancing, keeping both feet on the ground while balancing, acceleration, or deceleration), and risk management outcomes (eg, number of times the child falls off the playground equipment).

Eye Tracking

Eye-tracking technology is used extensively in research to explore topics such as how humans learn [72] and how humans use their gaze when performing safety practices [73], as well as for medical training (eg, in laparoscopic surgery or when detecting anatomical injuries) [74]. The technology is also used to measure how children's eye movements are related to their performance, risk, and safety behavior when cycling [69]. In street-crossing VR tasks, eye-tracking data from one study demonstrated that children's ability to focus on factors most salient for a safe crossing is compromised when the environment is more visually loaded, possibly causing them to miss critical information [75]. However, knowledge about the relationships between children's eye movements and their risk management is limited.

In this study, we will use eye-tracking technology (Tobii Pro) integrated in the VR goggles to explore how children use their gaze and eye movements to identify risk factors that guide their navigation, bodily movement, and risk decisions in the VR scenario environments. Eye-tracking data will be logged in 90 Hz and provide data on the eye-tracking target (x, y, and z coordinates), including what object the child looks at. Because this information is provided continuously with a refresh rate of 90 Hz, it can be transformed into variables describing the length of time children look at various objects or parts of the environment, direction, and shifts of the child's focus and information about how children follow moving objects such as vehicles with their eyes (Figure 4).

Figure 4. Screen shot from the bicycle path scenario, showing eye-tracking as a blue line.

XSL•FO
RenderX

The eye-tracking data from all VR tasks will be processed in MATLAB to generate quantitative measures related to the child's risk assessment (eg, fixation on vehicles before crossing the street, looking at oncoming or departing bicycles and cars before crossing, looking both ways before crossing the street, looking at planks and balance beams before and while crossing, looking at water and rocks, and looking at the ground below the playground equipment) and risk handling (eg, looking at oncoming bicycles and cars while crossing).

Motion Capturing and Analysis

Part of the innovative approach of this project is assessing children's motor competence when they navigate and explore VR scenarios. We will accomplish this through whole-body motion capture, which offers a comprehensive understanding of the individual's qualitative and quantitative signatures of movement. This methodology represents a novel approach toward the assessment and understanding of motor competence in children, extending current and predominant approaches that focus on tasks with down-scaled complexity, detailed instructions, and highly specific assessment criteria. Existing approaches have been critiqued for their lack of developmental and ecological validity [76].

The Xsens MTw Awinda system of motion-capturing technology is an innovative and user-friendly method to track human motion in real time. The portable system provides accurate time-synchronized data with accurate measures of whole-body movements. It has been used widely in research to capture human motion in sport, physical activity, and rehabilitation [77-80]. In this project, MTw Awinda is used to track and capture children's motion and bodily movements when handling risk in VR scenarios.

The Xsens MTw Awinda system consists of 17 wireless inertial measurement units, each of which consists of a gyroscope, an accelerometer, and a magnetometer. MTw Awinda samples data at 60 Hz through a proprietary radio protocol at 2.4 GHz, which provides accurate time synchronization across the wireless network within 10 µs. Physically, the inertial measurement units are 47 × 30 × 13 mm, weigh 16 g, and are attached to the children with Velcro straps on the following anatomical locations: forehead, sternum, palmar side of the hand (right or left), lateral side of the upper arm (right or left), wrist (right or left), lateral side of the lower leg (right or left), lateral thigh (right or left), foot (right or left), upper part of the scapula (right or left), and lower back (L5, height of the iliac spine). The system provides 3D kinematical data (position, velocity, acceleration, and orientation) on the movement of 23 different segments (eg, head, upper hand, or foot) as well as angular movements of 22 different joints. The dynamic accuracy is 0.75° root-mean-square (RMS) and 1.5° RMS for roll or pitch and heading, respectively. In the ViRMa project, children will wear the Xsens MTw Awinda sensors while completing all VR tasks.

The raw Xsens data will be exported and further processed in MATLAB R2022a (MathWorks Inc) by algorithms developed by the research group. After inspection of the frequency spectrum content of the raw data with the periodogram method, low-pass (zero-phase) Butterworth filtering procedures will be applied to remove unwarranted noise. To obtain numeric measures related to children's motor competence and risk handling strategies (ie, bodily movement strategies), 2 main approaches to movement analysis will be applied. First, analysis of children's overall locomotory strategies, defined as the movement (transport) of the entire body as children navigate the VR scenarios, will be conducted by examining the 3D kinematic variability of the pelvis segment (ie, the location of the body center of mass). This analysis generates variables on various motoric risk handling strategies, such as velocity and acceleration profiles (ie, speeding up or slowing down), angle of projection when moving across the road, and degree or pattern of postural movements to maintain balance and stability. In the second approach, the kinematic variability of the major joints from the whole body (ie, neck, shoulders, elbow, hip, knee, and ankle) will be analyzed. Here, numeric measures closely associated with motor competence, such as degree of repetitiveness and variation in joint movements (entropy), association between upper body versus lower body movements, and interjoint coordination patterns, will be examined.

Child Questionnaires

Children's Sensation Seeking

Sensation-seeking personality, defined as an innate willingness to take risks and the extent to which children seek risk in their everyday life, will be assessed using the Sensation Seeking Scale for Young Children (SSSYC) [81]. A 27-item instrument, the SSSYC was developed to assess sensation seeking among children aged 7-12 years. Each item presents 2 statements of preferences that child respondents choose between. As an example, children are presented the following options: (1) *I am the sort of person who would like to sled fast down a steep hill* compared with (2) *sledding fast down a steep hill sounds scary to me*. The SSSYC includes three subscales, each with strong evidence for internal reliability: (1) thrill seeking (α=.85), (2) behavioral inhibition (α=.83), and (3) behavioral intensity (α=.83) [81]. Selecting the statement indicating higher levels of the measured subscale earns 1 point on the overall subscale score. In the above example, selecting the first option earns 1 point on the thrill-seeking scale, whereas choosing statement 2 earns 0 points.

For this study, the SSSYC was first translated from English to Norwegian by author OJS. Then all primary researchers in the project group discussed the translation to revise unclear wordings and adapt words and phrases to fit the Norwegian context. Next, the Norwegian version of the scale was back-translated to English by a professional translator, and then the 3 versions (original English, translated Norwegian, and back-translated English) were discussed among the project group to ensure that the original meaning of the statements was reflected in addition to being relevant and understandable for Norwegian children. In the ViRMa project, we will administer the SSSYC orally, with a researcher recording the child's responses on the web.

Children's Perceived Motor Competence

The Pictorial Scale of Perceived Movement Skill Competence [82] will assess children's perception of their own motor competence. In this 18-item measure, children view 2 drawings

XSL•FO
RenderX

of various movements or activities (eg, climbing up a rope or riding a kick scooter) in each item. In one drawing, the child manages the task well, and in the other, the child does not manage the task well. Children are asked which picture most resembles themselves and their skills and also to indicate their perceived competence in that skill as (1) really good, (2) pretty good, (3) sort of good, or (4) not too good. The scale has separate boys' and girls' versions, with three reliable subscales resulting (1) Active Play (α=.78), (2) Object Control—Hand Skills (α=.76), and (3) Fundamental Movement Skills with Leg Action (α=.84) [82].

For this study, the Pictorial Scale of Perceived Movement Skill Competence was translated from English to Norwegian by the author HL. Then, all primary researchers in the project group discussed the translation to revise unclear wordings and adapt words and phrases to fit the Norwegian context. Because this scale is primarily based on drawings and not words, it was not back-translated. In the ViRMa project, the Pictorial Scale of Perceived Movement Skill Competence will be conducted orally, with the drawings shown to the child on a tablet.

Parents Questionnaires

Parents' Tolerance of Risk in Children's Play

The Tolerance of Risk in Play Scale (TRiPS) [83] will be used to gather data on parents' tolerances of risk during their children's play. The TRiPS is a 31-item scale focusing on parents' willingness to let children take risks in play. Parents select "yes" or "no" for questions such as "Would you let your child jump down from a height of 3-4 meters (10-13 feet)," or "Would you allow your child to play on equipment if you thought there was the potential s/he may break a bone?" The original English version of the TRiPS was validated using Rasch analysis and found that all items had mean square values within an acceptable range for internal (construct) validity and that internal reliability statistics were excellent (showed a high person reliability index of 0.87) [83].

For this study, the TRiPS was first translated from English to Norwegian by the author EBHS. Then, all researchers in the project group discussed the translation to revise unclear wordings and adapt words and phrases to fit the Norwegian context. Next, the Norwegian version of the scale was back-translated to English by a professional translator, and the 3 versions (original English, translated Norwegian, and back-translated English) were discussed in the project group to ensure that the original meaning of the statements was retained in addition to being relevant and understandable for Norwegian children. In ViRMa, the TRiPS will be administered to all participating children's parents, both mothers and fathers, via a web-based platform using the survey tool SurveyXact [84].

Parenting Style

The Challenging Parenting Behavior Questionnaire (CPBQ) [85] will be used to assess the extent to which parents provide physical and verbal messages that encourage children to push their physical and mental limits. Parents are presented with 33 statements, such as "I play boisterously with my child" and "I encourage my child to do exciting things, such as jumping off high objects or climbing higher than he/she dares," which are answered on a scale from 1 (not applicable) to 5 (completely applicable). The instrument includes six subscales: (1) Teasing, (2) Rough-and-tumble play, (3) Encouragement of risk-taking, (4) Social daring, (5) Competition, and (6) Modeling. Internal reliability of the full scale ranges from α=.90 to α=.92 in samples of Dutch and Australian mothers and fathers, and the subscale reliabilities range between α=.63 and α=.84 in the same samples [85].

The original CPBQ was written in Dutch and translated to English using standard rigorous translation methods. For this study, the CPBQ was first translated from English to Norwegian by the author RK. Then, all primary researchers in the project group discussed the translation to revise unclear wordings and adapt words and phrases to fit the Norwegian context. Next, the Norwegian version of the scale was back-translated to English by a professional translator. The back translation to English was then discussed with Mirjana Majdandžić, who developed the original Dutch version, to ensure that the Norwegian version covered the meaning content of the original scale while still being relevant and understandable for Norwegian children. The project team also reviewed the back translation version in comparison with the original English version. In ViRMa, the CPBQ will be administered to all participating children's parents, both mothers and fathers, via a web-based platform using the survey tool SurveyXact [84].

Background and Demographic Information

To gather background and demographic information, children's parents, both mothers and fathers, will respond to items about children's age, ethnicity, past injury history, living conditions (urban vs rural), access and use of nature, modes of traveling to school, participation in extracurricular physical activity (eg, sports), ECEC experience, family socioeconomic background, and other relevant information. The survey will be administered along with the TRiPS and CPBQ via a web-based platform using the survey tool SurveyXact [84].

During the study, children will respond to questions to capture their experiences and feelings while participating in the VR scenarios. For example, they will be asked, "Did you feel it was for real?" and "Have you ever tried VR before?"

Data Collection Procedure

We will collect data in each school over the course of 2 to 3 weeks. We will install the VR equipment in a dedicated large room at each school, with enough space for a 7 × 6 m test area, with 4 SteamVR 2.0 Base Stations placed in each corner and room for children's free movement within the space. The test area, with all 4 base stations as well as the VR goggles, will be calibrated with the normal calibrating procedures in SteamVR 2.0. We will identify participating children individually in their classrooms and escort them to the test area. Sensors (17 Xsens sensors) and trackers (5 Vive trackers, version 3) will be placed on the child's body using Velcro bands. Next, we will introduce the child to the VR goggles and ensure that goggles are placed correctly on the head. VR goggles placement and eye-tracking measure sensitivity will then be calibrated through procedures in SteamVR 2.0. The child will enter a warm-up scenario in the virtual environment where they can explore a city park and

XSL•FO
RenderX

familiarize themselves with being within, and moving around, the virtual world. During the warm-up, we will calibrate the Vive trackers to enable children to see their feet and also calibrate the Xsens sensors to ensure that motion-capturing measurements are correct. The last part of the warm-up scenario instructs the child about safety routines, as follows:

> *You will now be taken to three different scenarios where you should perform different tasks. The first scenario shows several traffic situations, including cars and bikes, where your task is to cross the street without being hit. The second scenario is a river in the forest where your task is to cross the river without falling into the water. Some tasks include balancing on a beam and some include stepping on stones to cross the river. The last scenario is an urban playground where you are allowed to do whatever you want and to play and explore the playground equipment as you like, for three minutes. I will be here walking next to you to make sure you don't trip on the cable (attached to the goggles). If you ever want to quit the trial or skip to the next task, you can just let me know and I will help you.*

When the child indicates that they are ready to start the test, we will initiate the surround-sound headset for further verbal instructions, and the child will enter the first and simplest street-crossing scenario task (ie, bicycle pathway). The verbal instructions built into the headset when entering each task are simple.

- Street crossing: "Cross the road without getting run over."
- River crossing: "Cross the river without falling down."
- Playground: "Here you can move around on the playground, explore if you want, and try not to fall down."

Risk levels increase with each scenario as described previously. Children will complete all tasks in each scenario in the following order: street crossing, river crossing, and playground. The pilot (stage 2 of the overall project) found that completing the warm-up or calibration and all tasks in all scenarios took approximately 15 minutes for each child.

After the child has completed all VR scenarios, we will remove test equipment from their body and ask them to join a researcher for a short interview. During the interview, which will last approximately 15 minutes, the researcher will use a tablet to complete the child scales and background questions orally with the child. Parents will receive the survey via email with a web-based link that includes a code that matches their child's code to enable matching the dyad's data.

Three researchers will conduct the data collection procedures in each school. The group of data collectors consists of 5 researchers (EBHS, OJS, HL, RK, and LS) who are well trained, have developed all the primary and secondary outcome measures in this study, and designed and prepared (including piloting the implementation of all test procedures) the study protocol.

Ethics Approval

The Norwegian Social Science Data Services approved the ViRMa project (project 324155). We treat all data and information related to the project in accordance with the ethical guidelines of Norwegian Social Science Data Services. Child-friendly methods of seeking informed assent from children will be used, and informed consent will be obtained from the children's parents or guardians. We will take careful measures to avoid placing research participants at risk by being sensitive to the specific challenges that arise in connection with involving children in research, as well as securing their right to withdraw from the research at any point. In the ViRMa project, we emphasize ethical responsibility in the presentation of all research results involving research participants in the project.

One possible undesirable effect of carrying out the data collection with VR scenarios is that children may become frightened of the simulated situations they encounter. A second risk is that children are overconfident, overestimate their risk management skills, and experience virtual falls in the VR scenarios that they find traumatic. Our pilot research suggested that these outcomes are both unlikely, but to address them, we will debrief all participating children, discuss their experiences, and remind them that their performance in VR tasks does not reflect reality.

Analysis

The measures obtained from the VR, eye-tracking, and Xsens data include quantitative variables related to the child's risk assessment, risk willingness, risk handling, and risk management. This study's explorative and groundbreaking nature implies that an essential part of the analysis is to develop and validate new measures based on VR, eye tracking, and motion capturing. Consequently, the plan for data analysis is relatively general. The study therefore sets a conservative significance level ($P<.01$) to reduce the risk of type 1 error.

Cluster analyses will be applied to group children's movement profiles based on the Xsens data divided into potential distinct groups by comparison of hierarchical agglomerative clustering methods: the Ward method and the between-groups average linkage method. For both methods, the squared Euclidean distance will be used as the measure of proximity. The final number of clusters will be determined by examining the agglomeration schedules and dendrograms generated for both techniques. Visual inspection of each cluster's membership will be conducted to assess the utility of each potential cluster solution. Once the most statistically robust and theoretical relevant cluster solution is identified, a K-means iterative partitioning method will be applied to fine-tune the clusters [86,87].

Global measures on the child's risk assessment, risk willingness, risk handling, and management will be established using exploratory factor analysis [88] drawing on data from VR, eye tracking, and motion capturing from the VR street crossing, river crossing, and playground tasks. RMS error of approximation (RMSEA), standardized root-mean-square residuals (SRMR), comparative fit index (CFI), and Tucker-Lewis index (TLI) will be used to evaluate and refine the established measurement models. Acceptable model fit is defined as RMSEA <0.1, SRMR <0.1, CFI >0.9, and TLI >0.9 [89]. Chi-square and chi-square difference tests will be conducted between the fitted and saturated models. However,

XSL•FO
RenderX

no absolute thresholds for chi-square are set, following the sensitivity to sample sizes and the possibility that this measure may yield less precise estimates of the parameters [88,90]. Factor loadings will be investigated with the use of R^2 estimates (item >0.25) and standardized factor loadings (item >0.40) [88]. To validate the psychometric scales in the Norwegian context, factor analysis will be used. The scales with predefined subscales (SSSYC, Perceived Movement Skill, and CPBQ) will be validated using confirmatory factor analysis, and the TRiPS will be evaluated using exploratory factor analysis [88]. Acceptable model fit is defined as RMSEA <0.1, SRMR <0.1, CFI >0.9, and TLI >0.9. Factor loadings will be investigated with the use of R^2 estimates (item >0.25) and standardized factor loadings (item >0.40) [88].

Because the participating children are nested within schools, generalized structural equation modeling and multilevel regression analysis will be used in the primary outcome analysis to explore how children's past risk experiences through play and daily activities are associated with their risk management. Children's past risk experiences through play and daily activities will be measured primarily through the CPBQ and TRiPS, whereas measures related to the child's risk management will be obtained from global measures related to risk management from the VR simulation. The child's age, sex, and other relevant background and demographic information, as well as their sensation-seeking personality (measured through the SSSYC), will be included in the models.

Results

Funding to conduct the ViRMa project was confirmed in June 2021. From August 2021 to February 2022, the project group developed the VR scenarios, including eye-tracking technology and motion capturing, translated the scales, and developed the questionnaires. We will conduct the data collection from January 2023 to May 2023.

Four schools were recruited as data collection sites, with a total of approximately 660 students in second to fourth grade (7-10 years old). We aim to enroll 500 children and their parents for participation. The recruitment of children and parents for this study started in December 2022, and as of April 2023, a total of 433 parents consented for their children to participate.

Discussion

Principal Findings

This study will increase our understanding of child development. An essential goal of many educational, developmental, and pediatric health research studies is to understand how children's characteristics, upbringing, and previous experiences influence their learning and ability to handle challenges. This study focuses on children's abilities to manage risky scenarios and ties this to previous experiences. Using cutting-edge technology and previously developed measures to describe aspects of the child's past experiences, this project addresses crucial topics related to children's health and development. Such knowledge may guide pedagogical questions and development of educational and health-related interventions and reveal essential areas for focus in future studies.

One novelty of this study is related to technological and methodological advancements that may lead to new knowledge and discovery. The development and use of VR tools to explore how children handle real-life scenarios opens numerous avenues of research in different scientific fields. The integration of VR, eye-tracking, and motion-capturing technology has not been presented in published research to date and addresses many present scientific challenges. Moreover, the research represents methodological development in how VR technology may be paired with various measures in real time. Through life-like VR scenarios, it is possible to investigate children's risk-taking in a controlled and safe environment, which may lead to substantial theoretical and empirical progress. A key ambition of the study is to develop and use technology and methods in a way that enables large-scale, replicable, international studies in other cultural contexts. Thus, the tools and technology developed must be standardized and easy to use.

From the perspective of contributions to developmental science, the project can lead to further scientific understanding of children's motor competence and how it can be assessed. The combination of whole-body motion capture and VR embedded with tasks in which children can move around to explore and complete tasks represents a completely new research approach. With these features, children's motor competence can be examined through the lens of movement behaviors emerging when individual, task, and environmental components interact. This strategy circumvents shortcomings identified within existing motor competence assessments and has broad implications for further work in designing and evaluating interventions and programs, as well as for research into underlying developmental processes and the role of influencing factors in the adaptive change within individuals as they work toward motor competence throughout childhood and adolescence.

The ViRMa project results will also benefit societal goals related to health promotion, education, parenting, and city and regional planning. A cross-cutting trend today is related to risk aversion resulting from the fear of injuries to children. Compelling theoretical perspectives suggest that reducing children's possibilities to engage in risky situations may be counterproductive in terms of preventing injuries because children's opportunities to learn to estimate and manage risk are diminished. If this study establishes empirical support for this hypothesis, it may impact how risk is addressed in crucial societal institutions like the family, early childhood education, and schools. Specifically, the ViRMa project aims to develop knowledge that may lead to healthier lives and fewer injuries through new knowledge about how children best learn to judge and manage risky situations in playful contexts. Through the acquisition of knowledge about children's risk management in play, this study may benefit societal challenges related to children's health and development and reduce economic burden to society stemming from the cost of unintentional injury treatment among children and young people [91].

Strengths and Limitations

The use of VR tools along with integrated eye-tracking and motion-capture technology to explore in real time how children handle real-life scenarios in a safe context opens numerous possibilities to address scientific challenges and answer critical gaps in both the scientific literature and application of science for societal needs. However, our ambition to develop and use scientific methods that can be used in various contexts with portable data collection equipment comes with limitations. The test setup might be incrementally more accurate and valid in a controlled laboratory setting where the equipment could be mounted permanently, and the surrounding environment is ideal for the Vive equipment. In a standardized laboratory setting, the simulated planks we use might be replicated with actual wooden planks on the floor that are positioned accurately to match the VR simulation using trackers. Such measures would improve the realism of the balancing tasks but were not possible given this study's mobile and cost-efficient methodology.

The VR tasks we use in this project are newly developed and have not been validated against children's behavior in real life. Such a study would shed light on a critical question: to what degree does children's behavior in risky VR tasks replicate their behavior in similar real-life tasks? Previous work studying children's pedestrian behavior suggests that behavior in VR can replicate real-world behavior [67], and we dedicated extensive work to ensure and validate that the VR tasks were as realistic as possible; thus, we suspect this limitation is minimal.

Although one of our fundamental interests in this study is to explore how past childhood experiences influence children's risk management, the study design is cross-sectional. Using only retrospective data to assess children's past experiences with risky play and risk-taking activities could constitute a risk to reliability and validity of the data as recall and response bias could influence responses. This strategy only establishes association, rather than causation, in any statistical analysis. Nevertheless, this study's solid theoretical foundation and rich methodology ensures the potential to generate casual hypotheses that will advance our understanding of how children develop risk management skills and can be tested in future controlled, randomized, or longitudinal studies.

Other limitations are related to sample recruitment strategies. Participating children are all Norwegian children, and they are enrolled based on their schools' and parents' willingness to participate. The sample is not recruited randomly. Norwegian children are believed to engage in more risky play behaviors than children in many other cultural contexts [12,14], which may influence the results. We have chosen recruitment through schools to get a high response rate among the selected age groups and to carry out effective data collection generating an adequate number of participants for sufficient statistical power. Nonetheless, the recruitment strategy has consequences for generalizability of the sample, and the background of the participating children and the lack of randomization in sampling must be considered when generalizing findings to other contexts.

Acknowledgments

This study is funded by the Research Council of Norway (grant 324155). EBHS and OJS are supported by salary from Queen Maud University College, HL is supported by salary from the Norwegian University of Science and Technology, and RK is supported by salary from the Kanvas Foundation.

Data Availability

The data sets generated or analyzed from this study are available from the corresponding author on reasonable request.

Authors' Contributions

EBHS and MB conceived the study. EBHS led the development of the study design, with contribution from OJS, RK, HL, and MB. EBHS, OJS, RK, HL, and LS developed the data collection tools and conducted the pilot data collection. EBHS wrote the first draft of this manuscript and finalized the manuscript with input from all authors. All authors read and approved the final manuscript.

Abstract

Background: Keeping older veterans with high needs and high risk (HNHR) who are at risk of long-term institutional care safely in their homes for as long as possible is a Department of Veterans Affairs priority. Older veterans with HNHR face disproportionate barriers and disparities to engaging in their care, including accessing care and services. Veterans with HNHR often have poor ability to maintain health owing to complicated unmet health and social needs. The use of peer support specialists (peers) is a promising approach to improving patient engagement and addressing unmet needs. The Peer-to–Patient-Aligned Care Team (Peer-to-PACT; P2P) intervention is a multicomponential home visit intervention designed to support older veterans with HNHR to age in place. Participants receive a peer-led home visit to identify unmet needs and home safety risks aligned with the age-friendly health system model; care coordination, health care system navigation, and linking to needed services and resources in collaboration with their PACT; and patient empowerment and coaching using Department of Veterans Affairs whole health principles.

Objective: The primary aim of this study is to evaluate the preliminary effect of the P2P intervention on patient health care engagement. The second aim is to identify the number and types of needs and unmet needs as well as needs addressed using the P2P needs identification tool. The third aim is to evaluate the feasibility and acceptability of the P2P intervention delivered over 6 months.

Methods: We will use a quantitative-qualitative convergent mixed methods approach to evaluate the P2P intervention outcomes. For our primary outcome, we will conduct an independent, 2-tailed, 2-sample *t* test to compare the means of the 6-month pre-post

XSL•FO
RenderX

differences in the number of outpatient PACT encounters between the intervention and matched comparison groups. Qualitative data analysis will follow a structured rapid approach using deductive coding as well as the Consolidated Framework for Implementation Research.

Results: Study enrollment began in July 2020 and was completed in March 2022. Our sample size consists of 114 veterans: 38 (33.3%) P2P intervention participants and 76 (66.7%) matched comparison group participants. Study findings are expected to be published in late 2023.

Conclusions: Peers may help bridge the gap between PACT providers and veterans with HNHR by evaluating veterans' needs outside of the clinic, summarizing identified unmet needs, and developing team-based solutions in partnership with the PACT. The home visit component of the intervention provides *eyes in the home* and may be a promising and innovative tool to improve patient engagement.

Introduction

Background

Keeping older veterans with high needs and high risk (HNHR) who are at risk of long-term institutional care (LTIC) safely in their homes for as long as possible is a Department of Veterans Affairs (VA) priority [1,2]. The VA Geriatric and Extended Care Data Analysis Center (GECDAC) uses predictive modeling to identify veterans with HNHR at the highest risk of LTIC, hospitalization, or death [3]. The VA Geriatric and Extended Care (GEC) office recommends that veterans with HNHR be enrolled in long-term services and supports programs, including home- and community-based services, for best outcomes. Veterans with HNHR have complex needs that include not only physical but also mental, functional, and social needs, specifically frailty, social isolation, mobility challenges, and self-care deficits [4-8].

Older veterans with HNHR face disproportionate disparities and barriers to engaging in their care, which includes accessing care and services. Veterans with HNHR who are sicker and frailer often miss appointments and fail to visit the clinic for their care [9]. Their ability to maintain health is further complicated by complex unmet medical and social needs. When these needs go unmet, patients are at higher risk of adverse outcomes such as hospitalization, LTIC, and death [10-16]. Other adverse events include falls, inadequate nutrition, depression, incontinence, discomfort, and decreased quality of life [17,18]. Attending to the unmet health needs of older veterans with HNHR and planning services and solutions centered around what older people need based on *what matters most* to them is becoming an urgent public health priority [19,20]. Innovative interventions are needed to identify unmet needs and bridge the gap between needs and services in partnership with patients and family caregivers [1].

A promising approach to address these gaps at the VA concerns the use of peer support specialists (peers) [21-24]. Peers are veterans hired by the VA to help other veterans, usually those with serious mental illnesses, to engage them in their treatment successfully [25]. Peers are required to be veterans and must complete peer certification training. Peer certification training is conducted by a single contractor hired by the VA mental health services office. The training is at no cost to peers. Expected competencies include recovery principles, peer support practices, cultural competence, whole health approach to services, and advocacy. Continued education is required of all peers, including a minimum of 15 hours of competency-related training every year [25]. Peers promote recovery by using their common bond of being veterans and sharing their own recovery stories, providing encouragement, instilling a sense of hope, and teaching coping, empowerment, and social skills to veterans [25]. Peers understand the social and historical experiences shaping the veterans and connect with veterans in a different manner than the rest of their health care team. Being veterans themselves, peers are in a unique position to connect with veterans and assist with navigating the VA. Patient-aligned care teams (PACTs) at the VA are comprehensive medical homes that use a multidisciplinary team-based approach to effectively provide primary care and manage chronic conditions [26,27]. Preliminary studies suggest that embedded peers in mental health and primary care PACTs encourage veterans to be more active in managing their health [21-24,28-30]. Peers serve as role models, community connectors, and health care navigators. The preliminary success of the original peer support programs in specialty mental health led to congressional support for the creation of a peers-in-the-PACT program as part of the Maintaining Internal Systems and Strengthening Integrated Outside Networks (MISSION) Act of 2018 (section 506) with the implementation of peers at 30 VA sites [31]. Peers are relatively new members of the VA primary care PACT teams, and sites are working out the roles for peers in primary care.

Building upon the expansion of peers into VA primary care, we developed an innovative model for a peer-led home visit intervention to identify unmet needs in older veterans with HNHR as a home extension and *eyes in the home* for primary care PACTs called *Peer-to-PACT* (P2P). The peers work with the PACT to link veterans with HNHR to needed services and resources to address identified unmet needs. This paper describes the study protocol for a feasibility study to assess the preliminary

XSL•FO
RenderX

effect of the P2P intervention on patient engagement and the factors that could affect its implementation in the VA setting.

Study Goals

This study has three aims: (1) test the preliminary effect of the P2P intervention on patient engagement in care, measured by PACT outpatient health care use; (2) describe the number and types of needs and unmet needs identified, as well as needs addressed, among P2P participants; and (3) evaluate the feasibility and acceptability of the P2P intervention. The goal of the P2P intervention is to improve access to geriatric care and home- and community-based support services for older veterans with HNHR by providing patient-driven, proactive, personalized, and team-based care to link veterans and their caregivers to needed services and supports. We hypothesize that the P2P intervention will result in improvements in patient engagement by identifying unmet needs and addressing them.

Methods

Conceptual Design

The theoretical foundation of the P2P integrated intervention is grounded in the Andersen Healthcare Utilization Framework [32]. The Anderson model illustrates 3 main factors that influence the use of health care services: *predisposing*, *enabling*, and *need factors*. It incorporates the concept of mutability of factors, meaning that a factor with a high degree of mutability can be changed. Factors with a high degree of mutability, such as enabling resources, may thus justify deployment of resources. Therefore, the focus of our design emphasizes a peer-based approach to screening and identifying unmet needs in the context of the VA age-friendly health system (AFHS) mobility, mind, medications, and matters most (4Ms) framework as well as the fifth geriatric M, multicomplexity (mobility, mind, medications, matters most, and multicomplexity are together referred to as the 5Ms of geriatrics) [20,33], and then providing care coordination to link veterans with HNHR with services and resources to address their unmet health and social needs.

During the protocol development phase, we conducted a literature review of peer support and community health worker interventions, as well as assessments of the needs and unmet needs of older adults to draft the initial P2P intervention protocol. The final protocol and its component implementation materials were developed after iterative adaptations incorporating feedback from peers, PACT providers, veterans, advisory panel members, and various stakeholders.

P2P Interventionists

Two certified VA peer support specialists were hired and paid through the VA mental health services office through usual VA hiring practices. Hired peers completed the P2P training program in addition to the training required for peer certification [25]. The P2P training program consists of 16 hours of didactic sessions covering topics such as veterans with HNHR, social determinants of health, activities of daily living, and VA and community resources, as well as 24 hours of hands-on training covering practice home visits, use of P2P data collection tools, and computerized patient record system (CPRS) documentation (discussed in further detail in the P2P Implementation Materials section).

Advisory Panel

We established a national project advisory panel to guide intervention design, implementation, and dissemination activities. This panel includes key stakeholders from the VA offices of GEC as well as Mental Health and Suicide Prevention, the GECDAC, and the national VA peers in the PACT implementation team from the VA Center for Integrated Healthcare. The panel also includes subject matter experts in peer work at the VA, veterans with HNHR, home-based primary care, mental health, cultural competence, and non-VA community health worker programs, as well as Miami VA Healthcare System primary care PACT members. A biannual panel meeting was held to provide updates, solicit feedback, and consult one-on-one for specific matters.

Study Setting

This P2P intervention feasibility study was conducted at the Miami VA Medical Center in Miami, Florida, United States.

Study Design and Sample Size

This study uses a mixed methods (qualitative-quantitative convergent) design involving a nonrandomized 2-arm trial comparing the 6-month P2P intervention group with a 1:2 matched comparison group.

As this study is a pilot intervention, sample sizes were determined by what was deemed feasible within the available time frame and resources rather than power calculations. We aimed to recruit 35 veterans with HNHR or referred veterans for participation in the P2P intervention.

Eligibility Criteria

To be eligible for the P2P intervention, veterans had to be aged ≥60 years, receiving care at the Miami VA Healthcare System, living within a 50-mile radius of the Miami VA facility, and not be planning to relocate in the next year. Veterans were excluded if they were enrolled in the VA home-based primary care program or residing in a hospice or nursing home. We also enrolled veterans who were referred by Miami VA Healthcare System PACT providers and met the eligibility criteria but were not on the HNHR list.

Recruitment and Enrollment

Participant recruitment for this study is complete. Participants were enrolled into the P2P intervention at the Miami VA Healthcare System by peers. The peers recruited participants using three strategies: (1) calling eligible veterans identified from the quarterly GECDAC HNHR list; (2) mailing opt-in recruitment letters to veterans on the HNHR list; and (3) referrals made by PACT primary care clinicians, nurses, or social workers. In recruitment calls with eligible veterans, the peers described the P2P intervention to the veterans and how they might help the veterans manage their health conditions. If the veterans were interested, the peers obtained verbal consent to participate.

XSL•FO
RenderX

Matched Comparison Group

Veterans in the matched comparison group were identified from the HNHR list, similar to the method used to enroll veterans into the P2P intervention. Comparison group veterans did not receive any peer services before or during the study period as evidenced by CPRS chart reviews and use data provided by the GECDAC. Comparison group participants were matched with P2P intervention participants on age, care assessment need score [34], JEN Frailty Index [35], and Nosos score [36,37] from the HNHR list for the period during which the P2P participant was recruited. Veterans in the comparison group received care as usual.

P2P Intervention Overview

General Schedule

The P2P intervention is multicomponential and designed to support older veterans with HNHR to age in place. Peers provide usual peer support services (eg, facilitate peer support groups, advocate for veterans, and act as role models for recovery) in addition to the P2P intervention. The P2P intervention focuses on the home visit as an innovative tool to identify the unmet health and social needs of veterans with HNHR and linking them to solutions using an integrated P2P model. A general schedule of the intervention is presented in Table 1.

The intervention includes three main components detailed in the following sections: (1) needs identification via a peer-led home visit; (2) care coordination, health care system navigation, and linking to resources in collaboration with the PACT; and (3) patient empowerment and coaching using VA whole health principles.

Table 1. Peer-to–Patient-Aligned Care Team (P2P) intervention schedule.

When and what	How
Rolling recruitment and enrollment	
Patient identification	HNHR[a] list and PACT[b] referrals
Eligibility screening	Filtering of HNHR list for age, distance from Miami VA[c] Healthcare System, enrollment in HBPC[d], and hospice or nursing home residence
Recruitment	Telephone calls, letters, or referrals
Week 1: scheduling home visit	Peers schedule a home visit with veterans enrolled in the P2P intervention via telephone calls or remote video visits
Week 2: preparing for the home visit	Peers complete a chart review of problem list, consults, medication list, and past notes in the last 30 days
Week 3: home visit	Peers identify needs via home visits using the P2P needs identification tool; when a home visit is not possible, needs are identified via a remote video visit
Week 4: P2P care coordination	Care coordination to address unmet needs is discussed between the peers and PACT during team huddles, via telephone calls or Microsoft Teams messaging, or in person
Months 2-5	
Patient education	Peers and veterans meet once every 2 weeks via telephone calls, remote video visits, or in person to review relevant topics of the Passport-2-Wellness, an educational book encompassing 8 health-related topics; the educational component is flexible in terms of the needs of the veterans, and peers have flexibility on deciding when to cover topics during the follow-up months
Follow-up on care coordination	Peers follow up on the status of identified unmet needs (eg, resolved or not resolved) with both the veteran and PACT and assist with unmet needs; peers follow up on referrals and consults and complete follow-up notes in the CPRS[e]
Month 6	
Discharge	Peers assess whether further follow-up is needed to continue advocating for the veteran; peers complete a P2P discharge summary indicating reason for discharge (eg, veteran does not require any additional peer support, or veteran has stopped communication with peer, or voluntarily withdrawn) and summary of participation in the program

[a]HNHR: high needs and high risk.

[b]PACT: patient-aligned care team.

[c]VA: Department of Veterans Affairs.

[d]HBPC: home-based primary care.

[e]CPRS: computerized patient record system.

Needs Identification via a Peer-Led Home Visit

In preparation for the home visit, peers first ask pre–home visit safety questions, complete an initial contact note, and schedule a home visit. Before the home visit, peers review the patient's VA CPRS chart to ascertain medical problems, existing and previous VA services, recent VA visits, hospitalizations, emergency use, no-shows and appointment cancellations, mental

XSL•FO
RenderX

health history, cognition problems, medication list, social concerns, upcoming appointments, pending or cancelled consults and orders, and telehealth use.

During the home visit, peers provide additional information about the P2P intervention and verbally administer the needs identification tool, which is a health and social needs questionnaire (described in full detail in the P2P Implementation Materials section). Through conversations with, and observation of, the veteran and caregiver or caregivers, if available, as well as inspection of their home environment, the peers help the veteran to identify the key unmet needs that affect their overall health and well-being. During the visit, peers ask the veteran for permission to see different parts of their house. Specifically, peers ask to see bathrooms, living rooms, kitchens, floors, and entry ways. Peers use a home safety checklist within the needs identification tool to look for potential fall hazards (eg, loose cords, clutter, and carpets) and potential home safety equipment needs (eg, bath rails and entry ramp). The home visit takes approximately 2 hours. During the home visit, peers also provide the veteran with the Passport-2-Wellness, an educational book encompassing 8 health-related topics, and give them an overview of its contents (described in full detail in the P2P Implementation Materials section).

Care Coordination, Health Care System Navigation, and Linking to Resources in Collaboration With the PACT

The peers document the identified needs and a narrative of their observations in a templated CPRS note and add primary care PACT team members as cosigners. Peers collaborate with the appropriate PACT team member (primary care physician, nurse case manager, social worker, or pharmacist) to coordinate the ordering of needed consults and services. Care coordination to address unmet needs is discussed during team huddles (limited during the COVID-19 pandemic), via telephone calls or Microsoft Teams messaging, or in person.

Examples of unmet needs and linking to resources in collaboration with the PACT may include reaching out to the social work department for transportation concerns, linkage to food banks and meals on wheels for food insecurity concerns, or homemaker and home health aide for self-care concerns; reaching out to pharmacy for medication concerns; or working with the PACT nurse case manager or physician to refer veterans with falls or safety concerns to the falls clinic or order physical therapy, home safety assessment, or prosthetics for needed home safety durable medical equipment.

Peers may increase veteran health care engagement by bridging veterans back to their primary care team. Peers help veterans to navigate the health care system (eg, schedule appointments, send reminders, and provide guidance through the health care system bureaucracy) and provide emotional and social support (eg, identify VA and local social resources programs such as food banks and tenant advocacy). They continue to communicate with the veterans on the progress of their care plan and follow up on the status of the identified unmet needs (eg, resolved or not resolved) and assist with unresolved unmet needs by following up on referrals, consults, and orders.

Patient Empowerment and Coaching Using VA Whole Health Principles

During the initial visit and follow-up phase, the peers provide health and behavior coaching to the veterans. They review relevant sections of the Passport-2-Wellness with veterans as they deem fit and provide needed counseling in the context of the 5Ms of geriatrics [20]. They use VA whole health principles to teach veterans to "take charge of my life and health," self-manage their chronic conditions, and take part in problem-solving. Peers also help the veterans to complete a VA whole health personal health inventory to assist them with setting goals, describing *what matters most* to them about their health, and identifying methods for filling unmet needs in alignment with their needs and preferences. Through continued contact via telephone, in person, or via videoconferencing, peers empower patients with problem-solving skills to manage their health, including self-care, medication adherence, nutrition, physical activity, and emotional well-being, and cover the relevant materials in the Passport-2-Wellness. Contacts last approximately 30 minutes and are tailored to meet patient goals and needs, access to services, and care coordination.

Peer Assessment

Peers work with the veterans to ensure that they receive the needed services to enable them to remain in the community and address care fragmentation across providers and services. The P2P intervention is designed to be 6 months in duration, including 1 home visit during month 1 and contacts once every 2 weeks thereafter. The peers assess whether further follow-up is needed, past the 6 months, to continue advocating for the veteran or whether the veteran could be discharged from the P2P intervention. Peers complete a P2P discharge summary indicating the reason for the discharge (eg, veteran does not require any additional peer support, or veteran has stopped communication with peer, or voluntarily withdrawn) and a summary of participation in the program.

Remote Care

In keeping with VA's preference for remote care to enhance access and efficiency—and safety during the COVID-19 pandemic—we, too, implemented remote video visits by peers. Veterans are asked about interest in, and willingness to receive, a remote video visit, access to needed technology (internet and camera phone or computer), and help with technology access or use as required. For remote home visits, peers use the same in-person home visit template to identify unmet needs. During the remote home visit, peers ask veterans, whenever possible and safe to do so, to walk them through different parts of their house. Communication with the PACT follows the same process as outlined previously. Peers are provided tablet devices to be able to *telepresent* the veteran to a PACT provider at the VA site as needed and when possible. Peers may also work with social workers to provide veterans with tablet devices for remote visits if they qualify.

P2P Implementation Materials

Overview

The protocol development phase focused on planning the P2P intervention protocol and its component implementation materials, including (1) a needs identification tool and a CPRS template for documentation, (2) the Passport-2-Wellness education and resource book, and (3) a peer training curriculum. These have all been implemented and refined using an iterative series of modifications with feedback from the peers, PACT providers, and local and national stakeholders. Two certified peer support specialists were actively engaged partners in the design and trial phases, and the process was modified to stay within their scope of peer work (eg, advocate for veterans, act as liaison between staff and veterans, provide outreach and education and work with clinical teams [23]).

Needs Identification Tool

To effectively address the needs of veterans with HNHR, we developed a needs identification tool to identify and understand the needs and unmet needs of older adults and improve patient engagement through a peer-led home visit. Peers initially conducted home visits using a longer questionnaire of validated questions to identify needs. The needs identification tool was modified to reflect the peers' personalized holistic style using conversational language. The peers gather baseline information and identify unmet needs through a series of questions, conversations, and observations in the following domains: mobility, mind, medications, matters most, multicomplexity, and social determinants (Textbox 1). These needs domains were selected based on the 5Ms of geriatrics and previous studies showing that common barriers to patient engagement in outpatient programs include physical symptoms and limitations, mental illness, care fragmentation, isolation and lack of social support, financial insecurity, and poor social and neighborhood conditions [38-41]. These needs were then documented in a study-specific CPRS templated note to harmonize data collection and inform and coordinate care with the PACT regarding the veterans' needs.

Textbox 1. Needs domains.

Mobility and function

- Mobility, past falls, frailty, gait, and balance
- Activities of daily living and instrumental activities of daily living
- Homebound status
- Current use of support services

Mind

- Memory
- Mood (depression and anxiety)
- Substance use

Medications

- Medication insecurity, refills, questions
- Medication adherence concerns

Matters most

- Meaningful health goals

Multicomplexity

- Chronic medical conditions
- Chronic disease–related health care needs
- Hearing or vision problems
- Health care use

Social determinants

- Social support
- Transportation
- Food insecurity
- Financial stability
- Housing insecurity, housing density, neighborhood safety
- Legal concerns
- Technology access and ability to use technology

Home safety concerns and needs

- Outdoor grab bar
- Walker
- Assistive devices
- Bathroom assistive devices
- Smoke detector
- Presence of clutter, rugs, cords

The Passport-2-Wellness

We designed the Passport-2-Wellness educational book with 8 topics that were identified as being most common for, and most relevant to, older veterans with HNHR in the context of the 5Ms of geriatrics (Textbox 2). This Passport-2-Wellness book, which also contains a *Telehealth Visits* section and a section entitled *Healthcare Tools and Notes*, is provided to enrolled veterans as a resource and used by the peers as an educational tool. Peers, in collaboration with the veteran, select relevant topics to review during the intervention.

Peer Training Curriculum

Two hired peers were already certified peer support specialists [25]. There is onboarding training required for national peers in the PACT implementation team at all VA sites for usual peer activities. National peer training incudes competencies in recovery principles, peer support practices, cultural competence, communication, recovery and personal wellness goals, and whole health approaches to services. A complete list of expected knowledge and skill areas can be found in the *Peer Support Specialists Training Manual* [25]. To supplement this training, we developed an educational curriculum for the peers specific to the P2P intervention. This curriculum was developed integrating feedback from PACT providers, peers, key stakeholders, and the home-based primary care team. Overall, the duration of P2P intervention training is 40 hours: 16 hours for educational components and 24 hours for P2P hands-on training. Peer training was provided by multidisciplinary PACT and home-based primary care team members, including geriatricians, social workers, and nurses. Peers also received hands-on training in the use of VA CPRS, conducting chart review, and conducting a remote video visit. Peers made 3 home visits with the home-based primary care team to learn the process for conducting safe home visits, using personal protective equipment (because this intervention started during the COVID-19 pandemic) and checking for home safety and unmet needs. Some of the training was via *Talent Management System*, the VA's enterprise-wide education, leadership development, learning, and employee development system. Training components are shown in Table 2.

XSL•FO
RenderX

Table 2. Peer support specialist Peer-to–Patient-Aligned Care Team (P2P) training curriculum.

Component	Required training	Duration (hours)	Modality
P2P didactic training			
Veterans with high needs and high risk			
	Identifying the needs and unmet needs of veterans with high needs and high risk	1	Remote presentation
	Social determinants of health	2	TMS[a] course
Safety	Personal protective equipment training	1	In-person meeting with local occupational health
Mobility and functional limitations	Falls, assistive devices, ADLs[b], and IADLs[c]	1	Remote presentation
Mental health	Managing depression, SUD[d], and stress	2	In-person meeting with local recovery coordinator and mental health peers for information on VA[e] resources and hospital tour
VA vehicle			
	Courses for driving a government vehicle	1	TMS course
	Defensive driving, driving fundamentals, credit card, and so on (varies by facility)	1	TMS course
Motivational interviewing	Understanding good communication practices	1	TMS course
Social work	Social work services: transportation and long-term support services, VA and community resources, and caregiver resources	2	In-person meeting with local social worker
Telehealth	Remote care technology and tablet device use, digital divide consult, and mock remote video visit	2	TMS course
Research	VA required training in human participant research and HIPAA[f]	2	TMS course
P2P hands-on training			
Home visit	HBPC[g] training and shadowing on home visit safety	12 (3 home visits)	In-person home visits with HBPC team
P2P tools	Use of the Passport-2-Wellness, needs data–gathering tools, and mock telephone calls	8	P2P team in person and remotely
VA records	Use of CPRS[h] and chart review training	4	In person with program coordinator
Recommended training			
Whole health			
	Introduction to whole health, health coaching, and goal setting: SMART[i] goals	2	TMS course
	"Taking charge of my life and health" facilitator training	25 (5 days)	Remote learning (Zoom; Zoom Video Communications, Inc) and class discussion, partner activities, and small groups
Diabetes mellitus overview	About type 2 diabetes, hyperglycemia, hypoglycemia, and complications	2	In-person meeting with local diabetes nurse practitioner
Nutrition	Healthy eating, portion sizes, if you drink alcohol, and food shopping tour	4	In-person meeting with local dietician and nurse practitioner

Primary and Secondary Outcome Measures

Our primary outcome was patient engagement, defined as the number of outpatient PACT encounters. We obtained these data from the GECDAC and from CPRS chart reviews for both intervention and comparison groups. Patient engagement is a broad concept that combines positive patient behavior, such as obtaining preventive care, with patient activation [49]. In this study, we measured veteran engagement with the VA health care system by measuring participation in outpatient care and services. Peers collected data on frailty [42], homebound status [38], health needs, needs related to social determinants of health, and home safety needs. Secondary descriptive outcomes among intervention participants included prevalence and types of needs and unmet needs, actions taken to assist with meeting needs, and use of health care services, specifically services in the home (Table 3).

Implementation Measures

Quantitative process measures included number of unique veterans referred and enrolled, number of visits per veteran, total number of consults placed per veteran, and total number of GEC services received. We also conducted semistructured interviews at baseline and ongoing throughout the intervention period with key stakeholders (VA facility PACT providers and leadership, GEC leadership, GECDAC directors and staff, experts on VA peer support specialists, and national peers in the PACT implementation team). Detailed notes were taken on the interviews, and some of the interviews were audio recorded. The research team held ongoing periodic reflections [50] with the peers and study team to explore challenges and successful and unsuccessful strategies, as well as the peers' perspective on their role as part of the clinical team [50]. In addition, study-specific questionnaires were used to collect data on satisfaction with the intervention as well as its feasibility and acceptability (Table 3).

Data Analysis

We will use a quantitative-qualitative convergent mixed methods approach to evaluate P2P intervention outcomes. Specifically, we will use the reach, effectiveness, adoption, implementation, and maintenance (RE-AIM) framework to guide a formative process evaluation and assess the 5 key RE-AIM outcomes [51].

Quantitative Analysis

For our primary outcome, we will first calculate the difference in the number of primary care PACT outpatient encounters 6 months before and after enrollment for each participant in both intervention and comparison groups. An independent, 2-tailed, 2-sample *t* test will then be used to compare the means of the pre-post differences in the number of outpatient PACT encounters between intervention and comparison groups. The mean pre-post difference will be reported for each group with the corresponding SDs and 95% CIs. The folded F statistics will be evaluated to report either the pooled or Satterthwaite *P* value. We will calculate group-specific means and proportions for sociodemographic and clinical factors. At baseline, categorical variables will be compared between groups with the Pearson chi-square test or with the Fisher exact test for rare outcomes. The *t* test will be used to compare means across groups. *P* values will be reported, with lower values interpreted as more stable and less likely to be sporadic. All quantitative analyses will be performed using SAS 9.4 (SAS Institute Inc).

Qualitative Analysis

Qualitative data analysis will follow a structured rapid approach using deductive coding as well as the Consolidated Framework for Implementation Research (CFIR) [52]. A mixture of detailed note-taking and audio-recorded semistructured interviews will be used. Interviews will be transcribed and deidentified. Researchers will enter transcripts into NVivo 12 (QSR International), a software program used for qualitative and mixed methods research, and begin by reading each transcript repeatedly from beginning to end. To facilitate qualitative data coding and organization, we will use an NVivo project template, prepopulated with CFIR construct codes. Codes selected a priori include constructs within the following domains: outer setting, inner setting, and implementation process. Although constructs are selected a priori, we will allow for the expansion of codes and emergent themes as necessary.

To enhance validity and reliability of the qualitative data analysis, we will conduct exercise debriefings within the study team to evaluate potential differences in coding across analysts and resolve coding differences as needed. Running documents of all coding decisions, processes, and analyses will be kept, ensuring proper data management and coding practices.

Ethics Approval, Participation, and Privacy Considerations

This study was approved by the Miami VA Healthcare System institutional review board (#1592752). No compensation was provided to veterans for participation. A waiver of Health Insurance Portability and Accountability Act (HIPAA) authorization was granted based on the determination that the risk to the privacy of individuals is minimal. To ensure privacy, efforts were taken to protect the identity of participants and ensure that data were kept confidential. Names, addresses, and social security numbers were replaced with a unique code and will only be maintained on a VA server; documentation of the procedure used to code the data will remain within the VA. All identifiers collected as part of this research project will be destroyed as per the records control schedule (RCS 10-1) of the Veterans Health Administration (VHA). Electronic files will be stored in folders with restricted access on a protected computer shared drive behind the VA firewall in a secure server. Nonelectronic records will be maintained in locked cabinets and behind locked doors. Information will be located in an area with limited public access. Data will not be transmitted as an attachment to unprotected email messages. The data will be accessible only to personnel involved in the study. All staff will be trained to avoid breach of confidentiality issues.

XSL•FO
RenderX

Results

The P2P project was funded in October 2019. Study enrollment began in July 2020 and was completed in March 2022. Our sample size consists of 114 veterans: 38 (33.3%) P2P intervention participants and 76 (66.7%) matched comparison group participants. Data analysis is underway, and study findings are expected to be published in late 2023.

Discussion

Overview

Peers are increasingly being deployed in a variety of health care settings to provide patient-centered care. At the VA, efforts are underway to integrate peers in primary care settings. The role of peers is expanding and evolving, and peers are currently being proposed to be added in primary care PACTS at all VA facilities [53]. The use of peers in primary care settings at the VA is still relatively new, and innovative models for the use of peers are being developed at several VA sites based on local needs.

The P2P intervention aims to address unmet needs of older veterans with HNHR who are frail by addressing individual health and social needs as well as the home environment. Although peers are not medical providers, they are well suited to assess and understand patients' perspectives and needs and are empowered to recommend patient-centric strategies to address them. This intervention aims to improve patient health care engagement through the timely use of needed services and supports. The protocol presented has undergone multiple modifications using feedback from peers, the PACT, stakeholders, and veterans. This study originally aimed to test the integrated P2P intervention using a structured 6-month experimental design. However, veterans with HNHR are a population with complex needs and with multimorbidities and poor health care engagement. They are challenging to treat because they often have more immediate health and living concerns that make participating in long interventions a last priority. Taking these challenges into consideration, a more flexible intervention schedule was developed in response to feedback from veterans with HNHR regarding their concerns with the intervention duration and time commitment required. In practice, the educational components are not constrained to specific weeks within the 6 months; instead, peers have flexibility on deciding when to cover topics within the allotted time frame. This flexibility takes into consideration the heterogeneity and complex needs of this population.

During the design phase, we used several strategies to improve recruitment: reducing the number of data collection instruments to reduce respondent burden, allowing peers to use their peer style to gather data while maintaining trust with the veteran, increasing provider knowledge of referrals to the P2P intervention, accepting patients referred by PACT providers, mailing recruitment letters, and giving peers flexibility to adapt the intervention to make it more veteran-centric as needed.

Peers are currently delivering the P2P intervention, conducting home visits, and identifying unmet needs as part of their routine clinical duties at the Miami VA Healthcare System. Because of the limitations with enrolling participants owing to COVID-19–related delays and the complexity of veterans with HNHR, we obtained permission to use clinical data from all veterans who participated in the P2P intervention. Our ability to track health care use and collect demographic and clinical data from electronic medical records presents us with the opportunity to assess the efficacy of the P2P intervention with data that are not easily collected via questionnaires. The results from this study will aid our understanding of the acceptability and feasibility of the P2P intervention and its effect on health-related outcomes.

Strengths

The P2P intervention has several strengths. First, its novel approach of using peers in the PACT beyond the VA and into the home allows peers to serve as *eyes in the home* and identify needs that otherwise may continue to go unmet without proper care coordination. Second, using the AFHS and a whole health approach allows the peers and veterans to develop a personalized health plan based on individual values, needs, and goals. Third and last, prior VA research notes the need for functional and cognitive status as well as data related to social determinants of health to be a part of the routine electronic health record [54]. The needs identification tool we developed for this intervention was converted into a CPRS template with the goal of harmonizing data and coordinating care with the PACT on veterans' unmet health and social needs.

Limitations

As this is a nonrandomized study, the greatest challenge is the identification of an appropriate comparison group. We selected a matched comparison group from the same HNHR list from which the intervention participants were recruited to reduce selection bias. By selecting a matched comparison group that is similar according to a set of matching variables, we help to ensure that any observed differences in outcomes between the intervention and comparison groups can be more confidently attributed to the treatment itself, rather than other factors that may differ between the groups. The final sample size included 114 veterans: 38 (33.3%) P2P intervention participants and 76 (66.7%) matched comparison group participants. We made efforts to mitigate sample size limitations by including a 1:2 ratio of comparison group participants. In addition, the inclusion of referred patients may be deemed a deviation from the original protocol. However, the referred veterans will be assessed for comparable characteristics with veterans recruited from the HNHR list. Recent VA data demonstrate that using a combination of administrative data such as the HNHR list and clinician judgment is best suited for identifying patients for intensive care management interventions [54].

Safety precautions during the COVID-19 pandemic and home visits presented a potential risk for the intervention in terms of protection of the peers and the protection of older veterans with HNHR who are frail. The peers were trained by the home-based primary care team to make home visits and were trained on proper personal protective equipment use. Furthermore, peer use of remote care was limited by the access to, and willingness and ability to use, technology of the veteran with HNHR [55].

XSL•FO
RenderX

Peers used remote care where suitable. This aligns well with national VA priorities and stakeholder feedback.

Conclusions

Peers may help bridge the gap between PACT providers and veterans with HNHR by evaluating veterans' needs outside of the clinic, summarizing identified problems, and developing team-based solutions in partnership with the PACT. The home visit component of the intervention provides *eyes in the home* and may be a promising and innovative tool to identify unmet needs and home safety risks. The focus of our design emphasizes a community-based approach to successfully identify unmet needs and link individuals with HNHR with needed and effective health care services.

This project is timely because the *Veteran Peer Specialist Act of 2021* (Bill HR 4575) was recently approved by Congress to expand the peers-in-the-PACT program to all VA sites. The P2P intervention offers a protocol for integrating peers into the PACT that enhances and adds to the services provided by peers at the VA. The P2P intervention is being tested under real-world conditions using certified VA peer support specialists selected through usual VA hiring practices and assigned to the VA primary care service. The results collected from this study will provide important information on the effectiveness of a peer-led home visit intervention for veterans with HNHR who are considered vulnerable as an innovative strategy to identify need gaps using the AFHS 4Ms framework and coordinate care to increase timely access to needed services. Our findings will further gauge the feasibility of this framework in the existing health care system using peers. This intervention may highlight the innovative role that peers in the PACT may play to extend the reach of the PACT into the veterans' homes to implement evidence-based long-term services and supports proactively and more equitably. Timely access to needed long-term care services and supports as a *preventive* measure may help meet veterans' preference to age in place.

Acknowledgments

This work was supported in part by funding from the US Department of Veterans Affairs (VA) Health Services Research & Development service as a phase 1 innovation grant project (SDR 19-171) and the VA Maintaining Internal Systems and Strengthening Integrated Outside Networks (MISSION) Act. The authors also gratefully acknowledge the support of the Miami VA Geriatric Research, Education, and Clinical Center in Miami, Florida, United States; Bruce W Carter Department of Veterans Affairs Medical Center in Miami; and the Miami VA Research office. The authors also wish to thank the peers, Aisha Bryant and Michael Maxwell, for their dedicated effort on this project and the project staff for help with various aspects of the project. The authors also gratefully acknowledge the ongoing guidance provided by Laura Wray and Christine Shook from the VA Center for Integrated Healthcare; input from our various advisory committee members and stakeholders, including Tom Edes, Dayna Cooper, Cheryl Schmidt, and Marianne Shaughnessy from the VA office of Geriatrics and Extended Care; Andrew Pomerantz, Jennifer Patterson, and Michel Karel from the VA office of Mental Health and Suicide Prevention; Patricia Sweeney (VA peer support services); Matthew Chinman and Richard Goldberg, experts in VA peer work; and Miami VA Healthcare System champions Remberto Rodriguez and Sonia Madera.

Data Availability

The data sets generated and analyzed during this study are not publicly available owing to Department of Veterans Affairs and ethical redactions as well as redaction of ethically sensitive information; however, instructions on obtaining the data are available upon request.

Authors' Contributions

All authors contributed to the concept, preparation, and revision of the manuscript and approved its final version. The investigators retained full independence in the conduct of this research. Abstract

Background: Roots of Hope (RoH) is a multisite Canadian community-based suicide prevention initiative developed by the Mental Health Commission of Canada (MHCC), which is based on evidence for intervention effectiveness and World Health Organization recommendations. Seven communities developed local activities in the following 5 pillars: specialized supports, training and networks, public awareness, means safety, and evaluation research.

Objective: We aim to use an implementation research approach to understand the RoH model for reducing suicidal behaviors and their impacts in communities, and the lessons learned for the equitable development and implementation of RoH in different contexts. Moreover, we want to understand how the program is implemented in relation to the context, the causal pathways, and the factors influencing successful implementation. The evaluation includes assessments of short-term and intermediate effects at each site and overall.

Methods: The principal investigator (PI) developed a consensus among local research coordinators on common approaches and indicators through ongoing participation in an online community of practice, and regular virtual and in-person meetings. At the completion of the pilot phase, the PI will summarize evaluation results across sites and conduct pooled analyses. The RoH theory of change and evaluation model shows how evaluation activities from the planning phase through the implementation of activities in each of the pillars can help clarify the viability of the RoH model and identify factors that facilitate and inhibit effective and equitable implementation in different contexts. Beginning with a situational analysis to identify resources in each community and local specificities, we will examine the implementation characteristics of conformity, dosage, coverage, quality, utility, equity, appreciation, facilitators, and impediments. Evaluation of short-term effects will focus on changes in knowledge, attitudes, behaviors, help-seeking, service use, stigma, media reports, empowerment, and care experiences. Intermediate effects, long-term effects, and impact will include assessments of the changes in suicides, suicide attempt rates, and suicide risk indicators. A variety of data sources, both quantitative and qualitative, will be used.

Results: The quantitative and qualitative data from all sites will be summarized by the PI in March 2023 to draw conclusions to help the MHCC in its improvements to the RoH model, and to inform communities about how to better implement RoH. Since

XSL•FO
RenderX

the COVID-19 pandemic occurred at the beginning of program implementation, its impact and influence will be documented. The validity of RoH in contributing to the prevention of suicides and suicidal behaviors will be clarified in a variety of contexts. The final evaluation report will be available in September 2023.

Conclusions: The evaluation results, including the identification of factors that facilitate and inhibit the implementation of RoH and the adaptations to challenges, will be useful to the MHCC, current RoH communities, and those considering adopting the RoH model.

Introduction

Background

Roots of Hope (RoH) is a multisite national suicide prevention project initiated by the Mental Health Commission of Canada (MHCC) [1]. Its goal is to develop an evidence base, including best practices and suicide prevention guidelines and tools, to support the scaling up and implementation of a "made-in-Canada" community suicide prevention model across the country.

RoH was developed by the MHCC, based upon a systematic review the Commission conducted on the effectiveness of various suicide prevention programs and activities, as well as their review of evidence-based recommendations for community suicide prevention activities by the World Health Organization (WHO) [2,3]. The WHO proposes that key risk factors for suicide be aligned with relevant interventions at the societal, community, relationship, and individual levels. One of their key messages is that "Communities play a critical role in suicide prevention" [4]. This approach, which promotes community actions in suicide prevention, is mirrored in the comprehensive national Canadian Suicide Prevention Framework [5]. RoH provides structures around which communities can tailor their suicide prevention efforts to meet their unique needs. Each community develops strategies and activities in each of 5 "pillars" identified by the Mental Health Commission, which are evidence-based areas of prevention activities that can be found in all national suicide prevention programs that follow the WHO recommendations. The pillars are as follows:

1. Specialized supports: Prevention, crisis, and postcrisis services, such as peer support, support groups (including self-help), workplace interventions, and coordinated planning and access to services.
2. Training and networks: Training and learning opportunities for health care providers, such as physicians and nurse practitioners, mental health workers, as well as community gatekeepers, such as first responders, human resource staff, and teachers.
3. Public awareness campaigns: Locally driven campaigns to promote mental health awareness (posters, brochures, social media, etc) and collaboration with the media, with the goal of creating an effective suicide prevention awareness campaign and having safer conversations about suicide, including on social media.
4. Means safety: Identification of the methods or places where a high number of suicides occur and implementation of measures to ensure safe access to them. For example, building barriers on bridges or railway crossings, protocol for medication access, etc. These include helping to reduce suicides by creating a safer home.
5. Evaluation research: Setting research priorities, conducting surveillance, and monitoring and evaluating the implementation (using an implementation science approach) and effects of the project at each site and overall.

Evaluation Objectives

The overall objective of the evaluation is to understand RoH as a comprehensive model to reduce suicidal behaviors and their impacts in communities. Specific aspirational questions concerning this understanding that were formulated by the MHCC at the start of the project are included in Multimedia Appendix 1. An addition to these questions was made because of the timing of the implementation of the programs (an assessment of the impact of COVID-19 on the implementation and potential effects of the programs and their activities). The evaluation involves obtaining qualitative and quantitative data, including perspectives on the implementation and effects from members of the community, caregivers, and various stakeholders. The final report on the evaluation will identify lessons learned that could be useful for other communities implementing the model, and issues of equity and factors affecting the implementation will be discussed. In addition, actual and perceived impacts of the implementation of RoH will be assessed. We plan to analyze across sites the overall implementation and effects of common activities within each of the pillars, in order to better understand what appears to be effective and which factors influence the implementation of activities in different contexts. In addition to common quantitative metrics, a qualitative assessment will be carried out through semistructured interviews and focus groups. Analyses will include the assessment of possible unintended outcomes. In the RoH model, all of the areas of action have empirical evidence supporting the effectiveness of many activities. Most of the research has occurred in other cultures and in populations that may differ in terms of age, socioeconomic status, and local practices.

Roles of the Principal Investigator and Local Research Teams, and Development of the Evaluation Plan

In May 2018, Professor Brian L Mishara, Director of the Centre for Research and Intervention on Suicide, Ethical Issues and End-of-Life Practices (CRISE) and Psychology Professor at the Université du Québec à Montréal was appointed by the MHCC as principal investigator (PI) for the evaluation research of the RoH project. The PI (BLM) received funding for administrative support from the MHCC, which was used to hire an assistant to serve as research coordinator (ATT). The role of the PI is to develop a consensus on research methodologies and, to the extent possible, ensure that local research teams use the same common indicators in their evaluations. The consensus, which is reflected in this evaluation research plan, was developed over the course of 2 years through regular in-person and online meetings, and participation in a community of practice for only the research coordinators and a combined community of practice with the researchers and the implementation coordinators for each site. They also used a RoH research community of practice website to share information among local coordinators. Information about how to conduct the evaluation was discussed, modified, and approved by the lead researchers in each of the provinces and then by all the provincial intervention coordinators and the MHCC. Some of the tools and indicators that were adopted had been developed or used already in one or more communities as part of their ongoing evaluation activities. Some were created or adapted by the PI and, after consultations and modifications, were accepted by the local teams. In addition, the PI is available to consult with the teams, respond to local issues and questions, collaborate with the MHCC, and help to ensure conformity of evaluation measures across sites through participation in an ongoing community of practice involving all the research coordinators. Besides group consultations during research community of practice meetings, one-on-one consultations are available by email, telephone, and video conferencing whenever requested by researchers from local sites.

Since it is important to also obtain qualitative data from interviews and focus groups involving the people in charge of the implementation and the evaluation, the role of doing this was delegated to the PI, with MHCC providing some additional necessary resources made available to local researchers (software licenses and transcription services). This is because it could be difficult for employees working for a research or implementation coordinator to conduct a completely nonbiased interview with one of their supervisors or employers. In addition to locally obtained data, the PI team will obtain some pertinent centralized national data to support and share with local research teams.

The local research teams, hired by the local organization responsible for the implementation, are responsible for data collection and analyses in their communities, and they provide local reports and summaries that are requested or needed by those involved in the local implementation. They have a mandate to collaborate with the PI to determine the research methods, as summarized in this document, and participate in a community of practice with the PI and other RoH community researcher coordinators. A data sharing agreement has been developed to specify ethical and practical aspects of sharing and use of data by local researchers, the PI, and the MHCC.

The PI also has the roles, mandated by the MHCC and agreed to by all the local research coordinators, of summarizing the data from each of the local research teams, pooling data when possible, conducting analyses on pooled data, drawing overall conclusions concerning the RoH model and specific activities that exist at multiple sites, discussing site-specific aspects of the implementation and effects, and presenting potential implications of the evaluation results for scaling-up and implementation in different sites and contexts.

Methods

Ethics Approval

This evaluation protocol has been approved by the Ethics Committee for Research with Human Subjects (“Comité institutionnel d’éthique de la recherche avec des êtres humaines”) of the Université du Québec à Montréal (dossier number 2758).

Participating Communities

The initial sites of the implementation of RoH were Newfoundland and Labrador, New Brunswick, Saskatchewan (3 sites), Alberta, Ontario, and Nunavut. The first province to become part of the RoH project was Newfoundland and Labrador, which partnered with the Mental Health Commission in January 2018. This collaboration was developed by Eastern Health and a community coalition on the Burin Peninsula. The province of Newfoundland and Labrador was joined by New Brunswick, which launched a community suicide prevention project in Northwestern New Brunswick in the County of Madawaska-Victoria, which includes Kedgwick, Edmundston, and Grand Falls. Three additional provinces (Sakatchewan, Alberta, and Ontaria) also joined RoH. In Saskatchewan, with partnerships between local community coalitions and the Saskatchewan Health Department, the project was implemented in the Northern communities of La Ronge and Meadow Lake. The community of Buffalo Narrows, Saskatchewan joined in 2020. In Alberta, RoH was implemented in Edmonton as part of the Living Hope community suicide prevention of that city, in collaboration with local organizations and a partnership with the Canadian Mental Health Association. The Waterloo-Wellington, Ontario community signed on to RoH in August 2019, with the Waterloo Region Suicide Prevention Council leading this initiative and partnering with Here4Hope, the Wellington Suicide Prevention Initiative involving the Canadian Mental Health Association Waterloo-Wellington and Wellington County. The city of Iqaluit in the Canadian Teritory of Nunavut joined RoH in 2021 as part of the Department of Health of the Government of Nunavut’s Inuusivut Anninaqtua Action Plan for suicide prevention. At the time this evaluation plan was submitted, Iqaluit had not yet completed its planning phase and had not yet started implementation and evaluation activities, partly due to the COVID-19 pandemic.

Theory of Change and Evaluation Model

A theory of change is intended to generate “a description of a sequence of events that is expected to lead to a particular desired

XSL•FO
RenderX

outcome" [6]. Figure 1 presents a diagram with the theory of change and evaluation model for the implementation and evaluation of the RoH project. A theory of change, as represented in a diagram and narrative, aims to provide a guiding framework for the project team and stakeholders. The theory of change presented in Figure 1 is the result of a dynamic iterative process, based upon the study of documents provided by the MHCC and the PI, and discussions with the persons conducting the RoH program in each of the provinces and the provincial research coordinators, as well as the consideration of provincial evaluation proposals and local resources. The model in Figure 1 follows a logical sequential order, from the top to the bottom, with parallel evaluation activities being conducted at each step.

The evaluation model begins with an assessment of the planning, which occurred before implementation of the RoH activities and continues to be adjusted throughout the implementation of the activities. Changing realities oblige everyone involved in planning, implementation, and evaluation to constantly adapt what they are doing, based upon how they conceive of changing needs, priorities, and responses to their actions in the flux of change in complex real-life situations. For this reason, a theory of change has been described as both a process and a product that continually evolves over time [6].

The planning is based upon the community resources, strengths, and challenges, and the sociocultural community context. Furthermore, what constitutes evidence-based practices in suicide prevention is an important resource input to help guide planning of activities. In an ideal situation, before planning starts, one should begin with a needs assessment to understand the magnitude, nature, and characteristics of the target population, their needs, the community needs, and available resources. Although each of the RoH communities discussed and considered needs and resources in the development of their specific RoH activities before the evaluation team was put in place, this was not always complete, and certain aspects of needs were assessed differently at each site. Therefore, the evaluation of RoH includes a standardized systematic situational analysis in each of the communities in order to better understand the local contexts in which the RoH activities were developed. This situational analysis, conducted at each of the sites using available and reliable data sources, identifies the nature of the psychosocial context in the communities, the community resources and capacities, and the challenges within the community at the general level and for specific cultural and local subgroups, including particular populations at increased risk of suicidal behaviors.

Multimedia Appendix 2 lists the information gathered as part of the situational analysis. Besides describing the communities for use in local planning, the PI team summarized this information across communities in order to provide a portrait of similarities and differences. This comparative portrait can help in the interpretation of evaluation results by identifying common issues, strengths, and resources, as well as the specificities associated with each of the sites.

Planning in each site also involved consultations with stakeholders, structuring of roles, and concrete assessments of needs and resources. All this was considered in the context of the RoH model that was developed by the MHCC, which constitutes the basic framework according to which each community is expected to develop their local plan of activities.

The planning process in each community involves mobilization of stakeholders, service providers, and members of the community to become involved in both the planning and implementation activities of RoH. In each of the communities, collaborations need to be established. This was generally concretized in the form of local coordinating and planning committees, as well as community consultations to not only provide information about what to do and how to do it, but also develop active engagement by individuals, organizations, and community agencies for realizing the RoH project.

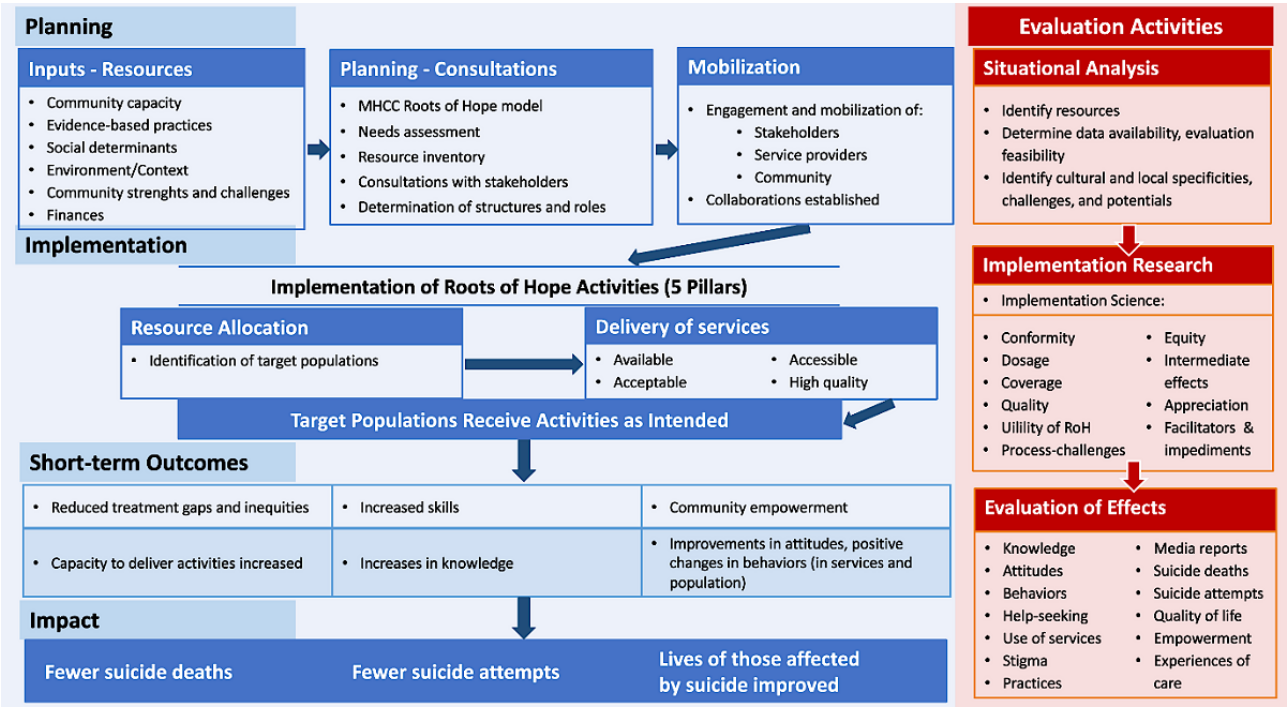
The planning phase, whose documentation is part of the RoH implementation evaluation, is translated in each site into specific implementation activities organized into the 5 "pillars" of RoH (Multimedia Appendix 2) as specified by the RoH model developed by the MHCC. For each activity, the nature and extent of resources allocated for each of the target populations, as well as the nature of the activities, need to be determined in relation to the community resources. Then, the delivery of services can begin. Characteristics of these services should be understood as part of the evaluation process in terms of their availability, accessibility, acceptability, and quality. In an ideal world, this results in the target populations receiving the activities as planned and intended. However, in reality, not everything can be implemented as planned, and multiple adjustments and adaptations need to be made throughout the implementation phase.

During this implementation phase, we assess important characteristics of the implementation of RoH activities in each of the pillars as follows: *conformity* in providing activities as planned; *dosage* (extent to which enough of the service or activity was effectively delivered); *coverage* (proportion of the general population and targeted populations reached); *quality* (degree to which activities and services were of high quality); *equity* (extent to which coverage was biased due to some systemic characteristics such as location and accessibility issues); *appreciation* (how services and activities were perceived and received by stakeholders and end users); and *conformity* to best practices in suicide prevention and to the RoH model (evidence based).

In addition, we focus on identifying facilitators that help with "successful" implementation and help the persons involved in the implementation address challenges and difficulties throughout the implementation process.

Although much of the RoH evaluation focuses on implementation, to the extent possible, the evaluation model includes assessments of short-term outcomes, and mid-term impacts and effects. As shown in Figure 1, the RoH evaluation focuses on the following 7 primary areas of short-term outcomes: (1) reductions in treatment gaps and inequities, (2) increases in skills, (3) community empowerment, (4) increases in capacity to deliver activities, (5) increases in knowledge, (6) improvements in attitudes, and (7) positive changes in behaviors

XSL•FO
RenderX



in providing services and the behaviors of members of the population.

The evaluation of effects is both specific to different RoH activities and general, in the sense that it also concerns the synergistic effects of the combination of all RoH activities in each community. Figure 1 lists the 12 main areas of the evaluation of effects. Most of these areas can be assessed in the short term regarding specific activities and more generally in the mid-term regarding the impact on the community. For example, evaluation of knowledge after participating in a training session can be assessed among participants in the session. However, a combination of multiple training and educational activities within the community could result in less stigma and negative attitudes about help-seeking. This, in turn, could facilitate increased use of mental health and suicide prevention services, and could have an impact on the prevention of suicidal behaviors.

Because of the low incidence of suicide deaths and the fact that suicide rates can have large fluctuations in relatively small communities, one cannot expect to observe significant decreases in suicide deaths over a short period (implementation period of approximately 2 years) and to reliably associate those changes with RoH. However, it is possible that pooling data across all RoH communities could indicate trends in suicide rates a few years after the implementation of RoH. Since there are far more suicide attempts than suicide deaths, if data are available, one may be able to document changes in suicide attempts in a shorter period of time. To the extent possible, RoH will examine existing data on attempted suicide. However, systematic suicide attempt data are not compiled in an exhaustive or accurate manner across Canada. Hospital records and visits to private physicians are rarely complete. Furthermore, a complete portrait of the incidence of suicide attempts in a community must include information from all individuals and institutions who have contacts with persons who have attempted suicide, which is often difficult and impractical. Again, we will analyze what data are available to determine if there is sufficient information to indicate changing trends in the rates of attempted suicide.

One can also assess the extent to which the lives of those affected by suicide may be improved as a result of RoH activities. Persons affected by suicide include those who are feeling suicidal and are in need of help; those at high risk of suicide who may or may not proceed with a suicide attempt; those who have attempted suicide and are at greater risk of attempting again; and the family, friends, and co-workers of persons who are thinking of suicide, who have attempted suicide, or who have died by suicide.

Figure 1. Roots of Hope (RoH) theory of change and evaluation model. MHCC: Mental Health Commission of Canada.

Methodologies and Measures

The methodologies and measures used to answer the major evaluation questions are listed in Multimedia Appendices 3-11. It is to be noted that all common measures proposed and listed are the result of a lengthy process of consultation and collaboration between the PI team and local researchers. They are to be understood as constituting a minimum set of information and data to be obtained in order to inform the implementation process of RoH as a whole. However, as explained below, this has proven to be particularly difficult in light of changing local contexts and resource limitations. Therefore, individual teams are encouraged throughout the process to make decisions on the most pertinent measures to retain in accordance with their local focus and the realities of local capacity. Nonetheless, all decisions concerning local measurements should be systematically documented and explained.

Although it seems desirable to determine which methodologies and instruments to use in advance and then simply proceed to

XSL•FO
RenderX

gather the information, an implementation science approach obliges researchers to be constantly aware of the practicalities involved. They should consider the extent to which the instruments and methodologies they planned to use actually provide accurate and useful information that they require within the constraints of local contexts (research acceptability, availability of reliable data, resources, and capacity). Therefore, successful evaluations are iterative processes involving continued mindfulness of how well the evaluation is going at every step, and an openness to making changes and improvements throughout the process. The preceding statement proved particularly pertinent to the evaluation of RoH in the context of the COVID-19 pandemic. The COVID-19 pandemic occurred just as implementation of RoH was beginning in most communities. Not only were many activities and evaluation components put on hold during the COVID-19 pandemic, but also creative adaptations and changes were often made to continue some activities in other formats and adjust priorities in the identification of vulnerable populations. During this period, information about the changes associated with the COVID-19 pandemic and their impacts was systematically gathered as part of this evaluation. Multimedia Appendix 3 shows the information gathered and methodologies to determine what factors could affect the planning components of the RoH model in different contexts as well as overall. Data on planning are obtained from documents and the situational analysis (Multimedia Appendix 2 and the discussion in the following section). However, the evaluation of the planning components is complemented by qualitative data from interviews with each of the community coordinators and coordination groups, stakeholder focus groups, interviews with key RoH personnel, persons with lived experiences, and other available local data.

One of the key issues involves the extent to which the implementation of activities and services is both adequate and equitable. This involves not only an assessment of the extent to which each component is implemented, but also an understanding of key target populations in each community and the extent to which RoH activities provide interventions to various subgroups in a manner that meets their needs. Some of the measures concern the nature of the implementation process (conformity, dosage, quality, and coverage). However, a true understanding of adequate and equitable implementation involves including an assessment of the adequacy of the activities in meeting the needs of different target populations, and their real and perceived impacts (Multimedia Appendix 4).

Each of the RoH communities provide multiple training activities to care providers. Care providers include not only professionals, such as general practice physicians and workers at crisis centers, but also members of the community, such as those receiving peer-support training in a workplace. Multimedia Appendix 5 lists the data sources for evaluating training activities. These include descriptions of the nature and extent of training activities, participants, quality assessments of sessions and activities, and indications of the impact of specific training activities in increasing knowledge, improving attitudes, and increasing positive helpful behaviors.

The nature of awareness activities in this RoH awareness pillar varies greatly among communities, because of different target populations, community resources, and needs. Besides assessing activities to increase awareness and knowledge in the general population, several communities are also conducting general surveys to assess changes in stigma associated with suicide and mental health, attitudes, knowledge, and openness to seeking help (Multimedia Appendix 6).

The specialized support pillar of RoH includes a wide variety of specific services provided, expanded, or improved as part of RoH. The evaluation of these specialized support activities varies according to which activities are initiated in each community. For example, when decreasing wait times to obtain mental health services is a specific focus, the extent that wait times decrease needs to be assessed. When specific activities and programs are provided to help people bereaved by suicide, specific assessments need to be made to evaluate their impact on program participants. As seen in Multimedia Appendix 7, quantitative data using questionnaires and survey instruments are complemented by qualitative data from interviews and focus groups with key informants, clients, and service providers.

Reducing access to potential means for suicide is a RoH component whose activities depend upon which suicide methods are used or increasing in each community. Although it is possible to assess the roll out of these activities, and their nature and quality, most prior evaluations of promoting means safety have involved assessing decreases in deaths by suicide and suicide attempts. It is not realistic to expect that we would have sufficient data on suicide deaths to link those data to the targeted means safety activities in RoH communities. However, as indicated in Multimedia Appendix 8, we can assess the availability, acceptability, accessibility, and quality of the means safety activities and their coverage of target populations.

When we look at potential effects, the RoH evaluation model includes “classic” measures of suicidal behaviors (deaths, attempts, and possibly some information on the experiences of people with lived experience). However, as already discussed, the low incidence of suicide in general, lack of sufficient valid data on suicide attempts, relatively small population base in RoH communities, and limited time frame of the evaluation make it difficult to evaluation the impact of RoH on suicidal behaviors. Still, we will examine changes in the available data. However, we will also examine changes in other outcome measures that have been associated with decreases in suicidal behaviors in past research (Multimedia Appendix 9). These include improvements in services and changes in community perceptions and beliefs. Multimedia Appendix 10 provides several data sources for obtaining information on suicidal behaviors, as well as improvements that may be associated with fewer suicides and suicide attempts (community focus groups and surveys; administrative information and media reports; improvements in delivery capacity; identification of treatment gaps and inadequacies; and improvements in the skills, knowledge, and behaviors of service providers).

Because of the nature of community involvement throughout the process of planning, implementing, and evaluating RoH, we could expect increased community empowerment and quality of life, as well as improvements in perceptions of services and a diminution of barriers to accessing help. Decreasing stigma

XSL•FO
RenderX

is one of the goals in each of the RoH communities that will be assessed. Increasing help-seeking behaviors, improving attitudes toward help-seeking, and increasing knowledge of services are the focuses of many of the RoH community interventions (Multimedia Appendix 10).

Data Analyses and Synthesis

The local evaluation research coordinators at each site will be responsible for conducting analyses of their quantitative and qualitative data and producing synthesis reports for local use and reports to the MHCC (Multimedia Appendix 11). The PI will be available to consult and assist local coordinators with their analyses and interpretation of results. The PI team will also propose guidelines for common coding and analysis to ensure consistency across sites. All results of the measures indicated in this plan, as well as additional measures used as part of the RoH evaluation, will be shared with the PI, including the necessary information needed to summarize results across sites. The PI will conduct additional analyses combining information from sites, synthesize and interpret the overall results, and provide reports in collaboration with all contributing local researchers. After consultations, reports combining and comparing information for the sites will be included in reports by the PI. All data sharing will observe the norms and procedures outlined in the Data Sharing Agreement signed by the provincial partners, the PI and his university, and the MHCC. All publications will follow the Publication and Dissemination Guidelines for RoH developed by the MHCC in consultation with the PI, provincial partners, and research coordinators.

Local research teams that could benefit from support and consultation in their analyses of qualitative data can call upon the PI and his team to help and support them with these analyses and their interpretation. The data gathered from the interviews and focus groups conducted by the PI's team at local sites will be analyzed by the PI team, and the results will be sent to the provincial research coordinators for use in their reports. The results combined across sites may be used in overall RoH reports and presentations produced by the PI and his team, in accordance with the Data Sharing Agreement and the Publication and Dissemination Guidelines, approved by the MHCC, the PI, and all local research coordinators.

Results

The evaluation research plan for RoH is a major initiative involving diverse sites across Canada, each implementing a variety of multifaceted suicide prevention–related activities to meet the local needs of various target populations. The RoH model, developed by the MHCC, includes "state-of-the-art" best practices that have been validated in prior research and are recommended by the WHO to be incorporated in national suicide prevention strategies. This model provides a general orientation to focus on 5 "pillars" of action, leaving it up to each site to engage in consultation, planning, and evaluation processes that take into account local problems, resources, and cultures, and the specific needs of priority target populations that are identified. In this context, one would expect that evaluations of the implementation and effects would need to be tailored to the local needs and resources, and the nature of the specific activities selected to be implemented as part of RoH at each site. Therefore, the evaluation model must carefully balance the need for standardization and the advantages of using common approaches and methodologies, against the necessity to tailor the evaluation activities at each site to the unique characteristics of the RoH activities that have been chosen. In this context, the extent to which the evaluation results across the diverse communities will be able to identify valid general conclusions that are applicable to current and future RoH sites will not be determined until the evaluation is completed.

The evaluation model presented in this document demonstrates the fruits of over 2 years of interactions between the PI team and local research and implementation coordinators, with input from the MHCC. Hopefully, this plan attains a balance between standardization and flexibility that will provide the necessary information to meet local needs at each site and also provide a comprehensive overall assessment of the RoH model across sites. However, differences in the nature and extent of funding at each site and differences in the availability of data in existing community organizations and records may compromise the ability of the evaluation to obtain enough of the essential information necessary to attain the evaluation goals.

We realize that real-world constraints and changes during the course of the RoH project will continually pose challenges to all those involved in the evaluation process. The COVID-19 pandemic is a powerful example of how radical changes in the planned roll out of the programs and evaluation activities had to be made, including refocusing and developing new activities to respond to suicide and mental health challenges associated with the pandemic, and changing data collection methods for the evaluation. These changes primarily concerned the need to cancel many in-person activities and replace them with online programs, services, and assessments. The advent of COVID-19 during the implementation phase resulted in the need to innovate and adapt, and caused delays in the implementation and evaluation processes. However, this also provided an opportunity to understand the process of adapting to the challenges of having COVID-19 present in communities, where new methods were developed to deliver services and to obtain data for the evaluation.

The quantitative and qualitative data from all sites will be summarized by the PI in March 2023 to draw conclusions to help the MHCC in its improvements to the RoH model, and to inform communities about how to better implement the RoH approach in an efficacious and equitable manner. Since the COVID-19 pandemic occurred at the beginning of program implementation, its impact on the implementation and evaluation activities and its influence on the RoH project will be documented. Overall, we aim to clarify the validity of RoH in contributing to the prevention of suicides and suicidal behaviors in a variety of contexts. The final evaluation report will be available in September 2023.

Discussion

Our aspiration for the evaluation is to be able to better understand the validity, feasibility, and evaluability of the RoH model for community suicide prevention. We also aspire to

XSL•FO
RenderX

identify the processes in planning, implementation, and evaluation that facilitate its usefulness for communities and their members. We hope to clarify its validity in contributing to the prevention of suicides and suicidal behaviors in a variety of contexts. We also hope that it may help others who are interested in developing suicide prevention strategies and activities, including those who are considering adopting the RoH model. In addition, the evaluation results may provide useful information to the MHCC on how RoH could be modified and improved to be more effective in the future.

Besides reaching general conclusions about the practicality and usefulness of the RoH model for communities, we hope to be able to identify factors that facilitate its implementation, factors that inhibit its implementation, and different adaptations and innovations that can be used to deal with challenges occurring during its implementation. We aim to identify the extent to which the implementation is successful and equitable, and explain why problems may have arisen, what facilitates success, and how the Mental Health Commission may be able to modify the RoH model to facilitate the implementation, equity, and positive effects of the program.

Although the evaluation is not complete, challenges in coordinating locally funded evaluation programs in multiple sites are evident. A better future approach could be to obtain sufficient central funding for the entire implementation and evaluation. This would better ensure that all sites have the necessary resources to complete all the essential evaluation activities and would minimize discrepancies between sites in which activities are implemented completely as planned. In a provincial context, such as Canada, where health and mental health services are planned, funded, and delivered by provinces, it may not be feasible to ensure uniform funding for the implementation of community programs for sites in different provinces. However, since there are national research funding organizations, there is hope that multisite evaluations of the implementation and short-term effects could be funded.

Acknowledgments

We thank the personnel at the Mental Health Commission of Canada, particularly Karla Thorpe and Nitika Rewari, for their help and support.

Data Availability

Raw data gathered by the principal investigator that are not reported in the final report of the evaluation research may be obtained (anonymized) by contacting the principal investigator once the report and articles reporting the findings have been published. Data gathered locally at each of the sites, which will be synthetized or interpreted by the principal investigator in the final report, will be made available according to the policies of each of the local research coordinators who obtained the data.

Abstract

Background: Brown Buttabean Motivation (BBM) is an organization providing support for Pacific people and Indigenous Māori to manage their weight, mainly through community-based exercise sessions and social support. It was started by DL, a man of Samoan and Māori descent, following his personal weight loss journey from a peak weight of 210 kg to less than half that amount. DL is a charismatic leader with a high media profile who is successful in soliciting donations from corporations in money and kindness. Over time, BBM's activities have evolved to include healthy eating, food parcel provision, and other components of healthy living. A co-design team of university researchers and BBM staff are evaluating various components of the program and organization.

Objective: The purpose of this study is to build culturally centered system dynamics logic models to serve as the agreed theories of change for BBM and provide a basis for its ongoing effectiveness, sustainability, and continuous quality improvements.

Methods: A systems science approach will clarify the purpose of BBM and identify the systemic processes needed to effectively and sustainably achieve the study's purpose. Cognitive mapping interviews with key stakeholders will produce maps of their conceptions of BBM's goals and related cause-and-effect processes. The themes arising from the analysis of these maps will provide the initial indicators of change to inform the questions for 2 series of group model building workshops. In these workshops, 2 groups (BBM staff and BBM members) will build qualitative systems models (casual loop diagrams), identifying feedback loops in the structures and processes of the BBM system that will enhance the program's effectiveness, sustainability, and quality improvement. The Pacific and Māori team members will ensure that workshop content, processes, and outputs are grounded in cultural approaches appropriate for the BBM community, with several Pacific and Māori frameworks informing the methods. These include the Samoan *fa'afaletui* research framework, which requires different perspectives to be woven together to create new knowledge, and *kaupapa Māori*–aligned research approaches, which create a culturally safe space to conduct research by, with, and for Māori. The Pacific *fonofale* and Māori *te whare tapa whā* holistic frameworks for interpreting people's dimensions of health and well-being will also inform this study.

Results: Systems logic models will inform BBM's future developments as a sustainable organization and support its growth and development beyond its high dependence on DL's charismatic leadership.

Conclusions: This study will adopt a novel and innovative approach to co-designing culturally centered system dynamics logic models for BBM by using systems science methods embedded within Pacific and Māori worldviews and weaving together a number of frameworks and methodologies. These will form the theories of change to enhance BBM's effectiveness, sustainability, and continuous improvement.

Introduction

Background to Brown Buttabean Motivation

In 2014, DL, a man of Samoan and Māori descent, set up an organization called Brown Buttabean Motivation (BBM) in south Auckland, Aotearoa New Zealand. DL had a personal weight loss journey from a peak weight of 210 kg to less than half that amount [1]. BBM provides support for Pacific people and Indigenous Māori to manage their weight, mainly through community-based exercise sessions and social support. Pacific and Māori people have much higher rates of obesity- and weight-related diseases than non-Pacific and non-Māori people.

While exercise boot camps were the entry point for community engagement, over time BBM's activities have evolved to include healthy eating and other components of healthy living, which are woven into a collective journey toward health and well-being [2]. DL is the high-profile leader of BBM, which is now a limited liability company. BBM's operations staff includes both paid employees and volunteers. Its funding comes from a variety of sources, including philanthropy, the Ministry of Health, and donations through its Just Move Charitable Health Trust funding arm. Its members, largely but not exclusively of Māori and Pacific ethnicities, are now located not only in south Auckland but also in the west of the city and other parts of Aotearoa New Zealand.

Researchers at the University of Auckland were asked by BBM to co-design an evaluation of the various components of the program and the organization. A qualitative study has been conducted to understand how participants experience and engage with BBM as a grassroots, Pacific-, and Māori-led holistic health program [2]. Most interventions to address obesity do not result in sustained weight loss over time, and a review of the literature recommended "Māori and Pacific-led, culturally tailored weight loss programs that promote holistic, small, and sustainable lifestyle changes delivered in socially appropriate contexts" [3]. A pre-post longitudinal quantitative cohort study is underway to evaluate the effectiveness of BBM for sustained health and well-being outcomes, especially weight loss [4]. A further study is underway to conduct a mixed methods process evaluation of BBM's community engagement through in-person, social, and news media outreach activities with respect to the health and well-being of the Māori and Pacific communities over time [5].

Systems Science

Overview

A system is an interconnected set of elements coherently organized in a way that achieves something [6]. The structure of a system is therefore comprised of a complex interplay of 3 types of things: elements, connections, and a function or purpose. The meanings that people attribute to these elements may or may not be universally shared. Understanding these components is required to accurately model the system. People may have different mental models of the same events and data, and visual mapping and modeling tools can help reveal these different interpretations and combine them into an overarching perspective. Once the structure is identified, it can be altered in order to make changes to the system.

Logic Models of Change

A logic model is a theory of change. It demonstrates the inputs (what goes in), outputs (what comes out), outcomes (what results from this), and the relationships between them. Often, logic models are linear in nature (eg, inputs leading to processes, leading to outputs, leading to immediate impacts, and leading to long-term outcomes), showing the intentions, assumptions, and rationale of an intervention and how it can influence a system to achieve an outcome. A dynamic model identifies and uses feedback loops and can show what things may lead to another and different factors that might lead to change, both those that can be controlled and others unrelated to the program and hence out of the organization's control [6]. A systems approach that can incorporate feedback loops will create sustainability in a rapidly evolving, responsive program.

Logic models are graphic depictions of the relationships between resources, activities, outcomes, and impacts of a program or a system. They have been used in a variety of settings, for example, to inform the development of interventions such as a rehabilitation service for youth with concussion [7,8], mobile health support for physical activity in people with spinal cord injuries [9], and digital self-management in inflammatory bowel disease [10]. They have been used to understand how digital health interventions for self-management might be used to facilitate effective behavior change [11], how to design a plan to transform a health care system [12], and to capture complexities in systematic and scoping reviews [13]. Tools to create dynamic logic models include cognitive mapping interview (CMI), sometimes referred to as causal mapping and group model building (GMB). To appropriately represent the theory of change within a complex adaptive system, like BBM, system dynamics logic models need to account for the feedback loops intrinsic to the system.

Cognitive Mapping Interviewing

CMI is a visual technique that captures a stakeholder's perspective on a problem or issue and how they or their organization relate to the issue. This tool is used in systems

XSL•FO
RenderX

research to view issues (for example, low fruit and vegetable consumption in children [14]) as emerging from complex and adaptive systems. A set process is followed during a semistructured interview to order and reflect the interviewee's view of the social system. The process of creating the CMI map aids participants' reflection and sense-making. The map produced during each interview consists of a network of nodes and arrows as links that are usually linear in structure. The themes that emerge from the analysis of the individual maps can then be combined to form a composite map, presenting the subjective data in a diagrammatic form that gives a holistic and systemic view of an issue. CMI has most often been applied to complex management problems and operational or action research. CMI was used in a health services project to develop a theoretical framework for implementing innovative practices in primary health care management in Aotearoa New Zealand [15], and other studies internationally have used similar system dynamics methods [16].

Group Model Building

GMB is a qualitative method that aims to engage stakeholders to collectively consider the dynamics of complex problems [17]. It involves a facilitation or modeling team and a group of stakeholders who cobuild a model to solve specific problems within a complex system [18,19]. GMB, as a participatory method, extracts the knowledge and understandings of a problem from people who engage with it by using a series of facilitated, structured discussions. GMB has applications ranging from problem definition to simulation system dynamics modeling [20]. In other words, in GMB sessions, people provide their individual perspectives on the problem, its structure, the resulting dynamic model, as well as its impacts and solutions. These views are improved by knowledge sharing among people, discussions, and group analysis. When a consensus model is achieved, the group then identifies leverage points within the system and the actions needed to reorient the system to resolve the problem. This approach ensures that people's perspectives and understandings are included, thereby increasing their commitment to execute their action tasks [21]. The GMB process enables the creation of visual system maps that identify the feedback loops that are holding a problem in place or that can be reoriented to reduce the problem.

Cultural Approaches and Frameworks

Overview

There are several Māori and Pacific frameworks and models that are appropriate to use in Aotearoa New Zealand to inform systems science approaches. The core personal and social values of Māori and Pacific people are love, humility, respect, and relationship. Connectedness and collectivity are key.

Kaupapa Māori

kaupapa Māori aligned research ensures that the experiences and outcomes of research are positive for Māori communities [22]. kaupapa Māori research prioritizes Māori knowledge, language, and customs research practice [23]. There are 5 key principles: tino rangatiratanga (self-determination), taonga tuku iho (cultural aspirations), ako Māori (Māori worldview), whānau (family), and kia piki ake i nga raruraru o te kainga (socioeconomic mediation) [24,25]. These key principles will guide the CMIs and GMB workshops to ensure that the researchers and the research process provide a culturally safe environment for our participants and that the outcomes of the study have a positive impact on Māori communities [25,26].

Fa'afaletui

The Samoan *fa'afaletui* research framework also informs our study design. *Fa'afaletui* requires different perspectives woven together to create new knowledge (from "ways of" [*fa'a*] "weaving together" [*tui*] deliberations of different groups or "houses"[*fale*]) and is derived from the Pacific philosophy of connectedness and a collective holistic approach [27,28]. This fits well with the use of a mixed methods approach with a range of different types and sources of data. This research framework is also reflected in our team, which includes researchers with expertise in obesity reduction, co-design, and systems science, as well as the Māori and Pacific investigators outlined below. In line with the *fa'afaletui* framework, the collective approach of our study places greater value on the research because of the shared vision and support of all members (researchers, BBM workers, and community members), which intertwines the skills and perspectives within the research team to work toward a shared goal [26]. The bodies of knowledge that each person brings are woven together to conduct this *mahi* (work). Different systems science methodologies will also be interwoven to create our system model of change.

Fonofale and Te Whare Tapa Whā

Fonofale (Pacific) [29] and *te whare tapa whā* (Māori) [30] models of inquiry are holistic frameworks for interpreting people's dimensions of health and well-being. These frameworks use the metaphor of a Samoan or Māori meetinghouse. In the fonofale model, the floor is the extended family and community; the 4 house pillars, or pou, represent physical, mental, spiritual, and sociodemographic components of health and well-being; and the cultural practices, beliefs, and values that shelter people are the roof. The fonofale is surrounded by the physical environment and the sociopolitical context and is set at a point in time. Similarly, the Māori te whare tapa whā model has the foundation of the house (whare) as the land and place of belonging (taha whenua), and the 4 posts are physical (taha tinana), mental (taha hinengaro), spiritual (taha wairua), and family (taha whānau) well-being. Good health requires that these 4 posts be balanced and in harmony with each other [31].

Why BBM May Have System Issues That It Would be Helpful to Address

BBM has a core vision to provide, in DL's own words, "a health hand-up" for Māori and Pacific people. This is a broad vision that, at its core, has the goal of improving the health of *whānau* (family). Consequently, BBM engages with the community to enhance physical, spiritual, mental, and social health. Specific examples of activities include addressing food insecurity, providing a hub for exercise, encouraging vaccination, and meeting the needs of those displaced by recent flooding in Auckland and Hawkes Bay. BBM changes its focus in direct response to perceived community needs. There is a risk that BBM will overextend and not be sustainable. The development

XSL•FO
RenderX

of a dynamic logic model of change can help identify organizational aspects that are functioning well independently and those that rely on DL's input. This knowledge may help BBM adapt and remain an effective and sustainable entity in his absence.

Aim

We aim to build a culturally centered system dynamics logic model to serve as the agreed theories of change for BBM and provide a basis for its ongoing effectiveness, sustainability, and continuous quality improvements. To achieve this, we are combining systems science approaches with several Pacific and Māori frameworks for health and processes for research.

Methods

Overview

This research will be *kaupapa Māori*–aligned. The principal investigator is of Samoan and Māori descent; our team also includes a Māori researcher to guide the team on *kaupapa Māori* research methodologies; and BBM staff, including DL, who identifies as Samoan and Māori, are coresearchers. The principal investigator and Māori researcher have been involved in all aspects of study conceptualization, design, and processes and will oversee data analysis and interpretation to ensure that the research is mana-honoring and safe for Māori. In alignment with *kaupapa Māori*, this research has been co-designed with BBM staff to ensure that the needs of the organization and the community are of the utmost importance. This is an example of the key principle of *whānau* . In this research, *whānau* refers both to people in a family (immediate and extended) and also to how Māori practice *whanaungatanga* (the way family members interact with each other) [25,30]. Everyone involved in the study is part of the research *whānau* , and the knowledge that each person brings to this research *whānau* is shared and valued.

The Pacific (*fonofale*) [28] and Māori (*te whare tapa whā*) [29] holistic frameworks for health will inform our research. Although its initial focus was on weight loss, particularly for the Pacific and Māori communities, BBM has evolved to provide social support for the overall health and well-being of its community, in line with the *fonofale* and *te whare tapa whā* frameworks.

There are 3 phases to our research. In phase 1, key stakeholders will be interviewed to produce cognitive maps of BBM's goals and cause-and-effect processes.

These maps will inform the main themes for exploration and questions in phase 2, which involves 2 series of GMB workshops, one with BBM staff and another with BBM members. During these workshops, participants will build visual system models. The process will identify feedback loops between the elements, structures, and processes of the BBM system, providing the theories of change for BBM to drive its effectiveness, sustainability, and continuous quality improvement. The goal of the staff workshop is to map the dynamics of the key parts of the BBM program itself that relate to its quality and sustainability, such as the continuous development of staff, program content, and funding. The members' workshop will focus on how to maintain and enhance participant engagement with BBM because program engagement is the best determinant of successful long-term weight loss. In the final phase, these visual maps will be used to create an integrated system dynamics model of change and the associated action plans needed to reorient BBM systems so that they can deliver optimum benefits for the BBM community.

Phase 1: Cognitive Mapping Interviews

Overview

The CMIs for this research will be used to identify a shared understanding of the purposes and goals of BBM. They will also identify the components and cause-and-effect processes of success and sustainability for BBM to deliver its purposes and goals. These concepts will initially become the indicators of change to inform the questions for further exploration in the GMB workshops.

CMI Recruitment

Between 5 and 10 key informants will be recruited as CMI participants. Participants will include 2 to 3 key people from the following groups: BBM staff members, long-term community members (including volunteers) who are focused on sustained engagement with BBM, and relevant funding representatives to BBM who are interested in the program meeting its purpose and remaining sustainable. Inclusion criteria for BBM staff are the founder and chief of operations; for male and female participants, they are adult (≥18 years) community members who have engaged with BBM for at least three years; and for funding representatives, the criteria are known funders of BBM projects or have an interest in potentially funding BBM projects. Participants will all give informed consent. Given the small number of participants required for the study's recruitment, they will be individually approached by our lead researcher, who has strong connections within the BBM community.

While standard qualitative approaches using thematic analysis require continuing recruitment until data saturation is reached, in this study the data are the complex maps created during the interviews. The purpose of the CMIs is not to get definitive maps but to better understand how to frame and define the central "problem" being placed on the table as the purpose of the GMB workshops.

The interviews will generally be 30 to 60 minutes long with a researcher hand-drawing the maps. Seeking clarification that the relationships and directions of influence are being accurately represented will help keep the interviewees engaged.

Developing the CMI Questionnaire

An open-ended questionnaire will be co-designed in consultation with all of the investigators and our BBM partners. This will ensure that the questions are inclusive of the frameworks and approaches guiding this study. For instance, prompts will support participants to think holistically, upholding Pacific and Māori cultural values housed within the respective models described above. The questionnaire will be piloted prior to the CMIs and assessed for cultural relevance. We will use the "purpose of BBM" for the lead staff and the funders to identify

XSL•FO
RenderX

common understandings of the BBM purpose and what drivers help if fulfill that purpose and what the consequences would be from achieving that purpose. For the participants, the central issue will be engagement with BBM—the antecedents that drive participation and the consequences of high participation.

CMI Processes

The purpose of the CMIs is to seek the views of these key stakeholders as to the purpose of BBM, what would ensure its success and sustainability in achieving that purpose, and what the outcomes for the community would be if BBM achieved that purpose. The interviews will be conducted by the lead researcher (FS), who is of Māori and Samoan descent, and an associate researcher (TH), who is of Māori descent. The mapping will be conducted by BS, who is experienced in CMI research. FS and TL have undergone training in CMI and GMB from Synergia, an analytical company with considerable experience and expertise in designing and developing health networks. Their combined knowledge and expertise will ensure appropriate cultural formalities to allow participants to feel comfortable and culturally safe during the interview process. Interviews can be conducted in English, Samoan, or Te Reo (Māori) if desired by the participants. To align with *kaupapa Māori* methodology, the interview will begin with the lead researcher offering a *karakia* (prayer) to appropriately open and guide the interview process. A closing prayer will be shared to bring the interview to an end for everyone involved. Interviews will be audiotaped to allow the researchers to refer back to their maps for review.

Consistent with Māori and Pacific preferences for engagement, we prefer that interviews occur face-to-face either at a BBM gym (for BBM staff) or at a location suitable to the participant. For external collaborators (eg, funding representatives), the researchers will offer a university campus meeting room (south or central Auckland), or participants may choose their place of employment. If face-to-face is not suitable, a virtual meeting platform (eg, Zoom) will be used, in which case only sound will be recorded. During the interview, one researcher will lead the interview guided by the questionnaire, and the other will construct a hand-drawn cognitive map. The interviewee will review the interviewer's interpretation of comments, illustrated in the map, throughout the session. The interview transcript, map, and consent form will be linked by participant number rather than name to maintain confidentiality. Participants will be given a small *koha* (gift) at the conclusion of the interview to thank them for their involvement and acknowledge their contribution to the study. Following the interview, the hand-drawn maps will be refined and drawn digitally. Participants will be emailed the transcript and the digital version of the cognitive map constructed during their interview, and they will be called to verify them and take any suggestions they offer.

The results from the interviews will form the basis of the GMB workshops. The purpose of using CMI is to generate an informed base of knowledge about what team members, community members, and funders believe are the strengths and challenges of delivering a holistic, effective, and sustained service for the community. In particular, the themes that emerge will provide the key indicators for the expected changes over time. These will form the "reference behaviors" for the GMB workshops. A reference behavior is a key indicator within the system that has a changing pattern over time and, looking into the future, has a more or less desirable trajectory. For example, participant engagement with the BBM sessions typically starts high with enrollment but then wanes over time. The less desired trajectory is a greater disengagement profile, in the future and the more desired trajectory is greater engagement because this is known to be a strong predictor of long-term weight loss maintenance. For sustainability, increasing funding will be needed over time, with declines in funding being the less desirable trajectory.

Phase 2: Group Model Building

GMB problems can be defined in terms of solutions; for example, how BBM may increase the degree and length of engagement of participants with BBM.

Developing the GMB Scripts

The structured scripts to use in the GMB workshops will be co-designed with the BBM coresearchers involved in this research project to align the research processes with the community's needs. Scriptapedia is a repository of short, facilitated activities (scripts). It is an evolving, open-source handbook of contributed scripts that can be considered best practices, promising, or under development [31]. These scripts can be easily edited to suit the local environment, cultures, and the problem or issue being investigated.

We will weave relevant scripts together to create the facilitated, structured discussions for our GMB workshops. This will help to ensure that the workshops achieve the desired outcomes of creating systems maps and action priorities, as well as upskill the participants in their systems thinking so that they can better understand the nature of the issue being mapped and the ways to orient the BBM systems for improved outcomes. The interactions within a group during a GMB workshop need to make the best use of their time and ensure that the overall process moves forward in an organized fashion, ultimately providing insights for the research team and stakeholders [20].

GMB Workshop Recruitment

Participants will be recruited for 2 series of workshops, with 15-20 participants per series. One series will be with BBM employees and volunteers (staff), and the other with active BBM community members, including volunteers, who engage with the organization on a regular basis (members). Each series will consist of 3 workshops with about 2 weeks between them. All workshops will be held at one of the BBM gyms in either south or west Auckland or the University of Auckland's south Auckland campus. Recruitment for both series will be a collaborative process between researchers and BBM staff to negotiate recruitment at a time and place suitable to participants and BBM. For BBM community members to be invited, they will need to have been active members for at least 6 months prior to the planned workshops and plan to continue to engage on a regular basis. BBM holds attendance records and member details, so the research team will work with BBM staff to purposively invite a representative balance of male and female adult (aged ≥18 years) members to participate. There will be

XSL•FO
RenderX

no ethnic exclusions, but the aim is to have predominantly Pacific and Māori participants. People who have previously participated in the CMIs and those who are not fluent in English, Māori, or Samoan will be excluded. All participants will give informed consent and will be offered *koha* (reimbursement) for their time, in line with our ethics approval.

GMB Processes

The GMB workshops will be co-designed by the research team and the coresearchers from BBM (DL and FL) to ensure that the questions asked, processes put in place, and language used are appropriate for the participants. Prior to the first series of workshops, the researchers will carry out training with a single series of mock workshops with a small number of Māori and Pacific staff and students as test participants to trial the structured scripts and activities for flow, cultural appropriateness, and timing.

Each workshop will follow a defined structure and process. In alignment with *kaupapa Māori*, a *karakia* (prayer) will be used to open and close the workshops. *Kai* (food) and *koha* (a small gift) for participants will be included. *Kai* is a sign of hospitality, an example of showing *manaakitanga* (kindness) and willingness to create an inviting environment. *Koha* is a sign of reciprocity. The participants will be sharing their knowledge and perspectives; therefore, we must acknowledge their valuable contribution and the time they have taken to take part in our research project.

The aim is to keep each workshop to less than 3 hours and to allow for appropriate *whakawhanaungatanga* (introductions and group activities) and breaks, as well as covering the necessary content.

Previous co-design research combining Indigenous and Pacific knowledge and systems thinking will help shape our processes. The goal of workshop 1 will be to orientate the groups and develop a shared understanding of the key issues through a series of constructed activities through the scripts, designed and edited from Scriptapedia. The first will be “hopes and fears” [32], which will assist with the *whakawhanaungatanga* (getting to know each other) process. This will be followed by another script called “reference behaviors over time” to help participants start thinking dynamically by looking at the key indicators (reference behaviors) identified from the CMIs. This is followed by a third script, “connection circles,” using software called STICKE (systems thinking in community knowledge exchange), which has been developed in collaboration with Victorian communities through research undertaken by Deakin University. The process helps participants start thinking about the components of an issue and their relationships, or cause and effect (eg, increasing stories and photos through the BBM Facebook page and media increases the sense of engagement with BBM among participants).

In workshop 2, participants will start to construct a visual map of the BBM organization through a series of “feedback” loops, also known as causal loop diagrams (CLDs), which demonstrate sustainable cause and effect loops; a classic example is the chicken and egg loop. The CLDs are also developed in STICKE and are a continuation of the connection circles activity.

In the third workshop, the participants will review and explore further these CLDs to ensure they fully represent their perspectives and visual maps, make any further additions or adjustments, and identify future actions using the identified system levers. Action ideas would be assessed based on practicality, whether they are achievable, and the size of the effect.

Quality criteria for phase 2 are the use of *kaupapa Māori* principles to ensure that participants feel culturally safe and are treated with respect; the researcher training sessions of mock workshops; the use of standardized scripts; support in the development of CLDs; and a final reflective session to make additions and adjustments and make sure their action ideas are practical, feasible, and achievable. Additionally, *kaupapa Māori* allows for flexibility; while each workshop has a defined structure and process, researchers are willing to adjust those processes if they are not helpful for the participants or make anyone feel uncomfortable. Finally, the lead facilitators of these workshops will remove any jargon or intimidating terms that may discourage participants from engaging in the workshops. It is important to note that it is the researcher’s responsibility to ensure that the way the content is communicated is just as important as the content itself. The lead Māori and Pacific researchers will be constantly checking in with participants to encourage feedback, increase engagement, and establish trust with them.

Phase 3: The System Dynamics Logic Model and Action Plan

In phase 3, the outputs of the CMI will inform the development of 2 system dynamic logic models, one from BBM staff and one from BBM members. In alignment with our methodologies for this study, creating a dynamic model allows for more community input and engagement. Māori and Pacific communities are unique population groups that require a system that is tailored to their sociocultural values and beliefs.

By focusing on creating systems models with feedback loops rather than linear models, this study aims to incorporate and highlight the actions and factors that specifically relate to Māori and Pacific communities. This is done by the research team and members of the BBM team using the visual systems maps created during the GMB workshops to build a system model of change that benefits the BBM community. BBM senior staff members, including DL, and the research team will collectively develop an action plan based on the learnings from these models.

Quality criteria for phase 3 include the final 2 system dynamics logic models, one from BBM staff and one from BBM members, informed by the robust processes conducted in phases 1 and 2. Adherence to Māori and Pacific cultural values and principles means that the models and subsequent action plans incorporate and highlight the actions and factors that specifically relate to these communities.

Ethics Approval

Ethical approval for the evaluation study was given by the Health and Disability Ethics Committee New Zealand for 3 years on June 30, 2021 (21/STH/122), with an amendment for

XSL•FO
RenderX

the cognitive mapping component of the project approved on November 9, 2022.

Participants in the CMI and GMB will be provided with participant information sheets and will give informed consent. All participants will be anonymous. Participants will receive NZD $50 (US $31) supermarket vouchers per session as compensation for their time.

Results

The 2 logic models will inform BBM's future developments as a sustainable organization. The end result of this study will be an action plan based on the logic model and system levers for how BBM can optimize its effectiveness, sustainability, and quality improvement.

BBM was developed by DL, who is a charismatic leader and continues to actively drive the organization in new directions to meet arising community needs. The action plan will include consideration of how and whether BBM can continue to grow and expand independently of DL's charismatic leadership.

Discussion

Summary of Findings

This study aims to build culturally centered system dynamics logic models to serve as the agreed theories of change for BBM and provide a basis for its ongoing effectiveness, sustainability, and continuous quality improvements. To achieve this, we will adopt a novel and innovative approach, using systems science along with collaborative co-design embedded within Pacific and Māori world views and weaving together a number of frameworks and methodologies to create a system dynamics logic model for BBM. These are highly compatible approaches with strong potential synergies.

The final result will be an action plan for BBM to hone the underlying system features identified in the 2 logic models.

A logic model that takes the dynamics of the system into account with feedback loops that improve effectiveness, sustainability, and quality can be explicitly considered in action plans for the ongoing success of BBM. The use of STICKE makes the process of creating the systems maps more accessible and available in real time.

The culturally centered design is to ensure relevance and connection to the cultures and world views of the participants, the BBM team, and their communities, and the innovations and learnings that could come from joining up these approaches will guide the further development of BBM.

How These Findings May Relate to the Literature

Having developed the models and the plan, we will determine how this compares with other published studies, and how it fits into the existing literature with respect to its interpretations and implications.

Limitations

The maps developed in the CMI phase will reflect the perceptions of the organizational structure of the key people selected to interview. There is a subjective component to generating these data. While 2 to 3 people selected for each of the 3 categories (staff, members, and funders) will be those seen as key personnel, it is possible that if a larger sample was used, there might be more variability in the information used to inform the GMB. However, we are not aiming to develop definitive themes from the CMIs. Instead, CLDs from these will provide a guiding example for the GMB participants who will go on to identify other major causal drivers to be considered thoroughly by the wider group.

Similarly, an increased number of participants in the GMI workshops might result in more divergency in the created maps.

Conclusions

This study will adopt a novel and innovative approach to co-designing culturally centered system dynamics logic models for BBM by using systems science methods embedded within Pacific and Māori world views and weaving together a number of frameworks and methodologies. These will form the theories of change to enhance BBM's effectiveness, sustainability, and continuous improvement.

Programs aiming to change people's health behaviors and reduce health inequities can be complex and fail to deliver because they do not overcome the barriers to the system and individual change that they encounter. This includes the application of Western principles to ethnic minorities. Beyond the goal of informing BBM on how it may introduce quality improvements and address identified system issues, we hope that our study will provide a framework for other organizations and networks to assess system factors that might be beneficial to address in a culturally centered and safe manner.

Acknowledgments

FS and TH drafted the preliminary protocol. FGS drafted the initial paper for publication. FS, FGS, WB, BS, DL, TH, and FL contributed to the design of the study. TH provided *kaupapa Māori* oversight. All authors contributed to the writing of the paper, and all have read and approved the final manuscript. This study is funded by the Health Research Council of New Zealand, (21-280) and University of Auckland (3722251). The funding body plays no role in the design of the study, the collection, analysis, and interpretation of data, or the writing of the manuscript.

Abstract

Background: Asthma attacks are a common and important problem. Someone experiences an asthma attack in the United Kingdom every 10 seconds. Asthma attacks cause coughing, wheezing, breathlessness, and chest tightness and are highly stressful for patients. They result in reduced quality of life, with days lost from work or school. Asthma attacks are treated with oral corticosteroids (OCSs), but these have many short- and long-term side effects. Asthma monoclonal antibodies (mAbs) have revolutionized the treatment of severe asthma by reducing asthma attacks and OCS burden by over 50%, but some people still experience attacks while on mAbs. The MEX study showed that residual asthma attacks are broadly eosinophilic (high fractional exhaled nitric oxide [FeNO]) or noneosinophilic (low FeNO), but it did not measure response to OCS treatment. There is an evidence gap in understanding the clinical and inflammatory responses that occur when using OCSs to treat residual asthma attacks in patients taking asthma mAbs.

Objective: The primary objective is to compare the clinical recovery between high-FeNO and low-FeNO attacks after acute treatment with oral prednisolone among people established on long-term asthma mAb treatment. The exploratory objective is to compare the inflammatory response to acute treatment with oral prednisolone between high-FeNO and low-FeNO attacks.

Methods: BOOST (Breakthrough Asthma Attacks Treated With Oral Steroids) is a single-center, prospective observational study of 60 adults established on long-term asthma mAb treatment who receive acute treatment with oral prednisolone (usual care) for an asthma attack. The primary outcome will be the proportion of treatment failure (the need to start oral prednisolone or antibiotics or an unscheduled health care visit for asthma, following an attack) at day 28. The secondary outcomes will be the change in forced expiratory volume in 1 second and the change in visual analogue scale symptom score between the stable state, attack, day 7, and day 28 visits. The exploratory outcomes include the changes in sputum, nasal, and blood inflammometry between the stable state, attack, day 7, and day 28 visits.

Results: The last asthma attack visit is anticipated to occur in December 2023. Data analysis and publication will take place in 2024.

Conclusions: We will test the hypothesis that there is a difference in the rate of recovery of clinical and inflammatory measures between high-FeNO and low-FeNO asthma attacks that occur in patients on mAb therapy. The study data will help power a future randomized placebo-controlled trial of prednisolone treatment for nonsevere attacks in patients treated with asthma mAbs and will provide important information on whether corticosteroid treatment should be FeNO-directed.

Introduction

Asthma is a common and important problem. Clinically, asthma is characterized by variable symptoms of breathlessness, coughing, chest tightness, and wheezing. Asthma attacks are acute deteriorations in asthma symptoms and affect a person's physical activity, work, personal life, and mental health [1]. The presence of raised type 2 airway inflammation increases the risk of asthma attacks and lung function decline. Blood eosinophils and fractional exhaled nitric oxide (FeNO) have emerged as key biomarkers of type 2 inflammation [2].

The cornerstone of asthma treatment is inhaled corticosteroids (ICSs), which reduce type 2 inflammation. However, 10% of adults experience severe asthma with frequent asthma attacks, despite ICS treatment [3]. These attacks are treated with 5- to 7-day bursts of high-dose oral corticosteroids (OCSs), based on trial data showing a 50% lower risk of relapse at 21 days in comparison to a placebo [4]. However, all of the randomized placebo-controlled trials of OCSs for asthma attacks were conducted in an era before the widespread use of ICSs, implying that the efficacy of OCSs in mild to moderate attacks may be overstated. Moreover, OCSs have a significant acute side effect burden, and their cumulative toxicity is serious [5].

Asthma monoclonal antibody (mAb) therapies have revolutionized the treatment of severe asthma. They target specific parts of the type 2 inflammatory pathway and have fewer side effects than OCSs. The key classes of mAbs are anti-immunoglobulin E (omalizumab), anti–interleukin (IL) 5 and anti-IL5R (mepolizumab, reslizumab, and benralizumab), anti-IL4Rα (dupilumab), and anti–thymic stromal lymphopoietin (tezepelumab) [6]. The randomized trials of these drugs versus a placebo demonstrated an over 50% reduction in asthma attacks requiring OCSs [7]. On average, people continue to experience 1 asthma attack per year. The current practice is for these asthma attacks to be treated with OCSs.

Patients effectively treated with asthma biologics generally exhibit reduced type 2 inflammation. Consequently, they are ideal patients for testing the hypothesis that OCSs are only useful in treating attacks with evidence of type 2 inflammation. This has already been explored in patients with chronic obstructive pulmonary disease (COPD) but not asthma. Two randomized controlled trials undertaken in patients with COPD showed that among the patients with low blood eosinophil levels at the time of a COPD attack, OCS treatment did not improve outcomes, when compared with a placebo, in terms of treatment failure [8,9].

The MEX study was the first prospective, multicenter, observational study to characterize asthma attacks in patients on mepolizumab [10]. It found that attacks were often clinically mild and heterogeneous in nature. Attacks were broadly defined as eosinophilic (high FeNO) or noneosinophilic (low FeNO). BenRex is a similar ongoing study characterizing attacks in patients treated with benralizumab [11]. Neither study was designed to examine recovery from an attack after treatment with OCSs.

The findings from the MEX study point to a possible biomarker-directed option for treating asthma attacks based on FeNO. Attacks among people on anti-IL5 treatment with raised FeNO may imply ongoing IL-4, IL-13, or alarmin activity, which may be OCS-responsive [12]. The noneosinophilic attacks were frequently positive for viruses or bacteria and had a higher C-reactive protein level, indicating that they were probably pathogen-driven. This process would not be expected to respond to OCSs.

There is a large evidence gap in understanding the clinical and inflammatory responses that occur when using OCSs to treat asthma attacks in patients treated with asthma mAbs. Our prospective observational study will examine these responses to help inform whether a future randomized placebo-controlled trial of prednisolone treatment for nonsevere attacks in patients treated with asthma mAbs should be FeNO-directed.

Methods

Hypothesis

In people established on anti-IL5, anti-IL5Rα, and anti-IL4Rα mAb treatment for asthma, high-FeNO asthma attacks will show more clinical and inflammatory responses to acute oral prednisolone treatment than low-FeNO asthma attacks.

Objectives

The primary objective is to compare the clinical recovery between high-FeNO and low-FeNO attacks after acute treatment with oral prednisolone among people established on anti-IL5, anti-IL5Rα, and anti-IL4Rα treatment for asthma. The exploratory objective is to compare the inflammatory response to acute treatment with oral prednisolone between high-FeNO and low-FeNO attacks among people established on anti-IL5, anti-IL5Rα, and anti-IL4Rα treatment for asthma.

Study Design

BOOST (Breakthrough Asthma Attacks Treated With Oral Steroids) is a single-center, prospective observational study of 60 adults established on long-term asthma mAb treatment who receive acute treatment with oral prednisolone (usual care) for an asthma attack.

Participant Recruitment

All participants will be recruited from the Oxford Special Airways Clinic, which is based at the Oxford Centre for Respiratory Medicine at the John Radcliffe Hospital. This service provides specialist assessments for patients with complex airway diseases and has a large cohort of patients on asthma

XSL•FO
RenderX

mAb treatment under regular review. The service also provides a rapid assessment clinic for the clinical review of patients who experience an asthma attack while on mAb treatment.

There are 2 routes for a participant to enroll into the study. Participants can be enrolled into a study pool at stable state. If they exacerbate, they can contact the department to initiate an attack visit to the rapid assessment clinic. Alternatively, participants may directly enter the study at the time of an attack if they have contacted the rapid assessment clinic for review but are not in the study pool. These participants will have a stable state visit at least 2 months after the attack date.

If a participant in the study pool has not experienced an asthma attack when the study's attack recruitment target has been met, they will be invited for an optional additional visit at stable state to form a stable control group.

Ethical Considerations

BOOST is a substudy of the Oxford Airways Study (Integrated Research Application System Project number: 234581; Oxfordshire Research Ethics Committee B reference number: 18/SC/0361). The Oxford Airways Study is an observational study that will measure clinical measures, biomarkers, inflammation, and mediators among participants with airway diseases at stable state and during an acute attack.

Participants will be consented to the Oxford Airways Study at their first study visit.

Inclusion Criteria

The inclusion criteria are as follows: (1) people treated with an anti-IL5, anti-IL5Rα, and anti-IL4Rα mAb for asthma (mepolizumab, benralizumab, reslizumab, or dupilumab) under the Oxford Special Airways Clinic; (2) patients established on the same mAb treatment for at least 2 months; (3) male or female patients aged 18 years or older; and (4) patients who experience at least 1 asthma attack requiring oral prednisolone treatment since starting mAb treatment.

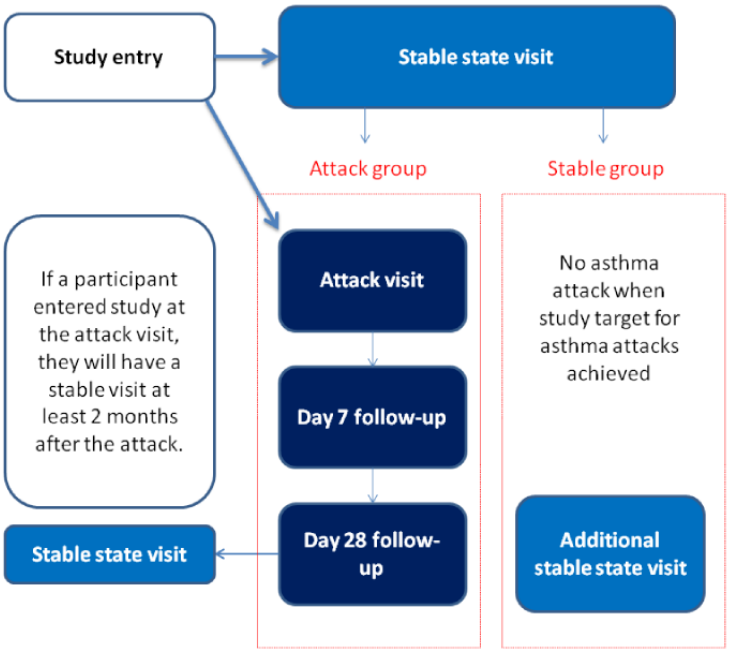
Exclusion Criteria

The general exclusion criteria are as follows: (1) maintenance OCS treatment for asthma or any other condition, (2) people who are unwilling or unable to attend follow-up visits, (3) people who are pregnant or are planning pregnancy at the time of study entry, and (4) people on long-term systemic immunosuppressive treatment for a condition other than asthma.

At asthma attack visit, the following exclusion criteria will be assessed: (1) pneumonia on a chest radiograph at the time of an attack, (2) any treatment with OCSs in the preceding 1 month, and (3) the trial physician's opinion that a person needs hospitalization at the time of assessment.

Intervention at Asthma Attack Visit

A consultation will be arranged at the rapid assessment clinic if a participant feels that their asthma symptoms have deteriorated and they need treatment. The participant will be assessed by the study physician via medical history taking, clinical examination, and chest radiograph examination. This is in line with our usual practice. If a diagnosis of an asthma attack is made and the participant is eligible, they will start the study-specific measurements (Table 1).



Each participant will be treated with 40 mg of oral prednisolone once per day for 7 days as part of usual care for an asthma attack, as per British Thoracic Society guidelines. Antibiotic treatment will not be routinely prescribed at the asthma attack visit. If a participant is already on antibiotic therapy prior to the attack visit (eg, prescribed in general practice), this will be continued until the prescribed course is complete, as per usual care (Figure 1).

Unplanned Study Visits

If a participant feels that their asthma symptoms have deteriorated or that they need more treatment, between the attack visit and day 28 visit, they will be encouraged to contact the study team. As per usual care, the participant will be assessed by the study team, by the participant's general practitioner, or in an urgent care setting. If the participant is assessed by the study team, routine clinical measurements will be taken at the discretion of the study physician, but no research samples will be taken. If a participant is assessed by their general practitioner or in an urgent care setting, the study team will ask the

XSL•FO
RenderX

participant what medical treatment they received and whether they needed a hospital visit. Where possible, this information will be corroborated with health records.

Outcomes

The primary outcome is the comparison of the proportion of treatment failure at day 28 between high-FeNO and low-FeNO attacks.

The secondary outcomes are as follows: (1) comparison of the change in forced expiratory volume in 1 second (FEV_1) from stable state to day 0, day 7, and day 28 between high-FeNO and low-FeNO attacks; (2) comparison of the change in visual analogue scale (VAS) symptom score from stable state to day 0, as well as daily VAS symptom score changes from day 0 to day 28, between high-FeNO and low-FeNO attacks; and (3) comparison of the change in Asthma Control Questionnaire and Asthma Control Test symptom scores from stable state to day 0, day 7, and day 28 between high-FeNO and low-FeNO attacks.

The exploratory outcomes are as follows: (1) comparison of the changes in sputum, blood, and nasal lining fluid inflammometry; (2) comparison of the changes in sputum and blood transcriptomics; (3) comparison of microbiology statuses at asthma attack; (4) comparison of neutrophil elastase detection findings at asthma attack; (5) comparison of genomic data; (6) determination of the predictors of clinical and inflammatory responses to prednisolone treatment; and (7) inhaler adherence data, which will be obtained from prescription refill records at asthma attack visit.

Sample Size Requirements

The clinical and inflammatory effects of prednisolone for asthma attacks in patients treated with asthma mAbs are unknown. Therefore, an important aim of this observational study is to understand the proportions and SDs of key measurements related to these effects. These will help determine if a future randomized placebo-controlled study of prednisolone treatment for attacks in people treated with asthma mAb therapy should be FeNO-directed.

Because there are no published data on treatment response to prednisolone for asthma attacks in this population, we based our hypothesis and sample size estimates on our clinical experiences with attacks that we assessed and treated locally over recent years. We estimated the proportion of treatment failure at 28 days to be 0.05 in the high-FeNO group and 0.35 in the low-FeNO group. Further, based on the MEX study, in which roughly half of the asthma attacks among patients on mAbs were high-FeNO attacks and the other half were low-FeNO attacks, we estimated an average treatment failure proportion of 0.2 for our sample. This proportion is consistent with published systematic review data on the treatment failure at 28 days after an asthma attack (ie, among patients not on mAb therapy) [13].

Using a 2-sided α of .05, a β of .8, an equal high-FeNO and low-FeNO group ratio, and a 10% dropout rate, the total sample size required to detect the estimated proportions of treatment failure described above was calculated to be 60 asthma attacks. Additionally, 60 asthma attacks are also adequate for detecting a clinically meaningful difference in the change in FEV_1 from day 0 to day 7 between the high-FeNO and low-FeNO groups (mean 0.4 vs mean 0, SD 0.5 L). Further, 60 attacks can be used detect a clinically meaningful difference in the change in VAS symptom score from day 0 to day 7 between the high-FeNO and low-FeNO groups (mean 15 vs mean 0, SD 17 mm).

Statistical Analysis Plan

Overview

Descriptive statistics will be used to describe variables. For continuous variables, the differences in the means and the corresponding 95% CIs will be reported between the high-FeNO and low-FeNO groups and for the overall sample. For categorical variables, chi-square tests will be used for comparing treatment groups if the variables are normally distributed. If a variable is not normally distributed, a nonparametric test will be used for the analysis.

Primary Analysis

In our study, treatment failure will be defined as a need to start oral prednisolone or antibiotics or an unscheduled health care visit for asthma.

The comparison of proportions of treatment failure at day 28 between the high-FeNO and low-FeNO groups will be conducted with a Fisher exact test. The comparison of the time to treatment failure between the high-FeNO and low-FeNO groups will be presented with a Kaplan-Meier analysis. Additionally, we will construct a Cox proportional-hazards model to compare the time to treatment failure between high-FeNO and low-FeNO groups based on the following two interactions: (1) specific mAb treatment and (2) the use of antibiotics within the 2 weeks preceding the attack visit (inclusive of the attack visit day). We will construct a forest plot to assess potential predictors of treatment failure among the high-FeNO and low-FeNO groups.

There is no consensus for a low-FeNO versus high-FeNO attack threshold regarding response to prednisolone. For the purposes of the primary statistical analysis, we prespecified 25 parts per billion (ppb) as the main threshold to define low-FeNO and high-FeNO attacks. This threshold is based on sputum eosinophil data from the MEX study [10].

Any missing treatment failure outcome data will be dealt with via nonresponder imputation.

Secondary Analysis

We will analyze treatment failure by using a threshold of 50 ppb to define low-FeNO and high-FeNO attacks. This is based on data showing that an FeNO level of ≥50 ppb (high FeNO) is associated with a high risk of future asthma attacks for any patient with asthma [14].

We will use linear mixed-effects models to compare continuous data from the three secondary outcomes, across different time points, between high-FeNO and low-FeNO attacks. The random effect will be the participants. The fixed effects will be (1) specific mAb treatment, (2) the use of antibiotics within the 2 weeks preceding the attack visit (inclusive of the attack visit day), (3) the number of asthma attacks in the 12 months prior

XSL•FO
RenderX

to the attack visit, and (4) percent predicted FEV_1 at the attack visit.

Any missing secondary outcome data will be dealt with in the linear mixed-effects model by using the missing at random assumption.

The prediction of clinical responses to prednisolone will be performed via the generation of receiver operator characteristic curves and correlation coefficients, cluster analysis, and regression models.

Exploratory Analysis

We will run paired statistical tests and regression models to analyze the exploratory outcomes.

Results

Recruitment started in September 2022. The target number of asthma attacks is expected to be reached by December 2023. Data analysis and publication will take place in 2024. Results will be published in peer-reviewed journals.

Discussion

Our observational study aims to explore whether the presence of type 2 inflammation, as measured based on FeNO, predicts response to oral prednisolone for an asthma attack in an mAb-treated person. The study is novel because this response has not yet been assessed in a structured way before and after prednisolone treatment. We will measure response by using treatment failure, as this is a clinically important outcome for both people with asthma and health care professionals. It represents disruption to a person's life, as well as health care utilization. Additionally, it is equivalent to the relapse outcome measured in the randomized placebo-controlled trials of OCSs in the 1980s and 1990s [4]. Other important outcomes will include symptom recovery, which is important to patients, and lung function, which captures a physiological change. Exploratory outcomes will include nasal, sputum, and blood inflammatory markers, which will be measured by using immunoassays and transcriptomics to assess whether high-FeNO attacks display evidence of ongoing pathways of inflammation not targeted by the mAb treatment.

There are several goals in our observational study. First, we expect to see a better clinical response in high-FeNO asthma attacks than in low-FeNO asthma attacks among people on mAb therapy. This is based on evidence from COPD exacerbations, wherein biomarker evidence of inflammation predicts response to OCSs—an anti-inflammatory treatment [8]. These data will help inform whether a future randomized controlled trial of prednisolone treatment for nonsevere attacks in patients treated with asthma mAbs should be FeNO-directed. This future trial is important because OCSs have significant side effects; therefore, a precision medicine approach is preferable to the existing one-size-fits-all approach. Second, we will start to explore the question about whether high-FeNO attacks have different underlying pathophysiological processes that are still steroid-responsive. This will provide novel data to the field, and such data are important, as they will help with the development of biomarkers that can predict whether certain people will respond better to a particular mAb therapy.

The main limitation of the study is that it is observational in nature, with no randomization, blinding, or placebo control. It is therefore subject to selection, reporting, and experimenter biases. We have tried to minimize these with our inclusion and exclusion criteria and by controlling for confounders in the statistical analyses. Ultimately, our study is hypothesis-generating research and is pilot work on which a larger, definitive trial will be based.

With our study, we hope to continue precision medicine research in asthma and begin to challenge the dogma that OCSs are effective in all asthma attacks.

Acknowledgments

The project and authors are supported by a grant from the National Institute for Health Research (NIHR) Respiratory Biomedical Research Centre. Additionally, TSCH is supported by a grant from the Wellcome Trust (grants 211050/Z/18/z and 211050/Z/18/A).
