Abstract

Background: Malnutrition among older adults with dysphagia is common. Texture-modified foods (TMFs) are an essential part of dysphagia management. In long-term care (LTC) facilities, health professionals have implemented TMFs, but their application has not been fully elucidated, making them heterogeneous.

Objective: We aim to explore the implementation of TMFs in LTC facilities, particularly focusing on the role of health professionals in nutritional care involving TMFs (eg, deciding the type of food, preparing and giving the food, and evaluating the outcomes).

Methods: A scoping review using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodological approach will be performed. A comprehensive search for published literature will be systematically performed in PubMed, CINAHL, MEDLINE, ProQuest, PsycINFO, and Science Citation Index (Web of Science). Data screening and extraction will be performed by 2 reviewers independently. The studies included will be synthesized, summarized, and reported, following the preferred reporting items of the Mixed Methods Appraisal Tool. Our review will consider the following study designs: mixed methods, quantitative, and qualitative. Studies with patients who are not older adults will be excluded.

Results: Data extraction will be completed by February 2023. Data presentation and analyses will be completed by April 2023, and the final outcomes will be completed by June 2023. The study findings will be published in a peer-reviewed journal.

Conclusions: Our scoping review will consider studies related to TMF interventions for older adults in LTC residential facilities, with no exclusion restrictions based on country, gender, or comorbidities. Studies on interventions that address TMF-related issues, such as deciding the type of food, preparing and giving the food, and evaluating the outcomes, are qualified for inclusion.

Introduction

Background

Malnutrition is prevalent among the older adult population. The prevalence of malnutrition among older adults has been reported to be between 1.3% to 47.8% in the community [1], but in long-term care (LTC) facilities, the prevalence of malnutrition is much higher, ranging from 30% to 60%, and malnutrition has a significant negative impact on the health of older adults [2-4]. Malnutrition in older adults is often associated with dysphagia [5]. The prevalence of dysphagia among older adults ranges from 12% to 60% [6-8]. Texture-modified foods (TMFs) are commonly prescribed for older adults to address the problem of dysphagia [9,10].

Although standardized terminology and international terminology for TMF have been established [11-13], the implementation of TMF is still reported as a public health concern and has resulted in adverse events [14-16]. The implementation of TMF in LTC facilities is related to many factors, including health professionals' knowledge, health facility financing, infrequent dysphagia screening, and the misunderstanding of TMF calories. To understand the gap in TMF implementation, the exploration of TMF implementation by health professionals needs to be reviewed to understand future directions.

Previous studies have reported on the implementation of TMF in LTC facilities [17-19]. However, relatively little research that explores complete information on TMF implementation by health professionals in LTC facilities has been conducted [20]. TMF implementation, the frequency of giving TMFs, target patients, the types of TMFs used, and the implementers of TMF in LTC facilities need to be explored to improve TMF implementation and identify research gaps in TMF implementation within LTC facilities.

An international framework for the implementation of TMF has been developed [13,21]. However, there is no existing literature review on TMF implementation in LTC facilities [22]. There are no clear rules regarding the implementation of TMF in LTC facilities, how to implement TMF, and who should implement TMF. We conducted a preliminary search of PubMed, and no current or underway scoping reviews and systematic reviews on the topic were identified.

The objective of our scoping review is to explore the implementation of TMF in LTC facilities, particularly focusing on the role of health professionals in nutritional care involving TMF.

Review Questions

Our scoping review will address the following research question, mainly focusing on the role of health professionals in nutritional care involving TMF (eg, deciding the type of food, preparing and giving the food, and evaluating the outcomes): how is the implementation of TMF in LTC facilities?

Participants

Our scoping review will consider studies describing the implementation of TMF in LTC residential facilities. Older adults will be defined in our study as those aged ≥60 years [23]. No exclusions will be made based on country, gender, or a specific medical condition.

Intervention

Health professionals have implemented TMF in LTC facilities. Health professionals undertake remunerated work for which formal education is required (eg, nurses, dietitians, physicians, speech therapists, and paramedical workers). They are classified based on the International Standard Classification of Occupation [24,25]. Studies will be excluded if the roles of health professionals in the provision of TMF are not clearly defined. We aim to explore the implementation of TMF in LTC facilities, mainly focusing on the role of health professionals in nutritional care involving TMF (eg, deciding the type of food, preparing and giving the food, and evaluating the outcomes).

Concept

The concept of interest is any implementation of TMF. TMFs and thickened drinks are commonly used to reduce choking risks and aspiration [26]. Studies on the implementation of TMF will be considered eligible if they explain who implemented TMFs in LTC facilities; how to implement TMF; and at least one of the following: how to decide the type of TMF, how to prepare and give TMFs, how to improve nutritional support in geriatrics through TMFs, how to evaluate the implementation of TMFs, or how to address any other TMF-related issues. Our study will include older adult–reported outcomes and health professional–reported outcomes described by the authors. Studies will be eligible if they include at least one TMF-related implementation.

Context

We will select studies set in LTC facilities. LTC facilities are designed institutions that provide formal (paid) accommodation and include health or social LTC facilities [27]. Studies will be included if their contexts suit this LTC facility description. Studies will be included regardless of the registration, orientation, type, or scope of the LTC facilities or the qualifications of health care professionals. Studies will be excluded if patients were cared for without health care professionals working in LTC facilities. Studies will also be excluded if institutionalized care was conducted as home care. Studies conducted in diverse facilities will be included if findings from LTC facilities can be identified [28].

Types of Sources

Mixed methods, quantitative, and qualitative study designs are eligible for inclusion in our review. We will include studies published from database inception to the date of the search. Documents will be considered eligible only if the full text is available. Only articles available in English, Japanese, and Bahasa Indonesia will be considered for inclusion due to limited resources that do not allow for the screening and translation of studies in other languages. The search process will include a filter for participants aged ≥60 years.

XSL•FO
RenderX

Methods

Overview

The final scoping review will be reported based on the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [29]. A preliminary search was carried out on Google Scholar on September 3, 2022, using keywords (*texture modified food*, *health professional*, and *long term care*). There is no existing review that addresses a similar aim as that of our review. Our scoping review is registered in Open Science Framework (registration number: 79AFZ).

Search Strategy

The comprehensive search of bibliographic databases will use PubMed, CINAHL, MEDLINE, ProQuest, PsycINFO, and Science Citation Index (Web of Science). Our search strategies will use the following process [30,31]. First, the scoping review protocol constructs will be identified with an initial logic grid that aligns with the participants, intervention, concept, and context of interest. Second, a pilot search of 2 databases—PubMed and Web of Science—will be conducted. An author will analyze the titles and abstracts of retrieved papers and then confirm the index terms used to describe the articles. Third, the initial logic grid will be reorganized, using all identified keywords and index terms for all included databases (Textbox 1). Fourth, the databases will be screened in the last search for potentially relevant records that were missed in the previous search. The full texts of retrieved review articles will also be reviewed to identify additional potentially relevant documents. An example of the search strategy is presented in Table 1. The pilot search was completed between August and September 2022.

Textbox 1. List of search terms.

Search terms related to participants

- *Older adults, Elderly, Aged, and Senior*

Search terms related to intervention

- *Health professionals; Personnel, Health; Health Care Providers; Health Care Provider; Provider, Health Care; Healthcare Providers; Healthcare Provider; Provider, Healthcare; Healthcare Workers; Healthcare Worker; Health Care Professionals; Health Care Professional; and Professional, Health Care*

Search terms related the concept

- *Texture modified foods, Texture modified, Texture food, and Texture modified diet*

Search terms related to the context

- *Long-term care, Care residential facilities, Residential care, Residential facilities, Residential care institutions, Nursing homes, Elderly homes, Care homes, Assisted living facilities, and Skilled nursing facilities*

XSL•FO

Study Selection

Reference management software (Mendeley [Elsevier]) will be used to manage the retrieved sources and identify duplicate references. The full-text version of an article will be reviewed if the article's eligibility is unclear based on the abstract. Two independent reviewers will screen the full texts of selected studies based on the inclusion criteria. The exclusion of references will be recorded and reported in the scoping review. Any disagreements between reviewers will be resolved through discussion or with the help of a third reviewer.

Data Extraction

The extraction of qualitative data will be carried out in 2 stages. First, the reviewers will read the studies and identify different opinions in the paper, such as original statements from the study participants (ie, first-order constructs) and their interpretations by the researchers or authors (ie, second-order constructs) [32]. Second, the reviewers will reread the studies to extract all raw data. The Excel (Microsoft Corporation) database program will extract the papers included in the review process (Multimedia Appendix 1). The Excel data will include information about the characteristics of the publications, residential facilities, older adults, and health professionals; the implementation of TMF; and the assessment of TMF implementation. The data extraction form will be modified if needed and detailed in the full scoping review. Further, 2 researchers will independently extract the data, 2 researchers will confirm the consistency of the extraction, and 1 reviewer and 1 verifier will review all papers. Any disagreements among reviewers will be resolved through discussion. If a paper has missing data or needs additional data, we will contact the authors of the paper. Such papers will be omitted or described as papers that are missing data if the papers' authors do not respond in 14 days.

Data Presentation

A thematic analysis approach will be used to synthesize the data. The data synthesis will consist of the following three stages: (1) synthesizing, (2) summarizing, and (3) reporting the papers reviewed. The stages will follow the preferred reporting items of the Mixed Methods Appraisal Tool [33,34]. A synthesis of analytical themes will be performed. Appropriate information will be reported for our conclusions, including study types, aims, characteristics, types of providers, types of recipients, and information on the implementation of TMF. The study will provide descriptive data (eg, number of studies included, types of study designs, and characteristics of study populations). The implications of the study for future research priorities will be defined.

Results

Data extraction will be completed by February 2023. Data presentation and analyses will be completed by April 2023, and the outcomes will be completed by June 2023. The main results of our investigation will be presented in a narrative form, focusing on research results to date regarding TMF implementation by health professionals. Additional data on publication years, countries, study designs, populations, and settings will be presented in diagrams or in tabular format.

Discussion

Anticipated Findings

The results from our scoping review will explore the implementation of TMF in LTC facilities, particularly focusing on the role of health professionals in nutritional care involving TMF (eg, deciding the type of food, preparing and giving the

XSL•FO
RenderX

food, and evaluating the outcomes). Health professionals play a vital role in TMF-related intervention and decision-making within LTC facilities. To our best knowledge, our study will be the first review of the implementation of TMF in LTC facilities, and it will mainly focus on the role of health professionals in nutritional care involving TMF.

We propose that the results of our study will support the development of existing feeding policies in LTC facilities, especially by identifying current knowledge on the role of health professionals in TMF implementation. Several literature reviews have been performed regarding TMF [22,35,36], including a recent review that focused specifically on the unique challenges in LTC.

The implementation of TMF is tightly related to the quality of care in LTC facilities. Older adults' safety while eating is an essential part of standard safety care in LTC facilities [37]. However, choking incidents in LTC facilities still have low levels of attention, although they may be recognized and understood by health professionals [38]. TMF is provided clinically to reduce choking risk among older adults [13,22,39]. This knowledge may help to improve the design and implementation of future TMFs in LTC facilities, so that their benefits become clear and valuable to older adults.

A limitation of our study might be the concepts of LTC facilities among countries and papers. The country-specific terminology about LTC facilities that has been used relates to goals, providers, activities, and target groups [27,40,41]. Comparing types of LTC facilities is beyond the aim of our study. Therefore, our scoping review will define *LTC facilities* as designed institutions that provide formal accommodation and health or social LTC services for older people.

Conclusion

To our knowledge, our review will be the first systematic scoping review to provide knowledge about the implementation of TMF in LTC facilities, particularly focusing on the role of health professionals in nutritional care involving TMF. Our study will address the evidence-practice gap regarding nutritional sustenance in LTC facilities. The policy makers, decision makers, and health professionals in LTC facilities have insight on TMF implementation. This knowledge may help to improve the design and implementation of future TMFs in LTC facilities. The review will also seek to identify further research gaps and the possible need for further study on TMF.

Acknowledgments

We thank Dr Zhao Ni (Yale School of Nursing, Yale University, Connecticut, United States), for his guidance and support.

Data Availability

All data that have been generated or analyzed during the study are included in this published research protocol (and its supplementary information files). The main outcome analyses are being conducted at the time of publication of this protocol, but specific data sets might be available from the corresponding author upon reasonable request.

Authors' Contributions

DWS and GEA wrote the manuscript and designed figures. RI, FF, MT, and ER contributed to drafting the protocol and were responsible for the conception of the study. All authors read the paper, provided feedback, and approved the paper for submission.

Conflicts of Interest

None declared.

Abstract

Background: Numerous reports contend opioids can augment or inhibit malignancy. At present, there is no consensus on the risk or benefit posed by opioids on malignancy or chemotherapeutic activity. Distinguishing the consequences of opioid use from pain and its management is challenging. Additionally, opioid concentration data is often lacking in clinical studies. A scoping review approach inclusive of preclinical and clinical data will improve our understanding of the risk-benefit relationship concerning commonly prescribed opioids and cancer and cancer treatment.

Objective: The aim of the study is to map diverse studies spanning from preclinical to clinical regarding opioids with malignancy and its treatment.

Methods: This scoping review will use the Arksey six stages framework to (1) identify the research question; (2) identify relevant studies; (3) select studies meeting criteria; (4) extract and chart data; (5) collate, summarize, and report results; and (6) conduct expert consultation. An initial pilot study was undertaken to (1) parameterize the extent and scale of existing data for an evidence review, (2) identify key factors to be extracted in systematic charting efforts, and (3) assess opioid concentration as a variable for its relevance to the central hypothesis. Six databases will be searched with no filters: MEDLINE, Embase, CINAHL Complete, Cochrane Library, Biological Sciences Collection, and International Pharmaceutical Abstracts. Trial registries will include ClinicalTrials.gov, Cochrane CENTRAL, International Standard Randomised Controlled Trial Number Registry, European Union Clinical Trials Register, and World Health Organization International Clinical Trials Registry. Eligibility criteria will include preclinical and clinical study data on opioids effects on tumor growth or survival, or alteration on the antineoplastic activity of chemotherapeutics. We will chart data on (1) opioid concentration from human subjects with cancer, yielding a "physiologic range" to better interpret available preclinical data; (2) patterns of opioid exposure with disease and treatment-related patient outcomes; and (3) the influence of opioids on cancer cell survival, as well as opioid-related changes to cancer cell susceptibility for chemotherapeutics.

Results: This scoping review will present results in narrative forms as well as with the use of tables and diagrams. Initiated in February 2021 at the University of Utah, this protocol is anticipated to generate a scoping review by August 2023. The results of the scoping review will be disseminated through scientific conference proceedings and presentations, stakeholder meetings, and by publication in a peer-reviewed journal.

XSL•FO
RenderX

Conclusions: The findings of this scoping review will provide a comprehensive description of the consequences of prescription opioids on malignancy and its treatment. By incorporating preclinical and clinical data, this scoping review will invite novel comparisons across study types that could inform new basic, translational, and clinical studies regarding risks and benefits of opioid use among patients with cancer.

Introduction

This project stems from a multidisciplinary team approach to better understand the consequences of drug interactions known to occur commonly in the management and care of patients with cancer. In contrast with typical scoping review methodology comprised exclusively of clinical data, this study incorporates a more comprehensive mapping of the literature, inclusive of preclinical data. In many clinical studies, it is difficult or impossible to disambiguate patient outcomes related to opioid use from the consequence of pain or pain management. This is because opioid use is often the measure by which pain is assessed. Therefore, our approach will enable a new perspective on an old and controversial problem.

Opioid analgesics are among the most frequently administered drugs for patients with cancer, and their use often coincides with active chemotherapeutic regimens [1]. The intended target for opioid analgesics is the μ-opioid receptor (μOR) expressed within the central nervous system [2]. However, the μOR is also present in diverse cancer types [3]. In cancer cells, μOR activity can stimulate intracellular signal cascades that regulate processes of cell survival and death and can coincide with the same signal cascades triggered by cytotoxic chemotherapy [3-12]. Some clinical studies for specific cancer types have identified the μOR as a negative prognostic factor and associated with chemotherapy resistance [3,13-23].

Paradoxically, opioids have demonstrated potential to both augment and inhibit cancer cell growth and survival as well as chemotherapeutic activity. For some types of cancers, opioid use is linked to metastasis, proproliferative effects, and decreased patient survival, while in other cancer types, opioids are associated with improved cancer cell killing and improved patient outcomes [16-19,21-47]. At present, there is no consensus on the risk or benefit posed by opioids in the context of malignancy and its treatment.

While multiple clinical studies have been conducted to evaluate the relationship between malignancy and its treatment with the μOR and analgesic opioid use, interpreting the risks or benefits of opioid use on tumor growth remains challenging and often confusing. Public response to some literature reports has led to surges in demand for opioids as potential antineoplastics. In contrast, other published data have led to concern that opioids will be withheld in the presence of suffering for fear of promoting malignancy [11,48,49]. Therefore, an improved understanding of the effects routinely prescribed opioids can have on any neoplasm, cancerous lesion, or malignancy and its treatment is an urgent public health need. A scoping review approach can help meet this need by organizing the existing clinical and preclinical evidence in a manner suitable to better distinguish clinically meaningful patterns and identify key knowledge gaps.

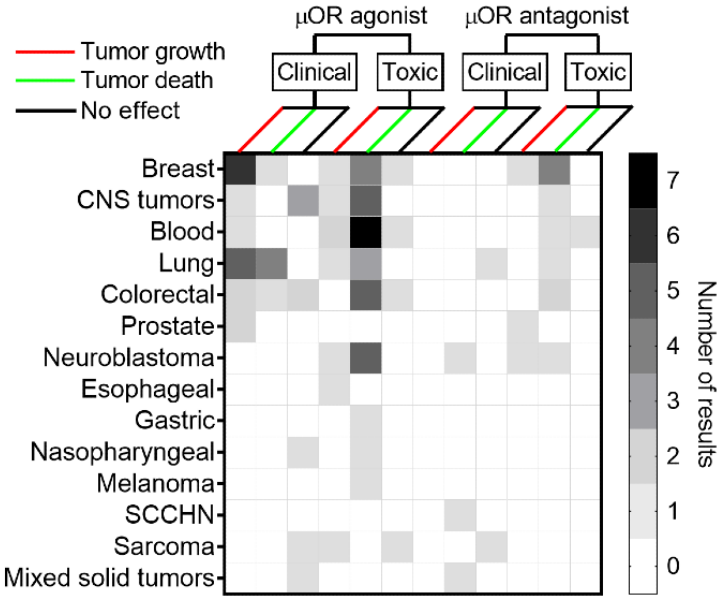
By examining both clinical and preclinical evidence together, 3 major challenges found in interpreting the clinical literature can begin to be addressed. First, clinical studies typically have a small n and focus on a specific cancer subtype, and among these, they differ in experimental design, intervention (eg, type, timing, and route of opioid administration), and patient population. Second, clinical opioid concentration data are lacking. Opioid concentration data are critical to establish the consequences of opioid use in the context of malignancy. As opioids are characterized by high inter- and intraindividual pharmacokinetic (PK) variability, the common practice of using opioid dose as a surrogate is a highly flawed means of estimating tumor tissue concentrations [50,51]. Finally, clinical studies seeking to assess the risks and benefits of opioids related to disease progression are frequently confounded by the role of pain and pain management on patient outcomes [41,52]. Preclinical studies have the potential to fill gaps in knowledge regarding opioid effects for certain cancer models at known concentrations and are not influenced by pain.

It is to be expected that the relationship between heterogeneous forms of cancer, μOR expression, and the clinical use of various analgesic opioids (routes of administration, formulations, and patterns of use) will be complex. Nonetheless, a scoping study approach can map evidence from both clinical and preclinical studies that will augment one another in the detection of meaningful associations between analgesic opioid exposure and the potential risks or benefits to patients with cancer.

Our objective is to map preclinical and clinical study data on therapeutically relevant concentrations of opioids effects on tumor growth or survival, or alteration on the antineoplastic activity of chemotherapeutics. We will map and evaluate published evidence regarding (1) opioid concentration data from human subjects with cancer, yielding a “physiologic range” to better interpret available preclinical data, (2) patterns of opioid exposure and disease and treatment-related patient outcomes, and (3) the influence of opioids and μOR activity on cancer cell survival and growth, as well as changes in susceptibility to

XSL•FO
RenderX

clinically used chemotherapeutics. Apparent contradictions and clinically relevant knowledge gaps concerning the risks or benefits of analgesic opioid use in the context of malignancy can be better understood and clarified by using a systematic approach to catalog and examine existing literature from a pharmacologic perspective.



A search for existing evidence reviews or protocols on topic has been conducted (TC) in PROSPERO and MEDLINE (Ovid) on February 6, 2021. None were identified by the team as being on topic.

Prior to developing the scoping methodology protocol, a pilot study was undertaken to evaluate existing clinical and preclinical data concerning the effects of analgesic opioids on malignancy and its treatment (JEC). The central research question proposed for this study has been sought before and remains the source of much controversy. However, as the pilot study demonstrated, harnessing both clinical and preclinical information can bring into focus central concepts, such as the use of physiologic versus supraphysiologic opioid concentrations and biologic context. These concepts are often absent in the broader discussion of opioids and malignancy yet essential to solving some of the seeming contradictions. As this prestudy data, using an inclusive approach, revealed novel and informative patterns, we anticipate, a full scoping review will provide a new framework to view existing evidence and therefore, its interpretation.

The pilot study used MEDLINE (Ovid) for years 1946-2021, titles and abstracts were screened for inclusion (full publication). References of included studies were additionally assessed for relevancy and potential inclusion. Study data were collected and managed using Excel (Microsoft Corp) and GraphPad Prism (version 9; GraphPad Software, Inc). Data elements extracted were manuscript information (journal, title, authors, and year), study type (clinical [human subjects], including ex vivo), preclinical (in vivo [animal model] or in vitro), malignancy (type, subtype, model, or cell line), ligand (μOR agonist [ie, most analgesic opioids], antagonist, and partial agonist) and concentration information (eg, IC_{50}), any coinciding antineoplastic treatment, and predominant effect reported (ie, promotion or inhibition of tumor growth or chemotherapeutic activity). For ex vivo or in vitro data, "clinical" concentrations of μOR agonists were based on human subject studies reporting maximal peak concentrations experienced by adult patients with cancer receiving opioids as part of the standard of care: morphine (≤350 nM), fentanyl (≤10.8 nM), methadone (≤3.2 μM), and oxycodone (≤320 nM), and antagonists: nalmefene, methylnaltrexone, naltrexone, and naloxone (≤1 μM).

Data were extracted from 94 studies found to meet the pilot study criteria. From each study, findings were categorized as "tumor growth," "tumor death," or "no effect." A given study could report multiple findings, for instance, morphine (μOR agonist) could be found to stimulate cancer cell proliferation in a breast cancer cell line, while naloxone (a μOR antagonist) may be found to induce cancer cell apoptosis. Aggregated findings of opioid-associated effects on cancers are presented in Figure 1 [7-10,12,17-23,30,31,33-40,42,46,52-121].

Figure 1. Summary data from in vitro, in vivo, and clinical studies of opioids at "clinical" or "toxic" concentrations grouped by cancer type. μOR: μ-opioid receptor; CNS: central nervous system; SCCHN: squamous cell carcinoma of the head and neck.

The following conclusions have been drawn:

- The magnitude of the literature makes a scoping approach feasible, with fewer than 100 total clinical and preclinical studies found to meet the pilot study criteria for inclusion.
- Clinical studies evaluating opioid effects on malignancy are typically retrospective, and opioid concentration data among patients with cancer are scant.
- Preclinical studies often use opioids at concentrations exceeding those considered safe for humans. Additionally, preclinical studies which use opioid concentrations reflecting physiologically relevant concentration ranges for humans, on the basis of comparison with existing clinical concentration data, can offer important dose-response information but pose challenges for clinical interpretation.

XSL•FO
RenderX

- Important patterns emerged, including confirming the hypothesis that for cancer tissue, opioid concentration is a critical dimension to understand the effect. Clinically relevant μOR agonist concentrations were often associated with cancer growth, while "toxic" or supraphysiologic concentrations were associated more often with cancer cell killing. Concentration is a critical, but often overlooked, dimension of opioid influence on malignancy and emphasizes the need for PK data in patients with cancer.
- The expression profiles of the μOR are poorly understood for many cancer types.

Methods

Study Design

We will conduct our scoping review with guidance from the latest version of the *JBI Manual for Evidence Synthesis* [122]. Using the framework as outlined by Arksey [123] and expanded by Peters [124], we will conduct our scoping review with Arksey's [123] six stages: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) expert consultation involving oncologists, pain management specialists, and basic and translational scientists with expertise in pharmacology and cancer biology. Consultations will be held to inform the process of project conception, protocol development, study design and conduct, and finally, the interpretation of data, including discovery and description of key knowledge gaps [123,124]. For transparency and reproducibility, we will adhere to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) reporting guidelines in reporting our results [125].

We will use Covidence (Veritas Health Innovation), a web-based systematic reviewing platform, to screen and select studies. Citation management and duplicate detection and removal will be accomplished with EndNote (Clarivate Analytics). Research Electronic Data Capture (REDCap) tools hosted at the University of Utah will be used for data capture and charting [126].

Literature Searching

Overview

A librarian (TC) will develop and translate search strategies for the web-based databases using a combination of keywords and controlled subject headings unique to each database. Peer review of the strategies will be conducted by an information specialist (MMM) using the Peer Review of Electronic Search Strategies guidelines [127]. Preliminary searches by 2 reviewers (JEC and VY) resulted in pilot data of 94 studies, which will be used by the librarian to harvest search terms.

Electronic Sources

We will search the following databases: MEDLINE (Ovid) 1946-2022, Embase 1974-2022, CINAHL Complete (Ebscohost) 1937-2022, Cochrane Library 1898-2022 including CENTRAL 1898-2022, Biological Sciences Collection (ProQuest) 1946-2022, and International Pharmaceutical Abstracts (Ovid) 1970-2022.

Other Sources

Trial registries will include ClinicalTrials.gov, Cochrane CENTRAL Register of Controlled Trials (Wiley), International Standard Randomised Controlled Trial Number registry, European Union Clinical Trials Register, and World Health Organization International Clinical Trials Registry.

No gray literature will be designated for searching. For studies meeting inclusion criteria, references will also be evaluated for relevancy and potential inclusion.

Study Selection (Eligibility Criteria)

Inclusion Criteria

Participants

Patients in clinical studies diagnosed with any type of malignancy will be included.

Concept

We will assess the use of therapeutic opioids or assessment, direct or indirect, of opioid receptors or any other proposed mechanism for opioid action.

Context

For preclinical studies, any investigation involving any cancer cell lines, xenografts, ex vivo specimens, or relevant in vitro models of cancer related to clinically used opioids, opioid receptors, opioids purported to act upon, bind to, or influence cell processes via known or unknown targets will be included.

For clinical studies, patients diagnosed with, or survivors of, any type of cancer may or may not have received opioids at any time. Studies including patients with cancer but without opioid exposure will be included, if the study concerns biomarkers, outcomes, or other parameters related to opioid receptor or opioid influence on a malignancy or its treatment.

English-language studies will be preferred. We will chart non–English-language studies meeting or appearing to meet inclusion criteria.

Exclusion Criteria

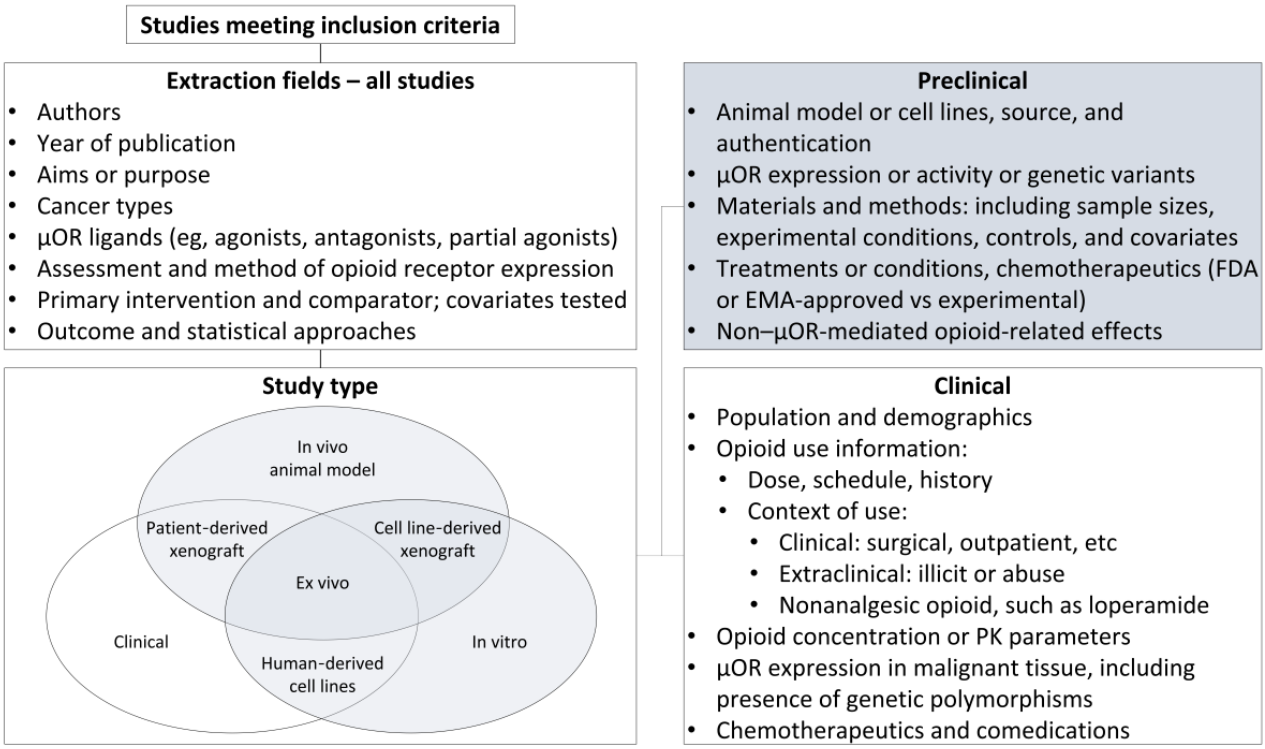
Conference abstracts, studies exclusive to the topic of opioid addiction and abuse and not involving a cancer diagnosis or containing opioid concentration data, and those exclusive to the topic of pain and pain management and do not involve a cancer diagnosis or contain opioid concentration data will be excluded.

Team

Reviewers (JEC, VY, and KJ) will screen, independent of each other, the titles and abstracts of search results. Reviewers will then review the full text, also independent of each other's vote. Consensus will be reached through discussion among the reviewers. Any ties will be decided by a fourth independent reviewer (KMW, CSL, EYE, or RSL).

XSL•FO
RenderX

Quality Assessment



In compliance with scoping review methodology, no quality assessment of included studies will be performed as our goal is to rapidly map the literature.

Data Extraction: Charting the Data

Study data will be collected and managed using REDCap tools hosted at the University of Utah [126]. REDCap is a secure, web-based application designed to support data capture for research studies, providing (1) an intuitive interface for validated data entry, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for importing data from external sources [126].

Extraction fields were developed based on the initial prescoping review pilot study to adequately address the primary research question (Figure 2). This includes extraction and charting of general manuscript information as well as adopting strategies to facilitate disaggregation of studies dependent upon data type (eg, clinical vs preclinical) for analysis.

Figure 2. Data extraction and charting. Studies concerning the influence of clinically used opioids on malignancy and its treatment do not align with a strictly "clinical" versus "basic" science dichotomy. Capturing data elements from across the spectrum of study types will provide a more holistic view to benefit the goals of this scoping review and distinguishes it from other reviews. µOR: µ-opioid receptor; EMA: European Medicines Agency; FDA: U.S. Food and Drug Administration; PK: pharmacokinetic.

Analysis of Evidence

Overview

A descriptive analysis will be used across all studies (eg, retrospective, clinical trial, and in vitro) and be inclusive of reported outcomes. For each cancer subtype, a descriptive synopsis of opioid-related data will be compiled, including conditions or variables associated with opioid or µOR activity influencing malignancy or its treatment. The analysis will be split into 2 main components based on the "Research question."

Component 1: Do Therapeutically Relevant Concentrations of Opioids Affect Tumor Growth and Survival?

Data extracted from clinical and basic research studies will be aggregated by µOR ligand and cancer type. µOR ligands will be categorized by class (agonist, antagonist, and partial agonist) as well as by individual entity (morphine, oxycodone, etc) and by measures of µOR ligand exposure (eg, concentrations, PK parameter estimates, dosage, and route of administration) or exposure-response (eg, IC_{50}).

For basic (animal, in vitro) study results, µOR ligands will be categorized according to effect on malignancy (ie, no effect, promotes, or inhibits malignancy), and for clinical study results, µOR ligands will be categorized according to effect on malignancy, chemotherapeutic activity via clinical indices, or patient outcome (eg, minimal residual disease and progression-free survival). Clinical data will be further categorized by covariates such as sex, age range (pediatric vs adult), new diagnosis, or relapse.

Due to differences in study design, direct comparisons between studies are not feasible. Data will be aggregated by category, and a count of results will be conducted. An illustration: consider a study that demonstrates that morphine administered in high doses, generating supraphysiologic blood concentrations (considered toxic for humans), stimulated metastases, as compared to controls, in a xenograft murine model of breast cancer. This study result would be tabulated as breast cancer,

XSL•FO
RenderX

μOR agonist, supraphysiologic exposure, promotes cancer. If, in addition, to the experimental conditions above, morphine was administered to generate clinically relevant blood concentrations, and these were associated with diminished tumor growth, this would be tabulated as breast cancer, μOR agonist, physiologic exposure, inhibits cancer.

Component 2: Do Therapeutically Relevant Concentrations of Opioids Alter the Antineoplastic Activity of Chemotherapeutics?

Data extracted from clinical and basic research (preclinical) studies, incorporating μOR ligand use coinciding with chemotherapeutics used to induce malignant cell death will be aggregated by μOR ligand, cancer type, and chemotherapeutic class.

Chemotherapeutics and μOR ligands will be classified by class as well as by individual entity. Chemotherapeutics will include conventional (anthracyclines, antimetabolites, alkylating agents, mitotic spindle inhibitors, topoisomerase inhibitors, antitumor antibiotics, platinum-based agents, corticosteroids, biologicals [enzymes], or nitrosoureas), targeted (kinase inhibitors, proteasome inhibitors, and antibodies), and agents undergoing clinical trials or considered experimental.

Measures of chemotherapeutic agent or μOR ligand exposure (eg, concentrations, PK parameter estimates, dosage, and route of administration) or exposure-response (eg, IC_{50}) will be considered.

For basic (animal, in vitro) study results, μOR ligands will be categorized according to effect on chemotherapeutic activity (ie, no effect, antagonism, or synergism). For clinical study results, μOR ligands will be categorized according to the effect on chemotherapeutic activity via clinical indices and patient outcomes studies attribute to or suggest as being related to changes in treatment efficacy. Clinical data will be further categorized by covariates such as sex, age range (pediatric vs adult), new diagnosis, or relapse.

As with component 1, it is anticipated that differences in study design and experimental conditions will preclude direct comparisons between data generated across studies. As above, data will be tabulated by category, including chemotherapy type, and a count of results will be conducted.

Ethical Considerations

This study does not require ethical approval as data and information collected, using scoping review methodology, has previously been made available through publication. The results of this scoping review will be submitted for publication in a relevant peer-reviewed journal as well as disseminated through presentations at scientific conferences. Any changes from our protocol during the conduct of the scoping review will be acknowledged and defined in the manuscript.

Results

The results of this scoping review will be presented using a descriptive narrative form as well as graphical and tabular representations. The results will be structured, as appropriate, to emphasize the effects of prescription opioids by cancer classification as well as chemotherapy type. Additionally, study results concerning data classified as preclinical, translational, and clinical will be presented distinctly to facilitate comparison. The protocol for the scoping review was initiated in February 2021 at the University of Utah and is expected to be completed in August 2023. The results of the scoping review will be disseminated through regional and national scientific conference proceedings and presentations, stakeholder meetings, and by publication in a peer-reviewed journal.

Discussion

This scoping review will map diverse studies spanning from preclinical to clinical regarding the intersection of opioids with malignancy and its treatment. The interpretation of opioid-malignancy interactions within a clinical context is often confounded by pain and its management. It is therefore both novel and necessary to include preclinical study data to identify key knowledge gaps, begin to reconcile seeming conflicting data (eg, opioids foment cancer growth vs opioids kill cancer cells) by setting a context to parse the biologic and molecular complexities of opioid impact on malignancy and its treatment, and ultimately, inform patient treatment algorithms to optimize outcomes. The knowledge presented in the scoping review will help to inform and improve the design of studies to assess the unmet medical need to understand the risks and benefits associated with opioids extending to the potential to impact cancer and its care.

This scoping review study has several strengths. First, our scoping review approach will be inclusive of studies spanning the spectrum of published data available from clinical to in vitro. Popular opinion and clinical judgment regarding the potential for opioids to affect malignancy have been deeply influenced by the publication of basic (in vitro or ex vivo) studies. Therefore, expanding this review to include both clinical and preclinical studies provides a new perspective on the topic, acknowledges that basic studies impact clinical care and shape patients' attitudes, and addresses limitations specific to the opioid-malignancy question in the context of clinical studies. Current clinical studies examining the opioid-malignancy question, often retrospective, are confounded by pain and the management of pain. Adequate pain management is associated with improved patient survival; therefore, interpretation of the potential effects of opioid use on the malignancy itself is challenging to interpret. Finally, despite the intense attention the topic has received, the key dimension of opioid concentration is often not addressed. Therefore, incorporating data from clinical and preclinical studies into this review with an emphasis on systemic opioid exposures (concentration) is warranted, and based on the preliminary data collected, aids in clarifying seemingly contradictory findings pointed to in existing reviews.

This scoping review also has limitations. Specifically, no quality assessment of the included studies will be performed. Relevant data may be missed, as we are searching for published studies only. We selected several sources and developed sensitive search strategies to increase the discovery of eligible studies.

XSL•FO
RenderX

The topic of opioid impact on cancer and its treatment is not new but remains controversial and clinically relevant. This scoping review seeks to encompass preclinical and clinical studies to generate a comprehensive landscape for interpreting the existing literature within pathophysiologic and pharmacologic contexts. We hope this study will be used to identify key knowledge gaps and advance future studies aimed at improving patient outcomes.

Acknowledgments

Research reported in this publication was supported by the Primary Children's Hospital Foundation and the National Center for Advancing Translational Sciences of the National Institutes of Health under Award Number UL1TR002538 (JEC) and the National Cancer Institute of the National Institutes of Health under Award Number K22CA258671 (JEC). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

Data sets will be presented in the main manuscript and as additional supporting files or made available upon request.

Authors' Contributions

JEC wrote the manuscript and provided data, VY conceptualized the project as a scoping review, TC aided in methodologic approach for scoping protocol development, and MMM provided oversight for scoping review protocol development. All authors helped in the preparation, critical review, and revision of the scoping protocol.

Conflicts of Interest

None declared.

Abstract

Background: Climate change is a major threat to human health. Nurses are in contact with patients suffering from the effects of climate change in their daily work. Therefore, they need to be involved in combating it at both the individual and collective levels. However, there is still very little known about nurses' perception of climate change and their role toward it. A few recent studies have embarked on the process of examining the perceptions of these health professionals relative to climate change, but no exploratory review of the literature has been conducted on nurses' perception of this phenomenon.

Objective: The purpose of this protocol is to develop a research strategy for an exploratory review of the literature focused on identifying nurses' perceptions of climate change.

Methods: Firstly, with the help of a specialized librarian, we defined keywords and their combinations, using an iterative process, to develop a documentary search strategy. This strategy was tested in the following four bibliographic databases: MEDLINE (PubMed), CINAHL, Embase, and Web of Science. A search of the grey literature will also be conducted to supplement the results of the bibliographic database search. The next step will be for 2 members of the research team to carry out a 2-stage selection process using the web-based systematic review software Covidence. They will carry out this selection process independently, with the aim of identifying relevant studies that meet the inclusion criteria for our exploratory review. Finally, data on year of publication, authors, geographic area, article type, study objectives, methodology, and key findings will be extracted from selected articles for analysis. The data will be analyzed by the research team based on an in-depth examination of the findings and will be directed toward answering the research question and fulfilling the study's objective.

Results: The results will help in defining nurses' perceptions of climate change more clearly as well as the role they can play and what they need to be able to bring forward solutions to this phenomenon. The findings should also serve to guide the health sector and nursing faculty's interventions aimed at preparing health professionals to act on the potential threats associated with climate change.

Conclusions: The preliminary search suggests a possible gap between the importance of the nursing role in addressing the health impacts of climate change and the nurses' lack of knowledge and awareness on this matter. The results will allow for raising nurses' awareness of their role in the fight against climate change and the ways to address its health effects. This study

XSL•FO
RenderX

will also open up new research perspectives on how to equip nurses to better integrate response to climate change issues into their professional practice.

Introduction

Climate change represents one of the greatest threats to human health in the 21st century [1-4]. The new report from the Intergovernmental Panel on Climate Change indicates that climate change is already affecting the physical health and well-being of many people around the world [5]. This is reaffirmed by a recent Health Canada report, which states that climate change is already having a negative impact on the health of Canadians due to increased temperatures, extreme heat, forest fires, and the geographic spread of zoonotic diseases such as Lyme disease [6]. Climate change affects the physical and mental health of populations in direct and indirect ways. Examples of the direct health effects of climate change include extreme weather events, such as storms, wildfires, floods, or drought; increased exposure to pollens; and heat waves [7]. Moreover, a 2011 study published in the journal *Science* found that the frequency of such events is expected to increase by a factor of 5 to 10 over the next 40 years [8]. Examples of indirect effects include air pollution (causing respiratory and heart diseases), water pollution (causing gastroenteritis), changes in ecosystems and in the geographic distribution of vector-borne diseases, food insecurity, population displacement, conflict, and mental health [7,9-12]. The World Health Organization estimates that climate change could cause approximately 250,000 additional deaths per year between 2030 and 2050 due to malnutrition, malaria, diarrhea, and heat stress [13].

Health professionals have an important role to play in combating health threats related to climate change [14]. Nurses, who make up a significant portion of health professionals engaged in improving the health and well-being of individuals [15-17], have a critical role to play in responding to and reducing health issues stemming from climate change [18]. Because they benefit from a high degree of public trust [19], nurses can play a leadership role in the health sector both by increasing awareness of climate change as an important health issue and by spearheading action and advocacy in the fight against climate change [20]. In their daily work, nurses also have an advocacy role toward their patients experiencing the effects of climate change, especially those who are the most vulnerable. Therefore, nurses need to be involved in combating climate change at both the individual and collective levels. However, there is still very little known about nurses' perception of climate change and of their role toward it. A few recent studies have examined nurses' perceptions of climate change and health [16,17,21-23]. In addition, two exploratory reviews of the literature have been conducted. The first, conducted in 2018, focused on health professionals' knowledge, attitudes, perceptions, and practices related to climate change and its health impacts [14]. The second, conducted in 2022, concerns awareness and attitudes among nursing students and educators related to sustainability and climate change [24]. To the best of our knowledge, no study has yet been conducted for the purpose of identifying and synthesizing nurses' perceptions of climate change in an exploratory literature review. The 2018 study considers health care professionals in general, and the 2022 study focuses on nursing students and educators.

The purpose of this protocol is to develop a research strategy for an exploratory literature review aimed at identifying nurses' perceptions of climate change.

Methods

Overview

The exploratory literature review will be conducted in 5 steps, as described by Arksey and O'Malley [25] and refined by Levac et al [26]. These steps are as follows:

1. Identification of the research question
2. Identification of relevant studies
3. Selection of relevant and reliable studies
4. Charting the data from the included studies
5. Collating, summarizing, and reporting the findings

Identification of the Research Question

As recommended by Levac et al [26], the question we wish to answer through this exploratory review has been clearly articulated and focused. The question under study in this exploratory literature review is, "what are nurses' perceptions relative to climate change?" This question is justified by the need to advance knowledge about nurses' perceptions of climate change to better prepare them to tackle these climate issues [16,20,22,23].

Identification of Relevant Studies

We first developed a search strategy with the help of a specialized librarian using an iterative process. Searches were conducted in the following four bibliographic databases targeting biomedical and interdisciplinary topics: MEDLINE (PubMed), CINAHL, Embase, and Web of Science. Two concepts were used to identify keywords for the literature search strategy: climate change (concept 1) and nurses' perceptions (concept 2). Once identified, the keywords were classified into free-text search terms and controlled vocabulary to define a search strategy specific to each database. The characteristics of free-text and controlled vocabulary searches in the databases used are presented in Table 1.

XSL•FO
RenderX

Table 2 presents the keywords (free-text search terms) and thesauri terms (controlled vocabulary) for each of the four databases for each of the two concepts defined previously. An example of a preliminary MEDLINE (PubMed) search strategy is shown in Table 3.

Table 1. Free-text and controlled vocabulary search characteristics for databases used for this study.

Selected databases	Search vocabulary
MEDLINE via PubMed	• Free text: title/abstract or tiab (advanced) • Controlled vocabulary: MeSHa
CINAHL Plus with full text (EBSCO)	• Free text: title + abstract, ti+ab (two separate searches) • Controlled vocabulary: CINAHL descriptors
Embase	• Free text: title, abstract, keyword, ti,ab,kw (quick search) • Controlled vocabulary: EMTREE
Web of Science	• Free text only: topic (includes title, abstract, author keywords, and Keywords Plus).

[a]MeSH: Medical Subject Headings.

Table 2. Free-text search terms (keywords) and controlled vocabulary.

Concepts and free-text search terms (Keywords)	Controlled vocabulary (thesaurus terms in electronic bibliographic databases)		
	MEDLINE (PubMed)	CINAHL Plus with Full Text (EBSCO)	Embase
Concept 1: climate change			
"Climate change*" OR "global warming" OR "climate crisis" OR "climate warming" OR "climate issue*" OR "Climate vulnerabilit*" OR "Climate Emergenc*" OR "Greenhouse Effect" OR "climate action"	"Climate Change"[Mesh[a]] OR "Greenhouse Effect"[Mesh]	(MH "Climate Change") OR (MH "Greenhouse Effect")	'Climate change'/exp OR 'greenhouse effect'/de
Concept 2: nurses' perceptions			
(Nurse OR nurses OR nursing) AND (attitude* OR perception* OR awareness OR perspective* OR belief* OR views OR behavior* OR opinion* OR concern* OR understanding OR knowledge*)	("Nurses"[Mesh]) OR "Nurse's Role"[Mesh]) AND ("Perception"[Mesh:NoExp] OR "Attitude"[Mesh:NoExp] OR "Attitude of Health Personnel"[Mesh:NoExp] OR "Awareness"[Mesh] OR "Knowledge"[Mesh] OR "Behavior"[Mesh:NoExp])	(MH "Nurse Attitudes") OR ((MH "Nurses+") OR (MH "Nursing Role")) AND ((MH "Attitude") OR (MH "Perception") OR (MH "Knowledge") OR (MH "Nursing Knowledge") OR (MH "Behavior"))	'Nurse attitude'/de OR ('nurse'/exp OR 'nursing role'/de) AND ('perception'/de OR 'attitude'/de OR 'awareness'/de OR 'knowledge'/exp OR 'beliefs'/de OR 'behavior'/de)

[a]MeSH: Medical Subject Headings.

Selection of Relevant and Reliable Studies

For this step, studies identified by the database search were first imported into the bibliographic management software EndNote and then transferred to Covidence (Veritas Health Innovation) to remove duplicates and facilitate the sorting and selection of relevant studies based on previously defined inclusion and exclusion criteria.

Once the duplicates were removed, an initial selection was begun based on the titles and abstracts, by 2 members of the research team (TD and AB) working independently. Studies

XSL•FO
RenderX

focused on nurses' perceptions of climate change will be retained. No date limits will be applied. All studies that address an environmental issue other than climate change, concern health professionals other than nurses, or are published in a language other than English or French will be excluded. Any disagreement regarding inclusion or exclusion will be resolved by consensus and, if necessary, by consultation with a third team member.

Once this initial stage of selection is completed, a second stage of selection will determine which articles will be included in the final analysis, based on their full text. This stage will be carried out by the same 2 researchers performing the initial selection. Studies whose full text is not available, studies that do not provide the authors' names or publication dates, or those that constitute expert opinions or commentaries will be excluded. Accordingly, only empirical studies will be considered. Once again, any disagreements will be resolved by consensus between the 2 reviewers. A third reviewer will be consulted to establish consensus if the 2 reviewers' opinions diverge.

The results of the selection process will be presented in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram [27], showing the number of studies selected at each stage of selection.

Charting the Data From the Included Studies

This step consists of extracting the data from the full-text articles selected. For this purpose, a Microsoft Excel table will be developed. It will include the following sections: title, authors, year of publication, geographic area, study objectives, methodology, and key findings.

Collating, Summarizing, and Reporting the Findings

The data extracted in the previous step will be analyzed by the research team. This analysis may include an informed discussion based on an in-depth examination of the findings and directed toward answering the research question and fulfilling the study's objective. Quantitative and qualitative data will be analyzed altogether and categorized according to the type of perception to which it refers (eg, perception of nurses' role toward climate change or perception of their needs regarding climate change).

Grey Literature Search

To supplement the results of the bibliographic database search, we plan to also conduct a search of the grey literature. To this end, we will consult the websites of associations and organizations related to nursing and those focused on the environment. Social media searches or reporting were not considered. We targeted nursing associations and organizations in the province of Québec, those at the federal level in Canada and the United States, and those at the international level. The following associations in Table 4 were identified through the scientific literature [18,28,29] and through a Google search using a combination of keywords related to nursing associations or organizations, climate change, and geographic area of interest (ie, Canada, United States, or international).

Table 4. Nursing associations and organizations identified for grey literature search.

Location and name of the association or organization	Website
Province of Québec	
Quebec Nurses' Association	[30]
Ordre des infirmières et infirmiers du Québec	[31]
Canada	
Canadian Nurses Association	[32]
Canadian Association of Nurses for the Environment	[33]
Canadian Federation of Nurses Unions	[34]
Canadian Nurse Educator Institute	[35]
Canadian Association of Schools of Nursing	[36]
United States	
American Nurses Association	[37]
American Association of Colleges of Nursing	[38]
American Academy of Nursing	[39]
Alliance of Nurses for Healthy Environments	[40]
National Student Nurses' Association	[41]
International	
World Health Organization	[42]
International Council of Nurses	[43]
Secrétariat international des infirmières et des infirmiers de l'espace francophone	[44]
Nurses Climate Challenge	[45]

XSL•FO
RenderX

Three approaches will be used to search the grey literature. The first approach will consist of searching by navigating the websites of the various associations and consulting their different sections, such as the section on publications; the second approach will involve using the search function of the websites to search for the keywords that were defined for the bibliographic database searches; finally, the third approach will consist of searching on Google by combining the name of the association with the keywords defined for the bibliographic database searches. The data will be extracted into an Excel spreadsheet that will contain the following sections: date of search, site searched, type of search performed (referencing one of the three approaches listed above), number of results found, number of results retained, and comments. For searches conducted by navigating the sites, the sections consulted will be specified, and for keywords searches, the terms or expressions used in searches will be specified.

Results

The results will allow us, firstly, to ascertain how nurses perceive climate change; and secondly, to analyze these perceptions in relation to nurses' contexts (personal or professional), the roles they can play, and what they require to better address this phenomenon.

The results will be gathered and shared according to the type of perception they refer to (eg, perception of climate change's causes and impacts, perception of nurses' role toward climate change, and perception of their needs regarding climate change).

We hope that the results will point toward targeted climate change awareness, raising interventions for nurses and guide new interventions aimed at improving nursing practice in a climate change context. In addition, with climatic hazards, such as extreme heat episodes and floods, expected to become increasingly frequent in coming years, a better understanding of climate issues among nurses will enable them to better assess risks and provide patients with appropriate advice and care. The results may also move forward engagement and dialogue on this important topic among nurses as well as raise awareness in nursing faculty to include these important issues in the education of future nurses. The findings will also open avenues for future research on the potential of nursing involvement in the mitigation, adaptation, and resilience of communities in the context of climate change.

Discussion

Expected Outcomes

To our knowledge, this study is the first exploratory review of the literature aiming to identify nurses' perceptions of climate change. Its relevance comes from the fact that studies have been conducted in recent years that address nurses' perceptions of climate change [16,17,21-23] but have not been compared and interpreted as a body of literature. The preliminary results of this exploratory literature review suggest that nurses could be preoccupied about climate change to a certain extent [20] but could lack knowledge about climate change, its causes, and its impacts on health [15,20,22]. The perceptions of their role in the fight against climate change as well as concrete ways to include the fight against climate change in their daily work despite constraints seems also unclear [17,22]. The full results of this review of the literature will allow us to cross-reference the different perceptions nurses have of climate change, as described in the various studies, and to develop an overall portrait of these perceptions. These results will allow us to identify ways to fill the possible gap between the importance of the nursing role in addressing the health impacts of climate change and the lack of knowledge and awareness of nurses in this matter. Therefore, this study should also help nursing organizations, educational institutions, and policy makers to better identify the elements that would help prepare these health care workers to face this climate crisis and the subsequent impacts on the health and well-being of the communities and populations they serve. Research could also help better identify promising strategies to empower nurses to fully carry out their advocacy role toward their patients who are the most vulnerable to climate change.

One of the strengths of the search strategy is that it targets diverse interdisciplinary databases in which articles from different fields, such as biomedical sciences and social sciences, are indexed. This will give us a broader view of the scope of the existing literature. In addition, this search is supplemented by a search of the grey literature, which will allow us to find relevant documents that cannot always be found in current bibliographic databases.

Review Limitations

One of the limitations of this exploratory review of the literature is that it only includes publications in French and English, which means that all publications in other languages that may be relevant to the topic will not be taken into consideration. Nevertheless, as the vast majority of scientific publications are written in English, our findings should be of interest. Another limitation is that we do not plan to assess the quality of studies. However, this step is optional in the case of a scoping review [25].

Conclusions

The full results will be disseminated through various means, such as international nursing conferences and articles, including an article in a nursing association journal. Authors will also publicize the published articles in their respective professional network. This dissemination strategy hopes to reach nurses and raise awareness toward their role in the fight against climate change and the ways to address its health effects.

Abstract

Background: Drug-resistant tuberculosis (DRTB) is an increasing threat to human health and economic security worldwide. Exacerbating the severity of DRTB is the low rate of service delivery, leading to increased community transmission of the disease, further amplified by stigma. Health workers are on the front line of service delivery; their efforts in all areas of disease control are suspected of having resulted in stigmatization, impacting patient-centered care. As a growing concern, attention to addressing the DRTB stigma confronting health workers is required. However, little is known about stigma among health workers delivering services to patients with DRTB. This scoping review will provide an overview that could help inform appropriate responses toward stigma-reduction interventions for these health workers.

Objective: This scoping review protocol articulates a methodology that will examine the facets of DRTB-related stigma confronting health workers in high TB- and DRTB-burdened countries. This scoping review will (1) summarize stigma barriers and facilitators contributing to stigmatization among health workers delivering services to patients with DRTB, (2) identify the most common stigma barrier and facilitator, and (3) summarize the stigma-reduction intervention recommendations in the studies.

Methods: Guided by Arksey and O'Malley's framework and the recommendations of Munn et al, we will conduct a scoping review of relevant literature providing evidence of DRTB-related stigma among health workers from countries with a high burden of tuberculosis (TB) and DRTB. We will search published articles written in English from 2010 onward in electronic databases using Medical Subject Headings and keywords. Our search will apply a 3-step search strategy and use software tools to manage references and facilitate the entire scoping review process. The findings of our review will be presented following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Scoping Reviews checklist. Our study is registered with Open Science Framework Registries.

Results: This scoping review is part of a bigger project that will critically investigate stigma among health workers delivering services to patients resistant to TB medications. This study began in November 2021 and is expected to finish in 2023. The study has retrieved 593 abstracts out of 12,138 articles searched since February 2022 from the identified databases. The findings of this study will be published in a peer-reviewed journal.

Conclusions: This review will provide an outline of the aspects of DRTB-related stigma confronting health workers. The findings of this review could help inform appropriate responses toward stigma-reduction interventions for these health workers. This is significant because interventions addressing related TB (and DRTB) stigma in the workplace are lacking.

KEYWORDS

drug-resistant tuberculosis; health workers; stigma; tuberculosis stigma; TB stigma; DRTB stigma

Introduction

Background

Tuberculosis (TB) exists in every part of the world. Approximately 25% of the world's population has latent TB and is at risk of developing the disease during their lifetime [1]. Accordingly, about 10 million people fall sick with this disease each year, two-thirds of whom are in Bangladesh, China, India, Indonesia, Nigeria, the Philippines, and South Africa [1]. Meanwhile, drug-resistant tuberculosis (DRTB) is the highest in China, India, and Russia, while 9 of the 30 countries with the highest DRTB burden are within the European region [1].

With over a million people becoming ill with DRTB each year, the disease is considered a significant contributor to drug resistance worldwide [2]. In 2021, overall, 3.6% of new TB cases and 18% of previously treated patients were resistant to at least 1 anti-TB drug [3]. However, DRTB has become more challenging as the number of people previously treated for the disease had declined because of COVID-19 pandemic–related disruptions to TB service delivery. In 2021, the burden of DRTB increased by 3%, with 450,000 new cases [3]. As the increasing incidence of DRTB burdens public health, the country's economic security is threatened. Treatment of DRTB is prolonged and requires new-generation drugs, making it financially burdensome [4]. Additionally, the DRTB treatment success rate is lower than for new TB cases.

Ending the TB epidemic by 2035 is one of the priority goals of global health organizations. However, attaining this goal requires an urgent action that will accelerate efforts to diagnose, treat, and prevent TB (including DRTB). Such efforts can be achieved strategically by focusing on cutting-edge research and innovation, improving drug resistance surveillance, and strengthening public-private partnerships [3]. In the community, essential services such as case finding, diagnosis, treatment, health promotion and education, and psychosocial support are among the current strategies used to reduce the disease burden [1]. Central to these activities are the health workers, where DRTB essential services are integrated into community health services and directed toward patient-centered care [5]. Patient-centered care involves clinical service delivery and provides support for the patient's social and economic conditions that increase the burden of DRTB, such as malnutrition, poor housing, and financial and geographic barriers to health care access. In addition, it provides a holistic approach by incentivizing patients, treatment supporters, and health care providers [6].

The burden of DRTB is a multifaceted health challenge and social issue [6,7]. Medications for DRTB are more toxic and expensive [8], and the risks and treatment outcomes are influenced by various determinants and are commonly associated with stigma [9,10]. Stigma is the negative evaluation of oneself tainted by a particular attribute, making one constantly unsure how others will identify or receive it [11]. In terms of stigma in health, patients and communities distinguish and label various health conditions, views, and perceptions differently. As such, stigma influences community norms, interpersonal relations, and health institutions' culture [12,13].

A growing area of research has evidenced the stigma associated with DRTB. Datiko et al [14] posited that stigmatization of TB (including DRTB) affects prevention, care, and treatment. As a result, TB-related stigma contributes to the increasing DRTB burden and is a crucial predictor of its high incidence [15], and thus, warrants reduction interventions [9]. Tackling DRTB stigma is significant because it affects the quality of life of people affected by the disease and, in part, confronts health workers [16-18]. In health care, for health workers delivering essential services, the stigma surrounding TB (in general) is commonly associated with the "dirty work" stigma [19]. Hughes (1962) referred to dirty work as tasks and occupations perceived by the community as disgusting or degrading.

Current literature reviews on TB-related stigma suggest that most studies are geared toward understanding stigma among patients and their families. For example, in their qualitative review, Juniarti and Evans [20] explored stigma and the impact of either having TB, or a family member having TB. Craig et al [21] mapped TB stigma research and found that the majority of studies aimed to assess the knowledge, attitudes, and beliefs regarding TB (including DRTB) in low-incidence countries. The review of Sommerland et al [22] evaluated TB stigma–reduction interventions within the community. Notably, their reviews generally highlight the impact of TB stigma on individuals and communities. However, the growing evidence of DRTB-related stigma among health workers requires attention. There is a need to better understand the stigma surrounding the disease and how it is currently addressed in health facilities.

We conducted a preliminary search of MEDLINE, the Cochrane Database of Systematic Reviews, and Joanna Briggs Institute (JBI) Evidence Synthesis and found no current systematic reviews or scoping reviews underway on DRTB-related stigma among health workers. Using Arksey and O'Malley's [23] methodological framework and the recommendations of Munn et al [24], we will conduct a scoping study to examine the literature about the stigma of health workers delivering services for DRTB, explicitly examining the facets of disease stigma. Stangl et al [25] mentioned that the facets of stigmatization primarily constitute drivers and facilitators (eg, government policies, institutional support, and exaggerated fear) that influence disease outcomes among affected populations, organizations, and institutions. This scoping review will provide an overview of the aspects of DRTB-related stigma confronting

XSL•FO
RenderX

health workers and other relevant information. The result of this review could help inform appropriate responses toward stigma-reduction interventions for these health workers. This is significant because interventions addressing related TB (and DRTB) stigma in the workplace are lacking [9]. Nyblade et al [26][26] stated that it is crucial to sustainably address this issue, from national to facility levels, because it undermines the delivery of quality health care and successful health outcomes.

Review Question

Based on our objective, the overarching research question in this review is: "What aspects of DRTB-related stigma are confronting health workers in high TB- and DRTB-burden countries?" We will consider subquestions:

- What are the stigma drivers confronting the health workers, and what is the most common stigma driver?
- What are the stigma facilitators confronting the health workers, and what is the most common stigma facilitator?
- What stigma-reduction interventions are recommended in the study?

Methods

We will apply the JBI scoping review methodology and use the features and functionalities of the JBI System for the Unified Management, Assessment, and Review of Information (SUMARI) [27] web-based software tool throughout the review process. The scoping review is registered with OSF Registries.

Inclusion and Exclusion Criteria

Our review will apply the Participants/Concept/Context criteria recommended by Peter et al [28]. The eligibility criteria for this review will be as follows.

Participants

The participants in the study are health workers, including physicians, nurses, midwives, medical technologies, pharmacists, and other allied professionals in health care settings such as hospitals, clinics, community centers, and TB treatment facilities delivering DRTB services such as case-finding, screening, diagnosis, treatment, and prevention.

Concept

This review will include evidence of the stigma of health workers delivering services to patients with DRTB. Concepts to be examined are stigma drivers and facilitators, including but not limited to beliefs, fears, lack of awareness about the DRTB and stigma, inability to clinically manage the condition, negative attitudes, and institutionalized procedures or practices.

Context

This review will consider available data from countries identified in the World Health Organization's list of high TB- and DRTB-burden countries (Table S1 in Multimedia Appendix 1). Any article whose study participants are not included in the list will not be considered. To be eligible, stigma confronts the health worker delivering services to patients with DRTB. Studies in which the context of stigma relates to drug-susceptible TB (DSTB), DRTB patients, and their families will be excluded from the review. We will also exclude sources coming from opinion articles, commentaries, or editorial reviews.

Types of Sources

We will consider qualitative, quantitative, and mixed study designs, including descriptive observational studies, case reports, and gray literature on stigma confronting health workers delivering essential services to patients with DRTB. Peters et al [29] noted that one crucial point in scoping reviews is to draw upon data from any source of evidence and research methodology; thus, identifying articles for a scoping review will be less restrictive. As a result, an appraisal of the methodological quality of the available evidence on health workers' stigma in this scoping review will not be performed. As mentioned, we could not find any systematic or scoping reviews on this topic. However, if any review is found as a result of a rigorous literature search in this study, those that meet the inclusion criteria will also be considered, depending on the research question.

Search Strategy

This review will locate published articles using the 3-step search strategy recommended by the JBI scoping review guidelines [28]. We first conducted a pilot search of the PubMed and EBSCO databases to identify articles on the topic using Medical Subject Headings terms and keywords. In the next step, we will create a search protocol using the identified text terms in the titles, abstracts, and keywords and use the protocol to develop a full search strategy for CINAHL and MEDLINE (Table S2 in Multimedia Appendix 1). To enhance our search strategy, we will seek expert advice from university librarians to develop a search protocol that will be used to retrieve potentially relevant articles from the databases. The search strategy will be applied to Cochrane, ProQuest, Scopus, Web of Science, and other databases and information sources. Finally, we will search for gray literature and additional resources in electronic sources such as Google Scholar, ProQuest Dissertation, Open Access Theses and Dissertations, Networked Digital Library of Theses and Dissertations, and researchgate.net.

Study Selection

After the initial search, all identified citations will be collated and uploaded to EndNote X9, de-duplicated, and imported to JBI SUMARI. Two independent reviewers will subsequently screen the titles and abstracts to assess the inclusion criteria for the review. We will retrieve potentially relevant sources for full-text screening to confirm the eligibility of the study for analysis. Any study that includes stigma associated with DRTB and health workers will qualify for the analysis. The bibliographies of studies meeting the inclusion criteria will be scanned to identify additional articles eligible for inclusion. Any disagreements between the reviewers at each stage of the selection process will be resolved through discussion or with an additional reviewer. The scoping review will record and report reasons for excluding sources of evidence in the full text that do not meet the inclusion criteria.

Data Charting

We developed a draft extraction chart (Table S3 in Multimedia Appendix 1) that will be piloted to examine results from 3 to 5

XSL•FO
RenderX

articles. The piloting is aimed to ensure that the extraction chart captures all relevant information to satisfy the scoping review objectives and questions. The data extraction chart includes specific details about the participants, concept, context, study methods, and key findings relevant to the review questions. Henceforth, to ensure comprehensive coverage in the literature search, the search process will be iterative and require reviewers to engage reflexively [23]. We will have an opportunity to modify and revise the data extraction chart at this stage to suit our needs. Once all the reviewing team members are satisfied with the pilot charting, the 2 independent reviewers will use the finalized chart to extract relevant data from the identified studies. The reviewers will detail the modifications in the scoping review. If appropriate, we will contact the authors of papers to request missing or additional data, where required.

Data Analysis and Presentation

We will use the Preferred Reporting Items for Systematic Reviews and Meta-analyses extension for scoping review flow diagram [30] to report the review search and inclusion pathway. First, the details of the included articles will be summarized and presented in tabular form outlining the authors, year of publication, settings, outcome measures, and main descriptions of the results to provide an overview of the extent, nature, and distribution of the studies in this scoping review. Second, we will present a summary list of findings with illustrations and narratives. Third, we will thematically synthesize the key findings of the studies and will present a graphic diagram following the aspects of DRTB stigma (stigma drivers and facilitators) identified in the research questions of this scoping review. Lastly, we will provide a summary of our findings and describe how the results relate to the objectives and questions of this scoping review.

Results

This study commenced in October 2021. After conception, this scoping protocol was registered in OSF to promote transparency in our research and prevent duplication by others. The protocol refinement was completed in December 2021, and soon after, a pilot search of the PubMed and EBSCO databases was performed to inform the search strategy's development. The study has retrieved 593 abstracts out of 12,138 articles searched since February 2022 from the identified databases. This study is expected to finish in 2023. The findings of this study will be published in a peer-reviewed journal.

Discussion

Principal Findings

The stigma surrounding DRTB is a growing concern. Research has shown that frontline health care workers delivering DRTB services are affected by such stigma, so it requires attention [9]. In scanning the literature, gaps emerged as most interventions were geared toward patients with DRTB and their families, less toward health workers. Also of note was the focus of reviews on DSTB-associated stigma in health facilities. As of yet, no literature review summarizing the stigma surrounding DRTB among health workers has been found.

Addressing the multiple facets of stigma from national to facility levels is important for a sustainable response to stigma. At the facility level, there is increasing recognition to target the primary factors—the drivers and facilitators—that constitute the stigmatization process. Akin to stigma-reduction interventions for patients and their families that primarily result from an understanding of the factors contributing to the stigma process, DRTB stigma–reduction interventions for health workers likewise require critical analysis of what drives and facilitates the stigmatization. However, unlike patients and their families, where beliefs and lack of knowledge of the disease are common stigma factors, the stigma among health workers could be originated from a range of other factors. Such factors could include innate disease characteristics (eg, being a potent version of TB), and certain features from within the health facilities (eg, institutional policies) and from individual health workers (eg, attitudes and behaviors) [25]. Without an analytic study, intervention reduction efforts for health workers could be undermined.

This scoping review is part of a bigger project that will critically investigate stigma among health workers delivering services to patients resistant to TB medications in the Philippines. This study will provide an overview of the health workers' stigma surrounding DRTB by explicitly examining the available literature regarding drivers and facilitators contributing to disease stigma, and how it is currently addressed. The findings of this review will offer insights that could help inform appropriate responses toward stigma-reduction interventions for these health workers. Moreover, being part of a bigger project, this review's findings could also be valuable in the translation and implementation of stigma-reduction measures.

A limitation of this review is its inclusivity in time, language, and place of study; thus, it will only capture part of the picture regarding the stigma associated with DRTB and health workers. Also, the methodological quality of the searched literature will not be assessed. However, the results of this review will inform knowledge users, researchers, DRTB program managers, and implementers to identify key factors leading to stigma among health care workers. The findings of this scoping review will be disseminated through conference and webinar presentations and peer-reviewed journal publications. Should there be modifications to the protocol after its publication, we will provide the details and rationale for the changes, including the dates.

Conclusions

This review will provide an outline of aspects of DRTB-related stigma confronting health workers. The findings of this review could help inform appropriate responses toward stigma-reduction interventions for these health workers. This is significant because interventions addressing related TB (and DRTB) stigma in the workplace are lacking and such interventions are likely to have a positive impact on both patient care and patient outcomes.

Abstract

Background: Medical cannabis is one of the most commonly reported treatments for chronic pain. The wide acceptance and research in alternative medicine have put medical cannabis in the limelight, where researchers are widely examining its therapeutic benefits, including treatment of chronic pain.

Objective: The purpose of this scoping review is to provide an overview of the perspectives on cannabidiol as an alternative treatment for chronic pain among health professionals and legal cannabis users.

Methods: The framework of Arksey and O'Malley guides the design of this scoping review, and the elements reported use the recommended guidelines of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews). A comprehensive literature search accessed the databases CINAHL Complete and MEDLINE via EBSCO, Australia/New Zealand Reference Centre, PsycINFO, Ovid Emcare, Wiley Online Library, Scopus, Informit New Zealand Collection, and Google Scholar for published literature, and then it was extended to include gray literature. Gray literature searches included searching the databases Australia/New Zealand Reference Centre, Informit New Zealand Collection, INNZ: Index New Zealand, ProQuest Dissertations & Theses Global, and AUT Tuwhera Research Repository, and the website nzresearch.org.nz. The studies included in this scoping review were assessed for eligibility for inclusion using the following criteria: published in English after 2000, conducted in New Zealand (NZ) or Australia, and aimed to investigate the perspectives of health professionals and medical cannabis users using interviews for data collection. Studies were screened for inclusion using Covidence, a software tool to filter search results, and the risk of bias was assessed using the Critical Appraisal Skills Programme tool. Although this is not a required step for scoping reviews, it added an element of strength to this scoping review. Data will be analyzed using thematic analysis guided by Braun and Clarke. The findings from the data analysis will be presented in a table, which will then inform the key themes for discussion.

Results: The database search started in October 2021 and was completed in December 2021. The total number of studies included in this review is 5 (n=5). Studies included were conducted in NZ or Australia and examined the perspectives using participant interviews. This scoping review is anticipated to be submitted for publication in December 2022.

Conclusions: Using perspectives is a valuable tool to understand the challenges experienced by health professionals and medical cannabis users associated with medical cannabis treatment. Addressing these challenges through interventions that are highlighted through perspectives such as educating health professionals to increase access to medical cannabis in NZ may aid in policy

XSL•FO
RenderX

reformulation for medical cannabis in the context of NZ. Thus, this scoping review highlights the importance of medical cannabis research and suggests recommendations to guide and inform medical cannabis policy in the context of NZ.

KEYWORDS

CBD; cannabidiol; medicinal cannabis; medical cannabis; chronic pain; pain; perspectives; opinions; health professionals; medical professionals; users; medicinal cannabis users; medical cannabis users; New Zealand; NZ

Introduction

Overview

Medical cannabis is one of the most reported treatments for chronic pain [1,2]. Chronic pain is one of the most disease-burdening conditions in the world [3,4], which is estimated to affect 1 in 5 adults of the world's general population [5]. Opioids are currently the preferred method of treatment, trusted by physicians to manage chronic pain [6]. However, although opioids are readily attainable and a preferred method of treatment, there is excessive use of opioids globally as more people access opioid prescriptions for chronic pain management [7]. The commonly reported reasons for researching opioid alternative treatments are opioid-related drug abuse, overdosing, associated risks, and high prescription rates [8].

Medical cannabis, or *Cannabis sativa* L. (*C sativa*), is a plant of the Cannabaceae family, which has properties that are particularly interesting to researchers for their therapeutic benefits as alternative treatments for varying chronic conditions including chronic pain [9]. It comprises 2 elements: delta-9-tetrahydrocannabinol (THC) and cannabidiol (CBD). THC is the psychoactive compound, consuming which produces a "high" as it alters the functioning of the central nervous system (CNS). CBD, however, tends to be the focus of modern-day research for its medical benefits when consumed in small doses. The exact mechanism of how CBD works in the body is unclear. However, it is known to activate the body's internal endocannabinoids via the endocannabinoid system [10]. It is suggested that the neurotransmitters emitted from the CBD products bind to the cannabinoid receptors in the body's CNS and activate signals. The activated signals cause signal blocking, which results in relief from discomfort caused by medical conditions [10].

Background

In 2018, New Zealand (NZ) legalized medical cannabis by amending the Misuse of Drug Act 1975 to control the use of cannabis as medicine. In April 2020, the Medical Cannabis Scheme was implemented in NZ. The Medical Cannabis Scheme aims to allow qualifying users to access quality medical cannabis products. Currently, qualifying users are limited to only those diagnosed with multiple sclerosis [11]. However, chronic pain management is one of the more commonly proposed reasons to use medical cannabis [3,4]. While some studies show improvements when using medical cannabis for chronic pain [12,13], others have emphasized their apprehensions with study designs and research affiliations with pharmaceutical companies suggesting more positive applications [8,14-16]. Others explain that studies investigating the relationship between medical cannabis and chronic pain have a high prevalence of reporting bias, over-reporting of results, small sample sizes, short-duration outcomes, and short follow-up periods [8]. These concerns are further justified by similar concerns voiced by researchers who strongly argue for the need to expand research on medical cannabis and its use for chronic pain [16]. Overall, the findings from studies suggesting the effectiveness and efficiency of using medical cannabis as a treatment for chronic pain are considerably low, and therefore, further research is required [4].

Rationale

In addition to literature highlighting the inconsistencies of medical cannabis as an alternative treatment for chronic pain, seeking the opinions of health professionals and medical cannabis users may add another dimension to this body of evidence. The studies exploring the perspectives of health professionals and legal cannabis users using a government-standardized CBD product are limited. Previously, studies explored the perspectives of health professionals and medical cannabis users using surveys without performing participant interviews. Therefore, this scoping review adds a methodological dimension too [17-19]. Furthermore, when these studies were conducted, medical cannabis was not legal in NZ. Therefore, these studies have not examined a form of standardized CBD treatment legal for use in NZ. This highlights a possible limitation as the participants would have reported outcomes consuming substances from the black market.

For this reason, study results cannot be directly linked to chronic pain treatment with CBD, considering the unknown concentrations of CBD, THC, and other contaminants in black market substances. The perspectives of individuals with chronic pain who use medical cannabis and the perspectives of health professionals who prescribe medical cannabis are essential and should contribute to the clinical, social, economic, and political discussion of medical cannabis in NZ. This scoping review aims to examine the perspectives surrounding medical cannabis use to treat chronic pain among health professionals and legal cannabis users. This scoping review is being performed as part of a qualification intended for achievement by the primary author (PK), which is not reported in this scoping review protocol.

Overall Aim

This scoping review aims to provide an overview of the perspectives on CBD as an alternative treatment for chronic pain among health professionals and legal cannabis users.

XSL•FO
RenderX

The specific objectives are as follows:

1. To search and synthesize literature on the perspectives of health professionals and legal cannabis users in treating chronic pain with CBD
2. To provide literature that will add to the current knowledge that may inform policy regarding prescribing CBD treatment for chronic pain in NZ.

Methods

Overview

The framework of Arksey and O'Malley [20] guides the design of this scoping review, and the elements reported will use the recommended guidelines of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [21]. Scoping reviews have become a popular tool for synthesizing evidence. Similar to a systematic review, a scoping review follows a structured process. A scoping study is practical when providing an overview of what is already known about a particular topic or in circumstances where the literature volume is broad and detailed. The most common reason to perform a scoping review is to identify and map the currently available evidence [20,22]. A useful aspect of performing a scoping review is when studies aim to identify themes and concepts reported and discussed in the literature on a particular topic. To address the purpose of this review, a scoping review is a better suited approach compared with a systematic review as it seeks to examine the perspectives of health professionals and legal cannabis users while identifying and mapping the currently available literature on medical cannabis and chronic pain [23].

Developing the Research Question

The search protocol was developed using the PICO(T) tool, developed by Richardson and Wilson [24], which comprises the components People, Intervention, Comparison/Control, Outcome, and Time. Scoping reviews have broad questions, as the general aim of a scoping review is to map the literature available on a topic. Therefore, 2 elements of the PICO(T) tool were used to formulate a broad question sufficient to perform a scoping review. The 2 elements of the tool that were used in formulating the question for this scoping review are population/problem (P) and intervention (I) [25].

Research Question

What are the perspectives of health professionals and legal cannabis users (population) about the use of medical cannabis (intervention) in treating chronic pain (problem)?

Searching the Literature

The literature search was performed from October to December 2021. In the initial stages of searching, there was no restriction on searching by geography; however, because of the number of results that were present for each search, the supervisors were consulted to narrow the search to studies limited to NZ and Australia. To our knowledge, this is the first scoping review to explore the perspectives of health professionals and legal cannabis users restricted to NZ and Australia. The decision to restrict the literature search by geographical location was taken given the nature of the study to explore the perspectives of health professionals and legal cannabis users where studies were limited. This scoping review also aims to add knowledge through a wider qualification to aid policy changes in NZ. Therefore, it is vital to explore the perspectives of health professionals and legal cannabis users to ensure informed policy change decisions in NZ. As a result, the literature search for this scoping review was restricted to NZ and Australia. In addition, reviewing the availability of literature without a geographical restriction is beyond the capability of the primary researcher in the time allocated for the completion of the intended qualification.

The databases that were searched included the following: CINAHL Complete and MEDLINE via EBSCO, Australia/New Zealand Reference Centre (EBSCO), PsycINFO, Ovid Emcare, Wiley Online Library, Scopus, Informit New Zealand Collection, and Google Scholar.

In addition to the databases listed above, gray literature was searched using platforms dedicated to this purpose. The platforms that were used to search gray literature included the databases and website listed as follows: Australia/New Zealand Reference Centre, Informit New Zealand Collection, INNZ: Index New Zealand, ProQuest Dissertations & Theses Global, AUT Tuwhera Research Repository, and nzresearch.org.nz.

The keywords and phrases used to search were kept the same for consistency. The keywords were often combined with truncation and Boolean search techniques. An example of the search string is presented in Textbox 1, and the full search string can be found in Multimedia Appendix 1. All the keywords used to modify the search during the database, gray literature, and website searches are presented in Textbox 2.

Textbox 1. An example of the search string used to search databases, gray literature, and websites.

Example of the search string used to search

CBD
CBD, Cannabidiol, Medical cannabis, Medicinal cannabis, Medical marijuana, Medicinal marijuana
Pain
Pain, Chronic pain, Neuropathic pain, Chronic condition, Non cancer chronic pain
Perspectives
Perspective, Opinion, Attitude, View, Experience, Lived experience, Knowledge User experience, Professional experience
Population
Professional, Health professional, Medical professional, User, Patient, Doctor, Nurse, Pharmacist
Geography
New Zealand, NZ, Aotearoa, Australia, Aus, Auz

Eligibility Criteria

Eligible studies were those published in English between 2000 and 2021 and were either qualitative or mixed methods studies using interviews. The recruited participants were 18 years or older and used medical cannabis for chronic pain, or chronic pain in conjunction with another condition. Also, studies were eligible to be included if they were conducted in either NZ or Australia and must have aimed to investigate the lived experience, perspectives, or opinions of health professionals of all categories, for example, general practice, mental health professionals, nurses, and medical cannabis users, specifically CBD.

Exclusion Criteria

Studies were excluded if they were conducted outside of NZ or Australia, did not use interviews, and used other methods of analyzing perspectives such as surveys. Studies focusing on medical cannabis for mental health–related disorders, those examining the efficacy of cannabis treatment, and recreational cannabis studies were also excluded from this review.

Screening or Selecting the Studies

After the search was completed in each database, the search results were exported as an RIS file into the reference manager EndNote X9. After all search exports from each database were completed, a final XML file was exported from EndNote X9 and imported into Covidence, a web-based software tool useful when performing a type of comprehensive literature review [26]. The purpose of the software is to aid in screening studies, data extraction, and quality assessment required to perform a full review [26,27]. The software Covidence was used in all stages to screen titles and abstracts for the first screen, the full-text screening stage where studies were either included or excluded, data extraction, and quality assessment of the studies included. The primary researcher (PK) completed the initial screening and selected the articles to be screened in the abstract screening stage. The second reviewer, also the secondary supervisor in this research project (DW), also individually screened the titles for abstract screening in Covidence. Although an appraisal of the literature is not required to be included in a scoping review, articles included in our scoping review will be critically appraised using the Critical Appraisal Skills Programme (CASP) tool. Appraising literature that is included in the review will aid in further identification of research gaps.

The quality assessment was performed in Covidence. At this stage, the template provided by Covidence was customized to suit the data present in qualitative studies, adapting it to the CASP checklist for qualitative studies [28]. The CASP tool is a simple tool that can be used to appraise the strengths and limitations of qualitative research methodology. CASP is commonly chosen among novice researchers as the tool is user friendly and easy to understand. It was created for appraising health-related research and is endorsed by Cochrane and the World Health Organization for use in qualitative evidence synthesis [29,30]. It is for these reasons that CASP was selected as the most appropriate tool to be used in this scoping review.

The full-text screening was completed by both the primary researcher (PK) and the second reviewer (DW) in December 2021. Data extraction and CASP were initially completed by the primary researcher (PK) and reviewed by the second reviewer (DW). The third reviewer, also the primary supervisor of this project (CM), was assigned to resolve conflicts after discussions at each stage. However, no conflicts were present throughout the stages of progress. Therefore, the third reviewer's involvement was not required in the process. At the completed full-text screening stage, five studies met the eligibility criteria to be included in the review (Figure 1). Considering the low number of studies (n=5) to be included, the researcher consulted with supervisors to seek advice to proceed. The consensus was reached to expand to include more gray literature. The search results yielded from the gray literature search and selection process of results are shown in Figure 2.

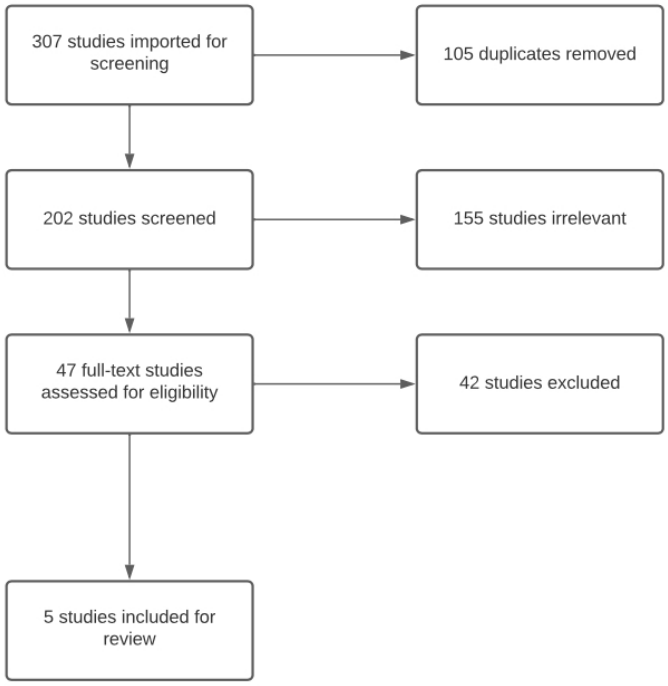
Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram of the study selection process from databases.



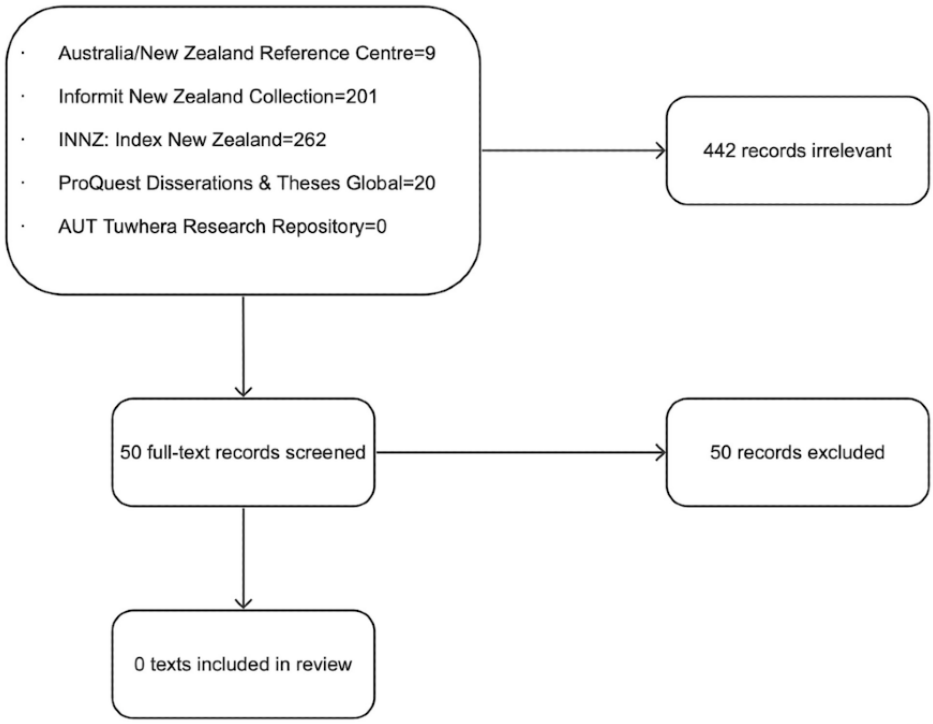


Figure 2. Flow diagram of the study selection process from gray literature.

Data Analysis and Presentation

The findings of this scoping review will be presented in a tabular format. The articles included in the review will be summarized and displayed in categories describing the studies included in the full review. Analysis of the results will consist of a narrative synthesis to link the results and research objectives using thematic analysis guided by Braun and Clarke [31], a commonly used technique suitable for analyzing qualitative literature. The data analysis will be carried out by the primary researcher (PK) and will be validated by the primary (CM) and secondary (DW) supervisors. The template to extract the relevant data from the included studies and the description of information that will be extracted are presented in Textbox 3.

Participants
Description of information being extracted: details of the participants, number of participants, age, etc.
Main findings
Description of information being extracted: results of the study, highlights, limitations, and conclusions

Results

An initial search of the databases was conducted in October 2021. After consulting with the supervisory team (CM and DW) for this project to continue, the search was completed in December 2021. We anticipate that the full scoping review will be completed in December 2022, as this scoping review is part of a qualification that the researcher PK is currently undertaking. The full scoping review is anticipated to be submitted for publication in December 2022.

The scoping review includes 5 articles in the initial review. The process of finding the articles to be included in the review is presented in Figure 1, which shows the PRISMA-ScR flowchart. Of the final articles included, one article is a study performed in NZ, while the others were performed in Australia. All five studies included in the scoping review were qualitative studies conducted by interviewing participants and had the common aim of understanding perspectives. Four of the articles explored medical cannabis–related perspectives, while one explored the use of opioids in the population of pharmacists. Although this study is not directly related to medical cannabis perspectives for pharmacists, the themes present in the study are associated with the aim of this scoping review and will contribute valuable insights to the discussion.

The databases Australia/New Zealand Reference Centre, Informit New Zealand Collection, INNZ: Index New Zealand, ProQuest Dissertations & Theses Global, and AUT Tuwhera Research Repository were searched along with the website nzresearch.org.nz. This website enabled searching of theses, dissertations, and academic articles produced at educational institutes throughout NZ. The databases did not reveal relevant information specific to this scoping review. The search for gray literature was performed after consultation with supervisors to find more texts relevant to the aim to be included in the full review. However, the search results were unable to yield results related to the topic of this review (n=0). Given the limited timeframe to complete the scoping review as part of a qualification for the primary author (PK), the supervisory team agreed that data saturation was reached at this stage of the literature search.

Discussion

To our knowledge, this is the first scoping review to explore legal cannabis users and health professional perspectives to treat chronic pain with medical cannabis in NZ and Australia since the rollout of medical cannabis in both countries. Studies that have been previously conducted on medical cannabis occurred before medical cannabis legalization and mostly used surveys [17,32-36]. This makes our review focusing on regulated and prescribed medical cannabis products using interviews unique as it examines perspectives to develop themes that highlight the research gaps and challenges to accessing medical cannabis relevant to NZ. The developed themes discussed in this scoping review may highlight why medical cannabis users prefer medical cannabis over other first-line treatments and aid in improving medical cannabis treatment for chronic pain in NZ.

This scoping review highlights the current barriers for patients using medical cannabis through their health system experience. These outlined barriers may assist in proposing recommendations that may guide policy shifts in NZ and suggest future study directions. These suggestions will be formed from the themes that arise from this scoping review results, such as spillover effects of medical cannabis, the impact of medical cannabis on the youth, the existing barriers to accessing medical cannabis treatment, for example, the associated treatment costs, the limited knowledge of health professionals to recommend medical cannabis treatment, and the stigma associated with medical cannabis use.

The suggestions and recommendations in this review will focus on highlighting and addressing the barriers identified through perspectives to improve the future of accessing medical cannabis in NZ. Suggestions may include improvements to education of health professionals in other countries and the effects of education in medical practice, for example, achieving higher prescription rates to access medical cannabis for users through the health system that may improve access to medical cannabis. Increasing education among health professionals and increasing access to medical cannabis using the health system may also reduce the stigma surrounding medical cannabis use. Other suggestions may include conducting a study examining the perspectives of health professionals and legal CBD users in NZ to understand the reasons for using medical cannabis. A future

XSL•FO
RenderX

study in this direction may highlight the challenges experienced by health professionals and medical cannabis users in NZ. Therefore, studying the perspectives of health professionals and medical cannabis users to suggest recommendations may aid in informing knowledge for NZ policy makers that may provide better access to medical cannabis and guide future policy making on medical cannabis in NZ.

The future directions of this study will include suggesting the current research that the primary author (PK) is undertaking, which includes interviewing medical cannabis users and health professionals to examine CBD user perspectives in NZ and highlight their experiences of using medical cannabis through the NZ health system. This research will follow the suggestions of this scoping review and interview participants that may provide valuable information to guide policy reformation of medical cannabis in NZ.

Limitations

The inclusion criteria for this scoping review are limited to studies that use qualitative methods. Therefore, the results may not represent the broader population of perspectives studied using other methods, for example, surveys. However, this scoping review will recommend a future study in NZ that uses interviews to add knowledge that examines the reasons for using medical cannabis in NZ. We also recognize that limiting the scoping review to include studies from only NZ and Australia may not represent the body of knowledge that exists on medical cannabis user and health professional perspectives globally. However, it is essential to note that this scoping review aims to provide suggestions for policy recommendations in NZ. Therefore, it contributes to the currently limited evidence for the country for which recommendations are being suggested.

Conclusions

The conclusions of this scoping review will summarize the importance of medical cannabis and the reasons for its use among medical cannabis users and health professionals using perspectives. A summary of the evidence discussed will be an important component to reinforce the success of addressing the overall aim. The challenges highlighted through the discussions of this scoping review include access to medical cannabis due to the associated treatment costs, the limited knowledge of health professionals to recommend medical cannabis treatment for chronic pain, and the stigma associated with its use.

These elements indicate that using perspectives to understand the reasons for medical cannabis use may enforce policy changes that address the current challenges in NZ for chronic pain treatment with medical cannabis. Through this scoping review, the importance of implementing interventions that educate health professionals to increase access to medical cannabis using the health system may address a significant barrier, for example, the limited knowledge of health professionals to prescribe medical cannabis. Additionally, this scoping review may suggest introducing a wider selection of medical cannabis products into the NZ market. Introducing new products may reduce the associated costs of treatment through competition and will increase product variety for consumers that are currently limited.

Highlighting the concerns raised by health professionals and medical cannabis users may reinforce the importance of medical cannabis research using perspectives. The same is demonstrated through the overall aim of this scoping review that highlights the importance of understanding perspectives to contribute to effecting a positive change for the future policy reformation of medical cannabis in the context of NZ. Future research directions undertaken by the primary author (PK) will be summarized. The summary will acknowledge the contribution of the research currently being undertaken as a valuable contribution to advancing medical cannabis research using perspectives in NZ that may contribute to future policy reformation for medical cannabis in NZ.

Acknowledgments

This protocol and the subsequent review will contribute toward the primary author's (PK) Master of Public Health degree. The wider project that is being undertaken by the primary author (PK) is being supported by a research budget from the Auckland University of Technology and the dedication and guided direction of the primary (CM) and secondary (DW) supervisors.

Conflicts of Interest

Abstract

Background: Malaria is still a public health threat. From 2015 to 2021, a total of 23,214 malaria cases were recorded in Malaysia. Thus, effective intervention and key entomological information are vital for interrupting or preventing malaria transmission. Therefore, the availability of malaria vector information is desperately needed.

Objective: The objective of our study is to update the list of human and zoonotic malaria vectors in Malaysia. This work will include (1) the characterization of the key behavioral traits and breeding sites of malaria vectors and (2) the determination of new and potential malaria vectors in Malaysia. The findings of our scoping review will serve as decision-making evidence that stakeholders and decision makers can use to strengthen and intensify malaria surveillance in Malaysia.

Methods: The scoping review will be conducted based on the following four electronic databases: Scopus, PubMed, Google Scholar, and Science Direct. A search strategy was conducted for articles published from database inception to March 2022. The criteria for article inclusion were any malaria vector–related studies conducted in Malaysia (with no time frame restrictions) and peer-reviewed studies. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) will be used to guide our systematic approach. Data from published research literature will be extracted by using a standardized data extraction framework, including the titles, abstracts, characteristics, and main findings of the included studies. To assess the risk of bias, articles will be screened independently by 2 reviewers, and a third reviewer will make the final decision if disagreements occur.

Results: The study commenced in June 2021, and it is planned to be completed at end of 2022. As of early 2022, we identified 631 articles. After accessing and evaluating the articles, 48 were found to be eligible. Full-text screening will be conducted in mid-2022. The results of the scoping review will be published as an open-access article in a peer-reviewed journal.

Conclusions: Our novel scoping review of malaria vectors in Malaysia will provide a comprehensive evidence summary of updated, relevant information. An understanding of the status of *Anopheles* as malaria vectors and the knowledge generated from the behavioral characteristics of malaria vectors are the key components in making effective interventions for eliminating malaria.

Introduction

Malaria is still a public health threat. The World Health Organization (WHO) recorded a total of 241 million malaria cases and 627,000 malaria deaths worldwide in 2020 [1]. Further, Malaysia recorded 23,214 malaria cases from 2015 to 2021, of which 87% were zoonotic cases [1]. Malaysia is facing increasing cases of zoonotic malaria due to *Plasmodium knowlesi*. The number of *P knowlesi* cases increased from 1960 to more than 4000 between 2016 and 2018. This number declined slightly in 2019 and 2020 (to 3213 and 2609 cases, respectively), but *P knowlesi* infection still resulted in 6 and 5 deaths in 2019 and 2020, respectively [1].

Malaria is caused by parasites of the genus *Plasmodium*. These parasites harm not only humans but also other vertebrate species, including birds, reptiles, and mammals. *Plasmodium* species that naturally infect humans and cause malaria in large areas of the world were limited to the following four: *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium malariae*, and *Plasmodium ovale* [2]. However, studies conducted by Cox-Singh et al [3], Piera et al [4], Siner et al [5], and Yek et al [6] confirmed that there is a fifth *Plasmodium* species responsible for zoonotic malaria—*Plasmodium knowlesi*.

Malaria is a vector-borne disease transmitted by *Anopheles* mosquitoes [7-9]. The WHO recorded 4500 species of mosquitoes worldwide in 34 genera from the family Culicidae, the order Diptera, the class Insecta, and the phylum Arthropoda [10]. Interestingly, only 70 species of anophelines were confirmed as malaria vectors around the world [10]. A total of 434 mosquito species have been recorded in Malaysia [11], including 75 species of *Anopheles* mosquitoes [12]. Previous studies recorded the following nine species of *Anopheles*, which were established as malaria vectors in Malaysia: *Anopheles balabacensis*, *Anopheles maculatus*, *Anopheles campestris*, *Anopheles sundaicus*, *Anopheles letifer*, *Anopheles donaldi*, *Anopheles dirus*, *Anopheles leucosphyrus*, and *Anopheles flavirostris* [12,13]. It is important to investigate potential malaria vectors when developing new technology for species complex identification. A potential malaria vector is defined by the vectorial capacity of a vector population to transmit malaria [14].

Malaysia is working toward eliminating malaria and preventing malaria re-establishment [15]. Effective entomological surveillance tools are the most important tools for interrupting malaria transmission [16-18], which can be achieved by designing a targeted control intervention based on the behavioral characteristics of malaria vectors [17,19-21]. For example, *Anopheles balabacensis* rests outdoors after feeding [22]. Therefore, vector control tools need to be developed for and applied on the walls of houses, tree trunks, bushes, or any possible resting places of *Anopheles balabacensis*, and existing outdoor vector control interventions should be strengthened. Our review will serve as a resource for informing entomologists, malaria personnel, and physicians about malaria vectors in Malaysia. Entomological information accelerates the process of malaria elimination by enhancing the impact and efficacy of the intervention needed [18]. The objectives of our study are to establish protocols for determining new and potential malaria vectors and to update the list of existing human and zoonotic malaria vectors in Malaysia.

Methods

Protocol Design

Our study will broadly cover the subject area—the nature of research activity on malaria vectors—in accordance with the 6-stage framework of Arksey and O'Malley [23], which was refined by Levac et al [24]. The six stages of the review process are as follows: (1) identifying the research question; (2) identifying relevant studies; (3) selecting studies; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) consulting with relevant stakeholders. The scoping review will adhere to the 22-item PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Review) checklist [25].

Stage 1: Identifying the Research Questions

In order to develop and identify the research questions, the subject area—the nature of research activity on malaria vectors—was examined. Thus, the following research questions were identified: (1) what are the established malaria vectors in Malaysia and (2) what are the potential malaria vectors in Malaysia?

Stage 2: Identifying Relevant Studies

A search strategy was conducted for articles published in scientific journals and peer-reviewed publications, using the following electronic databases: PubMed, Scopus, Google Scholar, and Science Direct. Relevant research websites, such as Portal Data Terbuka Malaysia [26], WHO websites, and Ministry of Health Virtual Library, were also searched.

Articles were identified by using Medical Subject Headings and keywords. Using a systematic approach, titles, abstracts, and keywords were searched, screened, and reviewed, and data were extracted. The search was not restricted by year or language. All selected search results were imported into Mendeley software (Elsevier) and Microsoft Excel spreadsheets (Microsoft Corporation) to manage references and duplicates.

Stage 3: Study Selection

All entomological research conducted in Malaysia will be included in the study, including longitudinal studies, cross-sectional studies, observational studies, and descriptive reports. The literature search was only conducted for peer-reviewed articles published from database inception to March 2022. The exclusion criteria for the scoping review are gray literature, annual reports, and bulletins. First, inclusion and exclusion criteria will be used to determine the eligibility of articles based on their titles during the screening portion of the review process. Any articles with titles indicating that the research was conducted outside of Malaysia will be excluded. Second, titles and abstracts will be selected based on eligibility criteria. Only abstracts that fulfill the inclusion criteria will be further analyzed. Finally, full-text articles that are selected based on their abstracts will be reviewed and included in the study if they are considered significant and relevant studies.

XSL•FO
RenderX

Stage 4: Charting the Data

The significant study characteristics of published research literature will be extracted by using a standardized data extraction framework. Two independent reviewers will conduct the data extraction, and they will discuss any discrepancies or disagreements with a third reviewer. A data extraction framework was developed to guide the extraction and charting process for the data from the articles. It will consist of standard bibliographical information (title, author, journal, year of publication, language, location of the study, and study objectives). Additional information, such as the type of study, the primary outcome, and other valuable information, will be included as well. The framework will provide an overview of the significant information about the studies and facilitate data analysis.

Stage 5: Collating, Summarizing, and Reporting the Results

Our scoping review intends to present an overview of the study area, unlike a systematic review, which requires meta-synthesis reporting. Thus, we will report on the information we gather based on the selection criteria. Our study will summarize all of the data and information from relevant articles and will emphasize the scope of malaria vectors in Malaysia. Furthermore, gaps in research regarding specific study areas will be identified and determined. The study will use the PRISMA-ScR reporting guidelines to accurately report the scoping review and search results.

Ethical Considerations

Ethical approval is not required, as our study does not involve collecting data from human participants.

Dissemination

An article detailing the findings of the scoping review will be submitted to a scientific journal for publication. Study findings will be disseminated via open-access publications in peer-reviewed journals, presentations to stakeholders, relevant meetings, conferences, and continuous medical education at the department level, as well as future seminars and workshops. The published article will be included as part of a dossier for the Malaria Elimination Program of Ministry of Health Malaysia.

Results

The literature search was conducted in March 2022, yielding 631 malaria vector–related articles. A total of 48 studies were found to be eligible after accessing and evaluating the articles. As of early 2022, our scoping review reached the data synthesis stage. Results are expected to be published by the end of 2022 in a peer-reviewed journal.

Discussion

Malaria is incredibly harmful to very young children and low-income individuals [27]. The eradication of malaria is among the best returns on investments in public health and is very cost-effective [27]. In endemic nations, including Malaysia, initiatives for preventing and eventually eradicating malaria are increasingly seen as high-impact strategic investments that will benefit public health, reduce poverty, advance equity, and advance overall development [28].

Vector control is a crucial part of malaria prevention, control, and eradication programs due to its tremendous potential to improve personal protection and reduce disease transmission [29]. The ability of vectors to transmit parasites and their susceptibility to vector control techniques vary by mosquito species and are impacted by regional ecological parameters. Vector control must be implemented on the basis of local epidemiological and entomological data. Entomological surveillance and monitoring of the coverage and effects of vector control interventions must be included in national surveillance systems in order to provide an efficient vector control response [30].

The distribution of mosquitoes in Malaysia was last reviewed in 1997, with a focus on *Anopheles* mosquitoes, by Rahman et al [12], but their focus was not specifically on malaria vectors. Later, Vythilingam and Hii [13] outlined the malaria vectors in Malaysia, focusing on human malaria. The desired elimination of malaria is thought to be affected by extended delays in updating information on vectors. A systematic study conducted by Bertola et al [31] on the occurrence and bionomics of potential malaria vectors successfully supported the identification of 3 new potential vectors in Europe, along with a study conducted by Sinka et al [32]. Our scoping review will provide up-to-date insights on established and potential human and zoonotic malaria vectors, which we believe will contribute to the development of strategies for achieving malaria elimination in Malaysia. However, it is crucial that Malaysian researchers continue to study malaria vectors in order to make decisions about vector control measures that will help to eradicate the disease.

The lack of current information on malaria vectors in Malaysia indicates the need for more extensive research and the systematic compilation of entomological data. The development of effective malaria interventions, such as tools for selecting vector control options and strategies and managing vector control, as well as the acceleration of the certification of malaria eradication, can benefit from such information. However, a limitation of our study is the exclusion of any unpublished data, as we aim to ensure that the sources on which our findings are based are reputable by only including peer-reviewed studies in our scoping review.

Our novel scoping review of malaria vectors in Malaysia will provide a comprehensive evidence summary of the updated status of malaria vectors. An understanding of the status of *Anopheles* as malaria vectors and the knowledge generated from the behavioral characteristics of malaria vectors are the key components in making effective interventions for eliminating malaria.

Acknowledgments

We would like to thank the director general of Ministry of Health Malaysia for his permission to publish this article, and we give special thanks to DD Nor Asiah for constructive comments on the initial manuscript draft.

Data Availability

Data sharing is not applicable to this article, as no data sets have been generated or analyzed during the study at this time.

Authors' Contributions

RA contributed to the study concept, developed the research questions and study methods, was involved in the data extraction process, and contributed to the drafting and editing of the manuscript. WNWMA was involved in the data extraction process and the editing of the manuscript, while PWP supervised the writing of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Occupational health hazards and injuries are an alarming concern among traffic police. Occupational injuries affect the physical, social, and mental well-being of police personnel, which has various public health implications. The evaluation of occupational health and safety policies and regulations for the traffic police relies on their occupational exposure and health hazard statistics and assessments.

Objective: The purpose of this scoping review is to systematically explore, analyze, and describe relevant findings from all studies conducted on occupational exposure and associated health hazards among traffic police in South Asia.

Methods: The scoping review will include studies that assessed occupational exposure prevalence, types, knowledge, predisposing factors, and prevention strategies. Databases like PubMed, Springer Link, EBSCOhost, the Cochrane library, and Google Scholar will be used to obtain both published and unpublished works in the English language. Relevant gray literature, including governmental and international organization reports, will be examined. After removing duplicates and screening titles and abstracts, the full-text analysis will begin. Arksey and O'Malley's methodology framework for scoping reviews will be followed. According to Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews, the scoping review will be reported. Two qualified reviewers will independently conduct article screening and data extraction. The extracted data will then be tabulated and accompanied by an explanation to facilitate comprehension. We will extract relevant article results using NVivo (version 10; QSR International) and thematic content analysis. The included articles will be evaluated using the mixed methods appraisal tool (version 2018).

Results: The scoping review will provide insight into how occupational health hazards affect traffic police physically and psychologically in South Asia. The theoretical conceptualization of different aspects of the occupational health of traffic police will emphasize future studies in this region, which will inform policy makers to revise their occupational health and safety policies and principles. It will have implications for taking necessary preventive measures in the future to reduce occupational injuries and fatalities resulting from different types of occupational hazards.

Conclusions: This scoping review will describe the overview of occupational hazards among South Asian traffic police and will provide insights for policy makers to implement changes and to adapt new strategies.

Introduction

Where there is unplanned urbanization, occupational- or work-related health risks related to environmental pollution have become a serious public health problem [1]. Workplace health risks include injuries, illnesses, and diseases that originate from a particular occupation and chronic exposure to certain chemicals or progressive physical actions. According to the International Labour Organization, 2.3 million individuals are injured at work every year. Moreover, each day, more than 6000 individuals die as a consequence of workplace accidents [2]. Occupational risks can cause fatalities and prolonged absences from work. Occupational hazards are estimated to cost the global economy 4% of the gross domestic product each year [3].

Traffic police perform crucial actions in maintaining the country's law, regulations, order, and safety-security. They are actively involved in managing the city's commutation system. They ensure that automobiles may travel freely on the road. Their responsibilities include controlling traffic on cross streets, settling roadside traffic disputes, and collecting penalties for breaking traffic regulations. Traffic police officers are continuously compromising their health for the general public and are more exposed to occupational hazards. Since occupation is a major determinant of health, traffic police personnel face multiple occupational hazards, and it has become a serious public health concern. Thus, duty-bound personnel like traffic police are continuously exposed to occupational health risks and hazards and experience severe related health problems [4]. A Canadian study reported that 42% (n=1500) of working Canadians had hazardous occupational noise exposure and 80% (n=373) of them used to wear hearing protection [5]. They are constantly and concurrently exposed to vehicular pollution, noise from vehicle honking, harsh weather conditions, and interpersonal tension between drivers and pedestrians. Traffic police can also get injured or killed due to car accidents and assaults. These can happen while driving, patrolling, or when police are dealing with violence, particularly in the context of South Asia. The possible occupational hazards for traffic police include respiratory illness, noise-induced hearing loss or impairment, skin diseases brought on by UV radiation, musculoskeletal disorders or backaches, psychological issues, occupational cancer, and other diseases [6].

Traffic police encounter a variety of occupational dangers, as one’s occupation is a major driver of one’s health [7]. A systematic review of 36 global studies among police officers concluded that traffic police officers were exposed to noise-induced hearing loss, dermatitis, cancer, posttraumatic stress disorder, and musculoskeletal disorders [8]. Another systematic review revealed that traffic police officers are one among those who are at risk of developing lung cancer due to environmental exposure to polycyclic aromatic hydrocarbons, benzene, and so forth [3]. According to a European study, air pollution is responsible for 6% of all deaths, whereas vehicular pollution is responsible for 50% of all deaths caused by air pollution [7]. Similarly, noise is one of the world's most common occupational health hazards, and the connection between excessive noise levels and noise-induced hearing loss (NIHL) is widely established. As traffic police officers spend most of their day exposed to noise and air pollution and remain in close proximity to the smoke and fumes emitted from vehicles, they experience air- and noise-induced illness. A cross-sectional study was conducted on the respiratory health status of traffic police in Dhaka, Bangladesh, and reported 84.4% of the respondents had different types of respiratory problems, such as cough, whistling problems, and breathlessness. About 3.1% of the traffic police had been experiencing asthma, and 9.1% of respondents had a history of parental lung disease [9]. A study in Mangaluru city, India, found that the prevalence of respiratory morbidity, eye symptoms, and ear problems were 51.2%, 61.6%, and 47.5%, respectively [4]. Research conducted in Patiala, India, showed that out of 100 traffic policemen, 68% had a frequent cough, 22% had shortness of breath, and 36% had irritation in the respiratory tract [10]. Another study conducted in Gujarat, India, studied the different disease prevalence in traffic police personnel and revealed that about 7% of traffic police personnel experience eye problems, 35.5% from blocked ear sensations, and 51.50 % from mild hearing loss, 13.6% from moderate and 0.90% from severe hearing loss. The most common physical problems include joint problems (62.65%), burning soles (42.37%), back pain (20.3%), and disturbed sleep patterns (16.3%) [11]. A study conducted among traffic police in Kathmandu found that 72.3% of the respondents had a complaint of burning eyes or tearful eyes. Ear ringing was reported by 37.8% of the study subjects [12]. Therefore, skin, respiratory, and eye problems were the most common physical problems seen among traffic police reported in another study in Kathmandu [13]. A Malaysian study reported that traffic police experience hypo- or hyperthermia, skin cancer, depression, lower back pain, asthma, NIHL, and so forth due to occupational exposure to major environmental hazards [14]. A study conducted in Hong Kong has assessed that 80% of traffic constables have reported exposure to environmental tobacco smoke, and the odds ratio of having respiratory systems is 20.4 times more in men as compared to women [15].

While dealing with heavy traffic congestion, traffic police become mentally and physically exhausted, making them susceptible to physical and mental stress, increasing with the duration of employment [6]. A study conducted in Kathmandu, Nepal, revealed a significant prevalence of mental health problems, such as depression (41.3%), anxiety (47%), and stress symptoms (44%), among traffic police officials. This study also

XSL•FO
RenderX

reported that smoking and longer working hours were significantly associated with depression, anxiety, and stress [16]. About 73% of traffic police were reported with anxiety, while stress-related problems were identified among 40.6% in another study conducted in Kathmandu [13]. Poor pay, workload, and irregular working hours were stress factors causing psychological hazards among Malaysian traffic police [14].

Cardiovascular disease and cancer risk are also linked to traffic pollution [17]. The leukocyte telomere length might reduce in persons exposed to traffic pollution, resulting in early biological aging and an increased risk of developing coronary heart disease, heart failure, diabetes, cancer, and osteoporosis [18]. The time-weighted average exposure to benzene, a carcinogen, was generally higher for traffic police than indoor workers [19].

Many traffic police officers experience work-related musculoskeletal diseases, particularly in the lower back, neck, and shoulders [20]. Musculoskeletal issues related to work are the leading cause of absenteeism and decreased productivity [21]. Standing in a static posture for lengthy periods exposes them to ergonomic issues [22]. Overall, 12% (n=24) of the traffic police in Nepal were found experiencing varicose veins due to long-standing working hours [23]. Another study in Bengaluru, India, reported 60% of study participants had varicose veins associated with long standing hours [24]. An Indian study on traffic police officers reported disorientation in working schedule, fear of being vulnerable to disease, and pressure of maintaining law and order during the COVID-19 lockdown increased their stress level [25]. Job conflict, lack of autonomy, and organizational policies were found to significantly affect burnout among Islamabad traffic police officials [26].

This implies that traffic enforcers' occupational health and safety (OHS) is a critical public health issue, especially in South Asian countries.

Occupational health hazards may be preventable, and the majority of people are ignorant of them. As a consequence, a safety culture must be developed in the workplace. Occupational infection prevention and control training programs are developed at a local level by hospitals or at a national level by Ministry of Health and Professional Organizations in the United States and Australia [27]. New Delhi traffic police have various preventive measures and safety recommendations. They have extensive safety and skill training, they exercise often to stay fit and limit the risk of injury, they use personal protective equipment or other barriers for the duty, and they learn safe lifting techniques. They follow a recommended shift work pattern to protect themselves from the consequences of continuous long shifting hours. They receive first aid training to combat any emergency situation. Blood pressure checkups, cholesterol tests, and psychiatric screenings are provided as part of the Health Surveillance program to ensure general well-being of traffic police officers in New Delhi. Baseline health assessments are carried out before starting training or deployment to a specialty police duty [28]. According to another study conducted in Ahmedabad, traffic officers standing for a long period of time in hot and humid weather and their traffic intersections are not equipped with shade and existing uniform material for traffic police diminish the effectiveness of sweating. In order to deal with the heat, traffic officers drink lemon water, sugarcane juice, and buttermilk. They cover their faces with a handkerchief, which they also use to protect themselves from smoke from car exhaust [29].

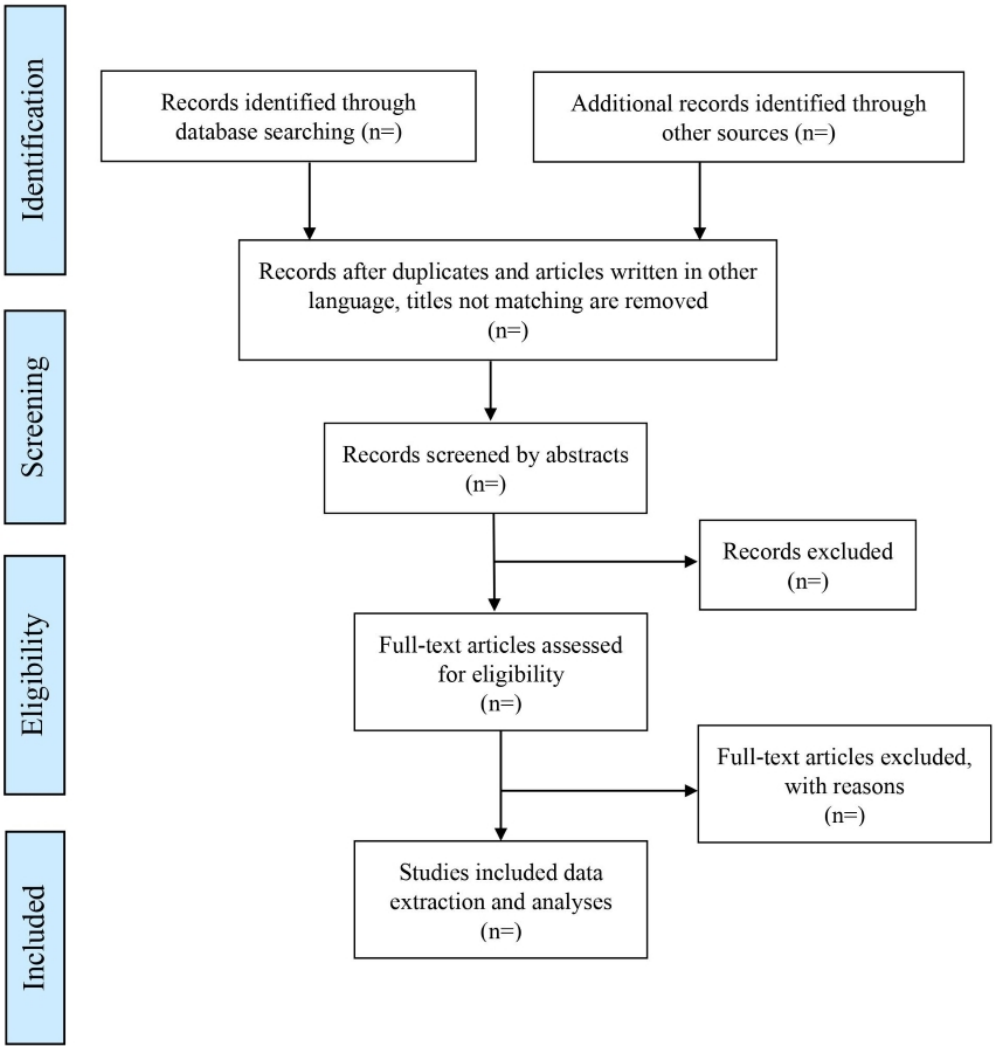
In India, regarding OHS policies, key activities include reviews of the labor administration system at the national and state levels, and conduction of workshops to promote ratification of the International Labour Organization conventions on OHS [30]. Control measures being implied among traffic police through the OHS policy of Malaysia were job rotation, using earplugs if necessary to prevent NIHL, counseling by Religious and Counseling Division of the Royal Malaysian Police to prevent psychological hazards, following self-hygiene practices such as handwashing, using face masks, and so on [14]. In Bhutan, though the OHS laws are in place, the Department of Labour is still incompetent to implement the legislation fully. The situation is impaired resistance from employers and employees to comply with the OHS legislation and to adopt a safety culture [31]. The enforcement of OHS laws is being carried out through inspections, emphasizing on the prevention, protection, and promotion. Although the National OHS policy of Bangladesh has gaps, it includes multiple clauses based on international labor policy such as workplace safety, accident prevention, workplace environment and prevention of hazards, disease prevention, and safeguards. The policy stipulates the need to ensure workplace safety and health protection in the light of international conventions, to develop a strategy and action plan to ensure proper implementation of national laws, and to include OHS issues in the policies and programs of all related ministries and agencies [32].

Therefore, directly or indirectly, traffic police face a wide variety of health hazards at their working environment, namely, physical, biological, psychosocial, chemical, and ergonomic hazards. Thus, duty-bound personnel like traffic police get exposed to various occupational hazards with different work-related injuries or diseases that have profound public health implications. These identified impacts pose severe health and safety problems and require inculcating a safety culture in the workplace. After a careful search, limited studies were found focusing on occupational health hazards among traffic police officers in South Asian countries. However, a few relevant studies regarding OHS practices, and guidelines for traffic police officers were conducted in this region. Hence, the conduct of this scoping review is imperative to explore the knowledge gaps, prevalence, possible risk factors, and control or preventive measures of occupational health hazards among traffic police in South Asia.

The suggested scoping review will include studies conducted on the occupational health of traffic police. It will cover all aspects of health, including the physical, psychological, social, and environmental components in this vulnerable group related to their occupational exposure. Furthermore, risk factors causing these exposures, such as insufficient knowledge and preventive measure, will be explored. This study is directed to come up with a complete evaluation of the evidence on occupational hazards among South Asian traffic police.

XSL•FO
RenderX

We will follow the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) guidelines, use reliable tools to assess study quality [33,34], and propose a method to query the literature about the occupational exposures and health hazards among South Asian traffic police.



Methods

Protocol Design

This scoping review will synthesize all available information by systematic research, selection, and amalgam of current knowledge. The conceptual framework developed by Arksey and O'Malley [35] will be followed to develop this protocol. The development of a scoping review will involve six steps: (1) identifying research question; (2) identifying suitable publication or studies; (3) selection of studies; (4) data charting; (5) collating, summarizing, and reporting results; and (6) quality appraisal.

To assess the quality of the articles incorporated in the review, the mixed methods assessment tool, 2018 will be used [34]. NVivo (version 10) [36] will be used to obtain meaningful outcomes for thematic content analysis. After the observations are input into NVivo, information about occupational health risks among traffic police will be coded. The findings on the number of studies retrieved from the search and the total number of studies excluded at each screening stage guided by the Preferred Items for Systematic Reviews and Meta-Analyses extension for scoping reviews will be reported and is outlined in Figure 1 [33]. Therefore, scoping review will give an outline relevant to our interest, allowing for the clarification of key concepts and the identification of gaps. This scoping review will be used to help us choose an appropriate arena for a future systematic review.

Figure 1. Study selection process.

Eligibility of Research

Studies will be selected according to the population, exposure, and outcomes framework outlined below (Textbox 1).

XSL•FO
RenderX

Textbox 1. Structure to determine eligibility for the research question.

Population

- Traffic police in South Asia

Exposure

- Occupational exposure (air pollution, noise pollution, exposure to chemical substances, and negative workplace exposure)

Outcomes

- Types
  - Physical hazards: noise-induced hearing loss
  - Chemical hazards: cancer
  - Biological hazards: blood-borne diseases
  - Ergonomic hazards: musculoskeletal disorders
  - Organizational hazards: burnout
  - Psychological hazards: anxiety, depression, insomnia, and posttraumatic stress disorder
- Prevalence
- Level of knowledge
- Predisposing factors or risk factors
- Preventive measures
- Usage of preventive measures

Identifying Research Questions

Overall, the research questions are as follows: what is the current status of occupational health hazards among South Asian traffic police? Based on this research question, the following questions are specified: (1) what kind of occupational health hazards do traffic police face, and how common are they? (2) What are the traffic police's understanding or knowledge of the occupational hazards related to their jobs? (3) What are the potential risk factors that put traffic police at risk for health hazards related to their occupation? (4) What are the preventive strategies accessible for use by traffic police to avoid occupational health outcomes? (5) What preventive steps the traffic police might use to avoid workplace health risks or hazards? (6) Is there awareness of various protocols for occupation-related injuries or chronic disease management?

Identifying Suitable Studies

The scoping review also aims to compare patterns, prevalence, and characteristics of occupational hazards of South Asian countries (India, Pakistan, Bhutan, Bangladesh, Nepal, and Sri Lanka) in which there will be a search for common patterns in regard to occupational health hazards as well as comparison of patterns, characteristics, and prevalence of occupational health hazards by country. We assume that there could be a common culture, common characteristics of the occupational health hazards among the traffic police, and even there could be a similar pattern of environmental exposures as these countries belong to the same subcontinent. On the other hand, there could be variance in prevalence, national policies, and preventive measures in different countries of South Asia. Moreover, most of the studies were conducted on various types of occupational health hazards among traffic police in different countries of South Asia. There are very few studies, which are focused on occupational health hazards of traffic police, thus generalizing findings for South Asia. Therefore, there will be an inclusion of all types of studies conducted on occupational health hazards of traffic police in countries as well as a whole of South Asia to identify the root causes behind prevalent occupational health hazards and also to have a clear picture on the emergence of tailoring any program for traffic police to prevent occupational health hazards.

Another goal of this review is to discover a wide range of literature including published studies, policy reports, newspapers, gray literature, and so on. The following electronic databases will be searched for keywords: PubMed, Springer Link, as well as EBSCO host, the Cochrane library, and Google Scholar (Multimedia Appendix 1). In addition, investigators will also look for appropriate research in gray literature, such as dissertations, as well as reports from governmental and international organizations such as World Health Organization and abstracts from conferences as there are very limited published studies focused on this topic in South Asia available in web-based sources. Finally, investigators will examine the reference lists of the incorporated research for related articles. During database searches and article retrieval, assistance from North-South University library services will be sought. The following are the keywords that will be used to find these databases: traffic police, occupational health hazards, prevalence, types, level of knowledge, predisposing factors or risk factors, preventive measures, and level of use of preventative measures (Multimedia Appendix 1). While searching, Boolean terms (AND, OR) will be used to separate

XSL•FO
RenderX

relevant keywords. Additionally, MeSH terms will also help to specify the search. As each database has a distinct search method, the result of database searches will be transferred to the Mendeley library for additional screening of abstracts and complete articles. Every search will have its own specific documentation, which will include all details of the literature such as the search terms, the date of the search, the search engine used, the total number of articles found, and so on Research teams, important stakeholders, and knowledge consumers working in this field, such as health care professionals, university professors, will be polled to choose the search terms that will be used by the search strategy. Search terms or strategy will be changed based on the comments of other partners. In order to avert any risk of bias while selecting publications, the final step of the search process will be conducted in complete anonymity.

Study Selection

The review approach will consist of two screening steps: (1) A title and an abstract and (2) a full-text evaluation.

Two nonpartisan investigators will review the titles and abstracts of manuscripts to determine whether or not they meet the minimal set of inclusion as well as exclusion criteria.

Inclusion criteria are as follows: (1) studies carried on traffic police; (2) studies conducted on job-related exposures to biological and nonbiological hazards, prevalence, different kinds of hazards, risk factors, knowledge levels, and preventative methods; (3) studies carried out in South Asian countries (Bangladesh, Bhutan, Pakistan, India, Nepal, and Sri Lanka); (4) studies that are based on cohorts, case-control studies, cross-sectional studies, randomized controlled trials, and nonrandomized controlled trials; and (6) scholarly work published in English as well as in other languages with an English translation.

Exclusion criteria are as follows: (1) studies that did not focus on traffic police and occupational health hazards, (2) studies published in languages other than English, and (3) qualitative studies.

Before the actual review of article abstracts, the minimal inclusion and exclusion criteria will be evaluated on a sample of abstracts to make sure they are robust enough to include any studies on occupational exposures among traffic police in South Asia. Articles matching the inclusion criteria will be chosen for a full-text review. Based on the sample review, the inclusion and exclusion criteria will be finalized. In the subsequent step of the process, out of 2 investigators, each will conduct their own independent evaluation of the complete texts of the publication using the study criteria. If reviewers disagree with any article, it will be given a second look, and any further disagreements about the article's eligibility will be discussed with a third investigator. In order to provide a comprehensive record of the review procedure, a flowchart known as the PRISMA-ScR [33] will be constructed (Figure 1).

Data Charting

The relevant data will be drawn out using an extraction form. Specific details such as year of publication with date, study design, population, study aim, study title, study setting, intervention, proportions, result of the study, key findings pertinent to the study questions, and observations will be extracted and will be used to organize the data of all analyzed studies using a codebook. An extraction sample is provided in Textbox 2. Alterations will be made to the data extraction form on a regular basis. The given data extraction instrument will be then adjusted and adapted as needed while processing data from a source of evidence. Two independent reviewers will extract data from the submitted data separately. Extracted data from the reviewers will then be analyzed and compared. To ensure data accuracy and integrity, any inconsistencies will be addressed. In order to assure data validity and coding, all extracted data will be compiled in a single Excel (Microsoft) document.

Textbox 2. Data charting form.

- Name of author, date of publication
- Study title
- Objective of the study or research question
- Population
  - Sample size
  - Characteristics of participants
- Geography of the study
- Study design
- Recruitment setting
- Sampling strategy
- Most relevant and significant findings
- Conclusions

RenderX

Collating, Summarizing, and Reporting Results

The objective or goal of the scoping review is to outline the existing evidence and give a comprehensive summary of occupational health risks and hazards among traffic police in South Asian countries. It will not only incorporate the prevalence of hazards but also ensure the usage of preventive strategies. It will also serve as a guide to identify the risk factors. According to Arksey and O'Malley methodology [35], the investigators will use thematic content analysis to extract data linked to the research objectives and code them using NVivo software (version 10) [36]. The full-text papers will subsequently be analyzed for documented evidence on occupational health concerns among traffic police. Through coding, all data on occupational health hazards among traffic police will be collected from the included publications. Lastly, an overall interpretation of how the various concepts relating to the research topic and thematic areas relate to one another will be undertaken.

Quality Appraisal

For the quality evaluation, evidence from various research will be evaluated. This will be performed to confirm that the research strategy is suitable for the study's objectives and to limit the likelihood of bias. The 2018 version of the mixed methods appraisal tool (MMAT supported by the Canadian Institutes of Health Research) will be applied to evaluate the standard of the study's chosen articles [36]. Using this instrument, researchers will be able to evaluate the objective, methodology, research design, recruitment of study participants, data collection, data analysis technique, description of study outcomes, and authors' debates and conclusions. It will also help to evaluate the quality of primary research. Due to the necessity of making judgments, this technique requires the participation of 2 independent reviewers. Reviewers will adhere to the scoring manual included in the MMAT 2018 version. The overall percentage score for quality will be calculated for each study evaluation, scores below 50% will be regarded as poor and scores between 51% and 75% will be considered average. A score between 76% and 100% will be considered as of good quality.

Ethical Considerations

This scoping review requires no ethical approval as it does not involve human subjects; yet, it might have some limitations. Limited studies are conducted regarding this topic in this region. Again, this review will only consider published and gray literature written in English.

Results

A preliminary search of the primary databases has been conducted. Electronic database searches will be completed by October 2022. Disseminating the findings from this scoping review in a scientific peer-reviewed journal has been envisaged. It is anticipated that the theoretical conceptualization on different aspects of occupational health of traffic police will emphasize future studies in this region, which will inform policy makers to revise their OHS policies and principles. Additionally, it will have implications on taking necessary preventive measures in the future to reduce occupational injuries and fatalities resulting from different types of occupational hazards.

Discussion

Principal Findings

The scoping review aims to systematically explore, analyze, and describe relevant findings on occupational exposures and their associated health hazards among traffic police in South Asia. However, a few relevant studies regarding OHS practices, policies, and guidelines for traffic policies were conducted in this region. Hence, this scoping review will explore the knowledge gaps, prevalence, possible risk factors, and control or preventive measures of occupational health hazards among traffic police in South Asia.

The scoping review will outline and perform a detailed discussion on occupational exposure focusing on the physical, psychological, and environmental aspects of health affecting traffic police in the South Asian region. The extracted data will be provided in a tabular format and a descriptive summary will explain how the results relate to the scoping review's goals and objectives. The scoping study is expected to shed light on the information and evidence that are currently available on occupational exposure and health hazards for South Asian traffic police, and the summary will also be evaluated, interpreted, and compared considering the existing literature. The review may have far-reaching implications for future projections of occupational exposures and for revising the current policy if needed. It may also reveal different research areas into multiple aspects of occupational exposure and occupational health hazards among traffic police in South Asia.

The findings of this scoping review will be impactful as it will explore in detail the health hazards associated with this profession, and an evidence-based review of the current status of occupational health safety policy and preventive measures as well as interventions will be explained.

The study will explain the need for occupational safety and health strategy for traffic police with the overall vision of providing a healthy, safe, and productive working environment, which should be implemented by all the relevant agencies such as government, industry, and general public. This study will inform policy as well as management principles and interventions. When a strategy on the OHS of traffic police is well developed and implemented, there will be effectiveness on how the traffic police keep themselves safe from occupational health hazards.

Strengths and Limitations to the Scoping Review

This scoping review will describe its findings in accordance with the Preferred Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews guidelines. Five electronic databases and gray literature, such as unpublished theses and dissertations will be used as a primary source of relevant studies. All articles will be screened by 2 independent researchers using a minimum set of inclusion and exclusion criteria. The study will evaluate the quality of included studies in accordance with an established MMAT. However, there is a

XSL•FO
RenderX

possibility to overlook some relevant studies as only English-language publications will be considered and reviewed.

Authors' Contributions

IJ, MASK, and AM conceptualized the study and prepared the draft proposal. IJ, AM, MAH, and SS contributed to the development of the background, the research questions, and study methods. IJ, MASK, MH, and MUR planned the output of the research and contributed meaningfully to the drafting and editing. SS, MUR, MMAH, and MHN aided in developing the research questions and critically reviewed the study methods. IJ, AM, MASK, MDHH, MHN, and MAH wrote the first draft of the manuscript. All authors read and approved the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Lifelong premature ejaculation (LPE) is a rare sexual condition believed to be caused by genetic neurobiological disorders. In the field of LPE, 2 main types of research have been conducted: direct genetic research and pharmacotherapeutic interference of neurotransmitter systems that can relieve the symptoms of LPE in male patients.

Objective: We aim to provide an overview of studies on neurotransmitter systems as the pathophysiological cause of LPE by investigating direct genetic research or pharmacotherapeutic interference that relieves the main symptom of LPE in male patients.

Methods: This scoping review will use the PRISMA-ScR tool (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews). In addition, this study will use a peer-reviewed search strategy. Systematic searches will be conducted using 5 scientific databases (Cochrane Database of Systematic Reviews, PubMed or MEDLINE, Cumulative Index to Nursing and Allied Health Literature [CINAHL], EMBASE, and Epistemonikos). Additionally, pragmatic searches for relevant information in gray literature databases will be performed. Two reviewers will independently include relevant studies in a 2-stage selection strategy. Finally, data will be extracted from the studies and charted to summarize relevant study characteristics and key findings.

Results: As of July 2022, we completed the preliminary searches according to the PRESS 2015 guidelines and started to determine the final search terms that we will use in all selected 5 scientific databases.

Conclusions: This scoping review protocol is the first to focus on neurotransmitter pathways in LPE by combining the results from the genetic and pharmacotherapy studies. The results could help identify potential research gaps or target candidate proteins and neurotransmitter pathways in LPE for further genetic research.

KEYWORDS

drug therapy; genetic research; lifelong premature ejaculation; scoping review

Introduction

Premature ejaculation (PE) is a common sexual problem among men, with a prevalence of 20%-40% when using a broad definition of the term [1-4]. To obtain valuable standardized and reproducible research on PE, a sharp demarcation of the research field and a clear definition of PE are needed. A distinction can be made between the different types of PE. As defined by a panel of experts at an International Society for Sexual Medicine (ISSM) meeting in 2013, the internationally

XSL•FO
RenderX

accepted definition of lifelong premature ejaculation (LPE) and acquired premature ejaculation is as follows [5,6]: (1) Ejaculation that always or nearly always occurs prior to or within about 1 minute of vaginal penetration (LPE) or a clinically significant and bothersome reduction in latency time, often to about 3 minutes or less (acquired premature ejaculation); (2) the inability to delay ejaculation on all or nearly all vaginal penetrations; (3) negative personal consequences, such as distress, bother, frustration, or the avoidance of sexual intimacy.

LPE is a subtype of PE with a prevalence of <4% in the general population [7]. The other suggested subtypes of PE include variable PE and subjective PE. Since these variants are not part of the genetic LPE, they fall outside the scope of this scoping review.

In 1943, Schapiro discovered a possible genetic component in the occurrence of LPE in men [8]. Waldinger further elaborated on this result and thus extended the field of genetic research since 1998 [9]. Thereafter, several studies have examined multiple genes and associated them with the occurrence of LPE [10-27]. Although a clear cause of LPE has not yet been revealed, Schapiro [8] reported that patients responded well to sedatives. Other successful treatments for LPE have been described since 1973 and have been further developed in the past 20 years [28-31]. Some drugs, such as dapoxetine, were specifically registered for the treatment of PE [32]. Additionally, neurobiological causes for LPE are supported by the findings that demonstrate that single-psychotherapeutic treatments or sex therapy is not effective for a significant remission of symptoms [5,33-36]. It has been pointed out that neurotransmitter pathways have multiple complex mechanisms, multiple families, and subtypes of receptors, all of which affect one another, making one polymorphism unlikely to be the sole cause of LPE [10,12,37,38]. It is therefore likely that a subset of polymorphisms in one or more neurotransmitter systems may lead to LPE.

In the field of LPE, 2 main types of research have been conducted. These include genetic research and pharmacological mechanisms that successfully prolong intravaginal ejaculation latency times (IELTs) through pharmacotherapeutic treatment. It is therefore possible to collect evidence on specific neurotransmitter systems. To study neurotransmitter pathways in relation to LPE in this manner, one or more targets can be identified to conduct a targeted strategy for conducting genome-wide association studies (GWAS) and ultimately resolve the cause of LPE.

A preliminary search for the existing scoping and systematic reviews on this topic was conducted on the January 12, 2022, in the following journals, databases, and search platforms: JBI Evidence Synthesis, Cochrane Database of Systematic Reviews, CINAHL (Cumulative Index to Nursing and Allied Health Literature), PubMed or MEDLINE, Embase, and Epistemonikos. Scoping reviews that combined pharmacological evidence with genetic causes were not available.

The objective of this scoping review is to provide an overview of studies on neurotransmitter systems as the pathophysiological cause of LPE by investigating direct genetic research or pharmacotherapeutic interference that relieves the main symptom of LPE in male patients.

Methods

Overview

This scoping review will be conducted from April 2022 in 6 stages using the methodology outlined in Levac et al [39], Peters et al [40], and the JBI Manual for Evidence Synthesis [41]. All sections will be reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses-extension for Scoping Reviews) guidelines [42]. Any amendments will be uploaded on the Open Science Framework public page of this study.

Identifying the Review Questions

What evidence is currently available that could explain the potentially affected neurotransmitter systems in the pathophysiology of LPE?

The following evidence can be referred: (1) genetic variation correlated with the occurrence of LPE in affected versus unaffected men or (2) successful neuro-targeted pharmacologic treatment of LPE.

Identifying Relevant Studies

Studies will be collected from the Cochrane Database of Systematic Reviews, PubMed or MEDLINE, CINAHL, Embase, and Epistemonikos databases. Additionally, references of studies will be checked for relevancy and, if eligible, added to this scoping review (snowballing). The reference list of reviews found through the electronic search will be checked to ensure that relevant articles are included in the scoping review. Finally, we will perform pragmatic searches in gray literature databases for relevant information. These include the Grey Literature Report, OpenGrey, Web of Science Conference Proceedings, and local, national, and international organization websites. For inclusion websites should comply with the eEurope 2002 quality criteria [43].

A publication timeline or language restriction will not be set. A systemic search term will be developed using keywords and MeSH terms with the Boolean operators “AND/OR.” Search terms will be applied to the titles and abstracts of the relevant studies. An example of the initial search terms is included in Multimedia Appendix 1. The generated search terms will be peer-reviewed according to the Peer Review of Electronic Search Strategies 2015 guidelines [44]. Google translate will be used as a supportive tool for screening and including non-English studies [45]. Eventually, all included studies will be imported into the Mendeley research software. Studies collected from different sources will be deduplicated in EndNote [46].

Study Selection

Study selection will occur in 2 stages. The first inclusion will be based on eligibility by screening the title and abstract. Articles that are classified as relevant will be included for full-text review and for final inclusion in the scoping review. The Rayyan software tool will be used for the blind systematic

XSL•FO
RenderX

inclusion and exclusion of studies [47]. Studies will be independently selected by 2 individual reviewers. Reviewers will meet when approximately 10%, 50%, and 90% of the studies have been screened to discuss dissent regarding study selection. A PRISMA-ScR flow diagram will be used to describe the study selection process. The diagram will be added to the publication of this scoping review.

All inclusion and exclusion criteria are displayed in Table 1.

Table 1. Search strategy using inclusion and exclusion criteria based on the patient population, intervention, comparison, outcomes, and study designs.

Parameter	Inclusion criteria	Exclusion criteria
Patient	Adult males with LPE[a] (aged ≥18 years)	Populations not matching with one of the following definitions: ISSM[b] 2007, ISSM 2013, DSM-5[c], or Definition 1[d]
Intervention	Genotyping or pharmacotherapy treatment	Pharmacotherapy studies using a topical anesthetic or locally active agents or with traditional or herbal medicine
Comparison	Males without LPE in genotype studies or drug naïve or washed-out patients with LPE in pharmacotherapy studies	N/A[e]
Outcome	Comparison of genotype or gene's or *x*-fold increase in sIELTs[f] by drug treatment	N/A
Study design	In pharmacotherapy studies: RCTs[g], cross-over drug studies, single-arm trials with a baseline sIELT, or case reports with a baseline sIELT	N/A

[a]LPE: lifelong premature ejaculation.

[b]ISSM: International Society for Sexual Medicine.

[c]DSM-5: Diagnostic and Statistical Manual of Mental Disorders.

[d]Definition 1: studies using a cut-off IELT of approximately 1.5 minutes after vaginal penetration, measured using the stopwatch method. Symptoms must be present from the first sexual encounter to all sexual partners.

[e]N/A: not applicable.

[f]sIELTs: stopwatch-measured intravaginal ejaculation latency time.

[g]RCT: randomized controlled trial.

Inclusion Criteria

Patient Population

Studies qualify for inclusion if the patient population meets the criteria for LPE, as stated in the ISSM 2007-2013 definition or in the 2013 Diagnostic and Statistical Manual of Mental Disorders (DSM-5) [5,7,48]. IELTs must be measured using the stopwatch method that is the standardized outcome method demanded in drug registration by the European Medicine Association [49]. As these criteria were defined in 2007, the studies performed before this time have a risk of diagnosing patients with LPE with vague terminology or less reliable parameters such as self-reported estimated ejaculatory latency times (eIELTs) using questionnaires [30,50,51]. However, by rejecting the studies executed before 2007, we may overlook useful data; we have therefore designed a secondary inclusion term for the studies performed before 2007. These terms approach the ISSM 2007 or DSM-5 definition as closely as possible. The prior and post-2007 definitions used in the DSM-III [52], DSM IV [53], DSM-IV-TR [54], ICD-9 [55], ICD-10 [56,57], and ICD-11 [58] or the definition used by the American Urological Association Guideline on the pharmacologic management of PE [59] have been found to be inferior to correctly diagnosed LPE [1,60].

Studies before 2007 are eligible if they use a cutoff of approximately 1.5 minutes after vaginal penetration, measured using the stopwatch method. Symptoms must be present from the first sexual encounter to all sexual partners. This additional definition is based on the proposals for definitions published by Waldinger et al in 2006 [1].

Pharmacotherapy Studies

We will include the pharmacotherapy studies that meet the following criteria: (1) randomized placebo-controlled trials; (2) cross-over designs; (3) single-arm trials with a baseline stopwatch measuring intravaginal ejaculation latency time (sIELT); and (4) case reports with a baseline sIELT.

Exclusion Criteria

The exclusion criteria here are pharmacotherapy studies using traditional or herbal medicines and local topical anesthetic agents, as these drugs do not interfere with the central neurotransmission systems.

Charting the Data

Data will be collected by the research team with research software that is yet to be specified. Data will be collected as an iterative process, in which reviewers extract and update data continuously. Data will be collected as shown in Figure 1. To test whether the framework matches the research question and aim of the study, 2 reviewers will independently use the data charting form using the data extracted from the first 5 articles.

If any data are unclear or incomplete, the corresponding authors will be contacted for additional details on the performed studies. If additional information will not be obtained, a comment on this issue will be placed in the charting table.

XSL•FO
RenderX

Figure 1. Example of data charting form. LPE: lifelong premature ejaculation; sIELTs: stopwatch-measured intravaginal ejaculation latency time; Tx: drug therapy; wk: week(s).

Agent/ polymorphism	Author/ year	Origin/ country of origin	Aim(s)	Study design	LPE definition	Primary outcome	Secondary outcome measure(s)	Number of subjects	Age	Duration (wk)	Pre-Tx sIELT	Post-Tx sIELT	ΔsIELT (fold)	Key finding(s) related to the scoping review questions	Notes

Collating, Summarizing, and Reporting the Results

The key findings of the included studies will be summarized. A distinction will be made between genotype research studies and pharmacotherapeutic drug studies, ordered by the targeted neurotransmission protein subtype. Quantitative data will include, for example, a factor-fold increase in sIELTs by pharmacotherapy or a correlation with specific gene types. This will provide an overview of evidence in the field and could help identify potential research gaps or target protein and neurotransmitter pathways for further genetic research.

Results

As of July 2022, we completed the preliminary searches according to the PRESS 2015 guidelines and started to determine the final search terms that we will use in all selected 5 scientific databases.

Discussion

This scoping review protocol is the first to focus on neurotransmitter pathways in LPE by combining the results from the genetic and pharmacotherapy studies. The results could help to identify potential research gaps or target candidate proteins and neurotransmitter pathways in LPE for further genetic research. This could ultimately lead to an improvement in therapy for patients with LPE.

In this scoping review a sharp demarcated definition of LPE will be used to prevent inclusion of non-LPE males by overdiagnosis. Furthermore, the method of this scoping review complies with the most recent guidelines using the PRISMA-ScR tool. In addition, this study will use a peer-reviewed search strategy without language restrictions; therefore, a robust and systematic foundation for thorough scientific research is laid. The final scoping review will be published in a peer-reviewed journal and information will be disseminated in scientific meetings.

This scoping review is limited to wide evidence collection; the quality of evidence of studies will only be partly evaluated since it is not a standard element of scoping review methods. In LPE research the quality of studies is widely discussed [51,61-63]. Confounded published studies are not excluded in advance because this scoping review focusses mainly on wide evidence collection as input for a targeted strategy in a GWAS. To assess potential confounders or outcome differences by ethnicity, patient characteristics and social information of studies will be charted and discussed.

To date several reviews on LPE have been conducted. However, this will be the first scoping review focusing on neurotransmitter pathways in LPE by combining the results from the genetic and pharmacotherapy studies. With this protocol a scoping review could be conducted systemically leading to further input for future candidate gene studies or GWAS and ultimately improve LPE care.

Acknowledgments

The authors thank Frits van Osch, a research assistant, who provided critical feedback and helped shape this research. This study was funded by the Prof Dr Marcel Waldinger Foundation, The Netherlands. The funding body had no influence or participation in shaping the research protocol.

Authors' Contributions

PKCJ is the guarantor. JJVR took the lead in writing and shaping the protocol. PKCJ provided feedback.

Conflicts of Interest

None declared.

Abstract

Background: People living with dementia and their care partners who identify as a sexual and gender minority (SGM) often experience specific health inequities and disparities due to discrimination related to age, cognitive impairment, and being SGM.

Objective: The purpose of this scoping review is to identify, explore, and synthesize the state of the science regarding the health and health care experiences of SGM people living with dementia and their care partners. This review also aims to identify gaps in research and set forth key recommendations to improve the health and health care experiences of SGM people living with dementia and their care partners by advancing health equity through research, policy, and practice.

Methods: The protocol follows the guidelines set forth by Joanna Briggs Institute protocol for scoping reviews. Steps of this framework that will be followed include (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) consultation. This scoping review will explore several electronic databases, including MEDLINE, Embase, CINAHL, AgeLine, PsychINFO, and Scopus. Health librarians will conduct the initial search for articles that are in English, include people living with dementia who identify as SGM, SGM people living with dementia and their care partners, or SGM care partners caring for people with dementia. Studies must be peer reviewed and focus on the phenomenon of interest, which is the health and health care experiences of participants. Covidence will be used to review abstracts and full-text articles and to screen articles. After the search has been completed, 2 independent reviewers will screen article titles and abstracts to identify eligibility. Discrepancies will be discussed and decided upon by the 2 reviewers. Relevant studies will be collected, and data will be extracted and charted to summarize key findings. Key findings will be presented to a community stakeholder group of SGM care partners and people living with dementia, and a listening session will be convened.

Results: This scoping review will identify the state of the science of health and health care experiences of people living with dementia and their care partners who identify as SGM. We will identify gaps and provide recommendations to inform future research, policy, and practice to improve health and health care experiences of SGM people living with dementia and their care partners.

Conclusions: Little is known about people living with dementia and their care partners who identify as SGM. This scoping review will be one of the first to identify the health and health care experiences of people living with dementia and their care partners who identify as SGM. The results of this review will be used to guide future interventions and to inform future policy and practice to improve health care and reduce health disparities in this population.

Introduction

Older adults are often at the intersection of multiple minoritized identities due to stigma surrounding aging and age-related conditions [1]. Older adults who identify as lesbian, gay, bisexual, transgender, queer, as well as other sexual or gender minority (SGM) identities are known to experience unique, compounding stressors and resultant disparities in health outcomes (eg, depression, anxiety, posttraumatic stress disorder, cognitive impairment, cardiovascular disease, hypertension, and diabetes) due to discrimination, stigma, and structural inequities [2-5]. Prior research supports older adults living with dementia and their care partners experience disparities in health outcomes due to individual (eg, grief, comorbid conditions, as well as limitations with physical and cognitive abilities) [6-8] and social stressors (eg, declining social networks and relationship strain) [9-11] that are distinct from the already complex, stigmatized process of aging [12]. People living with dementia and their care partners who identify as SGM represent a unique intersecting population at risk of experiencing health disparities and care inequities due to longstanding false beliefs and discrimination surrounding aging, cognitive impairment, and SGM status.

Many SGM older adults experience health care access barriers, including nonaffirming providers that can delay pursuit of general and specialist care [2]. Care partners of SGM older adults also experience barriers to providing optimal care due to discrimination, providers that may not acknowledge nontraditional partnerships, and health care systems and interventions that do not promote health equity or address social determinants of health [13,14]. Although such barriers are known to affect health outcomes among SGM older adults, little is known about the unique health and health care experiences of SGM people living with dementia and their care partners. This knowledge gap is especially concerning considering that the number of SGM people living with dementia and those providing care to them is anticipated to rise in the coming decades as the population ages [15].

Understanding the health and health care experiences of SGM people living with dementia and their care partners is critical to elucidating health disparities and inform targeted strategies to better support families living with dementia. To date, no prior review has synthesized the evidence surrounding people at the intersection of being SGM and living with dementia or caring for someone with dementia. Foundational knowledge and recommendations to inform policy initiatives that promote health equity for SGM people living with dementia are needed [16,17]. The purpose of this scoping review is to identify, explore, and synthesize the state of the science regarding the health and health care experiences of SGM people living with dementia and their care partners. This review also aims to identify gaps in research and set forth key recommendations to advance health equity by improving the health and health care experiences of SGM people living with dementia and their care partners through research, policy, and practice.

Methods

Procedure

A scoping review framework will be used broadly to explore the state of the science pertaining to SGM people living with dementia and their care partners, which represent a historically underexamined group of older adults [18]. The Joanna Briggs Institute protocol for scoping reviews [19], which is informed by the advancing methods of Levac, Colquhoun, and Peters will be used to guide the scoping review process [20,21]. Steps of this framework that will be followed include (1) identifying the research question; (2) identifying relevant studies; (3) study selection; 4) charting the data; (5) collating, summarizing, and reporting the results; and (6) consultation. Consultation is an optional step of the framework that will be addressed in this review. Adherence to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines will be used to promote rigor in this review [22].

Step 1: Identifying the Research Question

This review is guided by the following research questions:

- What is the extent and nature of research relating to the health and health care experiences of SGM people living with dementia and their care partners?
- What gaps exist in the evidence surrounding health and health care experiences of SGM people living with dementia and their care partners?
- What areas in research, policy, and practice warrant further exploration to advance health equity by improving the experiences of SGM people living with dementia and their care partners?

Step 2: Identifying Relevant Studies

Relevant studies will be identified through a comprehensive database search conducted by health librarians. Two reviewers will independently screen titles and abstracts and review full-text articles to identify relevant studies using predefined eligibility criteria.

Eligibility Criteria

Eligible studies will include participants living with dementia who identify as SGM, SGM people living with dementia *and* their care partners, or SGM care partners caring for people living with dementia. Dementia will be broadly defined as any self-report or medical diagnosis of dementia of any type or severity. Studies focused on mild cognitive impairment will not be included. Studies will focus on the phenomenon of interest, which is the health and health care experiences of participants. The studies must be in English; the 2 researchers conducting the review are English speakers. Studies will not be excluded based on research methods (eg, qualitative, quantitative, and

XSL•FO
RenderX

mixed), setting (eg, hospital, long-term care, and community), or publication date. Dissertations, conference proceedings, working papers, and non-English studies will be excluded.

Search Strategy

The following databases will be searched to identify relevant studies: MEDLINE (PubMed), Embase (Elsevier), CINAHL (EBSCOhost), AgeLine (EBSCOhost), PsychINFO (EBSCOhost), and Scopus (Elsevier). These databases were selected by the authors with guidance of a health librarian to ensure that a wide variety of publications from various fields are located. A combination of keywords and database-specific subject headings for the concepts of gender or sexuality and dementia will be used. No restrictions will be placed by date in the database search. A health librarian will assist in developing the keyword search and conduct the search strategy. A draft of what the search might look like for PubMed with relevant combinations of Medical Subject Headings and keywords is included in Table 1. Additionally, a health librarian will conduct a separate search of the grey literature to identify relevant policy papers, white papers, blog posts, and op-eds [23]. Electronic database searches will occur within the same week and extracted into Covidence (Veritas Health Innovation) software [24]. Covidence will be used to organize, review, and remove duplicate citations.

Table 1. Draft PubMed search strategy.

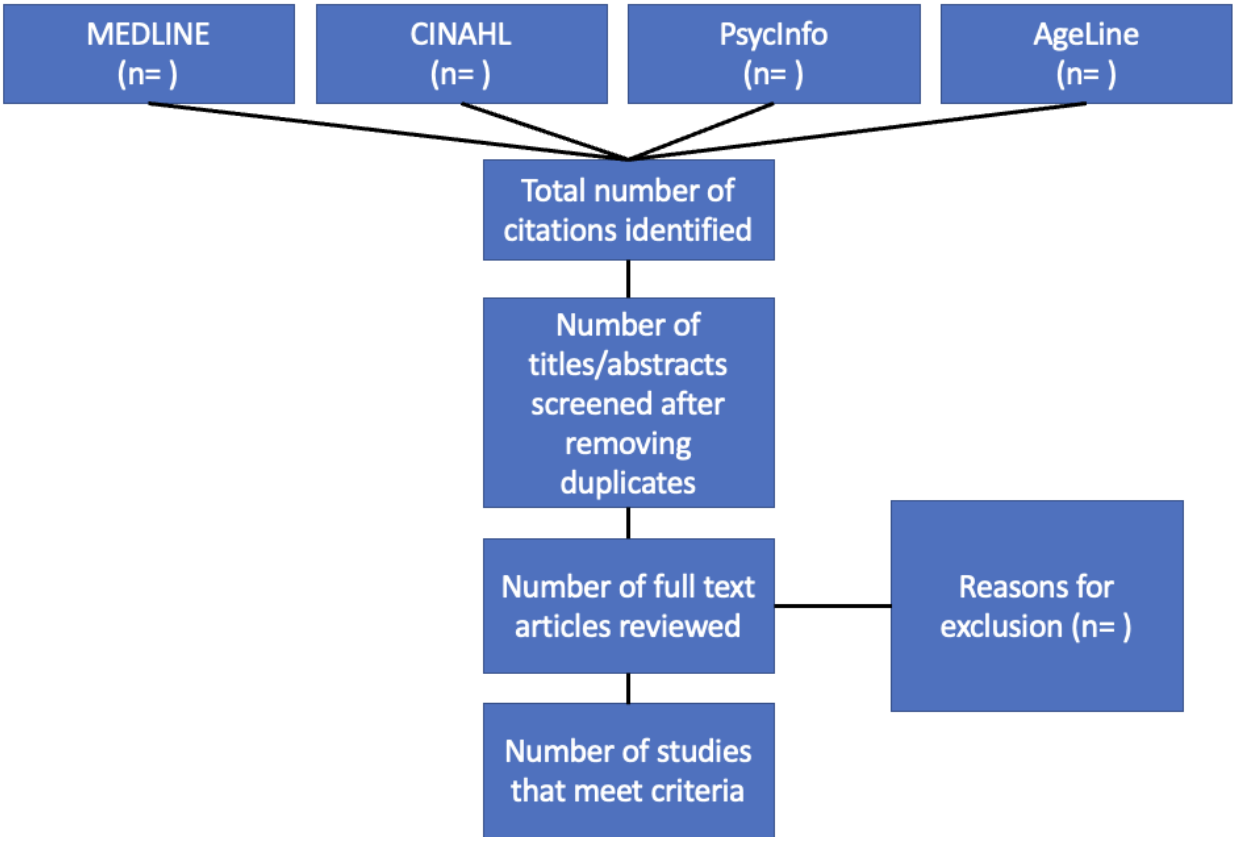
(3)	1 AND 2
(4)	3 NOT (Editorial[pt] OR Letter[pt] OR Comment[pt])

[a]MeSH: Medical Subject Headings.

Step 3: Study Selection



Titles and abstracts will be reviewed independently by 2 reviewers (JTM and MLH) according to the defined eligibility criteria. Weekly meetings will be held to resolve discrepancies and reach consensus on final titles and abstracts. Each author will then independently review all full-text articles to determine eligibility. Discrepancies will be resolved through discussion between the 2 reviewers.

Step 4: Charting the Data

Covidence will record the number of articles included, excluded, and the reasons for exclusion, which will be used to develop a PRISMA-ScR flowchart (Figure 1).

XSL•FO
RenderX

Figure 1. PRISMA flow diagram of the studies to be included in the scoping review.

Data Extraction

A data extraction tool will be used to collect publication details, and information pertaining to study characteristics, findings, and author conclusions of included studies. Textbox 1 shows information to be included in the data extraction tool. The tool will be modified as needed during the data extraction phase; these changes will be reported in the final scoping review.

XSL•FO
RenderX

Textbox 1. Information gathered using data extraction tool.

Publication details

- Author
- Year of publication
- Country of origin
- Publication type

Study characteristics

- Aims or purpose
- Study design
- Methods used
- Participants
- Sample size
- Setting
- Recruitment strategy

Key findings

- Qualitative findings
- Quantitative results
- Context to which the findings apply (health or health care experiences? Community vs health care system?)

Author conclusions

- Study limitations
- Implications
- Recommendations for research
- Recommendations for policy
- Recommendations for practice

Data Management

The 2 reviewers will independently extract data manually from each study and chart it in Microsoft Excel spreadsheets. Data extraction tables will be compared through regularly scheduled team meetings.

Step 5: Collating, Summarizing, and Reporting Results

Data Analysis Procedure

Following data extraction, we will use the data extraction tables to identify key information that will be collated in a comprehensive summary table. The summary table will include author and year, study aims or purpose, study design and methods, country, sample, key findings, limitations, implications, and recommendations. In the summary table, a brief description will be added regarding the sociopolitical climate surrounding SGM populations for each study's country of origin. This information will be gathered from the article itself and by analyzing survey data reports from reputable sources like Pew Research Center and The Williams Institute at University of California, Los Angeles School of Law. Content and structure of the summary table may change based on the results of the data extraction process.

Data Analysis

To further synthesize results of the included studies, each reviewer will independently analyze each study and the tabulated summary data to identify common concepts and themes across studies. Concepts and themes will be discussed through regular team meetings, and discrepancies will be resolved through discussion. Reviewers will finalize and define each concept and theme together. A table of themes, concepts, definitions, and exemplars (eg, qualitative findings, quantitative results, and key statements) from the included studies to support each theme will be developed (Table 2 is an example of a themes table).

XSL•FO
RenderX

Table 2. Example of a table depicting themes, concepts, definitions, and exemplars identified through thematic analysis.

Major theme name 1 (theme definition, as defined by thematic analysts MLH and JTM)			
Concepts	Concept definition	Support or exemplars	Paper
• Concepts identified through thematic analysis	• Defined by thematic analysts (MLH and JTM)	• Raw quantitative data or results • Qualitative quotes and themes or subthemes • Key statements from author conclusions	• Author and year

Step 6: Consultation

The final step in the Joanna Briggs Institute protocol for scoping reviews is consultation. With support and guidance from the authors' institutional Community-Engaged Research Initiative, a stakeholder group of SGM care partners and people living with dementia will be developed, and a listening session will be convened. Stakeholders will be recruited from, for example, SGM-friendly church organizations, SGM and dementia care support groups, and SGM or dementia community organizations. Stakeholder participants will be compensated for their time with a gift card. The listening session will include a presentation of the scoping review themes, followed by open discussion for stakeholders to provide feedback on the findings. Stakeholders will be asked to discuss whether the themes resonate with their personal experiences, and they will be asked to identify topics that were left out of the scoping review themes. They will then be asked to propose key recommendations for future research, policy, and practice initiatives based on their own lived experiences and the scoping review themes. Stakeholder feedback provides those who are affected by these experiences with relevant research and findings [25].

Detailed notes will be kept by 2 trained notetakers during the listening session. MLH and JTM will compare and contrast the topics discussed or the notes taken during the listening session with the original themes identified through thematic analysis. A series of meetings will be held to refine and synthesize themes, gaps, and recommendations based on the combined results of the thematic analysis and listening session. The themes table (Table 2) will be updated based on results of the synthesis meetings. Findings generated through this consultation process are anticipated to inform future research, policy, and practice initiatives focused on SGM people living with dementia and their care partners.

Results

Results of this review will include a PRISMA-ScR flow diagram to illustrate results of the database search and the final included studies. Key study information for all included studies will be presented in narrative and tabular format. Integrated findings from the thematic analysis and listening session will be presented through a narrative synthesis with detailed description of the final themes, gaps, and recommendations. Finalized themes, definitions, and exemplars from the thematic analysis and listening session will also be depicted in a table. We will present a discussion regarding the significance of the findings of this scoping review as well as concrete recommendations to inform future research, policy, and practice to improve health and health care experiences of SGM people living with dementia and their care partners.

Discussion

Overview and Expected Outcomes

Older adults living with dementia and their care partners who identify as SGM are at the intersection of several identities associated with disparities in health outcomes and health care provision [2-4,26]. Understanding the health and health care experiences of individuals and families living at the intersection of such identities is critical to inform practice and policy initiatives to address health disparities and advance health equity. No prior reviews have focused on synthesizing the evidence relating to the health and health care experiences of SGM people living with dementia and their care partners. This review will characterize the extent and nature of the research surrounding SGM people living with dementia and their care partners and identify meaningful gaps that warrant future examination. Findings of this review are anticipated to act as a stepping stone to inform a future program of action-oriented research aimed to address health inequities experienced by SGM people living with dementia and their care partners.

The innovation of this review is the use of community-engaged methods to address the consultation step of the scoping review framework, which is currently considered an optional component [27]. Engaging members of a target population early in the research process is pivotal to uncovering the experiences and needs of groups that have historically been socially and economically marginalized. Given the focus of this review on members at the intersection of multiple stigmatized identities, convening a listening session with stakeholders who identify as SGM and are living with or caring for someone with dementia will be critical to not only identify disparities but also elucidate potential paths to advance health equity. Integrated findings from the scoping review and the community-engaged listening session are likely to yield concrete recommendations and areas to explore to address health inequities experienced by this population. Other strengths of this review include collaboration with health librarians in building and conducting the database search, searching multiple databases across several disciplines (medicine, nursing, and gerontology), and including 2 independent reviewers in the screening process.

Potential limitations of this review include the lack of critical appraisal of included studies, which would provide deeper insight into the overall quality of research. Additionally, this review will not contribute essential data to advance equity; it will instead focus on synthesizing the extent and nature as well as gaps in this area of research. Finally, although a comprehensive database search will be conducted, it is still possible that studies will be missed, as the grey literature and non-English studies will be excluded. These limitations

XSL•FO
RenderX

notwithstanding, findings of this review will be the first to summarize the research focused on SGM people living with dementia and their care partners, and they are likely to yield concrete areas to explore through future efforts in research, policy, and practice.

Future Directions

Findings from this review will be used to inform a future program of research focused on advancing equity for SGM families living with dementia. Based on what is learned in relation to the state of the science, further exploration through qualitative inquiry to understand disparities may be warranted, while recommendations from key stakeholders will be used to directly inform action-oriented pilot studies aimed at addressing gaps in health and health care of this population. Community-engaged methods used in this review will provide a foundation to inform the design of future studies as well as policy initiatives focused on advancing health equity for aging adults.

Conclusions

In this scoping review, we aim to understand the health and health care experiences of SGM people living with dementia and their care partners. This study may provide a deeper understanding of the health disparities and challenges navigating the health care system for this population. We hope to gain insight for future studies and the development of interventions that advance health equity for SGM people living with dementia and their care partners.

Abstract

Background: Older adults have a higher visit rate and poorer health outcomes in the emergency department (ED) compared to their younger counterparts. Older adults are more likely to require additional resources and hospital admission. The nonspecific, atypical, and complex nature of disease presentation in older adults challenges current ED triage systems. Acute illness in older adults is often missed or commonly disguised in the ED as a social or functional issue. If diagnostic clarity is lacking or safe discharge from the ED is not feasible, then older adults may be labelled a "social admission" (or another synonymous term), often leading to negative health consequences.

Objective: This scoping review aims to describe and synthesize the available evidence on patient characteristics, adverse events, and health outcomes for older adults labelled as "social admission" (and other synonymously used terms), as well as those with nonacute or nonspecific complaints in the ED or hospital setting.

Methods: A literature search of MEDLINE, Embase, Scopus, PsycINFO, and CINAHL was completed. Relevant reference lists were screened. Data have been managed using EndNote software and the Covidence web application. Original data have been included if patients are aged ≥65 years and are considered a "social admission" (or other synonymously used term) or if they present to the ED with a nonacute or nonspecific complaint. Two review team members have reviewed titles and abstracts and will review full-text articles. Disagreements are resolved by consensus or in discussion with a third reviewer. This review does not require research ethics approval.

Results: As of January 2023, we have completed the title and abstract screening and have started the full-text screening. Some remaining full-text articles are being retrieved and/or translated. We are extracting data from included studies. Data will be presented in a narrative and descriptive manner, summarizing key concepts, patient characteristics, and health outcomes of patients labelled as a "social admission" (and other synonymously used terms) and of those with nonacute and nonspecific complaints. We expect the first results for publication in Spring 2023.

Conclusions: Acute illness in the older adult is not always easily identified. We hope to better understand patient characteristics, adverse events, and health outcomes of older adults labelled as a "social admission," as well as those with nonacute or nonspecific complaints. We aim to identify priorities for future research and identify knowledge gaps that may inform health care providers caring for these vulnerable patients.

Introduction

Background

In recent years, visits to the emergency department (ED) by older adults (generally those aged ≥65 years) have significantly increased [1-3]. Between 2021 and 2050, the global population of older adults is expected to double [4], likely exacerbating the already existing problem of ED overcrowding [5]. The ED often serves as a "point of entry" for older adults, particularly for those without access—or perceived lack of access—to primary care [6,7]. Compared to younger counterparts, older adults in the ED have a higher visit rate and a longer length of stay and are more likely to be admitted to the hospital [3,8,9]. Older adults who visit the ED have a high mortality rate and increased likelihood of dependence for instrumental and basic activities of daily living [1,2].

The nonspecific and atypical nature of disease presentation in older adults presents a challenge in the ED. For example, issues may be missed at triage (ie, undertriaged), as many triage tools do not identify atypical, nonspecific, or multisystem complaints commonly seen in older adults [10-12]. Furthermore, older adults may present with no apparent acute medical reason for their visit, or at least none that can be quickly identified [13,14]. However, it is known that older adults who present with nonspecific complaints, such as "fatigue," "weakness," or "feeling unwell," are at risk for serious conditions (ie, acute coronary syndrome, metabolic or endocrine disturbances, transient ischemic attack, urinary tract infection, dehydration, etc) [15,16]. Older adults may also present with a combination of acute, chronic, social, or functional issues [17-20]. If diagnostic clarity is lacking or if patients are unable to be safely discharged—but they also do not seemingly require a hospital bed—they are often labelled as a "social admission" [17,19]. Other synonymous labels include "failure to cope/thrive" [13,21]; "community emergencies" [22]; or other colloquial terms based on local hospital policy, culture, or media [19,21]. There is no single common term used to describe this older adult population. However, it is known that these patients are at high risk for inappropriate disposition and adverse outcomes [23].

Older adults typically present with geriatric syndromes, including delirium, falls, poorly managed pain, malnutrition, depression, functional decline, sensory impairment, and incontinence [17,19]. If older adults present with poorly controlled or multiple geriatric syndromes, then a "social admission" may occur if no specific diagnosis can be identified [21]. Not infrequently, these patients cannot return to their prior place of residence without additional support, which may require extensive discharge liaison and planning. Examples of these discharge predicaments include the need for additional home supports (including nursing and/or social supports), home equipment or structural remodeling to accommodate physical decline, or placement in a care facility, among others.

Many of these older patients present to the ED in the later stages of their complex health issues and may not return home [21]. There are a few potential contributing factors that may lead to a "social admission," which include patient (eg, multimorbidity, polypharmacy, frailty, medication adverse events, or progression of or poorly managed health conditions), family/informal caregiver (eg, caregiver burnout, lack of a "back-up" plan, or time and financial constraints for caregiver), peer group (ie, social isolation), institutional (eg, single-system complaints or barriers to formal caregivers), or societal and policy (eg, government policy, accessibility, or age-friendly activities) factors [17,24-29]. If admitted, many health care providers may continue to view these patients as "bed blockers" or "inappropriate admissions" [19,28]. In addition, community-based health care professionals lack the resources, collaborative networks, and organizational infrastructure necessary to provide medical, social, and functional support outside of the hospital setting [30-32]. Thus, these patients continue to use the ED [33,34] and are at risk for further decline (eg, pressure ulcers, sleep deprivation, or delirium) once there [2,35-37]. Several studies also report high mortality rates among older adults with "acopia" (22%) [13], "failure to thrive" (32.5%) [38], and nonspecific chief complaints (20.2%) [39] that present to the ED.

Ideally, alternative pathways to care should exist outside the hospital setting, but our health care systems have not adapted to the demographic changes and increased health care needs of older adults [40]. Thus, many EDs remain ill-equipped to provide adequate care for these patients [40,41]. Historically, medical education systems train physicians and health care systems are designed with a focus on single-system complaints. However, this approach does not effectively meet the needs of older adults with nonacute, nonspecific, or multifactorial complaints [19,21]. The issue is perpetuated when ED health care professionals lack the expertise or comfort in managing these complex patients, while ED trainees often prefer to focus their efforts on more acute presentations [19]. ED-trained health care professionals are not equipped to manage these patient presentations from a time, training, or resource perspective [19,21].

While many EDs have implemented programs or interventions for older adults, they do not specifically target the older adults that present as a "social admission," "failure to cope/thrive," or "community emergency" [22,42]. There is a paucity of data around the patient characteristics, adverse events, and health outcomes of these patients that present to the ED. In this scoping review, we hope to describe what is currently known about these patients and identify knowledge gaps that may direct future research or interventions to potentially improve health outcomes.

Review Aim and Objectives

The aim of this scoping review is to describe older adults (aged ≥65 years) who present to the ED and are labelled as a "social admission" (or other synonymous terms) or present with

XSL•FO
RenderX

nonspecific complaints or without an apparent acute medical reason for their visit. The review objective is to summarize patient characteristics, adverse events, exposures, interventions, and disposition from the ED/hospital from the included study population.

Methods

Overview

The protocol was developed based on the proposed framework from the Joanna Briggs Institute for scoping reviews [43], which builds on the framework previously described by Arksey and O'Malley [44]. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist has guided the reporting of this protocol and will guide the future reporting of the review itself [45] (see Multimedia Appendix 1).

A scoping review was felt to be the most appropriate to (1) map key concepts and evidence available, (2) summarize current evidence, and (3) identify knowledge gaps in the literature. We also recognize the need for a scoping review to be iterative and that the protocol may deviate to obtain the best results. If a study author identifies the need for a protocol update, other authors will be notified and involved in the process. A consensus will be reached between authors. Protocol deviations will be reported to *JMIR Research Protocols*.

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria are described in Table 1. The criteria are not exhaustive and may be modified throughout the search process, as necessary. If a study author identifies a search term, type of participant, variable, or outcome that they deem potentially relevant, other authors will be notified. A consensus will be reached between authors on whether to update the inclusion and exclusion criteria.

Table 1. Inclusion and exclusion criteria.

Criteria	Description

Types of participants	• Inclusion criteria
	  • All patients who present to the emergency department (ED) without an apparent acute medical reason for their visit or a combination of acute, chronic, functional, or social issues (ie, nonacute or nonspecific complaints)
	  • Labelled as a "social admission" or other synonymous term (ie, failure to thrive/cope, community emergency, etc) or with clinically relevant presentation
	  • Male or female
	  • Aged ≥65 years
	• Exclusion criteria
	  • Aged <65 years
	  • Not labelled as a "social admission" or other synonymous term or with nonacute or nonspecific complaints

Variables and outcomes	• We will collect data, as available, to include: • All types of patient characteristics[a] • All exposures in the ED/hopsital[a] • All adverse events in the ED/hospital[a] • All interventions in the ED/hospital[a] • Disposition from the ED/hospital[a] • All other measured outcomes reported in included studies[b]
Setting	• ED • Hospital
Types of evidence sources	• Original journal articles (no systematic reviews or meta-analyses) • Observational studies (cohort, case control, or cross-sectional), descriptive studies, case series, case reports, opinion pieces, and letters to the editor[c]

[a]See Textbox 1 for details.

[b]When an outcome is identified by an author as being potentially relevant, that author will notify the other authors. All authors involved in the title and abstract review, full-text review, and data extraction processes will be informed, and a decision will be made via consensus.

[c]Any opinion piece or letter to the editor that contains original research data will be included.

XSL•FO
RenderX

Textbox 1. Variables for data extraction.

- Publication details (ie, author, journal, year of publication, country, and grey or peer-reviewed)
- Methodological data (ie, study type, sample size, etc)
- Patient characteristics (ie, age, past medical history, presenting complaint, triage score, arrival mode, place of residence, recent admissions, recent emergency department visits, etc)
- Adverse events (ie, falls, delirium, pain, infection, etc)
- Exposures (ie, infectious diseases, antipsychotic medication use, etc)
- Interventions (ie, antibiotics, intravenous fluids, new medications, etc)
- Other measured health outcomes
- Disposition (ie, home, home with supports, nursing homes, long-term care, etc)

Search Strategy

A research librarian, in collaboration with the review team, developed search strategies to identify potentially relevant articles for screening. The following databases will be searched: (1) MEDLINE, (2) Embase, (3) Scopus, (4) PsycINFO, and (5) CINAHL. The search strategies are presented in Multimedia Appendices 2-6. Search dates are from 1946 to November 8, 2022. Some of the search terms included are “social admission,” “social patient,” “acopia,” “bed blocker,” geriatric emergenc*,” and “community emergency,” among others (see Multimedia Appendix 1). The search strategies were piloted by ensuring that they captured a few key articles that are likely to be included in the final review. Records will be exported to EndNote software (Clarivate Analytics) [46] for deduplication and citation management and then into Covidence [47] for article screening. A final search will be repeated prior to the draft of the manuscript. Searches of the databases will be supplemented by manual searches through the references lists of original journal article publications, as well as citation searching when appropriate. If a relevant review or meta-analysis is identified, we will manually search the associated reference list.

Study Selection Process

Two reviewers will independently screen titles and abstracts identified by all electronic databases against the predetermined inclusion and exclusion criteria (see Table 1) and document their findings in Covidence [47]. To ensure interrater reliability, 10% of the titles and abstracts were piloted before starting the formal screening process. A flow chart will be used to report the study selection process according to the PRISMA-ScR statement. Any disagreement of the titles and abstracts identified between reviewers will be resolved via consensus between reviewers or via arbitration by a third reviewer if consensus is not achievable.

Next, articles that are deemed relevant will be reviewed in full and screened according to the inclusion and exclusion criteria. Any disagreement of the full-text review between reviewers will be resolved via consensus between reviewers or via arbitration by a third reviewer if consensus is not achievable. When a duplicate study is identified, the data will be extracted from the most informative study sample, but all published articles will be included in the reference list. When important data are missing, the authors of all eligible studies will be contacted.

Data Charting, Analysis, and Synthesis

Reviewers will use standardized pro forma data extraction Microsoft Excel sheets to independently extract relevant data from included studies. To ensure interrater reliability, we will pilot 10 studies prior to formally starting the data collection process using the data extraction sheets. Variables and data to be extracted are listed in Textbox 1. Other key information related to the review objectives may also be collected. Further data points may be added if unforeseen, useful data can be extracted. We will provide a narrative synthesis of study data. Text and tables will be used to provide a descriptive summary of included studies and study characteristics.

Risk of Bias (Quality Assessment)

As this is a scoping review of the available evidence, no quality assessment will be performed.

Results

Our search strategies were applied to the 5 databases as described above (see *Search Strategy*). Prior to starting data collection, 2 authors (KRF and KOD) piloted 100 studies to review their titles and abstracts. Disagreement was identified for 8 (8%) studies. All disagreements were resolved via consensus between the 2 reviewers (KRF and KOD). A third reviewer was not required.

In total, 1860 titles and abstracts were identified for screening after the removal of 115 duplicate articles. Thus far, 30 full-text articles were identified for inclusion. As of January 2023, we have completed the title and abstract screening. The full-text review is ongoing as we await the retrieval of some texts and translation of others. A manual reference search has been completed. We are currently extracting data from identified studies for inclusion. We will present data in a narrative and descriptive manner. We expect the first results for publication in Spring 2023.

Discussion

Expected Findings

The results of this scoping review aim to inform ED physicians and other ED health care practitioners about this population.

XSL•FO
RenderX

We hope that appropriate stakeholders and policy makers can adapt their approach to the population labelled as a "social admission" and with nonacute, nonspecific complaints. We aim to describe the characteristics of this population, how they present, and any exposures or adverse events experienced during their ED stay or "social admission." It is expected that this population may demonstrate frailty, comorbidity, and polypharmacy. We expect the reasons for presentation to include nonspecific complaints, such as "weakness" or "generally unwell," but to also include functional or social reasons that are difficult for ED physicians to navigate. We expect acute medical illnesses to be missed and for disposition and discharge planning to be difficult. We also expect adverse events, revisit, admission, and mortality rates to be high, if documented.

To date, several original journal articles have been published in this area. However, the terms used to describe this population varies greatly between institutions and over decades. To our knowledge, this is the first review to be conducted on this topic with the intention of including all synonymous and colloquial terms in the literature equivalent to "social admission" and nonacute and nonspecific complaints in the ED. Strengths of our study include our broad-scope search strategies and the inclusion of a wide range of study designs. We chose to conduct a scoping review and not a systematic review as we wanted to focus on the state of research that exists for this emerging topic, not necessarily its quality. Limitations may include the inability to make evidence-based recommendations for clinical guidelines and a lack of risk of bias assessment for included full-text studies.

Dissemination Plans

We hope that this scoping review identifies priority areas for future research. Dissemination will help practitioners and the public understand this patient population. A multidisciplinary approach will help guide the dissemination of results at local hospitals and clinical sites. We plan to publish our results in a peer-reviewed academic journal and present at national and international conferences.

Acknowledgments

This research study is partially funded from the Carbonear Institute for Rural Reach and Innovation by the Sea (CIRRIS).

Data Availability

The data sets generated during and/or analyzed during the current study will be available from the corresponding author on reasonable request.

Authors' Contributions

All authors contributed to the protocol writing and revisions. AF formulated and modified the search strategies. KRF and KOD screened titles and abstracts and reviewed full-text articles. KRF and KOD will perform manual reference searching and extract relevant data.

Conflicts of Interest

None to declare.

Abstract

Background: Leading nurse education and research in the higher education (HE) sector has become increasingly challenging over the last decade with many universities in Australia and New Zealand having undergone academic restructuring. The future of HE faces many challenges including recruitment of suitably qualified staff to lead teaching and research and advance professional disciplines. Increasing cultural diversity of the Nursing workforce and the communities' nurses serve, and the identification of cultural attributes in the context of racial inequities exposed by the pandemic and the climate emergency suggest different forms of leadership may be required in the future by those leading nurse education in the HE sector. Currently, there is a dearth of research evidence that identifies the qualities, behaviors, and characteristics (collectively identified as core attributes) required by nurse academic leaders.

Objective: This research aims to identify an evidenced based set of core attributes that are required to lead the discipline of Nursing in the Australian and New Zealand HE sectors.

Methods: This research is using a 2-phase sequential mixed methods design incorporating a scoping review; and Delphi technique. In phase 1, a scoping review will be undertaken to identify the qualities, behaviors, and characteristics that can influence the evolution of the next generation of academic nurse leaders. A set of draft statements and questions will be prepared based on analysis of findings from the review. Phase 2 uses Delphi technique consisting of e-survey rounds with experts in leading nursing faculties in Australia and New Zealand. An Expert Advisory Group will consider the initial set of draft statements and questions from phase 1. Consistent with Delphi technique, a series of "rounds" will then occur using an e-survey method. Established leaders (Professors and Associate Professors who are members of the Council of Deans Australia and New Zealand) will rate their level of agreement to statements on the qualities, behaviors, and characteristics required to lead the discipline of nursing in the HE sector in Australia and New Zealand.

Results: The findings of the scoping review will identify what is currently known about the qualities, behaviors, and characteristics of academic nurse leaders. Quantitative and qualitative results from the Delphi study will initially be reported in separate manuscripts for publication. It is projected that a final paper will be prepared from aggregated research data and outline how the findings can inform the preparation of future academic nurse leaders.

Conclusions: The generation of an evidenced-based set of core attributes will serve to inform the next generation of academic nurse leaders including informing recruitment processes and postgraduate nurse leadership programs. It is anticipated that the data sets and findings will be transferrable to other disciplines within HE to aid in future-proofing discipline-based expertise and leadership in the context of academic restructure.

Introduction

Background

Nurse leaders exist across the professional spectrum including clinical practice, education, management, policy, and research. Nursing is now a well-established discipline in higher education (HE) in Australia and New Zealand, creating knowledge through research inquiry and producing graduates for employment in health through accredited program pathways. However, there are now significant challenges in HE to growing the next generation of academic nurse disciplinary leads [1]. A key focus of the nursing profession remains the commitment to teaching, supervision of students, and assessment to develop the nursing workforce across the professional spectrum [2]. Where once academic appointments in HE were seen as an attractive option for RNs seeking to move away from clinical practice to a well-remunerated workplace setting with autonomy and flexible working arrangements, this is no longer the case. As an applied profession, there is the expectation that registered nurses **(**RNs) working in HE have significant years of clinical experience to effectively mentor students and provide the next generation of nurses with foundation knowledge on which they can safely commence their careers in industry [3]. Despite these high expectations, there is a disparity between health industry salaries that sit significantly higher than a commensurate salary of a Lecturer (or level A and B academic). In contrast, a career in HE requires a postgraduate qualification and for advancement, doctoral preparation is often an essential criterion. As an applied discipline, nurses employed in the HE sector to teach nursing theory and practice in Australia are required to be an RN and hold a qualification higher than the program level that they are teaching into or have equivalent professional experience [4]. These requirements are embedded in Standard 3.14 of the current Registered Nurse Accreditation Standards 2019 through the Australian Nursing and Midwifery Accreditation Council on behalf of the Nursing and Midwifery Board of Australia. In New Zealand, individuals employed as a nurse academic must be an RN and hold a relevant master's degree (or have a professional development plan in place to obtain a master's degree within 4 years of initial appointment), have completed a program in adult teaching and learning within 2 years of appointment, and be involved in research and scholarship activities. These requirements are embedded in Standard 3.10 of the current RN Education Programme Standards (2021) [5]. Commitment to gaining the requisite qualifications for a career in HE can present as a financial burden and requires a considerable time commitment. For these reasons, RNs with the potential to be excellent academic nurse leaders may not find a move to HE as an attractive alternative to staying in clinical practice.

COVID-19–induced cost-saving measures in HE have compounded the need for fiscal restraint measures and have placed additional pressures on university staffing budgets [6]. While now in a recovery phase staff recruitment is a growing concern across the sector raising questions as to how the next generation of nurse academics and leaders in HE will be supported into a sustainable career pathway.

The HE sector in Australia and New Zealand is at a crossroad. As a key contributor to the Australian and New Zealand economies, the HE sector holds a significant role in ensuring workforce supply needs are met and graduates meet diverse employability requirements. The past 15 years have seen a change in the global economy resulting in streamlining of service delivery to reduce operational costs and a stronger dependence of local society on the income brought about through education. This altering climate has been at the forefront of structural changes across Australian and New Zealand HE. The key considerations of HE in the 21st century include internationalization, student learning outcomes, diversification, racial inequities and gender equity, societal need, and strategic planning [7-11]. There are also challenges for leaders going forward in the context of racial inequities shown during the pandemic and climate emergency. Leaders into the future may need to demonstrate different forms of leadership and have additional skill sets that recognize these significant challenges.

For many RNs working within the HE sector, career advancement is another challenge. Structural challenges and changes have become increasingly common, with some nursing schools losing standalone "disciplinary" status as they become part of larger multidisciplinary cognate units led by nonnurses. With such significant structural changes there has been an increase in the number of fixed-term (nontenured) teaching specialist positions; an increased reliance on a casualized workforce; and in many instances fewer senior nurse academic leadership roles, or these roles have cross-disciplinary implications.

Aim

This research aims to identify the qualities, behaviors, and characteristics that exist within academic nurse leaders (senior, established leaders) to provide the evidence in which to develop a set of core attributes to support the development of emerging leaders. Core attributes comprise the key qualities, behaviors, and characteristics that exemplify the essence and culture academic staff should emulate [12].

Objectives

This research will identify the qualities, behaviors, and characteristics (core attributes) that are exhibited by exceptional nurse leaders who are associate professors or professors (levels D and E) in Australian and New Zealand HE schools and faculties of nursing. These concepts will be explored as the foundation to developing a successful career pathway for emerging academic nurse leaders. This research is using a 2-phase sequential mixed methods design incorporating a scoping review and the Delphi method. In phase 1, a scoping review will be undertaken to identify the qualities, behaviors, and characteristics that can influence the evolution of the next generation of academic nurse leaders. Phase 2 uses the Delphi technique consisting of e-survey rounds with experts in leading

XSL•FO
RenderX

nursing faculties in Australia and New Zealand. An Expert Advisory Group consisting of past or current Deans or Heads of nursing faculties will consider the initial set of draft statements and questions arising from the analysis of the scoping review findings. Consistent with the Delphi technique, a series of "rounds" will then occur using the e-survey method. Established leaders (professors and associate professors who are members of the Council of Deans of Nursing and Midwifery [Australia & New Zealand]) will rate their level of agreement via a Likert scale to statements on the qualities, behaviors, and characteristics required to lead the discipline of nursing in the HE sector in Australia and New Zealand. The questions for each round will be based on the findings of the previous round until consensus (set at 90% agreement) has been achieved. Participants will also have the opportunity in the e-survey to provide qualitative comments.

Primary Research Question

What are the core attributes (qualities, behaviors, and characteristics) required to succeed in the role of academic nurse disciplinary lead?

Methods

Study Design

Overview

Mackenzie and Knipe [13] argued the existence of a "pragmatic paradigm" that is not committed to a particular view of the world. Pragmatist researchers focus on the "what" and "how" of the research problem [14]. Pragmatism is seen as the paradigm that provides the underlying philosophical framework for mixed methods research [15,16]. The pragmatic paradigm places the research problem as central and applies all approaches (methods) to understanding the problem [14]. With the research question "central," data collection and analysis methods are chosen as those most likely to provide insights into the question with no philosophical loyalty to any alternative paradigm [13]. To achieve the research objectives, the research design must capture the qualities, behaviors, and characteristics that are required to succeed in the role of academic nurse leader (qualitative data) and must also capture the degree to which established senior academic nurse leaders and the Expert Advisory Group believe these are agreeable (quantitative data). This is to ensure that the data captured meet the expectations of those who make employment-related decisions (ie, senior leaders) and resonate with the emerging leaders who are looking to pursue a career pathway in nurse academe. A sequential mixed methods approach with 2 clearly defined methods has been chosen as the research will be an iterative process, specifically with the scoping review findings informing the Delphi method [17]. This approach requires flexibility and adaptability while maintaining the research question as central to the design.

Phase 1: Scoping Review

A scoping review of the literature will be undertaken to identify qualities, behaviors, and characteristics that are considered desirable in academic nurse leaders. A scoping review method has been chosen as it enables the mapping of a wide-ranging set of relevant literature and key concepts underpinning the research topic [18]. While an initial review of published research showed a gap in this area, there were surmountable findings to support a search of the literature that specifically targeted the qualities, behaviors, and characteristics that support career success. This approach allowed for consideration of published and gray literature and the identification of a range of potential qualities, behaviors, and characteristics and the development of an early set of core attributes that will be presented to an Expert Advisory Group (phase 2, round 1). The scoping review aligns to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews (PRISMA-ScR) published in 2015 by Peters et al [19]. Specific questions pursued during the scoping review included: What are the qualities, behaviors, and characteristics required for a nurse disciplinary lead? What are the qualifications required to work as a nurse disciplinary lead? What are the intrinsic and extrinsic factors that may affect an individual's ability to succeed as an academic nurse leader? Does mentorship have a positive impact on academic nurse leadership skill development? What type of framework could assist supporting nurses into the role of academic nurse leader? Searches for MEDLINE, Embase, Emcare, ProQuest Dissertations and Theses Global, and Open Access Theses and Dissertations were undertaken. An extraction table was created to identify and analyze how each article addressed one or more of the research questions and a content analysis was conducted [20]. The findings of this review will be written up as a qualitative data set informing an early list of qualities, behaviors, and characteristics that will be built on and refined through phase 2.

Phase 2: Delphi Method

A Delphi method will be conducted to establish consensus on the core attributes required for future academic nurse leaders. The Delphi technique has been chosen due to the ability to refine the thoughts and ideas of a large cohort of experts to form a consensus view, defined at ≥90% agreement on a set of core attributes [17,21,22]. While agreement of ≥80% is deemed sufficient to validate content, the researchers have set an agreement of ≥90% to ensure a high level of validity [22].

Round 1: Expert Advisory Group

In round 1 of the Delphi method, an Expert Advisory Group will be sought to confirm the broader understanding and application of the preliminary list of key qualities, behaviors, and characteristics for academic nurse leader success as informed by the scoping review in phase 1. The research will specifically target senior leaders from Schools of nursing within Table A or public universities throughout Australia and New Zealand [23]. These Table A or public universities have been chosen due to their strong research divisions, participation in the development of nursing academe (through the Council of Deans of Nursing and Midwifery [CDNM; Australia & New Zealand]), and their support of "balanced" academic positions—where individuals are required to attend to both teaching, research, and professional engagement duties to maintain their academic skill sets. Senior leaders have been identified to participate in this Expert Advisory Group due to their significant experience within academe, their influence and

XSL•FO
RenderX

insight in developing staff, and the distinctive understanding and views they hold of academic hierarchy having succeeded in the role of associate professor or professor. Analysis of these traits, followed by further testing with established leaders, will assist in the creation of a set of agreed core attributes to support succession planning and growing the next generation of academic nurse disciplinary leads. Such measures are necessary to address a potential future shortage of transformational nurse leaders who are able to influence future academic leadership roles in HE during a time where many universities are undergoing restructure. Disciplinary leads are the leaders who hold decision-making, executive roles within Table A or public universities and are responsible for leading the Discipline [24]. Participants will be invited to an internet-based meeting and asked to review the list of qualities, behaviors, and characteristics determined in phase 1, identify definitions for terms with multiple meaning, identify gaps, and address these gaps. As an iterative process, the data will then lead to the undertaking of round 2.

Rounds 2 and 3: Delphi e-Survey

In round 2 of the Delphi method, the refined data from round 1 will be tested through at least 2 rounds of the Delphi e-survey targeting all established leaders. The Delphi e-survey has been chosen to facilitate the collation of information beyond the Expert Advisory Group as it facilitates the easy circulation of survey material and collation of high-quality data across Australia and New Zealand at the convenience of the research participant (ie, no restraint due to time zones or travel required) [21]. The Delphi e-survey will aim to further refine any areas of ambiguity in the list of qualities, behaviors, and characteristics while also gauging prioritization to inform the development of a final list of core attributes. Content analysis will be undertaken after round 2. In round 3, the findings of round 2 will be presented to the participants of round 2. Participants' reactions to the findings will be sought. Consensus on the list of core attributes will be defined as ≥90% agreement [22,25]. The number of rounds of the Delphi method will be dependent on the establishment of consensus [25].

Round 4: Achieving Consensus

In round 4, the Expert Advisory Group will test the consensus opinion of the established leaders. The purpose of testing this research with the Expert Advisory Group is to ensure the proposed attributes and steps toward the research objectives meet the practical requirements of the role and end user—the future academic nurse disciplinary leads. As round 4 of the research will be an iterative process, the number of rounds will be dependent on the establishment of consensus and, if needed, further refine the core attributes. Content analysis will be used to further validate if consensus has been met across the participants in terms of the accuracy and resonance of the final list of core attributes and any further areas for considerations or areas for investigation. Consensus on the final list of core attributes will be defined as ≥90% agreement [22,25].

Mixed Methods Approach

The qualitative data captured throughout the Delphi method will be synthesized through content analysis. Content analysis is advantageous in this research design as it allows for the analysis of qualitative data while also quantifying its importance [20]. Content analysis is suitable to provide simple reporting of common issues identified in the data, which will likely be necessary to refine the qualities, behaviors, and characteristics into a list of core attributes for consideration in round 2 of the Delphi method. Content analysis allows for coding of the data to assume a quantitative measure—or weight—to which the qualities, behaviors, and characteristics can be measured in degree of importance or value [26,27].

Setting

It is noted that in some instances, schools or faculties of nursing in Australia include Midwifery to provide a multidisciplinary school reflective of a single regulatory board for both professions [28]. Universities in New Zealand do not have this "merged" model as Nursing and Midwifery have separate regulatory authorities, that is, the Nursing Council and the Midwifery Council [29,30]. This research will focus on the discipline of nursing. Although some nurse leaders may also be registered as a Midwife, midwifery has been excluded from this research to maintain comparable data specific to nurse leadership within academe. In examining qualities, behaviors, and characteristics exclusively within the discipline of nursing, this study will take on a similar approach to the research conducted by Carryer et al [31] in 2007, which explored the core role of nurse practitioners specifically within a clinical setting in Australia and New Zealand. Carryer and colleagues' study [31] recruited participants through the Nurses Board or Council of each respective country and excluded midwifery. A similar approach was again taken by Gardner and colleagues [32] in 2016. In this research, specific steps will be taken to ensure trans-Tasman distribution of participation through improving accessibility (eg, using ZOOM) and consideration of terminology to target both Australian and New Zealand HE sectors' requirements.

Participants

Overview

This study will focus on the recruitment of a sample population from within schools and faculties of nursing at identified Table A or public universities in Australia and New Zealand. These public universities have been chosen due to their strong research divisions, delivery of education in the nursing discipline, participation in the development of nursing academe (through the CDNM), and their support of "balanced" academic positions—where individuals are required to attend to both teaching and research duties to maintain their academic skill sets. Thirty-three Australian universities and 5 New Zealand universities have been identified—although it is noted that there have been significant changes in discipline delivery in some universities over the past 2 years and this may impact inclusion at the time of phase 2.

Participation for rounds 1 and 4 (Expert Advisory Group) will target senior leaders. The commitment of a participant to the Expert Advisory Group is likely to reflect their interest and involvement with the issue being addressed [22]. Recruitment of this Expert Advisory Group will be through direct invitation,

XSL•FO
RenderX

initially made via email (through the CDNM) and then followed up by telephone. Representatives from Australia and New Zealand will be chosen because of the similarities in the standards of practice and regulatory structures for nursing.

Inclusion Criteria

The inclusion criteria are as follows: (1) well-renowned and recognized senior leaders who have currently or previously represented their institution as the named Member of the CDNM (Australia and New Zealand); (2) currently or previously employed as a dean, head of school, or head of discipline; and (3) actively working within Table A or public universities in Australia and New Zealand.

Exclusion Criteria

The exclusion criteria are as follows: (1) designated proxies to the CDNM (Australia and New Zealand) and (2) members of the PhD candidate's supervisory panel who would meet the inclusion criteria.

Recruitment

Overview

A minimum threshold of 5 participants has been set for the Expert Advisory Group to establish initial priorities. Prospective participants will be recruited through email contact from the researcher, outlining the purpose of the research, participation requirements, and consent. If available, the researcher will also approach the CDNM for their support in promoting the research initiative to improve the likelihood of participation.

Participation for rounds 2 and 3 (Delphi e-survey) will target established leaders.

Inclusion Criteria

The inclusion criteria are as follows: (1) established leader within the discipline of nursing, including those responsible for leading nursing programs; (2) employed as an associate professor (level D or E); (3) actively working within Table A or public universities in Australia and New Zealand; (4) is an active member of the CDNM (Australia and New Zealand); and (5) is a designated proxy to the CDNM (Australia and New Zealand).

Exclusion Criteria

The exclusion criterion is not participating in CDNM (Australia and New Zealand).

Recruitment: Rounds 2 and 3

A minimum threshold of 15 participants has been set for rounds 2 and 3 of the Delphi method to refine and test the resonance of the qualities, behaviors, and characteristics to create the draft list of core attributes. Prospective participants will be recruited through similar means to round 1 (direct email contact through the CDNM); however, they may also be recruited through referral from round 1 participants or through advertising, to ensure a broad capture of evidence.

Ethical Considerations

Approval

Ethics approval was obtained for all phases of this study from the University of South Australia's Human Research Ethics Committee (HREC) on April 30, 2020 (202862). Phase 1 of the research was a scoping review and as a literature-based form of inquiry it did not require ethics approval; however, the researchers noted that there are still some considerations regarding scoping review methods that include studies wherein the researchers have included human participants without approval of a duly constituted ethics committee. Key ethical considerations for phase 2 of this research are obtaining informed consent, ensuring that participants' details are treated in a manner that ensures an appropriate degree of privacy, and the safe storage of confidential data collected within the research.

Consent

Participants in phase 2 of the research will be provided a Participant Information Sheet (PIS) specific to the phase of research. The PIS details the purpose of the research including the aim, objectives, and potential outcomes. The PIS provides prospective participants with details on participation, including what participation would involve, potential benefits, potential risks, confidentiality, and strategy for managing any adverse events. If prospective participants have any unanswered questions, the contact information of the research team is provided within the PIS, thereby further enabling informed decision-making and consent.

Participants' Safety and Withdrawal

In the unlikely event a participant suffers an adverse event as a result of participating in the research, the research will be suspended while investigation into the occurrence is considered and risk analysis is completed, inclusive of HREC advice being obtained and acted upon. Prospective participants will be advised that participation is voluntary and they may withdraw their interest and participation at any time. This information is documented in the PIS. If a participant withdraws after their contribution has been deidentified, the contribution or data will be unable to be extracted from the study.

Confidentiality

Participants will offer their voluntary consent to the research team using data to inform the research. Any information obtained in connection with the research that may identify participants will remain confidential.

Data Management

All data will remain confidential to the researcher and stored on a password-protected computer, and in the University of South Australia's Research Data Storage and University of South Australia server. Access to data will be limited to the research team. Expert Advisory Group data may potentially be individually identifiable through voice recognition if recordings of Zoom contributions are made. These recordings may be required to ensure accurate documentation of participant contributions in a busy meeting setting. The researcher will undertake to deidentify this data at the point of transcription.

RenderX

Results

This research will identify an agreed set of core attributes required to develop and support successful disciplinary nurse leaders in academe.

Discussion

Anticipated Findings

It is anticipated that the findings of this study will inform the design and delivery of postgraduate nurse leadership programs and assist senior nursing faculty in HE to support the development of the next generation of academic nurse leaders. The findings will contribute to recruitment strategy, including succession planning and job description development. Upon completion of this research it is anticipated that the data sets and findings will be transferrable to other disciplines within HE to aid in future-proofing discipline-based expertise and leadership in the context of academic restructure.

Limitations

The scoping review process will align to the PRISMA-ScR, and the selection of studies will be guided by a protocol reviewed by the research team with expertise in conducting scoping reviews and prospectively published on the Open Science Framework [19]. While the researchers aim to ensure the rigor of the scoping review design is upheld, potential limitations include relevant articles published in languages other than English that may be missed, the exclusion of articles that focus on clinical leadership, and characterization and interpretation bias. A data extraction tool will be used to ensure that the selected studies are independently mapped to the research questions by two of the researchers with conflicts reviewed by the third researcher [18].

The Delphi method has been adopted due to the ability to refine the thoughts and ideas of a large cohort of experts to form a consensus view; however, the limitations of this method include timeliness and the potential complexities of conducting multiple rounds to achieve agreement among participants [22,33]. The validity of the Delphi studies can be called into question due to the varied definitions of “consensus” [33]. While agreement of ≥80% is deemed sufficient to validate content, the researchers have set an agreement of ≥90% to ensure a high level of validity and increase the rigor of this study [22]. The researchers will use e-surveys to improve accessibility for participants in an effort to increase participation in and improve the validity of the study [33]. The use of e-surveys also reduces the likelihood of bias developing through participants who may seek to demonstrate the same view as the majority [33].

Conclusions

The development of a set of agreed core attributes will assist current disciplinary leads to support early career trajectory identification and fast-tracking of the next generation of nursing disciplinary leaders in Australian and New Zealand HE institutions. It is anticipated that the findings of this research will inform postgraduate nurse leadership programs and assist senior nursing faculty in HE to effectively implement recruitment strategies, including succession planning and job description development. Ensuring the next generation of nursing disciplinary leaders hold or are supported to grow the qualities, behaviors, and characteristics that will empower them to succeed will assist in future-proofing discipline-based expertise and leadership in the context of academic restructure.

Acknowledgments

This proposed research is being undertaken as a PhD degree and the candidate and supervisors will all contribute to the research.

Data Availability

Data sharing is not applicable to this article as it outlines a prospective research protocol and therefore at this stage no data sets have been generated.

Conflicts of Interest

None declared.

Abstract

Background: Quantitative gait analysis can support clinical decision-making. These analyses can be performed using wearable sensors, nonwearable sensors, or a combination of both. However, to date, they have not been widely adopted in clinical practice. Technology adoption literature has highlighted the clinical efficacy of technology and the users' perspective on the technology (eg, ease of use and usefulness) as some factors that influence their widespread adoption.

Objective: To assist with the clinical adoption of quantitative gait technologies, this scoping review will synthesize the literature on their clinical efficacy and clinician perspectives on their use in the clinical care of adult patient populations.

Methods: This scoping review protocol follows the Joanna Briggs Institute methodology for scoping reviews. The review will include both peer-reviewed and gray literature (ie, conference abstracts) regarding the clinical efficacy of quantitative gait technologies and clinician perspectives on their use in the clinical care of adult patient populations. A comprehensive search strategy was created in MEDLINE (Ovid), which was then translated to 4 other databases: CENTRAL (Ovid), Embase (Ovid), CINAHL (EBSCO), and SPORTDiscus (EBSCO). The title and abstract screening, full-text review, and data extraction of relevant articles will be performed independently by 2 reviewers, with a third reviewer involved to support the resolution of conflicts. Data will be analyzed using content analysis and summarized in tabular and diagram formats.

Results: A search of relevant articles will be conducted in all 5 databases, and through hand-searching in Google Scholar and PEDro, including articles published up until December 2022. The research team plans to submit the final scoping review for publication in a peer-reviewed journal in 2023.

Conclusions: The findings of this review will be presented at clinical science conferences and published in a peer-reviewed journal. This review will inform future studies designed to develop, evaluate, or implement quantitative gait analysis technologies in clinical practice.

Introduction

Gait impairments increase risk of falls and the level of disability, thus negatively influencing a person's involvement in society and quality of life. There are many causes of gait impairments, including neurological, musculoskeletal, and other health conditions. Gait assessments are an important aspect of a clinical assessment because they provide clinicians with information to support diagnosis, risk assessment, and treatment planning, with the goal of optimizing a person's independence and physical function. In clinical practice, gait assessments are primarily performed using observational gait analysis, which involves a clinician's visual assessment of the patient's gait [1,2]. This analysis can also be supported by outcome measures such as the Functional Gait Assessment in the adult patient population [3]. However, the reliability of observational gait analysis has been questioned [4], with the amount of experience performing this analysis influencing reliability [5]. Additionally, observational gait analysis may lack precision in identifying the subtle nuances of gait that are important for treatment planning, understanding treatment outcomes, and clinical decision-making. Quantitative gait analysis can provide clinicians with objective measurements of the gait cycle that can help them assess and monitor changes in gait, thus better informing clinical decision-making. Quantitative gait analysis makes use of wearable sensors, nonwearable sensors, or a combination of both (eg, hybrid systems) [6]. Wearable sensors are attached to the patients themselves and allow for monitoring within or outside of a controlled environment [6-9]. Nonwearable sensors allow for the monitoring of gait within a controlled environment [6]. Examples of common wearable and nonwearable gait technologies are shown in Textbox 1.

Textbox 1. Common quantitative gait analysis technologies.

Wearable [6-9]

- Inertial sensors (eg, accelerometers and gyroscopes)
- Force sensors (eg, instrumented insoles)
- Electromyography
- Flexible goniometers
- Ultrasonic sensors

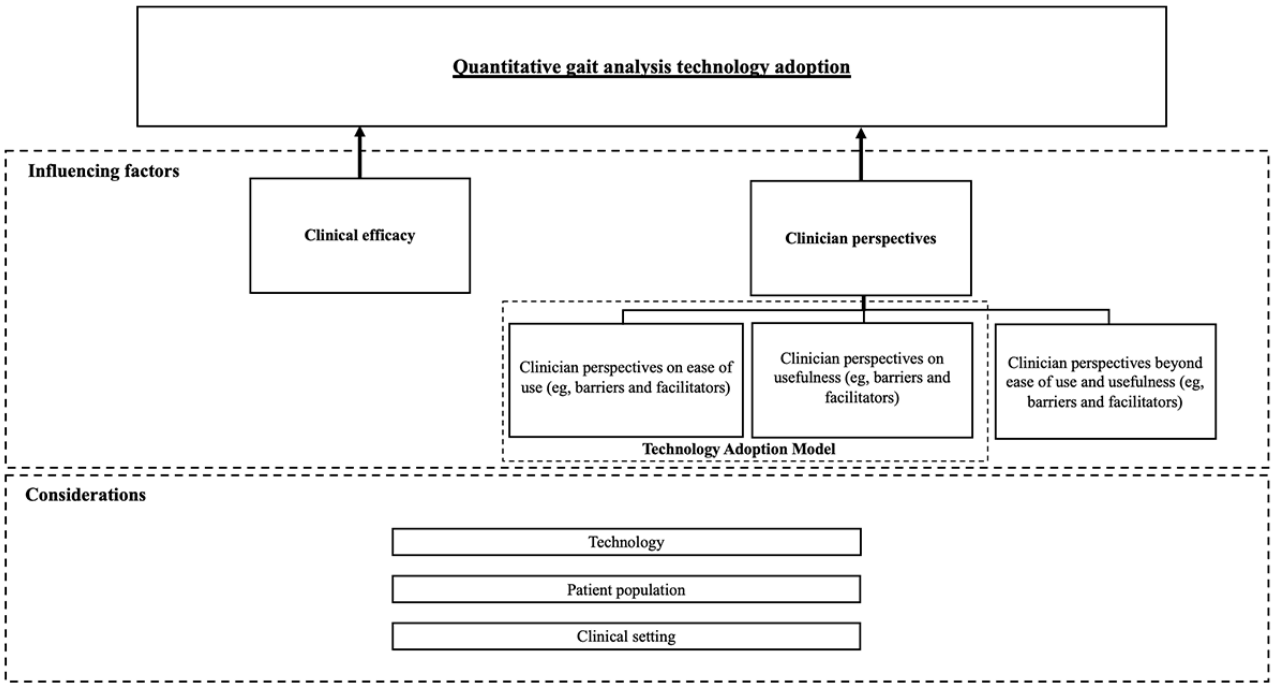
Nonwearable [6,7]

- Pressure sensor mats
- Force plates (eg, ground reaction force plates)
- Motion capture
- Vision-based gait assessment [10]

Research on quantitative gait analysis technologies has increased nearly 10-fold over the last 10 years [11], with a nascent but expanding literature in support of the clinical efficacy of gait technologies. For example, 2 retrospective studies highlighted the role of gait technologies in guiding and optimizing treatment plans for people with stiff knee gait and spinal cord injury [12,13]. Both studies provide preliminary evidence for using gait technologies to enhance patient care. Moreover, guidelines for gait assessments [14-16] have been developed and can help support the use of these technologies in practice. However, despite this preliminary evidence of clinical efficacy, quantitative gait analysis technologies have yet to be widely adopted into clinical practice [2,17].

There are many factors that influence technology adoption [18-20], with evidence for clinical efficacy (ie, efficacy and effectiveness) only being a piece of the puzzle [20,21]. Instead, consideration must also be given to clinicians' perspectives on using technology in their practice. The Technology Adoption Model suggests that 2 key factors influence users' attitudes toward using a technology: perceived usefulness and perceived ease of use [18]. Perceived usefulness is defined as "the degree to which an individual believes that using a particular system would enhance his or her job performance" [18] (ie, perceived facilitator to usefulness) or the degree to which an individual believes that using the technology would not enhance his or her job performance (ie, perceived barrier to usefulness). Perceived ease of use is defined as "the degree to which an individual believes that using a particular system would be free of physical and mental effort" [18] (ie, perceived facilitator to ease of use) or the degree to which an individual believes that using the technology is not free of physical and mental effort (ie, perceived barrier to ease of use). Previous studies have used perceived usefulness and perceived ease of use to study technology acceptance in health care [22,23]. Beyond clinicians' perspectives on ease of use and usefulness of technology, thought must also be given to their perspectives on factors that exist beyond ease of use and usefulness, such as whether they believe their workplace would support their use of the technology [20,24].

In applying these learnings to the clinical adoption of quantitative gait analysis technologies, we then consider some factors that influence their successful adoption to be clinical efficacy and effectiveness, and clinicians' perspectives on the use of gait technologies in practice (ie, perceived barriers or facilitators to ease the use and usefulness of the technology, and beyond). As there are many different gait analysis technologies, consideration must be given to how and whether the above factors differ between each respective technology,



XSL•FO
RenderX

patient population, and clinical context. A visual representation of how we consider these factors to influence the clinical adoption of quantitative gait technologies in the care of adult populations is shown in Figure 1.

To our knowledge, no previous review has synthesized the evidence for clinical efficacy and a clinician's perspective that influences the use of gait technologies in the clinical care of adult patient populations. A preliminary search for similar existing scoping and systematic reviews was conducted up until April 2021 in PubMed and Google Scholar. Two related systematic reviews were published in 2011 [25,26]. Bergmann and McGregor [25] focused on clinician and patient preferences for wearable technologies. This review addressed wearable technologies broadly and did not examine gait analysis specifically. Wren et al [26] investigated the clinical efficacy of quantitative gait analysis in a review of studies up until 2009, which was recently updated in 2020 [11]. This review investigated the clinical efficacy of gait technologies across 6 categories: technical efficacy, diagnostic accuracy efficacy, diagnostic thinking, treatment efficacy, patient outcomes efficacy, and societal efficacy. However, this review did not consider clinicians' perspectives on the ease of use and usefulness of gait technologies, and the recent update solely focused on 3D motion capture technologies.

The objective of this scoping review is to describe the factors influencing the clinical adoption of quantitative gait analysis technologies with a focus on their clinical efficacy, and clinicians' perspectives on their use in the clinical care of adult patient populations. We will also explore how these components differ across gait technology types, patient populations, and clinical contexts. A scoping review approach has been chosen to explore the extent of literature on this broad topic and is a necessary step in identifying how gait technologies can be integrated into clinical practice.

Figure 1. Factors influencing the clinical adoption of quantitative gait analysis technologies.

Methods

Overview

This scoping review protocol follows the recommendations outlined in the Joanna Briggs Institute (JBI) methodology for scoping reviews [27].

The conduct and reporting of results will conform to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist [28].

Inclusion and Exclusion Criteria

A list of inclusion and exclusion criteria can be seen in Textbox 2.

XSL•FO
RenderX

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- All adult patient populations (18 years and older)
- All health care professionals
- Quantitative gait analysis technologies
- Clinical efficacy studies (ie, efficacy and effectiveness)
- Clinician perspectives on the use of gait technologies in practice
- Clinical setting

Exclusion criteria

- Gait training technologies
- Gait technologies used solely to measure movement or activity levels
- Gait technologies in the development or preliminary validation phase

Types of Participants

There are 2 categories of participants included in this review. The first category of participants includes all adult patient populations (18 years and older), and the second category of participants includes all health care professionals. There will be no restrictions with regards to gender, sex, or ethnicity.

Concept

There are three components to the concept of this scoping review: (1) quantitative gait analysis technologies, (2) clinical efficacy (ie, efficacy and effectiveness), and (3) clinicians' perspectives on the use of gait technologies in practice (eg, perceived barriers or facilitators to ease of use and usefulness of technology or factors beyond ease of use and usefulness). First, gait analysis technologies are defined as those used to quantitatively measure the different phases of gait for the purpose of assessment or monitoring changes in gait. This can include collecting kinetic or kinematic measures or muscle function data. By this definition, articles studying gait training technologies or technologies used solely to measure movement or activity levels (eg, number of steps per day) will be excluded. Additionally, studies focused on gait technology development or preliminary validation will be excluded from this review. Second, we define clinical efficacy similarly to the "diagnostic thinking and treatment efficacy" and "patient outcomes" categories as outlined by Wren et al [26]. This includes studies that investigate how clinicians use gait technologies (eg, treatment planning) with patient populations and what impact, if any, there is on patient outcomes. Both efficacy and effectiveness trials were included in this review. However, for simplicity, the term clinical efficacy will be used throughout this protocol. Third, clinicians' perspectives on the use of gait technologies in practice encompass their perception of ease of use and usefulness of the technology and barriers or facilitators beyond ease of use and usefulness that they perceive to impact the use of gait technologies in practice. Barriers or facilitators beyond ease of use and usefulness include a clinician's perception of how factors about themselves or their surroundings (eg, supportive environment, training, experience) influence the use of gait technologies in practice. The components of clinical efficacy and clinician perspectives do not need to occur within a given paper, but rather these components are combined using "OR" (eg, gait analysis technologies AND (clinical efficacy OR clinician perspectives)). How these components differ between the type of technology, patient population, and clinical context will also be examined in this review.

Context

There are no restrictions on geographical location or cultural factors in this review. The context of this scoping review includes "clinical care," which encompasses a wide range of settings, including but not limited to hospitals, homes, community-based locations, and private health clinics. Because we are investigating clinician perspectives, it is likely that many of the articles will be qualitative in nature. Thus, the context of these papers may include interview or focus group settings.

Types of Evidence Sources

Primary research studies of all designs, including both quantitative and qualitative work, as well as gray literature (ie, conference abstracts), will be included in this review. Secondary research studies (eg, systematic reviews) and other gray literature (eg, textbooks and dissertations) will be excluded from this review. Additionally, articles and conference abstracts will be excluded if there are no reported results.

Search Strategy

A 3-step search strategy was performed as outlined by the JBI methodology for scoping reviews [27]. First, a preliminary search of relevant sources consisted of hand-searching primary research articles that met the above inclusion criteria in PubMed and Google Scholar. Search terms included: Gait technologies AND clinician perspective, gait technologies AND clinical care, gait analysis AND barriers. A thorough analysis of the keywords included in the title and abstracts of selected articles was then conducted. Second, a comprehensive search strategy was created in MEDLINE (Ovid) based on the list of keywords and subject headings derived from the previous analysis and synonyms found by the first author. Boolean operators were used in the search strategy in two separate ways: (1) to combine all keywords that describe a single concept using "OR" and (2) to

XSL•FO
RenderX

combine all 3 concepts using "AND" to develop a final search. The MEDLINE (Ovid) search strategy was created in collaboration with an information specialist at the University Health Network. Search terms were tested, and adjustments to the search strategy were made based on the identification of new keywords. Between March and April 2021, the final MEDLINE (Ovid) search strategy was translated to 4 other databases: CENTRAL (Ovid), EMBASE (Ovid), CINAHL (EBSCO), and SPORTDiscus (EBSCO). Engineering databases are excluded from this search because this review considers technology applications in a clinical context. The list of keywords and subject headings used in the MEDLINE (Ovid) search string was modified (eg, synonyms found) to suit the search capacity of the other databases. In the SPORTDiscus (EBSCO) database, subject headings from the MEDLINE (Ovid) search were omitted as no synonyms were found. The search will be iterative in nature, with adjustments being made to the search strategy in all databases as new keywords are identified. The third search strategy involved scanning the reference list of included literature and relevant review articles. To add to the breadth of the search strategy, supplemental searching through PEDro and Google Scholar was performed. If the full text of the included articles cannot be found, the reviewers will contact the primary authors for this information.

Only articles written in the English language will be included in this review because that is the language understood by the authors. Both peer-reviewed and gray literature (ie, conference abstracts) discussed in the above 3-step search strategy will be included in this review. Conference abstracts are included to increase the comprehensiveness of this review and will be searched in Embase (Ovid) and CENTRAL (Ovid). These 2 databases were chosen because conference proceedings are indexed in Embase (Ovid), with some also being found in CENTRAL (Ovid). There is no date limit on the articles included in this review, because to our knowledge, no other scoping review has addressed this specific question. An information specialist at the University Health Network was involved in the development and review of the search strategies created in all 5 databases. The complete MEDLINE (Ovid) search strategy can be found in Multimedia Appendix 1.

Description of Source Selection

Covidence (Veritas Health Innovation) systematic review software will be used for the management of the articles identified in the search strategy. Prior to performing the formal selection process, pilot testing will be completed with 4 reviewers (YS, LC, AI, and KKP). In accordance with the JBI methodology for scoping reviews, 25 titles and abstracts will be chosen for the reviewers to screen based on the inclusion criteria previously mentioned [27]. Inconsistencies found during the pilot testing will result in further refinement of the inclusion criteria. The formal screening process will begin once there is a 75% or greater agreement among reviewers on the chosen 25 titles and abstracts [27].

During the formal screening process, 2 reviewers (YS and LC) will independently perform title and abstract screening. Both reviewers must agree on the inclusion of the article for it to be processed in the full-text review stage. Conflicts between the 2 reviewers at this stage will be resolved by a third reviewer (AI). Once title and abstract screening is complete, pilot testing for the full-text review stage will begin with the same 4 reviewers (YS, LC, AI, and KKP). Similar to the pilot testing for title and abstract screening, all 4 reviewers will independently read 5 full-text articles and assess them for inclusion. Any discrepancies during the pilot testing will result in further refinement of the inclusion criteria. The formal full-text review process will begin once 75% agreement or more is reached during pilot testing. Once the pilot testing is complete, both reviewers (YS and LC) will independently read the full-text articles for inclusion. Where articles are agreed upon for exclusion but the chosen exclusion criteria differ between reviewers, both reviewers (YS and LC) will decide on the most appropriate exclusion criteria by consensus. A third reviewer (AI) will resolve conflicts as they pertain to including and excluding articles. The complete review process will be illustrated using a flow diagram and included in the appendices of the scoping review. A short explanation regarding the inclusion and exclusion of sources of evidence will also be included in the appendices of the scoping review.

Critical Appraisal

This review will also include a critical appraisal of all full-text articles included in this review. The critical appraisal will be used to assess the quality of the study design, methods, and analysis of the included literature. The JBI critical appraisal tools will be used, as this is recommended to authors who are conducting reviews following JBI guidelines [29]. JBI critical appraisal tools will be chosen based on the study design of the literature and may include checklists for cross-sectional studies, case control studies, case reports, case series, cohort studies, qualitative studies, quasi-experimental studies, and randomized controlled trials [30-33]. The JBI critical appraisal tools will be piloted by both reviewers (YS and LC) on 3 studies: a randomized controlled trial, a qualitative study, and a case report. The remaining articles will be divided between both reviewers; one will critically appraise the evidence source, and the other will review the appraisal for accuracy. The results of the critical appraisal will not be used to determine the inclusion or exclusion of literature in this review. This is because the authors consider including papers of all methodological quality to be valuable to the research community because it shows the state of the literature in this field and whether higher-quality evidence is warranted. No scoring system will be used during critical appraisal. Authors will report on the quality of the articles by sharing the results of the critical appraisal in tabular format in the final review. This will allow readers to see how each study attempted to limit bias in the design, conduct, and data analysis.

Data Extraction

A draft data extraction form has been created in accordance with the JBI methodology for scoping reviews [27]. Information retrieved from the included sources will include the following as available: study characteristics (eg, authors, year of publication, location of where the article was published or conducted, aims or purposes, population or sample size, type of population or sample), methods or methodology (eg, tradition

XSL•FO
RenderX

of inquiry or quantitative design), intervention (if any), and findings as they address the scoping review question (eg, clinical efficacy or clinician perspectives). In situations where conference abstracts are associated with a full text, the reviewers will only extract data from the full text. In cases where there is no full text associated with the conference abstract, the abstract itself will be used for data extraction.

The data extraction form will be piloted by both reviewers (YS and LC) on 3 articles to ensure that relevant information is being extracted. Pilot testing will involve both reviewers (YS and LC) extracting data from 3 articles. The first reviewer (YS) will check for consistency in the extracted information between both reviewers. Both reviewers will then meet to discuss whether additional modification of the data extraction form is needed. Recognizing that the development of the data extraction form is iterative, modifications may be made throughout the extraction process by both reviewers. For modifications to be made, both reviewers will need to agree upon the added information categories. If disagreements arise, a third reviewer (AI) will be involved. The included literature will be divided between both reviewers (YS and LC); one will complete data extraction and the other will review the extraction for accuracy.

Analysis of the Evidence

The results of this scoping review will be synthesized and presented using both quantitative and qualitative methods. Quantitative methods will include counts of the number of unique clinical uses, clinician perspectives, types of gait analysis technologies used, patient populations, and clinical contexts. Qualitative methods will be used to organize the findings into Figure 1. We will use a combination of deductive and inductive content analysis in this review. Deductive content analysis will be used to code the literature, similar to the visual representation outlined in Figure 1. Inductive coding will be used to describe how and whether the clinical efficacy of gait technologies and clinician perspectives (eg, ease of use, usefulness, and factors beyond ease of use and usefulness) differ depending on the type of gait technology, patient population, and clinical context. This process involves coding the data, developing categories, and forming concepts [34]. The first author (YS) will be responsible for completing all stages of the content analysis process. NVivo (version 12, QSR International Pty Ltd) software will be used as the data management system for the qualitative content analysis. To ensure the trustworthiness of the analysis, the first author will provide justifications for how the literature was organized into the components outlined in Figure 1. The first author will also meet with the research team throughout all stages to receive team feedback for further refinement of the content analysis process.

Ethical Considerations

This scoping review does not require research ethics board approval.

Patient and Public Involvement Statement

There was no patient or public involvement in the development of this protocol.

Results

Results of this proposed scoping review will be presented in both a tabular format and a diagram. The table will display the quantitative analysis of the results. Results of the critical appraisal for each study will be shared within the text of the scoping review as well as in tabular format. The diagram will display the qualitative results and be similar to what is shown in Figure 1. In summarizing the results both quantitatively and qualitatively, this review will highlight the gaps in the literature surrounding how gait analysis technologies are used in practice and what supports or hinders their clinical adoption.

A search of relevant articles will be conducted in all 5 databases and through hand searching in Google Scholar and PEDro, including articles published up until December 2022. The research team plans to submit the final scoping review for publication in a peer-reviewed journal in 2023. If we experience any delays to the timeline (eg, a greater number of papers to screen than expected), we will recruit others to assist with screening and data extraction.

Discussion

Impact

Preliminary research suggests gait analysis technologies have a role in clinical decision-making [12,13]. Despite this potential value, gait analysis technologies are not commonly found in clinical practice. This review will describe the factors that influence the clinical adoption of quantitative gait analysis technologies with a focus on clinical efficacy and clinicians' perspectives on their use in the clinical care of adult patient populations. To be comprehensive, this review will also highlight how these components differ across gait technology types, patient populations, and clinical settings.

To our knowledge, this will be the first review to synthesize the evidence on the clinical efficacy and a clinician's perspective on the use of gait technologies in the clinical care of adult patient populations. This review differs from related systematic reviews [11,25,26] for several reasons. First, this review focuses on gait analysis technologies (ie, wearable and nonwearable) and how these technologies impact clinical decision-making or patient outcomes. Lastly, this review also takes into consideration the perspectives of clinicians on the use of gait technologies in practice.

Limitations

This review has some limitations. First, this review will only consider conference abstracts as a source of gray literature, and second, this review will only consider studies written in the English language. Thus, relevant articles may be missed if written in another language.

Conclusions

We anticipate that this review will provide insights into the clinical adoption of quantitative gait analysis technologies by highlighting their role in clinical decision-making and clinician perspectives on using gait technologies in practice. The results of this review can also be used to inform and guide future work

XSL•FO
RenderX

focusing on facilitating the translation of technologies into practice. Recognizing the role of this review in technology adoption and clinical sciences, the results will be disseminated at clinical science conferences and through publication in a peer-reviewed journal.

Acknowledgments

We would like to acknowledge Jessica Babineau, the information specialist with the University Health Network Library and Information Services, for her assistance in developing the search strategy. This research was supported by AGE-WELL NCE Inc, a member of the Networks of Centres of Excellence Program, and a Canadian Institute of Health Research Project Grant (169166).

Authors' Contributions

YS led the development of the search string and protocol. LS was the second reviewer on the scoping review and provided feedback to the protocol. KKP provided feedback on the protocol and is the cosupervisor of the first author. AI provided feedback on the search strategy and protocol and is the primary supervisor of the first author.

Conflicts of Interest

None declared.

Abstract

Background: Transportation is essential for people of all ages and backgrounds to live a fulfilling and satisfying life. Public transport (PT) can facilitate access to the community and improve social participation. However, people with disabilities may encounter barriers or facilitators in the whole travel chain that can lead to negative or positive perceptions in terms of self-efficacy or satisfaction. These barriers may be perceived depending on the nature of the disability. Few studies have identified PT barriers and facilitators experienced by people with disabilities. However, findings were focused mainly on specific disabilities. Access requires broader considerations of barriers and facilitators for various types of disabilities.

Objective: This scoping review aims to describe the barriers and facilitators to the use of PT experienced by people with various disabilities in the whole travel chain and to explore perceived experiences, self-efficacy, and satisfaction when using PT.

Methods: A scoping review will be conducted using Arksey and O'Malley's framework and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist. The literature search will be conducted using the electronic databases MEDLINE, Transport Database, and PsycINFO via Ovid platform, Embase, and Web of Science from 1995 to 2022. Two reviewers will independently identify studies based on inclusion (published in English or French, outcomes on PT accessibility for people with disabilities, peer-reviewed or guideline reports or editorials) and exclusion (no full text, focused on a technology system, outcome validation study, study on no-fixed route PT accessibility, etc) criteria and extract the data. When a study has addressed the accessibility of multiple modes of PT, including fixed-route PT, it will be retained. However, only data on fixed-route PT will be extracted. Any related systematic reviews identified through the search will be retained, and the reference lists will be hand-searched and screened for inclusion criteria.

Results: The search we performed on July 21, 2022, in the databases mentioned above allowed us to retrieve 6399 citations. Of these citations, 31 articles were identified, and data extraction was performed. As of March 11, 2023, we have started data analysis. The findings will be synthesized narratively to summarize the barriers and facilitators to PT, perceived experiences with PT, self-efficacy for using PT, and satisfaction with PT according to the Human Development Model-Disability Creation Process conceptual framework.

Conclusions: The results of this scoping review could lead to a better understanding of the potential barriers and facilitators to the use of PT by people with various types of disabilities and how negative or positive experiences throughout the travel may influence their self-efficacy and satisfaction. The results may be used to provide recommendations to PT providers and policy makers to work together to make PT accessible, usable, and inclusive for all people with disabilities.

KEYWORDS

accessibility; public transport; disability; experience; self-efficacy; satisfaction; scoping review

Introduction

On the basis of the 2010 global population estimates, the World Health Organization (WHO) and World Bank [1] report that more than 1 billion people live with some form of disability, including motor, sensory, and cognitive; intellectual; or mental disabilities. This represents approximately 15% of the world's population, which is 5% more than a previous WHO estimate from the 1970s. More than 46% of people 60 years and older have disabilities and more than 250 million older adults experience moderate to severe disabilities [2].

Given their disability or aging-related health conditions, many people may experience restrictions in accessing transportation. In transportation modes, public transport (PT) is essential for people of all ages and backgrounds to live a fulfilling and satisfying life. For example, PT plays a vital role in many aspects of daily life including access to employment, education, health care, shopping, social occasions, and multiple recreational activities [3]. Thus, it may facilitate participation in community activities and employment if it is accessible to people with disabilities. PT is a system of vehicles such as buses and trains that operate at regular times on fixed routes and are used by the public [4]. Accessible PT enables people with disabilities to live independent lives and means having access to transport services that are available where and when one wants to travel, being informed about the services, knowing how to use the services, being able to use the services, and having the means to pay for them [5]. This suggests that the accessibility of PT involves more than simply boarding and disembarking. To ensure access, an understanding of all the elements that make up the travel chain is required [6], such as leaving the home to wait for the transport at the stop or station, availability of timetable information, boarding, moving within the transport, disembarking, the use of sidewalks, and the attitudes of drivers and other passengers toward people with disabilities [7]. Thus, people with disabilities may encounter barriers or facilitators related to any element of the travel chain that can lead to negative or positive perceptions in terms of self-efficacy or satisfaction, and these may, in turn, affect their willingness to use PT.

Defined as the belief in one's ability to perform a specific task [8], self-efficacy has been identified as the most important predictor of travel behavior change [9]. Self-efficacy is determined by factors such as past experiences or accomplishments and emotional reactions [8,10,11]. Past accomplishments that are interpreted as the result of a skill developed in the past [12] have been found to be the most important in influencing self-efficacy [10]. Emotional reactions can improve or reduce self-efficacy. Thus, positive experiences with PT use may generate positive emotions that can enhance feelings of personal efficacy toward PT use. Conversely, negative experiences can induce negative emotional reactions such as anxiety and doubt, which in turn may impact self-efficacy for using PT. Therefore, low self-efficacy may be a barrier to PT use [9].

Satisfaction is described as an intrinsic positive consequence emerging from a behavior that fulfills the expectations of an individual [13]. Satisfying experiences have been shown to increase intrinsic motivation, which increases the likelihood to continue the behavior. Consequently, experiencing satisfaction during interventions is assumed to increase the likelihood that the individual will sustain the behavior change [9]. The most relevant features of the transportation system, such as trip duration, accessibility, fare, network connectivity, information, comfort, safety, and employees' kindness, may influence user satisfaction. Satisfaction with travel can have a significantly positive effect on the frequency of PT use [14]. Indeed, the more satisfied PT users are with their travel experience, the more they tend to use PT for their work commute [14].

We are interested in all PT modes including buses, trains, tramways, subways, and ferries because people with disabilities travel less frequently and rely on PT more than the general population [15]. Long before the adoption of the United Nations Convention on the Rights of Persons with Disabilities (UN-CRPD) in 2006 [16], many countries including the United States, Canada, and Australia developed regulations, codes, and standards to regulate the practices related to the accessibility of PT [17]. Indeed, in 1990, the Americans with Disabilities Act (ADA) qualified accessible and usable transportation as a qualified civil right [5]. In Australia, the Disability Standards for Accessible PT 2002 (as amended in 2010) were enforced to provide transport operators and providers with information on their obligations under the Disability Discrimination Act (DDA). Under the Canada Transportation Act (1996), the Canadian Transportation Agency was made responsible for removing obstacles to mobility in all federally regulated (air, rail, marine, and interprovincial bus) transportation services and facilities. Despite these efforts, many people with disabilities continue to face barriers including physical and social barriers [3,18-24] that limit their use of PT.

Recently, Unsworth et al [20] examined, in their systematic review, the evidence that solely investigated the use of PT by mobility device users, which largely comprised people with mobility disabilities. The study identified problems encountered by mobility devices users, such as uneven pavement surfacing, lack of dropped curbs, steps instead of ramps, narrow doorways, controls for pedestrian lights or lift access that are too high, and badly designed street displays; problems with information being placed out of reading reach, inappropriate spaces for wheeled mobility devices, and lengthy wait times with little shelter [20]. Since the study excluded other types of disabilities such as visual; hearing; autism; and cognitive, mental, or intellectual disabilities, its findings cannot be generalized to all people with disabilities. Identification of needs related to PT of people with other types of disabilities is also important. For example, people with mental health conditions might not use certain services because of the existing social barriers, such as stigma [1], which differ from physical barriers commonly encountered by people with mobility impairment.

XSL•FO
RenderX

This study primarily aims to examine barriers and facilitators to the use of the PT (buses, trains, tramways, ferries) by people with different types of disabilities in the whole travel chain, where disability is defined as the interaction between individuals with a health condition (could be physical or mental) with personal and environmental factors including negative attitudes, inaccessible transportation and public buildings, and limited social support, etc [25]. For the purpose of this review, the definition includes older adults, as people with disabilities are aging with the increase of level of disabilities, and older adults commonly experience disabilities because of various age-related health conditions [26]. Second, this study aims to highlight the perceived experiences of individuals with disabilities when using PT in terms of their self-efficacy and satisfaction.

Methods

Design

A scoping review will be conducted using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist [27]. The extent, range, and the nature of research activity will be explored to determine the value of undertaking a full systematic review, to summarize and disseminate research findings, and to identify research gaps in the existing literature [28]. For this scoping review, the methodological framework described by Arksey and O'Malley [28] will be used. It includes five stages: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; and (5) collating, summarizing, and reporting the results. This last stage is described in the Results section.

Identifying the Research Question

This phase involved a discussion among the authors (CRM, KLB, and FR) to identify the relevant research that arises from the gaps in the existing literature on the topic of this scoping review. The main research questions identified by the authors to guide the scoping review process were as follows: What are the different barriers and facilitators to the use of PT experienced by people with various types of disabilities including older persons? Second, what is their perceived experience in terms of satisfaction or self-efficacy when using PT? These questions emerge from a preliminary search of the literature using Google Scholar.

Identifying Relevant Studies

An extensive literature search of both peer-reviewed and gray literature databases will be performed to identify relevant information about the topic. To conduct this research robustly, we will seek the collaboration of a librarian (MG) who specializes in the use of databases related to the rehabilitation and accessibility of PT by people with disabilities. Given that PT accessibility should consider several fields such as biomedical, transportation, psychological, and human and social sciences, the literature search will be conducted in 5 relevant databases including MEDLINE, Transport Database, PsycINFO (from Ovid platform), Embase, and Web of Science from 1995 to 2022. 1995 date was selected as the start date because very little literature was published in the field prior to this time [20]. The keywords and terms that will be used are as follows: (((Aged or ag?ing or old*) ADJ2 (person* or adult* or people or individual* or man or men or woman or women or user*)) or elder* or geriatric*).ti,ab,kw OR ((mental* or intellectual*) ADJ2 (retard* or deficien* or ill or illness)).ab,ti,kw OR ((physical* or hearing or visual* or cogniti*) ADJ2 (deficien* or impair* or challenge*)).ab,ti,kw OR (disabled or disabilit* or Handicap*or blind* or "hard of hearing" or deaf*).ab,ti,kw OR (((walking) ADJ2 (frame or stick)) or wheelchair* or scooter* or walker* or rollator* or crutche* or cane* or brace*).ti,ab,kw OR ((mobility or walking) adj2 (difficult* or limitation*)).ti,ab,kw AND ("Public transport* accessibility" or bus or buses or tramway* or train or trains or subway* or metro or underground or ferry or ferries).ti,ab,kw AND (satisfaction or "self-efficacy" or "self-efficacy" or confiden* or experience or "quality of life").ti,ab,kw. Since the quality of life includes many aspects of life, such as psychological factors, we inserted this term just for optimizing the search function. This search function could be modified, if necessary, by switching from one database to another. A special mention has to be made for the Web of Science database. Indeed, we will activate the exact search from the advanced search to limit the lemmatization of the results. All retrieved literature will be imported into Covidence (Veritas Health Innovation), which is a software in which all the steps of a knowledge synthesis can be completed, where the duplicates will be removed from the selection of articles for the extraction of obtained data. The literature that meets the criteria presented in Textbox 1 will be included in our scoping review. Moreover, when a study has addressed the accessibility of multiple modes of PT, including fixed-route PT, it will be retained. However, only data from fixed-route PT will be considered in this study. In addition, when any systematic review related to the topic of this scoping review will be identified, we will count the number of studies included in the review that potentially meet our inclusion criteria and will note how many studies are not present in our search [27].

XSL•FO
RenderX

Textbox 1. Inclusion or exclusion criteria.

Inclusion criteria

- Original peer-reviewed manuscript
- Guideline report
- Editorial
- Concerned with PT (public transport; bus, train, tramway, ferry) accessibility or confidence and satisfaction with PT for people with disabilities including older people
- Published from 1995 to 2022
- Published in English or French

Exclusion criteria

- Article for which the full text is not available
- Article focuses on the use of technology while using the PT system
- Article generally discusses universal design or transportation
- Validation study of measurement tools assessing PT accessibility or travel confidence or travel satisfaction for people with disabilities
- Study on no-fixed route PT accessibility (eg, adapted school bus for students with disabilities, paratransit)

Study Selection

Two reviewers (CRM and SG) will independently select the literature to be included in the scoping review in the 2 steps of screening provided in the Covidence platform, based on the inclusion and exclusion criteria. The first step, after removing duplicates, will consist of screening the title and abstract for each document by examining how they are related to the topic. The second step will be reviewing the remaining full articles. All reasons for exclusion will be recorded in the Covidence platform, and cases of disagreement will be resolved through discussion between at least 2 reviewers. To prevent errors and reduce the risk of discrepancies between the 2 reviewers, each screening phase will start with a calibration exercise. In case of persistent disagreement, a third evaluator will be involved.

Charting the Data

This stage involves the use of a data-charting form to extract relevant information from the reviewed literature [28]. For this scoping review, the data-charting form will be jointly developed by 2 reviewers to determine which variables to be extracted. The same reviewers (CRM and SG) will independently chart the data, discuss the results, and continuously update the data-charting form in an iterative process [29] by using Covidence. Information, such as author names and year of publication, setting of the study, study objective, sample, study design, intervention (if applicable), outcomes, and relevant findings to the research questions, will be extracted.

Ethical Considerations

Research ethics approval is not required for this scoping review as the study will not include human or animal participants. Data will be sourced only from peer-reviewed and gray literature.

Results

The search we performed on July 21, 2022, in the databases mentioned above allowed us to retrieve 6399 citations. Of these citations, 31 articles were identified, and data extraction was performed. As of March 11, 2023, we have started data analysis. Relevant findings related to barriers and facilitators, as well as the perceptions of people with disabilities in terms of self-efficacy and satisfaction when using PT, will be presented in tables. In addition, a narrative report will allow us to summarize the relevant findings from the key terms. For this purpose, a brainstorming session that involves all authors will be organized. The results will be described according to the Human Development Model-Disability Creation Process (HDM-DCP) conceptual framework [30] with respect to the research questions, and the aims of this scoping review. This conceptual framework addresses situations of disability that occur when personal and environmental factors restrict life habits, thereby decreasing social participation. Any gap or limitation in the existing literature will be identified and highlighted. We expect to complete this scoping review by June 2023.

Discussion

Expected Findings

This scoping review aims to examine the barriers and facilitators to the use of TP (buses, trains, tramways, and ferries) by people with various disabilities in the whole travel chain and highlight their perceived experiences in terms of satisfaction and self-effectiveness during their travel in PT. Since barriers and facilitators differ between people with disabilities, focusing on the literature on these indicators of PT use by people with various disabilities might help to provide recommendations for making PT more accessible and usable equitably by all passengers. Accessibility and use of PT ensure the participation and social inclusion of people with disabilities. In contrast, an inaccessible mode of PT will never be used by people with disabilities, and therefore may lead to their isolation and social exclusion. To better understand the issue of barriers and facilitators to the use of PT, Iwarsson and Ståhl [6] proposed

XSL•FO
RenderX

the concept of the travel chain in PT. The travel chain suggests that any given travel starts at the origin of the users (eg, their home) and ends at the final destination. Thus, travel needs to be considered an indivisible whole rather than singling out each element. Jensen et al [31] underlined taking a sustained look at all the problems that people with disabilities might experience along an entire route, not simply considering the physical accessibility of PT vehicles. In this way, the elements of the travel chain mentioned above, including drivers' and passengers' attitudes, cannot be considered individually. For example, encountering a sidewalk lacking a curb cut for a wheelchair user is similar to a nondisabled person who encounters an impassable brick wall along their route to the bus stop. Minimally, such barriers can cause distress to the individual with a disability involved, and in the worst case, they can lead to journeys not being made [7]. Any barrier to all or part of the chain of PT use, and negative experiences, may affect the self-efficacy and satisfaction levels of people with disabilities, and therefore their willingness to travel. In return, these psychological factors may enhance travel behavior if PT is accessible and people with disabilities experience positive emotions throughout the travel.

This review will contribute evidence on the multiple barriers and facilitators that may be encountered by people with various forms of disabilities or in situations of autonomy loss (eg, older adults) throughout the fixed-route PT. Barriers and facilitators to PT may be experienced differently by people with disabilities depending on their individual situation of disability (eg, physical, intellectual, cognitive, visual, or hearing disability). It is therefore important to review the scientific literature that addresses PT issues to provide recommendations for best practices in PT to transport providers and policy makers to work together to make PT accessible, usable, and inclusive for people with all types of disabilities. Modifications to the environment (eg, installation of ramps) and interventions (eg, staff awareness and education, training in the use of PT for people with disabilities) may facilitate accessibility and use of PT by people with disabilities. Improved use of PT may develop access to the community and community-based services. Therefore, improved use of PT may facilitate social inclusion, participation, and well-being for people with disabilities.

Limitations

This scoping review may exclude some studies. Indeed, the keywords to be used in the search strategy are broad and may not identify all specialized studies in PT accessibility for people with disabilities. Moreover, the fact of having considered only English and French as the languages of publication could exclude papers that are relevant for our scoping review.

Conclusion

The identification of barriers and facilitators to the use of PT by people with disabilities is an important step that may help policy makers and transport operators around the world to develop and implement interventions to facilitate access, use, and inclusion of this mode of transport, as the experiences of people with disabilities when using this mode of transport have an impact on their well-being. The results of this scoping review could lead to a better understanding of the potential barriers and facilitators to the use of PT by people with various disabilities and how negative or positive experiences throughout the travel may influence their self-efficacy and satisfaction.

Acknowledgments

This study was funded by the Social Sciences and Humanities Research Council of Canada, *Réseau provincial de recherche en adaptation-réadaptation (REPAR)*, and *Office des personnes handicapées du Québec (OPHQ)*. FR and KLB are research scholars of the *Fonds de la recherche du Québec – Santé (FRQ–S)* (Junior 1 and Senior, respectively).

Data Availability

The data sets generated or analyzed during this study are available from The Open Science Framework (OSF; registration DOI: https://doi.org/10.17605/OSF.IO/2JDQS).

Authors' Contributions

CRM, FR, and KLB contributed to the conceptualization of the study. CRM prepared the draft protocol under the supervision of FR and KLB. MG refined the search function. CRM, FR, KLB, and SG contributed to the development of the background, design of the study, and planned outcomes of the research. CRM prepared the manuscript, and FR, KLB, and SG reviewed it. The authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: With the increased adoption of technology, the use of digital health interventions in health care settings has increased. Patient-clinician digital health interventions have the potential to improve patient care, especially during important transitions between hospital and home. Digital health interventions can provide support to patients during these transitions, thereby leading to better patient outcomes.

Objective: This scoping review aims to explore the available literature, specifically (1) to examine the impact of platform-based digital health interventions focused on care transitions on patient outcomes, and (2) to identify the barriers to and enablers for the uptake and implementation of these digital health interventions.

Methods: This protocol was developed based on Arksey and O'Malley's, Levac and colleagues', and JBI scoping review methodologies, and it has been reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Statement for the Scoping Reviews) format. The search strategies were developed for 4 databases: MEDLINE, CINAHL, EMBASE, and the Cochrane Central Register of Controlled Trials by using key words such as "hospital to home transition" and "platform-based digital health." Studies involving patients 16 years or older that used a platform-based digital health intervention during their hospital to home transition will be included in this review. Two reviewers will independently screen articles for eligibility by using a 2-stage process (ie, title and abstract screening and full-text screening). We expect to refine the eligibility criteria during the title and abstract screening process as we anticipate retrieving a significant number of articles. In addition, we will also perform a targeted search of the grey literature, as well as data extraction. Data analysis will consist of a narrative and descriptive synthesis.

Results: The review is expected to identify research gaps that will inform the development of future patient-clinician digital health interventions. We have identified a total of 8333 articles. Screening began in September 2022, and data extraction is expected to commence in February 2023 and end by April 2023. Data analyses and final results will be submitted to a peer-reviewed journal in August 2023.

Conclusions: We expect to find a wide variety of postcare interventions, some gaps in the quality of research evidence, as well as a lack of detailed information on digital health interventions.

care transitions; digital health; targeted patient/client communication; scoping review protocol; patient care; patient support; hospital-to-home transition; hospital discharge; implementation; barriers

Introduction

Patient-clinician digital health interventions have been described by the World Health Organization as "targeted patient/client communication" [1] and have become increasingly popular in health care settings [2]. Such interventions can support patients and caregivers in navigating a complex health system by utilizing information technologies to facilitate communication between parties [1,3]. Digital health interventions that use platform-based technology to facilitate communication and information-sharing between patients and clinicians have the potential to improve care coordination and outcomes during care transitions.

Specifically, asynchronous digital platforms such as web-based or mobile applications contain information that is shared or stored between patients and clinicians. These digital platforms often include patient information and education for discharge planning, follow-up appointments and services, patient empowerment and engagement, and health status updates [1]. In a recent scoping review by Zhang and colleagues [4], the role of digital health interventions for patients with hip fractures was examined. Results of the scoping review indicated that digital health interventions were generally used to support health care providers in the care of such patients. In another systematic review by Free and colleagues [3], digital health interventions were shown to have increased the engagement of patients in their health care journey and a corresponding reduction in hospital admissions.

Engaging patients in their care through digital health interventions is possible given the widespread use of internet-based personal communication devices [5] and the effective use of such interventions with patients and their clinicians. Although asynchronous digital platforms can sometimes be challenging, especially in relation to technological issues [6], successful use of these platforms has been described with patients living with diabetes [7,8], cardiovascular disease [9,10], chronic obstructive pulmonary disease [11], and patients recovering post surgery [12-14].

The multi-service and multi-sector coordination of care after an acute event or diagnosis can be complicated for patients and caregivers to navigate. After acute care admission, patients often receive inadequate information about discharge instructions [15], whereas others have unanswered questions [16]. Some studies have described how patients may experience poor retention of verbal instructions during post-discharge periods [17,18], and how effective education and written discharge instructions may help improve a patient's understanding and facilitate transition from hospital to home [19-23]. A critical gap that has been identified is poor communication between clinicians and patients and their caregivers [24,25]. Digital health interventions can provide opportunities for ongoing support from clinicians to patients and their caregivers [12], which can improve the overall level of communication and lead to better adherence to care instructions [26].

The emerging research highlighting the benefits of patient engagement [27] reinforces the importance of developing patient-centered discharge planning processes [28]. This may include education for patients and their caregivers regarding their health conditions, medication, and common symptoms; a mechanism for exchanging questions and obtaining feedback from patients; and guidance on when to seek appropriate medical care or follow-ups. Using integrated [29] and holistic patient and caregiver interventions [19-23,30], and digital platforms [31] in particular, can help minimize avoidable readmissions and other challenges with the transition of patients from hospital to their homes. Digital health interventions should be inclusive and consider unique patient characteristics such as age, disability, and level of cognition to optimize success [32]. The usability of digital health interventions for patients and clinicians is also crucial for their successful uptake [33].

Despite the widespread development and use of information technology [5], the desire of patients and caregivers for readily available information [34], and the need for better engaging patients in their care process to optimize patient outcomes, only limited research has examined the specific platform-based patient-clinician digital health interventions that are in use for discharge and care transitions.

Our goal is to explore the available literature, specifically (1) to examine the impact of platform-based digital health interventions specific to care transitions on patient outcomes, and (2) to identify the barriers to and enablers for the uptake and implementation of these digital health interventions. The findings from this work would inform future work on the "MyPath to Home" digital health intervention [35].

Methods

Protocol Design

This protocol was developed based on Arksey and O'Malley's [36] methodology, elaborated by Levac and colleagues [37] and JBI Manual for Evidence Synthesis [38], which involves the following stages: (1) identify the research question; (2) identify relevant studies: (3) select studies; (4) chart the data; and (5) collate, synthesize, and report results. For this protocol, we also followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Statement for the Scoping Reviews) reporting format [39].

Stage 1: Identify the Research Question

The research questions guiding this scoping review are as follows:

1. What is the impact of platform-based patient-clinician digital health interventions used for discharge or care transitions on patient outcomes?

XSL•FO
RenderX

2. What are the barriers to and enablers for the uptake and implementation of these interventions for clinicians and patients transitioning from hospital to home?

Stage 2: Identify Relevant Studies

A comprehensive search strategy will be developed by an information specialist relevant to MEDLINE, CINAHL, Embase, and the Cochrane Central Register for Controlled Trials. The MEDLINE strategy will be peer-reviewed by another information specialist according to the PRESS (Peer Review of Electronic Search Strategies) guidelines [40]. The search strategies are available in Multimedia Appendix 1.

Once the searches have been completed, the results will be exported to Covidence [41] for storage, removal of duplicates, and screening. In addition, we will conduct a manual search of the references from the included studies and a targeted grey literature search of ClinicalTrials.gov [42] and the International Clinical Trials Registry Platform Search Portal [43], as well as key digital health technology websites.

Stage 3: Select Studies

Preliminary inclusion criteria are defined following the Population, Concept, Context (PCC) format:

- Population: Patients (16 years or older) recruited before hospital discharge;
- Concept: Postcare interventions (eg, self-care, symptom monitoring, pain control and management, mobilization, follow-up appointments, ability to ask questions) using any asynchronous digital platforms such as web-based or mobile applications where information is shared or stored between patients and clinicians; and
- Context: Discharge episode from hospital to the community.

We will include primary studies (ie, randomized controlled trials [RCTs], quasi-experimental studies, pilot or feasibility studies, observational studies [case-control, cohort, cross-sectional, and descriptive studies], and qualitative studies) published between 2012 and 2022. Preliminary exclusion criteria will include: (1) pediatric, newborn care, mental health, and cancer populations; (2) synchronous non–platform-based digital health care interventions (eg, chat platform, wearable devices, prosthetics, robotics, medical imaging technology such as x-rays and ultrasounds, interventions only using a standard telephone); and (3) nonprimary studies (eg, commentaries, editorials, study protocols, and policy briefs).

Study selection will be performed independently by two reviewers (AF and RP) in two steps: (1) screening of abstracts and titles and (2) screening of full-text articles. Any disagreement in screening decisions will be resolved through discussion among the reviewers or by a third reviewer (CB). A list of the excluded studies from the full-text review will be reported using the PRISMA-ScR reporting format [39].

Stage 4: Chart the Data

Two reviewers (AF and RP) will independently pilot the data extraction by using a form designed in Microsoft Excel (Microsoft Corp.). These reviewers will then independently extract the data from the eligible studies. Data extracted will include authors, year of publication, study location, purpose, study design, theoretical approach, study population, description of intervention (and comparator), data analysis, and study results or outcomes (eg, patient outcomes, barriers, and enablers). To describe the interventions, we will follow recommendations from the Template for Intervention Description and Replication checklist [44], comprising brief name of the intervention; why; materials used; procedures; who provided; how; where; when and how much; tailoring; modifications; how well (planned); and how well (implemented).

Stage 5: Collate, Synthesize, and Report Results

We will conduct a narrative data synthesis, including quantitative descriptive analyses for quantitative studies and thematic analyses for qualitative studies. We will group data into tables by type of intervention, and by outcomes or findings.

For the barriers and enablers analysis, we will group the findings using the 14 domains of the Theoretical Domain Framework: knowledge, skills, social or professional role and identity, beliefs about capabilities, optimism, beliefs about consequences, reinforcement, intentions, goals, memory, attention, and decision processes, environmental context and resources, social influences, emotion, and behavioral regulation [45-47]. Specifically, the analysis will follow 3 steps. First, two reviewers (AF and RP) will independently map the findings to each of the Theoretical Domain Framework domains. Second, similar findings will be themed and grouped together. Third, each theme will be coded as either a barrier or an enabler. We will report the top barriers and enablers using descriptive statistics (eg, frequency and percentage for each barrier and enabler). Disagreements will be discussed and resolved by the two reviewers (AF and RP) or by consulting a third reviewer (CB).

Results

The scoping review began in September 2022 and is expected to be completed in August 2023. We have identified a total of 8333 articles. The screening process took place between September 2022 and February 2023, and data extraction is expected to be completed in April 2023. Data analyses and final results will be submitted to a peer-reviewed journal in August 2023.

Through this review, we intend to provide an overview of the current state of research on platform-based, patient-clinician digital health interventions for care transitions, including a discussion of the different types of platforms and interventions that have been studied, the evidence for their effectiveness, and the barriers to and enablers for future research in this area.

Discussion

Overall, we will provide a comprehensive picture of the current state of knowledge on the use of digital health interventions in care transitions, and the potential for these interventions to improve patient outcomes. We expect to find a wide variety of postcare interventions, some gaps in the quality of the research evidence, as well as a lack of detailed information on the digital health interventions. Our results will include an overview of patient-clinician digital health interventions for discharge or

XSL•FO
RenderX

care transitions, as well as barriers to and enablers for their implementation. In addition, this review is expected to identify research gaps that will inform the development of future patient-clinician digital health interventions.

Our review has several strengths and limitations. We designed an in-depth a priori protocol. The search strategy was developed and peer-reviewed by a research librarian with extensive knowledge in scoping and systematic reviews. However, we anticipate that the digital health interventions will be heterogeneous, making it more difficult to make comparisons and draw specific conclusions.

The results of our review would be beneficial to various stakeholders such as researchers, clinicians, administrators, and policymakers. We will disseminate our findings through publication in a peer-reviewed journal as well as by presenting our results at a scientific conference.

Acknowledgments

We thank Valentina Ly, MLIS (Health Sciences Library, University of Ottawa) for peer review of the MEDLINE search strategy and Rosie Papp for assisting with the full-text screening and data extraction.

Conflicts of Interest

None declared.

Abstract

Background: Ageism and stigma reduce the quality of life of older adults living with dementia. However, there is a paucity of literature addressing the intersection and combined effects of ageism and stigma of dementia. This intersectionality, rooted in the social determinants of health (ie, social support and access to health care), compounds health disparities and is, therefore, an important area of inquiry.

Objective: This scoping review protocol outlines a methodology that will be used to examine ageism and stigma confronting older adults living with dementia. The aim of this scoping review will be to identify the definitional components, indicators, and measures used to track and evaluate the impact of ageism and stigma of dementia. More specifically, this review will focus on examining the commonalities and differences in definitions and measures to develop a better understanding of intersectional ageism and stigma of dementia as well as the current state of the literature.

Methods: Guided by Arksey and O'Malley's 5-stage framework, our scoping review will be conducted by searching 6 electronic databases (PsycINFO, MEDLINE, Web of Science, CINAHL, Scopus, and Embase) and a web-based search engine (ie, Google Scholar). Reference lists of relevant journal articles will be hand-searched to identify additional articles. The results from our scoping review will be presented using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Scoping Reviews) checklist.

Results: This scoping review protocol was registered with the Open Science Framework on January 17, 2023. Data collection and analysis and manuscript writing will occur from March to September 2023. The target date for manuscript submission will be October 2023. Findings from our scoping review will be disseminated through various means, such as journal articles, webinars, national networks, and conference presentations.

Conclusions: Our scoping review will summarize and compare the core definitions and measures used to understand ageism and stigma toward older adults with dementia. This is significant because there is limited research addressing the intersectionality of ageism and stigma of dementia. Accordingly, findings from our study may provide critical knowledge and insight to help inform future research, programs, and policies to address intersectional ageism and stigma of dementia.

KEYWORDS

stigma; dementia; ageism; definitions; measures; older adults; quality of life; social inclusion; health care access

Introduction

Background

Ageism and stigma reduce the quality of life of marginalized older adults, including those living with dementia. Research shows that ageism and stigma are associated with higher rates of discrimination, lifetime victimization, social exclusion, and poorer physical and mental health [1]. Older adults are often stigmatized because of stereotypes and negative beliefs associated with old age. This type of stigma related to aging is often referred to as age stigma or ageism [2]. Ageism, like other types of stigmas (eg, stigma based on disability or a health condition, such as dementia), can exist at the individual, community, and policy levels. Ageism can occur internally or externally [2,3]. For example, ageist stereotypes can be self-internalized and create barriers to accessing health care and support services, especially for older adults with dementia. Specifically, older adults living with dementia can face intersectional or combined stigma of ageist stereotypes that overlap with dementia myths. For example, misinformation about dementia is often exacerbated by ageist stereotypes and inaccurate beliefs that dementia is a normal part of the aging process [3]. However, these myths and ageist stereotypes are harmful as they can delay a timely dementia diagnosis required for accessing support services and planning for the future. Despite this knowledge, there is a lack of understanding about the intersection and combined impact of ageism and stigma of dementia [2-4]. Accordingly, this intersection of ageism and stigma of dementia may exacerbate existing health inequities grounded in the social determinants of health, such as access to health care and support services.

Ageism and stigma of dementia are complex constructs that are often embedded within deep-rooted societal issues. More specifically, different forms of stigma (eg, stigma based on age, health condition, and disability) often converge and intersect (ie, intersectionality) to create health inequities and reduce health outcomes at the population level [5-7]. Accordingly, stigma toward individuals based on their age cannot be addressed separately from stigma based on individuals' health conditions, such as dementia.

Any intervention designed to mitigate the combined effect of ageism and stigma of dementia requires knowledge of the core definitions, indicators, and measures used to track and evaluate their outcomes. Currently, there is a paucity of literature and no scoping review examining both ageism and stigma. However, a review is necessary to provide evidence-informed research of key measures to identify, monitor, and evaluate the impact of ageism and stigma of dementia. Accordingly, our scoping review will focus on understanding the core definitions and measures used to address ageism and stigma toward older adults living with dementia.

Stigma

In Goffman's renowned work, "Stigma: notes on the management of spoiled identity" [8], stigma is defined as attributes or characteristics that are socially discrediting. In comparison, Corrigan and Watson [9] describe stigma in terms of stereotypes (negative beliefs), prejudice (agreement with beliefs), and discrimination (discriminatory actions or behaviors) against themselves (self-stigma) or a group of people (public stigma). Corrigan and Watson [9] further explain that prolonged exposure to stigma contributes to the internalization of self-stigma. Link and Phelan [10] suggest that stigma involves components of stereotyping, labeling, and categorization of separation between "us" and "them," which can lead to social exclusion, rejection, and discrimination. Although several definitions of stigma exist, there remains little consensus on a shared definition of stigma [11]. Without a shared definition, it is difficult for researchers to compare, monitor, and evaluate the impact of stigma on dementia.

Ageism

The term ageism was first coined by Robert Butler [12] to define structural stereotypes and discrimination against older adults based on perceived old age. Ageism is often described in terms of negative beliefs, discriminatory actions, and stereotypes (e., severely impaired) toward older adults held by young, middle-aged, and older adult age groups [5,13,14]. Issues of ageism transcend our societal fabric through cultural values, beliefs, and media [15]. Research shows that ageism negatively impacts the health equity and outcomes of older adults. Specifically, ageism is linked to reduced physical health, poorer mental health, and earlier mortality [16,17]. Ageism is also associated with risky behaviors that impact health outcomes, such as excessive alcohol consumption, smoking, addiction, poor diet, and a reduced quality of life [5,18].

Rationale

Ageism and stigma toward older adults can lead to serious consequences, including depression, social isolation, feelings of shame, and social exclusion [5,19]. More specifically, research shows that older adults with disabilities are often shunned, excluded, and stripped of their social status [20]. Despite this knowledge and the fact that dementia is one of the major causes of disability, few studies examine the intersection of ageism and stigma toward older adults with dementia [5]. However, to address the intersectionality of ageism and stigma of dementia, a comprehensive understanding of the definitional components and measures is required. Accordingly, the objective of this scoping review will be to identify the existing definitions and measures used to track and evaluate the impact of ageism and stigma on older adults with dementia. More specifically, this review will explore the commonalities and differences in definitions and measures to develop a better understanding of intersectional ageism and stigma of dementia.

Methods

Scoping Review Framework

Guided by Arksey and O'Malley's [21] scoping review framework, our review will include the following five steps: (1) identification of the study's aim; (2) examination of relevant studies; (3) study selection; (4) extraction of the data; and (5) collating, summarizing, and reporting the research findings. Arksey and O'Malley [21] propose an optional consultation process (step 6) involving key stakeholders to provide input in the scoping review (eg, references, interpreting the findings, and dissemination strategies). However, due to limited time and financial resources, this step will not be included in our study.

Step 1: Identification of the Study's Aim

The aim of the scoping review will be to synthesize the current state of the research by identifying the definitional components, indicators, and measures used to track and evaluate the impact of ageism and stigma of dementia. More specifically, this review will examine the commonalities and differences in definitions and measures to gain a better understanding of intersectional ageism and stigma of dementia.

Step 2: Identification of Relevant Studies

Studies will be retrieved by searching various electronic databases, including PsycINFO, MEDLINE, Web of Science, CINAHL, Scopus, Embase, and Google Scholar. In addition, reference lists of relevant studies will be searched to identify any additional journal articles. The initial keywords that will be included in our search strategy are outlined in Table 1. We will also consult with a research librarian to inform our search strategy and provide expertise to ensure that no relevant databases or search words are missed. More specifically, each database (eg, MEDLINE) may require its own search strategy using Medical Subject Heading terms, which may greatly improve our search results. Our search timeline will focus on peer-reviewed journal articles published from January 1, 2008, to January 1, 2023. This time frame was selected to ensure that our findings are representative of relevant theories and methods that are currently being used to define and measure ageism and stigma of dementia.

Table 1. Keyword search strategy. Databases and search engines used were PsycINFO, Web of Science, MEDLINE, CINAHL, Embase, and Google Scholar.

Concept	Keywords
Older adult	Older adult* OR Older adulthood* OR Aged* OR Aging
Dementia	Dementia* OR Cognitive impairment* OR Alzheimer's disease* OR Parkinson's disease* OR Cognitive aging*
Stigma OR Ageism	Stigma* OR Ageism* OR Attitude* OR Stereotype* OR Discrimination* OR Bias* OR Prejudice*
Definition	Define* OR Definition*
Measure	Measure* OR Indicator*

Our inclusion criteria will focus on the following four parameters: (1) articles that are written in the English language; (2) full-text, peer-reviewed journal articles; (3) studies that include a definition of ageism and stigma or includes measurements to study the psychometric properties of ageism and stigma; and (4) research that focuses on older adults living with dementia (aged ≥60 years). Given that young onset dementia only occurs in approximately 2%-8% of people before the age of 65 years, we have decided to focus our review specifically on older adults with dementia [22].

Step 3: Study Selection

We will use Rayyan [23], a leading software tool, to help manage our data and organize our reviews. Following our inclusion criteria, 2 reviewers will independently conduct title and abstract screening. The 2 reviewers will be delegated to oversee the full-text screening of the articles. Any questions on the inclusion of articles will be resolved by discussion with a third reviewer. However, any remaining issues of uncertainty will be resolved through consensus with the full research team. Reasons for study exclusion will be documented and reported in our scoping review publication. The results of our scoping review will be presented using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Scoping Reviews) checklist [24].

Step 4: Data Extraction

Data will be extracted from the included studies using a systematic extraction approach. More specifically, a standardized data extraction form will be developed and used to chart data from the included studies. Our data extraction form will focus on collecting information on the definitions and measurements for ageism and stigma of dementia as well as identifying any similarities or distinctions between ageism and stigma of dementia (ie, in intersectionality or in assessment measures). The following data may also be included in the form: authors, date of publication, study objective, sample size, sample characteristics (eg, age and gender), study design, and study results. This data extraction form will be pilot-tested with a small number of included studies and revised as necessary. Any modifications or revisions to our data extraction form will be described in our scoping review paper. To reduce errors and ensure consistency in data extraction, one author will oversee the data extraction process. All data collected and analyzed during our scoping review will be made available on an open repository (eg, Open Science Framework) and included as supplementary files with our scoping review manuscript.

XSL•FO
RenderX

Step 5: Collating, Summarizing, and Reporting the Findings

The analysis will synthesize the evidence based on the existing literature of ageism and stigma toward older adults with dementia. Guided by the work of Arksey and O'Malley [21], our scoping review will not evaluate the methodological quality and rigor of the included studies. Using tables, findings will be presented to showcase the summarized results based on our data extraction findings. Moreover, our findings will highlight research gaps that remain underinvestigated and require further investigation.

Results

This scoping review was registered with the Open Science Framework on January 17, 2023, prior to any title and abstract screening. Data collection and analysis and manuscript writing is scheduled to occur from March to September 2023. The target date for manuscript submission will be October 2023.

Discussion

Principal Results

Addressing issues of intersectional ageism and stigma are critical to improving the quality of life of older adults with dementia. To our knowledge, our research will be the first scoping review to examine and compare the definitional components and measures of ageism and stigma of dementia. However, developing interventions to mitigate intersectional ageism and stigma of dementia requires evidence-informed research of the existing definitions and measures. This scoping review will provide a comprehensive synthesis of the commonalities and differences of the definitions and measures used to address ageism and stigma of dementia. Moreover, this review will shed light on the existing knowledge gaps and the current state of the research, which may help to inform future research, programs, and policy responses.

Our knowledge translation and dissemination strategies will focus on a range of methods, including peer-reviewed journal articles, webinars, and conference presentations. We will also collaborate with our national research networks to disseminate our review's findings. The reach of our webinars and networks will enable us to develop widespread knowledge dissemination to inform policy, practice, and research.

Although we will aim to conduct a comprehensive scoping review, it will not be without limitations. For example, an important limitation of scoping reviews is that they focus on mapping and synthesizing data rather than evaluating the strength of the evidence or assessing risk of bias in the research. Thus, further research is required to evaluate and assess the quality of the existing studies on ageism and stigma of dementia. Another limitation is that our scoping review will only include peer-reviewed journal articles; as such, it is possible that relevant grey literature may be missed and excluded from our findings. Moreover, articles that are not written in the English language will also be excluded from our scoping review. Consequently, additional research examining grey literature and non-English articles may be useful for developing further insight on intersectional ageism and stigma of dementia.

Conclusions

This review will synthesize and compare the core definitions and measures used to examine ageism and stigma of dementia. To our knowledge, this study will be the first scoping review to examine ageism and stigma toward older adults living with dementia. Our study will shed light on the existing knowledge gaps and the current state of the research. This knowledge will enable researchers, clinicians, and policy makers to better understand ageism and stigma of dementia. Consequently, the findings from our review may provide pertinent knowledge and insight to inform future research, programs, and policies to address issues of intersectional ageism and stigma of dementia.

Acknowledgments

This work was supported by Team 15 in the Canadian Consortium on Neurodegeneration in Aging (CCNA). CCNA is supported by a grant from the Canadian Institutes of Health Research with funding from several partners, including the Saskatchewan Health Research Foundation, the Centre for Aging and Brain Health, and the Alzheimer Society of Canada (ASC). This research was funded by the Canada Research Chairs Program. Funding was also provided by the Undergraduate Research Apprenticeship Fund (UGRAF) at Thompson Rivers University to support student research assistant, JM.

Data Availability

All data collected and analyzed during our scoping review will be available on the Open Science Framework repository and included as supplementary files with our scoping review publication.

Authors' Contributions

MEO, AK, JM, ALC, JDB, and SF conceived the research focus and scoping review approach with support from the Canadian Consortium on Neurodegeneration in Aging's Stigma and Social Inclusion (SSI) working group. JDB wrote the first draft of the scoping review protocol with support from AK and JM. SF, ALC, and MEO provided revisions and critical review of the paper. All authors reviewed the final manuscript.

Abstract

Background: As researchers and implementors begin to acknowledge the repercussions of institutionalized colonialism on community and individual health, the need to decolonize research has become clear. Despite this, there is neither a singular definition of decolonizing methodologies nor an overview of the shared principles and characteristics of decolonized research needed to codify this work as common practice in global health.

Objective: The review will identify papers that reference principles of decolonization and identify shared characteristics between them. The aim of this scoping review is to review decolonized research methodologies through the lens of sexual health as a step in creating a shared understanding of best practices. We will further examine the tools and methods used to collect and analyze data within the included studies.

Methods: The protocol for this scoping review was developed using the framework from the Joanna Briggs Institute and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews). The search strategy will comprise a search of electronic databases (JSTOR, Embase, EMCare, MEDLINE [Ovid], Global Health Database, Web of Science), gray literature sources, and key studies. Titles and abstracts will be reviewed by 2 or more independent reviewers against inclusion criteria. Bibliometric details, study design, methodology, community involvement, and other indicators will be collected using a data extraction tool developed for this review. Extracted data will be analyzed using descriptive statistics and qualitative analysis of content and themes to identify common practices in decolonized methodologies within sexual health. Narrative summaries will be used to describe results in relation to the research question, and identified gaps will be discussed.

Results: The initial title or abstract review of 4967 studies identified by the search strategy was completed in November 2022. In total, 1777 studies met initial inclusion criteria and were sent to a second round of title or abstract review, which was completed in January 2023. In total, 706 studies were downloaded for full-text inclusion, which is expected to be completed by April 2023. We aim to complete data extraction and analysis by May 2023 and expect to publish the findings by the end of July 2023.

Conclusions: There remains a gap in the research on the meaning and application of decolonized research strategies, particularly within sexual and reproductive health. The findings of this study will contribute to a shared definition of decolonized methodologies and how they can be applied as a common practice in global health research. Applications include the development of decolonized frameworks, theoretical discourses, and methodologies. The study will inform the design and implementation of future decolonized research and evaluation strategies, particularly around sexual and reproductive health.

Introduction

Background

As researchers and implementors in the global health and development sector begin to acknowledge the repercussions of institutionalized colonialism, the call for the decolonization of research has grown [1]. Indigenous peoples globally have felt the othering effects of traditional research and implementation strategies. These strategies often frame them as numbers in a study designed by those operating within a dominant culture rather than individuals with unique perspectives and experiences. The colonialization of research manifests itself through the identification of funding priorities and recipients, academic imperialism, methodological imperialism, dominant culture definitions of success, and not least through the prominent use of western research ideals in research design and implementation. Funding for global health originates primarily in high-income countries where it shapes research priorities and establishes the measures and indicators of success without the involvement of communities of focus [2]. Western research paradigms, such as positivism or constructivism, as well as individualist roots, have shaped the way research and knowledge are conducted and perceived, superseding culturally relevant indigenous worldviews, learning, and language [3].

This approach to research serves to undermine indigenous knowledge and extracts data from communities without the intent of directly benefitting them [1], often removing them from accessing and using the information gathered. Relying exclusively on the western paradigm may also result in the use of evaluation and research tools that do not collect accurate and valid responses [4]. A unified definition of decolonizing methodologies and an overview of their shared principles and characteristics (or lack thereof) are necessary to codify this work as a common practice in global health research. This review will examine the meaning of decolonizing research by reviewing research methods, designs, and evaluation strategies through the lens of sexual health to identify the strategies used to implement and measure decolonized research.

Decolonization of Research

The premise of decolonization is one of critiquing existing power structures and dominant culture at multiple levels. The approach is not centered specifically on human rights, sexual autonomy, or social justice. Instead, decolonization is a method of centering research, methodology, and practice within indigenous communities rather than rooting research in colonized institutions and epistemologies [5]. This scoping review defines decolonizing research as the prioritization of the needs and voices of indigenous communities in research, methodology, and practice in order to improve the caliber of assessment, analysis, and evaluation [6]. As authors such as Battiste [7] and Smith [5] emphasize, to decolonize research, it is of the utmost importance that indigenous communities and their ways of knowing lead research and that their voices are central to the process. Research paradigms should align with localized and indigenous ways of knowing to reclaim research and knowledge for indigenous peoples [3]. The decolonization of research methods will lead to indigenous research methods and provide a critique of dominant culture methodologies [5]. Decolonized research does not inherently mean oppositional to western methods but rather learning equally from dominant culture and indigenous methods in order to identify what is most applicable to a specific community.

While the need to decolonize research and practice has been identified and entered into the academic discourse, there is neither a clear definition for what a decolonized research methodology should entail or what elements these methodologies share nor an existing strategy to enter decolonized research methods into practice or best practice recommendations [8]. In particular, there is a need to identify these commonalities so that research strategies may be developed alongside communities to fit their specific needs, based on a body of foundational learning around decolonizing methodologies [9].

Research that is not rooted in decolonization can, and often will, result in the continued oppression of indigenous communities. These practices result in researchers and implementors entering communities and taking what they want, leaving behind little to no positive change and othering that community as a source of information rather than centering them in the work [10].

Defining Indigenous

This research frequently uses the term indigenous in reference to the communities and populations who would initially benefit from the process of decolonizing research. While there is no universally agreed-upon definition of indigenous, the United Nations proposes “those which, having a historical continuity with pre-invasion and pre-colonial societies that developed on their territories, consider themselves distinct from other sectors of the societies now prevailing on those territories, or parts of them” [11]. Based on this commonly used definition where indigenous peoples are those who existed precolonial intervention, this research uses the terminology indigenous to refer to all of the first peoples of colonized nations.

The term indigenous is also often used to refer to a minority population or a population whose practices and social norms differ from the dominant culture. In the context of decolonization, it is important to acknowledge that colonialism

XSL•FO
RenderX

has had lasting repercussions on the educational systems, research institutions, and governing bodies of the majority of the world. The argument can easily be made that the dominant culture and the institutions which uphold it do not reflect the cultures of even majority indigenous peoples. Colonialism has also had a lasting impact not only on indigenous peoples but also on formerly enslaved peoples who continue to live in spaces where colonial history has systemic ramifications on their health and well-being.

This review wishes to acknowledge the importance of indigenous research and knowledge within the context of decolonized research while still making an important distinction between the two. For the purpose of this work, indigenous research methods provide location or community-specific strategies and relationships to knowledge and data collection. Decolonization of research itself is the process of acknowledging and subsequently counteracting historical systems of power within and through the research being conducted. The two are linked, and in many scenarios, inextricable, but by no means the same.

Sexual and Reproductive Health

The recognition of colonial history, the need to decolonize research methods, and the importance of centering the voices of the community in research are of particular importance when it comes to sexual and reproductive health (SRH). Colonialism and its institutions have historically oppressed women and sexual minorities, removing the capacity for choice and agency in family planning. Colonial powers have a history of the oversexualization of indigenous women [12], gynecological experimentation, eugenics, forced sterilization [13], population control [14], homophobia [15], and more, all of which are echoed in an ongoing culture of medical experimentation in previously colonized nations [16]. This history of oppression has ramifications today in the form of perceptions around access to SRH services, reliability of institutions, discrimination in service delivery, and desire to access SRH services. As such, reproductive justice and freedom of choice are critical areas of focus for decolonization research [17].

SRH rights and services are a broad range of fundamental health rights that apply to the physical and mental health of all individuals. SRH applies to a variety of topics that include access to family planning services, sexual health information, autonomy of sexual health decision-making, pregnancy and prenatal care, access to a trained health physician throughout pregnancy and birth, prevention and treatment of sexually transmitted infections, prevention of gender-based violence, abortion services [18], the ability to freely express sexual and gender identities [19], menstrual health education and access to products, and community information on menstruation and other sexual health subjects [20]. Lack of access to SRH services can result in poor mental and physical health outcomes.

SRH is divided by sex and gender and riddled with challenging power dynamics. Gender inequality and norms affect the ability of certain populations, particularly those who identify as women or gender nonconforming, to access equitable service delivery [21]. Specific SRH outcomes, such as teenage pregnancy, unintended or complex pregnancies, underage marriage, or domestic violence, predominantly affect those who identify as women or have uteruses [22].

Colonialism is a key determinant of health outcomes and therefore must be explicitly acknowledged in research methodologies [23]. To conduct relevant and effective research on sexual health in previously colonized nations, the needs of indigenous communities must be prioritized, which require clear acknowledgment of the presence of colonialism and the ongoing ramifications of colonial intervention in communities, infrastructure, institutions, and research, in order to mitigate centuries of oppression.

There is a need to decolonize research, implementation, and evaluation design in order to ensure that the work being done is sustainable and effective, and the data collected are ethical, reliable, and replicable [24]. There is a lack of information and research on the shared characteristics of decolonized methodologies and the tools and measures of outcomes and success. This review will not assess the “efficacy” of programming in comparison with other research methodologies but rather seek to identify shared (or differing) research and data collection methods, evaluation strategies, outcome measurement, and other indicators and outcomes, and how effectively they incorporate community voices. This is the first step in developing a shared understanding of best practice in decolonized sexual health research.

An initial scan of PROSPERO, MEDLINE, Open Science Frameworks, and Joanna Briggs Institute (JBI) Database of Systematic Reviews and Implementation Reports has been conducted, and there are no past or ongoing reviews on shared characteristics of decolonized research methodologies in the context of SRH. While there have been reviews of the characteristics of specific indigenous research methodologies [25] and models of service delivery [26], participatory action research for SRH [27], and meta-reviews of the different forms of community-engaged scholarship [9], there still remains a gap in the assessment of what it means to decolonize SRH research and what tools and assessments of success researchers are using.

Objectives

There is no shared understanding of the characteristics that decolonized research methodologies share. We will address this gap in the literature by identifying the different characteristics of decolonized SRH research and interventions and the designs and methodologies on which they are based. The researchers will identify and map the tools used to define, measure, and analyze program outcomes and success in this context. Summarizing research strategies and findings will enable the researchers to identify not only recommendations for future research but also the space where there is room for growth in researching and designing decolonized SRH studies.

Review Questions

Through this scoping review, the researchers will answer the following question: What are the characteristics of decolonized research methodologies in SRH research?

The primary outcome of this research will be to identify the shared characteristics of these methodologies, including a

XSL•FO
RenderX

specific focus on the tools used to collect and analyze data. Secondary outcomes will include the specific measures and definitions of success, and how they are identified across geographic regions.

Methods

This protocol was designed using the framework for scoping review from the JBI [28] and referred back to the reporting framework of PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [29].

Search Strategy

The search strategy will aim to locate peer-reviewed published studies (including ongoing studies) and gray literature on decolonized SRH research or program implementation and evaluation published between January 2012 and December 2022. The decision to use this time frame was based on the increasing recognition of various decolonizing methodologies over the last decade [9]. This decade of research will cover a great deal of relevant research conducted while ensuring an equal representation of research based on recent methodological ideologies and trends. There will be no geographic exclusion criteria, as decolonized research can be undertaken in any location. Abstracts, posters, book reviews, and blog posts will not be included.

A 3-step search strategy will be used to ensure that the strategy is comprehensive and collects as many appropriate studies as possible. The search strategy was developed in cooperation with a librarian scientist at McMaster University. First, a preliminary limited search of 2 web-based databases (eg, MEDLINE [Ovid] or JSTOR) will be conducted (Multimedia Appendix 1). Second, an analysis will be done of the text words in the title, abstract, and index to develop an updated search strategy. This search strategy using these terms will be adapted and applied to each relevant database. The databases searched include Embase, EMCare, MEDLINE (Ovid), Global Health Database, and Web of Science. Gray literature sources include Advanced Google, World Health Organization (WHO), United Nations Children's Fund (UNICEF), United Nations Population Fund (UNFPA), Guttmacher Institute, and Médecins Sans Frontières (MSF). Finally, the resource lists of identified reports and papers will be reviewed for additional relevant studies.

Study Selection

Following the search, all identified citations will be uploaded into DistillerSR: Literature Review Software (Evidence Partners), and duplicates will be removed. Titles and abstracts will then be reviewed by 2 or more independent reviewers for assessment against the inclusion criteria for review. Potentially relevant sources will be retrieved in full and uploaded to DistillerSR for subsequent review. The full text of the citations will be assessed against the inclusion criteria by the reviewers. Reasons for the exclusion of sources of evidence will be recorded and validated by another reviewer and reported in the full scoping review. If there are any disagreements during this process, they will be resolved through discussion or by involving additional reviewers. If any existing systematic or scoping reviews are identified during the screening, relevant studies will be extracted and added to the review if not already present. The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA-ScR flow diagram to demonstrate the process of paper inclusion or exclusion.

Data Extraction

The data extraction process for reporting will first take a quantitative approach, which will allow reviewers to identify key themes for exploration. These themes will subsequently be reported in narrative form. The reporting will be compliant with the PRISMA-ScR checklist.

The reviewers will use a data extraction tool developed by them for this scoping review. The data extracted will include bibliometric details, geographic location of primary institution, geographic location of research, study design, methodology, and community involvement, as well as key findings relevant to the study question. A draft data extraction form is provided in Multimedia Appendix 2. The draft data extraction tool will be modified and revised as necessary during piloting, and all changes will be detailed in the final scoping review. The piloting process will involve researchers gathering to discuss the data extraction form, testing individually on papers selected from the preliminary research search, and making adjustments for usability. Once approved, this will be entered into DistillerSR into at least 3 levels of analysis.

Any disagreements between reviewers will be resolved through discussion. If no consensus can be reached, a third reviewer will adjudicate. Data will also be subject to quality control checks. If necessary, authors of papers will be contacted to request missing or additional data.

Analysis and Reporting

We will conduct quantitative analysis of the extracted data including descriptive statistics regarding areas of publication, institutions, income level and geographic location, and qualitative analysis of content and themes. The results will be presented in tables, charts, and figures, and a narrative summary of findings will represent the primary analysis and reporting.

Paper details will be presented in a table showing authors names, year research was published, location of research, aim or objective of study, methodology, and results. Charts and visualizations developed via descriptive statistics will be used to represent geographic location of lead author affiliations, location of funding institution, location of research, and comparison of these three. A narrative discussion of the results around shared characteristics between methodologies, data collection methods, study outcomes, community engagement strategies and leadership, development of data collection tools, and determinations of success will also be included. Thematic synthesis may be required to discuss these elements. If so, the reviewers will extract the key concepts from the text, develop descriptive codes for themes that carry across studies, and produce final analytical themes from this process [30]. The authors will further use these data to comment on unexpected findings, identified gaps, and implications for research and practice.

XSL•FO
RenderX

A narrative summary will accompany the charted results and will describe how the data relate to the stated objective and question, namely identifying shared characteristics of decolonized SRH findings. The summary will also discuss the ways in which the voices of the community of focus are centered and prioritized as well as other thematic areas that emerge over the course of the research. The team will work together to identify gaps in the research and present recommendations for future research and work in this area.

Ethics and Dissemination

Ethics approval is not required for a scoping review as the materials being used are publicly available. Dissemination will be done through conference presentation, publication in a peer-reviewed open-access journal, and dissemination among researchers and policy makers in the field of SRH research and practice. Input from leaders and practitioners in this field will be requested to support dissemination. Findings will also be available as an element of a doctoral thesis.

Results

The search strategy netted an initial 4967 studies for title or abstract review after the removal of duplicates. This initial review was conducted on Covidence and was completed in November 2022. In total, 1847 studies were marked for inclusion and exported to DistillerSR where a subsequent 70 duplicates were identified. The remaining 1777 studies were sent to a second round of title or abstract review, which was completed in January 2023. In total, 706 studies have been downloaded for full-text inclusion, which is expected to be completed by April 2023. We aim to complete data extraction and begin data analysis by May 2023. The final manuscript is expected to be submitted for publication by the end of July 2023.

Discussion

Principal Findings and Implications

The results from this scoping review will inform researchers and implementors as to the shared characteristics that decolonized methodologies in sexual health research share. In particular, in the field of SRH, where power and oppression play a critical role in the delivery and receipt of health care services, understanding how current interventions acknowledge and address this through their methodologies will provide guidance on future work. Findings from this study will provide guidance as to where there are gaps in defining and implementing decolonized research methodologies throughout the research process. Findings will also show where there are well-established methodologies for decolonizing traditional research practices, providing the first step toward the development of clear guidance for others hoping to replicate and expand on this style of research.

As the importance of decolonizing research evolves and expands, it will become important for a broad range of stakeholder groups to have access to a set of standards or recommendations regarding best practice. The findings from this scoping review will help to identify the commonalities that unite various forms of decolonized research and create a foundation for research strategies to be designed and used alongside communities of focus. Knowledge from this review may also inform researchers in the design and implementation of their own work as a point of reference for application of the strategies identified therein. Findings from this scoping review will support the existing theoretical literature from scholars such as Battiste [7] and Smith [5], who describe and identify the need for decolonized methodologies, and set the agenda for future work.The results of this analysis will support the findings of other literature which identifies the shared characteristics of related research methodologies [25] and identifies common strategies to guide researchers in the implementation of specific approaches [27], to create consensus. The findings from this review will add to the growing body of work describing and supporting the practical uses of new theories and methodologies [31].

Limitations

The primary limitation of this work is the challenge of uncovering interventions and research that may not have been conducted within the guidelines of dominant culture publication and academic authorship. A significant limitation of the search strategy was that the structure of a scoping review and the academic language used may limit the inclusion of materials outside of academic institutions. While open-source databases and other web-based resources were accessed in an attempt to identify non–peer-reviewed materials, community-led and organized interventions are less likely to have been identified and included based on how data on these projects are published and shared.

Conclusions

There remains a gap in the research on the meaning and application of decolonized research strategies, particularly within SRH. The findings of this study will contribute to a shared definition of decolonized methodologies and how they can be applied as a common practice in global health research. The study will inform the design and implementation of future decolonized research and evaluation strategies, particularly around SRH. Potential stakeholders who may use these findings include researchers, community-based organizations, and individuals within communities of focus.

Acknowledgments

We acknowledge Laura Banfield, an information specialist at McMaster University, for her expert assistance in developing the search strategy. This review will contribute toward a PhD in Global Health for MSU.

Thanks to AP for his diligent work as an independent researcher.

Abstract

Background: Indigenous food systems (IFS) consider the complex relationships and connections between land, animals, plants, water, and people. These food systems may differ between regions, Indigenous cultures, and history; however, given the similar colonial histories and policies influencing Indigenous groups in Canada, the United States, Australia, and Aotearoa (New Zealand), the IFS changes and responses in these regions may follow similar trends. Climate change and pollution continue to impact the environment in catastrophic ways, and this, in turn, impacts IFS. However, to date, there has been no review of the literature on IFS, how they are changing, and how communities are responding to these changes.

Objective: In this scoping review, we will summarize primary research in Canada, the United States, Australia, and Aotearoa related to IFS addressing the following questions: (1) What changes are IFS experiencing in the context of climate change and pollution? (2) What actions have been taken in response to IFS changes? (3) What are the characteristics of IFS research in peer-reviewed academic literature?

Methods: We will use the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for scoping reviews and the Joanna Briggs Institute reviewer's manual to inform the review process. MEDLINE, SCOPUS, International Bibliography of the Social Sciences, Sociological Abstracts, and the Bibliography of Native North Americans are the databases included in this review search. All screening and extraction have been supported by Covidence software (Veritas Health Innovation) with 2 independent reviewers conducting the abstract and full-text screening. We will map concepts and themes related to the research questions to contribute to the understanding of IFS within the academic literature and provide a narrative review of the outcomes.

Results: The electronic database searches for this review were conducted in May 2021. Screening and full-text review were initially completed in the winter of 2022. We are currently in the process of compiling results and aim to share findings in 2023.

Conclusions: This review will provide valuable insight into current IFS needs by summarizing the peer-reviewed literature on how IFS are changing because of climate change and pollution and how communities are responding to these changes. The results of this review will be shared with Indigenous communities, through academic publications, community conversations, and conference presentations.

KEYWORDS

Indigenous; food systems; Indigenous health; scoping review; traditional foods; colonization; climate change; pollution; environment

Introduction

Indigenous food systems (IFS) refer to the connections between Indigenous groups and the land; however, climate change, colonization, and pollution have resulted in detrimental impacts to the environment and access to it [1]. This influences food sovereignty and security for Indigenous groups in Canada, the United States, Aotearoa (New Zealand), and Australia in similar ways due to the shared impacts of Western-European colonization [2,3]. Food sovereignty refers to the sovereign rights of Indigenous Peoples to self-determine their own food systems, connecting with land, history, language, and ways of life [4]. Disruptions to food sovereignty can result in food insecurity, an issue disproportionately impacting Indigenous communities with prevalence rates consistently above 25% in Canada, the United States, Australia, and Aotearoa [5-7]. Additionally, inconsistent definitions and measures of food insecurity between regions and institutions may lead to underestimations of food insecurity among Indigenous communities [8].

Household food insecurity has several health implications including a greater prevalence of diabetes, heart disease, asthma, musculoskeletal diseases, intestinal disorders, and mental health disorders [9,10]. Food insecurity is more prevalent in households with children [5], and therefore it is important to consider health concerns throughout the lifespan. For example, children and adolescents in homes experiencing food insecurity are more likely to have suicidal ideation, mood disorders, and asthma [10,11]. Although much of the research to date has focused on physical and mental health implications, food insecurity is a complex public health concern that is deeply intertwined with Indigenous spiritual and emotional health and overall well-being [12].

To date, there have been no systematic explorations of IFS changes in the peer-reviewed literature. Therefore, this scoping review will characterize recent trends in peer-reviewed research concerning IFS changes and Indigenous food sovereignty with the objective of understanding the experiences of Indigenous Peoples living in Canada, the United States, Australia, and Aotearoa and how communities have observed and responded to changes in their traditional lifeways. IFS changes refer to broad adaptations to market and land-based food systems including both positive and negative impacts. For example, an IFS change could be the reduction of an animal population or a response to the loss of hunting skills where a community is educating youth through on-the-land hunting activities. This review will discuss the potential impacts of climate change and pollution on IFS, provide information on the significance of IFS, and explore how IFS have been changing in similar and different ways in these regions. Although each food system lies within a unique context, there is considerable similarity in the experiences of Indigenous Peoples within these regions, particularly as it relates to colonization [2,3]. This review will help identify those points of similarity and difference to generate a better understanding of the issues in IFS and facilitate connections between Indigenous communities and their shared experiences. The following research questions are of interest: (1) What changes are IFS experiencing in the context of climate change and pollution? (2) What actions have been taken in response to these IFS changes? and (3) What are the characteristics of IFS research in peer-reviewed academic literature?

Methods

Ontological Origins

This scoping review emerged from discussions between Indigenous scholars, academics, Elders, and community members who were focused on IFS as part of a proposed partnership between the University of Toronto, Canada and Moi University, Kenya. The creation of this review is tied to the goals of this partnership and informed by initial feedback from the community of practice in 2020 and 2021. In accordance with Indigenous communal decision-making traditions in Canada, all decisions were open to input from members of the community of practice with the goal of collective consensus on the direction of the project. Solicitation of feedback was facilitated by regular group meetings and the dissemination of project updates via email by those who were unable to attend meetings.

Eligibility Criteria

The eligibility criteria (Textbox 1) were amended following initial screening and calibration due to the significant number of citations involved. To maintain a focused scope, we excluded work that focused on colonization as a driver of environmental change and only included papers that primarily described climate change and pollution as influencing environmental changes. Works that only discussed environmental revitalization were also excluded as these papers differed significantly from the others and may require a separate review. We retained papers specific to colonization and revitalization so that we could do an additional review and synthesis if desired at a later date, as we recognize the value in these topics.

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Inclusion criteria

- Directly related to Indigenous Peoples living in Canada, the United States, Australia, or Aotearoa
- Related to Indigenous food systems or Indigenous food sovereignty
- About Indigenous food systems changes or actions to protect or revitalize Indigenous food systems related to climate change or pollution
- Primary research
- Published between 2016 and 2021
- Written in English
- Available electronically

Exclusion criteria

- Not related to Indigenous Peoples or Indigenous Peoples specifically residing in Canada, the United States, Australia, or Aotearoa
- Not related to Indigenous food systems or food sovereignty
- Not related to Indigenous food systems changes or actions to protect or revitalize Indigenous food systems related to climate change or pollution
- Not primary research (does not include data collection)
- Not published between 2016 and 2021
- Not available in English
- Papers that only document Indigenous foods (ethnobotany)
- Papers that only document the food consumption of Indigenous Peoples
- Papers that only document food literacy of Indigenous People
- Papers about teaching Indigenous Peoples how to grow or cook non-Indigenous foods or use capitalist market-based retail environments
- Papers focused on food security or insecurity for Indigenous Peoples without discussing Indigenous food systems and experiences or changes related to climate change or pollution
- Papers about Indigenous environmental management unless it explicitly includes information about Indigenous food systems

Information Sources

This protocol was developed using the methodological framework for scoping reviews outlined in the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [13] and informed by the Joanna Briggs Institute Reviewers' Manual [14]. An electronic search was conducted in the following databases: MEDLINE, SCOPUS, International Bibliography of the Social Sciences, Sociological Abstracts, and the Bibliography of Native North Americans for academic literature relating to IFS across the globe. The search strategy was developed to find journal articles focused on IFS changes or the protection or revitalization of IFS, and with the knowledge that the language used to describe those ideas can vary between countries and disciplines. Index terms were used for each database where index terms were available. Additionally, some databases may use terms that are no longer in use to refer to Indigenous Peoples, which is a limitation of the search functions. We took great care to find the articles within the limits of the databases despite knowledge of the outdated terms. All database searches were conducted on June 1, 2021. Citations obtained from the searches were exported to Covidence for the removal of duplicates and used for screening and data extraction [15]. Reference lists will not be searched for additional citations due to capacity limits. Documentation of the search strategy can be found in Multimedia Appendix 1.

Selection of Sources of Evidence

Two independent reviewers completed both the abstract and full-text screening using Covidence software [15] to facilitate the process, aligning with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. A sample of 10 papers was assessed by authors ECH and EVS to test the validity of the eligibility criteria, after which the 2 reviewers compared the screening results to calibrate the criteria and ensure a high level of rater interreliability. After calibration, screening proceeded until complete. The full-text review was completed by authors HM, ECH, YS, and EVS. All conflicts were resolved by meeting among the reviewers and reaching a consensus. Disagreements were solved by consensus, and if consensus could not be reached, the disagreements were resolved by a third reviewer.

Data Charting Process

Data extraction will be completed using a detailed template, and pilot testing will be completed with the team prior to moving forward with all data extraction. Once the data extraction tool has been adjusted, the data extraction will proceed independently. Should any clarifications be required throughout the process, the team will meet to ensure consistency with extraction. Textbox 2 provides detail on the data extracted for this review.

XSL•FO
RenderX

Textbox 2. Data extraction tool details (the data extraction tool collected information from 4 main categories with specific information represented below them).

Paper information

- Title
- First author
- Publication year
- Positionality of authors or researchers
- Additional notes

Location

- Country
- Specific Location details (ie, province)
- Type of region (ie, remote)
- Type of climate (ie, Boreal Forest)
- Additional notes

Study details

- Aim and objective
- Study design
- Dates and time
- Funding sources
- Indigenous community or organization
- Indigenous group/People
- Name of the nonhuman population (ie, Geese)
- Number of participants
- Indigenous engagement (yes/no and explain)
- Additional notes

Results

- Food system category (ie, food acquisition)
- Food system disruptors (ie, pollution)
- Food system changes
- Are food system changes the primary focus? Elaborate
- Policy recommendations
- Knowledge dissemination and translation
- Impact on community

Data Items

We are interested in collecting information on how the studies were conducted, where the study was done and with or for whom, the details describing the IFS, the changes related to the environment (eg, climate), and the community perspective and response to the food systems changes. The data extraction template addresses each of these key topics to enable us to answer the research questions of interest. Studies that only discuss changes related to colonization and community responses without describing specific IFS changes will not be captured in this review.

For this review, "Indigenous Peoples" are defined as those who self-identify as Indigenous. In Canada, Indigenous groups may include Inuit, Métis, and First Nations, including any of the over 600 First Nations communities. In Aotearoa, the Māori people are the Indigenous Peoples of the land, in the United States, Native American Peoples, American Indians, and Alaska Natives, and in Australia, this includes Aboriginal and Torres Strait Islanders. We recognize that not all Indigenous groups identify with the same terminologies, and so we aim to be inclusive and respectful of local terminology; however, previous publications included in this review may use outdated terms.

XSL•FO
RenderX

We will aim to use the most up-to-date terminology even if it differs from language used in previous publications.

"Indigenous food systems" (IFS) are any traditional foods and foodways that any self-identified Indigenous group living on the lands known today as Canada, the United States, Aotearoa, and Australia defines as such. Generally, these systems are deeply connected to the lands and environments from which they emerged within these regions.

Synthesis of Results

Results will be presented both quantitatively and qualitatively by providing numerical and descriptive details of the papers included. We will map the findings and conceptualizations of this work, and present the number of studies screened, included, and excluded at each stage of this review using tables and diagrams. The results will be mapped into categories based on research objectives (ie, climate change) and themes will be described. In addition to mapping and describing the outcomes specific to environmental changes and community responses to these changes, we will compare the methodologies used and discuss these approaches in detail. In addition, it is important to note that we will include Indigenous community and scholar involvement in the interpretation and mapping of this work.

Ethical Considerations

All data in this review will be gathered through database searches of primary research and does not include identifiable individual data. Only secondary analyses will be conducted; therefore, no research ethics approval is required for this scoping review. This protocol was registered with the Open Science Framework on January 13, 2022 (10.17605/OSF.IO/XRJ87).

Results

The electronic database searches for this review were conducted in May 2021. Screening and full-text review were initially completed in the winter of 2022. We are currently in the process of compiling results and aim to share findings in 2023.

Discussion

We describe the protocol for a scoping review of academic, peer-reviewed literature about IFS changes and Indigenous food sovereignty in Canada, the United States, Australia, and Aotearoa. To our knowledge, no review of the literature on IFS changes and community responses related to climate change and pollution has been completed to date. We will provide a description of the research area and identify gaps for future investigation, as well as lay the basis for future comparative work in IFS research on a global scale. We anticipate that this scoping review will provide knowledge about IFS changes and experiences related to climate change and pollution, actions taken to protect IFS, and characteristics of IFS. This focus on the impacts of environmental changes on IFS and responses to these changes is important in understanding community-driven solutions, which we hope will benefit Indigenous public health and provide knowledge for future research with Indigenous Peoples for IFS.

Through this review, we will help identify current demographic and methodological priorities and clarify what kinds of questions, methodologies, and conclusions are proliferating in the research area. Peer-reviewed academic literature is generally privileged in funding and dissemination, and therefore it is crucial to understand what messages are being sent about IFS through academic publications [16,17]. This is particularly important work as Indigenous voices have traditionally been excluded from institutional knowledge production [18].

In addition to the value of this review, our protocol is robust and limits bias by including various subject-specific databases, 2 independent reviewers, and consideration of region-specific terminology. However, this protocol is limited in that there are additional databases that could be included to expand the search. Our work also only includes primary research published in peer-reviewed journals; therefore, community projects that are published elsewhere are not included and may limit findings. While we do our best to use appropriate and context-specific terminology in our searches, it is possible that outdated terminology is included through database indexing and previous publications, and work using other terminology is missed.

Dissemination of this work will be completed through both academic publications and community conversations to ensure that communities can benefit from this knowledge. This review is important in understanding the primary research completed to date and areas for further exploration in the future. Ultimately, completing this review benefits not only academics but also Indigenous Peoples seeking to revitalize IFS for the health of their communities and future generations and will help to inform global climate policy directions.

Acknowledgments

For advice in the construction of the scoping review methodology, we would like to thank Jenaya Webb (Research Librarian, University of Toronto) and Desmond Wong (Outreach Librarian, University of Toronto). We also acknowledge the conceptual contributions of Erica Di Ruggiero, Paula Braitstein, and Kimberly Fairman.

With respect to the conventions of Indigenous literature, author positionality statements are offered to assist readers in understanding the worldviews contributing to this protocol (ie, its ontological origins) with additional details provided in the Authors' Contributions. HM is a registered dietitian with a PhD in Nutritional Sciences from the University of Toronto and is of Scottish, Irish, French, German, and English settler ancestry. ECH is a PhD student in Rehabilitation Science at the University of Toronto of Irish settler ancestry. YS is a Master of Medical Science candidate at the University of Toronto, with a focus on population health research. She is a settler of Iranian background. EVS is a research assistant of white settler ancestry who holds an MSc in Anthropology from the University of Toronto with a Collaborative Specialization in Indigenous Health. AMP is an Algonquin

XSL•FO
RenderX

Assistant Professor and the Associate Director of the Waakebiness-Bryce Institute for Indigenous Health, Dalla Lana School of Public Health, University of Toronto.

Data Availability

Our search strategy is available in Multimedia Appendix 1. Journal articles at each of the review stages and review results will be published and available upon request.

Authors' Contributions

HM began providing support to this review after the initial database search and then guided the full-text screening and data extraction, providing a significant contribution to the writing and registration of this protocol. ECH began supporting this review during the database searches and provided guidance throughout the duration of the project. YS assisted with the full-text screening, data extraction, and writing stages of the scoping review. EVS was recruited to the project based on experience with scoping study methodology; she had a significant role in conceptualizing the objectives of the review, developing search strategies, and supervising initial search strategy implementation. AMP developed the project and assisted with the protocol for the scoping review.

Conflicts of Interest

None declared.

Abstract

Background: Latin America, Africa, and Asia have high incidences of syphilis. New approaches are needed to understand and reduce disease transmissibility. In health care, spatial analysis is important to map diseases and understand their epidemiologic aspects.

Objective: The proposed scoping review will identify and map the use of spatial analysis as a tool for syphilis-related research in health care.

Methods: This protocol was based on the Joanna Briggs Institute manual, guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR). We will conduct searches in Embase; Lilacs, via the Virtual Health Library (Biblioteca Virtual en Salud; BVS), in Portuguese and English; Medline/PubMed; Web of Science; Cumulative Index to Nursing and Allied Health Literature (CINAHL); and Scopus. Gray literature will be searched for in Google Scholar, the Digital Library of Theses and Dissertations, the Catalog of Theses and Dissertations of the Coordination of Improvement of Higher Education Personnel (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior; CAPES), Open Access Theses and Dissertations, ProQuest Dissertations and Theses Global, and the Networked Digital Library of Theses and Dissertations. The main research question is “How has spatial analysis been used in syphilis-related research in health care?” Studies are included if they have the full text available, address syphilis, and use geographic information systems software and spatial analysis techniques, regardless of sample characteristics or size. Studies published as research articles, theses, dissertations, and government documents will also be considered, with no location, time, or language restrictions. Data will be extracted using a spreadsheet adapted from the Joanna Briggs Institute. Quantitative and qualitative data will be analyzed using descriptive statistics and a thematic analysis, respectively.

Results: The results will be presented according to the PRISMA-ScR guidelines and will summarize the use of spatial analysis in syphilis-related research in health care in countries with different contexts, factors associated with spatial cluster formation, population health impacts, contributions to health systems, challenges, limitations, and possible research gaps. The results will guide future research and may be useful for health and safety professionals, managers, public policy makers, the general population, the academic community, and health professionals who work directly with people with syphilis. Data collection is projected to start in June 2023 and end in July 2023. Data analysis is scheduled to take place in August and September 2023. We expect to publish results in the final months of 2023.

XSL•FO
RenderX

Conclusions: The review may reveal where syphilis incidence has the highest incidence, which countries most use spatial analysis to study syphilis, and whether spatial analysis is applicable to syphilis in each continent, thereby contributing to discussion and knowledge dissemination on the use of spatial analysis as a tool for syphilis-related research in health care.

KEYWORDS

treponema pallidum; syphilis; infectious diseases; spatial distribution; systems of geographic information; spatiotemporal analysis; health care; surveillance; spatial analysis; geographic information; policy maker

Introduction

Spatial analyses are techniques performed on geographic data that describe an entire geographic region or a single point in space [1] to measure, interpret, and explore characteristics and associations [2]. These analyses are an important tool in health care for mapping diseases and understanding their epidemiology [3,4].

The evolution of computer science has improved and expanded software development, increasing the applicability and accessibility of spatial analysis [2]. Visualizing geographic areas has enabled the mapping of disease distribution, risks and correlated factors, and the physical and human structures of health services. Spatial analysis is a useful tool to visualize areas with the greatest epidemiological pressure and infer associations between the studied phenomenon and sociopolitical and economic factors that contribute to it [5,6]. Therefore, spatial analysis contributes to planning, implementing, and assessing global health policies [3,4].

In the context of health care, it is equally important to consider the location and characteristics of where people seek care. Thus, spatial epidemiology has evolved rapidly in recent years. Research has developed to include geocoding, distance estimation, residential mobility, record linking, data integration, spatial and spatiotemporal clustering, small area estimation, and Bayesian applications for disease mapping. Computer-based geographic information systems for integrating and analyzing geographic data are applicable in epidemiology, contributing, for example, to disease mapping, rate smoothing, cluster or hot spot analysis, and spatial modeling [2].

Documenting the role of the geographic environment where individuals live and interact (often called “activity spaces”) will improve our understanding of health outcomes. This is because the place where an individual lives or works can be considered as a potential determinant of disease; this has profound political implications for local health interventions and resource-allocation decisions and will ultimately lead to a reduction in health disparities [2].

Previous research has used spatial analysis to map disease distribution (eg, for multiple sclerosis [7], HIV [8], and COVID-19 [9]), and spatial analysis could also guide health strategies against syphilis [10], which has a high incidence and represents a problem for public health worldwide, especially in Latin America, Africa, and Asia [11,12].

Syphilis spreads via sexual or vertical transmission. It can be asymptomatic, can manifest as spots on hands and feet, and can affect the functioning of several organs (in the systemic phase). Gestational syphilis and congenital syphilis directly impact reproductive and child health. During pregnancy, syphilis may lead to abortion, stillbirth, premature birth, neonatal death, and early or late congenital manifestations [13].

A previous study used spatial analysis to assess the epidemiological status of congenital syphilis in Brazil and found that the most affected municipalities were those with a large migratory flow, those bordering other countries, and those with many tourists [10]. Clusters of congenital syphilis were even identified in municipalities with prenatal care [14].

In China, researchers reported spatiotemporal changes in the incidence of syphilis; eastern coastal provinces showed a declining trend, whereas inland provinces showed an increasing trend, suggesting an association between epidemiological and economic issues [15]. In Italy, a study pointed out that women diagnosed with syphilis were more likely to be non-Italian, while men were more likely to be Italian [16]. Strategies to provide support services for accessing treatment have been implemented in Colombia for HIV and syphilis testing among Venezuelan migrants [17]. In Africa, the implementation of self-tests for HIV and syphilis in men’s workplaces can be thought of as an approach to increase the availability of and access to tests among men and provide linkage to treatment and prevention services [18].

New strategies are needed to reduce syphilis transmission, such as spatial analysis, which has previously been applied in syphilis-related research [10,14,15,19]. However, due to a lack of studies, how and to what extent this tool is being used is unclear. A search was conducted in July 2022 of the Joanna Briggs Institute, Cochrane Library, Web of Science, PubMed, Prospero, and Open Science Framework databases. The search found no review studies or protocols that used spatial analysis in syphilis-related research, highlighting this knowledge gap.

A scoping review identifying and globally mapping the application of spatial analysis in syphilis-related research would help researchers, managers, and health policy makers manage methodologies for disease control. Thus, this study describes a protocol for a scoping review to identify and map the use of spatial analysis in syphilis-related research in health care.

XSL•FO
RenderX

Methods

Overview

This is a protocol for a scoping review to answer broad research questions based on defined selection criteria [20]. We used the guidelines of the *Joanna Briggs Institute Reviewer's Manual* [20], based on the theoretical framework proposed by Arkey and O'Malley [21], updated by Levac et al [22], and guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) [23].

The stages of the scoping review include (1) definition and alignment of research objectives and questions; (2) development and alignment of inclusion criteria; (3) description of the search for evidence, selection and extraction of data, and presentation of evidence; (4) the search for evidence; (5) selection of evidence; (6) extraction of evidence; (7) analysis of evidence; (8) presentation of the results; and (9) a summary of the evidence, conclusions, and the implications of the findings [20].

Stage 1: Definition and Alignment of Research Objectives and Questions

The mnemonic PCC (population, concept, context) underlay formulation of the research question. This model allows broadly mapping information to identify knowledge gaps, present key concepts, quantify aspects of interest, and expose practices and evidence of a particular theme [20]. We defined the population as people diagnosed with syphilis, the concept as spatial analysis, and the context as health care. Thus, the research question is "How has spatial analysis been used in syphilis-related research in health care?"

Stage 2: Development and Alignment of Inclusion Criteria According to Research Objectives and Questions

Studies will be included if the full text is available, they address syphilis, and they use any geographic information systems software and spatial analysis technique. Studies will be included independently of sample characteristics and size. Studies published as research articles, theses, dissertations, and government documents will be considered with no location, time, or language restrictions. An external translator will be used when needed.

Studies will be excluded if they are literature reviews, debates, documents, editorials, expert opinions, comments, opinion articles, or conference or poster abstracts. Studies that do not have syphilis as the primary outcome, have an insufficient methodological description, or do not answer the research question will also be excluded.

Stage 3: Description of the Search for Evidence, Selection, Extraction of Data, and Presentation of Evidence

The search strategy will be conducted in 3 steps to reach the largest number of publications possible.

First Step: Identification of Descriptors and Keywords

An exploratory search on PubMed and the Virtual Health Library (Biblioteca Virtual en Salud; BVS) was conducted to identify the main medical subject heading (MeSH) terms and health sciences descriptors (Descritores em Ciências da Saúde; DeCS) related to the topic. The search strategy was built using 4 controlled health vocabularies, including DeCS, MeSH, Emtree, and the Tesauro Cumulative Index to Nursing and Allied Health Literature (CINAHL), to identify relevant studies and expand the results in different databases.

A search was conducted to identify synonyms and keywords. The search strategy was then expanded, checked, and improved by a librarian. Descriptors were combined with natural language [24,25] to increase sensitivity and expand the search results. The construction of the search strategy used the extraction, conversion, combination, construction, and use model [24]. This model increases the sensitivity of the search strategy by following complementary steps. Table 1 shows the conversion of mnemonic elements into the main keywords.

Multimedia Appendix 1 shows the complete search strategy built for Medline/PubMed.

Table 1. Definition of the PCC (population, concept, context) mnemonic elements.

Mnemonic elements	Definition	Keywords
Population	People diagnosed with syphilis	Syphilis; treponema pallidum; treponema infections
Concept	Spatial analysis	Spatial analysis; geographic information system; geographic information systems; disease hotspot; spatiotemporal analysis; spatiotemporal analysis; geographic mapping
Context	Health care	Identification by document reading

Second Step: Database Definition for Data Collection

After defining a search strategy with high sensitivity, data collection will be performed in the following databases: Embase, Lilacs (in Portuguese and English) via the BVS, Medline/PubMed, Web of Science, CINAHL, and Scopus.

For a gray literature search, we will consult Google Scholar, the Digital Library of Theses and Dissertations, the Catalog of Theses and Dissertations from the Coordination of Improvement of Higher Education Personnel (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior; CAPES), Open Access Theses and Dissertations, ProQuest Dissertations and Theses Global, and the Networked Digital Library of Theses and Dissertations.

Third Step: Browse Additional Sources in Selected Publication References

The reference lists of selected articles will be searched to track down eligible sources not retrieved with the search strategy.

XSL•FO
RenderX

Authors of the included studies will be consulted by email for any additional information if needed.

Stage 4: Search for Evidence

The search strategy will be adapted to each database. The free version of Rayyan (Qatar Foundation) [26] will be used for duplicate removal and study selection. Two reviewers (JdCD and YTP) will conduct a pilot test to reduce biases, standardize the selection process, and verify agreement with the study protocol. Each author will select 25 studies and read the titles and abstracts; the screening will follow the eligibility criteria. The team will then discuss any discrepancies and make necessary changes to the criteria and definitions. The screening will start only after 75% agreement is reached [20].

After the pilot test, 2 blind reviewers (JdCD and YTP) will use Rayyan [26] to read the titles and abstracts of all identified studies, evaluating them according to the inclusion criteria. In cases of disagreement, a third reviewer (RARdS) will be consulted.

Stage 5: Selection of Evidence

After reading the full text, potentially eligible publications will be retrieved in full via their titles and abstracts and exported to a Microsoft Excel database (2020 version; Microsoft Corp). Full texts will be analyzed and reasons for exclusion will be recorded. Information regarding the selection of publications, eligibility criteria, and reasons for inclusion and exclusion will be reported in the PRISMA-ScR flowchart [27].

Stage 6: Extraction of Evidence

Data will be extracted using a spreadsheet built in Microsoft Excel (Table 2). Two trained reviewers (JdCD and YTP) will extract the data.

Two reviewers will map the application of spatial analysis in syphilis-related research using geographic data and by identifying where the study was performed. The map will be developed using a Google spreadsheet.

Table 2. Data extraction variables.

Variable	Standardized method
First author and year of publication	Identify the first author and year of publication of the study
Objective	Detail the study objective
Study design	Detail the study design described by the author or authors
Data collection procedures	List the data collection technique or techniques used
Geographic extent	Identify the city, state, region, or country where the study was conducted
Syphilis, gestational syphilis, congenital syphilis	Identify the classification of syphilis
Period (in years) of the collected data	Identify the period of data collection
Visualization software	Identify the geographic visualization software
Spatial analysis method	Describe the methodology developed in the spatial analysis
Results	Describe the main study results
Challenges and limitations	Describe the main study challenges and limitations mentioned by the authors related to using spatial analysis

Stage 7: Analysis of Evidence

Results will be interpreted qualitatively and quantitatively and presented using a PRISMA-ScR flowchart [27]. SPSS (version 24.0; IBM Corp) will be used for statistical analysis. The quantitative analysis will use descriptive statistics with the absolute frequency and percentage. Thematic analysis will be used in the qualitative analysis due to its flexibility in identifying patterns in research questions [28,29]. A thematic analysis will categorize the application of spatial analysis in syphilis-related research in health care. The results will be discussed using the literature and research objectives and questions.

Stage 8: Presentation of Results

The final report guided by PRISMA-ScR will include the results in flowcharts, graphs, or figures [23]. We will use images to help readers understand the results of the studies. As the theme of the presented protocol involves spatial analysis, it is very likely that some of the results will be shown in map images.

Stage 9: Summary of Evidence, Conclusions, and Implications of Findings

After carrying out the previous steps, we will prepare a summary of the results of the scoping review linked to the objective of the study. This way, the conclusion of the study will be grounded and presented effectively. We will highlight knowledge gaps that may arise in the development of the scoping review to provide direction for future studies.

Results

This protocol will guide a scoping review to identify and map the use of spatial analysis as a tool in syphilis-related research in health care. The results will be presented according to the PRISMA-ScR guidelines [23] and summarized regarding (1) the use of spatial analysis in syphilis-related research in health care in countries with different contexts, (2) factors associated with the formation of spatial clusters, and (3) impacts on population health; contributions to health systems, challenges, limitations, and possible research gaps will also be summarized

XSL•FO
RenderX

to guide future research. In addition, the results of this scoping review may be useful for public health and safety professionals, managers, public policy makers, the general population, the academic community, and health professionals who work directly with people with syphilis.

This protocol will enable method replication following the principles of open science [30], minimizing the risk of bias.

Data collection is projected to start in June 2023 and end in July 2023. Data analysis is scheduled to take place in August and September 2023. We expect to publish the results of the scoping review in the final months of 2023.

Discussion

Principal Findings

This protocol will guide a scoping review to identify and map the use of spatial analysis as a tool in syphilis-related research in health care. Spatial analysis in health care research can identify the spatial distribution of high-incidence diseases, identify associations in their distribution with determining factors, and support direct health planning and actions [31-33].

The United Nations proposed the elimination of congenital syphilis by 2030, reducing its incidence to 0.5 cases per 1000 live births [34]. Strategies to prevent syphilis are a concern of authorities worldwide and are included in the sustainable development goals. Therefore, this review will help develop specific health strategies to control syphilis.

The research team involved in this protocol has experience studying syphilis and spatial analysis and has knowledge and experience in scoping reviews. A librarian helped develop the high-sensitivity search strategy, which is based on a combination of 4 vocabularies and will expand the results and allow access to the literature; an especially important point is the lack of time and language restrictions.

A test search with terms for epidemiology, treatment, prevalence, and incidence was performed in the thematic context group (on the use of spatial analysis in health care). However, the search had restricted results and directed the research question to a certain type of technique, creating bias. Thus, we left the "context" field empty and searched for all possibilities for using spatial analysis in health care.

Limitations

The study limitations will include the lack of a search for institutional sites in all countries (ie, for gray literature at these sites), but this should not affect study development. We will select essential databases to minimize this limitation. The use of descriptors and search terms in only English and Portuguese may be another limitation of the study.

Conclusions

This study protocol presents the main methodological steps that will guide the proposed scoping review and identify and map studies that use spatial analysis as a tool in syphilis-related research in health care. The review may reveal areas with the highest incidence of syphilis, identify which countries most use spatial analysis to study syphilis, and determine the applicability of the technique for syphilis research in each continent.

The results will be published in open access and peer-reviewed journals, favoring the dissemination of knowledge in the scientific community.

Acknowledgments

All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article. Part of the APF was supported by the Sífilis Não program, a project by the Brazilian Ministry of Health in partnership with the Federal University of Rio Grande do Norte.

Authors' Contributions

JdCD contributed to conception of the study; JdCD, RHL, and RARdS contributed to study methodology; JdCD, RHL, and RARdS contributed to data management; JdCD, RHL, YTP, and CdSRM contributed to formal analysis; RARdS contributed to administration and supervision; JdCD and RHL contributed to original writing; and JdCD, RHL, YTP, CdSRM, and RARdS contributed to writing, review, and editing of the manuscript. All authors read and agreed with the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Diabetes—a high-burden chronic disease—requires lifetime active management involving the use of different tools and health care resources to improve patient health outcomes. Recent studies have demonstrated promising results regarding the impact of the use of virtual care technology on the treatment of chronic diseases, such as diabetes. However, it is unclear whether the use of technologies, such as secure messaging, improves the quality of care and reduces diabetes-related costs to the health care system.

Objective: The purpose of our scoping review is to explore what is known about the use of secure messaging in the treatment of diabetes within the primary care setting and how its impact has been assessed from the patient and health system perspectives. Our review aims to understand to what extent secure messaging improves the quality of diabetes care.

Methods: Our scoping review will follow the 6-step Arksey and O'Malley methodological framework, as well as the Joanna Briggs Institute methodology for scoping reviews and their recommended tools. The tools to guide the development and reporting of the review in a structured way will include the Population, Concept, and Context framework and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines and checklist. The search strategy was developed iteratively in collaboration with a professional information specialist. Furthermore, a peer review of electronic search strategies was also conducted by an independent, third-party, professional information specialist. A systematic literature search will be conducted against databases, including Ovid MEDLINE ALL, Embase, APA PsycINFO, Cochrane Library on Wiley, CINAHL on EBSCO, and PubMed. Grey literature sources will also be searched for relevant literature. Literature on the use of secure messaging in the treatment of diabetes (types 1 and 2) within a primary care setting will be included. Two reviewers will review the literature based on the inclusion criteria in the following two steps: (1) title and abstract review and (2) full-text review. Discrepancies will be discussed to reach consensus where possible; otherwise, a third reviewer will resolve the dispute.

Results: The results and a final report are expected to be completed and submitted to a peer-reviewed journal in 6 months.

Conclusions: The review will examine existing literature to identify the impact of secure messaging in diabetes treatment within primary care settings. Research gaps will also be identified to determine if there is a need for further studies.

Introduction

The prevalence of diabetes worldwide is expected to continue to rise. From 2010 to 2030, the prevalence of diabetes among individuals aged 20 to 79 years will likely increase from 6.4% to 7.7% worldwide and from 11.6% to 13.9% in Canada [1].

Diabetes is an endocrine disorder that arises from the body's inability to produce insulin, effectively use it, or both, resulting in an unhealthy rise in blood sugar levels. Insulin is a hormone that is produced by the pancreas to regulate blood sugar. Consequences of unmanaged diabetes include pain, nerve damage, amputation, the failure of different organs, cardiovascular diseases, and more. Complications of this disease are very serious and can lead to death [2,3].

Canada's public health care system spends billions of dollars annually in the treatment of chronic diseases, and this cost is rising due to population growth and improvements in screening, diagnosis, and care. Diabetes Canada estimated the direct cost of diabetes to the Canadian health care system to be about CAD $32 billion (approximately US $24 billion) in 2023 and predicted it to reach about CAD $39 billion (approximately US $29 billion) by 2028 [3]. The province of Alberta spends approximately twice as much money on patients with diabetes compared to the amount of money it spends on those without it [4].

The recent COVID-19 pandemic has acted as a catalyst for the adoption of virtual care technology and services around the world, including Canada. The Canadian government continues to invest in virtual care technology (eg, secure messaging technology, videoconferencing technology, and other tools), in addition to the billions of dollars already invested in digital health [5]. *Virtual care* is defined as "[a]ny interaction between patients and/or members of their circle of care occurring remotely, using any form of communication or information technology with the aim of facilitating or maximizing the quality of patient care." *Secure messaging* is a virtual care modality defined as "the asynchronous exchange of information between providers and patients, or between providers, through electronic platforms (e.g. texting, e-mail) that adhere to the standards of safety and privacy" [6]. Effective diabetes treatment involving the tracking and monitoring of diet, blood sugar, and physical activities that involve using technology together with active treatment is shown to be cost-effective in reducing complications. The provision of remote health care services by using a variety of virtual care tools is identified by Diabetes Canada as a delivery mechanism that can improve patient outcomes by providing timely and interdisciplinary care [3]. In contrast with other outcomes of conventional diabetes treatment, the use of virtual care offers benefits, such as improved access to services in rural or remote areas, reduced wait times, the avoidance of clinician and patient travel, cost efficiencies, and even reduced carbon emissions [3,7,8]. It is unclear to what extent the use of virtual care technology in health care helps to facilitate or maximize the quality of care for patients.

Our preliminary literature scan found many studies on the use of one or another form of digital health technology (telehealth, telemedicine, telemonitoring, videoconferencing, SMS text messages, electronic health records, etc) to improve diabetes management and patient outcomes, but only a small proportion are on the use of secure messaging for diabetes management. Similar findings were also suggested by a scoping review on the costs and benefits of eHealth applications that support the independent living of older adults [9]. A literature scan on virtual care evaluations, which was conducted by the Canadian Agency for Drugs and Technologies in Health in 2021, noted that studies tend to assess combined virtual care modalities (eg, video and telephone), making it difficult to provide informative evidence on the impact of a specific modality [10].

There is some evidence suggesting that the use of virtual care technology in the management of diabetes and other chronic diseases is associated with positive clinical outcomes that, in some cases, are comparable to those of in-person care [11-15]. Moreover, the use of asynchronous electronic communications tools is shown to improve primary care providers' access to specialists, minimize unnecessary referrals, and reduce call volumes to providers [3,16-19]. However, negative impacts on clinicians' workloads and mixed inconclusive impacts on certain clinical outcomes (eg, blood pressure and cholesterol) and aspects of the quality of care have also been reported [11,15,19-22].

We find that literature on the impact of secure messaging in diabetes management tends to focus on discrete outcomes, such as biomedical outcomes, cost, adoption, patient satisfaction, and workflows, among others. We posit that there is a research gap on studies that assess the impact of secure messaging in primary care through a more holistic quality of care lens (ie, safety, effectiveness, efficiency, timeliness, and patient centricity, as defined by the Institute of Medicine [23]). A recent systematic review of patient portal functionalities and outcomes of patients with diabetes also identified similar gaps and the need for further studies to understand how the use of patient portals by patients with diabetes improves health outcomes [15].

To continue investing in virtual care services, health care policy makers need evidence on both the clinical outcomes and the health system outcomes to inform their decisions. The purpose of our scoping review is to explore what is known about the use of secure messaging in the treatment of diabetes within the primary care setting and how its impact has been assessed from the patient, health system, and quality of care perspectives.

Our scoping review will contribute to existing literature by examining the literature for evidence on the impact of secure messaging in the treatment of diabetes from a more holistic quality of care perspective that includes both clinical outcomes and health system outcomes.

RenderX

Methods

Study Design

Our review will be based on the Arksey and O'Malley methodological framework for scoping reviews, which includes the following six steps: (1) identifying the research question; (2) identifying the relevant studies; (3) defining the study selection criteria; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) optionally consulting with peers for additional feedback and the validation of findings [24].

Our approach will result in the wide coverage of the literature. The decision to narrow down the literature will be made once the reviewers have a sense of the volume and general scope of the literature and gain familiarity with the literature and the field, after conducting the search [24]. The tools recommended by Levac et al [25] and the Joanna Briggs Institute [26-28], which are grounded on Arksey and O'Malley's [24] earlier work, will be leveraged to conduct and report our scoping review in a structured way. These tools include the Population, Concept, and Context (PCC) framework and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines and checklist.

Stage 1: Identifying the Research Question

Our scoping review aims to address the following research questions:

1. How is secure messaging used in the treatment of diabetes within the primary care setting?
2. Which outcome measures are used?
3. What is the impact of using secure messaging on the quality of care?
4. What are the facilitators, risks, and challenges of adopting secure messaging for diabetes care?

Stage 2: Identifying Relevant Studies

The PCC framework was utilized to identify the main concepts of the research questions (Table 1). Initial iterative searches in MEDLINE were conducted by the principal investigator (AL) to identify relevant articles and subject headings.

Table 1. Population, Concept, and Context framework and search terms.

	Main concept keywords	Alternative keywords	Medical Subject Headings
Participants	• *diabetic patients*	• *Diabetes Mellitus*	• *Diabetes Mellitus*
Concept	• *secure message*	• *secure messaging* • *secure communication* • *secure email* • *virtual care* • *virtual health* • *telehealth* • *telemedicine* • *e-visits data* • *mhealth* • *patient portal*	• *Electronic Health Records* • *Communication* • *Telemedicine* • *Patient portal* • *Personal Health Records* • *Computerized Medical Records Systems* • *Electronic Mail*
Context	• *Primary healthcare setting*	• *Primary care setting* • *Community setting* • *Outpatient setting*	• *Primary Health Care* • *Community Health Services* • *Outpatient*

Further iterative searches against MEDLINE were conducted in collaboration with a professional information specialist, resulting in a more refined search strategy that produced 4972 results (Multimedia Appendix 1). This search strategy was then submitted to a second information specialist for a peer review assessment and the validation of the quality and comprehensiveness of the search strategy, in accordance with the PRESS (Peer Review of Electronic Search Strategies) 2015 guideline [29]. Comments were reviewed, and adjustments were made to the strategy as deemed appropriate.

The intervention of interest is secure messaging use in the treatment of diabetes within primary care settings. The care settings will comprise noninstitutionalized and nonhospital settings. This aligns with the definitions of *primary care* by the World Health Organization [30] and Health Canada, whereby primary care is considered an "element within primary health care that focusses on health care services, including health promotion, illness and injury prevention, and the diagnosis and treatment of illness and injury" [31].

Our strategy utilizes a combination of controlled vocabulary (eg, *Diabetes Mellitus*, *Telemedicine*, and *Patient Portals*) and free-text terms (eg, *NIDDM*, *virtual consult*, and *secure email*). Using the Ovid platform, we will search Ovid MEDLINE ALL, Embase, and APA PsycINFO. We will also search the Cochrane Library on Wiley, CINAHL on EBSCO, and PubMed. Vocabulary and syntax will be adjusted across the databases. No language or date limits will be applied, but animal-only records will be removed where possible. Results will be downloaded and deduplicated by using EndNote 9.3.3 (Clarivate Plc) and uploaded to Covidence (Veritas Health Innovation Ltd).

The reference lists of all included studies will also be hand searched to identify additional literature that may not be captured through the database search. Additional grey literature will also be identified through an existing network of reviewers, relevant

XSL•FO
RenderX

journals, organizations, conferences, and a community of practices across the globe. EndNote software will be utilized to manage references.

Stage 3: Defining the Study Selection Criteria

Based on the research questions and objectives, the inclusion and exclusion criteria shown in Table 2 will be used to initially guide the review. The further refinement of these criteria will occur in an iterative manner as the reviewers gain a better understanding of the scope of available literature. In alignment with the PCC framework, the initial inclusion criteria will include those for the population (patients with diabetes), concept (secure messages), and context (primary and community care settings). The use of secure messaging for patient-provider, caregiver-provider, and provider-provider communications will be included. The initial exclusion criteria will be patients with gestational diabetes, other virtual or digital health interventions, and institutionalized or hospital settings.

Table 2. Inclusion and exclusion criteria.

	Inclusion criteria	Exclusion criteria
Year of publication	• No limit	• N/A[a]
Language	• English	• All other languages
Population	• Patients with diabetes (types 1 and 2)	• Patients with gestational diabetes
Concept or intervention	• Secure message	• Other virtual care modalities (videoconferences and phone calls)
Context and setting	• Primary health care setting • Primary care setting • Outpatient setting • Community setting	• Hospital setting • Inpatient setting • Institutionalized treatment within acute care setting
Study design	• Studies that contain defined impacts and outcomes of secure messaging for diabetes treatment	• Studies that do not contain defined impacts of secure messaging for diabetes treatment • Commentaries • Opinions • Summary articles • Clinical trial recruitments • Scoping or systematic review protocols • Abstracts
Outcomes	• All patient-related clinical outcomes and health system outcomes (eg, patient experience, patient clinical outcomes, health system outcomes, health care utilization, quality of life outcomes, health status, emergency room visits, follow-up visits, etc)	• Nonclinical outcomes and outcomes unrelated to health systems

[a]N/A: not applicable.

Stage 4: Charting the Data

The review team consists of the following three reviewers: the principal investigator (AL), the supervisor (DM), and the cosupervisor (TS). Due to its convenience, Covidence will be used by the reviewers to independently screen the articles, based on the inclusion and exclusion criteria, in the following two steps: (1) title and abstract review and (2) full-text review of the full-text articles and documents. To be more inclusive and reduce the risk of excluding relevant studies, any articles that reviewers are unsure of during the title and abstract scan will be moved forward to the full-text review stage.

Data extraction will be conducted outside of Covidence, using a charting form (Multimedia Appendix 2) that we initially created based on Arksey and O'Malley's [24] recommendations, which include the following elements: author(s), year of publication, study location, intervention type, comparator (if any), duration of the intervention, study populations, aims of the study, methodology, outcome measures, and important results.

Two reviewers will pilot the data extraction form on the first 30 articles to identify the need for modification. The review team will further revise the form, as needed, during the data extraction process as new relevant data types and themes are encountered.

Stage 5: Collating, Summarizing, and Reporting the Results

The review team will utilize the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) chart and PRISMA-ScR checklist [27] to report their findings in a clear, transparent way (Multimedia Appendix 3 [28] and Multimedia Appendix 4 [27]).

A narrative summary of findings will be developed based on the elements of the data extraction form and guided by the context of the research question and study objectives.

XSL•FO
RenderX

Throughout the course of the review, if other criteria or elements are uncovered, the authors will decide on other additional formats (eg, graphs, tables, and diagrams) for presenting the study findings.

Stage 6: Peer Consultation for Feedback and Validation

At different stages, experts will be consulted to review and provide feedback. In stage 2, prior to executing the final search, the search strategy will undergo a peer review by a qualified librarian to ensure relevance and achieve more holistic search results. Other experts within the field will also be drawn from our networks to ensure that relevant findings are captured and reported in a clear manner. In stages 3 to 5, experts will also be consulted to suggest additional literature and provide feedback on the data extraction form.

The experts we consult will include researchers and practitioners within the digital health field and decision makers from publicly funded payer organizations.

Ethical Considerations

Neither ethics approval nor participant consent is required, as our scoping review will not include human or animal participants. Data will be collected from published literature.

Results

The systematic literature search of databases has been conducted, and the title and abstract review is planned to commence in early September 2022.

An article of the scoping review findings will be submitted for publication in a peer-reviewed journal. The final version of findings and the full-text article will be shared with a panel and wider stakeholder organizations.

Discussion

Overview

Our scoping review will explore what is known about the use of secure messaging in the treatment of diabetes within the primary care setting. The review will contribute to knowledge on this topic by examining how the impact of secure messaging has been assessed from the patient, health system, and quality of care perspectives. To our knowledge, this has not been the focus of previous reviews [11,15,22,23].

The findings of the scoping review will inform health care policy makers' decisions on virtual care services.

Strengths and Limitations

Our scoping review will use an established framework and a comprehensive systematic search to identify and review existing literature on the use of secure messaging in the treatment of diabetes to date. The search strategy is peer-reviewed, and the grey literature search and the review will be informed and guided via consultation with experts. Although the findings will be useful in understanding the state of the literature and potential research gaps, the study does not aim to conduct a full assessment of the quality of the evidence in the literature uncovered.

Acknowledgments

The study design, conceptualization, and manuscript were developed by AL, under the supervision of DM and TS, who reviewed and approved the draft and final version of the review protocol. EA reviewed the draft and provided input and feedback on research objectives, definitions of key terms, and accompanying literature sources.

The authors consulted with Simon Hagen (Canada Health Infoway), who provided guidance on sources of grey literature for consideration.

We thank Kaitryn Campbell, MLIS, MSc (St. Joseph's Healthcare Hamilton/McMaster University), for peer reviewing the MEDLINE search strategy.

Abstract

Background: Pelvic fractures can lead to disability and a poor health-related quality of life, thereby contributing to the burden of disease in South Africa. Rehabilitation plays an important role in improving the functional outcomes in patients with pelvic fractures. However, there is limited published research that presents optimal interventions and guidelines to improve outcomes in affected individuals.

Objective: The purpose of this study is to examine and map the range of and gaps in rehabilitation approaches and strategies used by health care professionals globally in the management of adult patients with pelvic fractures.

Methods: The synthesis of evidence will follow the framework outlined by Arksey and O'Malley and supported by the Joanna Briggs Institute. The identification of research questions; the identification of relevant studies; the selection of eligible studies; charting data; collating, summarizing, and reporting of the results; and consultation with relevant stakeholders will be undertaken. Peer-reviewed articles written in English; from quantitative, qualitative, and mixed methods studies; and searched through Google Scholar, MEDLINE, PubMed, and Cochrane Library will be considered. Studies eligible for selection will be full-text articles written in English about adult patients with pelvic fractures. Studies on children with pelvic fractures and on interventions following pathological pelvic fractures as well as opinion papers and commentaries will be excluded from the study. Rayyan software will be used for title and abstract screening to determine inclusion in the study and to improve collaboration between the reviewers. The Mixed Methods Appraisal Tool (version 2018) will be used to appraise the quality of the studies.

Results: This protocol will guide a scoping review to examine and map the range of and gaps in rehabilitation approaches and strategies used by health care professionals globally in the management of adult patients with pelvic fractures, irrespective of level of care. Impairments, activity limitations, and participation restrictions in patients with pelvic fractures will be highlighted, which will give an indication of the rehabilitation needs of the affected individuals. Results of this review might provide evidence for health care professionals, policy makers, and scholars to aid rehabilitative care and further integration of patients into health care systems and community.

Conclusions: The rehabilitation needs of patients with pelvic fractures will be drawn from this review and will be presented in a flow diagram. Rehabilitation approaches and strategies in the management of patients with pelvic fractures will be identified to guide health care professionals in the promotion of quality health care for these patients.

rehabilitation approaches; rehabilitation strategies; adult patients; pelvic fractures; polytrauma; integrated health care; early intervention

Introduction

Pelvic fractures are mainly due to trauma [1] and can lead to disability and a poor health-related quality of life, thereby contributing to the burden of disease in South Africa [1]. The burden of disease hinders development and delays the attainment of sustainable development goals. Pelvic fractures may be complex injuries due to their association with polytrauma as a result of high-velocity impact [2]. The majority of individuals in India and South Africa who sustain pelvic fractures, secondary to motor vehicle accidents, are young male adults from both low and middle socioeconomic classes [3-5]. However, pelvic fractures in older adults are commonly associated with low-velocity impact in the United Kingdom [2].

The rate of survival of patients with pelvic fractures has increased significantly [6]. However, patients present with impairments and disabilities that affect their participation in the activities of daily living in their homes, society, and the community at large. Pelvic fractures present a challenge to the trauma and orthopedic surgeons due to their complexity [2]. They are further complicated by the associated injuries, which can lead to poor outcomes following management [3]. Poor outcomes were reported by patients following the management of pelvic fractures between 2008 and 2013 from different academic hospitals in Tshwane, South Africa (Sobantu, Skaal, and Tshabalala, unpublished data, 2017).

The aforementioned study explored the perspectives of patients on their health-related quality of life, following management of their pelvic fractures. Some of the challenges that were reported by the participants were poor mobility, chronic pain, lack of vitality, sexual dysfunction, and urinary and bowel incontinence. These challenges affected their day-to-day functioning at home, in society, in their communities, and at their workplaces. All these disabling outcomes resulted in low levels of physical health; psychological strain; poor social relations; and loss of independence in patients with pelvic fractures, regardless of the type of fracture. Pelvic fracture malunion leads to permanent disability in more than 65% of patients [7]. Some of the limitations in patients with pelvic fractures include gait abnormalities and chronic pelvic and back pain [8].

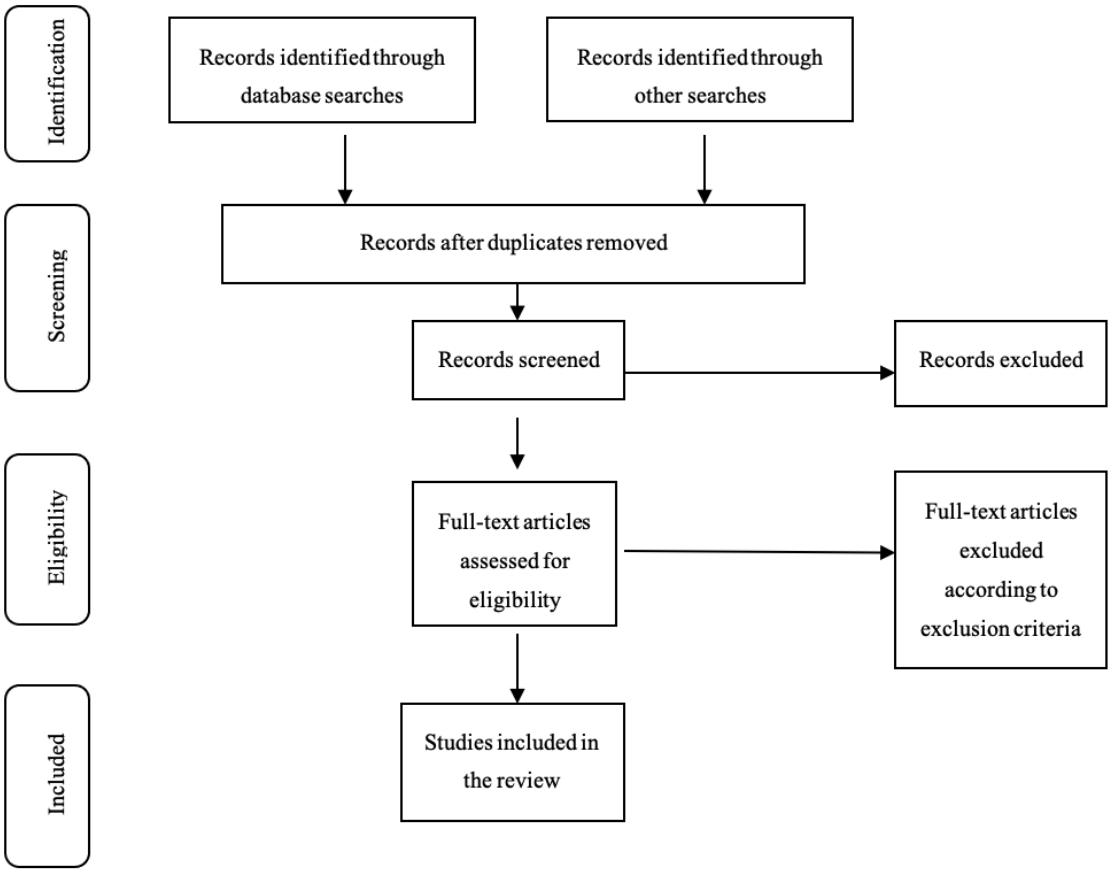
The increased survival rate of patients with pelvic fractures has been attributed to improved multidisciplinary health care management [9]. However, there is limited published research that presents optimal interventions and guidelines to improve outcomes in affected individuals. Patients with pelvic fractures commence their rehabilitation programs very late. Some patients even get discharged from hospitals before receiving rehabilitation. Health care professionals focus on the impairments that patients present with whilst hospitalized. Activity limitations and participation restrictions, which are more noticeable once the patient has been discharged, are rarely addressed. There is limited use of outcome measurement tools in these patients, especially by the rehabilitation team, to guide their progress.

Early appropriate care optimizes health care and results in fewer complications in patients following pelvic fractures [10]. The provision of early appropriate care has been a challenge in most health institutions due to limited human resources and few hospital beds. Few hospital beds lead to the early discharge of patients. These challenges lead to some patients not receiving optimum, integrated health care, including rehabilitation. Loss of continuity in health care can occur due to patients being discharged without home programs or relevant referrals for outpatient rehabilitation. Loss of continuity leads to an increase in long-term disabilities in these patients.

Even though pelvic fractures are a challenge to manage due to their complexity, no standardized comprehensive guidelines have been published to address the problems associated with them [11]. Guidelines and models are important in providing clear strategies to health care professionals involved in the management and rehabilitation of patients with pelvic fractures. Guidelines and models can assist in guiding the rehabilitation of patients with pelvic fractures within the biopsychosocial model of care, as guided by the International Classification of Functioning, Disability and Health framework [12]. An integrative rehabilitation approach will improve patient health outcomes and reduce the incidence of residual disabilities. Physiotherapists play a major role in the rehabilitation of patients with pelvic fractures. They work toward reducing pain, improving joint mobility, strengthening muscles, addressing pelvic dysfunction, and promoting function. The aforementioned aims are achieved by using therapeutic exercises, manual therapy, and electrotherapy.

Therefore, the aim of this scoping review is to examine and map the range of and gaps in rehabilitation approaches and strategies used by health care professionals globally in the management of both in- and outpatients with pelvic fractures, irrespective of level of care.

Methods



Overview

This protocol has been registered with the Open Science Framework (osf.io/f9w3z). This study protocol follows the reporting guidelines provided in the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) statement [12] and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews; Figure 1; Multimedia Appendix 1) [13]. Literature on rehabilitation approaches and strategies in the management of adult patients following pelvic fractures will be reviewed. This review will be guided by Arksey and

XSL•FO
RenderX

O'Malley's methodological framework [14]. The framework identifies 6 stages that must be considered when developing a scoping review. The 6 stages are as follows: identification of the research question; identification of relevant studies; selection of eligible studies; charting the data; collating, summarizing, and reporting the results; and consulting with relevant stakeholders. The stakeholders include the orthopedic surgeon, urologist, psychologist, physiotherapist, dietician, orthopedic nurse, occupational therapist, social worker, orthotist, and prosthetist, and general or trauma surgeon. Results of the scoping review will be sent by email to the stakeholders for critiquing and reflecting on the evidence. Virtual meetings may be arranged as a follow-up to emails should the need arise. Stakeholders will have an opportunity to provide possible solutions to develop a fit-for-purpose interprofessional education and collaborative practice model. The purpose of including the stakeholders is to ensure that the best quality of evidence is collated and implemented.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram [13].

Identifying the Research Question

The research question underpinning the review is "What rehabilitation approaches and strategies have been integrated in the management of adult patients with pelvic fractures?"

Subquestions that will guide the review are as follows:

- What evidence exists on the rehabilitation approaches and strategies for skeletal stabilization of pelvic fractures, globally?
- What evidence exists on the rehabilitation approaches and strategies for associated injuries (eg, rectal and urogenital, chest and abdomen, and other musculoskeletal systems) in adult patients with pelvic fractures?
- What evidence exists on rehabilitation interventions for impairments (eg, pain, joint mobility and function, as well as emotional and psychological challenges) experienced by adult patients following pelvic fractures?
- What evidence exists on rehabilitation interventions for functional disabilities, including mobility, urinary and bowel incontinence, and sexual dysfunction experienced by adult patients following pelvic fractures?

Information Sources and Search Strategy

Identification of studies relevant to this review will be achieved in accordance with the Joanna Briggs Institute search strategy [15]. A search for relevant literature will be conducted on the following electronic databases from 2002 to 2022: Google Scholar, MEDLINE, PubMed, and Cochrane Library. Keywords relevant to each search parameter will be separated by the Boolean terms "AND," "OR," and "NOT." A draft search strategy in PubMed is documented in Multimedia Appendix 2. The reference section of the selected studies will also be explored to identify further, potentially relevant studies that could have been missed in the initial search.

A pilot search using keywords to determine the feasibility of the study will be conducted (Multimedia Appendix 2). The search strategy will be adjusted for each database.

XSL•FO
RenderX

Eligibility of Research Studies

The study will incorporate the Population, Concept, and Context (PCC) model to align the study selection with the research question [15]. The Population, Concept, and Context model is a well-formulated model that improves scientific rigor for scoping review questions. Studies will have to include globally published articles on adult patients with pelvic fractures focused on rehabilitation approaches and strategies used during management. Rehabilitation approaches and strategies used to address skeletal stability, associated injuries, as well as impairments and disabilities in adult patients with pelvic fractures will be included. Articles on the functional outcome measurements used, home programs, and advice and education that can be given to adult patients with pelvic fractures will also be included. Peer-reviewed journal articles written in English will be included. Quantitative, qualitative, and mixed methods studies will also be included. All health care systems, including primary, secondary, and tertiary systems, will be included. Titles, abstracts, and full texts will be screened by 2 reviewers (MDT and NAS). Discrepancies and disagreements will be resolved by discussions between the 2 reviewers and a third reviewer (VC). Rayyan software will be used for title and abstract screening to determine inclusion in the study and to improve collaboration between the reviewers [16,17].

Inclusion and Exclusion Criteria

The Inclusion and exclusion criteria for studies eligible for selection are presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for study selection.

Inclusion criteria

- Articles about adults (aged ≥18 years) with pelvic fractures
- Global articles on rehabilitation approaches and strategies used during management
- Full-text studies
- Articles written in English

Exclusion criteria

- Articles on children with pelvic fractures
- Articles on interventions following pathological pelvic fractures
- Opinion papers
- Commentaries

Charting of the Data

A data charting template (Textbox 2) will be used to extract and capture information from studies through each phase of the review. The information will be about rehabilitation approaches and strategies used by the health care team in the management of patients with pelvic fractures. The chart will be continually and regularly updated by the reviewers through the scoping process to capture all possible results for the research question. Two reviewers will chart the data independently, discussing the results and updating the chart.

Textbox 2. Data charting form.

Data charting information

- Author(s)
- Year of publication
- Origin or country of origin (where the study was published or conducted)
- Aims or purpose
- Study population
- Sample size (if applicable)
- Methodology or methods
- Intervention
- Details of interventions (if applicable)
- Outcomes (if applicable)
- Details of these of outcomes (eg, how measured, if applicable)
- Key findings that relate to the scoping review question(s)
- Conclusions that relate to the scoping review questions

XSL•FO
RenderX

Collating, Summarizing, and Reporting Results

The data extracted from the studies will be guided by the research questions and subquestions. This will include evidence that exists on the rehabilitation approaches and strategies for each impairment as well as activity limitations and participation restrictions in adult patients with pelvic fractures. The stages of the scoping review promote transparency and allow reproducibility of the study by reducing the risk of bias and data duplication [14,18]. The extracted data will be summarized in the final write-up using a thematic analysis with flexibility in the capturing of data, as in the scoping review [18]. The results will be interpreted and described according to the research question and subquestions.

Quality Appraisal and Bias

Quality appraisal will be undertaken in this scoping review to ensure that strong evidence is collected, which will help to create a trustworthy guide for follow-up research projects. Performance of quality appraisal is informed by a study by Daudt et al [19] who underlined the importance of assessing the quality of studies and conducting a trial of the method before starting with the charting process, if the research is to be used to inform policy makers. The Mixed Methods Appraisal Tool (MMAT; version 2018) will be used to assess the quality of the studies from the search strategy, described above [19]. Moreover, MMAT will be used to assess and report bias from quantitative, qualitative, and mixed methods studies [20]. MMAT is suitable as the study excludes articles such as commentaries and opinion papers. The process requires critical appraisal, and therefore, 3 reviewers will be involved in the appraisal process. One reviewer has experience in MMAT application and will add rigor to the appraisal. The MMAT method allows for the inclusion of qualitative studies, quantitative randomized controlled trials, quantitative nonrandomized trials, and quantitative descriptive and mixed methods studies. Methodological quality criteria will be captured as per the MMAT by 2 reviewers, with the third reviewer overseeing the process.

Results

This protocol will guide a scoping review to examine and map the range of and gaps in rehabilitation approaches and strategies used by health care professionals globally in the management of both in- and outpatients with pelvic fractures, irrespective of level of care. Impairments, activity limitations and participation restrictions in patients with pelvic fractures will be highlighted, which will give an indication of the rehabilitation needs of the affected individuals. Results of this review might provide evidence for health care professionals, policy makers, and scholars to aid rehabilitative care and further integration of patients into health care systems and community.

Discussion

Expected Outcomes

These guidelines will inform the scoping review of examining the range of and gaps in the literature on the rehabilitation approaches and strategies for the management of patients with pelvic fractures. The rehabilitation needs of patients with pelvic fractures will also be drawn from the results of this review and presented in a flow diagram. This study might be used to inform health care professionals of the important aspects to be included in the assessment, management, and rehabilitation of patients with pelvic fractures. The results of this study might also be used to improve the physiotherapy curriculum. Approaches to health care management by health care professionals might be guided by the findings of this review. Health care professionals might be aware of the impact of pelvic fractures on the physical, mental, psychological, and socioeconomic status of the affected individuals. Health care professionals might be able to draw up relevant and patient-centered ward and home programs that can promote health-related quality of life in patients who had sustained pelvic fractures.

This scoping review is the first phase of a study that seeks to develop an interprofessional model of care for patients with pelvic fractures. It is hoped that this review will create awareness of the health care needs of patients with pelvic fractures. This awareness might prompt the health care professionals to set goals that will address most of the patients' needs. The rehabilitation approaches and strategies used by the health care professionals globally as well as gaps in the literature will be identified [21]. This information will be crucial in informing the envisaged model with the best practical evidence, especially pertaining to physiotherapy practice, for patients with pelvic fractures.

The findings of the study will also provide evidence for health care policy makers to assist the stakeholders in addressing the needs of this population by rendering quality health care.

Conclusions

This scoping review protocol outlines steps that will guide the scoping review. This review will also identify and map studies that indicate the rehabilitation approaches and strategies in the management of patients with pelvic fractures. The results of this study may promote circulation of information and knowledge among health care professionals at various levels of health care.

Limitations

Some articles might not be available in the databases that will be included in the study. Literature might also be limited since only articles written in English and available in full text will be considered for the study.

Acknowledgments

The authors acknowledge the support provided by Levin Chetty and the librarian Nomgcobo Ntsham during the development of the search strategy and literature search from the databases.

Abstract

Background: Black Canadians experience poor health care, poor health outcomes, and a greater burden of health inequalities, much of which is rooted in the unequal distribution of social determinants of health. Despite Canada's emphasis on social inclusion, Canada's Black population faces substantial social inequities that affect their health and well-being. These disparities may specifically be attributed to racial discrimination, immigration status, precarious housing, underemployment, and increased poverty among Black Canadians.

Objective: This paper describes a protocol for a scoping review that aims to understand the range and nature of research conducted on the health of Black Canadians as well as the gaps in this literature.

Methods: Arksey and O'Malley's methodological framework guided the conduct of the scoping review. We searched electronic databases (CINAHL, Embase, Global Health, MEDLINE, PsycINFO, Scopus, Sociological Abstracts, and Web of Science) and grey literature sources for peer-reviewed articles and grey reports on the health of Black Canadians. Six reviewers independently screened the abstracts and full text of studies to determine eligibility for inclusion. According to the PRISMA-ScR (Preferred Reporting Items for Systematics Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, the findings will be synthesized quantitatively and qualitatively through thematic analysis.

Results: Title, abstract, and full-text screening concluded in October 2022. Data collection is in progress and is expected to be completed by April 2023. Data analysis and drafting of the manuscript will be done thereafter. Findings from the scoping review are expected to be provided for peer review in 2023.

Conclusions: This review will collect important data and evidence related to the health (mental, reproductive, and sexual; social determinants of health) of the Black population in Canada. The findings could help identify existing gaps in the health of Black individuals in Canada and inform future research paradigms. The findings will further inform the development of a knowledge hub on Black Canadians' health.

International Registered Report Identifier (IRRID): PRR1-10.2196/42212

KEYWORDS

Black people; inequities; mental health; reproductive and sexual health; HIV; social determinants of health; Canada

Introduction

Background

Canada is a racially and culturally diverse country, much of which has been fueled by immigration and settlement of racial minority groups from Asia, the Caribbean, and Africa since the 1960s [1,2]. Today, Canada is one of the most popular immigrant destinations globally, with a growing inflow of Black migrants from sub-Saharan African and Caribbean nations [3]. Black people are the third-leading minority group in Canada, nearing 3.5% of the country's total population, with a projected increase to 5.6% by 2036 [4]. Despite persistent attempts to

XSL•FO
RenderX

support multiculturalism and racial equality in Canada, race-based social and health inequalities are still widespread [5,6]. The social, economic, and political conditions in which people grow, live, and work are largely responsible for the observed inequalities [4,7,8]. For this scoping review, we will adopt the World Health Organization's definition of health: "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" [9]. Therefore, health is broadly defined to include disease conditions; physical, mental, emotional, and spiritual well-being; access to and utilization of health care; barriers and facilitators to health; health interventions, etc.

Black people in Canada are disproportionately affected by social and health inequalities, including poor access to quality health care, education, employment, housing, and mental health support [10-13]. The inequities produced by these social determinants of health are exacerbated by Black people's experiences of precarious immigration status, poverty, and racial discrimination at both interpersonal and institutional levels [4,8,14,15]. Yet, Black people aged 25 to 54 years are more likely to have a bachelor's degree or higher (41.1%) than their nonvisible minority or non-Indigenous counterparts (34.2%) [16]. In 2018, the proportion of the Black population in Canada who resided in rented dwellings (n=695,900, 52%) was twice that for the overall population (n=9,749,700, 27%); furthermore, of those who lived in rented dwellings, the proportion of Black individuals living in unsuitable housing (n=209,800, 30%) was notably higher than that of the overall population (n=1,808,900, 19) [17].

The prolonged exposure to trauma caused by oppression, colonialism, racism, and segregation among Black people in Canada has resulted in them being underprivileged with respect to access to health services and social support systems [13]. Black Canadians experience disparities in health outcomes when compared to other ethno-racial groups in Canada [18]. For instance, heart disease and stroke are among the prominent causes of death in Canada, and Black populations are among those with the highest rate of risk factors for these conditions [4]. In addition, the proportion of Black Canadians aged 18 years and older who rated their health status to be either fair or poor was higher (14.2%) than that of their White Canadian counterparts (11.3%) [4]. About 64% of young Black women between the ages of 12 and 17 years described their mental health to be "excellent" or "very good," which is substantially lower than the 77.2% reported by their White counterparts [4]. Black Canadians experience notable social and economic difficulties that have deleterious consequences on their mental health [19]. This includes disparities in access to mental health services among Black Canadians, which may be attributed to having few Black mental health service providers in the health care system. Indeed, Black Canadians have indicated their interest in accessing mental health care services with Black service providers [20]. The mental health of youth and children in Canada has become a public health problem and has been attributed to the inaccessibility of mental health care services [21]. The Black community in particular has emphasized the need to tackle the mental health issues that are prevalent among youth and children in their communities [22]. Finally, the Black population in Canada has been disproportionately burdened with HIV in the last 20 years. In 2017, a total of 25% of reported HIV cases were among the Black population, which is noteworthy as Black people only account for 3.5% of Canada's total population; in contrast, their White counterparts, who make up almost 75% of Canada's population, represent only 35% of reported cases [23]. Timely access and provision of health care services are major determinants of health for people living with HIV; however, Black populations face inequities that hinder their access to health care services [24].

These disparities suggest a need for innovative research focusing on Black Canadians' health. A scoping review of the literature chronicling existing research on the health of Black Canadians is a critical step in this regard. This project will synthesize this literature and explain the nature and breadth of research on the health of Black Canadians, as well as gaps to be addressed by future research. The findings from the scoping review will inform the creation of a knowledge hub on Black health in Canada. The purpose of this scoping review is thus to map out the scope of the literature on health (including disease conditions; physical, mental, emotional, and spiritual well-being; access to and utilization of health care; barriers and facilitators to health; health interventions, etc).

Objectives

The review will address two specific objectives:

1. To identify the extent, range, and nature of the literature on the health of Black Canadians; and
2. To identify gaps in the literature on the health of Black Canadians.

Methods

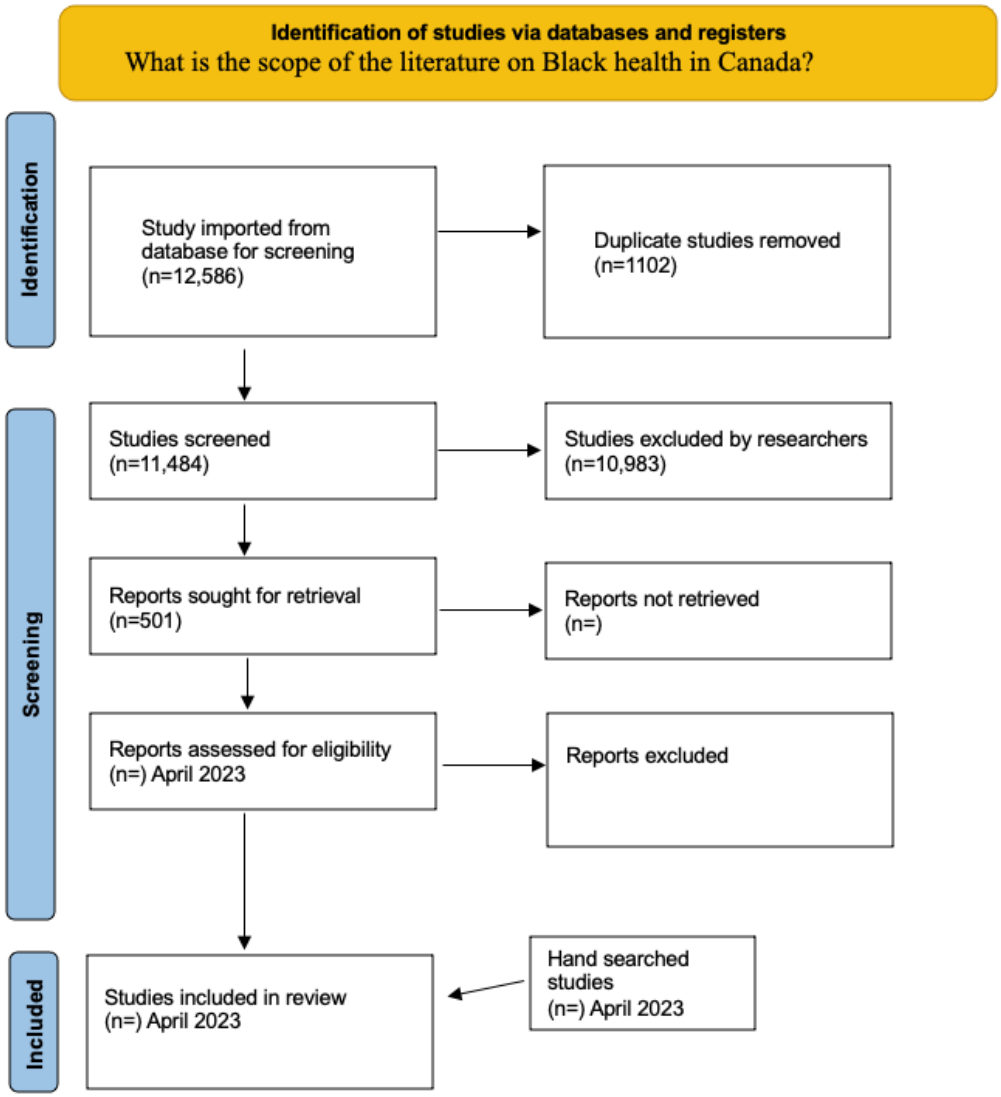
Stage 1: Identifying the Research Questions

Arksey and O'Malley [25] proposed an iterative process for developing research questions, where each modification is based on intensifying familiarity with the literature. Thus, the research question was as follows: What is known in the existing literature about the health of Black individuals in Canada?

Stage 2: Identifying Relevant Studies

Bibliographic database searches were conducted in June 2022. At this stage, we developed a search strategy, including the keywords to use, and searched the following databases: CINAHL, Embase, Global Health, MEDLINE, PsycINFO, Scopus, Sociological Abstracts, and Web of Science (Multimedia Appendix 1). We completed a search for grey literature by searching Google and the websites of agencies.

Stage 3: Study Selection



Search Strategy

A total of 12,586 articles were retrieved, of which 1102 were duplicates. A total of 11,484 citations were downloaded from the bibliographic databases into an Endnote library (Endnote 20) and, from there, exported into Covidence where titles and abstracts were reviewed independently by 2 research assistants. Studies that did not meet the inclusion criteria (n=10,983) were excluded. The full text versions of the remaining 501 articles

XSL•FO
RenderX

have been retrieved and are being independently reviewed by 2 research assistants to determine the eligibility of the articles. A third researcher will resolve disagreements between the 2 research assistants at all review stages. Reference lists of included articles will be scanned for any additional articles that meet the study's inclusion criteria (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) 2020 flow diagram: Black health in Canada. Adapted from Page et al [26].

Inclusion Criteria

Participants

The participants will include any Black/African individuals, populations, and communities living in Canada. We define Black Canadians as "People of African descent and those who define themselves as such, who are now residents/citizens of Canada" [27].

Concept

For this scoping review, we define health as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" [9]. A broader range of languages will be considered, and language translators will be engaged with articles published in other languages. The review team will include Black Canadians to ensure that the review is culturally sensitive and inclusive.

Geographical Location

Studies conducted in Canada will be included.

Types of Sources

Eligible study designs will include qualitative, quantitative, and mixed methods study designs. In addition, unpublished theses and dissertations will be included in this scoping review.

Exclusion Criteria

Exclusion criteria will include the following:

- Study types: secondary literature (scoping reviews, literature reviews, systematic reviews, and meta-analysis), letters to the editor, protocols, and case series
- Concept: studies that did not target the health of Black Canadians

XSL•FO
RenderX

Stage 4: Charting the Data

A data extraction sheet will be developed and used for extraction (Multimedia Appendix 2). It is anticipated that the data categories will include standard information such as author name(s), year of publication, the purpose of the study, study population, methods, results/findings, and comments/implications. Two trained research assistants will independently read each article and extract data. A third reviewer will verify a sample of the extraction for completeness and accuracy. We will ensure that methodological quality checks are conducted to ensure the consistency, accuracy, and thoroughness of the information extracted.

Stage 5: Collating, Summarizing, and Reporting the Results

Quantitative data will be analyzed through a numerical summary. Qualitative studies will be analyzed using thematic analysis to synthesize and categorize the findings of the included studies into themes (drawing from Braun and Clarke [28]). To do so, we will read the included articles several times and familiarize ourselves with the data. Subsequently, we will compile codes into potential themes, group all data relevant to the potential theme, and compare data across the coded excerpts and the entire data set.

Results

We started this project in June 2022 with the development of the search strategy and literature search. As of October 2022, the study team has completed the title, abstract, and full-text screening of imported citations. The articles selected to be represented in the table are important because they meet the inclusion criteria and contribute to the understanding of the health, quality of life, and well-being of Black Canadians. Articles that survive the screening process will provide valuable evidence on the topic of interest. As the study team is expected to complete data collection by April 2023 and the analysis of data and drafting of manuscripts will be done thereafter, this study may provide timely and relevant information to inform the development of the knowledge hub on the health of Black Canadians.

Discussion

Expected Findings

This research protocol aims to guide the researchers in conducting research using a method that entails exploring and mapping literature and identifying research gaps in the health of Black Canadians.

Several study protocols or reviews have been published on the health of Black Canadians. However, these tend to focus too narrowly on specific aspects of health and often neglect a more comprehensive picture. Nguemo et al [29] performed a scoping review of substance use disorders among Black Canadians and found that low income, economic deprivation, unemployment, the lack of health education, immigration, and limited access to treatment services intensified the rate of substance use among Black Canadians. Jefferies et al [30] described food security in African Canadian communities and indicated that food access and food availability are associated with an increase in the rate of dietary acculturation. Similarly, Lofters et al [31] noted that findings from a future review would help in the implementation of human papillomavirus self-sampling and the improvement of uptake of cervical cancer screening among women from African countries who resides in Ontario. Finally, Dogba et al [32] published a scoping review protocol to identify obstacles and enablers to participation by diabetic ethnocultural minority immigrants in retinopathy screening as well as generate results that would help in developing intervention schemes for behavioral modification.

The scoping review will evaluate various disease prevention strategies, access to and utilization of health care, and facilitators to health in Black individuals and communities in Canada. We will explore the resistance of Black Canadians in relation to the barriers they face in accessing health care services and other health intervention programs. Additionally, the impacts of social determinants of health and intersections of dimensions such as gender identity, sexual orientation, age, disabilities, language, educational attainment, and immigration status on the health of Black Canadians will be evaluated.

The completed scoping review will inform research, programs, and services as well as identify potential areas to facilitate and improve the health and well-being of Black Canadians. The findings will be relevant to a variety of audiences, such as researchers, policy makers, stakeholders, health care providers, clinicians, and governments who strive to better understand the health, quality of life, social determinants of health, and well-being of Black Canadians.

Limitations

One limitation of this scooping review is the wide range of inclusion criteria. Therefore, the hand searching of the literature by the research team may result in individual interpretation of the criteria. The lack of critical appraisal and the chance of omitting relevant studies have been reported as major challenges in conducting scoping reviews [33,34]. We acknowledge some biases such as the possibility of omitting studies not captured by our search terms or databases. As there is potential disagreement among reviewers in determining the eligibility of studies, a third reviewer will resolve disagreements at all review stages.

Implications

Our review will address the absence of a comprehensive review on the health of Black Canadians by taking a broader view of health than previous efforts. We will identify the full range of research on the health of Black Canadians and categorize such work into themes reflecting specific topical areas of health and well-being. We will synthesize the literature and identify trends and knowledge gaps in each category of research articles. This effort will contribute to the development of a knowledge hub on the health of Black Canadians that will serve as a resource for the Black communities, policy makers, stakeholders, health care providers, and the government at large. Our findings will also be disseminated in peer-reviewed manuscripts and at conferences.

Abstract

Background: There is no consensus on how the disruption or maintenance of heritage culture and language affect mental health outcomes in adolescents with a migrant (also known as “immigrant” or “international migrant”) background. Even though previous literature reviews have investigated the association between acculturation and mental health in migrants, none have explicitly focused on adolescents.

Objective: The aim of the scoping review described in this protocol is to understand (1) the focus, scope, and nature of quantitative empirical research investigating heritage cultural maintenance, including linguistic maintenance, and mental health outcomes in adolescents with a migrant background worldwide and (2) the potential effects of cultural and linguistic maintenance or disruption on migrant adolescent mental health outcomes.

Methods: A total of 11 key electronic health, medical, social science, and language databases (APA PsycArticles Full Text; Embase Classic+Embase; Ovid MEDLINE All and Epub Ahead of Print, In-Process, In-Data-Review and Other Non-Indexed Citations and Daily; Ovid MEDLINE All; APA PsycInfo; University of Melbourne full-text journals; Science Citation Index Expanded; Social Sciences Citation Index; Arts & Humanities Citation Index; Scopus; Linguistics and Language Behavior Abstracts) were searched. Databases were searched without time restrictions from the beginning of their coverage. Publication date, location, and quantitative study design (except for literature reviews) were not restricted; however, the search was only conducted in English. Data from included studies will be extracted using a template with predefined data items, and results will be summarized in a structured, narrative summary.

Results: A search was conducted on April 20, 2021, returning 2569 results. We are currently at the final stages of screening titles and abstracts of our search results, which will be followed by a full-text review and the data extraction of included studies. We expect to submit the full review for publication by the end of 2023.

Conclusions: The scoping review aims to provide a better understanding of existing research on the association between cultural (including linguistic) maintenance and mental health in migrant adolescents. It will help identify gaps in the existing literature and develop hypotheses that could inform future research, eventually facilitating the development of targeted prevention initiatives and improving migrant adolescents’ well-being.

Introduction

Background

The World Migration Report 2022 stated that 1 in 30 people globally resides in a country that differs from their birth country and that this number has increased over the last 5 decades [1]. With most migration streams flowing from low-income to high-income countries [1], many migrants experience differences between their heritage and host cultures.

Previous research into acculturation (ie, the impact of interacting with other cultures on an individual) has highlighted 2 key issues. First, the issue of cultural maintenance, which is the extent to which heritage cultural identity is considered important and practices are continued. Second, the issue of deciding on the extent of contact and participation (ie, interacting with the host culture or remaining within heritage cultural groups) [2]. Based on these 2 issues, Berry and Sam [2] proposed four acculturation strategies: (1) integration (whereby heritage culture is maintained while seeking to interact with other groups), (2) assimilation (whereby heritage culture is not maintained while interactions with other groups are sought), (3) separation (whereby heritage culture is maintained while wishing to avoid interactions with other groups), and (4) marginalization (whereby cultural maintenance is perceived as difficult, and little interest is demonstrated in interacting with other groups).

A considerable amount of research has examined the association between acculturation and mental health outcomes, including several systematic reviews [3,4] and meta-analyses [5,6]. However, despite age being identified as a key component of the association between acculturation and mental health [6], no review to date has examined how cultural maintenance affects mental health outcomes in migrant adolescents (aged 10-24 years [7]).

Marked as the transition into adult life, adolescence is a life phase of great change. Adolescence has been identified as "a second sensitive developmental period in which puberty and rapid brain maturation lead to new sets of behaviours and capacities that trigger or enable transitions in family, peer, and educational domains, and in health behaviours" [8]. As these transitions affect a child's future health outcomes [8], understanding factors shaping adolescents' mental health outcomes is important to support their healthy development.

Even though Viner and colleagues [8] caution that their ecological analysis does not imply causality, they found that "national wealth, inequality, and education had the largest effect sizes...and were associated with the largest range of health outcomes in young people." They further identified that similar factors, related to family, peers, and education, can help protect adolescents' health across countries [8].

Adolescents with a migrant background—specifically, first- or second-generation migrants—are faced with the added complexity of navigating this intense transitional phase within a multicultural or multilingual context. In fact, some research has identified a migrant background to be a predictor of poor mental health outcomes in adolescents [9]. A study in a regional child and adolescent mental health service in Australia reported that the majority of mental health support was needed by Aboriginal youth, followed by Asian-European heritage youth, with the researchers pointing at the role loss and disconnection from heritage culture may play in poor mental health outcomes [10]. Hallett and colleagues [11] had even more poignant findings related to Indigenous cohorts, identifying native language knowledge as correlating with a reduction in Indigenous youth suicide in Indigenous communities in Canada. The extent to which a similar effect of language or culture maintenance on mental health outcomes may be evident among adolescents with a migrant background remains unknown.

There is a large body of adolescent mental health research studying the effectiveness of interventions [12], help-seeking behaviors [13,14], and the applicability of information technologies [15]. Müller and colleagues [16] conducted a scoping review on the effect bilingualism has on family and child well-being, which provides valuable insights. However, rather than specifically looking at bilingualism, we are interested in research investigating the association between heritage culture or language knowledge and mental health outcomes in migrant adolescents.

This scoping review will provide a better understanding of migrant adolescents' ecological systems and identify modifiable risk factors associated with optimal mental health outcomes. This knowledge will inform future research leading to improved interventions and policies that contribute to improved mental health outcomes in migrant adolescents.

Objectives

This protocol outlines the methodology of a scoping review that will address the following questions:

(1) What is the focus, scope, and nature of quantitative empirical research investigating heritage cultural maintenance, including language maintenance, and mental health outcomes in adolescents with a migrant background worldwide?

(2) What effects, if any, do cultural and linguistic maintenance or disruption have on migrant adolescent mental health outcomes?

Methods

Protocol Development

This protocol adheres to relevant sections of the Preferred Reporting Items for Systematic Review and

XSL•FO
RenderX

Meta-Analyses–Protocols (PRISMA-P) [17], which we provide in the form of a checklist [18] in Multimedia Appendix 1.

Scoping Review Methodology and Reporting

We conduct the scoping review following the methodological framework outlined by the Joanna Briggs Institute [19], which is based on the Arksey and O'Malley framework [20] and Levac and colleagues' [21] elaborations. Reporting will follow the PRISMA Extension for Scoping Reviews (PRISMA-ScR) [22].

For an overview of the scoping review's inclusion and exclusion criteria, please refer to Textbox 1.

Textbox 1. A summary of inclusion and exclusion criteria.

Inclusion Criteria

- Published, peer-reviewed empirical studies.
- Any language (however, the search was only conducted in English, which indirectly excluded all studies without an English title, abstract, or keywords).
- Any publication date.
- Any study location.
- Adolescent study participants between 10 and 24 years.
- Studies focused on mental health outcomes, symptom severity, and diagnosis.
- Studies measuring mental health outcomes, specifically depression, anxiety, self-harm, suicide, substance misuse, and schizophrenia.
- Studies measuring any nondominant heritage culture or language.

Exclusion Criteria

- Qualitative studies, literature reviews, book chapters, dissertations, conference papers, conference abstracts, and editorials.
- Participants younger than 10 years, or those who are 25 years or older.
- Studies focused on help-seeking, or interventions in mental health dimension.
- Studies measuring trauma, self-esteem, life satisfaction, or well-being.
- Studies measuring the uptake of host language or culture without considering heritage language and cultural maintenance; studies measuring ethnic identity.

Eligibility Criteria

Participants

We include empirical studies examining the effect of cultural maintenance, including linguistic maintenance, on mental health outcomes in migrant adolescents. Participant age is limited to 10-24 years, in line with the contemporary definition of adolescence [7].

Outcome Measures

The scoping review is interdisciplinary in nature and included studies must measure mental health and cultural or linguistic maintenance outcomes. Appropriate mental health outcomes include depression, anxiety, self-harm and suicide, substance misuse, and schizophrenia. Studies measuring only trauma, self-esteem, life satisfaction, or well-being are excluded. Studies measuring mental health outcomes without measuring culture or language maintenance are also excluded. Studies examining help-seeking or interventions are also not included.

Heritage language or cultural maintenance must be measured for studies to be included. We do not include studies that examine only the uptake of the host language or culture without examining heritage culture or language maintenance, but we consider findings related to host cultural orientation if heritage cultural orientation is measured.

Study Design

We include published, peer-reviewed empirical studies measuring cultural or linguistic maintenance and mental health outcomes in migrant adolescents. We exclude qualitative studies, book chapters, dissertations, conference papers, conference abstracts, and editorials. We do not include literature reviews as they may include studies that do not meet our inclusion criteria. However, we will screen and review the reference lists of relevant literature reviews to identify studies not identified during our searches.

Information Sources

A total of 11 electronic databases were searched on April 20, 2021, from the beginning of each database.

The electronic databases are APA PsycArticles Full Text (coverage from 1894); Embase Classic+Embase (from 1947); Ovid MEDLINE All and Epub Ahead of Print, In-Process, In-Data-Review and Other Non-Indexed Citations and Daily (from 1946); Ovid MEDLINE All (from 1946); APA PsycInfo (from 1806); University of Melbourne full-text journals; Science Citation Index Expanded (from 1900); Social Sciences Citation Index (from 1900); Arts & Humanities Citation Index (from 1975); Scopus (from 1970); Linguistics and Language Behavior Abstracts (from 1973).

We will also screen reference lists to identify relevant studies that the electronic search might not have identified.

XSL•FO
RenderX

Search Strategy

The search strategy was shared with a university librarian, who provided feedback to further tailor the search strategy to each database. After the search of the electronic databases, the search results' titles and abstracts are screened in a Microsoft Excel (Microsoft Corp) spreadsheet, applying the inclusion and exclusion criteria as outlined by this protocol. To be eligible for inclusion, studies must fulfill all 4 categories (coded in the search query with "AND"). Within each category, studies must meet at least 1 search term (coded in the search query with "OR"). The search query syntax was adjusted to meet specific database requirements. An example of the search command used for Ovid MEDLINE All is provided in Table 1.

Table 1. Ovid MEDLINE All search strategy.

Category	Operators	Search field	Fields
1. Linguistic and cultural component	N/A[a]	"language maintenance" OR "language knowledge" OR "language transmission" OR "cultural maintenance" OR "cultural knowledge" OR "cultural transmission"	All fields
2. Mental health outcome	AND	"mental health" OR suicid* OR depress* OR anxiet* OR anxious* OR self-injur* OR self-harm OR nssi OR "non-suicidal self-injury" OR "substance abuse" OR "drug abuse" OR "substance use" OR "substance misuse" OR "substance-related disorder" OR "substance use disorder" OR "SUD" OR resilien* OR schiz* OR vulnerab*	All fields
3. Age group	AND	adolescen* OR "young person" OR teen*	All fields
4. Immigrant background	AND	refugee* OR cald OR "culturally and linguistically diverse" OR immigrant OR migrant OR aborigin* OR indigenous OR "Torres Strait"	All fields

[a]N/A: not applicable.

Study Records

Data Management and Selection Process

AH exported and consolidated all electronic database study results' titles and abstracts into a single Microsoft Excel spreadsheet before removing duplicates. AH is currently finalizing the screening of titles and abstracts, applying the inclusion and exclusion criteria, and recording reasons for inclusion or exclusion. JH and RB are involved in the screening of search results, checking 20% of included and excluded studies to test the validity of the approach and discuss potential alterations.

In the next stage, AH will download the full text of studies whose title and abstract appear relevant or unclear in answering the research question into citation management software Zotero (Corporation for Digital Scholarship). Each study will be read in full and assessed against each inclusion criterion using a simple charting form covering each of the 4 search categories. AH will consult the appropriate expert in the team to discuss studies that she is unsure about. If they cannot agree, the third team member will decide. JH and RB will review all included studies and at least 20% of excluded studies to detect and correct potential errors.

Data Collection Process and Data Items

AH will collect data using 2 separate spreadsheets. In the first spreadsheet, AH will record extracted information for each included study: authors, year, final sample size, other included cohorts (eg, parents), participant information (age, heritage, and culture), and geographical location.

In the second spreadsheet, AH will code data in a binary table, which will allow sorting and comparing study characteristics. Expected information categories that will be coded at the top level will be related to frameworks, the terminology used, cultural or linguistic measures, mental health outcomes measured, scales used, as well as key findings about this paper's second research question. These findings will be shared, reviewed, and discussed with JH and RB.

Outcomes and Prioritization

The primary focus of this review is to understand the research investigating the association between cultural or linguistic maintenance and mental health outcomes in migrant adolescents. As we are investigating a multidisciplinary field of study, there is a possibility of studies having heterogeneous research perspectives and findings. We aim to be rigorous in including only studies that fulfill all 4 search categories. When studies meet criteria in all 4 categories, we will also report on findings that may directly or indirectly affect the association between cultural maintenance and mental health outcomes, such as the effect of host cultural orientation, as well as moderating or mediating factors. This will allow us to understand the identified phenomena better.

Data Synthesis

We will provide a descriptive overview of included studies, stating sample size, age, and location, as well as mental health outcomes and cultural or linguistic maintenance factors measured. We will then provide a structured, narrative summary of study findings about our second research question in text and—depending on feasibility—table form. We will report commonalities and differences in findings, explore potential hypotheses, and identify gaps in the research. We will not assess the quality or bias of studies, grade evidence, or include a quantitative synthesis of evidence.

XSL•FO
RenderX

Ethical Considerations

Our review does not require ethical approval, as it reports on findings from published studies that have already obtained ethics approval. We will disseminate the findings of the scoping review through a peer-reviewed journal article and national and international conference presentations.

Results

Applying the methodology outlined in this protocol, we conducted a search in April 2021, which returned 2569 results. We are in the process of screening titles and abstracts of these results. We expect to submit the scoping review for publication by the end of 2023.

Discussion

Overview

This scoping review protocol outlines a rigorous and replicable methodology for the review of empirical research investigating cultural maintenance, including language maintenance, and migrant adolescent mental health outcomes. To our knowledge, no comparable study has been conducted. The search conducted in April 2021 returned 2569 results.

We will report results in the scoping review following the PRISMA-ScR. Our search strategy included 11 relevant academic databases, as well as a grey literature search. We are screening titles and abstracts and will extract data from included studies using predefined charting items. This will allow us to compare the nature of study elements and identify trends and gaps in the existing literature.

We will also extract relevant findings to address our second research question and present the results in a narrative summary, which will possibly result in the suggestion of hypotheses or research questions that could inform future research or systematic reviews. The preliminary review of literature has shown that rather than inferring causality, it is important to interpret findings considering adolescents' context. Some studies use an ecological approach [23] and, depending on our results, we are planning to use a similar approach to contextualize results.

Some existing reviews that were not adolescent-specific identified biculturalism to be advantageous on adjustment [5], and child well-being benefiting from bilingualism at home [16]. Our study will contribute to the existing literature, providing a better understanding of language or cultural maintenance, while specifically focusing on mental health outcomes in migrant adolescents who are and will constitute large cohorts within society.

Even though we conducted the search worldwide, we used only English search terms, limiting our results to studies with English titles, abstracts, and keywords. Included results that were written in another language are reviewed by a researcher proficient in the language. Another limitation of this study is that evidence will not be quantitatively synthesized in this review, as we will not do a quality or bias assessment of studies. Moreover, this highly multidisciplinary field of study leads to heterogeneous results from various disciplines (ie, psychology, adolescence research, and linguistics), which slows down the review process.

Conclusion

The scoping review outlined by this protocol will provide a more cohesive understanding of existing multidisciplinary research into cultural and linguistic maintenance and mental health outcomes in migrant adolescents. This will provide a more comprehensive understanding of how youth mental health outcomes and cultural factors, including linguistic factors, have been investigated to date, and what future investigations may be required. The outlined scoping review therefore plays an important part in improving migrant adolescents' mental health outcomes.

Acknowledgments

This work was supported by the University of Melbourne's Arts-MDHS Collaborative Research Initiative Seed Funding Scheme, which provided funding in part. RB is funded by an Australian National Health and Medical Research Council Emerging Leadership-2 Investigator Grant (GNT2008073).

Data Availability

All data generated or analyzed during this study will be included in the published article (and its supplementary information files).

Authors' Contributions

RB and JH developed the original research proposal and obtained funding to conduct the review. AH contributed to the design of the project. AH, RB, and JH developed the search strategy. AH wrote the initial draft protocol, and RB and JH contributed significantly to drafting and editing the manuscript. All authors approved the final manuscript for submission.

Conflicts of Interest

None declared.

Abstract

Background: The use of digital health technologies is becoming increasingly common across the globe as they offer immense potential to enhance health care delivery by promoting accessibility, flexibility, and personalized care, connecting patients to health care professionals, and offering more efficient services and treatments to remote residents. At the same time, there is an increasing recognition of how digital health can inadvertently foment psychological trauma. This phenomenon has led to the adoption of trauma-informed care in designing and deploying digital health technologies. However, how trauma-informed care is defined and characterized, and the various trauma-informed care strategies used in designing and deploying digital health technologies remain unexplored.

Objective: This scoping review aims to explore and synthesize the literature on how trauma-informed care is defined and characterized in digital health and the various trauma-informed care principles, strategies, or recommendations used in designing and deploying digital health.

Methods: This review will draw on the Joanna Briggs Institute's updated methodological guidance for scoping reviews. A search will be conducted on CINAHL, PubMed, Embase, Compendex Engineering Village, Web of Science, Scopus, and PsycINFO. This review will consider published research studies and unpublished work (gray literature). Studies will be included if they applied trauma-informed care in designing or deploying digital health for patients across all geographical locations or provide trauma-informed recommendations on how web developers should develop digital health. Studies will be limited to publications within the past 10 years and studies in all languages will be considered. Two independent reviewers will screen the titles and abstracts, and then perform a full-text review. Data will be extracted into a data extraction tool developed for this study.

Results: The scoping review was undergoing a full search as of April 2023. The main results will synthesize the peer-reviewed and gray literature on adopting trauma-informed care practices in digital health research and development. The study is expected to be completed by December 2023 and the results are expected to be published in a peer-reviewed journal.

Conclusions: This review is expected to provide the knowledge base on the adoption of trauma-informed care in designing and deploying digital health. This knowledge can lead to more engaging, and likely, more effective digital health interventions that have less potential for harm. A synthesis of the various trauma-informed care strategies in digital health will also provide a trauma-informed language by enabling researchers and digital health developers to consider trauma as a critical factor in each stage of the design process.

Introduction

Overview

Trauma is a term used to describe the challenging emotional and psychological consequences associated with an individual after going through a distressful event [1]. This definition of trauma is specific to emotional and psychological trauma, which is different from physical trauma (ie, injuries or body wounds produced by sudden physical injury from impact, violence, or accident). According to the World Health Organization, approximately 70% of people across the globe have experienced at least one traumatic event with varying emotional and psychological sequelae [2]. The number of reported cases of trauma increased across several countries during the COVID-19 pandemic [3]. Living through the COVID-19 pandemic has heightened the degrees of trauma with symptoms that can eventually harm a person's sense of safety and distort their ability to regulate emotions and navigate relationships [4]. At the same time, the outbreak of the pandemic saw an accelerated adoption of digital health for various clinical and public health services across the globe. In the United States, telemedicine appointments through "Plush Care" and "American Well" increased by 70% and 150% respectively [5]. In Canada, the number of people using digital health interventions increased from a prepandemic level of 72% to approximately 86% in some provinces during the peak of the pandemic [6,7]. Technologies such as Skype, WhatsApp, and FaceTime were adapted as alternative and complementary methods of health care delivery and health care access across Australia and various European countries [8,9]. While digital health is convenient and cost-effective, there are legitimate concerns about how the digital transformation of health care can lead to unintended consequences, including triggering or perpetuating trauma among end users [10]. The likelihood of perpetuating unintended consequences like trauma through digital technologies may be higher in patient-facing digital health interventions than in clinician-facing technologies. This is possible because, unlike technologies in clinical settings, patient-facing technologies (eg, patient portals, mHealth, and health-related websites) are more likely to be unregulated and unmoderated. Bonell et al [11] termed this the "dark logic" of interventions where digital health could result in unintended trauma-related consequences despite a generally virtuous intention.

Technology-Mediated Trauma

Trauma resulting from the use of digital health technologies (herein known as technology-mediated trauma) is becoming common with the increasing use of digital health interventions [12-14]. While technology-mediated trauma started emerging in social media platforms [15-17], emerging evidence shows that digital health technologies, especially patient-facing digital health technologies can also trigger or facilitate technology-mediated trauma depending on its' interface design [18,19]. Indeed, technology-mediated trauma perpetrated through digital health platforms may produce worse outcomes due to the potentially vulnerable nature of people who uses such technologies (ie, patients).

Technology-mediated trauma can occur in various forms. For instance, interventions delivered through web platforms that unexpectedly expose people's information or identities can cause reputational and psychological damage with associated trauma-related symptoms. Also, digital health technologies (eg, HIV/AIDS web-based platforms and social networking sites for people with mental health problems) that expose people to sextortion, identity theft, cyberbullying, and web-based scams, including the purchase of fake health products, could result in short-term or long-term emotional traumatic consequences, and sometimes, suicidal thoughts [20,21]. Other forms of digital communication channels embedded within digital health platforms, such as chatrooms, user subscription channels, forums and bulletin boards, social networking sites, and other platforms that enable information sharing, may also be used unscrupulously to victimize, and expose users of digital platforms in a manner that could result in technology-mediated trauma-related experiences [22-26]. While youth with mental health challenges found the use of social networking sites to be highly usable, engaging, and supportive [27], such sites could also pose avenues for web-based victimization and bullying with the potential consequences for trauma-related experiences [28]. For instance, cyberbullying activities perpetrated through web-based social networking sites for mental health patients, including negative forum posts and negative comments, have been shown to result in technology-mediated trauma experiences and other forms of mental health challenges among adults [28,29]. Web-based practices such as advertisements carried out on digital platforms like sexual health–related websites can inadvertently foment stigma [30]. For instance, discriminatory advertising on maternal health websites can inadvertently perpetuate trauma when a woman who just experienced a miscarriage is not able to opt out of pregnancy adverts when using such a platform [31]. Technology-mediated trauma experiences can result in devastating sequelae for people's overall psychological and physical well-being [32]. The negative effects of technology-mediated trauma on psychological well-being were demonstrated in a recent systematic review that revealed a negative association between digital technology use and emotional well-being outcomes among teenagers during the COVID-19 pandemic [33].

The pervasive and potentially negative impact of technology-mediated trauma on end users made it necessary within the digital health community to rethink "the usual way of doing business" by incorporating trauma-informed care in the design and deployment of digital health interventions. Some researchers subsequently coined the term "trauma-informed design" to denote the application of trauma-informed care in developing interactive technologies, including digital health platforms.

Trauma-Informed Care in Digital Health

Trauma-informed care in interactive digital technologies is a new concept that started appearing as blog posts among user interface and user experience practitioners across the United States, the United Kingdom, and Australia. The concept of trauma-informed design became prominent in the later parts of 2020 [34]. Since then, researchers have been actively engaged in developing approaches in which trauma-informed principles,

XSL•FO
RenderX

approaches, or practices can be translated into the design of digital health technologies to make them emotionally safer. Trauma-informed care recognizes the effects of trauma on users of digital health technologies and provides theoretical approaches and practical guidance for how such technologies can be designed to be emotionally safe and empowering for all users [34]. Indeed, several digital health interventions have adopted trauma-informed approaches in designing and developing digital health interventions or produced trauma-informed recommendations that can be used to adapt old interventions or develop new digital health services [35-38]. Other researchers have developed trauma-informed web heuristics for designing human-centered information systems, including digital health [39].

While trauma-informed care is gradually gaining ground in the digital health community, how the concept is defined and characterized, and the various trauma-informed care strategies used in designing and deploying digital health technologies remain unexplored and ill-understood. The purpose of this review is two-fold: (1) to explore and synthesize the current state of the literature that has defined and characterized trauma-informed care in digital health and (2) to synthesize the literature on various trauma-informed care strategies, practices, principles, or approaches that are used in designing and deploying digital health. A preliminary search was conducted in February 2023 in Cochrane Databases, the Joanna Briggs Institute (JBI) Evidence Synthesis, and PROSPERO to identify any possible reviews that might have been conducted on the topic. The search results did not reveal any scoping or systematic review that has been conducted on our proposed topic. However, the search did return relevant articles that were used in formulating our search terms [13,35-38].

Review Questions

1. How is trauma-informed care defined and characterized in the digital health literature?
2. What trauma-informed care principles, strategies, or recommendations are currently used in designing and deploying digital health technologies?

Methods

Overview

This proposed review will draw on the JBI updated methodological guidance for the conduct of scoping reviews [40]. We will use the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-analyses Extension for Scoping Reviews) framework to report the findings of this review [41]. Because trauma-informed care in digital health is an emerging area with varied sources of evidence, we consider a scoping review to be more appropriate in providing conceptual clarity on the topic than a systematic review.

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria for this proposed review will adopt the JBI criteria of population, concepts, and context outlined by Peters et al [40]. The details of each criterion are outlined below.

Population

This review will include 2 distinct populations. These include (1) digital health technology designers (eg, software developers, content creators, and user interface and user experience professionals) and (2) patients who use digital health technologies (without consideration to a type of patient or disease or age). For the first population, studies will be included if they provide trauma-informed strategies or recommendations for developers or designers of digital health technologies. For the second population, studies will be included if they explore ways in which trauma-informed care principles or strategies can be applied in designing or deploying digital health technologies for patients. Studies will also be included if they explore how trauma-informed care can be applied to digital technologies to improve patients' health outcomes. A patient in this study is used to refer to anyone who uses a digital health intervention for health-related purposes. Digital health technology studies on posttraumatic stress disorder (PTSD) that adopt trauma-informed care approaches or provide trauma-informed care recommendations will be included. However, digital health technology studies on PTSD that did not adopt or recommend trauma-informed care approaches will be excluded.

Concepts

This review aims to map the evidence on how trauma-informed care is defined and characterized in digital health and to synthesize the literature on trauma-informed care in designing and deploying digital health. Therefore, the review will include two major concepts: (1) trauma-informed care and (2) digital health technologies. Based on these concepts, we will consider studies that discussed the definitions and characteristics of trauma-informed care in digital health. We will also consider studies that provided trauma-informed care strategies, practices, approaches, or recommendations for designing and deploying digital health. Studies that provide trauma-informed care strategies which are not focused on designing or deploying digital health technologies will be excluded. In this review, trauma is limited to psychological trauma at the personal and interpersonal levels. Other forms of trauma, such as physical trauma, group trauma, community trauma, or mass trauma or casualties, are beyond the scope of this review. Digital health in this review is used to refer to patient-facing technologies, including mHealth, wearable devices, health-related websites, patient portals, social networking sites, etc. Digital health technologies that are focused on health care professionals (eg, electronic health records and clinical decision support systems) will be excluded from this review. We decided to exclude clinician-facing technologies because such technologies are more likely to be regulated and might have fewer chances of causing trauma among patients compared to patient-facing technologies.

Context

This review will include studies that are conducted with individuals in all age groups in any geographical location. Our search will not be limited to any specific gender or sex group, a particular disease condition, and a specific user group or population. We aim to include all outpatient or nonclinical

XSL•FO
RenderX

settings that explore how trauma-informed care can be applied in designing or deploying digital health technologies (community health centers, social service organizations, etc), and industry (technology design companies). We will also consider digital technology developers (eg, User Experience research centers) that have discussed, developed, or applied trauma-informed care principles in designing digital health.

Types of Evidence

This scoping review will include all types of peer-reviewed studies on trauma-informed care in digital health, including primary research studies (quantitative, qualitative, and mixed methods research) and review papers (systematic reviews or meta-analyses). We will also consider gray literature on trauma-informed care in digital health, including theses, editorials, commentaries, government reports, industry-sponsored works, guidelines, book chapters, and blogs. Abstracts, letters to editors, and short papers will be excluded. Gray literature is considered important because trauma-informed care strategies or recommendations for designing digital health may be developed and published outside traditional academic publishing and distribution channels. These include industry-sponsored works that may provide trauma-informed recommendations (software designers, software engineers, etc) but may not necessarily be published in peer-reviewed journals. Due to the emerging nature of the field and the rapid advancements in digital health technologies in the past decade [42], this review will be limited to studies conducted within the past 10 years.

Search Strategy

A strategy was developed in consultation with a university librarian at the University of British Columbia. Following Pollock's [43] practical guide to conducting scoping reviews, a preliminary search was conducted in Cochrane Databases, the JBI Evidence Synthesis, and PROSPERO to determine if any reviews were conducted on the topic and to identify additional words and phrases to inform the search strategy. Given the multidisciplinary nature of the topic (ie, trauma-informed care and digital health), we formulated a search strategy that reflected each dimension of the topic. The search strategy for the gray literature will be iterative depending on the emerging evidence. Using the refined search strategy, a literature search will be conducted on a variety of databases, including CINAHL, PubMed, Embase, Compendex Engineering Village, Web of Science, Scopus, and PsycINFO. These databases were selected because they covered a broad range of published literature that reflected the topic in nursing, medicine, psychology, allied sciences, engineering, and computer science. A reference list of articles that meet the inclusion criteria will be manually screened to identify additional eligible studies that were not returned by the search strategy. Using different search terms, we will also search for gray literature through Google and Google Scholar. We will open individual web links that contain blogs or industry materials on trauma-informed care in digital health. Multimedia Appendix 1 contains the detailed search strategy as well as the data extraction guide for both published and grey literature.

A preliminary search conducted on the 2 databases for gray literature produced results of less than 5 pages each. Since we do not expect these databases to produce results that exceed 10 pages by the time the review is completed (ie, December 2023), we are limiting the data from Google and Google Scholar to the first 100 results. Consistent with JBI recommendations, we will not apply language restrictions to our search. We will use translation services for eligible studies that fall outside the proficiency of the authors. Where necessary, the authors of relevant publications, blogs, and opinion pieces will be contacted to get additional information or seek clarification regarding their publications. As an emerging area of research, it is possible that some latest evidence might have been published after our literature search. To identify any latest publication, we will repeat the search strategy (but limited to the specific time frame) before the final manuscript is submitted for publication.

Study Selection

Search results from all databases will be exported into Endnote X9 (Clarivate, 2020). Search results from Google and Google Scholar will be manually added and duplicates will be removed accordingly. Two independent reviewers will then screen the titles and abstracts using the inclusion and exclusion criteria outlined under the population, concepts, and contexts. Studies that meet the inclusion criteria will undergo a full-text review by the 2 independent reviewers. Any discrepancies that result from either the title, abstract, or full-text review between the 2 reviewers will be solved through a discussion with a third reviewer.

Data Extraction

Specific information from the included studies will be extracted by the 2 independent reviewers. The data will be summarized on an Excel spreadsheet developed in line with the JBI guidelines for data extraction [43]. The data extraction sheet will contain specific information about each study, including the authors' names, the study's title, the year of publication, geographical location, the study population, type of digital health technology, target population, sample size (if applicable), purpose, and the findings of each study. Where applicable, information from each paper will be entered into the respective portion of the spreadsheet. We will also extract information specific to each of the 2 populations (ie, health technology developers and patients). For studies related to how technology developers adopt trauma-informed care, we will extract data related to the specialty, and place of work or origin (eg, industry and research). For studies on patient populations, we will extract data on age groups, sex and gender, socioeconomic status, and health issues. The data extraction tool will be amended for gray literature and will be iterative depending on the kind of emerging evidence. To reduce biases and ensure consistency and comprehensiveness of the data extracted, the 2 reviewers will each conduct independent data extraction on the first 4 papers (both published and gray literature). These preliminary data will be compared, contrasted, and discussed with a third reviewer to resolve any disagreements before they are applied to the rest of the papers. The remaining data extraction will occur through an ongoing team discussion and disagreements will be resolved by discussion with a third reviewer.

Data Analysis and Presentation

The search results as well as the inclusion and exclusion pathways for various studies will be reported in line with the PRISMA-ScR flow diagram [44]. The extracted data and the themes will be presented as narrative summaries. This will be augmented by numerical summaries to report each high-level domain that is common across the papers. Such numerical summaries may include the number of papers that adopt trauma-informed approaches and the number that provide trauma-informed recommendations. It may also include a summary of the number of trauma-informed guidelines and their area of focus in the digital health lifecycle (ie, the needs assessments, design, evaluation, or deployment phases of digital health). Research and gray literature will be grouped accordingly and papers that reflected the 2 research questions will also be grouped in the numerical summaries. To answer the research questions, the included papers will be analyzed thematically using inductive coding by 2 reviewers. Depending on the number of papers that meet the inclusion criteria, 3 papers will be reviewed and coded independently by 2 reviewers for each research question. The different coding frameworks will then be discussed among the reviewers to arrive at a final coding structure for each research question. The coding structure will then be applied to the rest of the papers to identify emerging themes. The emerging themes will then be clustered into major themes that represent the definitions of trauma-informed care in digital health and trauma-informed care strategies for designing and deploying digital health technologies.

Results

The scoping review was undergoing a comprehensive literature search at the time this protocol was being published. This will be followed by tile and abstract screening and then full data extraction. The scoping review is expected to be completed and the manuscript submitted to a peer-review journal by December 2023.

Discussion

Overview

Trauma-informed care in digital health is an emerging area of research that sought to explore various trauma-informed approaches in developing and deploying digital health interventions that limit the potential for further harm to end-user patients. There are several systematic and scoping reviews on trauma-informed care in various aspects of health care as well as in the built environment [37,45]. Despite an increasing application of trauma-informed care principles in digital health research, no reviews summarizing the definitions or characterization of trauma-informed care approaches in digital health were found. This scoping review was conceptualized in October 2022 to summarize the current state of the literature on trauma-informed care in digital health. This scoping review will form an evidence base for an emerging program of research on trauma-informed design in digital health. The results of this scoping review are expected to provide researchers with an extant knowledge of how trauma-informed care is defined, characterized, and adopted in digital health while providing directions for future research on the topic. Digital health technologies are increasingly developed for managing various traumatic stress and PTSD [46,47]. Therefore, we believe that this review will provide trauma-informed recommendations for designing health technologies that have the least chance of causing harm while ensuring emotional safety to end users.

Limitations

Abstracts, letters to editors, and short papers that might have been relevant to the topic will be excluded. Secondly, the methodological quality of this review will not be assessed. Therefore, we cannot conclude whether the trauma-informed strategies that would be synthesized from this review are indeed effective or applicable to digital health. While we acknowledged these limitations, we believe that they would not diminish the quality of our review because scoping reviews by their nature do not assess the methodological quality of studies.

Conclusions

This review is expected to provide the knowledge base on the definition, characterization, and adoption of trauma-informed care in designing and deploying digital health interventions. This knowledge can lead to more engaging, and likely, more effective digital health interventions by enabling researchers and digital health developers to consider trauma as a critical factor in each stage of the design and deployment process. A synthesis of the various trauma-informed care strategies used in digital health will also provide a trauma-informed language for developing digital health technologies that have less potential for harm.

Acknowledgments

We would like to acknowledge the UBC School of Nursing Librarian, Katherine Miller, for helping to develop and refine the search strategy. Finally, we would like to thank the peer reviewers for providing thoughtful and constructive feedback on this protocol.

Authors' Contributions

AFA conceived the idea for the scoping review, wrote the initial draft of the manuscript, revised the manuscript, and performed a supervisory role. HN, EG, FA, and EB refined the search strategy in consultation with AFA and the librarian and all authors contributed to writing and revising the manuscript.

Protocol

Conceptualizing Interprofessional Digital Communication and Collaboration in Health Care: Protocol for a Scoping Review

Abstract

Background: Effective communication and collaboration among health professionals are essential prerequisites for patient-centered care. However, interprofessional teams require suitable structures and tools to efficiently use their professional competencies in the service of high-quality care appropriate to the patient's life situation. In this context, digital tools potentially enhance interprofessional communication and collaboration and lead to an organizationally, socially, and ecologically sustainable health care system. However, there is a lack of studies systematically assessing the critical factors for successfully implementing tools for digitally supported interprofessional communication and collaboration in the health care setting. Furthermore, an operationalization of this concept is missing.

Objective: The aim of the proposed scoping review is to (1) identify factors influencing the development, implementation, and adoption processes of digital tools for interprofessional communication in the health care sector and (2) analyze and synthesize the (implicit) definition, dimensions, and concepts of digitally supported communication and collaboration among health care professionals in the health care setting. Studies focusing on digital communication and collaboration practices among health care professionals, including medical doctors and qualified medical assistants, in any health care setting will be included in this review.

Methods: To address these objectives, an in-depth analysis of heterogeneous studies is needed, which is best achieved through a scoping review. Within this proposed scoping review, which adheres to the Joanna Briggs Institute methodology, 5 databases (SCOPUS, CINAHL, PubMed, Embase, and PsycInfo) will be searched for studies assessing digital communication and collaboration among various health care professionals in different health care settings. Studies focusing on health care providers or patient interaction through digital tools and non–peer-reviewed studies will be excluded.

Results: Key characteristics of the studies included will be summarized through descriptive analysis, using diagrams and tables. We will synthesize and map the data and conduct a qualitative in-depth thematic analysis of definitions and dimensions of interprofessional digital communication and collaboration among health care and nursing professionals.

Conclusions: Results from this scoping review may help in establishing digitally supported collaborations between various stakeholders in the health care setting and successfully implementing new forms of interprofessional communication and collaboration. This could facilitate the transition to better coordinated care and encourage the development of digital frameworks.

Introduction

Overview

Efficient communication and collaboration among health care professionals are essential prerequisites for high-quality patient-centered care [1]. Among other things, this reduces readmission rates, improves patient health outcomes, increases time efficiency, partially improves clinical processes, and reduces health care costs [2-4].

Interaction among health care professionals can be denominated as inter-, multi- or transprofessional. Although the definition of each term is not uniform, they decipher different degrees of collaboration between professions [5]. In this review, we will use the term "interprofessional communication and collaboration" (ICC) to refer to any type of interprofessional interaction among health care professionals, from pure information exchange to collaborative working.

Key enablers for ICC are trust and respect, shared visions, as well as respectful and constant communication [6]. Barriers to ICC include a lack of funding and inadequate reimbursement, poor definitions of roles and responsibilities, insufficient training, a lack of time, hierarchical differences, and divergent communication styles [7-9]. Communication styles can be classified as either formally structured, such as team meetings or clinical rounds, or informal and opportunistic, such as hallway consultations [10].

Within our scoping review, we focus on 1 specific part of ICC, which is characterized by the use of digital tools to support its effectiveness [9,11]. Research shows that digitally supported interprofessional communication and collaboration (DICC) lead to better division of tasks; improve the definition of responsibilities; increase the accessibility, efficiency, and safety of clinical information transfer; and partly replace time- and resource-consuming face-to-face multidisciplinary meetings [2,12-15]. Despite the benefits, implementation of DICC is complex and challenging, with studies assessing critical factors for the successful implementation and use of DICC being scarce [16].

Although various definitions and conceptualizations of DICC are available in the literature, they largely neglect the technical dimension [16,17]. Greenhalgh et al [16] proposed the Nonadoption, Abandonment, Scale-up, Spread, and Sustainability (NASSS) framework, which helps predict and evaluate the success of a technology-supported health or social care program. Successful implementation of DICC tools depends on the material and technical features, the knowledge generated, the support and knowledge needed to use the tools, as well as their substitutability and sustainability. A definition of DICC that includes these dimensions may guide research activities and support implementation projects, improving the probability of success for DICC. Therefore, we aim to conduct a scoping review on the (implicit) definition and dimensions of DICC across health care settings and its driving factors.

A preliminary search of PubMed returned some systematic reviews on facilitators of and barriers to ICC [6,8,11,18] as well as a handful of scoping reviews on DICC in the primary health care system and for specific disease groups [19-24].

However, no current or ongoing PROSPERO-registered systematic or scoping review on our research aim was identified in previous primary and review studies.

Aim and Review Questions

This review aims to (1) identify the factors that influence the development, implementation, and adoption processes of DICC and (2) elicit, analyze, and synthesize the (implicit) definition, dimensions, and concepts of DICC among health care professionals.

Subquestions driving the analysis include the following:

- How can DICC be operationalized?
- How do DICC complement or interfere with existing ICC practices and pathways?
- What barriers and solutions exist in the use of DICC?
- How does the health care setting (eg, primary care or secondary care) impact key concepts of DICC practices?

Methods

Search Strategy

To be able to conduct an in-depth analysis of the literature, we will draw upon a broad range of heterogeneous types of primary research, which can best be obtained through a scoping review. To standardize the approach, we will adhere to the Joanna Briggs Institute methodology [25].

In accordance with the methodology, we adopted a 3-step approach for including articles. To start with, an initial screening of titles, abstracts, and index terms of relevant articles in PubMed was used to identify possible keywords and refine our final search strategy (Table 1). Specific instant messenger apps, such as WhatsApp and WeChat, were included in the search if they were demonstrably the most popular messenger apps in at least one country and were specific to the search, meaning we discarded Line and imo due to their ambiguity [26]. Table S1 (Multimedia Appendix 1) details the hits per search string in PubMed. In a second step, we adapted the search strategy to each database (ie, CINAHL, PubMed, Embase, PsycInfo, and Scopus; Table S2 in Multimedia Appendix 1). Search strings were tested across all databases for conclusiveness. Our third step will be to manually screen all references of the included full texts for additional studies according to the snowball technique described by Greenhalgh et al [27]. Due to the rapid development of digital technologies, we will limit the studies included to those conducted from 2012 onward and include studies in English, French, German, Portuguese, and Spanish.

[a]Title or abstract.

[b]Medical Subject Headings term for PubMed search string and title, abstract, or keyword for SCOPUS search string.

Eligibility Criteria

We defined several eligibility criteria based on formal issues, such as article type or language of publication, and issues related to the content of the manuscript, such as participants and context. These eligibility criteria are listed in Table 2 and described in detail below.

XSL•FO
RenderX

Table 2. Inclusion and exclusion criteria.

Feature	Inclusion criteria	Exclusion criteria
Article type	Any of the following published in a peer-reviewed journal: • Primary research approach and study design • Opinion pieces • Guidelines • Reviews • Meta-analyses • Meta-syntheses	• Unpublished studies • Non–peer-reviewed research papers • Grey literature • Conference abstracts • Editorials • Book chapters • Records for which we are unable to obtain the full text • Studies that focus on students of health care professions
Language	• English • French • German • Spanish • Portuguese	• All other languages
Participants	• DICC[a] among health care professionals, including medical doctors and nursing staff	• Studies focusing on DICC between patient groups and health care practitioners • Studies focusing on individuals in the same health care profession within the same setting
Concept	• DICC involving either at least two different groups of health care professionals • DICC among health care professionals working in similar roles but in different health care settings	• All other DICC among health care professionals
Context	• Any geographic and demographic health care setting	N/A[b]

[a]DICC: digitally supported interprofessional communication and collaboration.

[b]N/A: not applicable.

Participants

The scoping review will include studies that focus on DICC among health care professionals, including medical doctors and nursing staff. Studies focusing on DICC between patient groups and health care practitioners as well as among individuals of the same health care profession within the same setting will be excluded.

Concept

We will consider DICC either involving at least two different groups of health care professionals or among health care professionals working in similar roles but in different health care settings.

Context

The study will include any geographic and demographic health care setting, as understandings of DICC may vary among different groups and settings, such as primary and secondary health care systems. We will include sources, but not limit them to such, assessing the implementation, piloting, and adoption of new DICCs.

Types of Sources

We will consider any type of primary research approach and study design, opinion pieces, guidelines, reviews, meta-analyses, and meta-syntheses published in a peer-reviewed journal. We will not include any unpublished studies, non–peer-reviewed research papers, or grey literature. We will further exclude conference abstracts, editorials, and book chapters, as well as all records for which we are unable to obtain the full text. Furthermore, studies that focus on students of health care professions will be excluded.

Study or Source of Evidence Selection

For screening, review, and data extraction, the web-based review manager Covidence (Veritas Health Innovation) will be used. We will upload all identified records and remove duplicates. Following the Joanna Briggs Institute methodology, all authors will independently screen the title and abstract of the first 50 records sorted by first author's last name. Any discrepancies will be discussed to ensure a uniform understanding of the inclusion and exclusion criteria. All remaining records will be screened by 2 independent reviewers. Potentially relevant sources will be retrieved in full, and their details will be imported into Covidence. Two independent researchers will assess the full text against the inclusion criteria and note reasons for exclusion. Any discrepancies between reviewers' decisions will be settled by an additional reviewer throughout all stages of the screening process. The results of the search and the study inclusion process will be reported in full in the final scoping review report and presented in a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram [28].

Data Extraction

Data will be extracted from all included records by 1 reviewer using MAXQDA (version 2022; CERBI GmbH). Specific categories for data extraction are predefined (Table 3) and include details about the study setting, participants, and key

XSL•FO
RenderX

findings relevant to the review questions. The draft data extraction tool will be modified and revised as necessary during the process of data extraction. All modifications will be detailed in the scoping review.

We will extract data for sources that define DICC based on another reference ("secondary record") into a second data extraction sheet—if the secondary record is available to the researcher. No further inclusion or exclusion criteria will be applied to secondary records.

Table 3. Categories for data extraction.

Category	Item
Source details	• Journal • Year • Country of study setting • Study type

Details or results extracted from source of evidence	• Aim or purpose
	• Definitions (communication, collaboration, and digital tool)
	• Health care setting
	• Participants
	• NASSS[a] framework:
	  • Domain 1: the condition or illness
	  • Domain 2: the technology
	  • Domain 3: the value proposition
	  • Domain 4: the adopter system
	  • Domain 5: the organization
	  • Domain 6: the wider context
	  • Domain 7: embedding and adaptation over time
	• Other remarkable results

[a]NASSS: nonadoption, abandonment, scale-up, spread, and sustainability.

Analysis

The NASSS framework will be used as the basis for data analysis [16,17]. It consists of 7 domains, as follows: condition or illness, technology, value proposition, adopter system (intended users), organization(s), and wider context (especially regulatory, legal, and policy issues). The seventh domain, which is crosscutting, considers how the domains interact and change over time [16]. Through the NASSS framework, researchers can identify and explain the complex manifestations in technology-supported change efforts. Using the dimensions of the NASSS framework as predefined analytical themes, we will analyze the extracted data following a thematic analysis approach [29]. If necessary, we will inductively establish new themes or subthemes alongside the data analysis process.

Results

We will characterize the extracted data of all primary and secondary records by means of descriptive analysis, using diagrams and tables, accompanied by a narrative account of the findings, with a focus on the questions of this scoping review. A qualitative in-depth thematic analysis of definitions, dimensions, and concepts will be carried out, and data will be synthesized and mapped.

The scoping review was initiated in October 2022 with a protocol. Screening started in December 2022 and the analysis will be concluded in August 2023. We expect to submit the final scoping review manuscript by October 2023

Discussion

Contribution to Digital Health

The definitions and dimensions identified might have the potential to assist in the design, development, implementation, and evaluation process of DICC. They might further aid in understanding the barriers encountered in interprofessional use of DICC and identifying solutions. Furthermore, the results might help to advance new forms of interprofessional communication and to establish collaborations among different stakeholders in the health care setting. This might support a transition toward more coordinated care and help create digital frameworks for integrated patient care. Furthermore, the results might inform stakeholders from different backgrounds, including health care providers, health authorities and management staff, as well as entities developing DICCs.

Limitations

Our results will need to be interpreted with caution, as our search is limited in terms of language and publication time, which may have led to the exclusion of relevant literature. However, we deem the inclusion of manuscripts written in one of five languages to be quite extensive. In addition, we will not include any grey literature, as we want to address the current gaps in scientific literature. However, including non-peer-reviewed interventions and experiences assessing DICCs may provide further insights.

Conclusions

To the best of our knowledge, this is the first scoping review synthesizing definitions and dimensions of DICC among health

XSL•FO
RenderX

care professionals as described in peer-reviewed studies. Closing this definition gap will provide a differentiated definition system, informing future research activities and implementation projects alike. We additionally expect to identify areas that merit further research in the form of primary or review studies.

Acknowledgments

This study is undertaken without external funding.

Data Availability

All data supporting the results of the scoping review will be reported in the manuscript, and the entire raw data sets that support the findings will be made available by the authors.

Conflicts of Interest

None declared.

Abstract

Background: Psychotherapy manuals are critical to the dissemination of psychotherapy treatments. Psychotherapy manuals typically serve several purposes, including, but not limited to, establishing new psychotherapy treatments, training providers, disseminating treatments to those who deliver them, and providing guidelines to deliver treatments with fidelity. Yet, the proliferation of psychotherapy manuals has not been well-understood, and no work has aimed to assess or review the existing landscape of psychotherapy manuals. Little is known about the breadth, scope, and foci of extant psychotherapy manuals.

Objective: This scoping review aims to identify and explore the landscape of existing book-based psychotherapy manuals. This review aims to specify the defining characteristics (ie, foci, clinical populations, clinical targets, treatment type, treatment modality, and adaptations) of existing book-based psychotherapy manuals. Further, this review will demonstrate how this information, and psychotherapy manuals more broadly, has changed over time. This project aims to make a novel contribution that will have critical implications for current methods of developing, aggregating, synthesizing, and translating knowledge about psychotherapeutic treatments.

Methods: This scoping review will review book-based psychotherapy manuals published from 1950 to 2022.This scoping review will be informed by guidance from the Joanna Briggs Institute Scoping Review Methodology Group and prior scoping reviews. Traditional search and application programming interface–based search methods will be used with search terms defined a priori to identify relevant results using 3 large book databases: Google Books, WorldCat, and PsycINFO. This review will leverage machine learning methods to enhance and expedite the screening process. Primary screening of results will be conducted by at least 2 authors. Data will be extracted and double-coded by research assistants using an iteratively defined codebook.

Results: The search process produced 78,600 results, which were then iteratively deduplicated. Following deduplication, 50,583 results remained. The scoping review is expected to identify common elements of psychotherapy manuals, establish how the foci and content of manuals have changed over time, and illustrate coverage and gaps in the landscape of psychotherapy manuals. Results from this scoping review will be critical for future work focused on developing, aggregating, synthesizing, and disseminating knowledge about psychotherapeutic treatments.

Conclusions: This review will provide knowledge about the vast landscape of psychotherapy manuals that exist. Findings from this study will inform future efforts to develop, aggregate, synthesize, and translate knowledge about psychotherapeutic treatments.

Introduction

Psychologists have long disseminated therapeutic knowledge and procedures through writings such as books and papers. For example, Freud first published *The Interpretation of Dreams* in 1899. However, the origins of the psychotherapy manual are unclear, and what qualifies as the first psychotherapy manual has not been well-established. Previous work has endorsed different publications as the first psychotherapy manual, including Wolpe's [1] 1958 *Psychotherapy by Reciprocal Inhibition*, Kelerman and Neu's [2] 1973 (unpublished) *Interpersonal Approach to Treating Depression*, Paul's [3] 1966 *Insight vs. Desensitization in Psychotherapy*, and Beck's [4] 1979 *Cognitive Therapy for Depression*. Though the origins of manuals are not well-understood, psychotherapy manuals have evolved to play an important and prominent role in clinical research, education, and practice.

Since their emergence, the value of psychotherapy manuals for the field has been widely and contentiously debated, receiving both praise and criticism [5-11]. Critics have argued against the use of manuals for being prescriptive, difficult to apply to real-world clinical practice, antagonistic to clinician intuition, harmful to therapeutic alliance, and detrimental to the impactful delivery of therapeutic skills and techniques [5,6]. By contrast, proponents highlight the numerous functions that psychotherapy manuals serve. First, they are essential for conducting research and establishing evidence-based psychotherapeutic treatments as they provide a protocol for treatments to test and evaluate treatment efficacy [2,7-11]. Second, creation of a manual legitimizes new and emerging psychotherapy treatments, such that without a manual, it is difficult to disseminate new treatments to practicing clinicians [9-12]. Third, manuals provide a structure that can be used to understand and evaluate fidelity or adherence to treatment [2,7,9,10]. Fourth, manuals aid in the training and development of clinicians [2,7-10,13]. Throughout their careers, clinicians can use manuals to learn new practices or improve their own practice. Indeed, research has indicated that practicing clinicians have read multiple manuals [14]. Finally, manuals are used to communicate information about treatments and enhance the legitimacy of psychotherapy practice to outside stakeholders (ie, policymakers and consumers). Because of these benefits, manuals have become the primary method of disseminating psychotherapeutic treatments, and their proliferation has been extensive over the past half-century [11].

Despite the prominence of manuals in psychotherapy research and practice, what constitutes a psychotherapy manual is not well-defined [15]. Clarity about what defines psychotherapy manuals is also mixed among those who use them, as demonstrated through empirical research with clinicians [7,14]. Previous works have attempted to define the psychotherapy manual and its necessary components [2]. Common components include a theoretical basis for treatment, a historical overview of treatment, a guide for delivering treatment, an overview of information about delivering treatment, troubleshooting information, patient or client dialogue, case or vignette examples of treatment, and supporting resources for delivering treatment (eg, assessment tools, fidelity checklists, client worksheets, case vignettes, and session outlines) [7,14]. The form of psychotherapy manuals is also not strictly defined, with "psychotherapy manuals" being disseminated as multiple forms, including books, individual book chapters, journal papers, gray literature, theses or dissertations, government publications, and more. However, books remain a popular method for disseminating psychotherapy manuals.

Given that psychotherapy manuals have become the predominant method for disseminating psychotherapy techniques outside of direct face-to-face supervision, a review of existing book-based manuals is critical for understanding the evolution in foci and content of manuals over time, the elements of psychotherapy manuals, and the current coverage and gaps of specific topics in extant psychotherapy manuals. A scoping review is the optimal approach to review the landscape of existing psychotherapy manuals. Scoping reviews focus on mapping existing knowledge on a topic, and they can be particularly advantageous when all relevant information on a topic is infeasible or impossible to attain. Given the decentralization and unknown breadth of psychotherapy manuals, a scoping review is the ideal design for understanding this landscape and addressing this problem [16].

Although scoping reviews have typically relied on manual search, screening, and data extraction procedures, machine learning has increasingly been used to support the review process [17]. Conducting reviews is resource-intensive [17], and as the body of literature gets larger, the labor associated with conducting reviews increases. Previous work has illustrated that the disparity in size between search results and the final sample is vast, with an average inclusion rate of ~3% of search results [18]. To address this problem, machine learning has been used to efficiently and effectively aid the review process [17]. Previous work has illustrated the use of machine learning techniques in the search, title or abstract screening, full-text screening, and information extraction phases [19]. While rapidly expanding, current machine learning techniques are only recommended for certain phases of the process, including, particularly, the screening phase [19,20]. Review platforms themselves have also increasingly leveraged machine learning components within their own software [20-22].

Leveraging machine learning techniques, this scoping review will be the first to perform a high-level review of book-based psychotherapy manuals. Currently, there is no systematic or even quasi-systematic knowledge about the psychotherapy manuals that exist. Given the large role of psychotherapy manuals in training, practice, and research in clinical psychology, this is a critical gap in knowledge that this scoping review will fill. This review will address several aims. Primarily, this review will aggregate and synthesize information about a large portion of manuals that exist. Within this aim, this review will specify the foci, clinical populations, clinical targets, treatment type, treatment modality, and adaptations of existing manuals. Further, this review will demonstrate how psychotherapy manuals have changed over time. The findings from this review will also support future efforts to develop, aggregate, synthesize, and translate knowledge about psychotherapeutic treatments. This paper delineates the protocol and methods used to address these aims.

Methods

Study Design

This scoping review will be informed by guidance from the Joanna Briggs Institute Scoping Review Methodology Group [23] and previous literature on scoping reviews [20]. Specifically, this scoping review will use a modified form of the scoping review framework outlined by Peters and colleagues [16]. Slight modifications to this framework will be necessary to capture information specific to psychotherapy manuals in book form.

Search Strategy

Search terms and search strategy were developed collaboratively with the research team and subject matter librarians. The full search approach can be found in Multimedia Appendix 1. PsycINFO, Google Books, and WorldCat were searched for this review, searched in July 2022. These databases were selected based on (1) catalog size, (2) availability of relevant data for review, and (3) feedback from study authors and subject matter librarians. Some traditional scholarly databases, such as PubMed, do not consistently index psychotherapy books and thus were not used for this review. For PsycINFO, traditional database search methods were used. A search statement was developed for PsycINFO that combined both treatment and format language. Search terms for PsycINFO consist of "(psychotherap* OR therap* OR clinic* OR treat* OR interven* OR practi* OR counsel*) AND (manual OR protocol OR guide OR handbook OR primer)." PsycINFO offers over 5 million bibliographic records across numerous disciplines [24]. Search terms for PsycINFO included the aforementioned search statement as well as additional terms to include books but exclude book chapters (see Multimedia Appendix 1). Application programming interfaces (APIs) were used to search Google Books and WorldCat. As of October 2019, Google Books maintained a catalog of over 40 million books [25]. As of November 2022, WorldCat maintained a catalog of over 542 million bibliographic records [26]. APIs allow for the large-scale aggregation of search results that is unavailable through other methods. Compound search terms were created from the predefined search statement for the Google Books API. More specifically, permutations were created from terms from both sides of the search statement's "AND" to create briefer search terms (ie, "therap* manual," "therap* handbook," "clinic* primer," and "clinic* protocol") that were more feasible for API search methods (see Multimedia Appendix 1). Search strategy for WorldCat leveraged specific subject headings for the search process (see Multimedia Appendix 1). WorldCat search procedures were conducted by subject matter librarians from the University of California, Irvine. All initial search processes for this review were conducted in July 2022. Additional search processes will occur following the coding phase and be based on included results. This additional search process will be a snowball search based on bibliometric information of included results. Data from API queries were extracted and formatted to citations.

Deduplication was conducted in Python through an iterative duplication process. Deduplication focused on deduplicating by multiple parameters, given that some results may have the same titles (ie, books of different editions) or authors. Multiple rounds of deduplication were performed. First, deduplication by URL was performed to ensure that equivalent results from the same source were removed. Next, deduplication by ISBN identifiers was performed to ensure that duplicate results based on ISBN-10 or ISBN-13 numbers were removed. Finally, deduplication by a combination of title, description, AND year was performed, as well as a combination of title, author, AND year. Manual deduplication will be conducted throughout the later review phases, if necessary. Citations will be managed in reference management software.

Identification and Screening

Inclusion criteria were developed by study authors and subject matter librarians. First, manuals must be in the English language. Second, manuals must be a published book as this review focuses on books (ie, print books and electronic books), rather than other publication forms (ie, unpublished manuscripts, book chapters, journal papers, and research documents). Third, manuals must have been published between 1950 and 2022, as this reflects a broad time period that includes the creation of a vast majority of modern psychotherapies (ie, cognitive behavioral therapy and rational emotive behavior therapy). Additionally, this encompasses the time period in which previously identified "first" manuals were published [1-4]. Fourth, manuals must consist of a majority of instructional content about how to deliver a psychotherapeutic treatment or treatment components. This is defined as at least 50% or more content dedicated to instruction about delivering techniques or interventions. In cases where this is unclear, other resources may be used to assist with verification, such as book previews and freely available copies of books. Screening decisions will be made based on the information provided through titles or descriptions. After screening decisions have been completed, trained coders will code each included resource. For the coding process, more information may be sought through identified sources (ie, scholarly book reviews, publisher websites, and other book databases). If the additional information referenced during the coding process reveals that a manual should have been excluded, the manual will be excluded at this stage. This information may result in included resources being excluded during the coding process. Full information regarding inclusion or exclusion decisions at each stage will be outlined in the subsequent scoping review [16]. Fifth, manuals must be intended for use by a mental health professional (ie, psychologist, social worker, counselor, nurse, or physician). While some manuals have been previously addressed to consumers or lay providers, this review opts to focus on manuals that can be used by professionals to deliver mental health care. Results were excluded if they were a thesis or dissertation, another form of gray literature, or did not meet established inclusion criteria.

Screening of book descriptions and titles will be conducted in Rayyan (Rayyan Systems) [21]. Due to the size of this review, Rayyan's machine learning enhanced ranking system will be used as a form of active learning. Rayyan uses a support vector machine prediction system based on previous inclusion or exclusion decisions and text features (ie, unigrams and bigrams) [21]. Following an initial introductory period where eligibility

XSL•FO
RenderX

screening is conducted by the research team, Rayyan's ranking system will gradually "learn" the parameters (ie, lexical patterns in titles and descriptions) of results that are receiving certain decisions (ie, "included" and "excluded"). Rankings of results with no decision will be regenerated by KW on a regular basis throughout the screening process. Results will be screened in accordance with this ranking system, with highly ranked results (ie, those most likely to be included) prioritized for screening. Approximately 15%-20% of all results will be screened by KW and a member of the screening team. The remaining records will be screened for inclusion by machine learning enhanced inclusion or exclusion and supplemented input by KW, mirroring previous work and recommendations [20-22].

Screening fidelity (ie, 80% agreement) will be met through multiple rounds of test screening across the screening team and AZ. Results that will be screened by the screening team will receive 2 decisions, 1 made by KW and 1 made by another author. Screening decisions will be made on the basis of information provided (ie, book title and book description). All disagreements will be resolved through consensus discussions between screeners for each result in conflict.

Coding Process

A codebook will be devised by input from all authors. An initial codebook will be created by KW and AZ. Feedback on the codebook will be solicited from the screening team to ensure that codes reflect relevant and extractable information from results. Additionally, the codebook will be further iteratively defined through the test coding process, with additional codes proposed, discussed, and agreed upon by the coding team, KW, and AZ. Coding will be performed for all included manuals. Fidelity will be established through 3 rounds of test coding prior to the beginning of coding. The coding team will code each result based on the information provided through bibliometric information (ie, book title and book description) as well as open-access information such as scholarly book reviews, freely available published portions of the book, and information provided via official sellers (ie, publisher websites, Amazon, and scholarly databases). Information outside of bibliometric data will be used when coding cannot be adequately performed on the information provided. Scholarly databases will be used to search book reviews when more information is necessary for coding purposes. Code disagreements will be addressed through consensus discussion or adjudication of disagreements by KW.

The initial codebook includes bibliometric information (ie, title, author, publisher, and date published), edition number, clinical target, clinical population, treatment name, treatment orientation, treatment notes, mental health provider target, treatment delivery setting, type of treatment (ie, individual, group, couples, family, and parent-child), age of treatment target, as well as dichotomous codes for several potential adaptations to treatment based on gender identity, race or ethnicity, culture, physical illness or disability, religion, employment or role, and other adaptations that are not covered by previous categories.

Results

This scoping review is currently being conducted. Initial search across all sources was completed in July 2022. The search process produced 78,600 results, which were then iteratively deduplicated. Following deduplication, 50,583 results remained. Nearly 14.2% of results (n=7171) have been screened. A portion of included results (n=775) have been coded. Full results from this review will be submitted for publication in peer-reviewed journals.

Discussion

Principal Results

The proposed review will be the first to synthesize information about the existing landscape of psychotherapy manuals with the goal of addressing critical and unanswered questions. More specifically, we aim to identify the features of existing manuals (ie, foci, clinical populations, clinical targets, treatment type, treatment modality, and adaptations), illuminate the ways in which psychotherapy manuals have evolved over time, and highlight current resource allocation and gaps evidenced by existing manuals. The findings from this review will be critical for future efforts to develop, aggregate, synthesize, and translate knowledge about psychotherapeutic treatments.

Comparison With Prior Work

Prior work that has focused on reviewing psychotherapy manuals has been narrowly limited to a specific treatment type, treatment focus (ie, eating disorders) [27], or manual format (ie, manuals from randomized controlled trials) [28]. This work has been impactful for the field, but critical gaps remain as to the broader landscape and evolution of psychotherapy manuals. Digital methods have become increasingly important for conducting research across myriad disciplines [29]. Past scholarship in digital humanities and digital history has called for the use of digital technologies to supplement psychology research, particularly in the history of psychology [29], and this scoping review aims to build on this work.

Limitations

There are several limitations to this work. Psychotherapy manuals can be disseminated through myriad forms and methods. Because of the disparities in how psychotherapy manuals are published and disseminated, the ability to systematically aggregate all knowledge related to this topic is arguably impossible. Therefore, we limited the search strategy to books to capture the predominant method by which manuals are disseminated. This will exclude psychotherapy manuals disseminated through peer-reviewed papers and gray literature, for example.

Certain books used as psychotherapy manuals may not meet our inclusion criteria. For example, providers have previously used client-facing (ie, "self-help") books as psychotherapy manuals, yet these resources will be excluded from this review. This was decided by the authors to limit the inclusion of materials that are not focused on providing instruction to mental health professionals about treatments and treatment delivery.

XSL•FO
RenderX

Additionally, providers may use other types of books or resources to inform their clinical practice that do not focus directly on delivery of an intervention (eg, books focused on how to improve 1 specific technique within a treatment such as assigning homework, books on how to practice culturally competent care across many treatment modalities for specific populations, and books focused on developing therapeutic alliance across modalities). While these resources may be beneficial to delivery of psychotherapeutic treatments, they do not focus on instructing mental health professionals on how to deliver treatment.

Given the history of psychotherapy manuals and psychotherapy more generally, this scoping review aims to be informed by the changing definitions and ontologies in psychotherapy research. However, it is likely that through this scoping review, a modern qualitative coding may not encompass the changing definitions of psychotherapy treatments and the language used to describe them. Coding will be performed based on the bibliometric data, which is inherently reflective of the contemporary definitions in which a manual was produced. For example, the changing understanding of "behaviorism" and "behavioral treatments," as well as what constitutes "cognitive therapy" then versus now, may not be completely understood through the results from this review.

It is possible that the databases used within this review may not have a comprehensive list of psychotherapy manuals; however, the selected databases have extensive and growing catalogs [24-26]. Data quality may also differ widely within large databases. For some results, full information may be available, others may have gaps in information provided. Further, database entries may not be fully accurate, as some databases allow for manual entry of book information. Because of this, included references will be cross-checked with other sources (ie, scholarly book reviews, other databases, and publisher information), when possible. Finally, leveraging machine learning to expedite the screening process may result in increased false positives (ie, manuals that were included that should not have been included) and false negatives (ie, manuals that were excluded that should not have been excluded) [30]. Previous work using machine learning in title or abstract screening has demonstrated strong performance in not only accelerating the screening process but also doing so with high accuracy when combining with individual review [20,30].

Conclusions

Notably, this review will have numerous strengths. Although this is a scoping review, significant efforts will be taken to ensure that a wide variety of manuals will be included, increasing the potential representativeness of the results. Further, the use of these novel methods within this review will expand upon the growing literature on the use of machine learning to enhance reviews [17]. Most importantly, to our knowledge, this is the first large-scale review of book-based psychotherapy manuals. Thus, the benefits and implications of this work will be far-reaching for the development, dissemination, and implementation of psychotherapy knowledge. Given that a review of this topic and focus has yet to be done, this study will provide necessary information for the field's understanding of the landscape of psychotherapy manuals. Accomplishing this will not only provide critical information on the evolution of the treatment manual, but also how treatment manuals may be improved to meet the needs of users going forward. Previous work has indicated that use of manuals may vary across different types of users [14,31]. This review has particular use in identifying current resource allocation and extant gaps, as well as how this has shifted over time. With this information, future work will be able to better address those gaps, synthesize treatment-specific knowledge, and engage in the development of more effective methods of dissemination of psychotherapy.

Abstract

Background: A growing number of informal caregivers in many countries are important for effective functioning of health care in our society. Hence, they must receive the required support and services to continue providing care. IT applications can be used to support informal caregivers in their caregiving activities. However, evidence-informed guidelines for developing such IT applications and their evaluation are scarce. Hence, this scoping review can aid researchers and designers by providing design recommendations for IT apps for caregivers and potentially improve the design of IT applications for caregivers to meet their needs better.

Objective: This study aims to describe the proposal for a scoping review of current practices and recommendations in designing and evaluating IT applications for informal caregivers. The scoping review will also discuss the opportunities and challenges in designing these IT applications.

Methods: We will use a 5-step scoping review methodology to map relevant literature published as follows: (1) identify the research question, (2) identify relevant studies, (3) select relevant studies for review, (4) chart the data from selected literature, and (5) summarize and report results. A structured search will be conducted in PubMed, Scopus, IEEE digital library, Web of Science, and ACM Digital Library databases. In addition, hand searches of reference lists and keyword searches in Google Scholar will also be conducted. Inclusion criteria will be researched (journal and conference) articles focused on IT applications designed for use by informal caregivers and study type to be qualitative studies. Two reviewers will independently identify articles for review and extract data. Conflicts will be discussed, and a third reviewer will be consulted if a consensus cannot be reached. These data will be analyzed using thematic analysis.

Results: The results from this scoping review will be presented in a narrative form, and additional data on study characteristics will be presented in diagrams or tabular format. Uppsala University first initiated this scoping review protocol in December 2021 as part of the European Union–funded project ENTWINE. This work was also supported by the Swedish Research Council and the Swedish Cancer Society. The results will be presented in August 2023 and will be disseminated through a report to the European Union and a peer-reviewed journal publication. In addition, the team plans to share its findings on various public platforms, including social media, blog posts, and relevant conferences and workshops.

Conclusions: This is, to our knowledge, the first study to map the literature on the design and evaluation of IT applications for informal caregivers. The scoping review's results will detail the requirements, design suggestions, and user preferences, as well as the usability criteria and features of IT applications for informal caregivers. A mapping of studies could inform the design and implementation of future IT applications for informal caregivers.

Introduction

Overview

Informal caregivers voluntarily provide care for a relative or a friend facing illness, disability, or any condition requiring particular attention [1]. They are essential to the health care sector, providing critical care and support to those in need [2]. Informal caregivers play an important role in providing long-term care in people's homes and ensuring the quality of life for millions of individuals [3]. They must receive recognition and access to resources to help them better manage their responsibilities. Caregiving can be a burdensome role with negative consequences on the physical and emotional health of the caregiver [3]. Studies have consistently shown that informal caregiving is often associated with a sense of burden, resulting in psychiatric and physical illnesses and mortality [1,4,5]. Lack of choice in becoming a caregiver is often associated with a higher subjective burden [1,6]. Informal caregivers may experience burnout due to their role, which is characterized by feelings of exhaustion, lack of motivation, and difficulty concentrating [1]. This burnout can be caused by factors such as a lack of support from family and friends, financial strain, and feeling overwhelmed by the demands of caregiving [1]. The impact of informal caregiving on caregivers' health has been studied extensively. Informal caregivers face several challenges, including limited personal time, difficulty navigating the health care system, and care recipients with a higher awareness of needs [7]. Organizations have introduced digital tools to address these challenges to support caregivers [8]. Additionally, recognizing and acknowledging their role is important for providing adequate support [8].

IT applications can benefit informal caregivers by assisting with their caregiving activities, among other things. IT applications for informal caregivers are technology-based tools that aim to provide support, resources, and assistance to individuals who provide care for family members or friends with chronic illnesses, disabilities, or aging-related issues. These applications can range from mobile apps to web-based platforms, for instance, the mobile app and web-based application CareHeroes [9]. They can provide educational information, help remember doctors' appointments, and coordinate care among all involved parties [10]. Smartphone apps can deliver timely and personalized health information to families and friends of chronically ill adults living in the community [11]. Digital resources, such as webinars, handbooks, and more, can educate caregivers about conditions and improve care quality. IT applications can also support informal caregivers by streamlining the process of building an informal care team of friends and family members. By making it easier to share information, ask for help, and create sign-ups, tasks can be easily delegated from the informal caregiver to a wider network. Access to current information is essential for informal caregivers. They could benefit from technological services that provide up-to-date information on their loved one's condition [12]. However, it is important to note that not all IT applications effectively support informal caregivers. A previous scoping review found that IT applications focus more on supporting caregivers in their caregiving role than their private and professional life [13]. Therefore, it is important to identify IT applications that cater to the primary caregiving and personal need domains of informal caregivers. This means developing IT applications that not only support caregivers in their caregiving roles but also address their personal and professional lives, such as managing their health, work-life balance, and social connections leading to better well-being. Overall, there is a need to investigate the design guidelines and principles for IT applications that go beyond addressing the caregiving role and cater to the personal and professional lives of informal caregivers, as well as to the specific needs of different caregiver groups.

It is important also to evaluate the usability of IT applications for informal caregivers to ensure they are effective and useful. Research has shown that most applications offer limited evidence of effectiveness. This highlights the importance of conducting rigorous usability evaluations of IT applications to ensure that they are meeting the needs of their users and achieving their intended goals. Still, those evaluated have been found to help provide educational information, remember doctors' appointments, coordinate care among all caregivers, manage behavior problem checklists, provide alerts for care providers, and offer information about available services [10,14]. Evaluating IT applications for informal caregivers is important in identifying and addressing usability issues and ensuring that they are effective and useful for their intended purpose [14]. Caroço et al [15] and Gomes et al [16] report on the usability studies of Help2Care, an eHealth platform that provides digital training materials for informal caregivers. Both studies found that the platform had less usable aspects, such as navigation flow and design elements, which were identified through usability tests. Držanič et al [17] evaluated the usability of a smartphone telecare app for informal caregivers and found that users perceived the app as high in usability and user experience. Xiao et al [18] designed and evaluated web interfaces for informal caregivers in senior monitoring and found that combining evaluation methods is important in identifying usability issues. Overall, these papers suggest that usability evaluations are important in identifying and addressing usability issues in IT applications for informal caregivers.

There are some reviews in the field of IT applications for informal caregivers that have been discussed in recent literature. Sala-González et al [10] conducted a systematic review of mobile apps for helping informal caregivers, finding that most of the studies assessed caregivers' needs before designing

XSL•FO
RenderX

mobile apps to adapt them to the needs of their users which has proved useful. Martínez-Alcalá et al [19] and Powell et al [20] found that IT applications were useful in improving the life of informal caregivers. However, it was found that there were some challenges to deploy these IT solutions for informal caregivers, and Hassan [21] conducted a scoping review and provided recommendations for the deployment of IT applications for informal caregivers. Guessi Margarido et al [11] investigated the nature and extent of native smartphone apps for informal caregivers of chronically ill patients and found that most apps targeted a single chronic condition, with Alzheimer and other dementia being the most common. Meyer et al [22] conducted a systematic review of novel technology as a platform for interventions for caregivers and individuals with severe mental health illnesses and found that none of the studies focused on caregivers, and the ones identified using mobile or web-based apps were just for patients and not their relatives. While previous reviews have explored the effectiveness of IT applications and the challenges and recommendations for their deployment, our proposed scoping review aims to contribute to the existing literature on IT applications for informal caregivers by identifying and summarizing knowledge about the design recommendations and usability of such applications.

Study Objectives

The objective of the proposed scoping review is to identify and summarize knowledge about the design recommendations of IT applications and the usability of IT applications by informal caregivers. The scoping review will also discuss the opportunities and challenges in designing these IT applications. Design recommendations for IT applications refer to best practices and guidelines that can be followed by software designers and developers to ensure that the applications they create are user-friendly, efficient, and effective. For instance, a relevant design recommendation could be accessible information; the application should provide concise and relevant information that is easily accessible and available in different formats, such as text, audio, and video, to cater to the different learning styles and needs of informal caregivers.

Usability refers to the degree to which an IT application is easy to use, learn, and understand. A usable IT application is designed with the end user in mind, allowing users to complete their tasks quickly and efficiently without encountering unnecessary obstacles or confusion. Many IT applications are designed for caregivers based on identified unmet needs through interviews and focus groups. However, to the best of our knowledge, this literature has not been compiled. This scoping review can aid researchers and designers by providing design recommendations for IT applications for caregivers and potentially improve the design of IT applications for caregivers to meet their needs better.

Methods

Study Design

Arksey and O'Malley's [23] methodological framework for scoping reviews will be used for the proposed scoping review. The research topic addressed here includes a wide range of study designs and various support platforms and solutions for informal caregivers caring for a wide range of illnesses and care-recipient types carried out in multiple countries. Moreover, designing effective solutions for informal caregivers has been carried out in multiple fields like information systems, human-computer interaction, and health informatics. A scoping review methodology was considered suitable as this is an emerging topic where evidence is scarce and scattered. There is a need to bring results from these different fields of designing IT support together to generate a common knowledge pool, which is a major research gap. This scoping review methodological framework outlines the following five stages: (1) identification of the research question; (2) identification of relevant studies; (3) selection of relevant studies; (4) charting the data from the selected literature; and (5) collating, summarizing, and reporting the results.

We will follow the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews) guidelines [24] to complement the conduct and reporting of the results.

Step 1: Identifying the Research Questions

The focus of the proposed review was identified through a preliminary scan of the extant literature. Initially, the focus was the design recommendations for IT applications for informal caregivers. However, upon initial inquiry, it became clear that to have effective and user-friendly design recommendations, the review would benefit from also looking at the evaluation of IT applications for informal caregivers. The research question was also discussed, and feedback was obtained from experts from Uppsala University and the eHealth research group at the University of Twente. Based on multiple rounds of brainstorming, the following questions were developed for the scoping review:

1. What are the design recommendations for developing IT applications for informal caregivers?
2. How are these IT applications perceived and evaluated by informal caregivers?

Step 2: Identification of Relevant Studies

The literature search was conducted in collaboration with a health psychology information specialist at the University of Twente and some sessions with the university librarian at Uppsala University. Search terms focused on three components of the research question: (1) informal caregivers, (2) IT applications, and (3) design or evaluation. Terms related to caregivers were based on previous reviews on this topic from Lambert et al [25,26] and included terms, such as "home nursing," "informal caregiver," "family caregiver," "informal carer," "family carer," "caregiver," and "carer." Terms related to IT solutions included "mobile application," "ICT solution," "ICT," "e-coaching system," "coaching system," "digital solution," and "IT solution." Terms related to design and evaluation included "design," "evaluation," "effectiveness," "usability," "requirements," "needs," "perspective," and "user experience." Table 1 provides an overview of the different groups of keywords.

Studies included both conference papers and journal articles as publication types. The databases searched were PubMed,

XSL•FO
RenderX

Scopus, IEEE digital library, Web of Science, and ACM Digital Library. EndNote 12 was used to store the search results and remove duplicates. The quality of the searches was confirmed by verifying that the results contained relevant studies identified before the formal search.

Table 1. Keywords for the search string.

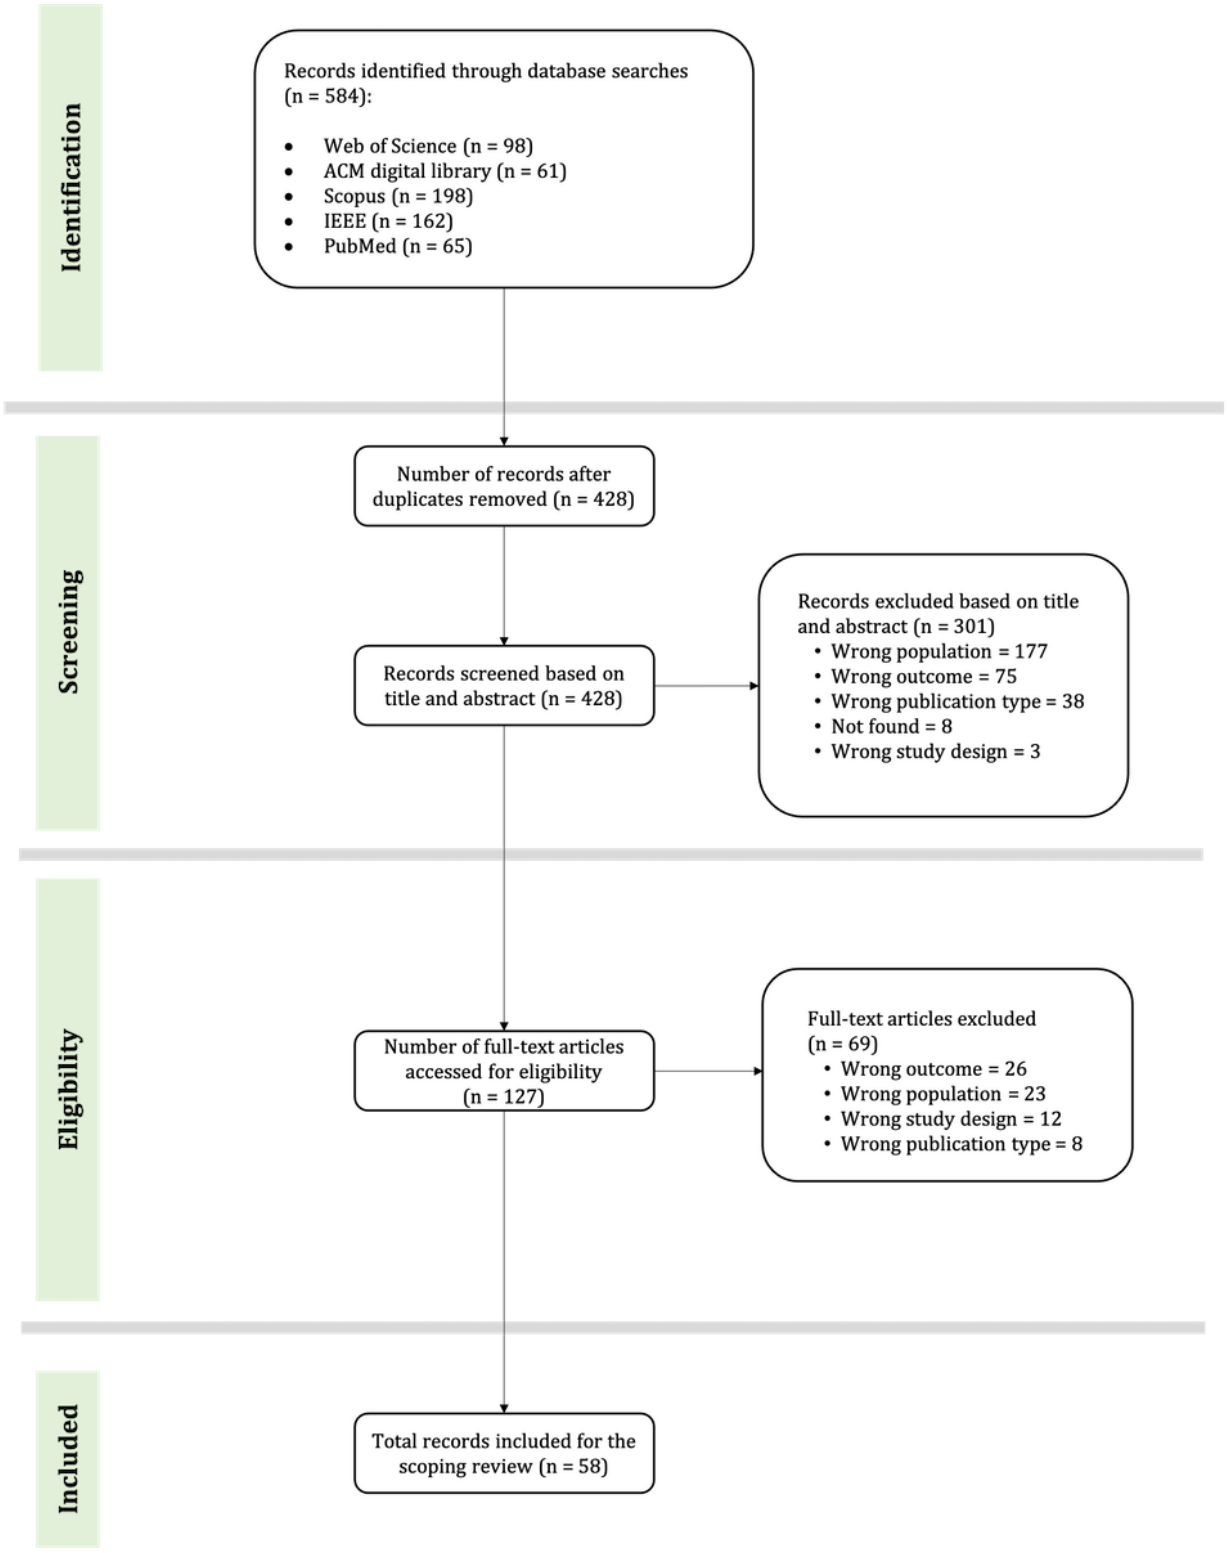
Keywords	Search terms
Group 1: informal caregiver	"Home nursing" OR "informal care*" OR "family care*"
Group 2: IT solution	"Mobile application*" OR "ICT solution*" OR "ICT" OR eHealth OR "e-coaching system*" OR "* coaching system*" OR "digital solution*" OR "IT solution*" OR "internet-based interventions*" OR telehealth*
Group 3: design or evaluation	Design OR evaluation OR effectiveness OR usability OR requirements OR needs OR perspective OR "user experience*"

Step 3: Selection of Relevant Studies for the Review

The initial screening of titles and abstracts was done only by the first author (SP) and was guided by the inclusion criteria using the web-based screening tool Rayyan [27]. At present, SP has also completed the full-text screening stage, while the second author (AA) will soon start full-text screening of all the articles. In the event of conflicts, a discussion will be held between the authors, and a third reviewer will be consulted if a consensus cannot be reached. Studies will be included if they are peer-reviewed conference articles, journal articles, or early-access articles. As the scoping review is restricted to peer-reviewed articles, the next stage includes removing proceedings, editorial and opinion papers, news articles, books and book chapters, theses, and clinical case papers. The inclusion and exclusion criteria to be used are summarized in Textbox 1. The study selection process is illustrated in Figure 1. The number of articles in each stage indicates the numbers from the first review. These numbers are expected to change based on the second review and further discussions.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:



- Publication type: conference articles, journal articles, and early access articles
- Studies regarding usability tests of IT apps or platforms
- Studies describing user needs or requirements for IT apps for informal caregiving
- Studies that describe the evaluation of IT apps focusing on what works or what is preferred along with user experience
- Studies describing the development process of IT apps for informal caregiving
- Studies on IT apps to train informal caregivers in their caregiving activities

Exclusion criteria:

- Study type: review articles, editorial and opinion papers, news articles, books and book chapters, theses, and clinical case papers
- Descriptive or quantitative studies assessing the adoption of a system or criteria for adoption based on a theoretical model
- Studies focused on care recipients and formal caregivers
- Studies on IT apps targeted at patients, but developed with interviews with patients and informal caregivers along with health care professionals

XSL•FO
RenderX

Figure 1. Study selection flow diagram.

Step 4: Charting the Data

The following information regarding the included studies will be extracted and stored in Excel (Microsoft Corp): authors, year of publication, the purpose of the paper or study and innovation, study location and context (setting and end users of innovation), study design, outcomes measured, main findings, and lessons learned used. Once the analysis and writing of the scoping review manuscript are finished, the articles used for the review will be accessible on the open science framework platform [28]. While submitting the scoping review manuscript, full citations of the included articles will also be added as supplementary files.

Step 5: Collating, Summarizing, and Reporting the Results

A descriptive-analytical narrative method was used to extract and chart the data from the selected articles. Using the same

XSL•FO
RenderX

process of team consultation, data from the selected articles were first extracted onto a data charting form developed by the research team using an iterative process. Charts were used to collate, summarize, and share data for team review and decision-making. Data entered included the following: authors, year of publication, the purpose of the paper or study and innovation, study location and context (setting and end users of innovation), study design, outcomes measured, main findings, and lessons learned. A coding scheme (framework) will be created under three thematic categories: (1) design and development, (2) evaluation, and (3) opportunities and challenges. Full articles were imported as PDF files into NVivo 12 (QSR International), a software program for qualitative analysis, for more detailed data extraction and coding. The authors applied the coding scheme to all pertinent text, and then further coded the data under emergent themes using an iterative process.

Results

The findings of our scoping review will be presented in a clear and coherent narrative, supplemented by relevant data on the study characteristics in diagrams or tables. The results can be broadly categorized into 2 main sections: design recommendations and usability criteria. Under the design recommendations category, we may have subcategories that address specific conditions or that are based on the type of system or caregiver characteristics. This will provide a more tailored approach to designing eHealth applications for informal caregivers that take into account their unique needs and circumstances. Similarly, the usability criteria category may also have subcategories that are specific to certain types of systems or caregivers. By considering the context in which caregivers use these applications, we can identify usability criteria that are most important to their overall experience. The presentation of our results will provide valuable insights for researchers and designers working in the field of eHealth applications for informal caregivers. The subcategories will help to further refine our understanding of the needs and preferences of this population and guide the development of more effective and user-friendly applications. The scoping review will also discuss the opportunities and challenges in designing these IT applications.

Uppsala University first initiated this scoping review protocol in December 2021 as part of the European Union–funded project ENTWINE. This work was also supported by the Swedish Research Council and the Swedish Cancer Society. The scoping review is being undertaken to delve into the potential design recommendations and usability criteria for IT applications catering to informal caregivers. The main objective of this scoping review is to produce 2 comprehensive lists: one comprising design recommendations and the other focusing on usability criteria for IT applications targeted toward informal caregivers. The first list will serve as a solid foundation for designers who are keen to develop IT applications for informal caregivers and will provide the answers to the first research question. If the chosen articles address both design recommendations and usability criteria for IT applications, the team will be able to effectively gauge whether these design recommendations are well-received by the caregivers. However, if some included papers only discuss usability criteria, the resulting list would still serve as a starting point for designers, as it would provide a comprehensive set of usability criteria for designing IT applications for caregivers and also help answer the second research question.

The results of the scoping review will be presented in August 2023 and will be disseminated through a report to the European Union and a peer-reviewed journal publication. In addition, the team plans to share its findings on various public platforms, including social media, blog posts, and relevant conferences and workshops.

Discussion

In this proposed scoping review, we will provide an overview of the current state of research on the design and usability evaluations of IT applications for informal caregivers. The review will identify the types of IT applications, their design recommendations, and the usability criteria. This information can guide the development of new IT applications or improve existing ones. The scoping review will also provide an opportunity to reflect on the challenges and opportunities associated with designing and evaluating IT applications for informal caregivers. To our knowledge, no previous studies have explicitly highlighted these factors. While Hassan's [21] study addressed the challenges and recommendations for the practical implementation of IT applications for informal caregivers, it solely focused on the caregivers of older adults. On the other hand, our study seeks to broaden the scope and delve into the factors essential for designing and evaluating IT applications for all informal caregivers.

The potential benefits of IT applications for informal caregivers are numerous [29,30]. They can provide support tailored to the individual caregiver's needs [2,31]. For example, an IT application could provide personalized reminders to take breaks or offer suggestions for self-care activities. IT applications can also connect caregivers to support networks, such as other caregivers or health care professionals [32,33]. This can help reduce the social isolation that is often associated with being an informal caregiver. Such apps can provide support for caregivers in the form of information, education, communication, and coordination of care. They also offer solutions for specific caregiver challenges, such as medication management and self-care. Moreover, these apps can potentially reduce caregiver burden, stress, and burnout, thereby improving the quality of care provided to the care recipients.

However, designing and evaluating IT apps for informal caregivers is a complex and challenging task. Many factors must be taken into account, such as the needs and preferences of caregivers, the technological capabilities of the target population, and the ethical and privacy considerations involved [21,34,35]. Additionally, evaluating the effectiveness of IT applications for informal caregivers requires using appropriate iterative evaluation methods that consider the unique characteristics of this population [29,36].

XSL•FO
RenderX

Our scoping review thus provides a comprehensive overview of the unique challenges and opportunities associated with designing and evaluating the usability of IT applications for informal caregivers across all age groups. The findings of our study will help researchers and developers create more effective and efficient eHealth interventions that cater to the diverse needs of informal caregivers.

Acknowledgments

We would like to thank Agnes Kotka (librarian at Uppsala University) and Carla Gerritsen (Information Specialist, Faculty of Behavioral, Management and Social Science, University of Twente) for assisting in the development of the search strategy. This research was funded by the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant (814072) for the 4-year innovative training network ENTWINE for informal care. This work was also supported by the Swedish Research Council (2019-01231) and the Swedish Cancer Society (20 1014 PjF).

Data Availability

Once the analysis and writing of the scoping review manuscript are finished, the articles used for the review will be accessible on the open science framework platform. While submitting the scoping review manuscript, full citations of the included articles will also be added as a supplementary file.

Authors' Contributions

SP is the principal author of this manuscript. SP designed the review, identified the research questions, worked with the search strategy, did the title and abstract screening and full-text screening, and wrote the manuscript. AA wrote parts of the manuscript. PÅ contributed to the study design. ÅC, PÅ, and LvGP critically revised the manuscript drafts. All authors approved the final draft of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Caregiver burden is highly prevalent among the informal caregivers of persons with severe mental disorders (SMDs). As such, strategies to support informal caregivers are necessary to enable them to cope with their caregiving role. Currently, there is limited evidence on the extent of existing strategies for supporting informal caregivers of persons with SMDs in transitional countries.

Objective: This study presents a scoping review protocol to identify and describe the extent and type of evidence on the existing strategies for alleviating caregiver burden among informal caregivers of persons with SMDs in transitional countries.

Methods: This scoping review will be conducted using the Joanna Briggs Institute's methodology for scoping reviews. The participants, concept, and context framework will be used to select relevant studies. This review will include studies on strategies for addressing caregiver burden among informal caregivers, with a specific focus on studies outlining caregiver interventions, caregiver support, and policies with strategies for supporting informal caregivers of persons with SMDs. Relevant studies conducted in transitional countries will be considered for inclusion. There will be no restrictions on publication type or design. Published literature will be accessed by searching electronic databases, including PubMed, MEDLINE, CINAHL, and PsycINFO; ProQuest will be used to access gray literature. Additionally, the reference lists of key studies will be reviewed to identify studies for inclusion. The search will be restricted to articles published between 2011 and 2021. Two reviewers will work independently to screen all abstracts and full texts for inclusion in line with the set inclusion criteria. Extracted data will be categorized and described using descriptive qualitative content analysis.

Results: This protocol will guide a scoping review to identify and describe the extent and type of evidence on the existing strategies for alleviating caregiver burden among informal caregivers of persons with SMDs in transitional countries. The main results of this scoping review will synthesize evidence from peer-reviewed and gray literature sources outlining various services and interventions for supporting informal caregivers of people with SMDs in transitional countries. In addition, existing gaps in the literature will be identified to inform future studies.

Conclusions: The increase in caregiver burden among informal caregivers in mental health warrants the development and implementation of strategies for alleviating the burden. This scoping review aims to increase awareness on the various services and intervention strategies for alleviating burden among informal caregivers in transitional countries.

Introduction

Severe mental disorders (SMDs) are disabling, chronic psychiatric conditions with a substantial burden on the patients and their caregivers [1]. These disorders include schizophrenia spectrum and other psychotic disorders, bipolar and related disorders, and depressive disorders [2]. People who are diagnosed with SMDs often exhibit long-term symptoms that compromise their ability to fulfill occupational and social roles [3]. For example, depressive disorder is characterized by prolonged feelings of sadness and guilt and reduced energy levels, which hinder participation in activities of daily living and work-related activities [4-7]. Those diagnosed with schizophrenia spectrum and other psychotic disorders often exhibit psychotic behavior, apathy, social withdrawal, and cognitive impairments, which all lead to a deterioration of social and occupational functioning [2,8]. Similarly, people with bipolar and related disorders are likely to experience considerable impairments at work and in their family lives and often struggle to form and maintain social relationships [9,10]. Given the chronic nature of SMDs, the symptoms are often persistent and thus require sustained care and management [11,12].

In resource-constrained settings in transitional countries, the care and management of those with SMDs relies on informal caregivers, making them instrumental in bridging the treatment gap [13]. Informal caregivers can be a family member, a friend, a neighbor, or any good Samaritan within the community responsible for providing care to a person with a chronic condition [14,15]. Informal caregivers assume responsibility for the health and well-being of those with mental disorders [16]. They are expected to manage the patient's behavior, structure their routines, and monitor their treatment [17-19]. To fulfill these responsibilities, most informal caregivers are obligated to live with the mental health care user 24 hours a day, every day of the year, to support them [16]. Fulfilling the responsibilities of caregiving and dealing with the recurring symptoms of SMDs result in high caregiver burden, stress, a decline in health and well-being, and a decreased sense of support [18].

Informal caregivers of persons with SMDs require ongoing access to information, guidance, and support to enable them to cope with their caregiving responsibilities. Various strategies for supporting and alleviating caregiver burden among the informal caregivers of persons with SMDs have been proposed in developed countries, including the United States and the United Kingdom. These strategies include the provision of family-based interventions and support programs. Family-based interventions encompass different combinations of psychotherapeutic strategies, including psychoeducation, stress management, cognitive appraisal, and problem-solving skills [20].

Psychoeducation is described as a systematic and structured psychotherapeutic intervention that contains a brief introduction to the mental disorder, presenting symptoms, and information on signs of early relapse [21]. This intervention aims to inform persons with SMDs and their caregivers about the available treatment with details on efficacy, safety, common side effects, cost, and methods to identify burden and coping strategies [17]. To ensure effectiveness, psychoeducational sessions can initially be offered weekly and later once a month [15]. Similarly, cognitive behavioral therapy (CBT) involves training informal caregivers to develop cognitive and behavioral skills to enable them to cope with current stressors [20]. This makes CBT suitable for addressing the complex demands and stresses attached to the caregiving role [20]. The cognitive skills gained through CBT address dysfunctional thoughts that may arise from a negative appraisal of the caregiving role, and the behavioral skills aim to increase pleasure when performing the caregiving activities [21]. This intervention seeks to promote positive attitudes such as empathy, affective support, and changing verbal communication patterns between the caregivers and the care recipients [21]. CBT can be offered individually or in a group through diverse platforms, including face-to-face, web-based, and phone-based modes [22]. CBT has been found to be beneficial in reducing burden among caregivers of persons with schizophrenia [23].

Most family-based interventions have been developed and tested in Western countries. The American Psychiatric Association and the United Kingdom's National Institute for Health and Care Excellence (NICE) guidelines for schizophrenia recognize the importance of family-based interventions for caregivers [24,25]. To ensure the effectiveness of these interventions, it is recommended that caregivers be involved in a minimum of 10 sessions over a period of 3 months to 1 year [26,27]. These interventions can be offered to caregivers individually or in a group session. Traditionally, a trained therapist or health care professional is required to offer these interventions to single or multiple families. Several randomized controlled trials conducted in the United States and the United Kingdom yielded positive results related to the effect of psychoeducation on families' social function and caregiver burden in those with psychotic disorders [28]. Additionally, these interventions have been shown to increase the quality of life for caregivers and care recipients and are associated with positive patient outcomes, including increased medication compliance, which reduces relapses and hospitalization [14,29].

Peer-led support groups have been identified as another strategy to alleviate caregiver burden among the informal caregivers of persons with SMDs. Peer-led support groups, such as the National Alliance on Mental Illness (NAMI), were established in the United States as part of the larger social movement of self-help [30]. These support groups are meant to address the needs of service users and their caregivers that are not adequately addressed by standard health care services. They

XSL•FO
RenderX

provide a platform through which informal caregivers can share and re-examine their own caregiving difficulties and challenges with other caregivers in similar situations. Additionally, it gives informal caregivers an opportunity to learn from others by exchanging information on SMDs and the experiences of caregiving [31]. Peer-led support groups are useful for improving caregiver attitudes, emotions, and empathy. Subsequently, they help improve effective communication and relationships among caregivers and their care recipients [32,33]. They are commended for being flexible and taking a more client-centered approach to enable caregivers to cope with the demands of their caregiving [28]. Previous studies conducted in the United States, the United Kingdom, and China demonstrated that peer-led support groups for informal caregivers of persons with SMDs can reduce caregiver burden and improve the caregivers' knowledge and stress management [32,33].

Although most research on strategies for alleviating caregiver burden among informal caregivers originated in Western countries, including the United States and the United Kingdom, there has been a phenomenal increase in studies conducted in transitional countries [34]. There has been an emergence of randomized controlled trials in transitional countries, including China, India, Iran, Pakistan, Thailand, and Malaysia, over the last decade [31,35-38]. The growing body of knowledge from studies outlining strategies for alleviating caregiver burden among informal caregivers in transitional countries calls for a review of the literature in this area. Currently, no scoping reviews have been published on strategies for alleviating caregiver burden among informal caregivers of persons with SMDs. This scoping review will therefore present available evidence on strategies for alleviating informal caregiver burden. Published and gray literature from caregiver burden studies, caregiver intervention and caregiver support studies, and mental health policy documents will be reviewed to allow for the synthesis of available evidence in transitional countries.

Methods

Overview

This protocol is a systematic scoping review of the literature reporting on strategies for alleviating caregiver burden among the informal caregivers of persons with SMDs in transitional countries. A scoping review method was selected to present an outline of the evidence that exists in the area of interest and the gaps for further research [39]. The proposed scoping review will be conducted in accordance with the Joanna Briggs Institute's (JBI) methodology for scoping reviews [39]. This methodology is based on 5 stages that guide the development of the protocol and the scoping review, which include identifying the research question and the relevant studies, selecting the studies, charting the data, and assembling the results to identify the relevant implications for policy, practice, and research [39].

First Stage: Identifying the Research Question

The main research question is: "What strategies exist for alleviating caregiver burden among informal caregivers of persons with SMDs in transitional countries?"

The Research Aims

The research aim is to present existing literature on strategies for alleviating caregiver burden among informal caregivers of persons with SMDs in transitional countries.

The Research Objectives

This study has the following research objectives:

1. To identify existing strategies for alleviating caregiver burden among informal caregivers of persons with SMDs in transitional countries.
2. To describe the characteristics of the strategies used to alleviate caregiver burden among informal caregivers of persons with SMDs in transitional countries.

This study will use the participants, concept, and context (PCC) framework (Textbox 1) to guide the selection of relevant studies and ensure alignment with the research question.

Textbox 1. The participants, concept, and context (PCC) framework for eligibility of studies.

Criteria and determinants

- Population
  - Informal caregivers of persons with severe mental disorders in transitional countries
  - Informal caregivers include family, friends, neighbors, or community members, often unpaid, to providing care
- Concept
  - Caregiver burden
  - Caregiver strain
  - Caregiver stress
  - Caretaker role fatigue
- Context
  - Transitional countries (including Africa, Asia, Latin America, and the Caribbean)
  - Lower- to middle-income countries

XSL•FO
RenderX

Second Stage: Identifying the Relevant Studies

This scoping review will consider both published and unpublished studies detailing strategies for supporting informal caregivers in mental health in transitional countries. The 3-step search strategy process will be used to identify relevant studies. An initial limited search of PubMed, MEDLINE, CINAHL, and PsycINFO will be undertaken to identify relevant articles published over the last 10 years. This will be followed by the analysis of text words contained in the titles and abstracts of relevant articles and of the index terms used to describe the articles. The initial key words will include [informal caregiver/s OR caregiver/s] AND [caregiver burden OR caregiver stress] AND [support strategy/ies OR intervention/s] AND [severe mental disorder/s OR mental illness] AND [developing country/ies OR underdeveloped country/ies]. The second search will include all keywords and index terms identified and revised with the assistance of a librarian at the University of the Witwatersrand. The search strategy will be adapted for each included database and information source (Multimedia Appendix 1). For unpublished or gray literature, a targeted search of dissertations, theses, and conference abstracts will be conducted on "ProQuest Dissertations and Theses Global" and public health and conference databases. Lastly, the reference lists of all included sources of evidence will be screened for additional studies.

Third Stage: Selection of Studies

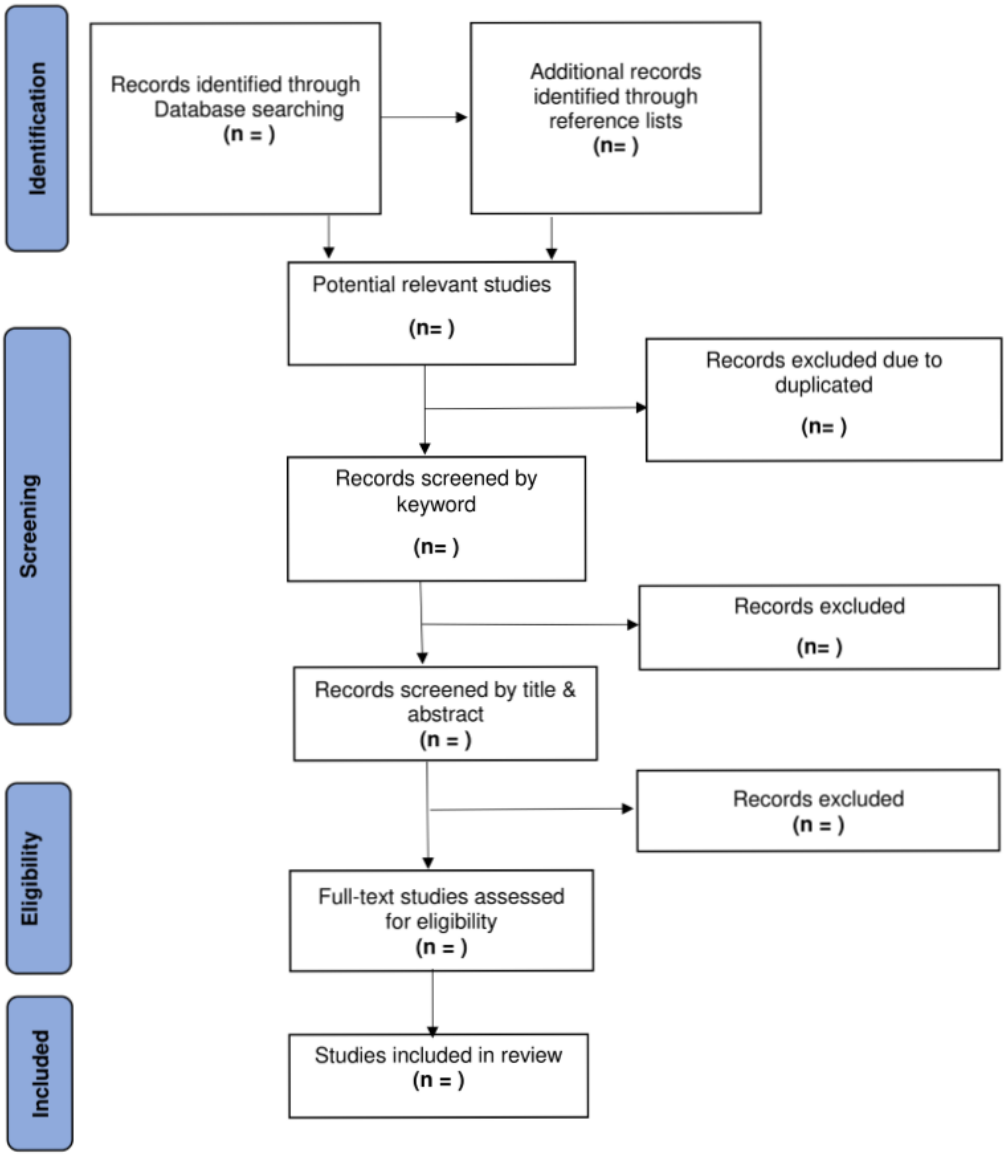
The PCC framework (Textbox 1) provides detailed eligibility criteria to ensure that the content of relevant studies aligns with the research question (Textbox 2).

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Contain details on strategies for alleviating caregiver burden among the informal caregivers of persons with mental disorders in transitional countries as classified by the World Bank
- Contain strategies for informal caregivers, which includes family, friends, neighbors, or community members, often unpaid, to provide ongoing care to a person with a mental disorder
- Contain strategies for caregivers of persons with severe mental disorders (SMDs), including schizophrenia spectrum and other psychotic disorders, bipolar and related disorders, depressive disorders, and personality disorders
- Contain strategies targeted towards alleviating caregiver burden, caregiver strain, caregiver stress, and caregiver role fatigue
- Include documents on caregiver intervention and caregiver support and mental health policy documents outlining relevant strategies
- Were published in the last 10 years, that is, between 2011 and 2021
- Be primary and secondary studies with both quantitative, qualitative, and mixed methods research approaches

Exclusion criteria



- Those outlining strategies for supporting caregivers who are paid to provide care
- Strategies that focus only on care recipients
- Strategies for informal caregivers of persons with intellectual disabilities, Alzheimer disease, and dementia

The search strategy will be piloted to check the appropriateness of the identified keywords and databases. All eligible articles will be uploaded on Mendeley Reference Manager. The identified articles will then be uploaded to Covidence, and duplicates will be removed. Covidence is a web-based primary screening and data extraction tool used to streamline the systematic review process. The author will be responsible for searching and uploading the identified studies, and the author and co-reviewer will be responsible for screening the titles, abstracts, and full texts of the identified studies.

The initial search and screening of titles and abstracts will commence in September 2021, and this will be followed by the second search and screening of titles, abstracts, and full texts in January-March 2022. In April-May 2022, the reviewers plan to conduct a full text review for additional studies identified in the references of the included studies. Throughout the process, all attempts will be made to obtain the full texts of the eligible studies by searching the University's library guides and the internet and by collaborating with a librarian at the University of the Witwatersrand Faculty of Health Sciences. The author and identified co-reviewer will be responsible for conducting a full text review of the identified studies. All excluded studies, along with the reasons for exclusions, will be tracked on Covidence. All identified conflicts will be resolved through constant discussions between the 2 reviewers and a web-based meeting will be held biweekly. The degree of agreement between the reviewers will be calculated on Covidence and reported in the findings. The results of the search and the study inclusion process will follow the recommendations in the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist (Multimedia Appendix 2) [39]. This will be mapped using the PRISMA-P (PRISMA Extension for Protocols) chart (Figure 1).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for the scoping review process [39].

Fourth Stage: Charting the Data

The data will be charted using an electronic data extraction form [39] on the Covidence software. A total of 2 separate data extraction forms will be used for the research articles (Table S1 in Multimedia Appendix 3) and the policy and guideline documents (Table S2 in Multimedia Appendix 3). This is useful for capturing the relevant information from each included study.

A total of 2 independent reviewers based at separate tertiary institutions will carry out the data extraction. Communications regarding consensus will be facilitated through regular web-based meetings and face-to-face meetings when necessary. Before using the data extraction forms, piloting will be done to ensure the standardization and relevance of the extracted information. This process will be conducted at the end of the initial limited search phase of the scoping review. This process is essential to ensure efficient, meaningful extraction of data from all included papers. This process will be conducted at the end of the initial limited search phase of the scoping review. A sample of 10 included papers meeting the eligibility criteria will be selected to test the quality and validity of the data extraction tools [40]. First, the included studies will be purposely sampled, and second, data will be extracted from the included studies. The sample synthesis will then be conducted after the data analysis process, which is outlined in the data analysis and presentation. The results from the synthesis will be used to inform the modification of the data extraction form. This process is essential to ensure efficient and meaningful extraction of data from all included papers. To ensure the quality and validity of the modified data extraction form, the piloting process will be repeated at the end of the second search.

Fifth Stage: Data Analysis and Presentation

A descriptive qualitative content analysis will be conducted inductively using NVIVO software to code the characteristics of the extracted data into overall categories [39]. This method of analysis is selected as it allows for rich meanings and insights to be derived from text by interpreting the manifest and latent content of the text, which is done through rigorous analysis and an understanding of a phenomenon's critical processes [41]. The outcome of this scoping review will inform the development of interview guides for the subsequent studies, and therefore, a

XSL•FO
RenderX

rigorous data analysis is required. A PRISMA-ScR flowchart (Figure 1) will be used to show the number of identified included and excluded studies. The various strategies for alleviating informal caregiver burden and their outcomes will be tabled under the different identified categories, including, but not limited to, the type of support strategies and interventions, the outcomes of the strategies and interventions used, and the challenges related to the implementation of these strategies and interventions [39]. Graphs and tables will be provided to enhance clarity. Existing gaps identified in the support strategies and interventions for informal caregivers in mental health, as well as the outcomes and challenges encountered will be identified to draw conclusions on the scoping review.

Ethics Approval

This scoping review forms part of a PhD project aimed at developing guidelines to alleviate caregiver burden among informal caregivers of persons with SMDs in South Africa, a transitional country. Ethical clearance (M200957) was obtained from the University of the Witwatersrand Human Research Ethics Committee.

Results

This protocol guides a scoping review aimed at identifying and describing the extent and type of evidence on the existing strategies for alleviating caregiver burden among informal caregivers of persons with SMDs in transitional countries. The initial search and screening of titles and abstracts commenced in September 2021, and this was followed by the second search and screening of titles, abstracts, and full texts from January to March 2022. A full-text review of the additional studies identified from the included studies was conducted from April to June 2022. Overall, 44 studies were identified for inclusion in the main study. The data were analyzed and written up for publication in September 2022. The scoping review article was submitted for consideration in a peer-reviewed journal, and the authors expect publication by the end of 2023. The results of this scoping review are useful to policy makers, mental health managers, health care professionals, and informal caregivers in mental health since they present the services and practical strategies that can be implemented to alleviate caregiver burden among informal caregivers. Additionally, existing gaps in the literature have been identified to inform future studies.

Discussion

Principal Findings

This protocol will guide a scoping review to identify and describe the extent and type of evidence on the existing strategies for alleviating caregiver burden among informal caregivers of persons with SMDs in transitional countries. There is acknowledgment of the unique role informal caregivers play in the care and management of people with SMDs within transitional countries and the subsequent burden arising from occupying this role [13,42,43]. A supported informal caregiver is likely to provide quality care, which is critical for the recovery of a person with a SMD [44]. The synthesis and analysis of existing literature on the various services and intervention strategies for alleviating caregiver burden forms a basis through which the development and implementation of these strategies can be facilitated within transitional countries where such evidence is lacking. Three researchers who have knowledge and experience in the JBI scoping review methodology developed the protocol. A librarian helped develop a comprehensive search strategy to allow for broad access to existing literature sources. To the best of our knowledge, there is no synthesis of literature in this area; this review therefore adds to the body of knowledge on the support for informal caregivers in mental health.

Limitations

The scoping review is limited to studies conducted in transitional countries; thus, the scope excludes studies conducted in developed countries, limiting the extent of the evidence on the strategies for supporting informal caregivers in mental health. Additionally, the review only includes studies conducted in English, creating a bias in the scope of the collated evidence. While the scoping review intends to include both peer reviewed and gray literature, it may not cover the entire existing evidence; as a result, studies in indexed databases may not be identified. The current review focuses on strategies for alleviating caregiver burden in SMDs, which locates it within the traditional Western medical health system paradigm. It is critical to acknowledge culture-bound syndromes, particularly within transitional countries; however, in other transitional countries, these syndromes are still classified under SMDs, which is within the Western medical terminology.

Conclusions

Informal caregivers are the backbone of recovery for persons with SMDs, and thus, strategies for alleviating their caregiver burden are critical, especially in resource-constrained transitional countries. With the growing research on the need for strategies aimed at supporting informal caregivers in their role, it is necessary to understand the extent of the burden and characteristics of these strategies in transitional countries. This scoping review will generate evidence to raise awareness on the various services and intervention strategies that can be developed and implemented to alleviate burden among informal caregivers in mental health within transitional countries.

Abstract

Background: Adverse drug events (ADEs) are a considerable public health burden resulting in disability, hospitalization, and death. Even those ADEs deemed nonserious can severely impact a patient's quality of life and adherence to intervention. Monitoring medication safety, however, is challenging. Social media may be a useful adjunct for obtaining real-world data on ADEs. While many studies have been undertaken to detect adverse events on social media, a consensus has not yet been reached as to the value of social media in pharmacovigilance or its role in pharmacovigilance in relation to more traditional data sources.

Objective: The aim of the study is to evaluate and characterize the use of social media in ADE detection and pharmacovigilance as compared to other data sources.

Methods: A scoping review will be undertaken. We will search 11 bibliographical databases as well as Google Scholar, hand-searching, and forward and backward citation searching. Records will be screened in Covidence by 2 independent reviewers at both title and abstract stage as well as full text. Studies will be included if they used any type of social media (such as Twitter or patient forums) to detect any type of adverse event associated with any type of medication and then compared the results from social media to any other data source (such as spontaneous reporting systems or clinical literature). Data will be extracted using a data extraction sheet piloted by the authors. Important data on the types of methods used (such as machine learning), any limitations of the methods used, types of adverse events and drugs searched for and included, availability of data and code, details of the comparison data source, and the results and conclusions will be extracted.

Results: We will present descriptive summary statistics as well as identify any patterns in the types and timing of ADEs detected, including but not limited to the similarities and differences in what is reported, gaps in the evidence, and the methods used to extract ADEs from social media data. We will also summarize how the data from social media compares to conventional data sources. The literature will be organized by the data source for comparison. Where possible, we will analyze the impact of the types of adverse events, the social media platform used, and the methods used.

Conclusions: This scoping review will provide a valuable summary of a large body of research and important information for pharmacovigilance as well as suggest future directions of further research in this area. Through the comparisons with other data sources, we will be able to conclude the added value of social media in monitoring adverse events of medications, in terms of type of adverse events and timing.

Introduction

Adverse drug events (ADEs) cause significant harm by influencing morbidity and mortality and increasing the economic burden on the health care system [1,2]. Furthermore, patients may prematurely discontinue treatment or hesitate to begin new drug treatments due to ADEs, depriving them of the potential beneficial treatment [3]. Not all adverse drug reactions can be detected before a drug is marketed; therefore, continuous surveillance and monitoring of their safety are important.

Traditionally, postmarketing pharmacovigilance for drug safety signals has relied on spontaneous reporting to regulatory agencies. Conventional pharmacovigilance systems have many limitations; most notably, the underreporting of ADEs experienced [4-7]. The low rate of reporting to these agencies has prompted researchers to examine other potential data resources to fill the gap in reporting.

Social media data analysis and monitoring have been investigated for its application in health research including health outcomes research, disease surveillance, and patient perspectives [8-10]. However, the most commonly studied outcome is that of safety [8-10]. Indeed, social media has been identified as a content-rich resource of patient reports of ADEs [11]. Given the volume, velocity, and variety of social media big data across platforms, using social media as a type of supplementary data source may be invaluable to provide perspectives of patients who are otherwise not usually reached through traditional pharmacovigilance channels. The combined use of different data sources may increase the representativeness and comprehensiveness of ADE synthesis by including ADEs experienced and reported by social media users, part of whom can belong to medically underresourced communities that tend to be neglected in regulatory agencies' reporting programs.

Researchers began exploring the potential value of retrieving drug safety data from social media as early as 2010 [11]. It was believed that social media data could be used to identify new signals or signals earlier than conventional methods [12]. To cope with the enormous amounts of text-based information posted on social media, natural language processing (NLP) and machine learning (ML) methods for automatic detection of mentions are continually being developed [13,14]. These methods have to overcome many challenges, for instance, the language in social media is highly informal, and user-expressed concepts are often nontechnical, descriptive, and challenging to extract [15,16]. NLP has been particularly instrumental in overcoming some of the barriers to identify adverse event mentions [13,14]. However, while the technological methods have advanced, the use of social media in identifying adverse events has not been sufficiently demonstrated, and thus, the debate as to whether (and if so, how) social media can enhance pharmacovigilance is still not resolved.

While many papers have concluded that social media has the potential to improve pharmacovigilance, others have argued that this is not the case, including the well-known Web-Recognizing Adverse Drug Reactions study [17]. These papers have tended to rely on case studies and the selection of these case studies, and the comparative analysis used may have impacted the results. The question that needs answering may be more complex and nuanced than whether or not social media can be used in pharmacovigilance, necessitating not a binary yes or no answer. The question may rather be how and in what circumstances social media can improve pharmacovigilance and when social media is less appropriate or even not appropriate in pharmacovigilance.

In total, 7 systematic reviews have been published from 2015 to 2021 that attempted to evaluate the potential use of social media in pharmacovigilance by either focusing on detection, such as safety signals, or the frequency of adverse event reports [12,18-23] (Table 1). These reviews, despite including over a hundred papers, largely concluded that the research is still in its infancy and that more research is required. Some of the reviews, however, did highlight that social media was more appropriate for mild symptomatic ADEs and for gaining patient perspectives of salient events and their impact or identifying adverse event signals earlier than regulatory agencies. The methods used to extract data from social media are continuously improving, and many more studies have been published since these reviews were published. These reviews also focused on ADE detection for pharmacovigilance or extraction methods, but they did not compare the types of drugs or the specific adverse events for which social media may prove more successful.

XSL•FO
RenderX

Table 1. Systematic or scoping reviews of the use of social media for pharmacovigilance.

Author (year)	Date searched	Included studies, n	Studies with comparison	Main focus of included studies	Review conclusions
Golder et al (2015) [18]	2015	51	29	ADE[a] detection	• Higher frequency of adverse events was found in social media and that this was particularly true for symptom-related and mild adverse events. Reliability or validity not thoroughly evaluated.
Lardon et al (2015) [23]	2014	24	6	ADE detection (11 papers) and extraction methods (13 papers)	• Detection: studies failed to accurately assess the completeness, quality, and reliability of the data. • Extraction: no study proposed a generic approach to easily adding a new site or data source. Additional studies are required.
Sarker et al (2015) [19]	2015	22	10	Extraction methods	• Annotated data are publicly available in a still very limited amount. As indicated by the promising results obtained by recent supervised learning approaches, there is a strong need to make such data available to the research community.
Tricco et al (2018) [12]	May 2016	70	19	ADE detection	• Social media is potential to supplement data from regulatory agency databases; it can capture less frequently reported AEsb and identify AEs earlier than official alerts or regulatory changes, but the use and validity of the data source remain understudied.
Convertino et al (2018) [20]	December 2017	38	38	ADE signal detection	• Poorer information quality as compared with spontaneous reporting databases. Rarely allows the evaluation of causal relationships. Proto signals had the potential of anticipating prespecified known signals in only 6 studies. Social media is not currently recommended for pharmacovigilance.
Pappa and Stergioulas (2019) [21]	Early 2018	100	Not reported	AE signal detection	• Developed new classifications of social data sources and taxonomies for social data, identified key challenges, and extracted new insights in terms of potential for practical applications.
Lee et al (2021) [22]	January 2021	14	14	ADE signal detection	• Assessed the time interval between signals detected on social media and regulatory authority action, revealing that most studies reported that meaningful signals could be identified 3 months to 9 years before regulatory authorities take action.

[a]ADE: adverse drug event.

[b]AE: adverse event.

We propose to undertake an updated analysis that allows us to validate the necessary conditions and methods to harness adverse event reports from social media as a complement to other sources. Given the wide breadth of studies conducted in this area and our objective to summarize the literature, we propose to undertake a scoping review using the Arksey and O'Malley [24] framework to answer the following questions: (1) what recent research has been undertaken into the detection of adverse events from social media at a large scale? (2) What types of drugs and adverse events have been studied to date with what findings? (3) How do the types and frequency of ADEs identified from social media differ from those identified from other sources, such as regulatory data or clinical trials? (4) What extraction methods are used to identify ADE data from social media and what impact may this have on the results?

Methods

Study Design

This scoping review protocol is reported in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist [25]. The inclusion and exclusion criteria present in Textbox 1 will be used in order to provide an understanding of the volume of the research in this area.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for studies on identifying adverse drug events data from social media.

Inclusion criteria

- Population
  - Any person (including pregnant women and young and older adults) with or without any condition or disease type (chronic or acute) states that they have taken any drug intervention (including vaccines) used in diagnosis, treatment, or prevention (as defined by the Food and Drug Administration [FDA]) and experienced an adverse event.
- Interventions
  - Any type of social media defined as any computer-mediated tools for users to create, share, or exchange information, ideas, or content via text, images, and audio (eg, message postings, pictures, and videos) in web-based communities and networks (such as message boards, social networks, patient forums, Twitter, Reddit, blogs, and Facebook).
- Comparators
  - Any data source other than social media (such as spontaneous reporting systems of the FDA or the Medicines and Healthcare products Regulatory Agency, clinical trials, or summary of product characteristics) is eligible as a comparator.
- Outcomes
  - Primary outcomes: Data on the type and frequency of adverse drug events (such as muscle aches, headaches, or rashes) are required from social media and at least one other data source.
  - Secondary outcomes: Data on the application of the adverse drug events (such as pharmacovigilance and hypothesis generation).
- Study design
  - Any type of assessment.
- Limits
  - Published 2017 onward in English, Spanish, French, or Chinese or in any language with an English translation available.

Exclusion criteria

- Population
  - Reports by health care professionals.
  - People reporting diagnosis, treatment, or prevention with a nonmedical intervention (such as medical devise, surgery, supplements, or natural remedy). People not reporting experience of an adverse event.
- Interventions
  - Simple, nonsocial internet-based interventions (ie, web 1.0).
  - Studies using social media to recruit participants.
- Comparators
  - No comparison undertaken to any nonsocial media data source.
- Outcomes
  - We are concerned with the properties of interventions under normal use. We therefore will not consider papers where the primary aim was to assess events such as intentional and accidental poisoning (ie, overdose), drug abuse, errors, or noncompliance. Drug-drug interactions are not eligible where they are the primary objective of the paper due to the different techniques required in identifying interactions as opposed to adverse events under normal use.
  - Papers focused on identifying patient perspectives of adverse events (such as fear or impact on quality of life) and papers on subsequent patient behaviors as a result of adverse events are also ineligible.
- Study design
  - Discussion papers, purely technical papers, and papers that only contain examples of posts from social media.
- Limits
  - Anything published before 2017 and anything published since 2017 that is not in English, Spanish, French, or Chinese or in another language with no available English translation.

Search Methods

In total, 11 databases covering a range of topic areas, including health and medical sciences, nursing, information and computer science, and gray literature will be searched. We will also search Google Scholar; however, due to the immense number of hits this will retrieve, we will only sift the first 300 records [26]. Searching databases may not retrieve all relevant available studies as there are delays in indexing, they may not have been indexed adequately (particularly where the database does not index using full text or uses automated methods) or they may have a lack of detail in titles and abstracts. We will, therefore, conduct handsearching of the most common journal titles from a previous review [18]: Drug Safety; Journal of Medical Internet Research, and Pharmacoepidemiology and Drug Safety (Textbox 2).

- *Pharmacoepidemiology and Drug Safety* (2017-2023)

The database search strategies will have 2 facets—"social media" and "adverse events" (see Multimedia Appendix 1 for draft search strategy in Ovid MEDLINE, which will be translated for other databases and interfaces as necessary).

A publication date restriction of 2017 onward will be placed on the searches as this review updates 7 previous reviews [12,18-23], the most recent of which is more focused than our review [22]. No language restrictions will be placed on the searches, although financial and logistical restraints will not allow translation from all languages; therefore, this review will be likely to focus more on papers published in English, Spanish, French, or Chinese and other languages for which an English language translation is available. We will also undertake forward and backward citation searching by checking the references of all included studies and forward citation searching using CitationSearcher to identify papers that have cited key papers we identify. Searches will be rerun before conducting the final analysis to retrieve any further includable studies.

The results of all the searches will be entered into an EndNote (Clarivate) library with the duplicates removed. Title and abstract screening will be undertaken independently by 2 reviewers in Covidence (Covidence) with any disagreements resolved by discussion or if necessary, a third reviewer. Full-text screening will again be undertaken in Covidence by 2 independent reviewers.

Data Extraction

A data extraction spreadsheet will be designed and piloted for this review. The form will record study characteristics of existing papers on using social media data to identify potential ADEs. Two reviewers will extract descriptive data independently, with findings compared and agreed. The following data will be extracted from included studies if available: (1) details on the type of social media platform used; (2) details on the primary aim of the study; (3) brief details of the methods used to extract data from social media including which drugs or adverse events are searched for and how and for what time period; (4) whether the study distinguished between personal and nonpersonal mentions, and whether it accounted for the influence of bots or nonindividual accounts; (5) the type and frequency of adverse events data identified for each drug and which drug; (6) comparator data sources along with any comparisons of the data collected; (7) conclusions of the original investigators; and (8) finally, whether code or annotated or raw data are made available by the authors.

XSL•FO
RenderX

As this is a scoping review, we will not assess the methodological quality (risk of bias assessment) of the studies or conduct any evidence synthesis. Nevertheless, we will summarize an array of NLP and ML (artificial intelligence) methods used for this task and synthesize the studies' self-reported performances and if available, scalability per method.

Ethical Considerations

Since the scoping review methodology consists of reviewing and collecting data from publicly accessible materials, this study does not require ethics approval.

Results

Unlike a systematic review, a scoping review does not "synthesize" the evidence or aggregate results from the included studies [24]. Although this scoping review does not involve raw data synthesis summary across all studies to be reviewed, descriptive statistics with each study as a unit of analysis will be used. Tables, graphs, and charts will be provided when applicable regarding the range of social media platforms evaluated, the frequency and types of adverse events and drugs identified, the types of methods used (including data collection), the types of data comparisons made, the data source compared to, as well as the results and conclusions. We will also require some form of analytic framework. The literature will be organized by type of comparison made (eg, spontaneous reporting systems, clinical literature, and summary of product characteristics). We will also seek to summarize our analysis by type of social media, type of adverse events, and type of ADE detection or extraction methods if applicable.

We will compare our results of studies from 2017 onward to the results of the 7 systematic reviews identified. Any discrepancies between the results will be investigated in terms of methods used and any other possible explanations.

Discussion

Principal Findings

Through the use of ML and NLP techniques, the automatic detection and extraction of ADEs from social media have been the focus of much research to refine the methods, including shared task competitions in the community [27]. This review will update and build upon previous reviews in this rapidly evolving field. Especially, the contributions to the current literature will be surrounding 2 contextual questions we asked in the beginning, namely, how and in what circumstances social media can improve pharmacovigilance and when social media may be less appropriate or even not appropriate in pharmacovigilance. Therefore, part of this review's objective is to suggest to fellow researchers the optimal use of social media data for ADE detection. Without suggesting that social media is a better or worse approach to pharmacovigilance than alternative data sources, we set this review to assist future research in this area in improving study design, validity, scalability, and reproducibility. We will also provide evidence-based discussions on the conceptual challenges we have identified through this review, the possible solutions to them, and future research directions.

We will review the latest research allowing us to elucidate how recent advances in the fields of ML and NLP are being used to advance discoveries in this research area. We will also address any patterns in the findings related to the methods and drugs and adverse events studied. Additionally, the results will objectively inform the debate regarding the value of social media in identifying adverse events and bring us nearer to a consensus. By systematically evaluating the comparisons made to other sources, we will be able to identify the similarities and differences in what is reported in social media, and by extension, identify the burden of ADEs from the patient's perspective. We will also highlight any gaps in the evidence and priorities for future research.

We will also discuss any issues that may have risen in terms of access to data subsequent to the time at which the studies were conducted. This will be particularly relevant given the new restrictions some social media platforms have placed on their data or application programming interface availability. For example, whether the data from the selected social media platforms are still available to access, and whether it is free to access or based on a commercial license. We will also discuss our results in the context of user privacy concerns, commercial interests, and barriers to social media research. This review is expected to be of particular use to regulatory agencies, and researchers wanting to prioritize research on suspected adverse events or monitor adverse events.

Strengths and Limitations

There are 2 main strengths to this study. First, different experts in the fields of NLP, ML, systematic review methodology, and information science will participate in the planning and development of the study. Second, we have already identified 7 previous systematic reviews or scoping reviews on which we can build our methods. The main limitations of our study are the exclusion of studies published in languages other than English, French, Spanish, or Chinese and the use of Anglo-dominated databases. This is also a fast-paced area of research meaning that the applicability of our findings may change over time.

Conclusions

This scoping review protocol outlines steps that will guide our scoping review. This review will also identify and map studies that indicate the value of social media in detecting adverse events and improving pharmacovigilance. The results of this study may help inform current recommended practices and the future direction of research in this area.

Data Availability

The full search strategies for all the databases, the data extraction sheets, and a full list of the included and excluded studies will be made available in the completed scoping review.

Authors' Contributions

SG, KO, YW, and GGH contributed to the development of the protocol. SG was in charge of developing the search strategy. SG, KO, YW, and GGH will develop the rest of the tasks of the scoping review.

Conflicts of Interest

None declared.

Abstract

Background: The anonymization of Common Data Model (CDM)–converted EHR data is essential to ensure the data privacy in the use of harmonized health care data. However, applying data anonymization techniques can significantly affect many properties of the resulting data sets and thus biases research results. Few studies have reviewed these applications with a reflection of approaches to manage data utility and quality concerns in the context of CDM-formatted health care data.

Objective: Our intended scoping review aims to identify and describe (1) how formal anonymization methods are carried out with CDM-converted health care data, (2) how data quality and utility concerns are considered, and (3) how the various CDMs differ in terms of their suitability for recording anonymized data.

Methods: The planned scoping review is based on the framework of Arksey and O'Malley. By using this, only articles published in English will be included. The retrieval of literature items should be based on a literature search string combining keywords related to data anonymization, CDM standards, and data quality assessment. The proposed literature search query should be validated by a librarian, accompanied by manual searches to include further informal sources. Eligible articles will first undergo a deduplication step, followed by the screening of titles. Second, a full-text reading will allow the 2 reviewers involved to reach the final decision about article selection, while a domain expert will support the resolution of citation selection conflicts. Additionally, key information will be extracted, categorized, summarized, and analyzed by using a proposed template into an iterative process. Tabular and graphical analyses should be addressed in alignment with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist. We also performed some tentative searches on Web of Science for estimating the feasibility of reaching eligible articles.

Results: Tentative searches on Web of Science resulted in 507 nonduplicated matches, suggesting the availability of (potential) relevant articles. Further analysis and selection steps will allow us to derive a final literature set. Furthermore, the completion of this scoping review study is expected by the end of the fourth quarter of 2023.

Conclusions: Outlining the approaches of applying formal anonymization methods on CDM-formatted health care data while taking into account data quality and utility concerns should provide useful insights to understand the existing approaches and future research direction based on identified gaps. This protocol describes a schedule to perform a scoping review, which should support the conduction of follow-up investigations.

KEYWORDS

EHR; electronic health record; data quality; common data model; data standard; data privacy models; data anonymization

Introduction

The anonymization of health data is a key approach for preserving patient anonymity during the secondary use of relational (ie, tabular) electronic health record (EHR) data [1]. However, to overcome the challenges related to the considerable heterogeneity in clinical data source systems (eg, due to diverse medical data coding frameworks, heterogeneous definitions of laboratory data values, or disparate setting- or task-dependent metadata), the use of common data models (CDMs) has been proposed and discussed [2]. Converting structured or unstructured source data to CDM standards helps to reach an understanding of commonly harmonized data into collaborative network research [3] and hence facilitates the cross-institutional exchange of medical data by using appropriate CDM metadata [2]. By approaching this, anonymization of CDM-converted EHR data promises patient privacy–secured sharing and analysis of harmonized data, which requires specific data anonymization components.

Extensive efforts describing the conduction [1,4-13] of data anonymization exist, and it is essential to differentiate and properly address 3 major aspects when dealing with relational data anonymization (anonymization of tabular data). This includes privacy models, data transformation models, and data utility models for assessing and ensuring the fitness of anonymous data for use. In terms of proposed privacy models, the k-anonymity privacy model [1,7] is one of the most widely used models. It consists of placing at least *k* patients in an equivalence class with the same patient-identifying data element values (so-called quasi-identifiers; eg, birthdate and zip code), so that the probability of reidentifying a patient becomes *1/k*. The value of the threshold *k* is determined by the data owner (eg, a hospital department sharing the data) depending on the size of the data and privacy protection level [1]. Because of the limitations of this model for fully protecting sensitive information (eg, patient health insurance and treating medical doctor), the *l*-diversity privacy model [1,8] was proposed. This ensures that at least *l*-"well-represented" values for sensitive data elements are presented within each equivalent class. Furthermore, additional data privacy models including the *t*-closeness privacy model [9] (for preventing linkage of the record and data elements) and the differential privacy model [10] (for preventing table linkage and probabilistic attacks) were also addressed. The strengths and limitations of these models were discussed in depth and extensively by Majeed and Lee [1] and Lei et al [11]. For implementing the data privacy models on data, a corresponding data transformation model is required, which may include a variety of technical operations. These comprise, for instance, generalization (by replacing some data values with parent values), suppression (implementing data record, value, or cell suppression), permutation (partitioning data records into dissociated groups), perturbation (partly or totally replacing original data with synthetic data), or anatomization (dissociating the relationships among patient-identifying data elements) [1,11,13]. Implementing the privacy- and data transformation models mentioned above leads to high impact on the quality of anonymous data in terms of utility. Nonetheless, utility models including metrics such as accuracy or error rate, the *F*-measure, precision, and recall have been proposed to assess the utility of anonymous data for special purposes [1]. Furthermore, the weighted certainty penalty, generalized information loss, the global loss penalty, relative error, or information theoretical metrics have also been recommended to estimate the utility of anonymous data for general purposes [1,12,13]. In addition, further evidence-based recommendations on how to assess and report on EHR data quality have been proposed [14-18] (eg, 3×3 data quality assessment guidelines [16], the framework of Kahn et al [15], or that of Fox et al [18]), and tools for data anonymization, transformation, and utility models have been proposed and discussed [4].

Among others, by using CDM standards in the clinical context, related source data can be more efficiently reused, organized, described, validated, searched, and queried [2]. International standards such as Fast Health Interoperability Resources (FHIR) [19] and CDM frameworks including the Informatics for Integrating Biology & the Bedside (i2b2) TranSMART CDM [20], the Observational Medical Outcomes Partnership's Observational Health Data Sciences and Informatics (OMOP OHDSI) CDM [21], the Patient-Centered Outcomes Research network (PCORNet) CDM [22], and the Clinical Data Interchange Standards Consortium's (CDISC's) Operational Data Model (ODM) [23] therefore gained widespread attention in the scientific community in the last decades. For instance, the Medical Informatics in Research and Care in University Medicine (MIRACUM) consortium of the German Medical Informatics Initiative [24,25] presents an illustrative deployment of some of these CDMs.

While the interoperable conversion and querying of source EHR data into multiple CDM formats has been demonstrated [26], it is nonetheless worth noting that an entire transformation of health care data from the original data format to CDMs, or from one CDM to another one, is barely practicable [2]. This leads to potential challenges related to data completeness in the context of the use of CDM-converted health care data. Moreover, the relational anonymization of CDM-converted data by using the k-anonymity or *l*-diversity privacy models might build an interesting lever to allow patient privacy–preserved sharing of harmonized health care data as shown by Almeida et al [6] and in a recent study by Pitoglou et al [27]. Nonetheless, the anonymization of health care data can disproportionally affect the quality of resulting anonymous data sets due to

XSL•FO
RenderX

information loss, and hence their suitability for medical research, as investigated by Langarizadeh et al [28] and Ferrão et al [29]. Especially in the case of CDM-converted data, anonymization may affect both cardinalities and completeness requirements of the respective CDM data models. This can be observed, for example, by the suppression of mandatory fields or by generalization through entering of ranges (eg, age range) into fields that only allow numeric values (not interval). Moreover, once CDM-converted data have been anonymized, it would be relevant to ensure whether the generated anonymous data may at all be stored in conformity with the CDM structures, or if it would be necessary to adapt the CDM specifications (eg, through some slicing in FHIR specifying both the exact and range-based anonymous age). This indicates the need for a thorough investigation of the suitability of CDM databases to record anonymized data in a quality-compliant format.

This raises problems related to how anonymization-assisted preservation of patient privacy in using or sharing of CDM-harmonized health care data with a reflection of anonymous data utility is addressed, and whether CDMs differ in terms of their ability to record anonymized data. Despite the large range of studies performed in the fields of relational data anonymization [1,4-13], CDM standards [19-22,30,31], and frameworks for medical data quality assessments [15-17,32], little attention has been paid to an extensive review of the existing literature addressing these questions. Reviewing the existing evidence concerning these issues might aid in identifying, describing, and understanding how relational data are anonymized, evaluated, and documented into specific CDM databases and to what extent the utility and quality of the obtained anonymous data are addressed. There could be some gaps in data utility research to be considered when anonymizing specific CDM-transformed clinical data for specific data mining scenarios such as predictive analysis or machine learning for improving health care quality. The evidence and identified gaps should serve as support for further investigations in the field of utility-compliant anonymizing of harmonized health care data.

Given this research scope, we plan to conduct a scoping review that aims to identify and describe (1) the current status and challenges of implementing formal privacy models (eg, k-anonymization, *l*-diversity, differential privacy, or *t*-closeness) on CDM databases (including i2b2, OMOP, CDISC, PCORnet, and FHIR), (2) the strategies used there to ensure the quality and utility of anonymized data, and (3) the differences in multiple CDM standards in relation to their suitability to record and document anonymized data.

Methods

Ethical Considerations

No ethics approvals are required since the planned study is only concerned with the assessment of the literature within a specific domain. Hence, no sensitive patient-identifying data will be processed.

Schedule

For conducting this scoping review study, we will use the methodological framework of Arksey and O'Malley [33], which recommends an analysis process based on 5 steps: step 1—identifying the research question, step 2—identifying the relevant studies, step 3—selecting studies, step 4—extracting and charting data, and step 5—collating, summarizing, and reporting the results. Below, we describe the methodology's stepwise concepts and the planned and already implemented in-between steps.

Step 1—Identification of the Research Questions

As a prelude, an initial exploration of the literature was manually carried out to gain an overview of the issues regarding data quality and data anonymization as well as to determine the appropriate keywords to be included. A search was undertaken using a combination of the search terms "data quality," "anonymi*ation," and "deidentification," and by querying the literature platforms PubMed and Web of Science Core Collection. The most relevant articles were selected and analyzed upon full-text reading. To form the final research questions, we additionally addressed an explicit focus on the most internationally adopted CDMs (including i2b2 TranSMART, OMOP OHDSI, PCORnet, and CDISC ODM) and the FHIR standard. The research questions were derived by considering both the research objectives stated above.

In doing so, the planned scoping review investigation will address the following 3 research questions: how are formal anonymization methods carried out with CDM-converted health care data and which challenges are observed? How are data quality and utility concerns considered during the anonymization of CDM-converted health care data? How does anonymization affect the specifications of different CDM data models, and which differences are observable in the CDMs regarding their suitability for recording and documenting anonymized data?

Step 2—Identifying the Relevant Studies

Overview

To identify the most relevant articles matching the research questions, we will explore a large set of articles by taking into account the literature databases to be used, language considerations, key concepts for retrieving the literature items, and construction of the search query. Additionally, here we show the designed query we tentatively implemented on Web of Science.

Literature Databases

The literature search should be performed by querying the literature engines PubMed and Web of Science Core Collection. These literature search engines cover an extended range of medical and health informatics–related studies, and the latter additionally includes the fields of biomedical sciences and engineering, which are of high relevance for retrieving relevant data anonymization of related papers. Similar review projects considered the Web of Science Core Collection database as well [34,35].

Article Language Considerations

We will include articles published in English for facilitating the selection and screening of identified literature items.

XSL•FO
RenderX

Key Concepts and Search Terms

To efficiently find suitable articles, we have proposed 3 categories (concepts) of search terms, reflecting each of the relevant investigation domains of the study objective. The proposed set of search terms can be extended and documented, if necessary, during the literature extraction process.

While the first category (A) relates to data anonymization methods, the second one (B) captures the field of medical CDMs and data standards, and the last one (C) covers the domain of data quality and utility assessment. Table 1 provides an overview of the key concepts and the explicit search terms.

Table 1. Key concepts.

Key concepts	Search terms	Investigation domains
A	• Deidentification/ De-identification • k-anonymity • t-closeness • l-diversity • Differential privacy • De-identified • Data masking • Data generalization • Data perturbation • Data permutation • Data suppression • Data anatomization	Formal data anonymization
B	• i2b2 • TranSMART • OMOP • OHDSI • CDISC ODM • PCORnet • FHIR	Medical research CDMs[a] or data standard
C	• Data quality • Data accuracy • Data utility • Data fidelity • Fitness for use • Fitness for purpose	Assessment of quality or utility of data

[a]CDM: common data model.

Search Query Construction

Based on the defined key concepts and search terms, we built a search string by combining the domain of formal data anonymization with those of CDM standards and data quality by using corresponding “AND” and “OR” Boolean operators.

The final search string is built using the following key concept combination:

Search query = A AND (B OR C)

The proposed citation search query is documented in Multimedia Appendix 1.

Step 3—Study Selection

After the collection of articles meeting the eligibility criteria, a diligent selection process will be followed. This will be based on independent reviews by 2 experts, while a third expert will ensure that a compromise is achieved in case of selection conflicts. Two major stages will constitute this paper selection process.

First, a general screening review based on the title and abstracts of each article will be carried out in order to exclude all references not useful to achieve the targeted research objective.

In the second phase, a content review will be conducted via a full-text reading of each remaining citation included, to determine their final eligibility by considering their relevance for responding to the research questions. In addition, we will document and provide a list of all excluded articles in a complementary appendix.

These 2 phases will be implemented independently by the 2 citation reviewers by using the free web-based application Rayyan [36]. This application supports the traceable management of the inputs of the different contributing stakeholders and transparent conflict management [36]. Thus, any conflict regarding the final decision about the inclusion or exclusion of a reference will be discussed and decided under consideration of the both reviewers’ viewpoints and input from the independent expert; this will be followed by interactive literature explorations within the Rayyan platform in a nonblinded form. Finally, a detailed description of the literature selection process and conflict management will be provided using a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flowchart [33].

XSL•FO
RenderX

Step 4—Extracting and Charting the Data

We will extract from each of the selected articles all relevant information (including metadata) and record these into a template-based documentation, so that a subsequent descriptive analysis (including information visualization) can be performed by using an appropriate statistics package. A general template has been provisionally proposed (see Table 2) considering approaches from similar review projects [34]. Updates on this template will be iteratively and collaboratively integrated, in accordance with requirements during the review, taking into account the concrete relevance for responding to the research objectives.

Table 2. Template to extract key information form the included articles.

Metadata	Description
Citation details	Name of first author and coauthors, digital object ID, and journal name
Year of publication	Year of publication of the article in a valid year format (eg, YYYY)
Study type	Use case, framework development, evaluation, etc
Study location	Continent, country, or city hosting the study
Institute	Research institution of the first author
Funding source	Public, industry, or missing
Aims of the study	Objective of the study
Methodology (including technical implementation)	Methods, techniques, models, framework, or approach implemented to achieve the research aims
Study populations (if described in the article)	Targeted research cohort, built on the basis of corresponding eligibility criteria
Summary of outcome measures	Summarizing the study results
Limitations or gaps	Strength and limitations of the study
Important results associated with research question 1	Description of formal relational data anonymization processes on CDM[a]-converted health care data
Important results associated with research question 2	Description of existing evidence to address anonymous data quality and utility: description of implemented strategies and description of observable gaps
Important results associated with research question 3	Description of differences in CDMs regarding how data anonymization modifies the specified table's granularity and how anonymized data are there recorded

[a]CDM: common data model.

Step 5—Collating, Summarizing, and Reporting the Results

We will carry out a narrative quantitative analysis of findings using a 2-way analytical framework [33], which will include a descriptive and thematic-based approach. This will generate comprehensive results, outlining the current evidence and research gaps related to the research questions. In doing so, we will first describe the implementation of data anonymization on FHIR- and CDM-formatted data, which include i2b2 TranSMART, OMOP OHDSI, PCORnet, and the CDISC. This will be accompanied by an analysis of deployment to ensure strategies for quality and utility assessment of anonymous data obtained, to present the current state of the art, and identify open research aspects. In addition, the effects of data anonymization on CDM specifications will be presented and discussed.

Furthermore, corresponding comparison tables and graphs (PRISMA-ScR model–oriented) will be presented. Second, the findings will be organized, analyzed, and discussed in accordance with the 2 research questions. A thematically oriented illustration will be additionally generated.

Results

Following the methodological elements, outlined in steps 2 (identifying the relevant studies) and 3 (study selection), we were able to generate a set of search keywords and design an appropriate literature search query. Furthermore, a tentative execution of this query on Web of Science resulted in the detection of 507 matching publications. In alignment with the presented methodology, these articles will be interactively scrutinized by the experts in order to gain relevant information regarding the research questions. This preparatory work will support the transparent execution of this scoping review study. In doing so, we intend to implement the full extraction of the literature and to proceed with the full execution of the review study by the end of the fourth quarter of 2023.

Discussion

During the planning stage, we designed and implemented a query allowing the identification of potentially eligible publications, in order to investigate the current status of evidence regarding data quality–preserving relational anonymization of

XSL•FO
RenderX

CDM-converted health care data. The considerable amount of eligible literature obtained from Web of Science showed that useful information could be found to describe how relational data anonymizations are performed in the context of CDM-transformed health data and to what extent the quality and utility of obtained anonymous data are addressed in consideration of CDM specifications.

However, a more detailed analysis of these citations should support (1) investigating how the several privacy models, data transformation techniques, and utility models [1] are applied on CDM-converted health data, and (2) document the findings into the CDM databases. Moreover, the obtained set of literature could cover a wide range of current formal anonymization techniques, technologies related to Extraction-Transformation-Load processes for converting source data to the CDM format, or numerous data quality assessment frameworks. This requires a meticulous literature analysis strategy to include the most pertinent citations, which should enable answering the research questions. By following up on the systematic review of Fernández-Alemán et al [37], revealing the necessity of complementary work concerning the security and privacy of EHR data systems, and the investigation by Majeed and Lee [1], presenting the quantification of both utility and privacy of anonymized sensitive data for some scenarios as a challenging task, this scoping review should serve as a response to these questions, capture and describe the current evidence about utility-preserving anonymization of tabular CDM-based health data, and help identify potentially existing research gaps. This aspect is adequately in line with some of the main goals for conducting a scoping review as proposed by Arksey and O'Malley [33], which are to summarize and disseminate research findings and to identify research gaps in the existing literature.

Nevertheless, the planned scoping review might include some restrictions. Regarding the scope of the intended literature review, just a focus on formal data privacy models should be addressed, including, for instance, the k-anonymization, *l*-diversity, differential privacy, and *t*-closeness privacy models. Moreover, only the relational (table-based) data anonymization methods should be approached due to their frequent application for anonymizing tabular data in the medical context. A follow-up review including further anonymization frameworks such as social network– or graph-based data anonymization [1] in the clinical context could be subsequently initiated. However, to address the four-eyes principle on the proposed literature search string early, we will proceed with the validation of the search query by a librarian from the licensed library of Medical Faculty Mannheim, Heidelberg University, in order to correspondingly mitigate any potential conceptual or technical issues in the query.

Among other aspects, it is pertinent to point out that the anticipated definition of the study's specifications is an essential approach for limiting decision conflicts and providing transparency in the completion of this literature review. This should foster a reproducible and transferable methodology and disseminate reliable insights necessary to enhance and to better understand the approaches for preserving patient privacy and data quality in the secondary use of harmonized health care data.

Acknowledgments

This work is funded by the German Federal Ministry of Education and Research within the German Medical Informatics Initiative (grant 01ZZ1801E; Medical Informatics in Research and Care in University Medicine). The authors would like to thank Kim Hee for critiquing the manuscript. For the publication fee, we acknowledge financial support from Heidelberg University and Deutsche Forschungsgemeinschaft within the "Open Access Publikationskosten" finding program.

Data Availability

Scripts for the technical implementation of citation visualization based on statistical software such as RStudio [38], as well as files containing the collected literature and other study documents, will be made available on an open publicly available repository such as Zenodo [39]. These data will be available in an anonymized format for facilitating more transparency and for offering the possibility to reproduce the literature extraction, charting, and analysis processes.

Authors' Contributions

All authors commented on the draft and approved the final manuscript version.

Conflicts of Interest

None declared.

Abstract

Background: Well-being at work can be defined as "creating an environment to promote a state of contentment which allows an employee to flourish and achieve their full potential for the benefit of themselves and their organisation." In the health care context, well-being at work of nurses and doctors is important for good patient care. Moreover, it is strongly associated with individual- and organization-level consequences. Relevant literature presents models and concepts of physical, mental, and social well-being. This study uses the 6 elements of the job demands-resources (JD-R) model to interpret well-being at work (job demands, job resources, personal resources, leadership, well-being, and outcomes) as part of a Netherlands Federation of University Medical Hospitals program to find ways to improve and monitor health care professionals' well-being in Dutch hospitals. Many instruments exist to measure well-being at work in terms of population, setting, and other aspects. An overview of available and eligible instruments assessing and monitoring the well-being of nurses and doctors is currently missing.

Objective: We will perform a scoping review aiming to provide an overview of validated instruments assessing and monitoring the well-being of nurses and doctors at work.

Methods: We will perform a search of published literature in the following databases: Medline, Embase, and CINAHL. Studies will be eligible if they (1) assess well-being at work of nurses and doctors employed in hospitals; (2) describe an evaluation of an instrument or review an instrument; (3) measure well-being at work or aspects of well-being at work according to the elements of the JD-R model, and (4) were published in English from 2011 onwards. Title/abstract screening according to the eligibility criteria will be followed by full-text screening. Data extraction of included studies will be conducted by 3 reviewers independently. Reviewers will use standardized data extraction forms that include study characteristics, sample characteristics, measurement instrument details, and psychometric properties. The analysis will be descriptive. When synthesizing the data, a distinction will be made between comprehensive instruments and common instruments.

Results: This scoping review identifies instruments that have been developed and validated for monitoring the well-being of nurses and doctors at work. Studies were searched between September and December 2021 and screened between December 2021 and May 2022. A total of 739 studies were included.

Conclusions: Timely screening of well-being at work may be beneficial for individual health care workers, the organization, and patients. There is often a substantial gap and mismatch between employer perceptions of well-being and well-being interventions. It is important to develop and implement suitable interventions adapted to the needs of nurses and doctors and their health or other problems. Well-being screening should be timely to gain insight into these needs and problems. Moreover, to

XSL•FO
RenderX

determine the effectiveness of well-being interventions, measurement is mandatory. The results will be critical for organizations to select a monitoring instrument that best fits the needs of employees and organizations.

well-being at work; well-being; well being; health care professionals; doctors; nurses; monitoring; assessment; measure; scale; instruments; scoping literature review; occupational health

Introduction

Well-being at work for nurses and doctors employed in hospitals is an important condition for achieving effective, safe, and good patient care [1-3]. Moreover, well-being at work is strongly associated with serious consequences at an individual level, such as poor work-life balance [3,4], obesity [3], reduced quality of life of the health care worker [3,5], substance abuse, and suicide [3,6]. At an organizational level it is related to high staff turnover [3,6], absenteeism [3,7], and high health care costs [3].

The Chartered Institute of Personnel and Development defines well-being at work as "creating an environment to promote a state of contentment which allows an employee to flourish and achieve their full potential for the benefit of themselves and their organisation" [8]. Well-being comprises psychological well-being, physical well-being, and social well-being [9]. Also, a variety of published literature presents models and concepts of well-being. Deci et al [10] reported the self-determination theory. The self-determination theory suggests that both employees' performance and their well-being are affected by the type of motivation they have experienced [10]. For medical students, the "coping reserve tank" was illustrated [11]. This is a coping reservoir that can be replenished or drained by various factors, such as stress, mentorship, time demands, and support [11]. Potential outcomes were described as resilience versus burnout [11]. Schaufeli [12] developed the job demands-resources model (JD-R model) facilitating communication about "work and well-being." In essence, the JD-R model integrates 2 processes: the stress process, which is sparked by excessive job demands and lack of resources, and a motivational process, which is triggered by abundant job resources and may lead to positive outcomes, such as organizational commitment, intention to stay, and work performance [12]. Thus, different components, including resources (eg, support, development opportunities, team atmosphere), demands (eg, stress, workload, conflicts), and personal resources (eg, leadership, intrinsic motivation, resilience), contribute to positive well-being (eg, job satisfaction) or negative well-being (eg, burnout). Abundant resources and reasonable demands will result in positive outcomes (eg, performance, commitment); the reverse will lead to negative outcomes (sickness, absenteeism) [12].

Measuring well-being at work among doctors and nurses is not easy, since this multidimensional concept encompasses diverse elements [8,13]. Instruments to measure well-being at work vary in specific professions [14] and specific settings [15] or include only one or two aspects of well-being at work [12,16]. This study is part of a program of the Netherlands Federation of University Medical Hospitals (NFU) about finding ways to improve and monitor health care professionals' well-being in Dutch hospitals. Strikingly, there is often a substantial gap and mismatch between employer perceptions of well-being and well-being interventions [8]. It is important to develop and implement suitable interventions adapted to the needs of nurses and doctors and their health and other problems [8,17]. Well-being screening should be timely to gain insight into these needs and problems. Moreover, measurement to determine the effectiveness of well-being interventions is mandatory [8,17].

To summarize, when hospitals assess and monitor the well-being of nurses and doctors with validated instruments, they can, in a timely manner, design and start tailored interventions to prevent negative well-being in the workplace, thereby contributing to sustainable employability and quality of care [18,19]. An overview of available and eligible instruments assessing and monitoring the well-being of nurses and doctors is currently missing. Scoping reviews are helpful to explore broad, complex, and heterogeneous literature [20]. For this study, a scoping review is planned to obtain an overview of the field of well-being instruments and identify its breadth.

Methods

Aim

This scoping review aims to identify instruments monitoring the well-being at work of nurses and doctors working in hospitals. The Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) [21] and the 6-stage framework of Arksey and O'Malley [22] for conducting scoping reviews will be used.

Information Sources

A priori, possible previous reviews of this topic were checked. Published articles will be searched in the following electronic databases: Medline, Embase and CINAHL. To avoid including outdated literature, we will include only articles published after 2011 [23]. To identify instruments that are applied in present clinical practice, preference is given to more-frequent, lower-volume searches to fit the exponentially changing field of health care [24,25]. Gray literature will not be used as an information source.

Search Strategy

The search strategy was created by AB with assistance by an information specialist and the research team. Several terms derived from the research aim were identified to develop search strings to find relevant literature. Keywords and Medical Subject Heading (MeSH) terms related to the domain (nurses and doctors

XSL•FO
RenderX

working in hospitals), the determinants (instruments for monitoring), and the outcome (well-being at work) will be used. The first draft of the search string was based on 5 relevant, previously published "golden bullets," sample articles that had to be found in the data set. Afterwards, a test data set was screened by the first author to optimize the search string. After this screening, the data set turned out to be too large (more than 17,000 studies), so to ensure the feasibility of the study it was decided to make the search more specific. For the search strategy see Tables 1, 2, and 3.

Table 1. Search strategy for Medline.

[a]The following abbreviations are applicable to the queries: T1: title; N1: adjacency of 1 word; AB: abstract; MH: mesh heading; MM: major mesh.

Inclusion Criteria

Studies will be eligible if they (1) assess well-being of nurses and doctors working in hospitals; (2) describe an evaluation of an instrument or review an instrument; (3) measure well-being at work or aspects of well-being at work according the elements of the JD-R model and (4) were published in English in or after 2011.

XSL•FO
RenderX

Exclusion Criteria

Studies will be excluded if they (1) describe only the development of the instrument but not its evaluation or (2) have a sample that consists only of students, without employees.

Data Management

Records and data will be managed by using the software Endnote (version 20.1; Clarivate Analytics), Rayyan (Rayyan Systems), EPPI-Reviewer (EPPI-center) and Mendeley Reference Manager (version 2.590; Elsevier).

Selection Process

Study screening and selection will be conducted independently by AB, KvdB, and NA using Rayyan. After the removal of duplicate records identified by the search strategy, articles will be screened on titles and abstracts for the inclusion and exclusion criteria. To ensure consistent screening, the first 100 articles will be pilot-screened by all 3 researchers until consensus is reached. After validation, the hits will be allocated to 1 of the 3 researchers. Eligible articles will then be assessed on their full text. To ensure consistent full-text screening, the first 18 articles will be pilot-screened by all 3 researchers until consensus is reached. After validation, the full texts will be subdivided among the 3 researchers. Justification for study inclusion and exclusion will be reported. Inclusion reasons and exclusion reasons will be marked with a label. Uncertainty in selection and the data extraction process will be resolved by consensus [12]. The JD-R model will be used to assess if the reported instruments appropriately measured well-being or aspects of well-being at work (job demands, job resources, engaged leadership, personal resources, employees' well-being, outcomes) [12]. The energy compass of the JD-R model includes all aspects of well-being at work and is applicable to different employees in different settings [12]. Included instruments will be categorized according to the 6 domains of the JD-R model. The domain "job demands" contains the categories "qualitative job demands," "quantitative job demands," and "organizational demands." The domain "job resources" contains the categories "social resources," "work resources," "organizational resources," and "developmental resources." The domain "engaged leadership" contains the categories "inspiring," "strengthening," and "connecting." The domain "personal resources" contains the categories "resilience," "self-efficacy," "optimism," flexibility," "setting one's own limits," "productivity," "goal direction," and "self-development." The domain "well-being" contains the positive and negative categories "burnout," "work engagement," "psychological distress," "boredom," "sleep problems," and "job satisfaction." The domain "outcomes" contains the categories "commitment," "employability," and "performance." Study search and selection will be illustrated using the PRISMA flow diagram.

Data Collection Process

Data extraction and full-text screening will be conducted at the same time. AB, KvdB, and NA will independently use the standardized data extraction form, which will be developed a priori in Excel (Microsoft Corp). The elements that will be charted for each article are (1) study characteristics, including year, authors, country, study ID, and study aim (validation study, measuring variables, both, other); (2) sample characteristics, including type of health care professionals (nurses, doctors, other), setting (hospital, partly hospital), and sample size; (3) measurement instrument, including the name of the instrument, main construct measured, subconstructs measured, job demands, job resources, leadership, personal resources, well-being, and outcomes; and (4) psychometric properties, including validity, reliability, responsiveness, and quality references. The aim of this study is not to evaluate psychometric properties but include only the evaluated instruments. Therefore, information about psychometric properties (whether validity, reliability, and responsiveness are tested) will be extracted. When no psychometric properties are reported, the references mentioned for evaluation will be extracted. Table 4 shows further details.

All instruments meeting the inclusion criteria will be extracted from studies. If more than one instrument has been described, instrument details will be extracted separately for each instrument. The data extraction form will be tested by AB, KvdB, and NA on 18 studies to ensure adequacy of the extraction. Disagreements will be discussed, and the form will be refined, if necessary, after the pilot phase with the 18 studies.

Table 4. Defining variables.

Item	Definition
1. Study characteristics	
Year	Picklist • Years from 2011, up to and including 2021
Authors	Last name, initials
Country	Country where participants are recruited
Study ID	Unique code to identify the study, found in Eppi-reviewer
Study aim	Picklist • Validation study: the study tests or evaluates instruments • Measuring variables: the study uses instruments to measure variables • Both: studies that both validate instruments and measure variables • Other: studies in which the above is not described (eg, study protocols)
2. Sample characteristics	
Health care professionals	Picklist • Nurses (exclusively or mixed with other types of participants): all kinds of nurses providing direct patient care in hospitals (eg, intensive care nurses and pediatric nurses) • Doctors (exclusively or mixed with other types of participants): all kinds of doctors providing direct patient care in hospitals (eg, residents, medical assistants, and medical specialists in various specialties) • Both: studies in which both nurses and doctors are described
Setting	Picklist • Hospital: full sample works in hospital • Partly in hospital: a part of the sample works in a hospital; any kind of hospital will be included (eg, psychiatric hospitals, general hospitals, and academic hospitals)
Sample size	Full sample size: if only part of the sample works in a hospital, the full sample needs to be reported
3. Measurement instrument	
Name of instrument	Full name of the instrument, including any abbreviations (eg, Professional Quality of Life Scale, version 5; ProQol-5).
Main construct measured	Main construct intended to be measured (eg, professional quality of life)
Subconstructs measured	Subthemes intended to be measured (eg, compassion satisfaction, secondary traumatic stress, burnout)
JD-R[a] demands	Picklist • Job demands: the outcome fits with “job demands” according to the JD-R model. • N/A[b]: the outcome does not fit with “job demands” according to the JD-R model
JD-R resources	Picklist • Job resources: the outcome fits with “job resources” according to the JD-R model • N/A: the outcome does not fit with “job resources” according to the JD-R model
JD-R leadership	Picklist • Engaged leadership: the outcome fits with “engaged leadership” according to the JD-R model • N/A: the outcome does not fit with “engaged leadership” according to the JD-R model
JD-R well-being	Picklist • Employee well-being: the outcome fits with “employee well-being” according to the JD-R model • N/A: the outcome does not fit with “employee well-being” according to the JD-R model
JD-R outcomes	Picklist • Outcomes: the outcome fits with “outcomes” according to the JD-R model • N/A: the outcome does not fit with “outcomes” according to the JD-R model

XSL•FO
RenderX

Item	Definition
4. Psychometric properties	
Validity	Picklist • Valid: the instrument is tested and proven valid in the study (eg, content validity, construct validity, criterion validity) [26] • N/A: validity is not tested in the study
Reliability	Picklist • Reliable: the instrument is tested and proven reliable in the study (eg, internal consistency, reliability, measurement error) [26]
Responsiveness	Picklist • Responsiveness: the instrument is responsive (the ability of the instrument to detect relevant changes in health status when they exist) [26] • N/A: responsiveness is not tested in the study
Quality reference	Only for reference(s) to the original evaluation study; formatted as author; year

[a]JD-R: job demands-resources.

[b]N/A: not applicable.

Risk of Bias

Evaluating evidence quality is not applicable for scoping reviews [22,27]. AB, KvdB, and NA are junior researchers with relatively little experience in conducting scoping reviews on the topic of the well-being of nurses and doctors, but they are supervised by senior researchers with ample experience. The variety of backgrounds, opinions, experiences, and perspectives within the interdisciplinary research team supports self-reflectivity about the subjective values, biases, and inclinations of the researchers. In addition to the medical doctors, other health care professional types are also represented within the research team and have experience with the well-being topic. The first author is a nurse and KvdB has a physiotherapy background. Likewise, LH specializes in the methodology of reviews.

Data Analysis

This scoping review will determine the size and nature of the evidence base for instruments evaluating well-being at work. The analysis will be descriptive and findings will be assimilated, synthesized, and described. The plan is to summarize validated well-being instruments in tables and figures according to the elements of the JD-R model. Additionally, we will report how often instruments have been extracted, which aspects of well-being are measured, and which types of health care professional are targeted. Synthesizing the data, a distinction will be made between comprehensive instruments and common instruments. The more JD-R domains an instrument encompasses, the more comprehensive (measuring entire well-being) the instrument will be considered to be. Most common instruments are instruments occurring frequently. Results will help readers interpret and choose fitting instruments.

Ethical Considerations

This study does not require ethical approval since it is a literature review.

Results

Studies were searched between September 2021 and December 2021. Studies were screened between December 2021 and May 2022. A total of 739 studies were included. Thereafter, data extraction and full text screening were conducted at the same time. The protocol was submitted for publication in October 2022. Before submission, we carried out our search and started screening and extracting data from relevant articles but had no insight into the overall data and had not yet performed data analysis.

Discussion

This scoping review gives an overview of instruments that have been developed and validated for monitoring the well-being of nurses and doctors at work.

Published research shows a great variety in concepts and measures of well-being at work in terms of target population (professions), settings, and aspects of well-being at work. However, a critical, overarching analysis of these concepts and measures is missing in the scientific literature. There is often a substantial gap and mismatch between employer perceptions of well-being and well-being interventions [8]. It is important to develop and implement suitable interventions adapted to the needs of nurses and doctors and their health or other problems [8,17]. Timely screening of well-being is necessary to gain insight into these needs and problems. Moreover, it is necessary to determine the effectiveness of well-being interventions [8,17].

Our study has some limitations that need to be considered. First, the articles will be divided among 3 researchers because of the amount of data. Consequently, data screening and extraction will be performed once. In order to avoid bias, pilot sets will be screened until consensus on eligibility criteria and JD-R classification is reached. Additionally, an audit trail is used to describe and link thoughts, doubts, and methodological choices.

XSL•FO
RenderX

This study is distinctive in that it does not focus specifically on one instrument but provides an overview of many instruments. By using the JD-R model, we are able to determine which instruments fit in the construct of well-being. By categorizing the instruments according to the elements of the JD-R model, the reader will be supported in selecting instruments appropriate to their context.

Data Availability

All data generated or analyzed during this study will be included in the published article or its supplementary information files.

Authors' Contributions

AB designed the research protocol and will carry out the data screening, extraction, and analysis. KvdB provided feedback on the protocol, including the methodological choices, will carry out data screening and extraction, and will be involved in the analysis and writing process. NA provided feedback on the protocol and will contribute to the screening and selection phase. LH, GW, AF, and MvdL provided critical feedback on revisions and methodological choices and approved the final version of the paper for publication. All the authors agree to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Conflicts of Interest

None declared.

Abstract

Background: Internationally, patient-accessible electronic health records (PAEHRs) are increasingly being implemented. Despite reported benefits to patients, the innovation has prompted concerns among health care professionals (HCPs), including the possibility that access incurs a "dumbing down" of clinical records. Currently, no review has investigated empirical evidence of whether and how documentation changes after introducing PAEHRs.

Objective: This paper presents the protocol for a scoping review examining potential subjective and objective changes in HCPs documentation after using PAEHRs.

Methods: This scoping review will be carried out based on the framework of Arksey and O'Malley. Several databases will be used to conduct a literature search (APA PsycInfo, CINAHL, PubMed, and Web of Science Core Collection). Authors will participate in screening identified papers to explore the research questions: How do PAEHRs affect HCPs' documentation practices? and What subjective and objective changes to the clinical notes arise after patient access? Only studies that relate to actual use experiences, and not merely prior expectations about PAEHRs, will be selected in the review. Data abstraction will include but will not be limited to publication type, publication year, country, sample characteristics, setting, study aim, research question, and conclusions. The Mixed Methods Appraisal Tool will be used to assess the quality of the studies included.

Results: The results from this scoping review will be presented as a narrative synthesis structured along the key themes of the corpus of evidence. Additional data will be prepared in charts or tabular format. We anticipate the results to be presented in a scoping review at a later date. They will be disseminated at scientific conferences and through publication in a peer-reviewed journal.

Conclusions: This is the first scoping review that considers potential change in documentation after implementation of PAEHRs. The results can potentially help affirm or refute prior opinions and expectations among various stakeholders about the use of PAEHRs and thereby help to address uncertainties. Results may help to provide guidance to clinicians in writing notes and thus have immediate practical relevance to care. In addition, the review will help to identify any substantive research gaps in this field of research. In the longer term, our findings may contribute to the development of shared documentation guidelines, which in turn are central to improving patient communication and safety.

Introduction

Background

Electronic health records (EHRs) are common in almost all areas of health care and are an indispensable tool for saving and sharing information between health care professionals (HCPs) [1]. A more recent development focuses on opening clinical notes or entire EHRs for patients [2] and their proxies [3-7]. These so-called patient-accessible electronic health records (PAEHRs) are well established internationally, especially in Scandinavian countries and the United States, but are not yet fully embedded even among high-income countries [8-11]. An essential part of patients' online record access (ORA) through a PAEHR is access to the clinical free-text notes written by clinicians. Giving patients access to these notes is often referred to as "open notes" in the literature [2].

Research shows that HCPs are often skeptical about giving patients ORA [12,13], and many of their concerns relate to how PAEHR use might impact their clinical routines, workload, and patient safety [11,13-20]. Regarding documentation, many HCPs anticipate changing the content and tone of their notes when patients have ORA, which, it is feared, might ultimately compromise the integrity of their records [11,19,21]. For example, a tendency to avoid technical terminology to facilitate patient understanding could have a negative impact on multidisciplinary communication within the team [21-24]. Also, some HCPs feel that they may be less detailed or less candid in their documentation and need to omit information or even start using parallel documentation (a "shadow record") to protect patients from information that they consider as potentially harmful or disruptive [14,15,20,25-27]. In contrast, however, there are other voices that assume the introduction of PAEHRs could make notes more patient-friendly by using a more patient-centered and less stigmatizing language and could also stimulate communication between HCP and patients [22].

As Blease et al [11] noted, while most studies explore subjective changes after introducing open notes, there are few studies demonstrating objective changes, and where these studies exist, they offer inconclusive results [22,28,29] and are often hampered by methodological limitations. There is a growing body of qualitative research [30] as well as research using natural language processing approaches to explore the language used by clinicians in their records, including the potential for stigmatizing language [31]. However, it is unclear from these studies whether access affects, or indeed, even improves the quality of recordkeeping with the knowledge that patients may read what the clinician has written [31]. Despite the increasing scientific interest and debate within medicine, little is currently known about how far sharing EHRs with patients affects clinical documentation [11,32].

Study Objectives

The objective of the proposed scoping review is to identify, collate, and evaluate possible changes of documentation after implementing patient access to EHRs. The scoping review focuses exclusively on studies including postimplementation data, such as experiences of the stakeholders (HCPs, patients, policymakers and designers of EHRs or patient portals), while excluding expectations prior to implementation.

As outlined, HCPs are often reluctant, or even critical of giving patients ORA, and expect an additional documentation burden through their introduction. To address these obstacles to implementation, it is timely and appropriate to review the existing body of literature and summarize what is currently known regarding PAEHR documentation change. This scoping review is intended to increase knowledge for stakeholders about the kinds of documentation changes that might arise with PAEHRs, illuminate how this relates to documentation practices, provide recommendations for future clinical practice, and identify further research gaps.

Methods

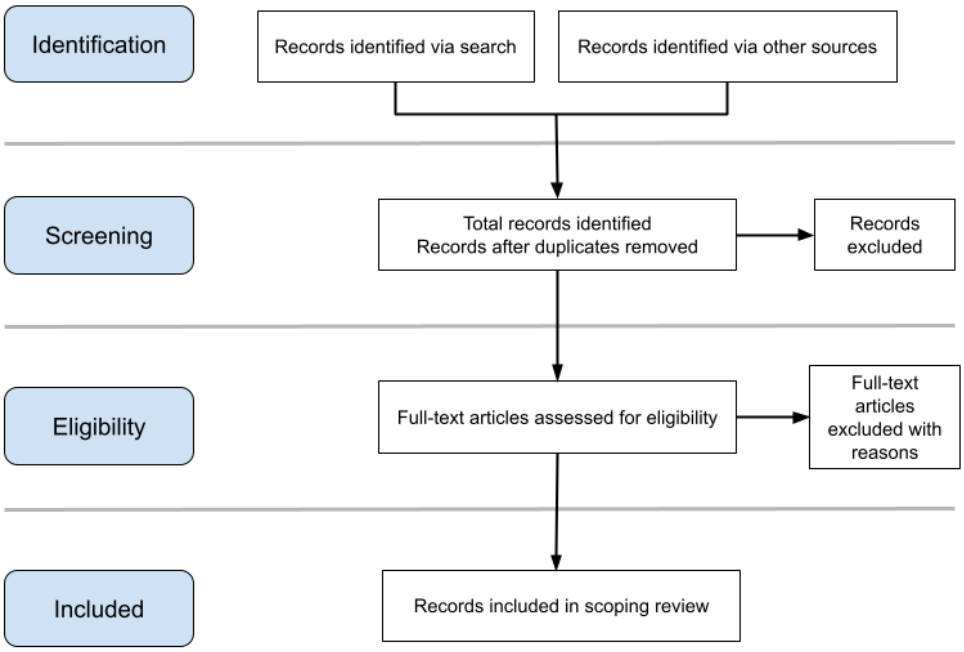
Scoping Review

Compared with the systematic review method, which is guided by a strongly focused research question, a scoping review aims to open up the spectrum of the available evidence on a relatively new field of research, so that its breadth and depth become visible [33]. We will conduct a scoping review following the framework proposed by Arksey and O'Malley [33]. Their approach consists of the following five stages: (1) identifying the research question, (2) identifying the relevant studies, (3) selecting eligible studies, (4) collecting data, and (5) summarizing data and synthesizing results. The review will be reported following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) Extension for Scoping Reviews checklist [34,35]. Any subsequent modification of the study design will be highlighted in the final publication, which is aimed at being published in a JMIR journal.

Stage 1: Identifying the Research Question

Through discussions with the research team, we decided on the following research questions: Does clinical documentation change after the introduction of ORA for patients? If so, what objective and subjective changes arise after PAEHR implementation? By objective, we mean such differences that can be demonstrated by a direct quantifiable comparison of clinical notes before and after implementation of PAEHRs. By

XSL•FO
RenderX



subjective, we refer to clinicians' perceptions of how they write their notes after PAEHR implementation. In the context of this scoping review, we define PAEHR to be any channel in which patients have electronic access to their patient record (eg, through the internet or via patient portals and apps).

Stage 2: Identifying Relevant Studies

The process of identifying relevant studies is outlined in the flowchart (see Figure 1). The deduplication process will be carried out by an experienced research librarian at Uppsala University, Sweden. In advance, the research team will conduct a rigorous manual search to obtain a basic overview of the available evidence and to refine the scope of the review as well as the search strategy as Popay et al suggest [36].

The literature search in the following 4 databases will be conducted by the librarian Malin Barkelind from Uppsala University: APA PsycInfo, CINAHL, PubMed, and Web of Science Core Collection. The search strategy was developed in collaboration with the Uppsala University library and consists of three key concepts: (1) EHRs, (2) sharing EHRs with patients, and (3) changes in documentation, which were combined with the Boolean AND (Textbox 1). The search terms were adapted according to different databases. The complete search string is stored in Multimedia Appendix 1. In addition, we will include individual relevant records from the hand search conducted previously.

Figure 1. Flowchart describing the multistage screening process.

Textbox 1. Key concepts of the search strategy.

Electronic health record search string

- "inpatient portal*" OR "open notes" OR opennotes OR PAEHR OR "patient portal*" OR "patient web portal*" OR "Electronic Health Records"
- "clinic notes" OR "clinical notes" OR "progress notes" OR "doctors notes" OR EHR OR "health record*" OR "health care record*" OR "medical record*" OR "mental health notes" OR "patient record*" OR "psychiatric notes" OR "psychotherapy notes" OR "visit notes"

Sharing electronic health records with patients search string

- "guardian access" OR "parental access" OR "parents access" OR "patient access*" OR "patients access*" OR "patient online access" OR "patients online access" OR "proxy access" OR "shared medical record*" OR "shared health record*"

Documentation changes search string

- OR adopt* OR alter* OR censor* OR change* OR changing OR difference* OR introduc* OR implement* OR modif* OR postimplement*

XSL•FO
RenderX

Stage 3: Selecting Eligible Studies

Inclusion and Exclusion Criteria

Inclusion and exclusion criteria (Textbox 2) were defined by the entire research team and will be applied in the study selection process. Due to the limited number of publications available on the subject, there will be no restrictions on the study type. As PAEHRs are only gradually being implemented in various countries, we will refrain from any location restrictions. A wide variety of approaches exist to make clinical notes available to patients electronically [37]. We will include all studies examining the actual implementation and the use of patient ORA regardless of the digital device used (eg, web-based and mobile apps). Varieties of studies exploring the sharing of hard copies of patients' clinical records will be excluded.

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Study design: all study types
- Publication: original, peer-reviewed work including empirical data published between January 1, 2005, and June 30, 2023 in English
- Study location: all medical disciplines, all health care settings, no location restrictions
- Study participants: patients and health care professionals of all ages
- Studies that examine actual use by stakeholders and their experiences with patient-accessible electronic health records

Exclusion criteria

- Paper-based, disc, or USB sharing of patients' records
- Papers without empirical data (eg, comments, editorials, news)
- Gray data (websites, tweets, blogs)
- Studies that exclusively investigate expectations about patient-accessible electronic health records

Study Selection Process

We will use Rayyan Software (Rayyan Systems, Inc) for conducting a collaborative, blinded title and abstract screening [38]. All members of the research team will participate in this process and each record of the result set will be evaluated by at least 2 people. Discrepancies will be discussed, taking the full texts of the corresponding studies into account. In case of disagreements that cannot be resolved, a third reviewer will be involved and entrusted with the decision of including or excluding the study.

Stage 4: Collecting Data

After selecting the studies to include, metadata (eg, title, authors, and publication year) of the remaining records will be exported and summarized in a Google Sheets (Google LLC) spreadsheet for further processing. To extract and organize relevant data from included studies, the spreadsheet will be extended by the following and other parameters based on the studies' full text: country, study design, sample, characteristics of study participants (eg, gender, age, ethnicity, type of stakeholder), treatment setting and medical specialty, and study purpose. Data extraction will be performed involving all members of the research team. Furthermore, the first author will check the data extraction for correctness and completeness. To assess the quality and methodological rigor of the studies, the Mixed Methods Appraisal Tool (MMAT) will be used [39]. Two researchers will independently conduct the MMAT grading of all studies and consent their results. If no agreement can be reached, a third independent researcher will be consulted.

Stage 5: Summarizing Data and Synthesizing Results

Narrative Synthesis

Study results will be extracted from the full texts by the lead author and summarized in (1) a reduced format within a textbox, providing an overview of the findings from all included studies, and (2) a detailed version for narrative synthesis. The latter will be analyzed independently by at least 2 researchers using thematic analysis [40]. Objective and subjective changes of HCPs' documentation practices after the introduction of patient ORA will be used as guiding deductive themes and are informed by the research question but may change in the analytical process. As Levac et al [35] suggest, we aim to identify patterns and relationships within and across studies to identify potential factors influencing documentation after PAEHR implementation. In assessing the methodological rigor of the studies, we also envisage the potential to identify research gaps; for example, we predict there may be a preponderance of survey research investigating clinicians' perceptions about documentation changes rather than studies investigating objective markers of any such documentation changes. While the former studies may be useful, they may be compromised by responder biases. Results will then be discussed and approved by the entire research team.

Assessing the Robustness of the Synthesis

As Popay et al [36] state, the robustness of the narrative synthesis depends on the quality of included studies as well as on the trustworthiness of the synthesis. In order to minimize bias, we will conduct the study quality appraisal through MMAT to ensure that studies of equal technical quality are given equal weight. To provide a high level of trustworthiness in our review, reviewers will have detailed information about the eligibility

XSL•FO
RenderX

criteria and the type of intervention (PAEHR) in order to provide sufficient information for replication.

Ethical Considerations

Since we will use only publicly available data material with the scoping review methodology, this study is not subject to ethical approval.

Results

The main results from our analysis will be presented in a narrative form, focusing on subjective and objective changes in clinical notes as well as on changes in HCPs' documentation after sharing EHRs with patients. Additional data on year, country, study design, characteristics of study participants, setting, sample, medical specialty, and study purpose will be presented in diagrams or tabular format.

Discussion

Research indicates that HCPs have concerns regarding the effects of ORA on clinical routines, workload, and patient safety as patients increasingly gain access to medical information on the internet [11-20]. Although a limited number of studies have examined alterations in documentation practices following the implementation of policies, these studies have primarily focused on subjective evaluations rather than objective assessments [11]. Furthermore, the few studies attempting to investigate objective changes in documentation have yielded inconclusive results that are further restricted by methodological limitations [22,28,29].

Although there are already a few reviews that address the use of patient ORA [32,41-43], no review specifically addresses the potential changes to clinical documentation that may result from the implementation and use of PAEHR. Our scoping review aims to map current research into documentation changes and to potentially raise awareness among many different involved parties about the risks and opportunities of PAEHR use.

A potential limitation of the study is a reduced depth of the analysis due to the broader nature of the scoping review. In addition, due to exclusion of gray literature, it is possible that some studies will be overlooked. Nevertheless, we defined our search strategy to identify the most comprehensive and high-quality evidence.

Dependent on the findings, this study may offer important insights on how to support effective documentation practice in the future. For example, the findings may provide a basis for a widely demanded "documentation training" that could better prepare HCPs and patients on how to read and write notes [20]. The scoping review will strive to identify any existing research gaps and to indicate directions for further studies in this field. The growing body of evidence on natural language processing in relation to documentation changes after PAEHR introduction will be explored.

Acknowledgments

This work was supported by NordForsk through funding from Nordic eHealth for Patients: Benchmarking and Developing for the Future (NORDeHEALTH; project 100477), as well as by FORTE, the Swedish Research Council for Health, Working Life and Welfare, through the research project Beyond Implementation of eHealth (2020-01229).

Data Availability

The data used for the scoping review are openly available and can be retrieved from the following databases: APA PsycInfo, CINAHL, PubMed, and Web of Science Core Collection.

Authors' Contributions

EM-D wrote the manuscript and designed Figure 1. JS contributed to drafting the protocol. CB and JS were responsible for the conception of the study. All authors read, provided feedback, and approved the paper for submission.

Conflicts of Interest

None declared.

Abstract

Background: The principles of gender equality are integral to the goals, targets, and indicators of all sustainable development goals. Higher education institutes can be powerful agents for promoting gender equality, diversity, and inclusion not only in the higher education context but also in society as a whole. To address and overcome gender inequality in the higher education environment, experts posit that change needs to occur from day 1 of the student's academic experience. To this end, training is required. A preliminary review of the literature indicates that multiple gender equality–based training programs or initiatives for students have been designed and evaluated in second and third-level education settings. Examples of educational activities undertaken include delivery of didactic teaching, participation in a face-to-face collaboration project, site visits, case studies, and coaching. Yet, our initial search indicated that, to date, a comprehensive review collating the available evidence on gender equality training for third-level students has not yet been carried out.

Objective: Our review seeks to identify and explore the existing literature on gender equality training interventions for third-level students, with a particular emphasis on training content, methodology, and outcome evaluation.

Methods: This scoping review will be structured using the Arskey and O'Malley's 5-stage framework and will consider empirical research and other relevant published works that address gender equality training. Systematic searches will be carried out in 6 research databases and the gray literature using key search terms. Inclusion and exclusion criteria have been defined, and a data charting tool created to methodically extract information from selected literature. The free web software Rayyan will be used for primary screening where each reference will be screened in duplicate first by title, then abstract, and finally by full text.

Results: This review forms part of the LIBRA (Balance) study and has received peer-reviewed grant funding from the Irish Higher Education Authority. LIBRA aims to use simulation-based education to develop a gender equality leadership training program for student leaders in higher education. The findings will be summarized in tabular form, and a narrative synthesis produced to inform curriculum development.

Conclusions: This review seeks to inform curriculum design by reporting on the gender equality–enabling skills and leadership skills necessary to foster gender equality. This paper should inform recommendations for training and catalyze future research in this rapidly evolving area.

Introduction

Background

Higher education institutions (HEIs) can be powerful institutions for promoting gender equality, diversity, and inclusion not only in the higher education context but also in society in general; however, universities remain both gendered and gendering organizations [1]. Recent statistical reports on gender equality data in the European Union show that female students make up the majority of the undergraduate population in HEIs, yet several published reports highlight ongoing cultural, institutional, and structural barriers inhibiting gender equality from true realization in this sector [2]. Despite the global feminization of the third-level student population, women are not progressing at the same rate as men in their academic careers. Male students remain a majority among postgraduates [2] and at leadership level, women accounted for only 24% of professorial chairs and 22% of heads of institutions in the higher education sector across the European Union in 2017 [1]. This gender imbalance is replicated in senior leadership in Irish third-level institutions [3,4].

Institutional structures involuntarily erect barriers against the recruitment, retention, and career progression of women. The fact that overt discrimination has been replaced with less obvious, primarily implicit preconceptions and prejudices against women makes gendered working circumstances even more difficult to change (eg, women have less career motivations, an assumed lack of confidence, and less ambition to take on leadership positions) [5]. Evidence suggests female researchers were disproportionately affected by the COVID-19 pandemic in terms of unequal distribution of childcare, elderly care, and other kinds of domestic and emotional labor reflected by a sudden drop in the number of female authors of scientific publications [6].

The National Surveys of Student and Staff Experiences of Sexual Violence and Sexual Harassment in Higher Education revealed over one-quarter of HEI staff did not feel safe from sexual harassment and 60% reported sexist hostility in the workplace. Among students, one-third or less felt safe socializing at night on campus or in the local community. In total, 66% of students reported experiencing sexist hostility [7].

A comprehensive review of state interventions to tackle gender inequality in Irish HEIs in Ireland from 2014 to 2019 indicated the ongoing presence of barriers impacting women's opportunity to occupy academic or managerial positions of formal power [8]. The authors acknowledge that the impact of several state interventions is not yet clear; however, they advocate for the continuation of a multifaceted approach, which addresses this issue at "the state (macro), the HEI (meso), and the situational (micro)-level simultaneously." To address and overcome gender inequality in the higher education environment, Acai et al [9] posit that change needs to occur from day 1 of the student's academic experience. Gender equality and fairness training in third-level institutions are important steps toward creating a more inclusive and equitable learning environment for all students, regardless of their gender identity. Promoting gender equality and fairness in higher education is a complex issue that requires a multifaceted approach. Barriers contributing to the shortage of women in academics and academic leadership are numerous, including a shortage of role models and mentors [10]. Training is a critical tool for addressing gender inequality and promoting gender equality in higher education. The importance of gender-sensitive training material and nondiscriminatory education and training has been highlighted [11]. Appropriate and timely training has the potential to help students, faculty, and staff to recognize and address unconscious biases, stereotypes, and discriminatory practices that may exist within the institution. It can also help to promote a culture of respect, dignity, and mutual understanding among members of the campus community.

A recent study highlighted the gender inequality that exists in student leadership, demonstrating that although females made up 55% of the student body, they represented only 33% of the leadership in student organizations [12]. The Irish Higher Education Authority has emphasized a need to train both male and female student leaders in gender equality to increase awareness and nurture competences in order to actively address gender inequality. Such training will have an impact on the wider HEI community [3]. According to the European Institute for Gender Equality, gender equality training should enable and empower participants to (1) define and understand gender equality principles, (2) identify gender inequalities in their field, (3) be aware of gender in their planning and policy implementation, (4) monitor progress, and (5) review and assess their work from a gender perspective. Developing competence in gender equality means identifying and changing gender stereotypes and gendered roles, thereby creating a more equal society [13].

Similarly, UN Women identifies gender-equality competence as possessing the "awareness, knowledge, commitment and capacity necessary to incorporate gender perspectives into substantive work among professional staff." At the heart of gender equality training lies transformation; to realize gender equality is to transform power sharing, control of resources, and decision-making to promote equal gender relations [14]. According to UN Women, gender equality training is not an event but a process. European Institute for Gender Equality and UN Women emphasize the necessity of *gender mainstreaming*, whereby individuals are provided with tools and training in gender equality competence-development and awareness-raising, but gender equality is simultaneously realized at an institutional and legal level [8,9].

At the heart of UN Women's approach to gender equality training is the theory of change, which acknowledges that training plays an integral role in enhancing participants' knowledge, motivation, and ability to promote gender equality, but that a long-term institutional commitment is also necessary to realize change. To optimize gender equality training, UN Women advises using Myra Marx Ferree's Knowledge, Desire, and Ability model. Applying this approach recognizes that participants require all 3 components in order to enact change, including a knowledge and understanding of gender equality principles and gender inequalities, the desire and motivation to implement changes and address gender inequalities, and the tools and competences required to bring about change. The

XSL•FO
RenderX

theory of change also encompasses engaging in reflexive practices to develop an awareness of one's own thinking and behavior to become a self-reflexive learner and to foster gender equality over time. UN Women notes that the theory of change should be recognized as both a process and a product in empowering people and institutions to bring about gender equality [14].

Study Aims

A preliminary literature review indicates that multiple gender equality–based training programs or initiatives for students have been designed and evaluated in second- and third-level education settings. Examples of educational activities undertaken include the delivery of didactic teaching, participation in a face-to-face collaboration project, site visits, case studies, and coaching [15-17]. Yet, our initial database searches indicated that, to date, a comprehensive review collating and synthesizing the available evidence on gender equality training for third-level students has not yet been carried out. Our review seeks to fill this gap.

This review will form part of the LIBRA study, which uses simulation techniques to develop a gender equality leadership training program for student leaders in higher education. This project is guided by the Irish Higher Education Authority's Gender Equality Task Force recommendations under *integrating the gender dimension into teaching and learning by embedding the gender dimension into undergraduate or postgraduate education* [18]. In carrying out a review, we aim to identify and explore the existing literature on gender equality training and gender equality interventions for third-level students, with a particular emphasis on training content, methodology, and outcome evaluation. Second, the review seeks to construct a consensus on gender equality–enabling skills and leadership skills necessary to foster gender equality.

Study Design

We considered a variety of approaches for analyzing the existing literature and deemed a scoping review most suitable for the requirements of this study. Arskey and O'Malley [19] list four principal reasons for conducting a scoping review, including (1) to explore the extent, range, and nature of available research on a specific topic; (2) to summarize and disseminate findings from the existing literature; (3) to identify a potential need for a systematic review; and (4) to identify gaps in the research literature. In line with these reasons, a scoping review will provide an appropriate methodology to explore the extent and nature of the existing research on gender equality training for third-level students. In designing the LIBRA gender equality simulation program, it will be essential that this process is informed by an evidence-based approach and uses the most up-to-date research regarding gender equality training in higher education. Leadership plays an integral role in the LIBRA program in order to empower student leaders to promote gender equality. This review also seeks to identify potential gaps in the literature regarding gender equality leadership training for third-level students.

Peters et al [20] explain that a scoping review is useful in clarifying key concepts and definitions in the literature. This will be particularly relevant within the LIBRA project to consolidate a definitive skills framework that outlines key competences required to promote gender equality and challenge gender inequality. Research questions informing a scoping review are typically wide in breadth, and researchers can draw on a diverse and heterogenous range of sources and study designs in carrying out the review. Conversely, the systematic review requires a detailed research question and generally includes a narrow range of quality-assessed studies [19-21]. This review will explore and present an overview of the existing literature on gender equality training, as opposed to ascertaining the efficacy of a specific intervention, so we deemed a scoping review the most suited approach for this study.

Methods

Overview

The review will be structured using Arskey and O'Malley's [19], 5-stage framework, which involves (1) identifying the research question, (2) identifying relevant studies, (3) selecting the studies, (4) charting the data, and (5) collating, summarizing, and reporting the results. The scoping reviews' systematic approach will also be informed by 3 additional studies, each of which has contributed depth and detail in advancing Arskey and O'Malley's [19] original framework, including Levac et al [22], Peters et al [20], and Tricco et al [21].

Identifying the Research Question

Tricco et al [21] list a variety of models to facilitate the development of a research question, including population, intervention, control, and outcomes tool and an adaption of the sample size, phenomenon of interest, study design, evaluation, research type tool. However, Peters et al [20] argue that the population, concept, and context mnemonic are more suited to crafting a research question suited to the exploratory and descriptive nature of the scoping review. The population, intervention, control, and outcomes model, in contrast, facilitates the development of focused and explanatory research questions more suited to a systematic review [20]. In forming the research question for this review, we selected the population, concept, and context approach: the population will include students in higher education, the concept will include gender equality training, and the context will encompass all HEIs.

The principal aims of this scoping review will be to (1) produce a descriptive overview of gender equality training and gender equality interventions for students in higher education or postsecondary education, including their core aims, key content areas, implementation methodology, and outcome evaluation, and (2) construct a consensus on skills and competences required to promote gender equality. A secondary aim of this study is to review the extent to which leadership is incorporated into gender equality training.

The principal research question for the review is: what is the current nature and scope of interventions promoting gender equality competences among students in higher education? The secondary research questions include (1) how is gender equality training delivered to students, and what are the key topics included in the intervention? (2) What specific skills and competences are taught to students to enable them to promote

XSL•FO
RenderX

gender equality? (3) How is gender equality training evaluated? (4) To what extent is the concept of leadership included in gender equality interventions, and how are gender equality leadership skills fostered among students?

Identifying Relevant Studies

The search strategy was designed in consultation with an experienced librarian. The search terms will comprise three thematic combinations, including (1) gender equality training, (2) HEIs, and (3) students, each separated with the Boolean operator AND. Within each thematic combination, search terms will be separated with the Boolean operator OR. Wildcards will be used to ensure the inclusion of plurals and variation in spelling across the search terms. The search will be limited to studies and other sources published between January 2011 and November 2021. Based on preliminary database searching, the majority of publications on gender equality training for second- and third-level students have been published in the last 10 years. Systematic searches will be carried out in 6 databases, CINAHL Plus and APA PsycInfo (accessed on Ebscohost), Embase, MEDLINE (Ovid), Web of Science (Science and Social Citation Indexes accessed on Clarivate), and Scopus (accessed on Elsevier). Textbox 1 provides an example of the search strategy, which will be applied. We will also carry out searches using MedEdPortal, MedEdPublish, and Open Grey to identify any gray literature that could further inform the review. The search will be limited to titles, abstracts, and keywords to ensure the search terms collate papers and sources whose focus relates to these topics.

Textbox 1. An example of search strategy applied for APA PsycInfo and CINAHL databases.

8. 1 AND 2 AND 3
9. LIMIT 8 to 2010-2021

Literature searches to be carried out in APA PsycInfo, CINAHL, Embase, MEDLINE (Ovid), Scopus, and Web of Science databases. Searches using MedEdPortal, MedEdPublish, and Open Grey will be carried out to identify gray literature to further inform the review. The search was limited to studies and other sources published between January 2011 and November 2021.

Study Selection

The search will be carried out by the librarian and subsequently prepared for screening in an EndNote library (EndNote, version 20.2.1; Clarivate Analytics), and duplicates removed. The EndNote library will be exported to Rayyan (Rayyan), which will be used to collaboratively complete paper screening. Rayyan is a web-based tool designed to speed up the screening process of systematic reviews, scoping reviews, and other knowledge synthesis projects [23]. The principal investigator and research assistant will each carry out the title and abstract screening. Tricco et al [21] advise establishing an agreed standard for reviewing texts prior to commencing the formal screening process. We will use the following inclusion and exclusion criteria as our agreed framework for paper screening. In line with the study’s research questions, our inclusion and exclusion criteria will be applied as detailed in Textbox 2.

Throughout the course of the screening process, the inclusion and exclusion criteria will be adapted and developed in an iterative fashion. Researchers will resolve disagreements through discussion and develop a finalized list of abstracts to be reviewed. If consensus is not reached on particular sources, one of the coauthors will act as a third party in finalizing the selection decision. All authors will collectively review the first 10 texts screened for applicability to the research questions and use group discussion to add depth and detail to the inclusion and exclusion criteria. The remainder of the texts to be reviewed will be divided among 3 groups, with each group consisting of 2, 2, and 3 authors, respectively. A collaborative and discursive process will be applied to resolve disagreements at the full-text screening phase, and the collective work and consensus among each group will form the finalized list of full texts to be included in the scoping review. Throughout the screening phase, the authors will use a reflexive approach in reviewing papers and consolidating the inclusion and exclusion criteria, given the iterative nature of this process [20].

XSL•FO
RenderX

Textbox 2. The inclusion and exclusion criteria.

Inclusion criteria

- Undergraduate or postgraduate students in higher education
- Interventions (eg, campaign or workshop) promoting gender equality awareness or gender equality competences:
  - Interventions inside or outside of the academic curriculum
    - for example, project within a module or exercise within a module
    - for example, course or program external to course of study
  - Papers or sources focusing on the experience of participation in an intervention
  - Interventions do not have to focus solely on gender equality; interventions can also focus on other aspects of equality, diversity, and inclusion (EDI) training; as long as gender equality is included in the intervention, it can be included
  - Interventions involving gender equality in terms of gender diversity (transgender, nonbinary, and gender-diverse students)
  - Teacher training
- Third-level education institutions
- Published between January 2010 and September 2021
- Publications such as peer-reviewed literature and gray literature (dissertations, conference papers, corporate documents, government reports, preprints, proceedings, research reports, and periodicals)
- Any relevant papers cited in literature, systematic, and scoping reviews focusing on similar subject matters
- Studies in English

Exclusion criteria

- Primary or secondary students, higher education staff, general public
- Papers or sources focusing on:
  - Measuring gender balance in higher education courses
  - Strategies to promote greater equality among applicants to particular courses
  - Experiences of gender or gender inequality among students
  - Impact of gender on subject-specific competences, for example, programing or spatial awareness
  - Recruitment or retention of female students in academic courses
  - Gender equality in health care
  - Mentorship programs
  - Diversity or EDI programs that do not include a gender dimension
  - Gender studies modules
  - Papers focusing on a whole-of-campus institutional change
  - Experiments on students' attitudes—unless these form part of a specified intervention.
- Papers referring to primary- or secondary-level school interventions, youth services, community services programs
- Published prior to January 2010
- Publications such as books, film reviews, and websites
- Studies for which no English translation is available

Reference lists of the included texts will be hand-searched for further relevant studies and sources, as will literature reviews identified in the database search. As per the exploratory nature of a scoping review, a variety of study designs and sources will be used to gather data, including empirical peer-reviewed research, periodicals, dissertations, conference abstracts, magazines, periodicals, and research reports. Appropriate gray literature will also be searched in the reference lists of selected texts. Quality appraisal will not form part of the screening and selection process. A scoping review principally seeks to identify, explore, and map existing literature on a given topic, so assessing the methodological and academic quality of the studies will not be applicable or necessary [20,22].

Finally, to optimize the comprehensiveness of the search, Levac et al [22] and Paez [24] recommend consulting experts in the field to inform and guide the review. We will liaise with several

XSL•FO
RenderX

experts in the field of gender equality and leadership training via email. Experts will be asked to review the list of papers selected, provide feedback, and identify any further papers or ongoing studies that should be included. We aim to liaise with a variety of organizations in informing the review, including the UN Women Training Centre, the European Institution for Gender Equality, the Gender Equality Academy, RCSI Institute of Leadership, Technology University Dublin Equality, Diversity, and Inclusion Unit, University College Cork (UCC) Equality, Diversity, and Inclusion Unit, UCC Business School, the Irish Management Institution UCC, Aurora Management, 30% Club, and Advance Higher Education. The study selection process will be laid out using a flow diagram as per the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses Extension for Scoping Reviews) Statement to make the search strategy and selection process transparent and auditable [19,21].

Ethical Considerations

This review will involve the analysis of publicly available empirical research and the production of secondary data, so ethical approval will not be required.

Results

Overview

The extracted data will be collated, and a narrative summary will accompany the results to explain how the results relate to the reviews' objectives. The findings will be discussed as they relate to higher education. Gaps and limitations of this literature will also be identified and presented.

Charting the Data

A data-charting form will be used to collect key information from each study using Word (Microsoft Corp) documents and Excel (Microsoft Corp). MP developed the original data-charting form, which will be expanded and refined in an iterative fashion by all authors during the full-text screening process. The researchers will independently chart the data and update the data-charting table as they see necessary. Group discussion will be used to address disagreements and create the final standardized data-charting table. Arskey and O'Malley [19] explain that data charting differs from the data extraction process used in systematic reviews and meta-analyses, where data extraction is specific and may involve statistical techniques, data charting within scoping reviews involves a broader approach and includes narrative information, capturing how the study was carried out.

Peters et al [20] explain that the information documented in the data-charting table should align with the research aims and research questions of the review. As such, the data collected for this scoping review will include study details (author or year), location, context, type of source, study aims or intervention aims, participant details and sample size, research questions addressed, study design, gender equality theories used, intervention style and duration, intervention content, intervention methods and format, outcome evaluation measures, key findings, interesting observations, incorporation of gender equality and leadership, incorporation of intersectionality, and incorporation of transgender and gender-diverse inclusivity.

Collating, Summarizing, and Reporting the Results

Levac et al [22] recommend dividing this final stage into 3 distinct components. To collate and summarize the results, we will use descriptive numerical summary analysis. The data will be mapped and presented in tabular format to make it easier to respond to the study questions. Basic descriptive analysis is both sufficient and the most suited approach of data analysis for the exploratory nature of the scoping review [21]. Finally, Levac et al [22] advise the researcher to consider the meaning of the findings in relation to the overarching purpose of the study. A narrative summary will accompany the results and will describe how the results relate to the review objective. Gaps and limitations of this literature will also be identified and presented.

Discussion

Principal Findings

HEIs have the potential to amplify gender equality through training for the betterment of society at large. We are undertaking this scoping review as part of a need assessment to provide the best evidence to inform intervention design and prioritize content for an educational program.

We aim to first synthesize the existing literature on training that supports gender equality in HEIs providing conceptual, theoretical, and evidentiary clarity on the current state of the art. Second, we aim to identify gaps and areas for future research to help define the research agenda for gender equality training in HEIs going forward.

Study Dissemination

Research findings will be disseminated using a variety of mediums, including publication in a peer-reviewed academic journal and presentation of the findings at national and international conferences and other academic events. The findings will also be used to inform the pilot study for the LIBRA gender equality–based training program, with the goal of a subsequent national roll-out across Irish HEIs. Further afield, the findings will be available to be used by other universities or institutions of education to inform the development of gender equality training for students in higher education.

Strengths and Limitations

To the best of our knowledge, this is the first review of the literature focusing on gender equality training and interventions for third-level students. The search strategy was comprehensively developed by all authors, with the support of an experienced librarian, which will facilitate a thorough and extensive database search. The university in which this study is being carried out is a medical and scientific institution, which will necessarily limit the full scope of databases available to the authors in carrying out the search. Following consultation with our librarian, hand-searching reference lists of the included papers and texts was considered sufficient to identify other important studies and gray literature in the event that they were

XSL•FO
RenderX

not retrieved in the database search. We originally intended to incorporate Google and Google Scholar searching into the search strategy; however, given time limitations within the allocated funding period, we decided to focus specifically on academic databases when carrying out the search. This review is limited to papers written in English or which have an English translation available, which may bias the evidence.

It is also important to note that there may be a lack of relevant literature available in this particular field, given the niche topic on which this review will focus. However, this finding in itself may encourage further research on the topic as it would highlight a significant gap in the literature following a comprehensive search of the databases. Excluding studies focusing on gender equality in health care, mentorship programs, and gender studies modules may lead to the exclusion of useful information, both within the review itself and later informing the LIBRA study. Yet, following the preliminary database searching and screening, we concluded that these particular studies did not fully align with the research questions.

Acknowledgments

The authors would like to thank Mr Paul Murphy, Information Specialist at the Royal College of Surgeons in Ireland, for his time and support in developing the search strategy for this review. This review forms part of the study “LIBRA: Future-proofing Gender Equality in Irish Higher Education Institutions.” This research is funded by the Irish Higher Education Authority.

Conflicts of Interest

None declared.

Abstract

Background: Digital technology is a means to uphold or violate human rights in various domains, including business, military, and health. Given the pervasiveness of mobile technology in low- and middle-income countries (LMICs), mobile health (mHealth) interventions present an opportunity to reach remote populations and enable them to exercise civil and political rights and economic, social, and cultural rights, such as the right to health and education. Simultaneously, the ubiquity of mobile phones involves processing sensitive data which can threaten rights, including the right to privacy and nondiscrimination. Digital health is often promoted as advancing human rights and health equity; however, digital rights are underexplored in the literature on mHealth in LMICs. As such, creating an understanding of the digital rights topics covered in the 2022 literature is important to avoid exacerbating existing inequities relating to digital health design, use, implementation, and access.

Objective: This scoping review aims to identify digital rights topics in the 2022 peer-reviewed literature on mHealth in LMICs.

Methods: The Arksey and O'Malley framework for scoping reviews guides this review. Searches were performed across 7 electronic databases (Web of Science, Scopus, Ovid, ACM Digital Library, IEEE Xplore, ProQuest, and PubMed). The screening processes were guided by the research question "What digital rights topics have been explored in the 2022 literature on mHealth in LMICs?" Only papers addressing mHealth in LMICs and digital rights topics were included. Data extraction will include publication title, year, and type; first author's affiliation country; LMICs implicated; infrastructure challenges; study aims, design, limitations, and future work; health area; mHealth technology, functions, purpose or application, and target end users; human or digital right terms used; explicit rights topics cited; and implied rights topics. The results will be reported using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist.

Results: This scoping review was registered in Open Science Framework (December 22, 2022). Title and abstract screening and full-text paper screening were completed in 2023. This resulted in 56 papers being included in the study. The target date for completing data extraction and publishing a case study of the initial findings is the end of 2023. The full scoping review findings are expected to be disseminated through various pathways benefiting academia, practice, and policy making by the end of 2024. These include journal papers, conference presentations, publicly available toolkits for research and practice, public webinars, and policy briefs with evidence-based policy recommendations emerging from this review.

Conclusions: The planned scoping review will identify digital rights topics in the 2022 literature at the intersection of mHealth and LMICs. Furthermore, it will highlight the importance of patient empowerment, data protection, and inclusion in mHealth research and related policies in LMICs.

Introduction

Background

In 2022, the European Commission signed "The Declaration on Digital Rights and Principles," acknowledging the power of digital technologies as enablers and inhibitors of human rights [1]. Further, it reshapes and applies existing human rights to the digital space (eg, the right to the protection of their personal data on the internet and the right to freedom of expression in the internet-based environment). Likewise, in 2020, the United Nations put forward the "Roadmap for Digital Cooperation," which acknowledged that digital technology, as a tool, is a means to exercise human rights and violate them [2,3]. Similarly, "the resolution on the promotion, protection, and enjoyment of human rights on the internet" in 2016 [4] affirmed the importance of protecting and realizing human rights on the internet and other information and communications technology. Clearly, human rights relating to the digital environment, or digital rights, are an emerging and evolving topic that concerns 2 key areas. First, the extension, realization, and protection of existing human rights in the digital space and over personal, digitized data (eg, freedom of expression). Second, the discussion around emerging human rights to access, use, and participate in the digital space (eg, the right to internet access) [5]. For this study, digital rights are all existing and emerging human rights that extend to, and relate to accessing and protecting, participation in the digital space.

The internet as an enabling technology is often at the center of the discussion around digital rights, with arguments made for the right to internet access [6-8]. Although the European Commission and United Nations do not explicitly identify internet access as a right, they proclaim necessary internet access protections for the sake of safeguarding, or at least not intentionally stifling, human rights [1,2,9]. So far, several countries have recognized the right to internet access, including Greece [10] and India [11]. Yet, the status of this right is still being discussed at the international level [12]. Beyond internet access considerations, the topic of digital rights also concerns the broader information and communications technology environment and addresses, for instance, health care systems and respect for human dignity [13], automation and the right to work [14], and surveillance technologies and the right to freedom of movement [15].

Low- and Middle-Income Countries

Digital rights discourse often focuses on high-income countries in which, in most cases, users enjoy significant digital access and considerable rights and legal protections [16]. This work seeks to explore low- and middle-income countries (LMICs) instead, which are more at risk of digital rights violations (eg, state-sanctioned internet shutdowns and internet-based censorship) [17-19] and where user rights are inadequately regulated [20,21].

Mobile Health

This study examines the underexplored digital rights concerns relating to mobile health (mHealth) in LMICs. mHealth refers to "the use of mobile and wireless technologies to support the achievement of health objectives" [22], categorizing various devices such as mobile phones, wearable and implantable devices, tablet computers, and personal digital assistants [23]. Digital health, including mHealth, is often promoted as advancing human rights and promoting "health equity, if implemented in partnership with communities and based on core values of local autonomy, fairness and ecological sustainability" [24]. However, to what extent the literature on mHealth in LMICs engages with digital rights topics is currently underexplored. Exemplary digital rights topics concerning mHealth in LMICs include the impacts of mandatory Subscriber Identity Module registration mobile app download taxes, cyberviolence over mobile phones, and internet-based censorship, as well as gender disparities and the gender digital divide, internet-based surveillance and the right to privacy, and prolonged data retention and the right to be forgotten [25-28]. To create knowledge in this underexplored space, this scoping review aims to identify digital rights topics in the 2022 peer-reviewed literature on mHealth in LMICs.

Methods

Scoping Review

This review follows the scoping review framework outlined by Arksey and O'Malley [29] and recommendations by Levac et al [30]. This involves adhering to and reporting the following six steps: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; (5) collating, summarizing, and reporting results; and (6) consultation [29]. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist will be used to report the review results. This review commenced in November 2022 and is expected to conclude by the end of 2023.

Step 1: Identifying the Research Question

The guiding question of this review is "What digital rights topics have been explored in the 2022 literature on mHealth in LMICs?" To limit the scope to digital rights, this review will not investigate well-explored mobile access topics (eg, infrastructure, literacy, connectivity, and cost) except in instances relating to digital rights. Further, the scope is limited to literature published in 2022 based on resource limitations and the saliency and engagement of digital rights topics in recent years.

XSL•FO
RenderX

Step 2: Identifying Relevant Studies

Searches were performed across 7 electronic databases. A preliminary search was performed on November 25, 2022, across 6 electronic databases: Web of Science, Scopus, Ovid, ACM Digital Library, IEEE Xplore, and ProQuest. The search strategy (Multimedia Appendix 1) consisted of terms considered to capture the nature of the research question. Multimedia Appendix 1 reports the numerous variations and abbreviations of terms used, as well as the search string adapted according to the requirements of each database. A second series of searches were performed on March 9, 2023, in the same databases to identify any papers published after the initial search date. On August 16, 2023, PubMed was added to the list of databases and searched. Search results were imported into Covidence (Veritas Health Innovation), a web-based tool for collaborative paper screening, reviewing, and data collection. Duplicate citations were removed using Covidence functions.

Step 3: Study Selection

The inclusion and exclusion criteria applied to the study selection process are described in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Paper type: Peer-reviewed papers.
- Language: English.
- Publication date: 2022.
- Subjects of interest: Mobile health (mHealth) in low- and middle-income countries (LMICs) and digital rights topics.

Exclusion criteria

- Paper type: Not peer-reviewed papers (eg, unpublished work and gray literature).
- Language: All other languages.
- Publication date: Before or after 2022.
- Subjects of interest: Not mHealth in LMICs (eg, reviews on health technology in LMICs not covering mHealth) and not digital rights topics specifically (eg, mobile phone accessibility topics such as cost and digital literacy).

Papers were screened by 2 reviewers (coauthors AP and YJCS) to assess relevance to the research question over two iterations: (1) title and abstract screening and (2) full-text paper screening. To aid in both screening iterations, the authors developed a screening form and integrated it into Covidence. Following recommendations by Levac et al [30], the reviewers regularly met during the screening process to resolve emerging conflicts related to study selection. An arbiter (coauthor EFV) settled the conflicts that could not be resolved in the reviewers' discussions.

Initially, during the search and title abstract screening, no limits were put on the publication date. However, the criteria were revised post hoc only to include publications from 2022 based on resource limitations and familiarity with the literature. As such, the search and title and abstract screening included papers published on any date, and only after the title and abstract screening were papers published before 2022 excluded. Post hoc, iterative revisions to the eligibility criteria are not uncommon [29,31] and are appropriate "to ensure that abstracts selected are relevant for full paper review" [30]. However, they should be reported with justification for transparency [32], as done here. The post hoc excluded papers will be retained for a later, larger review.

Step 4: Charting the Data

For the included papers, 2 authors (AP and YJCS) independently piloted the data extraction process with 5 papers to reach a consensus and check for consistency. Afterward, data extraction of the remaining papers will be conducted by one reviewer (AP). Data will be extracted using a data chartering form integrated into Covidence, initially developed by the authors before the data collection process and later revised by 3 coauthors (AP, YJCS, and HML) after the data extraction pilot. Data items included in the form were publication title, year, and type; first author's affiliation country; LMICs implicated; infrastructure challenges noted; study aims, design, limitations, and future work proposed; health area addressed through mHealth; mHealth technology, functions, purpose or application, and target end users; human or digital right terms used; explicit digital or human rights topics cited; and implied digital or human rights topics.

Step 5: Collating, Summarizing, and Reporting Results

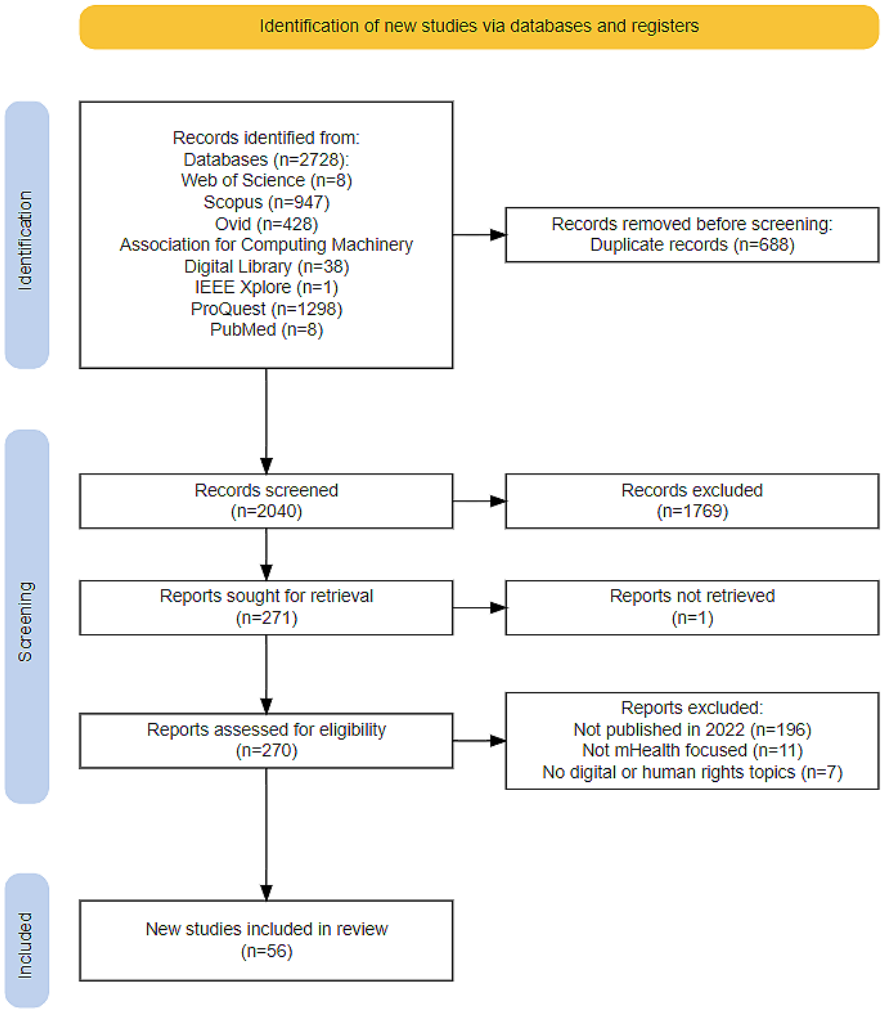
All data will be exported from Covidence and collated in a single spreadsheet on Excel (Microsoft Corp) for frequency and content analysis. Descriptive statistics will be calculated to summarize the general characteristics of the included literature. Content analysis will be used to interpret the extracted data. These methods are typical and recommended in scoping reviews [30].

Step 6: Consultation

No consultation outside of the primary author's wider research team will be performed in the design of this scoping review.

Ethical Considerations

As this scoping review will not include human or animal participants, neither ethics approval nor participant consent is required. Only secondary analyses will be conducted on data collected from published literature.



XSL•FO
RenderX

Results

The database searches yielded 2728 papers. After duplicates were removed, 2040 papers underwent title and abstract screening. This resulted in 271 papers being considered eligible for full-text screening. However, only 270 were retrieved for full-text screening (one was inaccessible and therefore excluded). Post hoc eligibility criteria were applied before full-text screening, excluding 196 not published in 2022. The post hoc excluded papers will be retained for a larger review to be completed in the future. The remaining 74 papers were considered eligible for inclusion. Following full-text paper screening of 74 papers, which excluded papers not focusing on mHealth (n=11) and not addressing digital or human rights topics (n=7), 56 papers were included in this scoping review. Figure 1 reports the scoping review process using the PRISMA-ScR flow diagram.

Data extraction is underway and expected to be completed by the end of 2023. Further, by the end of 2023, the initial findings of selected studies are expected to be published as a case study. The full scoping review findings are expected to be published by the end of 2024.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram of the scoping review process.

Discussion

Principal Results

This planned scoping review is designed to identify and map digital rights topics explored in the recent literature addressing mHealth in LMICs. Furthermore, it is projected to examine to what extent the literature engages with digital rights considerations relating to mHealth interventions; that is, whether digital rights topics are explicitly or implicitly deliberated. The review findings are expected to draw attention to the importance of data protection, inclusion, and patient empowerment in mHealth solutions and associated policies in LMICs to avoid exacerbating existing inequities relating to digital health design, use, implementation, and access. Moreover, this review is positioned to reveal existing knowledge and policy gaps relating to digital rights, which could help inform future mHealth research directions and relevant policy. The dissemination of findings will be varied, including journal papers, conference presentations, and publicly available research toolkits. Policymakers will be engaged through, for instance, webinars and policy briefs with evidence-based policy recommendations.

Due to the ubiquity of mobile phones in LMICs and continued interest in mHealth research in these contexts, this review will likely interest digital health researchers, making them aware of

XSL•FO
RenderX

digital rights considerations when realizing and investigating digital health interventions. Furthermore, the findings of this review may benefit policy makers in LMICs by adding to the emerging discussion about digital rights protections and violations in these settings, which may impact digital health access.

Limitations

This scoping review will follow well-established methods established by Arksey and O'Malley [29] and Levac et al [30]; yet, limitations will exist. First, scoping reviews lack formal bias and quality assessment methods, risking potential bias in the selection of included papers and derived conclusions [33]. Second, only peer-reviewed, English-language papers will be included in the review, thus excluding possible insights from the gray and non–English-language literature. As such, further research is needed to evaluate the quality of existing literature in this space and widen the scope of the included literature. Yet, acknowledging the strength of scoping reviews in providing an initial assessment of the size and scope of the available research literature, this review will provide the groundwork for research addressing digital rights and mHealth in LMICs going forward.

Conclusions

This scoping review will identify digital rights topics in the 2022 peer-reviewed literature on mHealth in LMICs. Moreover, it will highlight the importance of data protection, patient empowerment, and inclusion in mHealth research and related policies in LMICs. In addition to creating knowledge about the digital rights topics currently deliberated or implied in the recent mHealth research literature, the review findings will identify to what extent researchers engage with those topics. Furthermore, the results will identify knowledge and policy gaps and future research directions relevant to mHealth in LMICs research. The findings may advantage digital health researchers and policymakers operating in LMIC contexts, improving understanding of pertinent digital rights considerations relating to mHealth.

Acknowledgments

This research is being conducted by the University of Sydney's Brain and Mind Centre pursuant to an agreement between the University and Minderoo Foundation Limited (Minderoo). EFV would like to acknowledge that contributions to this research are supported by the European Research Council Starting Grant SAFE and SOUND project, which received funding from the European Union's Horizon-European Research Council program (grant 101076929). Views and opinions expressed are however those of the authors only and do not necessarily reflect those of the European Union or the European Research Council. Neither the European Union nor the granting authority can be held responsible for them. IBH is supported by a NHMRC L3 Investigator Grant (GNT2016346).

Data Availability

The data sets generated and analyzed during this study will be made available from the corresponding author upon reasonable request.

Authors' Contributions

IBH and YJCS were integral in securing funding to support the study. The study was designed by AP, YJCS, HML, OI, and MA. AP, YJCS, and EFV contributed to data collection. Scientific oversight and guidance were provided by IBH and HML to ensure that all activities were conducted responsibly. All authors contributed to and approved the final paper.

Conflicts of Interest

IBH is the Codirector, Health and Policy at the Brain and Mind Centre University of Sydney. The Brain and Mind Centre operates an early-intervention youth service at Camperdown under contract to headspace. He is the Chief Scientific Advisor to, and a 3.2% equity shareholder in, InnoWell Pty Ltd which aims to transform mental health services through the use of innovative technologies. HML is a section editor for JMIR Aging but does not receive any financial benefit nor preferential treatment in the review process. AP, YJCS, EFV, OI, and MA have nothing to disclose.

Abstract

Background: The Internet of Things (IoT) has gained significant attention due to advancements in technology and has potential applications in meeting the needs of an aging population. Smart technologies, a subset of IoT, can support older adults in aging in place, promoting independent living and improving their quality of life. However, there is a lack of research on how older adults and smart technologies coadapt over time to maximize their benefits and sustain adoption.

Objective: We will aim to comprehensively review and analyze the existing scientific literature pertaining to the coadaptation between smart technologies and older adults. The primary focus will be to investigate the extent and nature of this coadaptation process and explore how older adults and technology coevolve over time to enhance older adults' experience with technology.

Methods: This scoping review will follow the methodology outlined in the Joanna Briggs Institute Reviewer's Manual and adhere to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews) guidelines for reporting. Peer-reviewed articles will be searched in databases like Ovid MEDLINE, OVID Embase, PEDro, OVID PsycINFO, EBSCO CINAHL, the Cochrane Library, Scopus, IEEE Xplore, Web of Science, and Global Index Medicus. The research team will create a data extraction form covering study characteristics, participant characteristics, underlying models and frameworks, research findings, implications for technology coadaptation, and any identified study limitations. A directed content analysis approach will be used, incorporating the Selection, Optimization, and Compensation framework and Sex- and Gender-Based Analysis Plus theoretical framework.

Results: The results of this study are expected in January 2024.

Conclusions: This scoping review endeavors to present a thorough overview of the available evidence concerning how smart technologies interact with older adults over an extended period. The insights gained from this review will lay the groundwork for a research program that explores how older adults adapt to and use smart technologies throughout their lives, ultimately leading

XSL•FO
RenderX

to improved user satisfaction and experience and facilitating aging in place with tailored support and user-centered design principles.

Introduction

In recent years, the Internet of Things (IoT) has gained significant attention from researchers, health service providers, entrepreneurs, and technology developers [1,2]. The IoT refers to the interconnection of various devices, objects, and systems through the internet, enabling them to collect and exchange data and perform intelligent actions [1]. The rapid growth of IoT has been fueled by advancements in connectivity, sensors, data analytics, and artificial intelligence [3]. Concurrently, researchers have recognized the potential of various technologies in meeting the needs of a rapidly expanding aging population [2,4,5]. These technologies aim to enhance the quality of life, foster independent living, and address the challenges associated with aging in place.

Older adults (aged 55 years or older) are expected to make up 16% of the global population by 2050 [6]. Ensuring effective support for older adults who choose to "age in place," meaning they prefer to live independently in their own homes rather than relocating to institutionalized care facilities such as nursing homes, is of utmost importance [7-9].

Smart technologies are believed to have the potential to help older adults successfully age in place [10]. Smart technologies refer to a wide range of devices, systems, and applications that use sensors to collect data that can influence the machines' "decision-making," that connect with and share data with other systems, that use processors to run algorithms based on predefined rules or prescriptive models, and that have a user interface of some kind. Lyardet and Aitenbichler [11] define them as having "computational power, information and sensing capabilities into everyday objects and environments." These systems leverage technology to enhance functionality, automation, and interactivity [12] and are increasingly viewed as tools that expand both capability and capacity to support older adults, many of whom live with multiple chronic conditions and age in their homes [13].

Older adults can benefit from smart technologies to promote independent living [4,14]. Smart technologies can also be customized to a degree to the unique needs and preferences of older adults [15,16] and are increasingly used to support occupational and leisure activities in various aspects of daily life [14,17]. To date, research has demonstrated that smart technologies can promote independent living, enhance health and well-being, and help to improve the quality of life in older adults and their caregivers [14,18-21]. For example, smart wearable devices can serve as fall detection and prevention tools, providing alerts or notifications in case of a fall or sudden changes in movement patterns that can help older adults with their self-management and active engagement [22,23]. Other studies have explored the use of voice-activated virtual assistants like Amazon Alexa or Google Assistant by older adults [24,25]. For example, such assistants can help older adults with their exercise routines, engage in digital leisure, and support self-management of their health and well-being [24-27].

The literature exploring the interaction between smart technologies and older adults, from the young old (65-74 years old) to the oldest old (>85 years old), is limited. However, it is crucial to understand this interaction in order to maximize the benefits these smart technologies can provide. While several studies have explored older adults' use of smart technologies [14,15,28-30], fewer studies have explored how older adults coadapt to and with these technologies [31-35]. In the context of smart technologies and older adults, coadaptation refers to the process by which both older adults and the technologies they use adapt and adjust to each other over time [36-38]. As an example, a recent longitudinal study of Google Home suggests that patterns of use and benefits experienced by older adults from these technologies change as they get more used to its features and increase their confidence and digital literacy [39].

However, most existing studies fail to consider how older adults coadapt technologies over time to meet their evolving needs. Understanding how older adults adapt to and interact with smart technologies over an extended period is essential for the development of effective and sustainable technological solutions. Moreover, this is important to understand how to sustain adoption as we know from previous research that some abandon it after trial [40]. A recent qualitative systematic review and meta-synthesis explored the existing qualitative data on older adults' perspectives, opinions, and experiences regarding wearable devices [41]. The review synthesized the perspectives of 349 participants, ranging in age from 51 to 94 years, who wore smart devices for durations ranging from 3 days to 24 months [41]. Among other factors, the authors emphasized the importance of the technology's ability to adapt to user's preferences over time, as this was found to play a crucial role in determining the long-term adoption of smart technologies by older adults [41].

This scoping review protocol aims to address the existing research gap and to better understand the current body of scientific literature that explores the interaction between smart technologies and older adults over time. Furthermore, the review

XSL•FO
RenderX

will explore how their interactions coadapt to optimize user experiences and the benefits they may accrue from their use. This study will support further research on how older adults compensate for declines as they age, how to tailor artificial intelligence–enabled technologies for specific needs, inform the development of more intuitive technologies, alleviate caregiver stress, and develop policies that promote independent living.

Methods

Study Design

A scoping review was chosen as the systematic method for synthesizing knowledge [42-44] to comprehensively map the available evidence and provide a broad overview of the literature on the interaction between smart technologies and older adults, considering the diverse range of study designs, methodologies, and sources in this research area [44]. This scoping review protocol was guided by the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Protocols) guidelines [45,46]. Our proposed study will use the methods outlined in the Joanna Briggs Institute manual for knowledge synthesis [47] and will be reported following the PRISMA-ScR (PRISMA Extension for Scoping Reviews) guidelines [48]. Our study will not involve evaluating the quality of the included studies as scoping reviews seek to identify and map all relevant evidence rather than assessing the strength or validity of individual studies [43]. The study will be conducted in 2023.

Ethical Considerations

Ethics review board is not necessary for this particular study as all literature will be publicly available. The public was not involved in the design of this scoping review protocol. This scoping review protocol has undergone registration in the Open Science Framework [49].

Theoretical Lens

This study will be informed by 2 theoretical frameworks. This study will be informed by the Selection, Optimization, with Compensation (SOC) framework [50,51] that suggests as individuals age, they use adaptive strategies to maintain or enhance their well-being and achieve their goals, despite changes in cognitive and physical abilities [50,51]. This can be applied to understand how older adults coadapt with smart technology as they age. The selection aspect of the SOC framework refers to the process of choosing goals, activities, and resources that align with one's capabilities and priorities, whereas optimization involves actively engaging in practices to enhance performance and maximize benefits [50,51]. Compensation in the SOC framework refers to the adaptation strategies individuals use to overcome limitations or challenges in achieving their goals, such as using alternative approaches or tools to compensate for declines in cognitive or physical abilities [50,51]. Over the life span, there are 3 main functions associated with ontogenetic development, namely growth, maintenance, and the regulation of loss. The ability to manage weakening functionality and intellectual capacity using SOC lessens as we age, increasing the importance of research into scientific and cultural innovations that will extend the optimization of development and independence later into the lifespan [50].

The study will also incorporate the Sex- and Gender-Based Analysis Plus (SGBA+) theoretical framework [52]. SGBA+ draws on intersectionality frameworks and was specifically chosen to examine sample characteristics, including biological sex and various social positions of older adults, such as ethnicity, income, age, race, education, and gender within the existing body of research [52,53]. This framework was chosen based on the growing recognition that there are significant differences and disparities in older adults' technology use and adoption experiences related to socioeconomic, demographic, physical, cultural, and psychological factors [54,55].

Review Questions

What is the extent and nature of the existing scientific literature exploring the coadaptation between smart technologies and older adults and how do older adults and technology coevolve over time to enhance older adults' experience with the technology?

Subquestions are (1) what have been the outcomes of the coadaption between older adults and smart technology? (2) What specific outcome measures have been used in studies investigating the experiences of older adults in terms of coadapting with technology over time? (3) What specific strategies or approaches have participants used to adapt to the changing circumstances, challenges, or opportunities in their environment, and what process do they follow when making adaptive decisions? (4) What are the key characteristics of older adult participants who have been involved in studies examining the coadaptation between smart technologies and older adults? (5) What methodological strengths, limitations, and recommendations have been documented in the literature regarding the exploration of coadaptation between smart technologies and older adults? (6) What research models and theories contribute to the conceptualization of coadaptation?

Inclusion Criteria

Overview

We used the Population, Concept, and Context (PCC) framework to determine the elements of our inclusion criteria [47].

Participants

The participants included in this study will consist of individuals aged 55 years or older and living independently in the community. We operationalize independent living as individuals aging in place, that is, living within houses, apartments, and retirement communities (ie, not institutional care settings [56]). Thus, this review will encompass a diverse population with varying health conditions and levels of independence.

Concepts

The concepts of interest are smart technologies, interactions and coadaptations, and experiences and outcomes. Smart technologies, in the context of this study, refer specifically to wearables and voice-activated virtual assistants [57]. Older adults, as end users of smart technologies, gain a progressively

XSL•FO
RenderX

refined understanding of the technology's functionalities, operational nuances, and potential utilities [38]. Simultaneously, the technology itself assimilates and accommodates user preferences, habits, and behaviors through machine learning algorithms and adaptive interfaces [36]. In the context of older adults, it is notable that the iterative coadaptation process fosters an environment of familiarity and trust, resulting in reduced cognitive load and an enriched user experience [58,59]. As postulated by Melenhorst et al [60], further research should delve into the intricate interplay of individual differences, cognitive aging, and the evolution of technology in the context of sustained coadaptation over time. Thus, our concepts focus on the dynamic process of interaction between older adults and smart technologies and involve an exploration of how older adults engage with and adapt to the use of these technologies over time. We define coadaptation as the reciprocal adjustments and changes that occur in both older adults and smart technologies as they interact and learn from each other [36,37,61-63]. We will include any study that has explored coadaptation using older adults as the human component of the system. This includes, but is not limited to, quality of life, well-being, social connectedness, independence, and overall user experience.

Context

This review aims to encompass a wide range of contexts, settings, disciplines, and fields without imposing limitations. We will include articles from diverse areas such as clinical sciences, public health, social sciences, engineering, and policy. By adopting such a transdisciplinary approach, the review aims to provide a comprehensive understanding of the topic by incorporating insights from various domains and disciplines.

We will limit the search to literature published since 2000, in part to ensure the review can prioritize studies that are more likely to reflect current knowledge, practices, and technologies related to the topic of interest.

Types of Sources

Our sources will consist of peer-reviewed scientific literature that presents empirical study designs (eg, quantitative research studies, qualitative research studies, mixed methods studies, experimental studies, observational studies, case-control studies, cohort studies, and cross-sectional studies). We will also include conference proceedings and dissertations. By incorporating diverse empirical study designs, the review aims to gather a comprehensive range of evidence and perspectives on the topic, allowing for a more nuanced understanding of the interaction between smart technologies and older adults. Literature reviews and grey literature will be excluded.

Search Strategy

The search strategy for this scoping review will be developed by an information specialist (Centers for Disease Control and Prevention). The following subject headings and terms related to the following concepts may be included in the search: (1) aged, seniors, older adults, elderly, people with disabilities, cognitive and physical disabilities; (2) wearable electronic devices, voice recognition, artificial intelligence, smart technology, smart assistive technology, virtual reality, ambient intelligence; (3) coadaptation, double-loop learning, coevolution, human-computer interface, human-environment interaction, interaction design, personalization, customization, tinkering, crafting, redesign, modification, sensemaking, hacking, accommodation, mutual adaptation, symbiotic evolution, reciprocal adjustment, interactive iteration, user-technology synergy, dynamic interface refinement, adaptive coevolution, concurrent learning, and bidirectional refinement.

These terms will be combined using Boolean operators (such as AND and OR) to construct search queries tailored to specific databases or search engines.

An initial search will be conducted in Ovid MEDLINE, using text words in article titles and abstracts, as well as index terms, to identify relevant articles. This strategy will undergo press peer review to minimize biases and ensure comprehension prior to being finalized [64]. Once the strategy is finalized in Ovid MEDLINE by the research team, it will be translated and adapted for other databases including OVID Embase, PEDro (Physiotherapy Evidence Database), OVID PsycINFO, EBSCO CINAHL, IEEE Xplore, Web of Science, the Cochrane Library, Scopus, and Global Index Medicus by the information specialist. The aim is to ensure comprehensive coverage of relevant literature by searching multiple databases. The retrieval period for the search will span from January 2000 to August 2023.

The final search will be reported following the PRISMA-S (PRISMA literature search extension)—an extension to the PRISMA Statement for Reporting Literature Searches in Systematic Reviews [65]. To identify any studies that may have been missed during the search process, we will conduct a hand-search of the reference lists of the included articles [44] and conduct forward and backward searching [66]. Additionally, we will consult with experts in the field (eg, authors of the included paper) to gather their insights and recommendations on potentially relevant studies that should be included in the review.

Study Selection

The search results will be combined in EndNote reference management software and duplicates will be removed [67]. The deduplicated records will be imported into Covidence (Veritas Health Innovation Ltd), a tool for managing and documenting studies during the review process [68]. Screening will occur in 2 phases: level 1 for title and abstract screening and level 2 for full-text screening. To ensure consistency, a pilot test will be conducted on 10 titles and abstracts by all members of the research team to evaluate agreement among reviewers. Any discrepancies and ambiguity regarding the inclusion and exclusion criteria will be resolved through discussion, and another pilot test will be conducted until a consensus is reached. Following the pilot testing, the titles and abstracts will be screened by 2 reviewers against the predetermined inclusion criteria. The authors will use Covidence to vote yes, no, and maybe. Abstracts with uncertainty will undergo full-text review. Potentially relevant sources will be assessed at the full-text stage by the same 2 independent reviewers. Any disagreements in voting between reviewers will be resolved through discussion with the senior responsible investigator at both levels of screening. The reviewers will meet weekly with the research

XSL•FO
RenderX

team to discuss the screening process. The following inclusion criteria will be used to screen the literature: (1) be published in the English language in a peer-reviewed journal and include primary data on wearables and voice-activated virtual assistants as the primary smart technology interventions; (2) examine the interaction between smart technologies and older adults over a period of 6 months or more; (3) involve study samples of participants only aged 55 years or older.

Study Extraction

The research team will create a data extraction form to extract data related to the study aims and questions. Thus, the data extraction process will cover various categories, such as study characteristics (eg, the author's name, year of publication, country of origin, study purpose or aim, study design, data collection methods, sample size, and study setting), participant characteristics (ie, sex, gender, and other identity constructs), underlying models, theories and frameworks used to inform the research, findings, implications for the coadaptation of technology process, and any quality or limitations identified in the study. We will look for instances of shifts in user behavior patterns over time, reflect on adjustments in interactions with smart technologies, and identify instances where both users and technologies engage in reciprocal feedback loops, thereby leading to iterative adaptations.

Three reviewers (KK, AG, and JM) will first pilot the extraction tool on a subset of the articles. The data extraction tool will be modified and revised as needed during the extraction process for each study included. Any disagreements between the reviewers will be resolved through discussion or by involving additional reviewers if necessary. Next, 1 author (KK) will extract data from the included studies. All relevant data from the studies included will be extracted using free text. By extracting data using free text, the reviewers can capture a wide range of details and nuances, providing a detailed overview of the studies' content and enabling a thorough analysis of the research findings. The senior responsible investigator will then review all extracted data for accuracy.

Data Analysis and Presentation

The scoping review will use 3 reporting and presentation strategies to provide an overview of the literature.

First, a basic numerical account will be provided, presenting information on the number of included records, the year of publication, the types of study designs included details of included participants, and the outcome measures, among other relevant factors. This numerical summary will give a quantitative overview of the body of literature.

Next, a directed content analysis [69] will be conducted on the included literature, focusing on the purpose of coadaptation techniques used over time, study findings related to outcomes and experience, and implications for technology design and future research. The content analysis will involve inductive and deductive categories. Deductive categories will be informed by the SOC model to examine how older adults use the 3 strategies of selection, optimization, and compensation [51] in their interactions with smart technologies and the coadaptation process over time. We can examine how these strategies influence their satisfaction, experiences, and outcomes with technology. In addition, the model can help identify any gaps or areas where further support or intervention may be needed to enhance the coadaptation process.

To do so, all authors will read over the extraction to become familiar with the content related to older adults' experiences with smart technologies and coadaptation. The authors will then look for instances where older adults engage in selection, optimization, or compensation strategies in their interactions with smart technologies. This will help us identify key concepts derived from the research objectives, research questions, and the SOC. Once we have identified several initial concepts, we will group them into broader categories that align with the three strategies of the SOC model—selection, optimization, and compensation. This step involves organizing similar categories together based on their conceptual similarity. Through team discussion, these categories will be included in a codebook [70]. One author (KK) will then apply the coding framework to the extracted data and return to the full text of the articles if needed for more context [70]. Once the data have been coded, we will organize the coded content based on the patterns, frequencies, and variations within and across the categories to identify common themes [70]. As we explore themes, we will consider differences in various forms of technology [71]. Through team discussions, we will consider the implications of the findings in relation to the research objectives and research questions.

Finally, participant characteristics will be synthesized by having the first author (KK) map the findings into deductive categories informed by the SGBA+ framework [72], including age, patient population, race and ethnicity, sex and gender, sexual orientation, education, geography disability, language, and technology access and comfort [73].

Thus, the descriptive synthesis will also highlight any study limitations, identify knowledge gaps, and suggest opportunities for future research related to the inclusion of participants and gaps in knowledge.

Results

The results of this study and the submission of a manuscript for peer review are expected in January 2024.

Discussion

Preliminary Findings

The scoping review outlined in this protocol will serve as a foundation for a broader program of research exploring the experiences of older adults and smart technology over time. By expanding upon the proposed work in the scoping review, there is potential to leverage innovative technological solutions and evaluation to support optimized independent aging at home or in other environments such as the workplace, for diverse older adults. Additionally, we anticipate that the results of this scoping review will offer methodological clarity and guidance for exploring the development of coadaption features for technology in this context. The findings from the scoping review will be disseminated through a peer-reviewed scientific journal and conference presentations.

XSL•FO
RenderX

Limitations

One limitation is that the quality of the studies included will not be assessed. Moreover, we will only include articles that describe empirical evidence and have been published in English over the last 23 years. It is important to acknowledge this limitation as it may bias included studies to those conducted in western countries. Thus, readers of our review must interpret the findings of the review with caution, recognizing that the quality and generalizability of the included studies may vary. The terms coadaptation and smart technologies exhibit significant variation in their usage. During the development of our search strategy, we worked with an information specialist to conduct pilot tests using various terms to ensure comprehensive coverage. However, despite these efforts, there remains some uncertainty as to whether all relevant search terms will be included. As such, it is important to acknowledge that despite our best efforts, which include hand searching and expert consultation, there may still be some risk of missing articles in this rapidly evolving field.

Conclusions

This scoping review aims to present a comprehensive overview of the existing evidence concerning the interaction between smart technologies and older adults over time. The outcomes of this review will establish the basis for a research program investigating how older adults engage with and adapt to smart technologies across various contexts and throughout their lives. Recognizing the unique requirements of older adults, offering suitable assistance, and integrating approaches that prioritize user needs can substantially enhance the satisfaction and overall experience of older adults who aim to age in their preferred environment with the aid of smart technologies.

Acknowledgments

We would like to thank and acknowledge the contributions of Charmaine De Castro, Information Specialist at the Mount Sinai Hospital–Sinai Health System, for providing guidance on the search strategy development.

Abstract

Background: Aging exposes individuals to new health disorders and debilitating chronic diseases, yet most older adults, even in functional decline, do not want to leave their homes. Nevertheless, for many, institutionalization in a nursing home (NH) may become essential to ensure their continued safety and health. Depression is one of the most common psychiatric disorders among older adults, especially among those who are institutionalized. Depressed NH residents face a high risk of future functional decline and falls, decreasing their quality of life. The relationship between depression and falls is complex and bidirectional. Previous reviews have focused on home-dwelling older adults or explored the relationship between antidepressant drugs and falls. To the best of our knowledge, no integrative literature reviews have explored the relationship between depression and falls among NH residents.

Objective: Analyze studies on the relationship between depression and falls among NH residents.

Methods: We will conduct an integrative literature review of published articles in relevant scientific journals on the relationship between depression and depressive symptomatology and falls among NH residents. As usually defined, we will consider NH residents to be people aged 65 years and older who can no longer live safely and independently in their homes. We will also consider older adults on short-term stays in an NH for rehabilitation after hospital discharge. Retrieved articles will be screened for eligibility and analyzed following previously reported steps. The most pertinent bibliographical databases will be examined for qualitative, quantitative, and mixed methods studies, from inception until August 31, 2023, thus ensuring that all relevant literature is included. We will also hand-search the bibliographies of all the relevant articles found and search for unpublished studies in any language. If appropriate, we will consider conducting a meta-analysis of the studies retrieved.

Results: A first round of data collection was completed in March 2023. We retrieved a total of 2276 references. A supplementary literature search to ensure the most up-to-date evidence is ongoing. We anticipate that the review will be completed in late September 2023, and we expect to publish results at the end of December 2023.

Conclusions: This integrative review will increase knowledge and understanding of the complex relationship between depression and falls in NH environments. Its findings will be important for developing integrated, multidisciplinary models and care recommendations, adaptable to each NH resident's situation and health status, and for creating preventive interventions to help them maintain or recover optimal health stability.

depression; falls; nursing homes; nursing home residents; older adults; fall risk; intervention

Introduction

Overview

The world's population is aging fast. The World Health Organization predicts that about 2 billion people will be aged 65 years or older in 2030 [1-3]. For various biological, psychological, and societal reasons, older adults are at greater risk of developing psychopathologies such as depression and dementia, conditions which lead to further loss of autonomy and functional decline [4,5]. A recent study estimated a prevalence of depression of 7% among community-dwelling older adults [6]. A depressive episode can be defined as a mood disorder (a common mental and behavioral disorder) that persists for at least 2 weeks [7]. Depression can present at different levels of clinical severity—mild, moderate, or severe—and can occur on 1 unique occasion during a life course or be recurring or chronic [7]. Older adults enduring severe depression and other associated psychiatric diseases face a significant risk of planned or unplanned admission to a nursing home (NH) [8,9]. Several studies have reported that planned and unplanned institutionalization in an NH is often associated with debilitating medical comorbidities, a reduced ability to perform the activities of daily living, problems with mobility, and cognitive impairment [9]. NH residents, mostly older adults, are defined as people aged 65 years and older [10]. However, it is not easy to apply a strict definition because people age biologically at different rates, so, for example, someone aged 75 may be healthier than someone aged 65 [11]. NHs are facilities that provide 24-hour functional support for older adults who require assistance with the activities of daily living or the instrumental activities of daily living and have recognized health needs. They are staffed with health care professionals and provide long-term care and rehabilitation as part of hospital avoidance or to facilitate early hospital discharge; they do not function as hospital wards and are not hospital-based, and they may play a role in providing palliative and hospice care at the end of life [12]. We will also accept studies examining older adults staying in NHs for short-term rehabilitation after hospital discharge. However, most NH residents live there permanently because they have ongoing physical or mental conditions that require constant care and supervision [12].

The reported prevalence of depression among NH residents varies from 15%-48%, with variations caused by the diversity in methodological approaches and measurement instruments used [6,13-15]. Depressed NH residents often become less able to function, and the condition sometimes speeds them toward functional disability, with an increased risk of falls [16]. NHs implement person-centered care as best as they can, considering individuals' needs and striving to avoid functional and mental decline (including disease- and drug-related fall risks) to ensure the best possible level of overall physical, emotional, and mental well-being for their residents [17,18]. However, most care is aimed at residents' somatic complaints: even though psychiatric disorders are prevalent, particularly clinical depression, they frequently remain unidentified by health care staff [19,20]. Furthermore, concerning functional decline, it seems that falls are one of the most significant associated dangers faced by NH residents [21-25]. Multiple causes can contribute to heightening the risk of falls, including frailty, psychopathological disorders, and their pharmacological treatments—all of which are common among NH residents [26-28]. They can even include an NH resident's new, spacious surroundings, involving more distance to cover along corridors or less furniture to hold onto [29-31]. However, with any of these factors, a predicted higher or lower risk may be underestimated or overestimated, creating the false reassurance that something is being done about falls. Falls often have severe consequences for NH residents, and between half and three-quarters of them may take a fall in any given year. Recent research reported that 10%-20% of falls result in serious injury, and a significant fraction of NH residents die from fall-related injuries [32]. Numerous factors can contribute to falls [31,33]. (1) Many NH residents are prescribed antipsychotics, antidepressants, Z-drugs, benzodiazepines, and other drugs to abate neuropsychiatric symptomatology; however, these substances can cause confusion, unsteady gait, and loss of balance. (2) Inadequate or insufficient NH staffing, especially at night, can cause problems when residents need to get up but no one is immediately available to help them. (3) An absence of sufficient adaptive equipment for mobility-impaired NH residents. (4) Existing health conditions, such as orthostatic hypotension, Parkinson disease, Alzheimer disease, and other neuropsychiatric diseases, can result in an unsteady gait that leads to falls. (5) An absence of any comprehensive fall prevention plan for mobility-impaired NH residents at risk of falls.

Depression and falls have a significant bidirectional relationship [34]. Excessive fear of falling, which is frequently associated with depression, increases the risk of falls [35,36]. Both depression and fear of falling are associated with impaired gait and balance, an association that is mediated through cognitive, sensory, and motor pathways. Our integrative review will explore the relationship between depression and falls. The relationship between the variables will determine whether the right conclusions are reached. In our review, a relationship is defined as the existence of a correspondence between the 2 variables of depression and falls—it is a complex and bidirectional relationship. The relationship between depression and falls could be positive or negative associations, symmetrical, causal, linear, or nonlinear [37]. We will also consider these relationships according to their nature or pattern. A relationship suggests that as 1 variable changes, the other also tends to change. For example, 2 variables may have a quadratic relationship. Moreover, depression will be considered as an independent risk factor for falls. Previous studies of prospective cohorts have shown that depression increases the risk of future falls. A recent meta-analysis summarized the findings of 17 prospective studies and found an odds ratio for the association of depression with falls of 1.63 (95% CI 1.36-1.94) [37]. Retrospective studies have reported 4 determinants of falls: postural sway, history of falls, handgrip strength, and depressive

XSL•FO
RenderX

symptoms [38,39]. Symptoms of depression may have individual direct roles in promoting falls. Poor appetite and weight loss are commonly seen in geriatric depression, and nutritional deficiencies in vitamin D and folate may be related to falls [39]. The relationships between depression, cognitive performance, motor performance, and the risk of falls were illustrated by a recent study that found that the association between depression and slowed-choice stepping reaction time was mediated by 2 variables—quadriceps strength and executive function—that influenced choice stepping reaction time via simple reaction time and balance [40,41]. Depression and falls are also linked indirectly through several common risk factors. Functional decline, history of falls, and cognitive impairment has each been linked separately to both depression and falls. Poor physical health is also a notable risk factor for depression and falls. Vascular disease, in particular, and its related burden of white matter lesions, may produce concurrent changes in balance, gait, and mood [40]. The interaction between depression and falls may also be self-perpetuating. Depressive symptoms are particularly high among recurrent fallers, which may be related to the demoralizing effect of repeated falling [42]. Prospective cohort studies have reported that increased depressive symptoms were associated with increased falls [43]. Conversely, a lower rate of falls was associated with improved morale scores over the follow-up period. The depressive cognitive-affective symptoms seen in repeat fallers include a lower sense of self-efficacy and negative expectations of the future. Restricted activity and decreased social participation can be a complication of recurrent falls: the resulting social isolation is known to be a significant risk factor for depression among older adults [44].

Managing depression in fall-prone individuals is challenging since antidepressant medications can increase the risk of falls, selective serotonin reuptake inhibitors may increase the risk of fragility fractures, and data are lacking about the effect of fall rehabilitation programs on clinically significant depression [45]. Antidepressant medications are indicated to treat moderate to severe depression in fall-prone individuals, but this should include appropriate precautions, including a low starting dose and slow dose titration, the use of psychotropic monotherapy whenever possible, and monitoring for orthostatic hypotension [45-47]. Treating depressed NH residents at risk of falls is a major concern in those settings and deserves our full attention. There is a need to expand current knowledge about the potential relationship between falls and depression among NH residents.

Review Aims and Objectives

This review sought to analyze the literature examining the relationship between depression or depressive symptomatology and falls among NH residents.

Research Question

This integrative review will explore the following question: “What is the relationship between depression and falls among nursing home residents?”

Methods

Design

This integrative literature review aims to synthesize the literature reporting on the relationships between depression or depressive symptomatology and falls among NH residents receiving or not receiving treatment with antidepressant medication. The review will be conducted based on the guidelines contained in Coleen’s *Step-by-Step Guide to Conducting an Integrative Review* [48] in the following order: (1) formulation of a review question, (2) systematic literature search, (3) critical appraisal of the research retained, (4) literature analysis and synthesis, (5) discussion on new knowledge, and (6) preparing a dissemination plan for findings [49].

Types of Participants

The review will consider studies focusing on older adults with a mean or median age of 65 years or older living in a geriatric or psychiatric NH.

Eligibility Criteria

Textbox 1 presents the eligibility criteria for the types of information that publications retained in this integrative review should contain. These criteria were based on an exploratory literature review of sociodemographic features, long-term care facilities and rates of depression among NH residents. We also included NH residents’ contextual and empirical experiences. This review will consider NH’s skilled nursing facilities and long-term care facilities as synonyms, providing a wide range of health and personal care services.

A patient fall is defined as an unplanned descent to the floor, with or without injury [50]. The review will not consider publications reporting on the nonfatal falls of residents receiving antidepressant medication without a diagnosis of depression.

We will include mixed methods studies and use the Mixed Methods Appraisal Tool scale to assess their quality and bias [51], as reported on the Equator Network website.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for the population, phenomena of interest, type of publication, health care setting, and language.

Inclusion criteria

- Population: Older adults (65 years or older) living in nursing homes
- Depression criteria: Depression (diagnosed by a physician) and depressive symptomatology (reported by health care professionals using validated scales), whether treated or not treated with antidepressants
- Falls: Incidence, prevalence, or occurrence of falls; recurrent falls; and reported or assessed risk of falls
- Setting: Long-term geriatric or psychiatric nursing home o nursing home
- Article types: Original prospective research studies with a descriptive, correlational, or cohort design; retrospective cohort studies; and mixed-methods studies
- Language: No restrictions

Exclusion criteria

- Population: Adults younger than 65 years
- Depression criteria: Nursing home residents prescribed antidepressant medication but without recognized depression or depressive symptomatology
- Falls: Near falls (not reported in most publications)
- Setting: Intrahospital or private nursing home contexts (older adults' houses or apartments, assisted living apartments, and community care living)
- Article types: Meeting abstracts; conference abstracts; posters; guidelines, commentaries, editorials, opinion papers, and book reviews and case reports; literature reviews, whether narrative, rapid, scoping, or meta-syntheses, and systematic and meta-analyses

Types of Studies

This integrative review will include studies addressing depressive conditions or symptomatology and may include other types of neuropsychiatric symptomatology. Studies examining concepts surrounding falls and falling will also be associated with the literature search strategy to respond to the research question. Eligible studies will include prospective research studies with a descriptive, correlational or cohort design, retrospective cohort studies, and mixed methods studies.

Types of Sources

The integrative review's searches will consider original articles to identify the prevalence of falls among NH residents and their relationships with depression or depressive symptomatology. We will consider publications in any language but will focus on those identified in languages that the research team masters. In cases where the study language is not mastered, we will contact the authors and ask them to complete this study's data extraction and quality assessment forms. The articles retrieved have been screened, and the review was completed in August 2023.

Search Strategy

The search strategy is developed in collaboration with a medical librarian (JRA). The following bibliographic databases will be examined for qualitative, quantitative, and mixed methods studies to ensure that all the relevant literature is included: Ovid MEDLINE ALL, Embase, CINAHL with Full Text, APA PsycInfo Ovid, Web of Science Core Collection, ProQuest Dissertations & Theses A&I, and Cochrane Library. All searches will be conducted without language or date restrictions. Textbox 2 presents an example of the equation developed in Embase.

Textbox 2. Example of the Embase search strategy.

Data Management

Selection Process

All the titles and abstracts identified in the searches will be independently screened by 2 reviewers (AMQ and HV) to assess which studies met the inclusion criteria. Disagreements will be resolved through discussions, and in cases where no agreement could be found, a consensus was reached after discussions with the coauthors (AvG and MMM). In addition, the reviewers will independently assess the full-text articles to see if they met the literature review's inclusion criteria. Again, the coauthors discussed and resolved disagreements (HV, AvG, and MMM). The integrative review selection process flowchart will be drawn in accordance with the guidelines in the 2020 PRISMA

XSL•FO
RenderX

(Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [52] to present the number of articles identified at each step of the review selection process.

Data Extraction

Data extraction will use a specially designed and structured data extraction form. The following information will be collected from each study finally included in the review: (1) study authors, year of publication, study duration, and country location; (2) study characteristics, including setting, design, and sample size; (3) participants' characteristics, including sex and mean (SD) age; (4) types of results, such as the prevalence of depression or depressive symptoms, depression evaluation tools, the prevalence of antidepressant use, and the prevalence of falls; (5) statistical results; and (6) the studies' recommendations.

Assessment of the Risks of Bias in the Studies Included

The risks of bias in all the cross-sectional, retrospective, and prospective cohort studies; mixed methods studies; and pragmatic or randomized and nonrandomized controlled trials will be independently assessed by 2 reviewers (AMQ and HV). Disagreements will be resolved through discussion and consultation with coauthors (MMM and AvG). We will use the validated Robins-I tool for assessing the risk of bias in nonrandomized studies of interventions [53]: (1) preintervention and at intervention (bias due to confounding, bias in the selection of study participants, and bias in the classification of the intervention), and (2) postintervention (bias due to deviations from intended interventions, bias due to missing data, bias in the measurement of outcomes, and bias in the selection of the reported results) [53]. Bias in cohort and case-control studies will be assessed using the Newcastle-Ottawa Quality Assessment Form for Cohort Studies (NOSGEN) [54] and the Appraisal tool for Cross-Sectional Studies (AXIS) [55]. The NOSGEN tool covers two dimensions of bias and seven domains through which that bias might be introduced into nonrandomized studies of intervention: (1) preintervention and at intervention (bias due to confounding, bias in the intervention, bias due to deviations from intended interventions, bias due to missing data, bias in the measurement of outcomes, and bias in the selection of the reported results) [54]. The AXIS tool assesses study quality and risk of bias, but it does not provide a numerical scale for assessing that quality—a degree of subjective assessment is required [55]. How the tool is used thus has implications for interpreting the results as there will be differences in individuals' judgments. However, it has been argued that numerical scales for quality can be problematic as the outputs from assessment checklists are not linear and, as such, difficult to sum up or weigh, making them unpredictable for assessing study quality.

Our search strategy will include being very careful to select original research papers only, and it will try to avoid duplicates of published data reappearing in longitudinal studies. Additionally, our data extraction sheet will pay special attention to longitudinal cohort studies and any secondary analyses of published results.

Statistical Analyses

We will compute descriptive statistics of the review population's mean and median age, the distribution of men and women, and the number of falls recorded in the studies retained. Additional descriptive statistics will be computed to report differences between NH residents' profiles and types of NHs.

We will consider whether it is appropriate to combine the numerical results from all the studies retained—or at least 2 of them—in a meta-analysis to yield overall statistics (together with their CIs) summarizing the relationship between depression and falls based on risk ratios. For dichotomous outcomes, average intervention effects will be calculated as relative risks or odds ratio with 95% CIs using a random effects model [56]. A random effects model will also be used on continuous data to calculate weighted mean differences with 95% CIs. If required, we will calculate SDs from the SEs or 95% CIs presented in the articles. Heterogeneity will be quantified using the I^2 and chi-square tests. Funnel plots will be drawn, and Egger tests will be computed to explore the possibilities of publication bias [57]. Reasons for effect estimate heterogeneity will also be sought via meta-analyses [58]. To explore the possible determinants of heterogeneity, we will conduct subgroup analyses according to selected study characteristics (eg, participants' age and sex). Furthermore, sensitivity analyses will be calculated by (1) excluding relatively small studies (with fewer than 20 participants) and (2) restricting analyses to the best-quality studies. These data will also be analyzed using SPSS (version 29.0; IBM Corp).

Results

A first round of data collection was completed in March 2023. Our search in Ovid MEDLINE ALL (n=385), Embase (n=810), Cinahl with full text (n=303), APA PsycINFO Ovid (n=178), Cochrane Library (n=123), Web of Science (n=455), and ProQuest Dissertations and Theses A&I (n=22) returned 2276 references. A supplementary literature search to ensure the most up-to-date evidence is ongoing. Studies will be screened independently by 2 research team members. The inclusion and exclusion criteria will be rigorously respected throughout the study selection. Disagreements in article selection will be resolved through discussion. We anticipate that the review will be completed in late September 2023, and we expect to publish results at the end of December 2023.

Discussion

Principal Findings

This literature review will investigate original work on the sometimes complex and bidirectional relationship between depression or depressive symptomatology and falls or fall risks among NH residents. Depression will be considered an independent risk factor for falls, one that may lead to increased fall risks through behavioral, neuromuscular, or psychopathological pathways, as demonstrated in prospective cohort studies [59-61]. We will retrieve studies reporting on depression and falls identified as risks among NH residents, mostly presenting poor physical and mental health and producing concurrent changes in balance, gait, and mood. The review will explore studies indicating any evidence of the bidirectional relationship between depression and falls due to

XSL•FO
RenderX

deficits in executive function, poor nutritional status, and cognitive disorders. Factors related to falls will be highlighted if they are documented in the publications retrieved. Although the risk factors identified do not always contribute directly to falls, our review will assess whether these factors are useful for detecting fall risks among NH residents.

Limitations of the Literature Review

Although antidepressant medication can mitigate depression or depressive symptoms, which should lower fall risks, it can also increase fall risks independently of depression. We will not consider the contributing factor of antidepressant medication as an independent risk factor for falls within the relationship between falls and depression.

Conclusions

The researchers anticipate that this integrative literature review will increase overall knowledge and understanding of the complexity of the phenomena of depression and falls in NH environments. Indeed, most preceding reviews have focused on home-dwelling older adults or research into antidepressant drugs and fall. The proposed study's findings will be important for developing integrated, multidisciplinary models and recommendations of care that can be adapted to each NH resident's situation and health status, and for creating preventive interventions to enable them to maintain or recover optimal health stability.

Abstract

Background: Race-based health information is necessary to address disproportionate barriers racial communities face and to achieve optimal health outcomes. In Canada, Black people are disproportionately affected by HIV. There is an emerging body of literature on this topic, but a concise summary is lacking. There is a need to collectively and critically analyze research on HIV in the Black population in Canada to identify knowledge gaps and address this disproportionate burden.

Objective: The aim of this scoping review is to summarize the evidence on HIV and Black people in Canada. The main outcomes of interest are HIV prevalence, access to care, HIV prevention and treatment, the HIV care cascade, and related HIV outcomes. Through this scoping review, we aim to provide a comprehensive overview of the existing literature and highlight topics that need more investigation in future research.

Methods: We will conduct a scoping review of electronic databases using a systematic search strategy for qualitative, quantitative, or mixed methods studies reporting on HIV and Black people in Canada. We will conduct our searches in MEDLINE, Embase, CINAHL, Web of Science, EBSCO, and Google Scholar for literature published between 1985 and 2023. Gray literature, including government reports, dissertations, and other reports, will be included. Search results will be screened, and the full text of relevant literature will be retrieved. The extraction of data will be conducted independently by 2 reviewers. Consensus meetings will be held to resolve conflicts. Our results will be reported according to the PRISMA-ScR (Preferred Reporting Items for the Systematic Reviews and Meta-Analyses Extension for Scoping Reviews).

Results: The initial title and abstract review identified 447 articles. These articles will be critically appraised, and relevant information will be extracted. Information from these articles will be compared using charts and tables. Screening will start in November 2023, and we anticipate publishing the scoping review in June 2024.

Conclusions: The findings from this scoping review will help inform policy, practice, and research on HIV and Black people in Canada.

Introduction

In 2021, it was reported that the HIV epidemic had led to over 80 million people being infected and over 40 million deaths globally [1]. The World Health Organization reported in 2021 that approximately 38.4 million people worldwide are living with HIV [1]. In Canada, 4.5 people per 100,000 were diagnosed with HIV in 2021 [2]. For over 4 decades, the Black community has been disproportionately impacted by HIV [3]. Although the Black community makes up less than 5% of Canada's total population, 25% of new HIV infections are Black people [3-5]. Additionally, in 2023, Statistics Canada reported higher HIV-related mortality rates among Black Canadians when compared with other ethnicities [6].

In 2014, the Joint United Nations Programme on HIV/AIDS organization, a global initiative aimed at eradicating HIV, developed the 95-95-95 approach (where 95% of people living with HIV are diagnosed, 95% of those diagnosed are on treatment, and 95% of those on treatment have a suppressed viral load) [7]. The Government of Canada aims to end the transmission of HIV by 2030 by adopting the 95-95-95 approach [8,9]. Canada's action plan includes tracking prevalence, increasing access to HIV care and treatments, and focusing on prevention and the care cascade [3,9]. It is unclear how this goal will be fulfilled in the Black community, although Canada's Federal Initiative to Address HIV/AIDS aims to address inequities. In 2016, the results of a Canada-wide census illustrated lower educational attainment, housing access, income, and employment in the Black population when compared with the White population [10]. A study by Husbands et al [11] found that Black Canadian participants were less likely to be tested for HIV if they had racist experiences. Systematic disadvantages, lower income, poorer living conditions, higher rates of unemployment, stigma, precarious work, and many other socioeconomic factors plague the Black community and impact the effectiveness of HIV control and care [3,5,12]. These factors also affect Black people's ability to achieve and maintain viral suppression, which is necessary to end transmission [13].

In addition to behavioral modifications to prevent HIV infection, preventive treatment options for persons at high risk of acquiring HIV include pre-exposure prophylaxis, a combination of antiretroviral drugs [3]. On the other hand, people living with HIV can achieve viral suppression through antiretroviral therapy, therefore decreasing the risk of transmission [3]. Although these options are available, there are still many barriers to accessing them for people in the Black community [8]. A study conducted by Etowa et al [14] identified multilevel barriers, including those at the individual and health system levels that require community-level, health policy, and intersectional interventions. Barriers also remain at other stages of the cascade, such as diagnosis, adherence to antiretroviral therapy, and sustaining care over time [8]. Black French speakers living in predominantly English-speaking provinces also face additional language and communication barriers in HIV diagnosis and treatment [15]. Black people in Canada living with HIV may also be overlooked in surveillance data due to a lack of ethnicity- and race-based data [5]. Therefore, it is beneficial to review the available health literature pertaining to the people living with HIV in the Black community to capture the overall progress toward achieving the 95-95-95 and equitable care.

Some researchers are concerned that once the government of Canada meets the 95-95-95 target, investments in HIV care and research may wane, thus compromising outcomes for the Black community and other subgroups of people who have not met these targets [3]. Identifying the gaps in Black health literature related to HIV is necessary as it will help us better understand the specific vulnerabilities to HIV infection faced by Black people and identify how Black people living with HIV can be better supported. Additionally, having this knowledge can help in the development of a more inclusive HIV response plan and provide the necessary information to fulfill Canada's Federal Initiative [16].

Although several studies have investigated HIV in Black people, this evidence has not been synthesized in a systematic way, and therefore the state of the evidence is unknown and knowledge gaps have not been thoroughly mapped. This scoping review will highlight areas of HIV research that require further evaluation and identify gaps in the current research regarding HIV and Black people in Canada. A preliminary search was conducted using the Cochrane Database of Systematic Reviews and MEDLINE; no scoping or systematic reviews were found on this topic. The purpose of this scoping review is to inform health policy makers, HIV organizations, and researchers on the state of the evidence on the disproportionate burden of HIV on the Black community in Canada and its impact on their lives.

Methods

Overview

This scoping review will use the approach of Peterson et al [17] to inform current HIV research, policies, and education. In contrast to a systematic review, which aims to answer a research question, this scoping review will appraise a wide range of information to illustrate how HIV impacts the Black community in Canada.

This scoping review will be conducted and reported according to PRISMA-ScR (Preferred Reporting Items for the Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [18]. The data will be summarized in tables and described narratively. Where possible, we will use means (SD) or counts (percent) to summarize the data from the included studies. Key findings from the studies will be summarized narratively, and the data will be interpreted to identify knowledge gaps, challenges, and opportunities for evidence generation on HIV in the Black community in Canada.

Collaboration

The public and patients were not involved in this review.

Eligibility Criteria for Articles

Types of Studies

Qualitative, quantitative, mixed methods, experimental, and observational study designs will be considered. Additionally, systematic reviews and gray literature will be considered. To fulfill the eligibility criteria, a study must include data on HIV

XSL•FO
RenderX

and Black people in Canada and address an outcome of interest. Literature in English and French will be included, as our reviewers are not fluent in other languages (Textbox 1).

Textbox 1. Eligibility criteria.

Inclusion criteria

- Qualitative, quantitative, mixed methods, experimental, observational studies, systematic reviews, and government reports, dissertations, and gray literature
- Articles in English and French
- Prevalence, access to care, prevention, treatment, the care cascade (initiation of treatment, adherence to medication, and retention in care), and other HIV-related health outcomes

Exclusion criteria

- Other articles and websites
- Articles in other languages
- Other topics, whether related to Black people in Canada or not

Outcomes

The outcomes of interest are prevalence, access to care, prevention, treatment, the care cascade (initiation of treatment, adherence to medication, and retention in care), and other HIV-related health outcomes.

Search Strategy

We will conduct a comprehensive and exhaustive search of studies on HIV and Black people in Canada. The search strategy is shown in Textbox 2.

Electronic Search

We will search MEDLINE, Embase, CINAHL, Web of Science, and Google Scholar from 1985 (the date HIV surveillance began in Canada) to 2023 [19]. Key terms will be searched in combination with each other. Some examples include HIV, Black, African, Caribbean, and Canada.

Reference Lists

The list of references of the included studies will be examined for relevant articles.

Gray Literature

We will search various government reports, dissertations, and other reports that are significant to this scoping review. Relevant organizations and authors will be contacted.

Screening

Citations collected from the search will be collated in EndNote [20]. After updating the references and removing the duplicates, we will use the DistillerSR platform (DistillerSR Inc), literature review software, to process the articles [21]. We will first screen titles and abstracts. Only the articles that meet our eligibility criteria will be retained. Articles in languages other than English and French will be excluded, as our reviewers are fluent in those languages. Potentially relevant articles will be downloaded as full text for further screening.

A pilot of the eligibility criteria search strategy will be conducted by 2 reviewers. A sample data collection of 50 abstracts will be done to ensure consistency in the search strategy and approach. Interrater reliability will be measured using the Kappa statistic [22]. The screening will progress when there is at least 80% consensus. The process of screening will be as follows: examining titles and abstracts, analyzing full text for relevance, and then completing data extraction and quality review by 2 reviewers simultaneously.

Data Extraction

We will extract data from the full text of included articles, including bibliometric information (author, year, and language), study design, province, source of funding, main objectives, participants, sample size, proportion of females, outcome, community involvement, outcomes reported, and key findings. We will pilot our forms on 5% of the data to ensure that they are clear and can be used consistently. All data processing (title and abstract screening, full-text screening, and data extraction) will be conducted by 2 independent reviewers. Disagreement will be resolved by consensus, and if consensus cannot be reached, a third senior reviewer will adjudicate. Agreement will be measured using the Kappa statistic [22]. Data referring to HIV prevalence in the Black community and related statistics will also be extracted. The data extraction framework is shown in Table 1.

XSL•FO
RenderX

Table 1. Data extraction framework.

Main category and subcategory	Description
Authors	The institution where authors are based and country of primary affiliation
Lead author	The institution where author is based and country of primary affiliation
Funders	Funder country of origin
Year of publication	The year the research was published
Aims or objectives of study	Stated aim of the study
Methodology	
Study design: subcategory of quantitative, qualitative, or mixed methods	Study design of research within stated category (eg, cross-sectional, ethnography, etc)
Population	Eligibility criteria to participate in the study
Data collection method	Methods of data collection
Data collection and evaluation tools	Types of tools used if applicable and if developed or adapted specifically for this study
Outcome measures	Primary and secondary outcomes (where applicable), or selected measures of success (eg, how were objectives of the study measured)
Community involvement	Was the community involved in the development of methods or data collection tools (eg, key stakeholder involvement in design), co-designing activities
Data analysis	The method of data analysis
Results	
Reported outcomes	Key HIV outcomes or quantitative or qualitative results related to primary stated outcomes
Key findings	Summarize any key findings that report on HIV and Black people in Canada

Ethical Considerations

This study does not require human participants. Only secondary data from publicly available sources will be used, and thus ethics approval is not required. The findings will be disseminated through a peer-reviewed manuscript, conferences, abstracts, and an MSc thesis.

Results

We have identified 447 articles as of May 2023. A critical appraisal of the articles collected will be conducted for the extraction of relevant information. Tables and charts will be used to illustrate similarities and differences in data from various articles. Screening will start in November 2023, and we anticipate publishing the scoping review in June 2024.

Discussion

Overview

The current data and health information related to HIV in the Black population in Canada have not been synthesized systematically. There is a need to identify knowledge gaps in order for future research to fill those gaps. This is significant as it can help us understand how and why the Black population in Canada continues to have disproportionately higher HIV infection rates, HIV mortality, and limited access to HIV treatments and care. The lack of HIV health policies and approaches in Canada that are focused toward disproportionately burdened communities, such as the Black community, is concerning. The results of this scoping review will have implications for the development of health policy and how HIV organizations can better support Black people in Canada. As this scoping review is conducted, data will be critically analyzed to ensure that interpretations, comparisons, and implications are reported and concluded accurately.

Limitations

The Canada-focused approach in this study is the first limitation of this review, as the findings cannot be accurately generalized to global circumstances. However, there is potential for theoretical generalizations to Black communities in countries facing similar dilemmas. A second limitation of this review is that our eligibility criteria exclude articles that are not in English or French. There is a possibility that articles with important information will be left out of our review.

Acknowledgments

This scoping review is being contributed towards a thesis paper for a Master of Health Research Methodology at McMaster University (TG). This review will be supervised by Dr Lawrence Mbuagbaw, an Associate Professor and Research Methods Scientist in Clinical Epidemiology and Biostatistics at McMaster University.

Abstract

Background: There has been a significant increase in the use of e-learning for global and public health education recently, especially following the COVID-19 pandemic. e-Learning holds the potential to offer equal opportunities, overcoming barriers like physical limitations and training costs. However, its effectiveness remains debated, with institutions unprepared for the sudden shift during the pandemic. To effectively evaluate the outcomes of e-learning, a standardized and rigorous approach is necessary. However, the existing literature on this subject often lacks standardized assessment tools and theoretical foundations, leading to ambiguity in the evaluation process. Consequently, it becomes imperative to identify a clear theoretical foundation and practical approach for evaluating global and public health e-learning outcomes.

Objective: This protocol for a scoping review aims to map the state of e-learning evaluation in global and public health education to determine the existing theoretical evaluation frameworks, methods, tools, and domains and the gaps in research and practice.

Methods: The scoping review will be conducted following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. The initial search was performed in PubMed, Education Resource Information Center, Web of Science, and Scopus to identify peer-reviewed articles that report on the use of evaluation and assessment for e-learning training. The search strings combined the concepts of e-learning, public health, and health science education, along with evaluation and frameworks. After the initial search, a screening process will be carried out to determine the relevance of the identified studies to the research question. Data related to the characteristics of the included studies, the characteristics of the e-learning technology used in the studies, and the study outcomes will be extracted from the eligible articles. The extracted data will then undergo a structured, descriptive, quantitative, and qualitative content analysis to synthesize the information from the selected studies.

Results: Initial database searches yielded a total of 980 results. Duplicates have been removed, and title and abstract screening of the 805 remaining extracted articles are underway. Quantitative and qualitative findings from the reviewed articles will be presented to answer the study objective.

Conclusions: This scoping review will provide global and public health educators with a comprehensive overview of the current state of e-learning evaluation. By identifying existing e-learning frameworks and tools, the findings will offer valuable guidance for further advancements in global and public health e-learning evaluation. The study will also enable the creation of a comprehensive, evidence-based e-learning evaluation framework and tools, which will improve the quality and accountability of global health and public health education. Ultimately, this will contribute to better health outcomes.

Introduction

Even before COVID-19, health systems around the globe were confronted with multiple challenges that necessitated strengthening health systems based on the primary health care approach and maintaining a good balance between public health and clinical care. The shortage in the health workforce, including public health professionals, is among the challenges that hinder the achievement of global health goals [1-3]. Still, the medical education literature addressing public health is scarce [4].

e-Learning (also known as digital education or technology-enhanced learning, among other synonymous terms) is a promising educational strategy to address the shortage of skilled health professionals through strengthening education [2]. The electronic-based approach to learning and education uses different forms of electronic devices, applications, or processes. The internet is the commonly used mode to deliver e-learning content, though non–internet-based delivery, such as via CD-ROM, audiotape and videotape, satellite broadcasts, stand-alone computers, and interactive televisions, are also being used [5,6].

In higher education, including medical education, the use of e-learning began in the 1990s and has been documented in the scientific literature since 2000 [7,8]. Structuring learning outcomes around clinical or public health competencies is a common approach to classifying and reporting e-learning interventions [2]. However, the usefulness and effectiveness of e-learning in medical education have long been debated [9-11]. Nevertheless, a well-designed and implemented e-learning program has the potential to provide equal opportunities for medical education by maintaining flexibility, and at the same time, overcoming multiple barriers to building health workforce capacity, such as physical barriers and training delivery costs [2,3,12].

More recently, the COVID-19 pandemic pushed education toward a distance structure and stimulated the exponential growth of e-learning education [8,13]. Unfortunately, many institutions around the globe were not prepared for the digital transformation [14,15]. Moreover, the effectiveness of e-learning depends on many factors that go beyond the e-learning intervention [16,17].

Hence, a pressing need to evaluate the different dimensions of e-learning interventions has emerged. To do so, a standard and rigorous approach to evaluating e-learning is essential. Existing evidence suggests that e-learning is associated with high satisfaction and improvement in knowledge and skills [18,19], and the effectiveness of e-learning for health professionals is comparable to that of traditional educational interventions. However, the existing literature in medical education is usually limited to measuring e-learning outcomes and comparing e-learning with traditional methodologies. Further research is needed, particularly focusing on its impact on trainees' behaviors and patient outcomes [18,20].

Additionally, the validity of such evaluations is threatened by the dearth of literature that reports the use of standardized assessment tools [21,22] and theoretical foundations, which are essential to explain what and how learning can be facilitated [23-25]. Moreover, the methodological diversity among studies hampers the clear interpretation of the findings [26]. To establish a more definitive understanding of the benefits and limitations of e-learning in the health care sector, additional investigation and standardization of methods are essential.

The aim of the systematic scoping review will be to map the theoretical frameworks and models that explain the underlying concepts, domains, and constructs, as well as the assessment tools required, of rigorous e-learning evaluation. This will enable evidence-based practice as a means of ensuring accountability and validity in education.

It is worth noting that evaluation and assessment are often used interchangeably in the literature. In this paper, however, we will refer to evaluation as the process of obtaining information about any aspect of an educational program for subsequent judgment and decision-making. On the other hand, assessment will refer to the instruments that measure the learner's achievements, which comprise an essential component of the evaluation. To understand what is known about how public health e-learning is being evaluated, the scoping review will aim to identify and synthesize the available evidence on the evaluation frameworks and tools. The study will identify, describe, and discuss the theoretical frameworks and tools that are being used to evaluate public health e-learning. The PICO (Population, Intervention, Comparison, and Outcome) essential elements framework guided the development of the research questions (Table 1). Specifically, in the context of public health education, this study aims to answer the following questions: (1) How is e-learning evaluation conceptualized? (2) What are the existing theoretical models or frameworks to evaluate e-learning and what do they aim to evaluate? (3) How is e-learning evaluation investigated or measured? (4) Are there validated tools for evaluating e-learning? (5) What outcomes do these tools evaluate?

XSL•FO
RenderX

Table 1. PICO (Population, Intervention, Comparison, and Outcome) framework for the systematic scoping review.

Element	Description
Population	Health professionals or students
Interest	e-Learning evaluation and assessment frameworks and tools
Context	Public health and public health-related education
Outcome	Reporting the evaluation framework or tools

Methods

The scoping literature review involved a systematic search following the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses Extension for Scoping Reviews) checklist [27]. Unlike systematic reviews, which address a relatively narrow range of quality-assessed studies, a systematic scoping review addresses broad questions, mapping the key concepts underpinning a research area and the main sources and types of evidence with a range of methodologies, and does not undertake quality assessment.

Inclusion and Exclusion Criteria

The articles selected in this review aim to describe or use a framework or tool to evaluate e-learning used for public health education. The e-learning target group could be undergraduate, graduate, or continuing education programs. All types of study designs of peer-reviewed, original studies that were published after 2000 in English will be included. See Textbox 1 for further details about inclusion and exclusion criteria.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Population
  - Includes health professionals or students at any level (undergraduate, graduate, or continuing education programs).
- Interest
  - Articles addressing public health or public health–related fields (eg, global health, international health, One Health, planetary health, humanitarian health, disaster medicine or disaster management).
- Outcome
  - Articles that describe evaluation frameworks or tools for e-learning.
- Article type
  - Peer-reviewed original literature.
  - Empirical and theoretical articles, including those with experimental and quasi-experimental study designs, descriptive and analytical observational study designs, and qualitative studies.
  - Studies may or may not include comparison with conventional or other e-learning.
- Language, date, and availability
  - Articles published after 2000.
  - Articles written in English.
  - Articles for which the full text is available.

Exclusion criteria

- Population
  - The evaluated population did not include health professionals or students.
- Interest
  - Articles that did not address public health or public health–related education.
  - Articles focused on clinical skill evaluation.
  - Articles focused on medical education topics related to individualistic clinical care, diagnostics, or basic health science.
- Outcome
  - Articles that did not describe or use evaluation frameworks or tools.
- Article type
  - Non–peer-reviewed grey literature.
  - Secondary literature, such as reviews and meta-analyses.
  - Opinion articles, theses, dissertations, book chapters, protocols, and editorials.
- Language, date, and availability
  - Articles published before 2000.
  - Non-English articles.
  - Articles for which the full text is not available.

Information Sources and Search Strategy

On January 31, 2022, a preliminary limited search of the PubMed database was conducted to identify relevant articles and keywords. On July 31, 2023, an updated search was conducted in the PubMed, Web of Science, Education Resource Information Center, and Scopus databases for studies published from January 1, 2000, onward. The search was limited to the English language. Search terms included the concepts of e-learning, public health, and health science education and evaluation, frameworks, and tools using “text word searching,” which involves searching for a word or phrase appearing

XSL•FO
RenderX

anywhere in the document using Boolean operators and truncations (Table S1 in Multimedia Appendix 1).

Study Selection and Screening

The identified records will be imported into Rayyan [28] to streamline the screening process. Duplicates will be removed before titles and abstracts are reviewed independently by 2 authors for the inclusion criteria. We will use the standard PRISMA flow diagram to provide the study selection process. The articles included in the review must report the use of evaluation or assessment for e-learning training within the specified inclusion criteria for the population, topics, and level of education. After initial review, the reviewers will go through the complete text and apply the inclusion criteria.

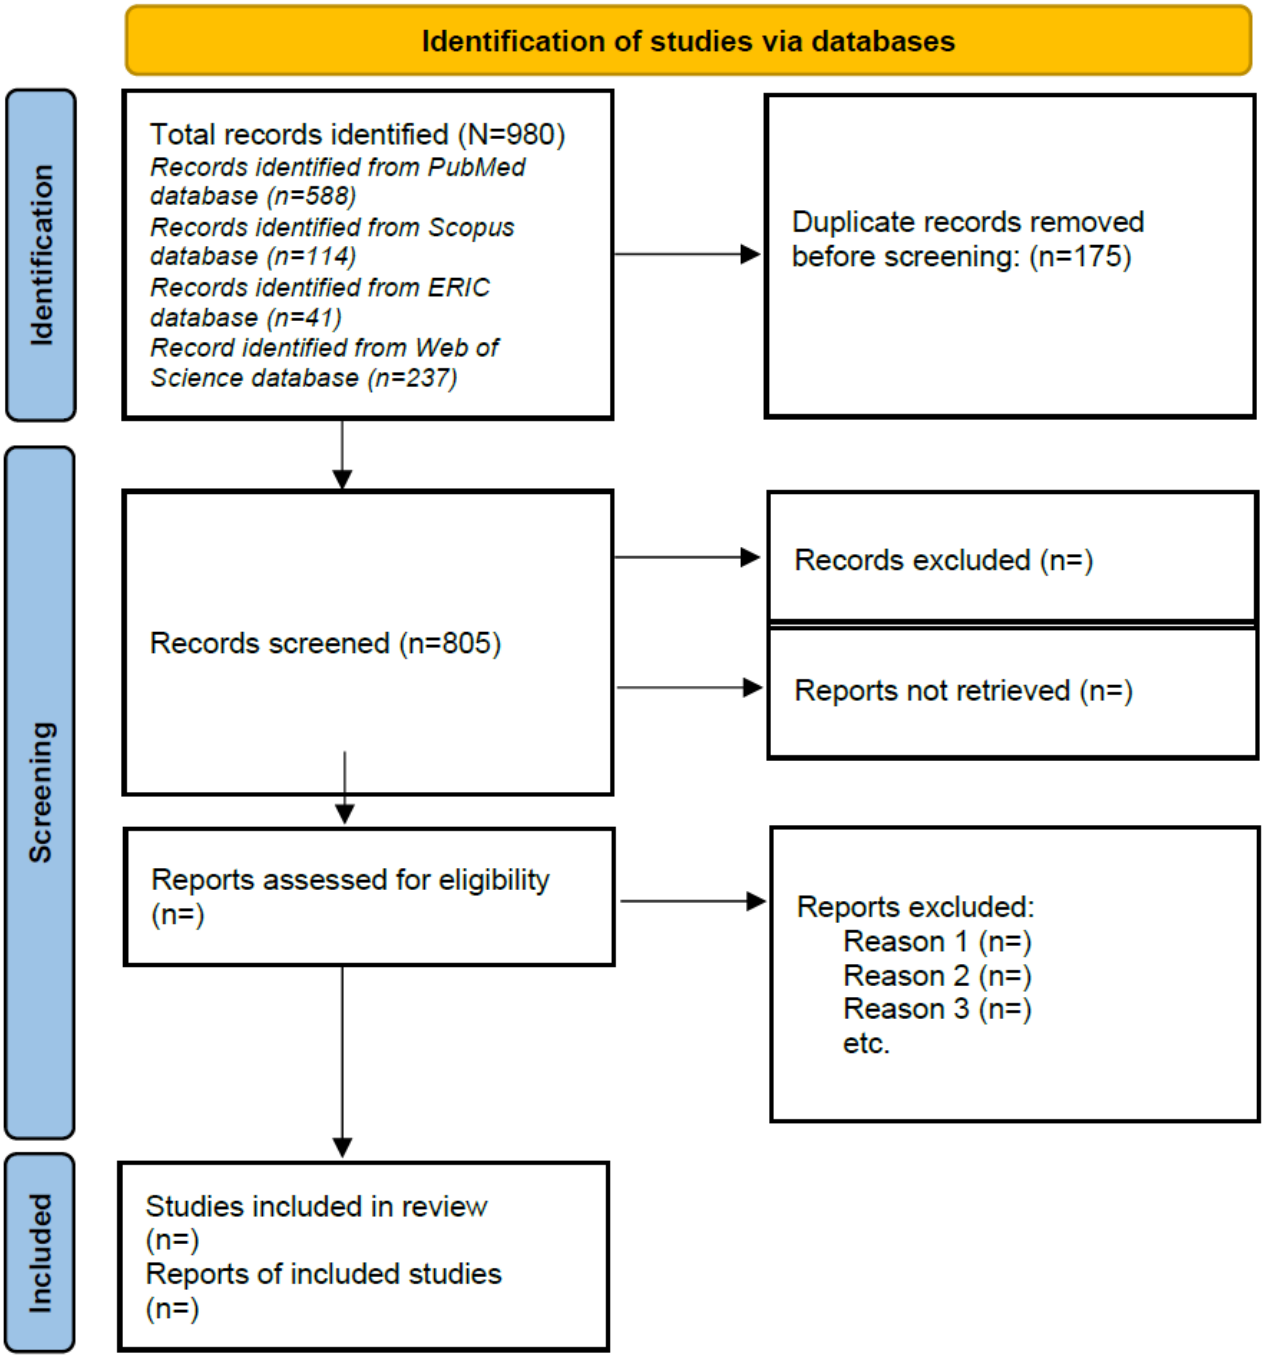
Data Extraction and Data Items

Data from eligible studies will be extracted by 2 reviewers. The following data will be extracted and charted from each paper: (1) descriptive data of the included study profile, (2) study characteristics data, (3) e-learning and technology characteristics, and (4) the study outcome, including evaluation framework, evaluation methods, and evaluation tools (Table S2 in Multimedia Appendix 1). The data extraction tool will be tested and may be adjusted and amended during the process, and any changes will be documented in the final report. The summary table will improve transparency and reproducibility by showing what types of data were extracted from which studies.

Analysis

The data will be synthesized using structured, descriptive, quantitative, and qualitative content analysis of the main themes and an overview will be provided for the current scope of the literature. In addition, the research team will analyze findings regarding the studies' overall purpose and evaluate the implications for future research, practice, and policy.

Ethical Considerations



No ethical board approval is necessary to conduct this scoping review.

Results

Targeted searches were conducted in January 2022 to inform the development of a comprehensive search strategy for electronic database searches. This strategy was iteratively developed for and tested in PubMed. Iterative refinements to the scoping review protocol and formalization of the methods were completed by July 2022 and updated on July 31, 2023. The final search was conducted in the PubMed, Scopus, Education Resource Information Center, and Web of Science databases. The initial database searches revealed 980 studies. The database searches were completed in August 2022, duplicates were removed, and title and abstract screening of 805 extracted articles is currently underway. Study selection, data extraction and analysis, and drafting of the manuscript to report the results of the scoping review will be conducted throughout 2023. Any changes to the methods reported here will be documented and reported. The PRISMA flowchart will be used to describe the research selection procedure (Figure 1), and the scoping review's findings relevant to the study objectives will be presented.

Discussion

Expected Findings

Comprehensive multifaceted evaluation of e-learning in the context of public health and global health training is essential to make an evidence-based decision about the future investment in health workforce capacity building. This scoping review is expected to identify existing evaluation frameworks and tools for evaluating public health e-learning.

To the best of our knowledge, this will be the first systematic scoping review to address public and global health as a growing field of medical education. While previously published reviews did not focus on medical education [29] or were limited in scope [29-31], this study will identify the theoretical framework, methods, and domains commonly used in the evaluation of public and global health e-learning. Thus, the study will underline the existing gaps in the scope and practice of e-learning evaluation.

A previous systematic review for e-learning evaluation identified 8 themes [29]. Most of these studies focused on only one or two aspects. Moreover, the representation of evaluation themes varied among different disciplines, technologies, and educational levels. Some of these themes were applied more than others, while others were underrepresented [29]. Still, previous reviews lacked or underrepresented information about public health and global health education [1]. Moreover, the proliferation of e-learning and related literature in the past few years necessitates reviewing the current status of the literature in the field. In

XSL•FO
RenderX

addition, previous systematic reviews revealed that educational theories and theoretical learning frameworks rarely guided e-learning evaluation, raising concerns about the quality and validity of training evaluation.

Strengths and Limitations

The review will adhere to a robust methodology following the recommended standards for conducting scoping reviews [27,32] that allows transparency and replicability.

The limitations of scoping reviews, which also apply to this review, will be noted. The literature search was applied to 4 relevant search engines. Due to limited time and resources, the search was restricted to English and peer-reviewed articles. Hence, some articles may be missed from the review. Since the scoping review aims to understand the status of evaluating e-learning rather than measuring effectiveness, we will not use a quality appraisal or bias assessment for the included studies.

Future Directions

The lack of comprehensive and robust guidance on e-learning evaluation is an obstacle for educators to ensure the quality and accountability of public health e-learning [3,33]. Hence, the results of this review will allow public health and medical educators to understand how public health e-learning is being evaluated from theoretical and practical points of view. The discussion will reflect on the current status of e-learning evaluation in public health education and compare the findings to the existing body of knowledge. Moreover, the results can guide the development of an evidence-based, field-specific, multifaceted, integrated model for e-learning evaluation and recommend the most appropriate evaluation methods, and tools, as well as domains to be evaluated.

Conclusion

In conclusion, this review will enhance our knowledge about the current practice of e-learning evaluation in global and public health education. The findings will inform the development of a comprehensive field-specific evaluation framework and tools, with the ultimate aim of improving the quality and accountability of global and public health e-learning.

Data Availability

All data generated or analyzed during this study are included in or alongside this article.

Conflicts of Interest

None declared.

Abstract

Background: Many children today are growing up in environments that predispose them to develop noncommunicable diseases. While no single preventive solution exists, evidence supports interventions in childcare settings for establishing good nutrition and physical activity behaviors as a "critical window" that could reduce the risk of developing noncommunicable diseases later in life. Emerging eHealth tools have shown potential in promoting best practices for nutrition and physical activity environments in early childhood education and care (ECEC) settings.

Objective: The primary objective of this review is to map the breadth of available evidence on eHealth tools currently available to assess and support best practices for nutrition, physical activity, or both in ECEC settings and to highlight potential research directions.

Methods: This scoping review will be conducted in accordance with the *Joanna Briggs Institute Manual for Scoping Reviews* with adherence to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist guidelines. Eligibility is based on the Population, Concept, and Context criteria as follows: (1) early childhood educators (population); (2) eHealth (digital) technology, such as websites, smartphone apps, email, and social media (concept); and (3) measurement and intervention tools to support best practices for nutrition, physical activity, or both in ECEC settings (context). The information sources for this review are the bibliographic databases PubMed, Scopus, CINAHL Plus, ERIC, and Embase in English and French with no date restrictions. Following this, a scan of gray literature will be undertaken. The electronic search strategy was developed in collaboration with two librarians. Two independent reviewers will screen the titles and abstracts of all relevant publications against inclusion criteria, followed by a full-text review using a data extraction tool developed by the reviewers. A synthesis of included papers will describe the publication, assessment, and intervention tool details. A summary of the findings will describe the types of eHealth assessment tools available, psychometric properties, eHealth intervention components, and theoretical frameworks used for development.

Results: Preliminary searches of bibliographic databases to test and calibrate the search were carried out in May 2023. Study selection based on titles and abstracts was started in August 2023. The developed search strategy will guide our search for gray literature. The findings will be presented in visualized data map format, waffle chart, or tabular format accompanied by a narrative discussion. The scoping review is planned for completion in 2024.

Conclusions: A structured review of the literature will provide a summary of the range and type of eHealth tools available for ECEC programs to assess and improve nutrition environments, physical activity environments, or both in order to identify gaps in the current evidence base and provide insights to guide future intervention research.

Introduction

Background and Rationale

Noncommunicable diseases (NCDs) are on the rise and represent the leading cause of disability and death worldwide [1]. In Canada, approximately 60% of deaths are due to chronic illnesses [2]. The latest statistics show that 1 in 3 Canadian adults live with at least one chronic disease, placing a significant physical, emotional, and financial burden on patients in addition to significant societal costs [3,4]. NCDs are largely preventable and share at least one predisposing risk factor related to unhealthy lifestyles, including physical inactivity and poor nutrition [5]. Thus, one avenue of prevention or treatment could be achieved through lifestyle modification of approaches such as good nutrition and physical activity.

Many children are growing up in environments that may predispose them to developing NCDs later in life. Research suggests that many preschool-aged children consume higher energy diets and do not meet the recommended intake for vegetables and fruits and have low levels of physical activity [6-10]. These findings are troubling, as lifestyle behaviors that contribute to the development of chronic diseases, such as eating habits and physical activity habits, are formed in the early years and often track into adulthood [11-13]. While the significance of early child development on adult health and lifelong outcomes is well acknowledged [14], health-promoting behavior interventions focused on healthy eating and physical activity in early childhood settings are an important area for critical inquiry to clarify optimal preventative strategies for support [15].

Early childhood education and care (ECEC) programs have been recognized as ideal settings to promote healthy behaviors. This is because an increasing number of children spend time in care during these formative years, and this represents a significant component of a young child's weekly waking hours [16-18]. Evidence from a review on children's physical activity correlates illustrates that on average physical activity levels are significantly associated with the ECEC setting they attend [19]. The influence on the development of eating behaviors and dietary intake in young children is also strongly influenced by educators and the ECEC setting [20-22]. As a result, ECEC centers are in a unique position to encourage and facilitate healthy behaviors in young children and represent a rich opportunity for interventions aiming at fostering healthier habits in children [23]. Moreover, recent studies suggest that professional development for childcare providers on nutrition and physical activity best practices can positively influence health-related practices and outcomes in children [24].

The proliferation of the internet along with the rapid growth and availability of digital technologies has provided a new platform for health interventions. eHealth refers to the use of information technology, including the internet, digital gaming, virtual reality, and robotics, in the promotion, prevention, treatment, and maintenance of health [25]. eHealth tools include digital technologies such as the web, smartphone apps, SMS text messaging, and social media modalities that may be used for measurement or intervention within a health improvement paradigm [26]. Among studies aiming at fostering healthier habits, many have adopted the eHealth modalities, including interventions targeting ECEC eating and activity practices. eHealth tools are becoming more popular as they can deliver information in various forms and have the potential to reach large audiences at low cost [27,28].

A preliminary search of PROSPERO, PubMed, the Cochrane Database of Systematic Reviews, and *JBI Evidence Synthesis* was conducted, and no current or in-progress scoping reviews or systematic reviews in the area of eHealth tools in the ECEC setting were identified. Previous reviews have primarily focused on examining the effectiveness of preschool-focused nutrition and physical activity interventions delivered face-to-face [29] or eHealth interventions in children and adolescents but not in preschool-aged children [27]. A previous review looked into health behavior resources for childcare educators but limited the focus to the Canadian context and did not consider international evidence [30]. Additionally, the authors explored both print and web-based materials [30]. With the rapid development of digital interventions, Prowse and Carsley [31] emphasize the need to examine those interventions to establish best practices for eHealth nutrition interventions for younger children. Hence, the specific focus of our review is on eHealth technologies. Furthermore, previous reviews emphasize the role of settings in the successful implementation of health promotion interventions [32,33]. For instance, in their review evaluating the success of childhood obesity interventions by setting, Flynn et al [32] found that interventions aimed at improving the food environment delivered in the ECEC setting were effective in improving childhood outcomes. Another important construct to consider is the theoretical basis of interventions. In a recent review conducted by Kracht et al [27] examining eHealth and mobile health interventions in children and adolescents, the authors underscored the importance of reporting on the theoretical underpinnings of eHealth interventions. The use of a theoretical framework in behavior change interventions was associated with increased effectiveness and maintenance of the desired behavior [28,31,34]. Additionally, the use of theory was noted as enabling potential replication for future intervention development [35]. Consequently, this underpins the importance of reporting and identifying the theoretical basis used to develop a given eHealth tool.

Rationale and Objectives

For these reasons and given that no reviews on the use of eHealth tools developed for educators in ECEC settings were

XSL•FO
RenderX

found, we are undertaking a scoping review in this area. This scoping review will allow a broad examination of the literature in this emerging field and provide directions for future systematic reviews.

Our broad objective is to explore which eHealth tools are available to assess and support best practices for nutrition, physical activity, or both in ECEC environments and to highlight potential future research directions. To map the breadth of the available evidence, the scoping review will address the following specific objectives: (1) to identify the existing eHealth tools that are used to assess or improve nutrition environments, physical activity environments, or both in ECEC centers; (2) to describe the components of the eHealth tools, including technology type (eg, websites, smartphone apps, and social media) and health purposes (eg, nutrition evaluation and movement promotion); (3) to describe the psychometric evidence provided; (4) to report the theoretical foundations used in developing the eHealth tools; and (5) to identify any evidence gaps.

Methods

Study Design

This scoping review will be conducted in accordance with the Joanna Briggs Institute methodology for scoping reviews [36] and follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [37].

Ethical Considerations

No ethics approvals are required since the planned study is an assessment of the literature and will not include human or animal participants.

Protocol and Registration

This protocol was written before the study commenced (ie, before the electronic literature search was performed). The protocol for this scoping review is registered on Open Science Framework (XTRNZ) [38].

Eligibility Criteria

Overview

The eligibility for our scoping review is based on the Population, Concept, and Context framework (Textbox 1).

Textbox 1. Eligibility criteria for the scoping review.

Inclusion criteria

- Population: early childhood educators within early childhood education and care (ECEC) centers
- Concept: eHealth (digital) tools
- Context: nutrition and physical activity ECEC environment
- Study type: primary studies with any design or data type
- Study focus: eHealth tool is the primary focus of the resource
- Publication status: peer-reviewed journals and gray literature
- Publication language: English or French
- Full text accessible

Exclusion criteria

- Data only collected on children within the ECEC centers
- eHealth technology is a minor component of the assessment or intervention
- Family-based childcare, preschool programs operating less than 4 hours, and before- or after-school care
- Publication language other than English or French
- Full text not available

Participants or Population

This review will consider studies that include early childhood educators within ECEC programs, publicly or privately operated, providing full-day care for children aged 0-5 years. Studies will be excluded if educators work in a family-based setting, preschool programs where children attend less than 4 hours per day, or before- or after-school care.

Concept

This review will consider studies that explore eHealth tools that aim to support nutrition environments, physical activity environments, or both in the ECEC setting. eHealth tools may be defined using any of the constructs displayed (Textbox 2). eHealth tools include digital technologies that (1) measure and (2) deliver interventions to improve nutrition environments, physical activity environments, or both. Additionally, eHealth tools that assess the ECEC environment must provide feedback to ECECs. We will consider all types of eHealth modalities

XSL•FO
RenderX

including but not limited to web-based tools, mobile apps, SMS text messages, social media, and gamification. We will only include studies where the eHealth tool is an essential assessment or intervention component. The eHealth tool should be the predominant mode of assessment or intervention delivery. We will exclude studies in which the eHealth modality constitutes a minor component, for example, if the majority of the assessment or intervention is conducted in person.

Textbox 2. Definitions of the inclusion criteria in the scoping review.

Population: early childhood educators within early childhood education and care (ECEC) centers

- Educators include the staff within an ECEC center with any responsibilities for the care of children aged 0-5 years, which includes teachers or center directors.
- Studies will be excluded if educators work within family-based care, before- and after-school care, or preschools where children attend less than 4 hours per day.

Concept: eHealth (digital) tools

- eHealth tools are digital technologies that are noninvasive and used to assess and track the health of a patient or consumer.
- eHealth assessment is used as a term to indicate eHealth tools that measure and evaluate ECECs' nutrition environment, physical activity environment, or both, policies, knowledge, and practices.
- eHealth intervention is used as a term to indicate eHealth tools that support ECEC centers to improve their nutrition environment, physical activity environment, or both, policies, knowledge, and practices.
- eHealth modalities are eHealth tools such as websites, mobile or smartphone (SMS text messages and apps), emails, digital games, and social media.
- Studies will be excluded if the digital technology is only a minor part of the assessment (ie, web-based survey without feedback to participants) or intervention.

Context: nutrition and physical activity environment within ECEC centers

- Focused on the domain of nutrition and physical activity related to child health
- Nutrition environments will be defined in the physical context (eg, availability of healthy food and dramatic play center toys) or the social context (eg, adult-child interactions during meals and ECEC mealtime policies).
- Physical activity environments will be defined in the physical context (eg, space for movement activities and time dedicated to activity) or the social context (eg, adult-child interactions during the outdoor time and ECEC physical activity policies).

Context

This review will consider the nutrition and physical activity environments in the ECEC setting as the context. We will focus on both the physical and social environment in ECECs.

Information Sources

The information sources for our scoping review include bibliographic databases PubMed, Scopus, CINAHL Plus (EBSCOhost), ERIC (EBSCOhost), and Embase (OVID). These databases were chosen because they host the most relevant literature in public health digital technologies within the education domain. We will also conduct a scan of the gray literature in accordance with Godin et al [39] that includes (1) the gray literature database ProQuest, (2) a customized Google search, and (3) targeted websites to identify unpublished studies and gray literature. This scoping review will consider all relevant literature including quantitative, qualitative, and mixed methods study designs. Systematic reviews, text, and opinion papers will be considered for inclusion in the proposed scoping review if identified.

Search Strategy

To ensure a comprehensive search, our search strategy will follow the 3-step search strategy from Peters et al [36]. First, an initial limited search of PubMed and Scopus will be undertaken to identify papers on the topic. The text words contained in the titles and abstracts of relevant papers and the index terms used to describe the papers will be used to develop a refined search strategy for PubMed (Multimedia Appendix 1). Second, the search strategy, including all identified keywords and index terms, will be adapted for each included information source. Third, the reference list of retrieved papers will be examined for additional relevant sources. Papers published in English and French with no limit on publication date will be included in this review.

Study Selection

Following the search, Covidence (Veritas Health Innovation) will be used to upload search results and identify and remove duplicates. A pilot test of 10 papers will be conducted by 2 independent reviewers to assess agreement regarding the relevance of titles and abstracts. Following the pilot test, the reviewers will conduct title and abstract screening against eligibility criteria to determine whether to include the study in the review. In the following step, a full-text screening of selected citations will be done by 2 independent reviewers, and a third reviewer will be consulted in the case of disagreements that cannot be resolved by discussion. Reasons for exclusion of full-text papers that do not meet the inclusion criteria will be recorded and reported in the scoping review. The results of the search will be reported in full in the final scoping review and

XSL•FO
RenderX

presented in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [40].

Data Extraction

Data will be extracted from papers included in the scoping review by 2 independent reviewers using a data extraction tool developed by the research team. The data extracted will include specific details about the population, concept, context, methods, and key findings relevant to the review question. The research team will use a data extraction tool adapted from the template provided in the Joanna Briggs Institute methodology for scoping reviews [36]. The data extraction form will include paper information (author, publication year, and country), study design and aim, study setting, participant information, inclusion or exclusion criteria, sample size, recruitment method, eHealth modality used, eHealth tool components, psychometric validation, theoretical underpinning, and outcome measures (Multimedia Appendix 2). For the gray literature, the extracted data will include (1) resource details (eg, title of document, author or organization, country, year, resource type, purpose, and participants) and (2) eHealth tool details (eg, type of eHealth tool, tool components, psychometric properties, and nutrition or physical activity measured or improved). The data extraction form will be piloted before implementation to ensure agreement in capturing relevant information. The data extraction form will be revised as necessary as the data extraction proceeds. Modifications will be detailed in the full scoping review. Any disagreements that arise between the reviewers that cannot be solved by discussion or consensus will be resolved by a third reviewer.

Methodological Quality Appraisal

Methodological quality or risk of bias will not be appraised, which is consistent with guidance on scoping review conduct [36]. This work will inform the next steps on a decision to conduct a systematic review where methodological quality appraisal will be conducted.

Results

The extracted data will be graphically presented in tables and charts in line with the objective of this scoping review. The presentation of results will be organized by each review question. First, a table of all included studies will be presented providing information on authorship, year of publication, country of origin, study design, aims, participants, and outcomes (Table S1 in Multimedia Appendix 3). A second table will display characteristics of the eHealth tools including eHealth modality used, tool components, and psychometric evidence (Table S2 in Multimedia Appendix 3). Data about the use of theoretical framework will be presented in a third table (Table S3 in Multimedia Appendix 3). A narrative summary will describe the results for each research question and will accompany the tabulated results. Data analysis and presentation will depend on data extraction and thus will be subject to change in case of potential modification of the data extraction form. Any changes will be documented in the review.

This study commenced in May 2023. The scoping review protocol was registered in the Open Science Framework to promote transparency and help avoid unintended duplication of reviews. The search strategy was developed in June 2023 in collaboration with 2 university librarians and was refined in August 2023. The title and abstract screening started in August 2023 and is ongoing. The final results will be submitted to an open-access peer-reviewed journal in 2024.

Discussion

Overview

Using eHealth tools can facilitate the evaluation of ECEC environments and the delivery of interventions aimed at enhancing nutrition and physical activity practices within those settings. The synthesis and analysis of existing literature are useful to characterize the current scope of evidence and identify opportunities for future reviews and studies. This protocol will guide a scoping review to identify the extent, range, and characteristics of available evidence [36] on eHealth tools in ECEC settings and to identify any gaps and limitations. This scoping review is also examining the use of theory in the development of the eHealth tools. This information can support the replication of effective tools and inform future intervention development. The results of this scoping review will be disseminated through publication in a peer-reviewed journal.

Strengths and Limitations

While we aim to conduct a comprehensive scoping review, some limitations should be considered. First, only studies written in English or French will be included. Second, this scoping review is limited to full-time day care centers and excludes home day cares and after-school cares. Family or home day cares are excluded due to the scarcity of formalized information available for this group, and after-school cares are excluded as they do not typically serve children aged 0 to 5 years.

This review has several strengths. First, the search strategy was reviewed by 2 librarians with extensive knowledge in scoping and systematic reviews. Second, our search strategy targets diverse databases that are known to host relevant peer-reviewed literature in public health digital technologies within the education domain. Additionally, the search will be supplemented by gray literature that will broaden the scope of the review. Lastly, this scoping review is the first to synthesize the eHealth tools that assess or improve the nutrition and physical activity environment in early learning settings. The results of this scoping review will provide valuable insights into the potential of eHealth tools to promote healthier environments in early learning settings.

Conclusions

This scoping review will identify the types of eHealth technologies in the context of health promotion within early learning settings. This knowledge could guide further research on how eHealth technologies can support the promotion of healthy practices in childcare settings and ultimately inform the development of evidence-based interventions to improve health behaviors and outcomes in children.

Acknowledgments

The authors acknowledge and thank Diane Lorenzetti, librarian at the University of Calgary, and Erik Christiansen, librarian at Mount Royal University, for their expert advice in developing and refining the search strategy. Funding for this study was provided by the Government of Alberta, Children Services (ACS565189). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the paper.

Authors' Contributions

All authors have read and approved the final paper. JH and LMZL participated in the conceptualization and paper composition and developed the data extraction form. All authors participated in piloting the extraction form.

Conflicts of Interest

None declared.

Abstract

Background: Clinical trials often use digital technologies to collect data continuously outside the clinic and use the derived digital endpoints as trial endpoints. Digital endpoints are also being developed to support diagnosis, monitoring, or therapeutic interventions in clinical care. However, clinical validation stands as a significant challenge, as there are no specific guidelines orienting the validation of digital endpoints.

Objective: This paper presents the protocol for a scoping review that aims to map the existing methods for the clinical validation of digital endpoints.

Methods: The scoping review will comprise searches from the electronic literature databases MEDLINE (PubMed), Scopus (including conference proceedings), Embase, IEEE (Institute of Electrical and Electronics Engineers) Xplore, ACM (Association for Computing Machinery) Digital Library, CENTRAL (Cochrane Central Register of Controlled Trials), Web of Science Core Collection (including conference proceedings), and Joanna Briggs Institute Database of Systematic Reviews and Implementation Reports. We will also include various sources of gray literature with search terms related to digital endpoints. The methodology will adhere to the Joanna Briggs Institute Scoping Review and the Guidance for Conducting Systematic Scoping Reviews.

Results: A search for reviews on the existing evidence related to this topic was conducted and has shown that no such review was previously undertaken. This review will provide a systematic assessment of the literature on methods for the clinical validation of digital endpoints and highlight any potential need for harmonization or reporting of methods. The results will include the methods for the clinical validation of digital endpoints according to device, digital endpoint, and clinical application goal of digital endpoints. The study started in January 2023 and is expected to end by December 2023, with results to be published in a peer-reviewed journal.

Conclusions: A scoping review of methodologies that validate digital endpoints is necessary. This review will be unique in its breadth since it will comprise digital endpoints collected from several devices and not focus on a specific disease area. The results of our work should help guide researchers in choosing validation methods, identify potential gaps in the literature, or inform the development of novel methods to optimize the clinical validation of digital endpoints. Resolving these gaps is the key to presenting evidence in a consistent way to regulators and other parties and obtaining regulatory acceptance of digital endpoints for patient benefit.

Introduction

Background

Digital technologies such as smartphones, wearables, implantables, digestibles, and other biosensors present new opportunities to collect and analyze health data [1,2]. They enable more accurate and reliable identification and quantification of different aspects of one's health [3]. A wide range of parameters can be collected by digital devices such as physiological, anatomic, and pathological, as well as behavioral-, social-, or activity-related characteristics [3]. The patient can use the device in everyday life while data are passively collected or can perform assessments at the clinic [4]. Before clinicians and researchers can use data acquired by digital technologies, algorithms transform the data into metrics designated as digital endpoints [4].

In clinical care, digital endpoints may increase diagnostic accuracy and improve treatment decisions, as the clinicians can be provided with more information about the patient's status and treatment response in everyday life [2]. In clinical trials, digital endpoints can be used as replacements or as a proxy for outcome measures. This new type of endpoint consists not only of traditional endpoints assessed in a new way but also endpoints that were not previously possible to obtain [5]. By being collected automatically outside the clinic, digital endpoints enable more frequent or continuous data collection while requiring fewer staff and fewer clinic visits and reducing the need for patients to respond to so many questionnaires [6-9]. Despite the concerns that digital literacy may restrict patients' access to clinical trials [8], many argue that technology can support increased trial participation and retention [6]. In addition, it is not consensual whether using digital endpoints will increase the efficiency and effectiveness of clinical trials [1]. Regardless of these concerns, pharmaceutical and technological companies have turned their attention toward digital endpoints, incorporating them into clinical trials as study endpoints [10,11]. So far, 436 clinical trials using digital endpoints have been registered in the Digital Medicine Society Library of Digital Endpoints, out of which 205 (47%) consisted of drug studies, 175 (40.1%) were device-related studies, 30 (6.9%) were biological products, 1 (0.2%) was genetic, and 25 (5.7%) were other medical products [3].

Digital endpoints have yet to be accepted to support new medical product (or new applications of medical products) approvals [12]. There appears to be a global regulatory consensus on using digital devices in clinical trials [1,7,12], but only validated digital endpoints will be suitable for supporting safety and efficacy claims in applications to regulatory authorities [13]. The same applies to digital endpoints intended to be medical products [13]. However, the current need for a well-defined methodology for the clinical validation of digital endpoints poses a critical limitation [13].

The V3 framework, which combines software and clinical development, establishes the foundation for evaluating digital clinical endpoints [13]. Clinical validation is defined in the V3 framework as an evaluation of whether digital endpoints "acceptably identifies, measures or predicts a meaningful clinical, biological, physical, functional state, or experience, in the stated context of use (which includes a specified population)" and takes place after both the verification and analytical validation processes [13]. This assessment evaluates the association between a digital endpoint and a clinical condition. It is subject to similar principles of research design and statistical analysis of clinical validation of traditional tests, tools, and measurement instruments [13,14]. In general terms, clinical validation comprises the assessment of content validity, reliability, and accuracy (which validates the digital endpoint against a gold standard) and the establishment of meaningful thresholds [12,15].

Some approaches have been suggested, such as the Food and Drug Administration Guidance on patient-reported outcomes [16] or the Clinical Trials Transformation Initiative Recommendations for endpoints generated by mobile technology [5], but no standardized framework for clinical validation is currently available. Standardization is challenging; indeed, there is a wide variety of digital endpoints [13]. If we consider bodily functions captured, a few examples include diverse parameters such as heart rate, cognition, lung function, and gait. If we divide digital endpoints by type of devices, we have, for example, smartphones, wearables, implantables, and digestibles. Adding to that, and similarly to traditional endpoints, the clinical goal of the digital endpoints (diagnostic, safety, response, monitoring, prognostic, risk, and predictive) also determines variations in methods of clinical validation.

A search for reviews on the existing evidence related to this topic was conducted and has shown that no such review was previously undertaken. This study aims to map the literature on the methods for validating digital endpoints used or proposed. A scoping review is a suitable approach to synthesize such a complex topic comprehensively [17-19]. We hypothesize that in a scoping review, important patterns of methods for clinical validation of digital endpoints grouped by bodily functions, type of devices, and clinical application goal will emerge. The results of this work will guide researchers and identify potential gaps in the literature, which in turn can inform the development of novel methods to optimize the clinical validation of digital endpoints.

Review Question

The main research question addressed by the scoping review will be "What methodologies have been employed or proposed for clinical validation of digital endpoints?"

Methods

Overview

This protocol is reported in line with the Joanna Briggs Institute (JBI) Scoping Review Protocol [8]. The scoping review will be conducted and reported following the methodology for scoping reviews by the JBI Scoping Review [8] and the Guidance for Conducting Systematic Scoping Reviews [9].

Search Strategy

An exploratory search of MEDLINE (PubMed) was performed to retrieve sentinel papers and identify text words contained in

XSL•FO
RenderX

the title and abstract and the index terms in the description of those papers to compile a list of terms to inform our search strategy. The search strategy for PubMed was drafted by the first author and further refined through team discussion with the remaining authors. In total, 2 librarians translated and adapted the search strategy for other electronic databases and ran the searches. The final search strategy is reported in Multimedia Appendix 1.

We ran the search query in MEDLINE (PubMed), Scopus (including conference proceedings), Embase, IEEE (Institute of Electrical and Electronics Engineers) Xplore, ACM (Association for Computing Machinery) Digital Library, CENTRAL (Cochrane Central Register of Controlled Trials), Web of Science Core Collection (including conference proceedings), and JBI Database of Systematic Reviews and Implementation Reports. We included databases indexing research related to life sciences and biomedicine and other databases of traditional engineering journals because digital medicine is a highly interdisciplinary field.

The search strategy was first developed for PubMed and then adapted to each additional database, including Boolean operators, various combinations of text words (including truncation), index terms related to digital endpoints for use in clinical practice and clinical trials, and validation studies methodologies. The search in electronic scientific databases will be supplemented by searching gray literature in Google Scholar, ClinicalTrials.gov, and at least 1 national and 2 international nonindexed conference proceedings using free text in the title and abstract related to digital endpoints and validation. This search aims to find conference papers, theses, dissertations, ongoing studies, white papers, academic and industrial reports, expert group documents, regulatory entity documents, blog posts, etc, of potential interest. These sources are essential to consider that information may be in various formats due to the novelty of the theme.

No time or language restrictions will exist, provided an English or Portuguese title and abstract are available. Relevant papers identified in languages other than English or Portuguese will be translated. Additionally, the reference lists of retrieved studies meeting the inclusion criteria will be manually searched to identify additional relevant studies. The final search results will be imported into the professional version of Rayyan [20], a web-based platform for literature review management hosted at NOVA Medical School–Universidade NOVA de Lisboa, and duplicates will be removed. In addition, we will cross-check authors' names across gray literature and results from electronic databases to identify and remove potential duplicates.

Study Selection and Eligibility Criteria

Study screening and selection will be performed using Rayyan [20] as it facilitates collaborative screening of papers while ensuring reviewers do not see each other's selections. The software logs reasons for exclusion and lists disagreements between reviewers. In total, 2 reviewers will independently perform the study selection process. Blinding will be switched off for reviewers to see papers with disagreements, which will be resolved by consensus. If consensus is not possible, a third reviewer will assess the discussed abstracts or full texts and provide a decision. Reviewer agreement will be calculated using the κ coefficient and reported in the scoping review paper.

Study selection will be undertaken in 3 phases: pilot testing, title and abstract screening, and full-text review. The first phase, a pilot, will involve the screening of the same random 20 publications (title and abstracts) by all reviewers, followed by a discussion to ensure consistency and that all relevant data were captured. Any resulting changes to the inclusion and exclusion criteria will be documented and reported. In the second phase, both titles and abstracts will be assessed.

For studies to be included, they must meet the inclusion criteria (Textbox 1), which were defined based on the "Population–Concept–Context (PCC)" framework recommended by the JBI for scoping reviews [9]. Studies will be excluded if they have any characteristics listed as exclusion criteria (Textbox 1).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Population: Human adults.
- Concept: Scientific methodologies used or proposed to validate digital clinical endpoints.
- Context: The review will include all study designs published in journals, conferences, theses, or dissertations, as well as clinical trials registered in platforms, white papers, academic and industry reports, opinion papers, blog or website or forum posts, letters, guidelines, book chapters, editorials, commentaries, papers or guidelines by an expert group, regulatory entities, or others; there will be no date and language restrictions.

Exclusion criteria

- Studies describing verification or analytical validation of digital endpoints.
- Studies describing clinical validation of surrogate endpoints.

In the third stage, the full texts of the selected publications will be reviewed for further assessment against the inclusion and exclusion criteria. Reasons for excluding sources of evidence at the full-text review will be recorded and reported. As an iterative approach to study selection is recommended [21], changes to this protocol may be made and reported accordingly in the scoping review.

Data Extraction

Reviewers will independently collect data from the full text of each included study using a structured extraction form adapted

XSL•FO
RenderX

by authors from the review of Polhemus et al [22] with an explanation for each data item. Our team will internally assess the appropriateness and comprehensiveness of the data extraction form. Then, following the "Updated methodological guidance for the conduct of scoping reviews" [21], all reviewers will pilot the extraction form on at least 3 (same) random studies to ensure consistency in data extraction. If a level of agreement indicated by a κ of at least 0.8 is achieved, the data extraction begins; and if not, a second (or more) round of the pilot is conducted. Modifications to the form identified through the pilot, including rewriting sentences for clarity and adding or removing items to the initial list of study characteristics, will be discussed by reviewers. The draft extraction form will include information about each included study, such as authors, year and type of source, and the key findings relevant to the review questions for original papers (Table 1) and regulatory guidelines, viewpoints, expert group recommendations, or other sources (Table 2).

Table 1. Preliminary data items to extract from original papers.

Data items	Explanation
Publication details	
Authors and reference	Who conducted the research? Include the reference.
Year	When was the study published?
Type of source	In what type of literature was the study published (journal, conference, or gray literature—conference, thesis or dissertation, clinical trials registry platform, white paper, book chapter, or others)?
Country or region	In which country or region did the study take place?
General details	
Study design	What was the study's design?
Study aims	What were the study's aims?
Population	What population was studied? What were the inclusion or exclusion criteria (eg, age, disease, and disease severity)?
Study size	How many people participated in the study?
Sampling method	What method was used for sampling?
Study limitations	What were the limitations of the study?
Validation method limitations	What were the limitations of the method used for clinical validation?
Digital endpoint details	
Digital endpoints	Which digital endpoints were measured? How and in what setting were the digital endpoints calculated?
Analytical methods	How did the authors measure the relationship between clinically relevant outcomes and digital endpoints? What association measure was used?
Clinically relevant methods	What clinically relevant endpoints were studied?
Type of clinical application	Which type of clinical application of the digital endpoints concerning the studied outcome? Diagnostic, safety, response, monitoring, prognostic, risk, or predictive?
Study endpoints	Was the digital endpoint used as a primary, secondary, or exploratory endpoint? What other primary, secondary, and exploratory endpoints were measured?
The device used for the collection of digital endpoints	Which devices were used to collect digital endpoints?

XSL•FO
RenderX

Table 2. Preliminary data items to extract from regulatory guidelines, viewpoints, expert group recommendations, and other similar sources.

Data items	Explanation
Publication details	
Authors and reference	Who wrote the paper? Include the reference.
Year	When was the paper published?
Type of source	In what type of literature was the paper published (journal, conference, gray literature—conference, thesis or dissertation, clinical trials registry platform, white paper, academic and industry report, opinion paper, blog or website or forum post, letter, guideline, book chapter, editorial, commentary, paper or guideline by expert group, regulatory entity, or others)?
Country or region	In which country or region was the paper written? To which regions do the recommendations apply (which country or region, global)?
General details	
Sampling size	What is the recommended or used sample size?
Sampling method	What method is recommended or used for sampling?
Study design	What study design is recommended or used for clinical validation?
Digital endpoint details	
Clinical application of digital endpoints	What is the clinical application of digital endpoints (diagnostic, safety, response, monitoring, prognostic, risk, or predictive)?
Type of validation methods	Which type of validation method is recommended? The trial, simulation, expert opinion, model-centered, and other?
Analytical methods	What methods are recommended to measure the relationship between clinically relevant outcomes and digital endpoints? What association measures should be used?
Analytical methods	Is there any consideration for using the digital endpoint as a primary, secondary, or exploratory endpoint?

Further refinement may be made to the extraction form at the review stage, and the final version will be included in the scoping review. If relevant missing or additional data are necessary, the studies' corresponding authors will be contacted. The data extraction process will involve 2 reviewers to minimize the chance of errors and bias [21]. Disagreements will be solved through consensus, and if that is not achieved, a third reviewer will provide the final decision. Reviewers will use the Rayyan [20] software to access the full texts of eligible studies and register the information extracted in a Microsoft Excel spreadsheet file.

Results

A narrative synthesis will be produced to summarize the extracted data and present a comprehensive overview of the methods for the clinical validation of digital endpoints. The study will be reported following the "Preferred Reporting Items for Systematic Reviews and Meta-Analysis: Extension for Scoping Reviews (PRISMA-ScR)" [19]. The search strategy and selection process results will be described, and a PRISMA-ScR flow diagram will be presented [23]. Moreover, the results relevant to this scoping review's objectives and research question will be described [23], namely, the methods for the clinical validation of digital endpoints, structured around the patterns identified per device, digital endpoint, and clinical application goal. Findings will be compiled in tables and figures where appropriate. We will also identify gaps in the evidence to inform areas of future research.

Discussion

This scoping review will map the methods for the clinical validation of digital endpoints. It will be unique in its breadth since it will comprise digital endpoints collected from several devices and not focus on a specific disease area. However, we expect to be able to derive more robust trends and patterns of clinical validation of digital endpoints generated from movement, physiological (electrical, optical, and imaging), and biochemical sensors.

Digital clinical endpoints are a new and rapidly growing research field [24]. Research studies assessing the clinical validity of digital clinical endpoints do not accompany the volume of studies reporting the development of digital endpoints [24], likely due to clinical validation being the last phase of the V3 framework, following verification and analytical validation. As research on digital clinical endpoints is a new field, the initial focus is the development phase. Moreover, it has been reported that deployment studies have been conducted without prior clinical validation, therefore not establishing fit-for-purpose and trustworthiness [24]. This can result in either resource wastage or harm [24]. The lack of a standardized methodology is likely a significant reason for the reduced proportion of clinical validation studies of digital endpoints. Without a well-defined and standardized method, more effort and time are required for each study. Hence, patterns must be identified so researchers can rapidly have a reference to guide clinical validation studies of digital clinical endpoints.

XSL•FO
RenderX

There is an asymmetry in the number of publications for body functions, diseases, or conditions, with a predominance of studies assessing digital endpoints derived from movement, physiological (electrical), physiological (optical and imaging), and biochemical sensors [24]. Those endpoints are most commonly used to answer clinical questions and are most common among studies promoted by pharmaceutical companies to support medical product development [11,24,25]. Thus, we may be able to examine better trends and patterns of digital endpoints. We may also be able to identify gaps in the literature, informing the need for further research in specific types of digital endpoints.

This scoping review study will conform with the recommended standards for conducting scoping reviews, which contributes to a robust methodology as well as transparency and reduced risk of bias. However, some limitations are expected. First, we will not undertake a methodological appraisal or risk of bias assessment of the studies included in the scoping review, as that neither is recommended in scoping reviews [21] nor would be adequate for all sources of evidence we are expecting to retrieve (eg, letters, guidelines, website, or blog posts). However, we are aware that the lack of methodological appraisal in scoping reviews is not consensual [26], with some authors defending that it prevents identifying gaps in the literature regarding the low quality of research and using the results to make recommendations for policy or practice [26]. Second, there is a heterogeneity of terms used to describe endpoints generated by digital technology. We included several terms in our search strategy, informed by a pilot search in PubMed we have conducted, but more may be needed to capture all existing studies exhaustively. In addition to that, digital endpoints can be identified using terms related to the technology (eg, inertial sensors, smartwatch, and smartphone), disease (eg, rheumatic diseases), or bodily function (eg, sleep, gait, and hemodynamic). We attempted to create an extensive list of appropriate search terms for all available technologies and bodily functions. Still, the search strategy retrieved a colossal number of results, making a scoping review unfeasible. Following expert advice, we maintained only some of the terms related to technology and the terms related to digital endpoints, expecting a low possibility that additional information of interest may be missed.

We believe this work will be relevant to various researchers, including those designing and developing clinical studies using digital endpoints and those involved in applications for marketing approval of either drugs assessed in clinical trials using digital endpoints or developing digital health technologies to collect data remotely and seeking regulatory approval. It will also inform health care professionals supporting the modernization and acceleration of clinical trials and those interested in integrating digital endpoints in their clinical practice. The study findings could further be used by regulators developing regulations and guidelines for clinical trials and medical devices. Therefore, we plan to disseminate the results of this scoping review through publication in an international peer-reviewed scientific journal and present the main findings in a workshop of the European project COTIDIANA [27] to a diverse group of stakeholders.

Acknowledgments

This work was supported by the project COTIDIANA (AAL2020-7-146-CP) funded under the Active Assistive Living (AAL) Joint Programme, the European Commission, and the National Funding Authorities of Portugal, Austria, and Switzerland. Funding bodies had no role in the design of this study and will not influence study execution, analysis, interpretation of the data, or decision to submit results.

Data Availability

Data sharing does not apply to this paper, as no data sets were generated or analyzed during this study.

Authors' Contributions

SR and FN conceptualized the study as a scoping review. AMR and FN provided oversight for scoping review protocol development. SR drafted the protocol. ARH, AMR, and FN helped to review and edit the protocol. SR, ARH, SSS, and TC drafted the search strategy and ran the search on electronic databases. All authors read and approved the final paper.

Conflicts of Interest

AMR Received independent grants or support from Amgen, Astrazeneca, Novartis, Abbvie, Pfizer, MSD, Lilly, and Boehringer Ingelheim.

Abstract

Background: Globally, health care systems are challenged with the shortage of health care professionals, particularly nurses. The decline in the nursing workforce is primarily attributed to an aging population, increased demand for health care services, and a shortage of qualified nurses. Stressful working conditions have also increased the physical and emotional demands and perceptions of burnout, leading to attrition among nurses. Robotics has the potential to alleviate some of the workforce challenges by augmenting and supporting nurses in their roles; however, the impact of robotics on nurses is an understudied topic, and limited literature exists.

Objective: We aim to understand the extent and type of evidence in relation to robotics integration in nursing practice.

Methods: The Joanna Briggs Institute methodology and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist will guide the scoping review. The MEDLINE (Ovid), Embase (Ovid), CINAHL Plus with Full Text (EBSCOhost), Scopus, Cochrane Library, and IEEE Xplore electronic bibliographic databases will be searched to retrieve papers. In addition, gray literature sources, including Google Scholar, dissertations, theses, registries, blogs, and relevant organizational websites will be searched. Furthermore, the reference lists of included studies retrieved from the databases and the gray literature will be hand-searched to ensure relevant papers are not missed. In total, 2 reviewers will independently screen retrieve papers at each stage of the screening process and independently extract data from the included studies. A third reviewer will be consulted to help decision-making if conflicts arise. Data analysis will be completed using both descriptive statistics and content analysis. The results will be presented using tabular and narrative formats.

Results: The review is expected to describe the current evidence on the integration and impact of robots and robotics into nursing clinical practice, provide insights into the current state and knowledge gaps, identify a direction for future research, and inform policy and practice. The authors expect to begin the data searches in late January 2024.

Conclusions: The robotics industry is evolving rapidly, providing different solutions that promise to revamp health care delivery with possible improvements to nursing practice. This review protocol outlines the steps proposed to systematically investigate this topic and provides an opportunity for more insights from scholars and researchers working in the field.

Introduction

Background

Globally, health care systems are challenged with the shortage of health care professionals, particularly nurses. Nurses and midwives account for nearly 50% of the global health care workforce [1], with the same proportion bearing out in the Canadian health care system [2]. It has been projected that by 2035, there will be a global deficit of 12.9 million health care professionals, with nurses and midwives making up half of the health care workforce shortage [1,3]. Several factors account for the increasing decline in the nursing workforce, including increased workload, insufficient resources, chronic burnout, stress, early retirement, understaffing, job dissatisfaction, work-related and musculoskeletal injuries, and low remuneration [4-10]. Other factors include post–COVID-19 discontentment, disease and patient acuity increase, and the aging population and workforce [4,7,11,12]. The COVID-19 pandemic exacerbated the already existing nursing shortage crisis.

Nurses undertake multiple and complex activities within any care setting, and their most central role is to provide efficient and effective patient-centric care [13]. Research shows increased staffing leads to greater job satisfaction and retention, reduced mortality and associated injuries among nurses and patients [14]. Nonetheless, about one-third of nurses' time is often spent on administrative and nonpatient care activities and auxiliary tasks that could be completed by other staff, such as nursing aides, assistants, or administrative staff [15,16]. Among health care professions, nurses are ranked with the highest prevalence of musculoskeletal pain and injuries [17] and an annual prevalence of work-related musculoskeletal diseases of 77.2% [18]. The results from these injuries are absenteeism, sick leaves, health-related problems, and disabilities, affecting the quality of health and putting added pressure on the health care workforce [19]. In addition, there is a significant rise in error rates among nurses resulting from physical and mental exhaustion, compromising patient and nurses' safety [20]. Nurses' time and skills are highly valuable, as they have specialized knowledge essential to achieving optimal health outcomes. Identifying alternative solutions that can decrease nurses' time lost in undertaking noncritical tasks is therefore necessary. Robotics is 1 solution that is gaining growing attention due to the many activities that robots can undertake to support nursing practice, strengthen health care delivery, improve overall health outcomes and the quality of care, and fill current and projected gaps in the workforce needed to meet population health needs [21]. When thoughtfully and appropriately integrated, robotics could also save money for the health care system and free up time for nurses to focus on patient care, thereby mitigating negative impacts on patients and the mental well-being of nurses [22]. On the other hand, robotics integration in nursing also raises inquiries regarding the methodologies, technologies, and ethics of developing robots to support the work of nurses and other health care professionals [23].

In broad terms, robots in health care are classified into surgical, rehabilitation, medical assistants, and hospital service robots [24]. These robots are referred to as assistive robots because they provide users with assistance and are subcategorized as physically and socially assistive robots [25,26]. Physically assistive robots are those robots that assist end users through physical interaction and may be designed to perform tasks without much physical human input, such as exoskeletons, intelligent wheelchairs, robotic manipulators, and walking assistive robots [26-30]. On the other hand, socially assistive robots are physical or digital entities capable of social interaction functions that promote users' psychological, emotional, cognitive, and overall well-being [26,31,32]. Socially assistive robots, such as Nao and Pepper robots, are used to provide affective therapy, social facilitation, companionship, and physiological therapy in patients [28,30,33]. The socially assistive robots have proved useful in caring for older people, assisting with activities of daily living such as medication reminders, undertaking household tasks, health monitoring to enhance safety, supporting independence and aging in place, and overall users' well-being [34]. Multimedia Appendix 1 provides a visual representation of classifications of the different types of robots used in health care.

The boundaries between the areas of application of robots in nursing are somewhat fluid. Different names are given to robots used by nurses in health care facilities, such as nurse assistants, hospital service robots, delivery care robots, and nurse robots. These names are based on their specification and practical use in care settings. For this review, the robots used in the nursing practice will be referred to as nursing robots. Nursing robots combine the features and functions of medical assistant robots and hospital service robots. The nursing robots are specifically designed to perform activities to supplement nurses' work at hospitals, long-term facilities, and home care [26]. These robots are socially and physically assistive and can be categorized into humanoids and nonhumanoid robots, including telepresence robots. Since nursing robots can provide assistance with complex activities within care settings, they can support nurses in providing services to patients unrelated to medical functions [24].

The surge in the interest in using nursing robots in health care is because of the technological capacity to strengthen health care delivery and improve quality health outcomes [21]. Nursing robots can complement nurses' efforts by undertaking repetitive work such as retrieving and delivering supplies, providing ambulation services, medication delivery services, assisting in patient transfers, lifting, and assisting with standardized approaches to care management [30,35,36]. In addition, robots can enhance nurses' work by monitoring patients' condition and vital signs and providing patient reminders [26,31]. Furthermore, nursing robots can serve as frontline actors during emergency response and routine care to prevent or reduce nurses' physical contact and exposure to hazardous substances, infections, or contamination. These tasks are usually physically and mentally demanding. They are routine activities that can be assigned to a nonhuman entity, thereby reducing the physical and mental stress for nurses, saving money for the health care system, and freeing up nurses’ time to focus on patient care [22]. To this end, nursing robots can decrease the physical demands of nurses' work and reduce the rate of injuries and human errors, thereby

XSL•FO
RenderX

increasing job satisfaction and improving patient care quality and outcomes [37,38]. For nurses, incorporating nursing robots in health care means improved workflow, increased work quality and productivity, and reduced workload. To health systems, robots could be an ideal solution to the wicked problem of nurse shortage.

To identify published literature reviews on the use of robotics or robots in nursing practice, a preliminary literature search was conducted (April 13, 2023) in CINAHL Plus with Full Text database, and 4 reviews were located. Ohneberg et al [35] focused their review on assistive robotic systems and their application areas in nursing practice. The other reviews focused on identifying the different tracks in which robots are used in nursing, barriers to implementation, and the outcomes of robots and other automated devices on nurses' activities [31,37,39]. Based on the findings from these reviews, the authors proposed that further research studies are needed to explore the acceptance and impact of robotics systems on nursing practice and examine facilitating factors and ethical concerns of implementing robots [35]. In addition, the authors suggested examining research designs used for undertaking studies in nursing robotics to ascertain the consistency and rigour of the quality of the studies [39] and evaluate which devices and functions will improve and support nurses' work [37]. Further, the authors noted the need to examine the human-robot interactions, focusing on monitoring robots and exploring psychological barriers that need to be overcome to influence and increase the acceptance of robots [31].

Despite the 4 reviews published on this topic, there remains a pressing need to map out the extant literature to better understand the current research discourses on the influence of robots (regardless of their type) on nurses and nursing practices across clinical care settings. A clear picture of what has and has not been attended to in terms of both (1) the robot's ability to reshape, reconstitute, and reconvene nursing practices, as well as (2) their influence on the nurse's mental, physical, and overall well-being is necessary to generate and inform future research. Scoping reviews are appropriate for examining emerging areas where little is known about a phenomenon of interest [40]. Broadly, this scoping review aims to understand the extent and type of evidence in relation to robotics integration in nursing practice. More specifically, the review will (1) identify the available evidence reporting on robots used in supplementing nursing and their related tasks in direct clinical care, (2) identify the benefits and challenges associated with their use, and (3) understand nurses' perceptions of the impact of robots on their work, and patient and clinical care.

Research Questions

The overarching question guiding this review is, what is the current evidence on the integration and impact of robots and robotics into direct nursing care? The following subquestions will be examined: (1) what are the types of robots and robotic technologies available to support nursing care? (2) What is the range of tasks (nursing and nonnursing related) that robots and robotic technologies can assist nurses with in providing direct clinical care? (3) What are the benefits and challenges associated with robotic integration in nursing? (4) What are nurses' perceptions and views on the impacts of robots and robotic technologies on nurses' work, patient care, and health systems that can be achieved when robots are used to supplement nursing practice from process, structure, and outcome perspectives?

Methods

Study Design

The Joanna Briggs Institute methodology and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist for scoping reviews will guide the scoping process [41,42]. We will review existing literature, examine the extent, scope, and nature of research activities to identify gaps and summarize and disseminate research findings [42]. An initial search (January 05, 2023) in the Open Science Framework revealed that no study of this nature had been registered; hence, this review will be registered in the Open Science Framework registry, which is a platform where researchers register prospective scoping reviews to inform other researchers interested in undertaking similar work, hence minimizing the risk for duplication.

Inclusion Criteria

The Joanna Briggs Institute's participants, concept, and context framework will be applied to guide the decision-making about the inclusion and exclusion of studies for the review, eliminate studies that are not essential to the central research questions, and maintain the consistency of the review process [42].

Participants

This review will focus on nurses working in different roles, including licensed practical nurses, registered practical nurses, registered nurses, registered psychiatric nurses, community health nurses, and nurse practitioners providing direct care within a variety of practice settings. Unless nurses are included as part of the study population, studies that report on other health professionals and patients will be excluded because they are not the participants of interest.

Concept

The authors recognize the differences in the classification of nursing robots; therefore, all papers that report on the use of nursing robots used in nursing practice, irrespective of the reported outcomes or the clinical context, will be included. In addition, any paper that does not report on robot use within the nursing practice or the use of socially assistive robots that focus on patient care will be excluded.

Context

This review will consider studies that examine robot use in all nursing practice settings, including long-term, primary care, acute care, rehabilitation, community care, and health care settings. In addition, the review will not be limited to any geographical location as the authors want to evaluate nursing robots from an international perspective and be comprehensive in the search.

Types of Sources

This review will consider all study types, including qualitative, quantitative, and mixed methods research, except for published

XSL•FO
RenderX

reviews on the topic, including systematic reviews, scoping reviews, narrative or traditional literature reviews, meta-analyses, and integrative reviews. Excluded reviews may be used later for discussion and comparison of results. In addition, studies that report on theoretical and methodological approaches will also be examined for relevance and considered for inclusion. Gray literature in the form of guidelines, theses, dissertations, discussion papers, white papers, reports, brief reports, specific guidelines, and unpublished papers that report on nursing robots or robotic technologies in nursing practice will be included. Blogs and internet research sites that report on the piloting of robots relevant to nursing practice will also be considered for inclusion. Conference proceedings and publications, opinion pieces and commentaries will be excluded as they might not provide in-depth information for analysis. Studies will be limited to the English language due to the lack of funding to support the translation of the materials, and reviewers can only speak English. Since the area of robotics in nursing is novel and evolving, the year of publication will be from the beginning of indexed papers in databases to the current search date. This will enable an assessment of the development of robots or robotics in nursing practice and their evolution over time.

An eligibility form for screening the papers will be used to guide the screening process (Multimedia Appendix 2), making the screening process clearer to the reviewers and maintaining the robustness of decision-making regarding the inclusion and exclusion of studies [43]. In total, 2 reviewers will independently screen data using the eligibility form provided and record the results. The kappa statistic, sometimes called Cohen kappa, a robust statistical method used most frequently, will be used to measure interrater reliability between the reviewers [43,44]. The kappa statistic method is applicable when two or more reviewers make decisions at various points in a study's screening and data extraction process [43,44]. Interrater reliability is important to ensure that data collected in the study are correct depictions of the variables measured [43].

Search Strategy

A comprehensive search strategy will be developed using predefined search terms in consultation with a health science librarian. A search was conducted in 1 database (CINAHL Plus with Full Text) to determine the appropriateness and effectiveness of the search terms and strategy (Multimedia Appendix 3) proposed for this review on September 26, 2023. The following Boolean operators and keywords proposed and identified will guide the search of the published and unpublished (grey literature) relevant to the topic: Automat* OR Robot* AND Nurs* AND Patient* OR In-patient* OR Hospital* OR "Nursing Care" OR "Clinical Care" OR "Direct Care," in four electronic bibliographic health databases, one interdisciplinary database and one electronic engineering database: Medline (Ovid), EMBASE (Ovid), Cumulative Index to Nursing and Allied Health Literature (CINAHL) Plus with Full Text (EBSCOhost), Scopus, Cochrane Library, and IEEE Xplore. The health science databases are appropriate for researching the topic because nursing papers are published in these databases. Whereas the IEEE Xplore database publishes papers from computer science, electrical engineering, and other technological disciplines, nursing robots are found in this database. The search strategy will be further refined and adapted to the remaining databases as necessary. In addition, the reference lists of all included studies retrieved from studies databases, and gray literature will be checked to ensure relevant papers are not missed.

For the gray literature, Google Scholar, dissertations, theses, registries, blogs, and relevant organizational websites will be searched to identify papers relevant to nursing robots. The gray literature provides studies that might not have been peer-reviewed or indexed in databases, thereby providing balanced evidence on the subject matter. Finally, the search strategy will use an iterative process until the search becomes robust to retrieve all related papers. The authors expect to begin the data searches in late January 2024.

Study Selection

The PRISMA-ScR checklist will be used as a guide in reporting the scoping review [45]. In addition, database search results will be exported to the Mendeley reference manager to keep track of search results, organize references and bibliographies, and facilitate collaboration among all authors [46]. Retrieved studies will then be exported into Covidence Management Software (Covidence) to remove duplicates and support organizing and screening the studies into a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) chart.

In total, 2 reviewers (EMD and GL) will screen the studies independently at each stage of the screening process. Stage 1 involves the title and abstract screening, where eligible studies are passed to stage 2 for full-text screening. In stage 2, the developed eligibility criteria form will be used to assess the eligibility of the papers for either inclusion or exclusion. Studies marked for exclusion will be assigned a reason for the exclusion to help keep track of and report on them in the findings. When conflicts arise due to disagreements between reviewers on studies during the full-screening stage, a third reviewer (MK), a content expert, will be invited to help resolve the conflicts. An interlibrary loan request will be sent to the library if full-text papers cannot be retrieved. Further, if possible, a request will be sent to the authors or journals to obtain more information about a study, as needed and feasible. If attempts made to retrieve papers are unsuccessful, the studies will be excluded and documented in the PRISMA diagram and reported in the findings.

Data Extraction

An Excel (Microsoft Corp) sheet extraction table will be developed and piloted to record essential information in the included studies to allow for transparency and clarity among reviewers. Each reviewer will independently extract the following data characteristics from the included studies grouped under the participants, concept, and context domains: study citation details (author's name, year of publication, country of publication, and title), study design, study purpose, participants (population and sample size), context (study settings), concept (types and range of tasks undertaken by the robots, benefits and challenges, nurses' views, and perceptions), and outcomes

XSL•FO
RenderX

(Multimedia Appendix 4). The identified extracted characteristics will support answering the research questions and in identifying the gaps in the literature. The extraction template is iterative; hence, it will be piloted on n=10 of the papers and may undergo refinement during the review and extraction stages to capture information based on how researchers reported information.

In total, 2 reviewers (EMD and GL) will undertake the data extraction process independently to reduce the chance of bias and errors [41]. Data extraction information will be compared for agreements and differences. In the event of discrepancies among the reviewers, a consensus will be reached by inviting a third reviewer (MK) and having a discussion for reconciliation. In scoping reviews, missing data are not usually dealt with, but the authors will decide how to proceed where possible. Scoping reviews do not aim to assess the quality of evidence, the robustness, or the generality of the evidence [40] but rather to identify literature that addresses the topic of interest. Therefore, the study quality will not be appraised in this scoping review.

Data Analysis

Data in this review will be systematically examined to minimize bias in interpreting the information abstracted from the included studies. Basic descriptive statistics will be applied to describe, aggregate, and report the findings in numerical values to enable a comprehensive evaluation of study characteristics such as the geographic distribution of included studies, populations studied, and publication time lines [47,48]. Content analysis will be applied to capture relevant information from each individual study to answer the research questions of interest in this review [49,50]. All team members will be involved in the data analysis to ensure a robust and timely analytical process.

Results

Information related to the characteristics of the included studies will be reported in the PRISMA chart to provide an overview of the body of the literature available, included and excluded studies, and the data sources used. This will be followed by a description of the characteristics of the included studies, using both a narrative and a tabular format. Graphs may also be used where appropriate to further illustrate the findings visually. A list of the excluded studies will also be provided with reasons for exclusion. To answer research questions 1 and 2, data related to the types of robots and robotic technologies available to support nursing care, the names of those robots and the different terminologies used to describe them in the literature, and the different tasks that these robots can assist nurses with will be reported in a tabular format to map out this literature. To answer research questions 3 and 4, abstractions from each included study in relation to the benefits and challenges associated with robotics integration, nurses' perceptions, and views on the impacts of robots and robotic technologies on nurses' work, patient care, and health systems will be summarized and reported narratively. Specific outcomes discussed in the literature will be noted and further organized according to the conceptual framework (structure, process, and outcome) proposed by Donabedian to facilitate a synthesis of these findings [51,52] to answer the research questions.

Discussion

Principal Findings

This scoping review aims to understand the extent and type of evidence in relation to robotics integration in nursing practice. Prior work has focused on investigating assistive robotic systems and their application areas in nursing practice [35]. Also, some reviews have identified the different tracks in which robots are used in nursing, barriers to implementation, and the outcomes of robots and other automated devices on nurses' activities [31,37,39]. The findings from these reviews reveal more research is needed to explore other areas of robotics in nursing practice, including human-robot interactions, and evaluating the robotics that supports nurse's work [31,35,37]. Building on the evidence, this review will (1) identify the available evidence on robots being used to supplement nursing and their related tasks in direct clinical care, (2) identify the benefits and challenges associated with their use, and (3) understand nurses' perceptions of the impact of robots on their work, patient care, and the health system.

The results from this review will be discussed in detail and in alignment with each research question. Furthermore, the results will be compared against what is already reported in the literature about robotics in nursing to help address the identified knowledge gaps and reveal new areas of research that have yet to be explored. In addition, other relevant literature sources, such as publications about digital health and health service research, will also be reviewed and used where appropriate. The discussion will also include detailed recommendations and implications relevant to nursing practice, education, research, and policy. The findings will also be published in a journal and disseminated at conferences, seminars, workshops, and web-based platforms.

Limitations

Only papers written in English will be included; hence, there is a possibility of missing out on other papers written in other languages. Furthermore, despite the comprehensive and extensive inclusion criteria, there is also the possibility of missing some relevant sources of information. Since the included studies will not be critically appraised, the rigor and trustworthiness of included studies cannot be ascertained; however, this scoping review may help provide a general assessment of the overall quality of research available and outline areas of research warranting further investigation.

Conclusions

This scoping review aims to investigate the current evidence on the integration and impact of robots and robotics nursing. By conducting a comprehensive search of peer-reviewed and nonpeer-reviewed sources, this scoping review will systematically map out and describe the current evidence about nursing robots and add to the body of knowledge on robots' integration in nursing. The scoping review is an appropriate method because the searches and inclusion of evidence are broad and unlimited to investigate an emerging area of science, identify knowledge gaps, and provide a direction for future research. Considering the novelty of robotics integration in

XSL•FO
RenderX

health care, the findings from this review will be instrumental in expanding the scholarly discourse about robotics as one of the emerging technologies that will have significant implications for patient care and nursing practice in the short and long term. This review protocol outlined the steps proposed to systematically investigate this topic and provide an opportunity to gain more insights on conducting the proposed review from scholars and researchers working in the field.

Acknowledgments

We want to express our gratitude toward Megan Kennedy, the health science librarian at the University of Alberta, for her valuable contribution to developing the search strategy for this review. It is also important to note that the authors wrote the paper without any assistance from generative artificial intelligence apps. We relied exclusively on our knowledge, literature, and experience while writing the paper.

Data Availability

All data used in this review, including the extraction table, the search strategy, and eligibility criteria, will be attached as appendices in the final paper. Any other document will be made available upon request to the corresponding author.

Conflicts of Interest

None declared.

Abstract

Background: Estimations show that at least one in every 3 people in the world needs rehabilitation at some point in the course of their illness or injury. Access to rehabilitation services is an essential part of the continuum of care and is integral to achieving universal health coverage. However, most of the world's population living in low- and middle-income countries, especially in the sub-Saharan African region, does not have access to adequate rehabilitation services. Wider adoption of digital solutions offers opportunities to support and enhance access to rehabilitation services in sub-Saharan Africa. A region where there is a greater burden and need for these services. There is also little published research about digital rehabilitation in sub-Saharan Africa, as it is an underexamined topic in the region.

Objective: This scoping review aims to provide a comprehensive picture of the current evidence of digital interventions in rehabilitation implemented in any health, social, educational, or community setting in the sub-Saharan Africa region.

Methods: We will conduct a scoping review using Arksey and O'Malley's methodological framework and follow the Joanna Briggs Institute methodology for scoping reviews. We will develop search strategies for a selected number of web-based databases, search for peer-reviewed scientific publications until September 2023, and screen the reference lists of relevant articles. We will include research articles if they describe or report the use of digital interventions in the rehabilitation of patients with any health problem or disability in sub-Saharan Africa. For selected articles, we will extract data using a customized data extraction form and use thematic analysis to compare the findings across studies.

Results: The preliminary database search in MEDLINE (EBSCO) was completed in May 2023. The research team will conduct a search of relevant articles in the autumn. The results will be synthesized and reported under the key conceptual categories of this review, and we expect the final scoping review to be ready for submission in early 2024.

Conclusions: We expect to find gaps in the research and a lack of detailed information about digital rehabilitation interventions in sub-Saharan Africa, as well as potential areas for further study. We will identify opportunities to inform the development of digital rehabilitation interventions.

Introduction

Background

Anyone with a health condition who experiences difficulties in any area of their life might need rehabilitation. According to the World Health Organization (WHO) [1], rehabilitation is defined as "a set of interventions designed to optimize functioning and reduce disability in individuals with health conditions in interaction with their environment." By aiming to optimize functioning, rehabilitation can help an individual be as independent as possible in everyday activities and support individuals to participate in education, work, recreation, and other meaningful life roles [2-4].

It is estimated that at least one in every 3 people in the world needs rehabilitation at some point in the course of their illness or injury [4]. According to the Global Burden of Disease study [4], the need for rehabilitation has increased by 63% since 1990, rising from 1.48 billion to 2.41 billion people [4]. Thus, the demand for rehabilitation services already exceeds availability, leaving a large unmet need, especially in low- and middle-income countries (LMICs) [5]. This provides strong evidence to prioritize rehabilitation and address the functioning needs of the population.

Rehabilitation has been effective in improving functioning outcomes in different health conditions in low-income and lower-middle-income countries, but it has not been prioritized in some of these countries and is underresourced [4]. Strengthening and reforming systems for health and collaborative practice requires a reconsideration of the role of the "patient." Patients are moving from being passive recipients to service and knowledge users, drivers, and partners in a shared approach to services, a person-centered framework. This requires collaboration, shared decision-making, and shared budgets to deliver services where the person is truly at the center [6,7].

Rehabilitation targets an individual's needs and priorities in functioning across the continuum of care and throughout the individual's life span. As countries move toward integrated person-centered care, it is imperative that quality rehabilitation be embedded in service delivery models [8]. The complexity of functioning should be acknowledged in relation to the context in which a person is striving to fulfill their life roles and goals [9,10]. There is a need for interprofessional, person-centered approaches within integrated community-based services to reform the rehabilitation and education of the health workforce [11]. By using technology, people with disabilities can share their functioning in their environment and make an impact by identifying their specific needs, both at an individual and population level [10,12]. Innovative technology, interprofessional teamwork, task shifting, and task sharing are recommended as catalysts for the reform.

Digital technologies are considered an essential solution to health services in countries with limited resources around the world, including those in sub-Saharan Africa [13,14]. Sub-Saharan Africa is home to approximately 1.2 billion people, half of whom are expected to be 25 years or younger by 2050. The region has the world's largest free trade area, is diverse, and offers human and natural resources that have the potential to yield inclusive growth. Sub-Saharan Africa is composed of 48 low, lower-middle, upper-middle, and high-income countries from Central, Eastern, Southern, and Western Africa, 22 of which are fragile or conflict-affected [15].

In the global context, rehabilitation models are costly and based on professionally delivered services. Most LMICs do not have a sufficiently educated rehabilitation workforce, leading to a situation where services do not meet demand [3]. Digital rehabilitation interventions hold significant potential to address key rehabilitation challenges [16], such as reduction in health care costs [17] and improving treatment adherence, functioning, and quality of life [18]. Strategically leveraging these interventions to address the needs of users directly and equipping different social and health systems with rehabilitation expertise could increase access. This will make present health care systems, especially in low-resource settings, more scalable, inclusive, and resilient in situations where systems become ineffective, overloaded, or do not meet demand [19].

Goal of This Study

We consider digital rehabilitation as an umbrella term, including different digital technologies that are used by rehabilitation professionals or self-driven service users as part of the rehabilitation process in its different phases (assessment, goal setting, intervention, reassessment, and secondary prevention). These include, but are not limited to, the use of tele- and distance rehabilitation applications and services [20] and the use and design of emerging technologies, such as artificial intelligence–powered conversational agents, wearable devices, emails, video, speech, and text messaging solutions. Digital rehabilitation aims to optimize functioning and reduce disability in individual's interaction with their environment. Digital rehabilitation has a strong link with the empowerment of individuals and communities (adapted from WHO [1]). The core is connecting and empowering persons and populations to improve functioning and well-being and managing rehabilitation needs.

A multidisciplinary approach considers the person and their entire needs. Rehabilitation is simply not a health issue but includes education, social, livelihood, and empowerment-related efforts [21]. If considered from the professionals' perspective, it means all professional groups related to rehabilitation, such as physiotherapists, occupational therapists, prosthetist-orthotists, speech therapists, and social workers.

Wider adoption of digital solutions has the potential to improve access to rehabilitation services and avail more research opportunities, especially in LMICs where there is a greater burden and need for rehabilitation services [22,23]. Some of the challenges hindering the adoption of digital rehabilitation identified in sub-Saharan African countries include inadequate and underdeveloped infrastructures for power supply, internet coverage, and transport; the need to train more professionals and enhance patient literacy; the financial implications of transitioning to digital services for health institutions; and the affordability of smart devices for patients [14,24]. However, the extent of research on digital solutions for rehabilitation in the region has not been mapped. There are also a limited number

XSL•FO
RenderX

of studies in LMICs about using digital services in rehabilitation. For example, in a review about the use of mobile health applications for stroke, healthy aging, Parkinson disease, and multiple sclerosis, only 5 studies out of more than 130 were from Africa [22].

We conducted a preliminary search of MEDLINE, the Cochrane Database of Systematic Reviews, and JBI Evidence Synthesis and did not identify current or ongoing systematic or scoping reviews on the topic. Unlike Kipruto et al's [25] ongoing scoping review aiming to map the digital health landscape and the stage of development in sub-Saharan Africa, our study specifically focuses on peer-reviewed digital rehabilitation research not limited to health contexts but includes social, educational, and community settings as well. A recent scoping review by Nizeyimana et al [26] investigated the feasibility and cost-effectiveness of telerehabilitation in a global context. The review focused on both high-income countries and LMICs, considering the accessibility of rehabilitation services and the facilitators and barriers of telerehabilitation.

Therefore, the objectives of this scoping review are to identify the scope and types of evidence of digital rehabilitation solutions and to examine how research about digitally delivered rehabilitation interventions is conducted in sub-Saharan Africa. We expect the review to summarize the available evidence of digital rehabilitation interventions and identify potential research gaps and avenues for development. We chose a scoping review to explore the extent of literature on the topic and as a necessary step in identifying how digital rehabilitation technologies can be integrated into primary health care.

Methods

Overview

We will conduct this review according to Arksey and O'Malley's [27] framework with the 5 mandatory stages and the Joanna Briggs Institute methodology for scoping review guidelines [28]. According to the framework, the stages in a scoping review include (1) identifying the research question, (2) identifying relevant studies, (3) selecting studies, (4) charting the data, and (5) summarizing and reporting the results. A scoping review is used to identify the key concepts relating to the research question, understand the conceptual boundaries of the research topic, and clarify definitions [29].

Review Question

The main research question guiding this review is: "What is the scope of research related to digital interventions used for rehabilitation in sub-Saharan Africa, and how is the research conducted?"

Eligibility Criteria

Overview

To select relevant studies, we have developed eligibility criteria (Textbox 1). These criteria are structured according to the population, concept, and context categories for scoping reviews suggested by Peters et al [28].

XSL•FO
RenderX

Textbox 1. Eligibility criteria structured according to the population, concept, and context domains. These outline the study population, the concept of digital rehabilitation, and sub-Saharan Africa as the locations of interest.

Inclusion criteria

1. Population: health professionals and patients
   - Social, health, and other professionals delivering rehabilitation services
   - Persons using or in need of rehabilitation services
2. Concept: use, experiences, and issues of integrating digital services in rehabilitation
   - Studies describing the use of digital interventions in rehabilitation
   - Studies evaluating the effectiveness of various types of digital rehabilitation interventions
   - Studies reporting the problems and barriers to integrating digital services into rehabilitation
3. Context: digital rehabilitation interventions adapted, piloted, and deployed in sub-Saharan Africa
   - Studies conducted in health, social, educational, and community settings in sub-Saharan Africa
4. Types of sources
   - Peer-reviewed articles, including research protocols
5. Other considerations
   - Published in English
   - Full article is available on the internet

Exclusion criteria

1. Concept
   - Studies reporting digitalization of health services other than rehabilitation
2. Types of sources
   - Editorials
   - Opinion and perspective articles
   - Abstracts only
   - Literature reviews

Population

The review will include studies involving patients of all ages receiving treatment through digital rehabilitation interventions delivered by multidisciplinary rehabilitation professionals.

Concept

The concepts of interest in this review are the use and effectiveness of digital rehabilitation interventions and how these interventions are implemented and evaluated in research. For the purposes of the review, we will only include digital rehabilitation interventions, such as telerehabilitation, wearable devices, robotics, virtual and augmented reality, smart device apps, and gamified mobile and web-based interventions.

Context

Studies conducted within any rehabilitation setting in sub-Saharan Africa will be eligible for inclusion.

Evidence Sources

The search strategy will be limited to peer-reviewed literature. Primary research studies of all designs, including both quantitative and qualitative, will be included in this review. Secondary research studies (eg, systematic reviews) will not be included.

Search Strategy

We planned a search strategy to identify a comprehensive list of research literature specific to digital solutions used for rehabilitation in sub-Saharan Africa. Text in the title and abstracts of relevant articles, and the index terms used to describe the articles, were used to develop a full search strategy for MEDLINE (EBSCO; Multimedia Appendix 1). We will adapt the search strategy with assistance from an information specialist for each included database and information source. We will search databases (MEDLINE [EBSCO], CINAHL, Cochrane Library, and Scopus) for peer-reviewed scientific publications. The reference list of all identified sources will be screened for additional studies.

XSL•FO
RenderX

Source of Evidence Selection

We will collate and upload identified citations from all databases into Covidence (Veritas Health Innovation) [30] and remove duplicates. Following a pilot test, 2 or more independent reviewers will screen the title and abstract of all retrieved citations for assessment against the inclusion criteria for the review. In the second step, 2 or more independent reviewers will then assess the full-text articles against the inclusion criteria. We will report reasons for the exclusion of sources of evidence in the full text that do not meet the inclusion criteria in the scoping review. We will resolve any disagreements that arise between the reviewers at each stage of the selection process through discussion or with additional reviewers. The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Review) flow diagram and checklist by Tricco et al [31].

Data Extraction

The research team will develop a data extraction tool to record the key information from the studies. Data will be extracted from papers included in the scoping review by 2 or more independent reviewers using the data extraction tool. The data extracted will include specific details about the participants, concept, context, study methods, and key findings relevant to the review question. These include author, publication year, publication type, country of origin, aims, population sample size and characteristics, methodology or methods, intervention type, outcomes and details of these, and other key findings that relate to the review's question as suggested by the Joanna Briggs Institute [28]. A draft extraction sample is provided in Textbox 2.

The research team will review the data extraction form and pretest it before implementation to ensure it is capturing relevant information. We will make modifications to the form after testing if necessary and state these modifications in the review. The extraction strategy will also be updated according to the categories emerging as the review progresses. We will resolve any disagreements that arise between reviewers through discussion and consensus, or with additional reviewers. The authors of the original papers will be contacted to request missing or additional data when required.

Textbox 2. Data extraction form.

1. Name of author, date of publication
2. Aims of the study and research question
3. Population
   - Characteristics of participants
   - Sample size
4. Country of origin (geography of the study)
5. Methodology
   - Study design
   - Recruitment setting
   - Intervention type, comparator, and details of these (eg, duration of the intervention; if applicable).
   - Sampling strategy (if applicable)
6. Key findings relating to the research question.
7. Conclusions

Data Analysis and Presentation

We will summarize the results using descriptive statistics. Descriptive statistics will be used to report the number of studies under each general category and additional conceptual categories, such as the study design, type of intervention, and the challenges and barriers to integrating digital solutions.

A narrative summary will accompany the tabulated and charted results and will describe how the results relate to the review's objectives and questions. Thematic analysis conducted according to Braun and Clarke's [32] outline will be used to contextualize the findings and describe the evidence and scope of the digital solutions. The process consists of developing initial coding ideas from the data, manually coding and matching codes to extracts, and sorting the codes into potential themes. Then analyzing the relationships between the themes, reviewing and refining them, and finally tabulating all codes under the final themes [32].

Ethical Considerations

We will collect all data through searches of web-based scientific databases. No information on individuals will be collected, so approval from a research ethics committee is not required. The study follows the ethical principles of Jamk University of Applied Sciences.

Results

The protocol was registered and submitted for publication in May 2023. Databases will be searched in September 2023.

XSL•FO
RenderX

Based on the preliminary search (Multimedia Appendix 1), we expect to have a reasonable number of references for screening. Screening and data extraction will be done between October and December 2023. The results will be synthesized and reported under the key conceptual categories of this review, and we expect the final scoping review to be ready for submission in early 2024.

Discussion

Overview

The review will examine published peer-reviewed research about digital solutions for rehabilitation to establish the extent of their use. This will provide a comprehensive picture of the current knowledge on the use of digital rehabilitation interventions in sub-Saharan Africa and the potential for these interventions to improve patient outcomes. The review extends previous research by Kipruto et al [25] and Nizeyimana et al [26] by emphasizing the "multimodal, patient-centered, and collaborative process" [33] of rehabilitation in a broader health care context, focusing on services to address the health care needs of individuals [1,8,33]. Unique to the present study is the focus on digital solutions for multidisciplinary rehabilitation in low-resource settings, which represents an underexamined topic.

This work is the initial step in a research project aiming to develop evidence-based, person-centered, and context-specific digital rehabilitation services in LMICs in East Africa and Southeast Asia. In the project, we aim to propose a digital-first multidisciplinary approach to address the challenges of access to rehabilitation services in low-resource settings. A digital-first approach will assist in delivering services directly to patients or through the primary health care system instead of solely through rehabilitation professionals, as is the case with the practice in high-income countries.

Limitations

A potential limitation is the availability of full-text articles. Some relevant articles may not yet be accessible during the search process; thus, limiting the reviewers' ability to give a summary that reflects all available evidence of digital rehabilitation. Lack of relevant studies because of the sole focus on peer-reviewed research is another limitation. As the digital landscape goes through rapid changes, there may be limited information about studies related to digital rehabilitation interventions in the sub-Saharan context if they, for example, do not progress beyond the trial phase of a project after deployment. Focusing solely on English-only articles also limits the review, as there may be relevant publications in other languages spoken in the sub-Saharan African region, such as French or Portuguese.

We expect the review to give us insights to develop the digital-first rehabilitation model proposed in the project. In addition, we expect it to outline research gaps and the implications for future research, policy, and practice. Other researchers, health professionals, and policy makers will benefit from the results. We will disseminate our findings through different channels, including peer-reviewed publications, presentations at scientific conferences, and web-based blogs.

Acknowledgments

This study is part of the project Co-innovation for Digital Rehabilitation in the Global Marketplace, funded by Business Finland (grant 6169/31/2021). The funders had no role in the review.

Data Availability

The data sets generated and analyzed during this study will be included as multimedia appendices in the resulting manuscript.

Authors' Contributions

KK is the research lead for the project. MO drafted the initial manuscript; MO and EA revised the search strategy; EA conducted the search and refined the strategy. MO and EA wrote the final manuscript in consultation with KK, JG, and DKT, who reviewed and approved the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The circular economy reshapes the linear “take, make, and dispose” approach and evolves around minimizing waste and recapturing resources in a closed-loop system. The health sector accounts for 4.6% of global greenhouse gas emissions and has, over the decades, been built to rely on single-use devices and deal with high volumes of medical waste. With the increase in the adoption of digital health solutions in the health care industry, leading the industry into a new paradigm of how we provide health care, a focus must be put on the amount of waste that will follow. Digital health solutions will shape health care through the use of technology and lead to improved patient care, but they will also make medical waste more complex to deal with due to the e-waste component. Therefore, a transformation of the health care industry to a circular economy is a crucial cornerstone in decreasing the impact on the environment.

Objective: This study aims to address the lack of direction in the current literature on circular business models. It will consider micro, meso, and macro factors that would impact the operational validity of circular models using the digital health solutions ePaper label (medical packaging), smart wearable sensor (health monitoring devices), smart pill box (medication management), and endo-cutter (surgical equipment) as examples.

Methods: The study will systematically perform a scoping review through a database and snowball search. We will analyze and classify the studies from a predetermined set of categories and then summarize them into an evidence map. Based on the review, the study will develop a 2D framework for businesses to follow or for future research to take a standpoint from.

Results: Preliminarily, the review has analyzed 26 studies in total. The results are close to equally distributed among the micro (8/26, 31%), meso (10/26, 38%), and macro (8/26, 31%) levels. Circular economy studies emphasize several circular practices such as recycling (17/26, 65%), reusing (18/26, 69%), reducing (15/26, 58%), and remanufacturing (8/26, 31%). The value proposition in the examined business model is mostly dominated by stand-alone products (18/26, 69%) compared to product as a service (7/26, 27%), involving stakeholders such as health care professionals or hospitals (20/26, 77%), manufacturers (11/26, 42%), and consumers (9/26, 35%). All studies encompass societal (12/26, 46%), economic (23/26, 88%), and environmental (24/26, 92%) viewpoints.

Conclusions: The study argues that each digital health solution would have to be accessed individually to find the optimal business model to follow. This is due to their differing life cycles and complexity. The manufacturer will need a layered value proposition, implementing several business models dependent on their respective product portfolios. The need to incorporate several business models implies an ecosystem perspective that is relevant to consider.

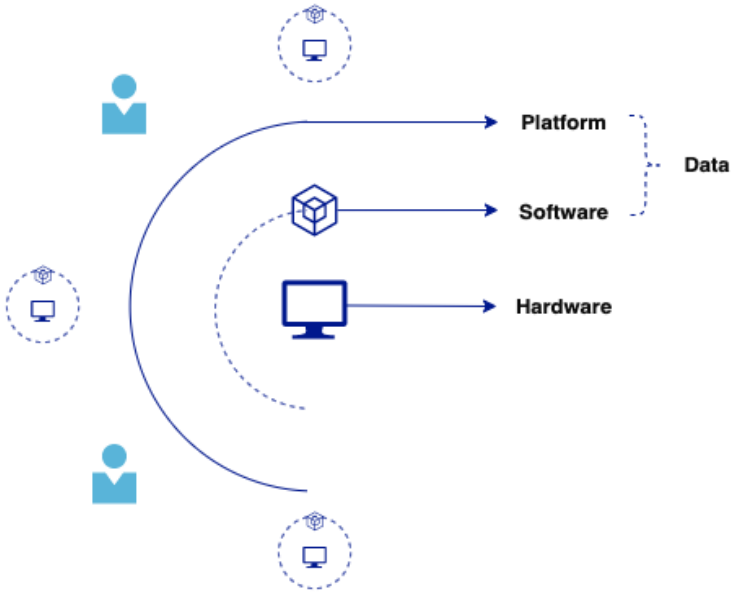
Introduction

Overview

A circular economy is a system that has been evolving in theory and practice for decades, with a core focus on minimizing waste and reprocessing products in a closed-loop system [1-4]. Grounded in a circular economy, a circular business model follows the same core fundament by emphasizing the creation and capture of value [2,5]. Businesses in resource-intensive industries, such as health care, can find a lot of value in implementing circular business models for their products to decrease their environmental footprints and become more resource efficient. Although circularity is not a mainstream model, several sectors have successfully started incorporating circular practices, especially in the utilities and consumer goods industries [6,7]. Yet with the advancement of circular models, health care seems to lag in the implementation of circular practices compared to other industries [8].

As global technological advancement continues, the health care industry has witnessed a surge in the adoption of digital health solutions across hospitals, health care professionals, and patients [9]. Given the increased production and use of digital health solutions, they have become a good use case for circular business models and could serve as a pivotal tool for reshaping the health care supply chain and business models. These intricate products are resource-intensive, comprising diverse materials such as metals, plastics, glass, and electronic components, all handled in the current linear waste management system. A waste management system refers to a strategy for how companies dispose of, reduce, and reuse waste [10,11]. Waste management in health care is often complex, especially in hospitals, with multiple streams of high volumes of waste generated daily [10-12]. Although several studies have delved into incorporating circular practices in hospital or home care waste management systems [10,11], research on a broader system-level viewpoint incorporating the supply chain, its stakeholders, and their interconnectedness is lacking [13]. Therefore, the main focus of this review will not be the patient but rather the system and its stakeholders. Nevertheless, as patient focus is at the core of all health care operations, this should be done while acknowledging and considering the role and importance of the patient in it.



The current literature landscape's lack of consensus on how to develop a circular business model in health care does not arise due to disagreements on how circular waste management should be introduced but rather stems from a lack of knowledge and research on the topic. This conundrum could hint toward current circular business model solutions being too generalized and not considering the specificities of the health care industry and digital health to be implemented. Circularity must thus be implemented on a product- or industry-specific level to succeed [7].

For instance, 2 crucial characteristics of digital health solutions would make the implementation of a generic circular model fail. First, the term digital health "solution" is used on purpose instead of "device" because the product not only contains hardware but also software and data components (Figure 1). Apart from the circular practices of the solution's hardware, we must also consider the waste of data, both in terms of the climate impact data storage has through embedded CO_2 emissions due to electricity use and the continuous use as well as the repurposing of data. Even within digital health solutions, a distinction must also be made between the different types of life cycles the solutions have due to their varying use. Some digital health solutions never leave the hospital, in which case it can be easier to control their reprocessing, while other solutions are owned by the patients, which can leave uncertainties on take-back schemes in a circular business model. Second, the contamination risk of medical solutions adds an additional layer of regulatory and operational complexity that also must be considered in the operations of the circular model. You need to ensure the product does not spread or contain harmful elements impacting human health and the environment. The motivation behind developing an industry-specific model forms the purpose of this scoping review: to theoretically develop a framework that businesses can take as a standpoint [7]. This fills the call for research combining circularity and digital health in health care and bridging the research gaps by merging the concepts.

To develop concepts for tailored circular business models for digital health solutions, this scoping review examines existing circular models in the health care industry and of other similar products in other industries. To make the analysis concrete, 4 product categories will be used as examples: medical packaging (ePaper label), health monitoring devices (smart wearable sensor), medication management (smart pill box), and surgical equipment (endo-cutter). These 4 products are representative of medical versus nonmedical, as well as single-use versus recurrent-use products.

RenderX

Figure 1. Illustration of components in a digital health solution.

Unit of Analysis

The unit of analysis in the scoping review is the circular business model. This is due to it being the core concept that motivates and justifies the performance of the study. The units of analysis can be broken down into circular and business models. Circularity will be defined through the concept of the 4 R's (recycle, reuse, reduce, and remanufacture) and the MacArthur butterfly model [2] and hence refers to the concept of creating a closed-loop system where resources are remanufactured, reused, and recycled instead of being disposed of after use. The 4 R's and the butterfly model both emphasize the importance of reducing waste and creating a circular economy. The second part of the unit of analysis, the business model, is a framework that describes how an organization creates, delivers, and captures value [14]. It is a conceptual tool that helps businesses articulate and communicate their strategy, operations, and revenue models in a concise and structured manner [5,14].

Theoretical Boundaries

A set of theoretical boundaries will guide the scoping review. First, as the research on circular business models in health care is limited, the search does not solely focus on the health care industry but also related industries such as wellness. To avoid a scope that is too broad, it is important to narrow down the types of solutions to be examined and only include products that have similar components (Figure 1) or business models to a digital health solution. The study will therefore include specific types of products that contain hardware, software, or data and preferably are part of a highly regulated industry. Second, the study will not only take into account traditional business model factors such as revenue stream and value proposition but also the environmental and societal impact of the circular model being examined. This would involve a comprehensive analysis of the economic, environmental, and social benefits and costs of the circular model being proposed or implemented, as well as any potential trade-offs that may arise.

Relevance

The scoping review will provide valuable information for future research in the circular economy as well as within the European Union (EU)–funded Digital Health in Circular Economy (DiCE) project and the stakeholders involved [15]. The adoption of circular economy principles by businesses developing digital health solutions has the potential to align with the United Nations' Sustainable Development Goals (SDGs) [16]. The scoping review addresses SDG 3 on good health and well-being and SDG 9 on industry, innovation, and infrastructure [16]. Furthermore, the circular economy can also support economic growth and job creation. Lastly, the research is also relevant to SDG 12, as part of the business model comes from the value of returned materials, both in economic terms and in more environmental settings, to avoid depleting scarce resources [15].

Methods

Overview

The scoping review will follow a systematic framework and best practices developed by Arksey and O'Malley [17], Durach et al [18], and the Joanna Briggs Institute scoping review manual [19]. To establish guidelines for the data collection, the protocol is outlined below before conducting the review. The process and data collection will be structured around the following steps: identify the research question, determine the required characteristics of relevant studies, search strategy, study selection, synthesize the literature, and report the results.

Identify the Research Question

The scoping review and its research question will be built around the unit of analysis and on the defined research boundaries listed. As the research question has an exploratory objective as well as an evaluation perspective on current circular business models, the following research question has been formulated: "How can circular business models be adapted and remodeled to digital health solutions?"

XSL•FO
RenderX

The research question will synthesize the literature on circular business models with a health care–oriented lens. To support the research question, a set of subquestions has been created to guide the analysis.

1. What are the barriers and enablers of implementing circular economy practices in the digital health market, and how can they be addressed? (This question will enlighten why traditional circular practices do not apply to the digital health market and where the existing models should be adapted.)
2. How are value and cost both negatively and positively redistributed in implementing a circular business model and impacting its key targets and performance indicators? (This question will discover how the business model of the solutions will change in terms of value. Value can be seen as financial, epistemic, ethical, service, and reputation.)
3. How would operating systems and data gathered by the solutions be affected positively or negatively by circularity? (This question focuses specifically on the software and data management parts of the solutions to ensure circularity is not only observed from the hardware perspective.)

Determine the Required Characteristics of Relevant Studies

To identify a relevant set of studies, the following inclusion and exclusion criteria (Textbox 1) have been chosen.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Studies focusing on one or more of the components in the solutions being hardware, software, and data
- Studies including health care or related industries such as fitness and wellness
- Studies including one or several stakeholders in a circular business model
- Studies illustrating environmental or societal impact by implementing circular business models

Exclusion criteria

- Studies that do not focus on economical, societal, or consumer outcome
- Studies published before the year 2010 [4,20]
- Non–peer-reviewed articles
- Editorials and commentaries
- Non-English studies

Search Strategy

In the literature search, 2 search strategies will be implemented: keyword search and snowball search. The keyword search will be performed in Scopus and Web of Science. Furthermore, a separate cross-checking search in PubMed has been done to ensure the databases include studies within the industry of interest, health care. Scopus and Web of Science have been chosen for several reasons. First, they both cover interdisciplinary results, thus fitting the scope of the scoping review into circularity, business model, and health care. Second, the databases have similar search functions, making the standard search protocol easier to follow without too much adaptation from one database to another. Third, they are some of the biggest databases and have a broad reach. Following the research protocol, a set of search criteria and search strategies have been applied when searching in the mentioned databases.

The snowball search will be performed by screening the reference list of selected studies and their references. The dual search approach will help ensure a more comprehensive scoping review and provide a complete understanding of the topic. The keywords have been chosen by testing the number of hits for each keyword and using the snowball search technique to choose relevant keywords.

A total of 3 search queries have been created to enlighten the different layers of the research question (Table 1). One topic is the life cycle and supply chain of digital health solution. No relevant results appeared when searching for explicit terms of digital health. Therefore, the first search has a broader level and focuses on products in health care, wellness, fitness, or medicine and will be manually sorted based on whether they are or resemble digital health solutions. The second and third topics are the solution's individual components, which are hardware, software, and data.

XSL•FO
RenderX

Table 1. Search queries.

Topic	Search query
Circular economy and processes	AB= (circul* OR “closed loop” OR “waste management” OR “Waste disposal”) AND AB= (“Business model*” OR “Operation*” OR “Value creation*” OR strateg*) AND AB= (“Supply chain*” OR “supply network” OR “process” OR “value chain” OR “life cycle” OR Logistic*) AND AB=(Healthcare OR Wellness OR fitness OR Medical))
Circular economy and hardware	((((AB=(circul* OR “losed loop” OR “waste management” OR “Waste disposal”)) AND AB=(“Business model*” OR “Operation*” OR “Value creation*” OR strateg*)) AND AB=(“Supply chain*” OR “supply network” OR “process” OR “value chain” OR “life cycle” OR Logistic*)) AND AB=(metal* OR plastic* OR e-waste OR “electronic waste” OR ceramics OR polymers OR glass OR composite))
Circular economy, data, and software	AB= (circul* OR “closed loop” OR “waste management” OR “Waste disposal” OR green OR sustain*) AND AB= (“Business model*” OR “Operation*” OR “Value creation*” OR strateg*) AND AB=(“Supply chain*” OR “supply network” OR “process” OR “value chain” OR “life cycle” OR Logistic*)) AND AB= (“information” OR data) AND (tech* OR platform OR Software OR system OR program*)

Study Selection

In the study selection, all duplication of records is removed before a screening of the topic is performed. Furthermore, the inclusion and exclusion criteria will be used to reduce the final selection of studies. The results from the keyword search will be manually screened by 2 independent researchers to be able to compare and discuss the final study selection. The tool Rayyan (Qatar Computing Research Institute) will be used for this procedure. This method ensures the screening is less biased by the researchers’ different fields of expertise. In the data extraction process, the data will be inserted into the reference manager Zotero (Corporation for Digital Scholarship).

Both empirical qualitative and quantitative studies, as well as literature reviews, conceptual pieces, and modeling research, will be considered to enlighten the topic from different methodological perspectives. Table 2 has been created to guide the study selection.

Table 2. Patient or population, intervention, comparison, and outcomes (PICO) model.

Criteria	Description
Unit of analysis	Users of digital medical solutions or users of similar products
Intervention	Noninterventional study. The study will observe business models of a digital health solution.
Comparison	Circular versus linear business models[a]
Outcome	Positive and negative outcome are accepted

[a]Linear model refers to a “take-make-dispose” operational practice [21].

Synthesize the Literature and Report the Results

The selected studies will be coded through an emerging and a priori coding structure to find relevant relationships between variables. With a priori code, we mean predetermined categories will be screened for when reporting the results. It will in addition extract relevant details on the studies such as title, author, publication details, and methods.

The results will be analyzed and summarized through a statistical view in tables and graphs as well as a narrative method. An evidence map will be created, with the set of categories that have been chosen below to categorize the data and find similarities and differences among the results to discuss (Table 3). The categories have been chosen to cover circular elements, characteristics of the unit of analysis, description of their business model, and their added value. At last, the results will be presented through both a descriptive analysis and a thematic analysis.

In addition to the categories chosen in the evidence map, the 3 levels, micro, meso, and macro, will be the structure of the discussion and help find the current research gaps in the literature.

XSL•FO
RenderX

Table 3. Evidence map categories described.

Categories and types	Description
Circularity industry focus	
General perspective	Circularity of any relevant product or process
Health care perspective	Circularity within the health care industry and its products
Level of circular adoption	
Micro	Product and single firm level
Meso	Network of firms
Macro	Regional, national, or European Union level
Butterfly model	
Technical cycles	Nonbiodegradable materials such as metals. The main strategy is maintaining or reusing the materials
Biological cycles	Biodegradable materials such as biodegradable plastic
4 R's	
Recycle	Collecting and processing materials into a new product instead of throwing them away
Reuse	Finding new ways to use products and materials to extend their life span and reduce waste
Reduce	Minimizing the use of resources, product, and packaging
Remanufacture	Rebuild or restore a product
Governance of the device	
Owned by consumer	The consumer has full ownership of the product and the use or disposal of it
Owned by intermediaries such as HCPs[a] or hospitals	The organizations buy the product from the manufacturer and use it or lease or lend out the product for a certain period of time to the consumer
Owned by manufacturer	The manufacturer lends or leases out products to HCPs or patients
Not applicable	Governance of product not specified
Value creation for stakeholders	
Manufacturer	A company that produces and sells the product
Consumer	The end-client or patient actively using the products
Government	Regulating and overseeing health care policies and practices
Intermediaries such as HCPs or hospitals	Organizations that operate between the manufacturers and end consumers
Value impacts	
Societal	Actions or events that are harmful or beneficial on the society
Economical	Actions or events that lead to a decline or growth in economic prosperity
Environmental	Actions or events harmful or beneficial to natural environment
Digital health solutions	
Single-use devices	Devices that are used a single time and thereafter obsolete, such as syringes, needles, etc
Imaging	Devices with the purpose of creating scanning or images of patients' body parts such as ultrasounds
Medical equipment	Devices used to monitor patients such as a wearable
Software	A computer system often used in collaboration with hardware, and can be used for diagnosing, monitoring, storing data, etc
In vitro diagnostics	Products used that come in contact with human tissue such as a glucose meter
Personal protective equipment	Worn by medical staff or used by patients as masks, gowns, and gloves
Surgical and laboratory instruments	Devices used in surgeries such as endocutters and endoscopes

[a]HCP: health care professional.

XSL•FO
RenderX

Ethical Considerations

This scoping review does not require ethical approval as it solely uses published articles with no research involving humans, medical records, patient information, or observations of public behaviors. Therefore, the term “not applicable” applies. Any deviations from this protocol will be disclosed in the following scoping review publication. Additionally, the outcomes will be disseminated in the research community, such as through conference participation.

Results

Overview

A preliminary description of the results has been performed. The results have been ranked according to the hierarchy of evidence to assess how likely they are to incorporate a systematic bias. There are 7/26 (27%) systematic reviews, 18/26 (69%) controlled studies, and 1/26 (4%) expert opinion. The results are well distributed among the 3 levels that will be analyzed: micro (8/26, 31%), meso (10/26, 38%), and macro (8/26, 31%). The reporting of results is divided into the unit of analysis, the circular business models, and the type of product analyzed in the studies.

Unit of Analysis

Circular Economy

Most studies incorporate 2 or more R’s in their analysis (18/26, 69%). Reuse (18/26, 69%), recycle (17/26, 65%), and reduce (15/26, 58%) are covered in most studies, with remanufacture being the least covered (8/26, 31%).

Business Models

Most studies focused on a stand-alone value proposition (18/26, 69%). Product as a service is mentioned in 27% (7/26) of the results. The main stakeholders covered by the studies are health care professionals or hospitals (20/26, 77%), manufacturers (11/26, 42%), and consumers (9/26, 35%).

Type of Product

The majority (17/26, 65%) of the studies have a product-specific focus, and 9/26 (35%) studies have a system-oriented focus. Out of the 17 studies that focus on a product, most of these are single-use devices (5/26, 19%) and medicine (5/26, 19%).

A more in-depth report of the results will be performed.

Discussion

Preliminary Findings

The review outlined will serve to understand and offer insights into the factors that influence the adoption of circular business models in health care. The findings within the micro level are expected to shed light on the product design and principles to design after. The findings within the meso level will focus on the role of stakeholders, the set of skills they must have, and key factors when collaborating. At last, the macro level will adopt broader legislation and guideline perspectives on the circular economy within health care at the national and EU levels. The findings from the review will be disseminated through a peer-reviewed scientific journal and conference presentations.

Limitations

A total of 2 main limitations have been identified. First, as the review’s macro level focuses partially on EU legislation, there may be an overrepresentation of European studies, and the review might oversee interesting legislative initiatives in a global context. Second, in the literature search, the review only focuses on studies from 2010 onward. Therefore, older, important articles might be missed and not included in the review, which the readers should be aware of.

Conclusion

The conclusion and outcome of the review will show that a circular business model for digital health solutions will be very specific to what kind of product it is. This will in the future require manufacturers to have a clear end-of-life management plan for their product and incorporate a layered value proposition. Furthermore, to make the value proposition and end-of-life management of the products successful, the review implies they must engage in an ecosystem with several actors to close the circular loop.

Acknowledgments

CR holds funding for a PhD through the IT University of Copenhagen. We acknowledge the financial support of the European Research Executive Agency under the powers delegated by the European Commission for the Digital Health in Circular Economy (DiCE) project (101060184) [15].

Data Availability

All data generated or analyzed during this study are included in this published paper (and its supplementary information files).

Authors' Contributions

CR and DF conceived the study, and CR wrote the first draft. AM, CL, AW, AS, and PL have commented on and approved the contents.

Abstract

Background: The epidemiology, morbidity, and burden of disease related to airway sequelae associated with invasive mechanical ventilation in the context of the COVID-19 pandemic remain unclear.

Objective: This scoping review aims to summarize the current knowledge regarding airway sequelae after severe SARS-CoV-2 infection. This knowledge will help guide research endeavors and decision-making in clinical practice.

Methods: This scoping review will include participants of all genders, and no particular age group who developed post–COVID-19 airway-related complication will be excluded. No exclusion criteria will be applied from country, language, or document type. The information source will include analytical observational studies. Unpublished data will not be completely covered as gray literature will be covered. A total of 2 independent reviewers will participate in the process of screening, selection, and data extraction, and the whole process will be performed blindly. Conflict between the reviewers will be solved through discussion and an additional reviewer. The results will be reported by using descriptive statistics, and information will be displayed on RedCap (Research Electronic Data Capture).

Results: The literature search was conducted in May 2022 in the following databases: PubMed, Embase, SCOPUS, Cochrane Library, as well as LILACS and gray literature to identify observational studies; a total of 738 results were retrieved. The scoping review will be finished by March 2023.

Conclusions: This scoping review will describe current knowledge on the most frequently encountered laryngeal or tracheal sequelae in patients exposed to mechanical ventilation due to SARS-CoV-2 infection. This scoping review will find the incidence of airway sequelae post COVID-19 and the most common sequelae such as airway granuloma, vocal fold paralysis, and airway stenoses. Future studies should evaluate the incidence of these disorders.

International Registered Report Identifier (IRRID): DERR1-10.2196/41811

(JMIR Res Protoc 2023;12:e41811) doi:10.2196/41811

KEYWORDS

airway; sequelae; COVID-19; mechanical ventilation; SARS-CoV-2; scoping review; pulmonary; mortality; voice production; health care cost; health intervention

Introduction

Airway sequelae can be due to several etiologies and cause disability by problems related to breathing, deglutition, and voice production [1-3]. Since the early decades of the twentieth century, when orotracheal intubation (OTI) became popular in clinical practice, the most frequent etiology of airway sequelae is iatrogenic and secondary to invasive mechanical ventilation

XSL•FO
RenderX

(IMV) [1]. The duration of IMV not only positively correlates with the probability of developing airway sequelae but also with severity [2,3]. These sequelae include the need for alternative airway (ie, tracheostomy), and the development of cicatricial lesions. For instance, according to Johnson et al [4], in the United States for 2016, the nationwide estimated incidence of laryngotracheal stenosis at 45 days from discharge among patients exposed to IMV was 1.98 cases per 1000 discharges. Current knowledge on airway sequelae in SARS-CoV-2 infection survivors exposed to IMV is limited. A preliminary search of PROSPERO, MEDLINE, the Cochrane Database of Systematic Reviews, and Joanna Briggs Institute (JBI) Evidence Synthesis was conducted, and no current or in-progress scoping reviews or systematic reviews on the topic were identified.

The COVID-19 pandemic has imposed great challenges to humanity, representing the most important public health concern in recent times. Although most people recover from SARS-CoV-2 infection, many are left with sequelae [5]. Every COVID-19–related death could result in 5 quality-adjusted life-years lost, and at least 30% of the burden of the disease could be attributable to disability [6]. While the economic impact of adult laryngotracheal stenosis has been described [7], it remains unclear in the setting of the COVID-19 pandemic. A survey on 488 patients at day 60 after discharge from 38 hospitals in Michigan [8] found that 188 (38.5%) did not return to normal activities, 45 (9.2%) did not return to work due to health issues, 75 (15.4%) reported persistent cough, 193 (39.5%) reported dyspnea, 34 (7%) used continuous positive airway pressure, and 32 (6.6%) required supplementary oxygen. Although the authors did not discuss the possibility of airway sequelae in some of the surveyed patients, their findings may raise concerns about that possibility.

The pathophysiology of airway lesions associated with IMV is believed to involve processes ranging from the initial insult (ie, the exerted pressure by the endotracheal tube pressure on the respiratory mucosa, traumatic intubation, etc) causing tissue damage, through the mechanisms of repair (ie, inflammation, scarring, keloid formation, etc) [9]. Several risk factors for developing airway sequelae associated with IMV have been recognized [4,10-13], many related to pathophysiological processes. These can be categorized into sociodemographic characteristics, comorbidities, medications, and other variables related to the intubation-extubation process. Interestingly, there is some evidence that SAR-CoV-2 may have direct effects on the airway mucosa, such as cytopathic insult [14-17]. Perhaps, airway sequelae could develop in SARS-CoV-2 infection survivors exposed to noninvasive mechanical ventilation.

The proportion of patients with COVID-19 requiring IMV varies across different reports. In the HIFLO clinical trial, 18.7% of the 652 confirmed severe cases required IMV [18]. A study from Seattle, WA, reported that 75% of 24 patients with respiratory failure required IMV [19]. Other authors from China reported that 47.2% of 36 intensive care unit–admitted patients required IMV [20]. Another study from New York analyzed 2634 hospitalized patients, from which 12.2% required IMV [21]. One Italian study describes that 88% of 1300 intensive care unit patients required IMV [22]. Although the proportion of patients requiring IMV is not described, other Chinese researchers reported 44,415 cases, from which 14% were severe and 5% critical [23]. In a prospective cohort of 1357 confirmed patients with COVID-19 from Brazil [24], 421 (31%) required IMV, and from these, only 172 (40.9%) survived and were discharged. From those who survived, 95 (55.2%) were followed by video endoscopy at approximately day 100 after extubation; 38 of these patients presented laryngotracheal lesions, resulting in an incidence of 40%, with 6.3% of the cases being severe. The authors suggest that major risk factors for developing laryngotracheal lesions after surviving IMV for severe COVID-19 include larger endotracheal tubes, prone position, duration of intubation, increased leucocyte count, and coagulopathy as determined by elevated D-dimer or PT/INR [25,26]. In addition, widely used pronation maneuvers may increase the chance of laryngotracheal trauma as higher endotracheal pressure may be required, increasing the chances of airway trauma [27].

In patients with prolonged IMV (>96 h) [28], since prepandemic times, early tracheostomy (at days 7-14 after OTI) was widely accepted to be associated with better clinical outcomes, including lower complication rates, such as airway sequelae, among others [29]. However, COVID-19 guidelines recommend waiting for this procedure to avoid SARS-CoV-2 spread among health care workers, resulting in prolonged IMV up to 4 weeks [15]. In a preliminary report on clinical outcomes in 543 patients with post–COVID-19 tracheostomy from the United Kingdom, by November 2020, the number of days between OTI and tracheostomy ranged between 0 and 35 (median 16, IQR 13-22) [16]. Early on in the pandemic in Italy, the world was alerted to expect a surge in the incidence of airway sequelae because of the overwhelming number of critical patients who would be exposed to prolonged IMV [17].

The epidemiology, morbidity, characteristics, and burden of the disease related to airway sequelae associated with mechanical ventilation in the context of the COVID-19 pandemic remain unclear. The purpose of this study is to perform a scoping review based on a systematic literature review to summarize current knowledge regarding these conditions. Putting in perspective this knowledge will help guiding research endeavors and decision-making in clinical practice.

Methods

The proposed scoping review will be conducted in accordance with the JBI methodology for scoping reviews [30].

Review Questions

The research questions for this study are as follows:

- What is the current state of knowledge on airway sequelae in patients after mechanical ventilation for severe COVID-19?
- What is the epidemiology?
- What are the most common features of the lesions?
- What is the most common approach to treatment?
- What are the knowledge gaps and future insights?

XSL•FO
RenderX

Eligibility Criteria

Participants

This review will consider studies of any design reporting airway sequelae encountered in patients of both sexes and all ages who survived after exposure to mechanical ventilation in the context of an infection with the SARS-CoV-2. Studies describing patients exposed to both invasive and noninvasive mechanical ventilation will be considered.

Inclusion Criteria

The following studies will be selected for this review:

- Studies including patients with airway sequelae after SARS-CoV-2 infection describing frequency, clinical features, and complications.
- Studies providing information about the effects and extent of complication in airways after mild, moderate, and severe SARS-CoV-2 infection.
- Studies providing information about the medical management of patients with airway sequelae after SARS-CoV-2 infection.

Exclusion Criteria

The exclusion criteria were as follows:

- Lack of full-text availability.
- Manuscripts describing an airway sequela before the COVID-19 pandemic.
- Review, state of the art article, comments, or expert opinions were not considered in this scoping review.
- Other SARS-CoV-2 infection sequelae, which do not include the airway, were not considered for the present scoping.

Concept

Airway sequelae developed after exposure to mechanical ventilation as part of the treatment for SARS-CoV-2 infection. These conditions may include the need for an alternative airway (ie, trachestomy) and cicatricial lesions, such as fistulae, granulomas, synechiae, malaciae, and other causes of stenosis, among others. This scoping review will include patients with early airway intervention after discharge and minor surgical interventions to address early post-tracheostomy complications and long-term sequelae for this group of patients with and without intervention. Finally, the scoping review will not be limited by the time frame of the airway complication after the SARS-CoV-2 infection.

Context

This review will consider studies that were published in the context of the COVID-19 pandemic. The scoping review would not be limited by language, but it will focus on the COVID-19 pandemic time frame from early 2020 to 2023.

Types of Sources

The scoping review will include any source of scientific evidence. It may be quasi-experimental and observational in nature. It will not discriminate among quantitative, qualitative, and mixed methods study designs. In addition, systematic reviews as well as text and opinion papers will be considered for inclusion in the proposed scoping review.

The proposed scoping review will be conducted in accordance with the JBI methodology for scoping reviews [31] and in line with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) [32].

Search Strategy

The search strategy is intended to locate published scientific studies that meet the inclusion criteria. A preliminary search was performed by a librarian on May 17, 2022. An initial search of Ovid MEDLINE identified the following keywords and index terms: covid-19, SARS-CoV-2, long COVID, coronavirus disease 2019, post-acute covid, covid sequelae, sequelae, and airway. Using these keywords and index terms, a second search on Ovid MEDLINE, PubMed, Scopus (Elsevier), Embase, Cochrane Library, Web of Science, LILACS, and gray literature resulted in 738 article references. A detailed search strategy is provided in Multimedia Appendix 1.

The search strategy included all identified keywords and index terms. All the key terms were adapted for each included database and information source. Search terms will be created by the entire team of reviewers, though the search will be conducted by 1 person. The reference list of all included sources of evidence will be screened for additional studies. Studies published in any language will be included.

Study or Source of Evidence Selection

The 738 article references were collated and uploaded to EndNote 20 (Clarivate Analytics), and 255 duplicates were removed. This resulted in a total of 483 references. Titles and abstracts will be screened by 2 independent researchers. Potentially relevant papers will be retrieved in full, and their citation details imported into the JBI System for the Unified Management, Assessment, and Review of Information. Articles published in languages different from English or Spanish will be initially translated through Google Translate, and, if deemed to meet the inclusion criteria, the full text will be professionally translated.

The full text of selected citations will be assessed in detail against the inclusion criteria by the same 2 independent researchers. Reasons for exclusion of full-text papers that do not meet the inclusion criteria will be recorded and reported in the scoping review. Any disagreements that arise between the researchers at each stage of the selection process will be resolved through discussion or with a third researcher. The results of the search will be reported in full in the final scoping review and presented in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [33].

Data Extraction

Data will be extracted from papers included in the scoping review by 2 independent researchers using a spreadsheet to include the following variables: title, authors, year of publication, origin or country of origin (where the source was published or conducted), aims or purpose, population and sample size within the source of evidence (if applicable), methodology

XSL•FO
RenderX

or methods, intervention type, comparator and their details (eg, duration of the intervention; if applicable), duration of the intervention (if applicable), outcomes and their details (eg, how measured; if applicable), and key findings that relate to the scoping review questions.

The draft spreadsheet will be modified and revised as necessary during the process of extracting data from each included paper. Modifications will be detailed in the full scoping review. Any disagreements that arise between the researchers will be resolved through discussion or with a third researcher. Authors of papers will be contacted to request missing or additional data, where required.

Data Analysis and Presentation

A narrative description of the findings will be discussed in the framework of the review questions. The data will be summarized and presented in tables.

Reference Searches

Citation tracking criteria will be used to identify important articles relevant to the topic of interest; this will also be done by using the reference list of a paper or citations of a paper by other articles to identify additional manuscripts relevant to the topic of the study, as it was previously mentioned by Diaz-Ordoñez et al [34]. Following that, papers from the list that have already been examined will be removed. If a paper meets the inclusion criteria, potential new manuscripts will be identified by checking the reference list of the included paper [35].

Results

The search was performed on May 17, 2022, in MEDLINE, LILACS, the Cochrane Library, ScienceDirect, and OpenGrey; a total of 214 results were retrieved. Complete review of the manuscripts is expected in August 2022. All potential manuscripts will be imported into the reference management software Rayyan QCRI 23 [36]. The results of this scoping review will identify and describe the epidemiology, clinical characteristics, classification, and management of upper airway sequelae after SARS-CoV-2 infection.

Discussion

Airway sequelae due to SARS-CoV-2 infection are described in most observational studies, most from the United States and Europe. The compromise of the upper airway was related to mechanisms to prevent the spread of the virus; as these interventions increased, the lesions became more severe. In the following years, the pressure over climate change increases the cross-species transmission of their associated viruses an estimated 4000 times [37], which may increase the chance of pandemics such as COVID-19. For this reason, all the lessons learned about it should change how the following epidemics will be addressed. For example, developing more efficient strategies with the help of technology or artificial intelligence to contain the respiratory virus would decrease the sequelae among patients and the related cost.

At the beginning of the pandemic, interventions began not only thinking about the well-being and recovery of patients but also about avoiding the transmission of the virus to health personnel. However, the involvement of the upper airway was related to the mechanisms used to prevent the spread of the virus [38]; as these interventions increased, injuries became more prevalent and more severe [17]. These sequelae are complications that, given the high need to perform the causal procedures, are a problem that will increase in the coming years. Otorhinolaryngologists and head and neck surgeons should know them in depth to make a diagnosis and timely treatment to reduce the high disease burden of affected patients evidenced in our review. Airway sequelae due to SARS-CoV-2 infection are described in most observational studies, most from the United States and Europe. The compromise of the upper airway was related to mechanisms to prevent the spread of the virus; as these interventions increased, the lesions became more severe.

Some of the frequent airway sequelae documented in the literature include the development of tracheal and laryngotracheal stenosis after prolonged intubation and subsequent tracheostomy [14,39,40]. Other articles reported aerodigestive complications, which include vocal fold paralysis and paresis, muscle tension dysfunction, laryngotracheal hypersensitivity, and laryngopharyngeal reflux [41]. Allisan-Arrighi et al [41] reported a broad spectrum of respiratory, swallowing, and voice difficulties, which cause distress in patients recovering from COVID-19 infection. The sequelae included structural and anatomic inflammatory changes of the upper airway trachea with the following frequency: 16.13% for tracheal stenosis, 16.13% arytenoid ankylosis, and 16.13% posterior subglottic stenosis [41]. In other articles, authors report airway granulomas as a frequent complication of severe COVID-19 infection [42]. In addition, Guarnieri et al [43] reported a high incidence of tracheomalacia after tracheostomy in patients with severe SARS-CoV-2 infection, as the tracheostomized patient had a longer intensive care unit and hospital stay [43]. In their study, Guarnieri et al [43] showed a 5% incidence of tracheomalacia, which is 10 times higher than the reported literature [43].

In the following years, the environmental and physiological stress to which the animals are subjected translates into an alteration in their immune system that provides greater susceptibility not only to being hosts of the microorganism but also to promoting its replication and therefore increasing the risk of a zoonotic overflow [44]. Environmental issues may be associated with pandemic occurrence [44]. For this reason, all the lessons learned in this regard should change how the following epidemics will be addressed; for example, by developing more efficient strategies [45] and artificial intelligence to contain the respiratory virus. These strategies would decrease the sequelae between patients and the high cost. Patients with pre-existing airway disease are thought to be at a higher risk of developing severe outcomes from acute COVID-19 [46]. Most of the evidence reports these effects on lower airways, and the effects on upper airways may start to be reported in the next few years.

This study has several limitations, including the following: a summary of results that would not reflect the entirety of the

XSL•FO
RenderX

literature available needs to be included. Additionally, the scoping review does not consider the risk of bias assessment [47]. For that reason, some included studies may incur bias. In our case, the data synthesis needs to address the weight of the evidence. We performed a narrative summary of the results and a descriptive form of the quantitative data. Finally, the broad search would dilute some specific results essential to the main objective of the scoping review.

Authors' Contributions

EC conceived this study. EC, OAV, JTA, FQ, DFIP, WV, and LFT developed the study and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Competency-based education (CBE) for midwifery programs is a system of academic instruction and evaluation that aims to achieve proficiency in midwifery student learning outcomes, which is based on students' ability to demonstrate the knowledge, attitudes, self-perceptions, and skills of a predetermined set of educational activities in theory and practice. CBE focuses on ensuring that midwifery students can develop critical thinking abilities, values, and the clinical decision-making abilities needed for the delivery of safe care in future practice.

Objective: The objective of this scoping review is to map and synthesize existing literature on the implementation of CBE for midwifery programs and its sustainability in Africa.

Methods: We will use the Arksey and O'Malley approach for scoping reviews for the research methodology. The 3-stage search process, proposed by the Joanna Briggs Institute, will be used to determine the eligibility of published and unpublished studies. PubMed, Science Direct, Web of Science, CINAHL, PsycINFO, and Scopus will be searched to screen published articles. ProQuest Dissertations and Theses and Google Scholar will be used to search for unpublished studies. Findings will only apply to studies conducted in Africa from 2010 to the present year in English. The 2 reviewers will work independently to carefully screen and compare the full text of the selected citations to the inclusion criteria. In the event of any disagreements between the 2 reviewers at any stage of the selection process regarding the inclusion of an article, this will be settled by discussion or consultation with a third reviewer. The extracted data will be presented using a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Review) flow diagram with an attached narrative summary. The review will summarize and disseminate findings on the implementation of the CBE for midwifery programs and its sustainability in Africa.

Results: It is intended that this scoping review will be completed within 6 months following the publication of this protocol.

Conclusions: The conclusions from this scoping review will inform midwifery educators, institutions, policy makers, and other stakeholders on the strategies to implement and sustain CBE for midwifery programs in Africa.

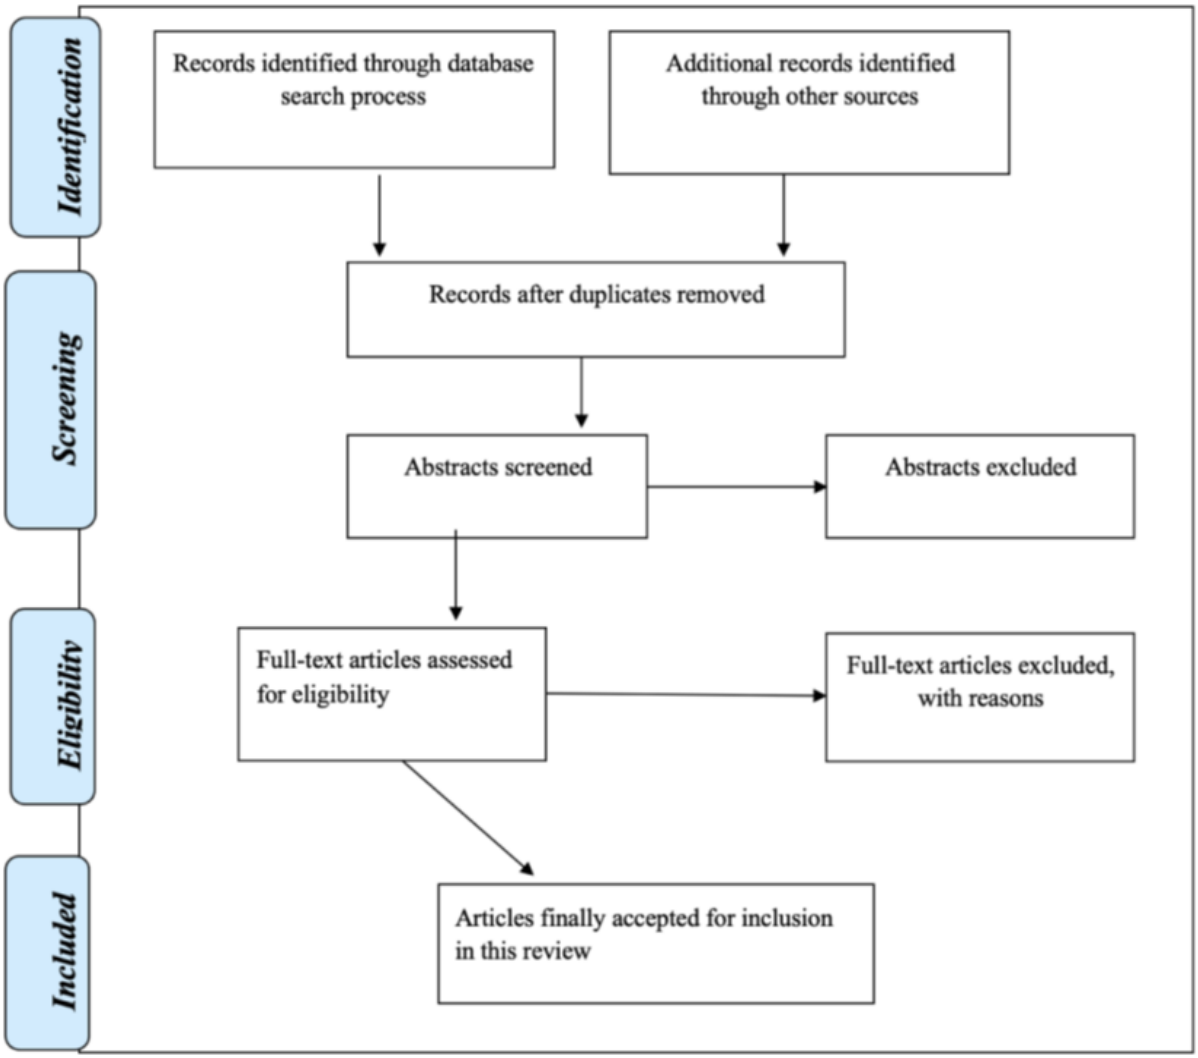
Introduction



The past few decades have witnessed a rapid and worldwide reform in traditional education toward competency-based education (CBE) at all levels and types of education [1,2]. The competency-based approach to education focuses on addressing positive educational outcomes that align with the needs and expectations of the workforce, employers, and the population they serve [3,4]. CBE places strong emphasis on learner-centered learning, which encourages better adaptability and accountability [5,6]. Through CBE, graduates can critically think, communicate effectively, and work collaboratively with others to provide solutions to problems [7]. This teaching and learning strategy differs from the traditional approach, which consists of time-based training, evidence of academic degrees, and the assessment of student progress based on lessons taught [8,9]. This paradigm shift evolved in an attempt to bridge the gap between students having completed their educational program yet still being unable to perform competently in the workplace or being inadequate to proceed to the next level of education [8,10], despite the immeasurable efforts, time, and resources invested in this traditional education without achieving positive outcomes [10].

The World Health Organization (WHO) and the International Confederation of Midwives (ICM) also adopted this educational trend in the education of midwives and other health professionals by using the term "core competencies" [11,12]. Core competencies, also known as essential competencies, are a set standard for preparing the health workforce to be current and responsive to dramatic health advances geared to meeting clients' expectations [13,14]. The midwifery set of competencies was created and published by the ICM in 2002 [15]. Since then, the competencies have undergone reviews and updates based on scientific evidence [16,17]. The updated competencies are arranged in a framework of 4 interconnected categories, including general competence, which applies to all aspects of a midwife's practice, and competencies that are particular to care throughout prepregnancy, antenatal care, labor, delivery, and the postpartum period [18]. These competencies represent the requirement for preservice education in midwifery and its intended outcomes [17]. CBE for the midwifery profession is, therefore, a system of academic instruction and evaluation that aims to achieve proficiency in midwifery student learning outcomes based on students' ability to demonstrate all the essential competencies for basic midwifery practice [18].

CBE aims at developing critical thinking abilities, values, and the clinical decision-making abilities needed by midwifery students for the delivery of safe care in future practice [10,14]. The design of CBE for teaching and learning activities should comply with standards by integrating knowledge, skills, values, and attitudes within each competency [19]. Midwife educators, midwifery regulatory bodies, midwifery institutions, and others involved in the development and implementation of preservice midwifery education are expected to adopt and adapt CBE to curricula [12,14,20]. However, reports on the integration of competency-based curricula and the approach to ensure sustainability are yet to be well documented, especially in Africa [14], whereas countries and institutions in which the CBE approach has been fully adopted have recorded positive outcomes in their education programs. Outcomes include, but are not limited to, producing competent and confident graduates and improved quality care for clients, contributing to improved family health [8,21-23]. Previous reviews on CBE in Africa focused on challenges regarding the implementation of CBE [24,25]. This review will, however, explore and synthesize existing literature on the implementation of CBE for midwifery programs and its sustainability in Africa.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Review) flow diagram showing the phases of the literature search and selection procedures of studies for the review.

Methods

Overview

The Arksey and O'Malley [26] approach for scoping reviews will be used for the research methodology. The Arksey and O'Malley [26] framework comprises the following steps: (1) identify the research question; (2) identify relevant studies; (3) perform study selection; (4) extract and chart the data; and (5) collate, summarize, and report the results. This framework will direct the scoping review methodology, and, if applicable, the protocol will adhere to the pertinent PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Review) guidelines [27].

Step 1: Identify the Research Question

The following research questions will guide this study:

1. What is the existing evidence on implementing CBE in midwifery education in Africa?

2. How has CBE for midwifery education been sustained in Africa?

Inclusion Criteria

The participants, concept, and context (PCC) framework will guide the inclusion of eligible studies in this scoping review [28].

Participants

Studies that include midwifery students, midwifery educators, midwives, obstetric nursing, obstetrics and gynecology nursing, and maternal and child health nursing relating to CBE will be included in this study, while studies on CBE relating to other health professions such as nursing, medicine, pharmacy, and allied health professions will be considered irrelevant to this study.

Concept

Studies that discuss the implementation of competency-based midwifery education in Africa will be considered in this scoping review. The concept of interest is competency-based curriculum and teaching and learning strategies used in theory and clinical practice. These strategies include the lecture method, demonstration, simulation, role play, etc. Competency-based

XSL•FO
RenderX

curriculum content includes the ICM competency framework, that is, prepregnancy, pregnancy, labor and childbirth, and the postpartum period.

Context

The context covers academic settings, including, but not limited to, schools, colleges, polytechnics, universities, and hospitals facilitating the teaching and learning of midwifery education programs. These settings where CBE is integrated into theory and practice will be considered in this review. Studies that relate to Africa, published from 2010 onward, will be considered.

Step 2: Identify Relevant Studies

The 3-stage search process proposed by Joanna Briggs Institute will be used to determine the eligibility of published and unpublished studies [29]. To develop a comprehensive search strategy, a preliminary limited search of PubMed and EBSCOhost will be performed to scrutinize text words found in the titles and abstracts, including any index keywords. Second, a second search across PubMed, EBSCOhost, Science Direct, and Scopus will be carried out using all specified keywords and index terms. Third, the reference lists of all accessed articles will be checked for additional studies and included, if considered eligible. Furthermore, ProQuest Dissertations and Theses and Google Scholar will be used to search for unpublished studies that would not have been easily accessed through conventional databases. Findings will only apply to studies conducted in Africa from 2010 to 2024, presented in English.

Step 3: Perform Study Selection

The aggregate citations found will be uploaded into EndNote (version 9; Clarivate Analytics) after the search, while duplicates will be deleted manually. Titles and abstracts will then be screened by 2 independent reviewers (WBI and OA) to assess eligibility using the PCC framework. The full text of potentially relevant articles that fulfill the eligibility requirements will be retrieved, and their citation information will be imported into Rayyan (Qatar Computing Research Institute). WBI and OA will work independently to carefully screen and compare the full text of the selected citations to the inclusion criteria. The reasons for the exclusion of the full text of articles not considered will be documented and reported in the scoping review. In the event of any disagreements at any stage of the selection process regarding the inclusion of an article between WBI and OA, this will be settled by discussion or consultation with WBN (the third reviewer). The final scoping review will include a narrative report on the search and study selection procedure and a diagrammatic presentation using a PRISMA-ScR flow diagram [27].

Step 4: Extract and Chart the Data

All eligible studies' data will be extracted and processed using data charting. A data charting table will be created using Excel (Microsoft Corp) to extract and chart relevant information. The team of reviewers will pilot the data charting form on 5-10 articles to ensure that vital information is completely extracted. All publications meeting the inclusion criteria will have their data extracted by 2 independent reviewers, and the data will then be validated by a third reviewer. The reviewers will independently draft and later compare the form for consistency, using the PCC framework of the review objectives and questions, and may also consider including emerging relevant variables that may arise during the process. These variables currently consist of (but are not limited to) the type of study, year, setting or context, aims, study population, research design, research techniques, and summary of findings. If applicable, this draft will be modified and revised.

Step 5: Collate, Summarize, and Report the Results

The aim of this study is to map existing evidence on the implementation of competency-based midwifery education across the various studies in Africa. The extracted data will be presented using a PRISMA-ScR flow diagram with an attached narrative summary. Descriptive statistical analysis (eg, frequencies) will initially be used to quantitatively summarize the extracted data. The reviewers will further analyze the data using a qualitative content analysis using the Graneheim and Lundman [30] approach to find new themes and present a narrative report and descriptive analysis of the studies included. This identified theme will be coded independently by the reviewers using NVivo software (version 12; QSR International) with reference to the variables mentioned earlier during the data extraction stage. To ensure validity and credibility, the team will discuss and cross-validate the findings, that is, the codes and emerging themes. The team will also address the implications for future research, clinical practice, and policy while critically evaluating the findings' significance to the study's primary objective.

Results

It is intended that this scoping review will be completed within 6 months following the publication of this protocol. The findings will be presented as outlined above.

Discussion

The purpose of this scoping review is to map and synthesize existing literature on the implementation of CBE for midwifery programs and its sustainability in Africa. The discussion of the findings will be contextualized based on previous studies on CBE for midwifery programs, its implementation, and the strategies used to sustain the implementation of CBE for midwifery programs in Africa. The scoping review is limited to midwifery education, which means other health care professionals' education will be excluded. The review is also limited to studies conducted in Africa in the English language. The findings of the review will be significant in identifying gaps in knowledge and research on this topic of interest. It is anticipated that understanding CBE for midwifery programs may contribute to strengthening midwifery education and advancing the standard of maternity care. The conclusions from this scoping review will inform midwifery educators, institutions, policy makers, and other stakeholders on the strategies required to implement and sustain CBE for midwifery programs in Africa. The results of this scoping review will be published in a reputable journal and presented at local and international conferences.

Abstract

Background: There are still unanswered questions regarding effective educational strategies to promote the transformation and articulation of clinical data while teaching and learning clinical reasoning. Additionally, understanding how this process can be analyzed and assessed is crucial, particularly considering the rapid growth of natural language processing in artificial intelligence.

Objective: The aim of this study is to map educational strategies to promote the transformation and articulation of clinical data among students and health care professionals and to explore the methods used to assess these individuals' transformation and articulation of clinical data.

Methods: This scoping review follows the Joanna Briggs Institute framework for scoping reviews and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist for the analysis. A literature search was performed in November 2022 using 5 databases: CINAHL (EBSCOhost), MEDLINE (Ovid), Embase (Ovid), PsycINFO (Ovid), and Web of Science (Clarivate). The protocol was registered on the Open Science Framework in November 2023. The scoping review will follow the 9-step framework proposed by Peters and colleagues of the Joanna Briggs Institute. A data extraction form has been developed using key themes from the research questions.

Results: After removing duplicates, the initial search yielded 6656 results, and study selection is underway. The extracted data will be qualitatively analyzed and presented in a diagrammatic or tabular form alongside a narrative summary. The review will be completed by February 2024.

Conclusions: By synthesizing the evidence on semantic transformation and articulation of clinical data during clinical reasoning education, this review aims to contribute to the refinement of educational strategies and assessment methods used in academic and continuing education programs. The insights gained from this review will help educators develop more effective semantic approaches for teaching or learning clinical reasoning, as opposed to fragmented, purely symptom-based or probabilistic approaches. Besides, the results may suggest some ways to address challenges related to the assessment of clinical reasoning and ensure that the assessment tasks accurately reflect learners' developing competencies and educational progress.

Introduction

Overview

Health care professional education has made significant progress in teaching clinical reasoning, a fundamental competency for professional practice. Clinical reasoning encompasses the cognitive and metacognitive processes necessary for clinical decision-making [1,2]. These processes enable health care professionals to understand the meaning of clinical data, make accurate decisions, and develop appropriate treatment plans [3,4]. Clinical reasoning is deeply intertwined with the context and environment in which it occurs rather than being disembodied from clinical situations [5].

Insufficiently developed clinical reasoning poses a risk of incidents or errors, which can negatively impact the quality and safety of care [6-8]. Therefore, promoting the development of clinical reasoning in both education and practice is crucial to ensure safe and effective care [2]. In that sense, many efforts have been made to develop different educational strategies aiming to foster the development of clinical reasoning (eg, case studies, concept mapping, simulation, and serious games) [9] and to assess competency (eg, scoring rubrics used during an objective structured clinical examination [OSCE] or a think-aloud exercise) [10]. However, the complexity lies in understanding how these educational strategies and assessment methods can stimulate or simulate the complex cognitive operations involved.

One such cognitive operation is transforming and articulating clinical data, where “raw” data from clinical situations are analyzed, transformed, and expressed using specific professional vocabulary [11]. Translating what students or health professionals hear, see, or perceive into specific professional vocabulary is essential for them to recognize the salient features of a situation and make connections between clinical data and professional knowledge [11]. This cognitive operation is vital in ensuring the consistency and efficiency of oral or written information exchanges between professionals, thus contributing to safe practice [12].

Despite its significance, there are still unanswered questions regarding effective educational strategies to promote the transformation and articulation of clinical data while teaching and learning clinical reasoning. While the analysis of the discourse of students or health care professionals can have a didactic value to promote learning or teaching of clinical reasoning and its assessment, the methods used to achieve this are less clear. In other words, what are the conceptual and methodological tools for analyzing the quality of health care professionals’ discourse? How can we ensure that educational choices are anchored in recognized theories of clinical reasoning to promote the development of professional knowledge structures? How other theories or approaches, particularly on language and health care professionals’ discourse, can support the learning or teaching and assessment of clinical reasoning?

Additionally, understanding how the cognitive process of transformation and articulation of clinical data can be analyzed and assessed is crucial, particularly considering the rapid growth of natural language processing (NLP) in artificial intelligence. NLP aims to develop machines capable of modeling and reproducing human language capabilities [13-16]. Applications of NLP include language translation aids, chatbots (eg, ChatGPT [OpenAI]), and voice-controlled technologies [13]. In clinical practice, for example, NLP can extract relevant information, categorize data, and identify patterns from large volumes of text in electronic health records. In education, NLP enables realistic interactions between students and simulated patients in training software.

Furthermore, challenges persist for educators’ assessment of clinical reasoning, in an educational context where machines attempt to replicate competencies such as clinical reasoning. These could support learning or, on other occasions, present threats to the validity or veracity of students’ cognitive efforts in the assigned tasks assigned to them. [17]. Assessment-related challenges include operationalizing the necessary validity and reliability standards and ensuring that the assessment tasks accurately reflect learners’ developing competencies and educational progress.

Thus, understanding how the teaching and learning of clinical reasoning align with learners’ NLP, specifically the transformation and articulation of clinical data, becomes crucial. Therefore, this scoping review protocol aims to map educational strategies to promote the transformation and articulation of clinical data among students and health care professionals. A secondary objective is to explore the methods used to assess these individuals’ transformation and articulation of clinical data.

Background

Research addressing the quality of language and discourse in clinical reasoning grew in the 1990s when George Bordage [11,18,19] introduced prototype theory. According to this cognitivist theory, the characteristics of clinical cases (eg, signs and symptoms, diagnosis, and treatment) are not directly stored in long-term memory. Instead, these characteristics undergo a process of abstraction, generating a set of generic characteristics or a brief, typical description of the case known as a prototype.

Prototypes play a significant role in health education as they facilitate creating and consolidating unit-meaning knowledge networks in long-term memory [12]. This allows students and health care professionals to decode the characteristics of a problem. These characteristics will be correlated or contrasted with those from other clinical problems in similar and different contexts [20], leading to densifying the scripts of students and health professionals, thus promoting the development of clinical reasoning. Professional knowledge and in-depth understanding of these prototypes in terms of pathophysiology, concomitant factors, evolution, and so forth, are therefore essential to the clinical reasoning process [21]. In line with prototype theory,

XSL•FO
RenderX

the theory of scripts postulates that well-organized knowledge networks and units of meaning stored in the memory of students and health professionals enable effective clinical reasoning [2,22]. Continuing, deliberate clinical practice allows them to densify their scripts by encountering diverse patients and cases.

It was through the use of conceptual and methodological tools derived from structural semantics that Lemieux and Bordage [20,23] analyzed the quality of clinical reasoning, in particular the capacity to diagnose. Issued from linguistics and semiotics (the study of signs and symbols in language), the object of structural semantics is to study the systems of meaning comprised in discourse [20,23]. According to medical semiotics, signs and symptoms represent 2 constituting units of clinical reasoning, highlighting that they must be interpreted in their contexts [24,25]. In structural semantic analysis, the discourse is therefore examined according to the linear and vertical dimensions. The linear dimension relates to the syntactic order, before and after, of the terms used (eg, signs and symptoms) [20,23]. The vertical dimension refers to the underlying semantic structures that allow a student or a health care professional to classify the meaning of clinical data into multiple levels of signification called semantic axes. The semantic axes represent logical levels of abstractions where the student or health professional uses qualitative semantic properties, which are structured on an axis into opposition pairs. Opposition pairs refer to various concepts, such as temporality (constant or intermittent and sudden or gradual), body space (left or right and proximal or distal), degree of impairment (low, moderate, or high), and the quality of the signs and symptoms (apparent or insidious) [20,23].

According to their approach, it is from the constituent units (signs and symptoms) and their forms (eg, syndrome, affected systems, processes, and predisposing factors) that the clinical discourse of students and health professionals can be analyzed, integrating cognitive operations in the latter (eg, being able to decode or define signs and symptoms, to classify them or associate them with others, and to prioritize data). Analyzing the students' and health professionals' discourse provides insight into their knowledge's richness and organization. The semantic component of discourse involves semantic qualifiers, which reflect the intelligible organization of knowledge into meaning units [11,18]. These semantic qualifiers, such as "acute" versus "chronic" pain or "proximal" versus "distal" region, serve as building blocks for organizing knowledge and function as cue mechanisms in long-term memory. Qualifiers can be seen as "useful adjectives" that characterize clinical data abstraction in a situation [12,26].

The syntactic component of discourse is linked to its richness and structure, as it mirrors the richness and organization of one's knowledge repertoire [11,18]. It refers to the associative competence between the constituent units (signs and symptoms) of the discourse as opposed to a simplistic enumeration of signs and symptoms without creating meaning or relationships between them [20,23]. In this sense, discourse can also appear scattered or reduced when there is an apparent lack of or insufficiently developed knowledge to understand and respond effectively to a situation. Bordage [11,18] proposed a discourse classification system that examines the organization of knowledge and the ability to contrast diagnostic hypotheses using clinical data. These categories are (1) reduced: discourse that lacks any effort of semantic transformation, with no connections between patient data and knowledge; (2) scattered: discourse that exhibits limited semantic transformation and disordered hypotheses, which do not reference the obtained data and are listed without contrasting; (3) elaborated: discourse with numerous semantic transformations used judiciously to contrast hypotheses; and (4) compiled: the individual immediately recognizes a semantic data set associated with a clinical hypothesis.

The semantic and syntactic components of discourse are important because they reflect the elaboration and organization of clinical knowledge in the minds of students and health care professionals [11,18]. Semantic qualifiers, integral components of professional vocabulary, are crucial in clearly communicating a patient's condition in the clinical setting. By mastering these qualifiers, students can effectively convey relevant clinical information and enhance their ability to participate in meaningful clinical discussions [12].

While the semantic competence of students and health professionals should be enhanced to understand, analyze, and develop or evaluate clinical reasoning, the question is how it is solicited or simulated in the educational strategies and evaluation methods used in health education.

Methods

Overview

This scoping review will be based on the methods described by Arksey and O'Malley [27]. A scoping review is a knowledge synthesis method to address exploratory research questions by mapping key concepts, types of evidence, and gaps in a research area. This scoping review will identify the extent and range of evidence [28-30] regarding the articulation and transformation of clinical data to guide educational practices and propose avenues of research.

The scoping review will follow the 9-step framework proposed by Peters et al [28] of the Joanna Briggs Institute. This framework includes several consecutive steps that are (1) developing and registering the protocol, (2) formulating the objective and research questions, (3) developing inclusion criteria, (4) identifying relevant studies, (5) selecting relevant studies, (6) charting the data, (7) analyzing the data, (8) reporting the results, and (9) summarizing the results. We will use the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension of Scoping Reviews) checklist [31] to report findings.

Developing and Registering the Protocol

A preliminary search was performed to assess the existing literature and ensure that no other reviews with the same focus were published. We then developed a protocol based on the 9-step framework mentioned above [28]. The protocol was registered on the Open Science Framework. Furthermore, publishing the protocol in a peer-reviewed journal aims to increase transparency [31].

XSL•FO
RenderX

Formulating the Objective and Research Questions

In this phase, the 2 primary tasks that are undertaken are (1) identifying research questions that provide a roadmap for the subsequent steps and (2) establishing the scope of inquiry, which encompasses defining the concept, the target population, and the context. The objectives of this scoping review are (1) to map the educational strategies to promote the transformation and articulation of clinical data by students and health professionals and (2) to examine the methods to assess the transformation and articulation of clinical data by students and health care professionals. We have developed the following research questions: (1) what educational strategies are used to promote the transformation and articulation of clinical data among students and health care professionals? and (2) what methods are used to assess the articulation and transformation of clinical data by students and health professionals?

Developing Inclusion Criteria

Peters et al [28] recommended that inclusion criteria are based on the Population-Concept-Context framework instead of the Population-Intervention-Comparator-Outcomes framework suggested in the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) [32]. Textbox 1 summarizes the inclusion and exclusion criteria.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Studies on students and health professionals
- Studies reporting educational or assessment strategies involving semantic transformation and articulation of clinical data
- Studies written in French or English
- All primary studies, regardless of study design and geographic areas
- Studies conducted in both academic and clinical settings across all geographic areas

Exclusion criteria

- Studies in fields other than health education programs, unlicensed health care providers, personal care providers, and caregivers
- Studies without a description of educational or assessment strategies; studies focusing on the developments and applications of intelligent or clinical decision support systems
- Studies in languages other than English or French
- Conference abstracts, protocols, editorials, expert opinions, commentaries, letters, book reviews, blogs and social media

For the population, we will consider literature that discusses educational strategies to foster the development of clinical reasoning among students and health professionals across various academic levels (eg, pregraduates and postgraduates) and disciplines. The included studies will encompass a range of health disciplines, such as medicine, midwifery, occupational therapy, speech-language therapy, and nursing. Conversely, we will exclude studies involving populations outside the field of health, unlicensed health care providers, personal care providers, and caregivers.

The central concept of this review will be the semantic transformation and articulation of clinical data during clinical reasoning [11]. This cognitive operation involves converting “raw” data from a clinical situation into specific professional vocabulary to describe the situation [11]. By organizing clinical data into meaningful units, this cognitive operation helps to understand the situation and generate clinical hypotheses. Clinical reasoning is a cognitive process underlying clinical judgment and decision-making [1,2,33]. These terms, often used interchangeably in the literature [1,4], will also be considered in the search strategy.

For the context, we will consider sources reporting on educational strategies or assessment methods involving the semantic transformation and articulation of clinical data in the context of clinical reasoning. These educational strategies may include, for example, case studies, concept mapping, and simulation. The assessment methods refer to the scoring grid used during OSCE or a think-aloud exercise, and so forth [10]. This review will consider studies conducted in both academic and clinical settings across all geographic areas. Studies examining the developments and applications of intelligent or clinical decision-support systems will be excluded, as technical or engineering procedures could be difficult to analyze and would deviate from the objectives of the review.

We will consider primary studies with quasi-experimental (eg, before and after studies and interrupted time series), experimental (eg, randomized controlled trials), observational (eg, cohorts, case-control, and cross-sectional), qualitative, and mixed methods designs. We will also include grey literature such as theses, dissertations, conference proceedings, and research reports. To focus on scientific literature with sufficient content to help answer our questions, the following will be excluded: conference abstracts, protocols, editorials, expert opinions, commentaries, letters, book reviews, blogs, and social media. Studies written in French or English will be included. The search will span the period from 1990 to the present, that is, after Bordage introduced semantic qualifiers in the 1990s. The objective is to comprehensively examine the literature on clinical reasoning in health professional education during this timeframe.

XSL•FO
RenderX

Identifying Relevant Studies

As recommended by Peters et al [28], a comprehensive 3-step search strategy was implemented with the support of a health science librarian. Initially, an exploratory search was performed in CINAHL and PubMed to identify keywords and medical subject headings from articles about the review topic. Subsequently, a thorough literature search was conducted in November 2022 using 5 databases: CINAHL (EBSCOhost), MEDLINE (Ovid), Embase (Ovid), PsycINFO (Ovid), and Web of Science (Clarivate). The search strategy was first developed in CINAHL and later adapted to other databases (see Multimedia Appendix 1). Considering the possibility of articles being present in fields other than health care, such as education or linguistics, the review team decided to manually select articles that specifically focused on students or health professionals to ensure relevance to the research topic.

In the future, we plan to use a hand search approach to review the reference list of the included records. This approach will help identify any additional relevant studies that may have been missed during the initial database search. Furthermore, we intend to search for unpublished studies using the ProQuest dissertations and theses electronic database and the ProQuest TDM studio tool and conduct targeted searches on Google Scholar. For the Google Scholar searches, we will use specific search string queries such as “semantic transformation and clinical reasoning,” “diagnostic reasoning and semantics,” and “semantic qualifiers and differential diagnosis.” We will analyze Google Scholar’s top 100 search results to identify additional studies aligning with the review questions and objectives.

Selecting Relevant Studies and Charting the Data

After conducting the initial database search, the retrieved references were imported into Covidence (Veritas Health Innovation) to facilitate the screening process and identify duplicate records. To ensure consistency and establish a shared understanding, 3 reviewers independently assessed the eligibility of a randomly selected sample of 25 articles based on the predefined inclusion and exclusion criteria. In all, 2 meetings were conducted to refine the selection criteria to improve agreement rates.

The screening of titles, abstracts, and full texts was carried out independently by 2 reviewers, following the predefined selection criteria. In the event of any disagreements, a third reviewer was involved. The reasons for excluding studies at the full-text stage were documented and will be reported accordingly.

In the upcoming phase of the scoping review, 2 independent reviewers will extract relevant data from all included studies. A structured data extraction form developed by the reviewers will be used to record the information. Microsoft Excel will be used for data management. The extraction form proposed by Peters et al [28] will serve as a foundation, encompassing article characteristics such as the first author’s name, year of publication, and country of origin, as well as study methods, including the aim, study design, and population. Additionally, we will create codes under the following categories: the transformation and articulation of clinical data to facilitate learning or capture clinical reasoning; educational strategies; any referenced theoretical framework; methods or tools used to analyze the articulation and transformation of clinical data; relevant results; and authors’ recommendations.

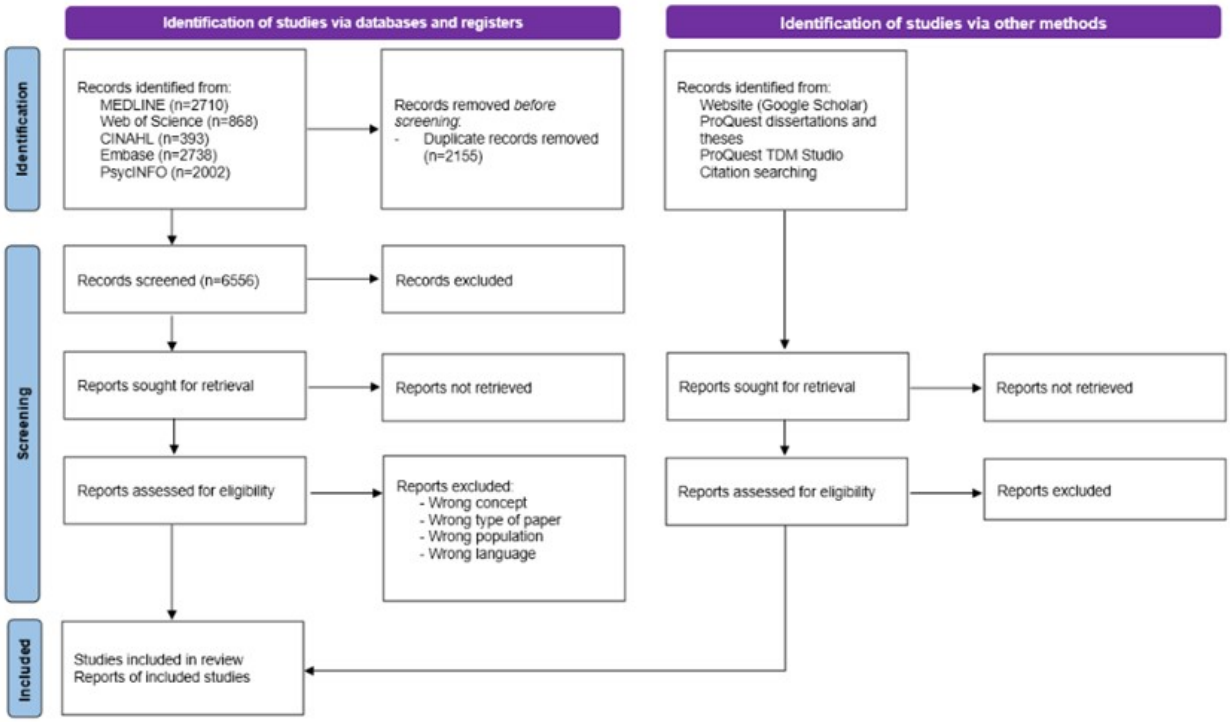
Following the recommendation of Peters et al [28], the extraction form will undergo a testing phase by the reviewers, who will extract data from 5 selected studies. This process will help ensure the effectiveness and consistency of the form. Based on their feedback, the reviewers will collaboratively refine the extraction form and create a comprehensive list of codes if any adjustments or modifications are required.

Subsequently, 1 reviewer will perform data extraction, and a second reviewer will independently review the results to ensure accuracy and reliability. In the event of any discrepancies, the reviewers who performed the data extraction will engage in discussion to reach a consensus. A third reviewer will be consulted to finalize the extracted data if a consensus cannot be reached.

Analyzing the Data and Reporting and Summarizing the Results

Extracted data will be processed using content analysis techniques inspired by Miles et al [34]. This data analysis method involves three steps, which are (1) data condensation, (2) data display of similarities and differences, and (3) drawing and verifying conclusions. Based on the review questions, relevant findings pertaining to the characteristics of the included studies will be presented in tables, along with insights into the transformation and articulation of clinical data for educational and assessment purposes. In addition, a narrative report will be used to summarize the key findings from the articles. For this purpose, a brainstorming session involving all reviewers will be organized. The findings will be described with respect to the research questions and the objectives of this scoping review. Additionally, gaps or limitations in the existing literature will be identified and highlighted to provide insights for future research. The search results and the study inclusion process will be reported comprehensively in the final report using a PRISMA-ScR flow diagram [31].

Ethical Considerations



All data will be collected from published and grey literature. Ethics approval is, therefore, not a requirement. We will present our findings at relevant conferences and submit them for publication in peer-reviewed journals.

Results

Database searches were conducted in November 2022. A total of 8711 results were retrieved, of which 2155 were duplicates. Figure 1 shows a flow diagram of the records identified. The review will be completed by February 2024.

Discussion

Principal Findings

The proposed scoping review aims to provide a comprehensive overview of the existing evidence on semantic transformation and articulation of clinical data during clinical reasoning education. The initial literature search yielded substantial results, totaling 6656 after removing duplicates.

Various educational strategies have been identified thus far. These include summary statements with simulated patients, verbal analysis of thoughts related to vignettes, tests to assess the association between clinical data and diagnoses, and examining written reports in actual or simulated contexts. Furthermore, the review has uncovered the presence of rubrics that incorporate both the semantic and syntactic dimensions of students' and health professionals' discourse, providing a framework for evaluating clinical reasoning. These findings highlight the diversity of educational strategies and assessment tools used in the field. Based on the review's preliminary findings, an initial evaluation of the theories about the articulation and transformation of clinical data has been formulated.

Despite a robust review design, some limitations can be identified in this protocol. This scoping review may exclude relevant studies as it will mainly include peer-reviewed journal articles. As such, some relevant grey literature may be excluded from our findings. Excluded studies examining developments and applications of intelligent or clinical decision support systems could contain some additional information to answer the review questions. Indeed, the keywords used in the search strategy are broad and may not identify all specialized studies. Moreover, only considering English and French as the languages of publication could exclude papers relevant to our scoping review written in other languages.

Conclusions

By synthesizing the evidence on semantic transformation and articulation of clinical data during clinical reasoning education, this review aims to contribute to the refinement of educational strategies and assessment methods used in academic and continuing education programs. The insights gained from this review will help educators develop more effective semantic approaches for teaching or learning clinical reasoning, as opposed to fragmented, purely symptom-based or probabilistic approaches. Besides, the results may suggest some ways to address challenges related to the assessment of clinical reasoning and ensure that the assessment tasks accurately reflect learners' developing competencies and educational progress.

Protocol

Pilot-testing a Multiplayer HIV and Sexually Transmitted Infection Prevention Video Game Intervention for Black Adolescent Girls: Protocol for a Randomized Controlled Trial

Abstract

Background: Black adolescent girls aged between 14 and 19 years are more likely than White girls to be diagnosed with a sexually transmitted infection (STI). As STI diagnosis is associated with an increase in the risk for HIV acquisition, an early intervention specifically tailored to Black adolescent girls is warranted. A web-based video game intervention has the potential to reach this demographic. Because studies of social and behavioral determinants of disease demonstrate the protective role of peer group structures on individual outcomes, a multiplayer game can facilitate opportunities to exchange and evaluate information, learn social norms, develop behavioral skills, and allow peers to influence attitudes and behavior. No prior research has examined the feasibility of a web-based multiplayer game intervention for this population.

Objective: This study describes the protocol for a randomized controlled trial (RCT) pilot-testing the feasibility, acceptability, and limited efficacy of a multiplayer game–based intervention for increasing HIV and STI testing and condom use in Black adolescent girls.

Methods: We enrolled 79 Black adolescent girls aged 14 to 19 years residing in the United States into a 2-arm parallel RCT. The intervention is a theory-based, community-informed, multiplayer game that can be played with peers on the web using videoconferencing software. The goal of the game is to empower Black adolescent girls to make healthy decisions regarding dating, relationships, and sex, thus reducing HIV and STI infection. Control condition participants received a list of resources after playing a time and attention control game. All study procedures were conducted via the internet. We conveniently sampled Black adolescent girls using web-based advertisements. Study assessments occurred at enrollment, 1 week, 1 month, and 4 months after enrollment. The primary outcome of this study is increased HIV and STI testing by Black adolescent girls. Secondary outcomes include increased condom use, self-efficacy to use condoms, positive attitudes toward condom use, intentions, harm perceptions, HIV and STI and pre-exposure prophylaxis knowledge, positive sexual norms, sexual communication with partners, and reduced incidence of sexual risk behaviors associated with HIV and STI transmission. Secondary outcomes also included assessment of intervention feasibility and acceptability.

Results: From February to April 2022, a total of 79 Black adolescent girls were enrolled, with 40 (51%) having been randomized into the intervention condition and 39 (49%) into the control condition. At baseline, participant ages ranged from 14 to 19 (mean 16.4, SD 1.23) years.

Conclusions: Web-accessible game interventions overcome common impediments of face-to-face interventions presenting a unique opportunity to reach Black adolescent girls and improve their sexual health and self-efficacy. Trial data will provide information about the limited efficacy of the intervention and inform future web-based studies and a larger RCT aimed at improving the sexual health of Black adolescent girls.

Trial Registration: ClinicalTrials.gov NCT04108988; https://clinicaltrials.gov/ct2/show/NCT04108988

Introduction

Background

Despite advances in HIV prevention efforts, Black adolescents continue to be disproportionately affected by HIV in the United States, comprising 54% of all new HIV diagnoses in 2016 [1]. In the United States, Black adolescent girls aged between 14 and 19 years have higher rates of sexually transmitted infections (STIs) than other ethnic minority girls and are more than twice as likely to be diagnosed with an STI than their White peers [2-5]. Racist, sexist, and classist views significantly disadvantage Black adolescent girls' achievement of positive health outcomes relative to White girls [6]. Indeed, mounting evidence implicates the role of gendered-racist stereotypes on increases in Black girls' sexual risk behaviors [7,8], indicating a need for the development of HIV and STI prevention strategies specifically tailored for Black adolescent girls.

A recent systematic review noted that many existing sexual health promotion interventions for Black youth are not specifically tailored for Black adolescent girls or made to account for their unique experiences because of the intersection of race and gender [9]. Because increased knowledge about HIV and HIV prevention strategies is associated with protective sexual behaviors such as condom use and HIV testing among adolescents of color [10,11], there exists a critical need for the development of more interventions specifically designed for Black adolescent girls that increase the knowledge about HIV and STI prevention and emphasize resisting and challenging gendered-racist stereotypes [12]. Although the recent systematic review identified 15 effective HIV and STI prevention programs that have been used with Black adolescent girls, only 4 were created specifically for this population [9]. In addition, challenges regarding implementation and fidelity of interventions have been a concern. Studies have cited several barriers to the implementation of HIV and STI prevention interventions, including access to adequately trained providers, staff turnover, resource constraints of agencies, and fidelity of the interventions [13-15].

One possible method for intervention delivery is through the creation of a self-contained video game, which can provide consistent fidelity, and places little demand on program resources [16,17]. Game interventions have demonstrated efficacy in increasing knowledge and affecting behaviors related to health promotion and disease management across domains [18]. Successful game interventions have focused on health topics ranging from asthma management, healthy diets, medication adherence, and even sexual health promotion through risk behavior reduction [19-22]. Because 83% of adolescent girls play video games on computers, web, phone, or console [23], a game-based HIV and STI prevention intervention specifically tailored for Black adolescent girls will likely be an acceptable and enjoyable means of delivering the material.

Among adolescent girls, social or multiplayer games are among the most popular and frequently played video games [24]. Because interactions within peer groups offer opportunities for individuals to exchange and evaluate information, learn social norms, develop behavioral skills, and influence each other's attitudes and behavior [25], an HIV and STI prevention initiative that targets peer groups by leveraging adolescent girls' preference for multiplayer gaming experiences has the potential to have benefits above and beyond an intervention designed for a single individual. Indeed, research suggests that peers often serve as a valuable source of information about HIV and as role models for prevention strategies such as condom use [26]. For instance, a community-based pilot study demonstrated a 72% increase in the number of individuals getting tested for HIV and STI when peers recruited others through their social network [27]. Similarly, a recent study of at-risk Black and Hispanic youth aged 13 to 24 years found that a female friendship network method of engagement was successful with increasing HIV testing rates by 90% [28].

Although Boyd et al [29] found that Black and Latinx adolescents who learned about HIV from their friends were *less* likely to get tested for HIV, the researchers note that youth surveyed in their study likely perceived the HIV-related knowledge gleaned from friends as unreliable. Therefore, to take advantage of the benefits that peer group structures can have on individual determinants of health, it is important that a multiplayer intervention create a shared experience where the information provided is known by all to be both factual and relevant to the players' lived experiences. Adopting this strategy in the creation of an HIV and STI prevention multiplayer video game specifically tailored for Black adolescent girls allows for conversations between players to occur in real time during gameplay, which deepens engagement with the material and provides girls the opportunity to positively influence attitudes, beliefs, and perceptions around serious topics. Moreover, the game environment encourages a safe and playful space where peer groups can normalize discussions about sex and safe sex practices. Because most research on Black girls' sexuality and sexual health is focused on the reduction of risky behaviors rather than fostering safe and healthy sex and sex positivity [12,30], a game-based sex positive intervention represents a novel strategy. Such an intervention has the potential to impact the sexual self-efficacy of Black adolescent girls, high levels of which have been associated with HIV-risk mitigation strategies such as consistent condom use by adult Black women [31].

In light of the COVID-19 pandemic, efforts to recruit groups of Black adolescent girls to gather in person for multiple

XSL•FO
RenderX

gameplay sessions were stymied. Thus, rather than continue to delay data collection, the research team used their extensive experience working with youth and decided to pivot to web-based data collection by following a model previously found successful in the collection of focus group data that served as the foundation for the development of this study's video game intervention [32,33]. This decision was made with knowledge from conducting numerous randomized controlled trials (RCTs) with schools and informed by processes that we developed to accommodate remote data collection.

With the ubiquity of the videoconferencing software Zoom (Zoom Video Communications, Inc) and recent reports that "gamified videoconferences" facilitated both connection and learning during periods of social isolation [34], the research team embraced the opportunity to recruit a sample of Black adolescent girls from across the United States, rather than wait for the resumption of in-person learning at local school partner sites. Although web-accessible game interventions overcome many common barriers of face-to-face interventions and offer a unique opportunity to reach Black adolescent girls across the United States, no previous studies have examined the use of multiplayer game interventions delivered remotely to this population. Therefore, pilot-testing the limited efficacy of this specifically tailored multiplayer game intervention is necessary to understand the acceptability of the gaming experience such that future expansions and adaptations can be created. Moreover, results of this pilot limited efficacy test can be used to estimate variability and precision to power a future larger RCT.

Study Aims

Primary Aim

Our primary aim of this study is to evaluate the feasibility and acceptability of a multiplayer game–based intervention designed to increase HIV and STI testing and condom use among adolescent Black girls.

Feasibility of this intervention is assessed by collecting data on the number of intervention sessions completed by participants and retention rates. We hypothesize that the intervention will have high completion and retention rates across survey time points (>80%).

Acceptability of the intervention condition is assessed via self-reported survey at the postgameplay time point using the game experience and satisfaction questionnaire, which is a 15-item scale with 4-point Likert-type responses ranging from 1 (strongly disagree) to 4 (strongly agree) [22,35-37]. Example questions include "I enjoyed playing the game" and "I would make decisions in life like I made them in the game." We hypothesize that in response to the question as to whether a participant would be interested in playing the game again and whether they would recommend the game to their friends, ≥75% of participants will "agree" or "strongly agree" that they would like to play the game again and ≥75% will "definitely" or "very probably" recommend the game to their friends.

Secondary Aim

Our secondary aim of this study is to determine the preliminary impact of the intervention on knowledge, intentions, beliefs and attitudes, self-efficacy, social norms, and behavioral skills related to HIV and STI testing, condom use, and sexual risk behavior reduction. We hypothesize that compared with control participants, participants in the intervention group will have greater improvements in all proximal outcomes.

Exploratory Aim

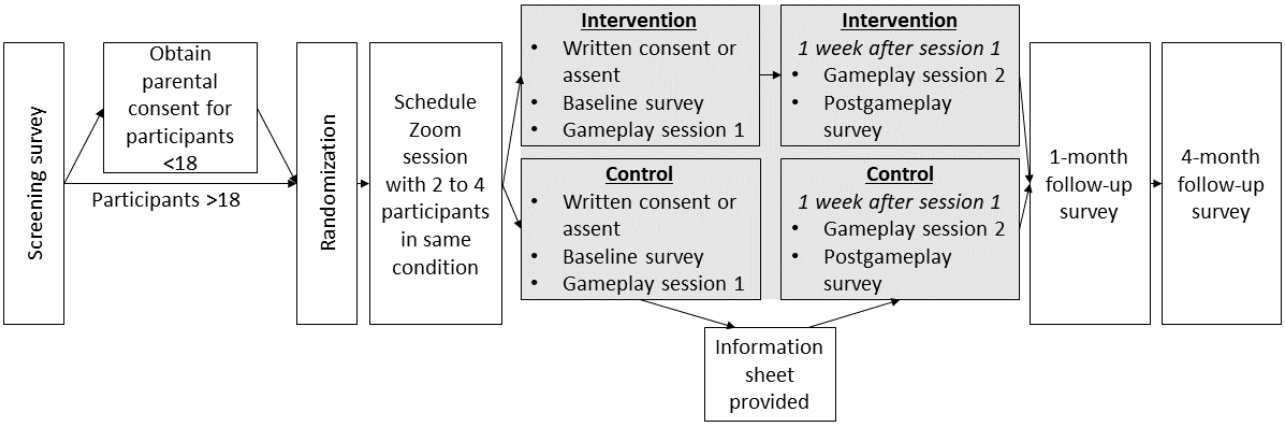
This study includes an exploratory aim designed to evaluate participants' real time responses to the game through the content analysis of audio recordings of gameplay sessions. We will investigate participant perceptions of research procedures and game content to analyze suggestions for the improvement of both. We will also explore whether connection to one's ethnic identity may be a protective factor against sexual risk behavior [38]. Because the exploratory aim concerns implementation procedures and the adaptation and expansion of the game, there are no a priori hypotheses.

Methods

Ethics Approval

All the procedures were approved by the Yale University Institutional Review Board (ID #2000026487). In addition, a Data Safety and Monitoring Board consisting of 2 experts in clinical trials in adolescents and in statistical analysis of clinical trials was formed to oversee the safety and data integrity of this study. The Data Safety and Monitoring Board also periodically reviewed the progress of the study. The following personally identifying and medical information were collected: email ID, phone number, self-reported HIV and STI testing status, test results, and sexual activity status. All data collected from the assessments were entered by participants directly into the secure web-based system, Qualtrics (Qualtrics International Inc), which is Yale's enterprise-wide data management system. This ensured participant confidence that their data would remain confidential. Study participation incentives were sent via email as Amazon e-gift cards. Written consent was obtained via digital signature from all the participants before their participation, as detailed in the section Study Population and Study Flow.

Study Design



This study is a pilot of a 2-arm RCT designed to evaluate the feasibility and acceptability of a multiplayer game–based intervention designed to increase HIV and STI testing and condom use among adolescent Black girls. The study is led by a team with expertise in conducting research with youth, as well as extensive experience with the design and evaluation of game-based health promotion interventions, including interventions specifically designed for HIV and STI prevention [22,37]. Our multiplayer video game intervention prototype and research protocol were developed through extensive collaboration with partners including a specialist in strength-based approaches to understanding HIV and STI disparities among girls and women of color, a biostatistician, and a professional game development company, PreviewLabs, Inc.

XSL•FO

Study Population and Study Flow

All study procedures including screening, consenting, and surveying were conducted through Qualtrics, a secure Health Insurance Portability and Accountability Act–compliant website for managing web-based surveys and databases. Study participant flow is depicted in Figure 1.

Figure 1. Two-arm randomized controlled trial design and data collection schedule.

First, to determine eligibility, respondents completed a brief web-based self-reported screening questionnaire, the link to which was displayed on the social media advertisements. Respondents were eligible if they met the following eligibility criteria: they must (1) be aged between 14 and 18 years; (2) identify as Black; (3) identify as female; and (4) identify as straight (ie, heterosexual), bisexual, or pansexual. Once ≥3 prospective participants signed up for a single study session, the project manager or research assistant emailed those 3 prospective participants the Zoom link for the study session and a description of the procedure, which included recommendations for equipment (a PC for Zoom and cell phone for gameplay). Respondents under 18 years of age were also required to provide an email address for a parent or guardian.

All the eligible respondents were assigned a participant number and were randomly assigned to either the experimental or control condition (full descriptions of conditions are provided in later sections). Eligible respondents then received an email from the project manager or research assistant with details about the study and exclusion and inclusion criteria, and for respondents under the age of 18 years, the parental information sheet and a link to the informed consent document was emailed to the parent or guardian using the address provided in the screening survey. Prospective participants who were 18 years old and respondents whose parent or guardian digitally signed the informed consent document were then invited to sign up for a study session.

Separate study sessions for experimental and control participants were determined each week by the project manager and research assistant. Prospective participants were instructed to indicate their availability for as many study sessions as possible. Respondents provided their email address and had the option to provide a cell phone number if they preferred to receive text messages for study communication. If additional prospective participants later indicated availability for a study session for which links had already been distributed, those participants were similarly provided with the Zoom link and study procedure description. Invitations to study sessions were capped at 8 prospective participants per session.

Adolescent assent for participants under 18 years and informed consent for participants aged 18 years were obtained at the start of each Zoom study session. After explaining the risks and requirements of the study in general terms, the researcher provided each participant a link to the full consent or assent document via Qualtrics. Participants were given ample time to fully read through the document and asked to provide their digital signature if they agreed to participate. The researcher was available to answer all the questions regarding the consent and assent document. Following consent procedures, the baseline survey was administered (full description of the baseline survey is provided in a later section). Once all participants had completed the baseline survey, the researcher launched the video game according to condition (intervention game vs control game; both described in detail in a later section). Throughout gameplay, participants were encouraged to use Zoom's chat feature to discuss the game.

Upon conclusion of the first gameplay session, participants were emailed an Amazon gift card worth US $30 and a second gameplay session at the same time in the following week was scheduled. Participants who were unable to attend a second gameplay session at the same time in the following week were scheduled for a different second gameplay session with another group via email. For all the participants, the second gameplay session began with playing either the control or the experimental game, followed by the completion of the postgameplay survey (full description of the postgameplay survey is provided in a later section). Once all the participants submitted their postgameplay survey, a second Amazon gift card worth US $30 was emailed to all participants.

The first follow-up survey was emailed to all the participants 1 month after their second gameplay session. The second follow-up survey was emailed to all the participants 3 months after the completion of their first follow-up survey. For each follow-up survey completed, participants received a US $30 Amazon gift card via email. Participants who did not complete either follow-up survey within 5 days of receiving the survey were reminded to complete the survey via email. An additional email reminder was sent 1 week after the first reminder.

XSL•FO
RenderX

Participants who asked to be contacted via text message additionally received survey links and reminders through text message.

Recruitment

Participants were conveniently sampled and recruited throughout the United States using advertisements on Facebook and Instagram. Instagram was our primary recruitment site because it is possible to target individuals of a particular age (14-18 years) and gender (female) through the advertising platform. Moreover, Instagram is used by approximately 71% of adolescents, making it an appropriate platform to reach our target demographic [23]. We created an advertisement and recruited participants from Facebook using the same advertisement and targeting criteria. An individual who was interested in participating clicked on the advertisement and was directed to the Qualtrics screening survey.

Assessments

To evaluate the multiplayer game–based intervention we collected assessment data at 4 time points during the study: baseline, after the gameplay, 1-month follow-up, and 4-month follow-up. The assessments administered at each time point are depicted in Table 1.

Table 1. Assessments and time of administration.

Assessment	Baseline	Postgameplay time point	1-month follow-up	4-month follow-up
Participant demographics (ie, gender, age, and sexual orientation)	✓			
Self-reported HIV and STI[a] testing rate (1 item)	✓	✓	✓	✓
Sexual Risk Behaviors and Sexual communication—self-reported measures of sexual intercourse with or without condoms and frequency of safe sex discussions with partners (27 items)	✓	✓	✓	✓
CUSES[b] (11-item Likert scale)	✓	✓	✓	✓
HIV and STI KQ[c] (12 items true or false questions adapted from HIV-KQ and STD-KQ)	✓	✓	✓	✓
PrEP[d] knowledge and attitudes (11 items)	✓	✓	✓	✓
Microbehaviors: discussing condoms with partners, purchasing condoms, and discussing testing with partners (4 items)	✓	✓	✓	✓
MEIM-R[e] (6-item Likert scale)	✓			✓
Self-efficacy in sexual risk behaviors—SRBBS[f] (27-item Likert scale)	✓	✓	✓	✓
Gameplay experience and satisfaction; *intervention participants only* (12-item Likert scale)		✓		
Game experience reflection; *intervention participants only* (4 items)			✓	✓

[a]STI: sexually transmitted infection.

[b]CUSES: Condom Use Self-Efficacy Scale.

[c]KQ: Knowledge Questionnaire.

[d]PrEP: pre-exposure prophylaxis.

[e]MEIM-R: Multigroup Ethnic Identity Measure—Revised.

[f]SRBBS: Sexual Risk Behavior Beliefs and Self-efficacy.

Materials

Control Materials

Participants randomized into the control condition attended live Zoom sessions with up to 4 other control participants and a researcher, who facilitated gameplay of the non–health-related attention and time control condition multiplayer video game. Players in control Zoom sessions played 1 of 2 Jackbox (Jackbox Games, Inc) games (Fibbage or Drawful), which were selected for use as attention and time control games for their similarity in game structure to the intervention game. Participants randomized to the control condition received a short list of links to resources with HIV- and STI-related general information, prevention, testing locations searchable via zip code, and suggestions for talking with partners about HIV and STI testing and prevention strategies such as condom use via email. Finally, after completion of the final 4-month follow-up survey, control participants were offered access to a web page that contained the information and resources provided in the intervention. Participants in the control condition played 2 full games of Jackbox during each gameplay session, resulting in 100 to 120 minutes of total playtime.

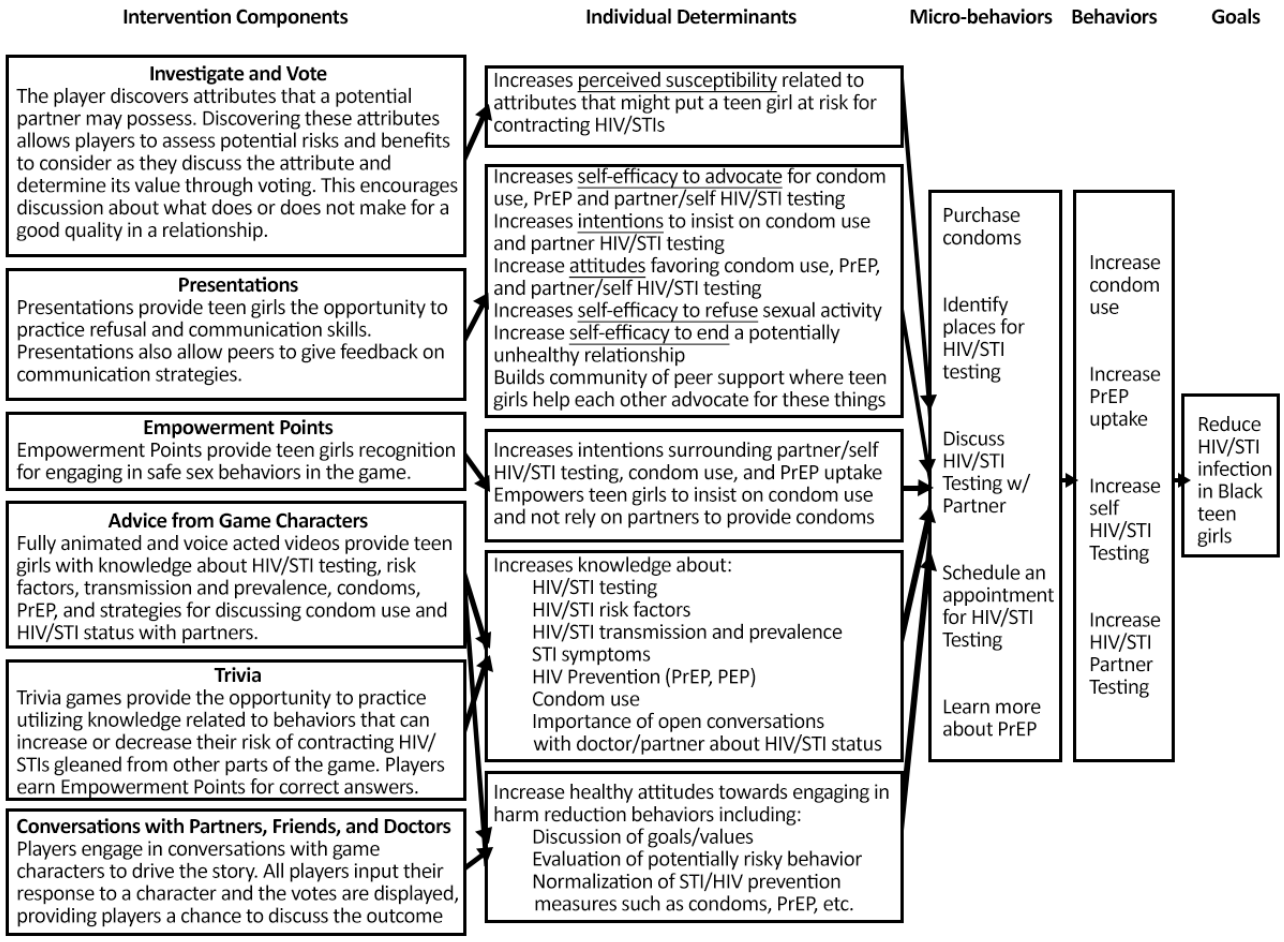
Intervention Materials

Participants randomized into the intervention condition attended live Zoom sessions with up to 4 other intervention participants and a researcher, who facilitated gameplay of the multiplayer intervention video game, *InvestiDate*. The design and story content of the intervention video game was based on information the research team gathered through focus groups with 27 Black

XSL•FO
RenderX

adolescent girls in which participants discussed their experiences with sex, dating, the use of social media to inform partner selection, and participants' experiences of gendered-racist stereotypes and how these experiences influenced their own sexual decision-making [32,33]. In addition, 7 participants from the focus groups further volunteered to guide the development of the video game by forming a Board of Advisors that oversaw the writing of game dialogue and creation of character storylines, as well as provided feedback on character art and design. The characters and background images in *InvestiDate* were designed and illustrated by a young Black female graphic artist. The educational content of the intervention game was determined through the examination of other HIV and STI prevention programs, existing literature, and through the creation of a Game Playbook [39] guided by theories of behavior change [40,41]. Game development was achieved through collaboration with professional educational game developers. A typical game takes between 30 and 45 minutes to complete. Participants in the intervention condition played 1 to 2 games during each gameplay session, resulting in 70-130 minutes of total intervention exposure.

Game Development



InvestiDate is based on a theory-driven and evidenced-informed HIV and STI prevention social card game designed for young Black women [37]. The video game adaptation was developed in collaboration with PreviewLabs, Inc, a rapid prototyping and game development company located in New Haven, Connecticut, United States. The video game intervention is a multiplayer and feminist take on a traditional dating simulation (sim) game and is dialogue based, containing no explicit sexual imagery or descriptions. Dating sim games are typically dialogue heavy and involve the building and maintenance of a relationship with one or more characters, with game outcomes largely dependent on statistics. The intervention game adds a social component to the dating sim genre by pitting players against one another in a race to develop relationships with the datable characters. Furthermore, an element of icebreaker games is added in that players are encouraged to predict each other's reactions to game events. The intervention game also borrows structural components form the hit social game series Jackbox, in that game action takes place on a single shared screen, which runs on desktops and laptops with Windows (Microsoft Corp) or Mac (Apple Inc) operating systems while players input gameplay decisions on separate internet-capable devices through a web-based interface.

Theoretical Underpinnings

The conceptual model of the game intervention depicted in Figure 2 is based on well-established behavior change theories, including social cognitive theory [40] and health belief model [42]. Social cognitive theory [43,44] posits that behavior change occurs through the development of self-efficacy and skill acquisition and that learning is expedited through the observation of behavior carried out by others similar to the observer. Self-efficacy can be achieved through behavioral rehearsal and feedback, and the observation of behavior is simulated through the inclusion of roleplaying storylines based on the lived experiences of Black adolescent girls who participated in the formative focus groups. The health belief model posits that if a person perceives a benefit from a particular change in behavior, they will be more likely to adhere to the change [42]. In the video game, players earn points for behaviors like testing for HIV and STI, insisting on condom use, and communicating with partners extensively. These vicarious learning opportunities model beneficial behavior for players.

XSL•FO
RenderX

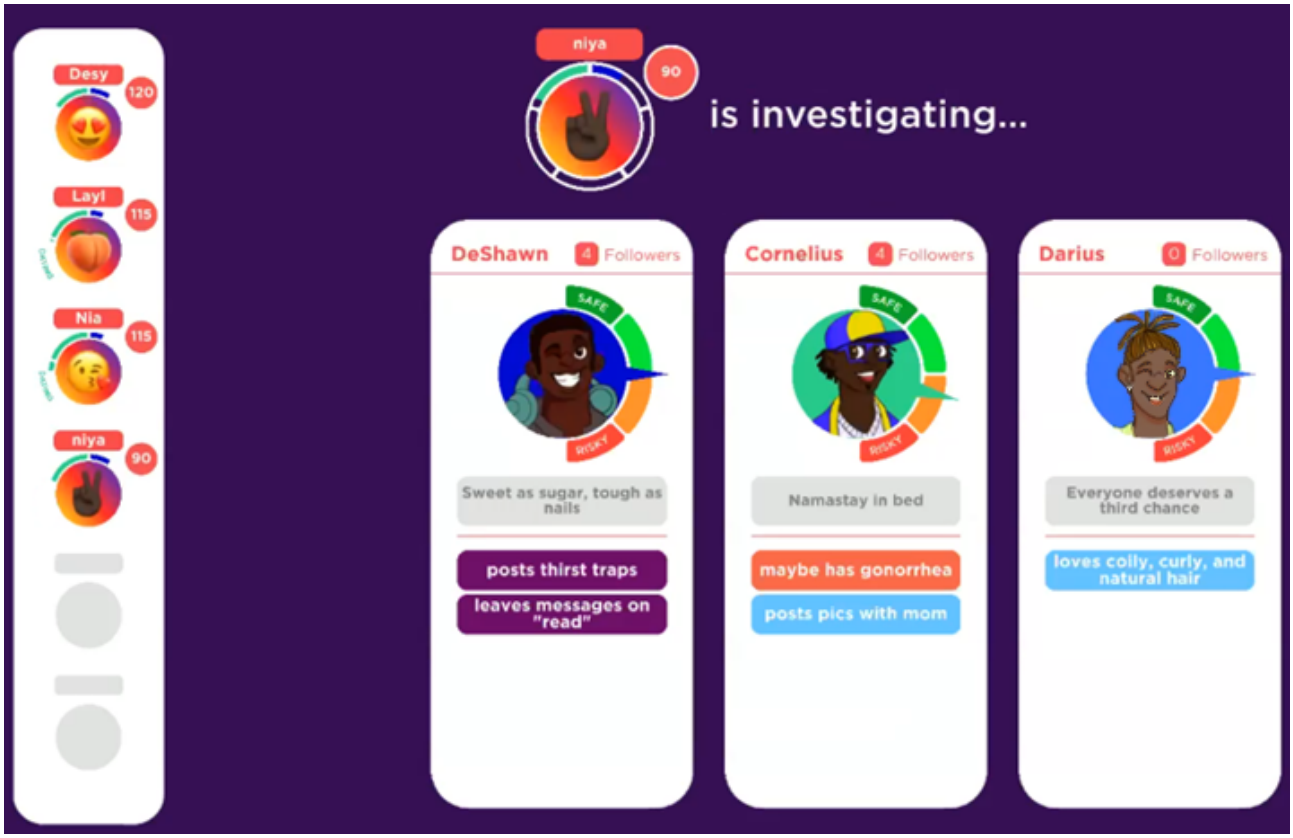
Figure 2. Game intervention conceptual model. PrEP: pre-exposure prophylaxis; STI: sexually transmitted infection.

Gameplay

At the beginning of the game, the players are introduced to "Chelsea" and "Brandon," 2 nonplayable characters who serve as guides throughout the game by providing instructions and verbal prompts to capture and direct player attention. In addition to learning a bit about the 2 host characters, all the players must pick 5 goals from options such as "talk to your doctor about PrEP," "convince a guy to use a condom during sex," "answer 9 trivia questions correctly," and "get tested for HIV and STIs," all with varying amounts of points awarded for completion. The game concludes when the first player reaches 300 points, and goal achievement provides the highest point awards. Figures 3-6 depict screenshots from the game and provide examples of actions players can take during the game to achieve goals.

XSL•FO
RenderX

Figure 3. Players, represented by emojis on the left of the screen, choose whom to "follow" based on biography and profile image and whom to investigate based on traits revealed on previous turns.



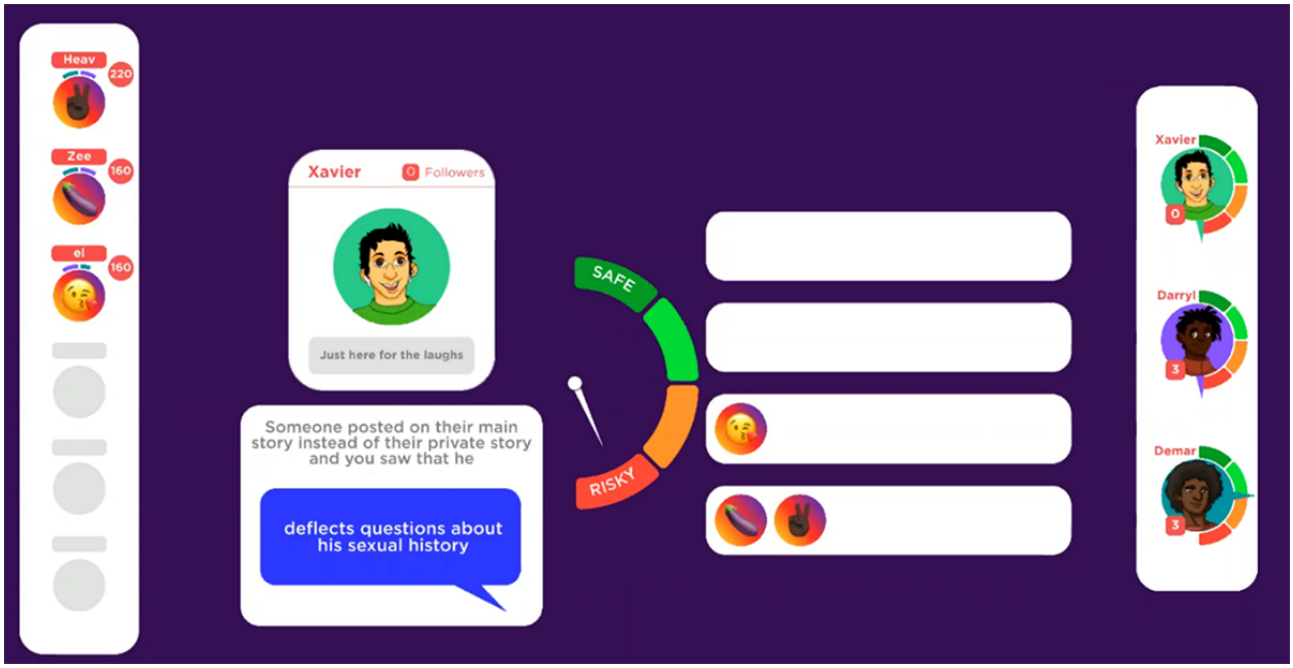


Figure 4. Players investigate datable characters and then vote on traits on a scale from safe-risky (pictured below) and cool-lame. Dating more risky characters increases the likelihood of a player becoming diagnosed with HIV or another sexually transmitted infection (STI).

XSL•FO
RenderX

Figure 5. The character Chelsea explains sexually transmitted infection (STI) prevalence in the United States in an animated voice-acted video.

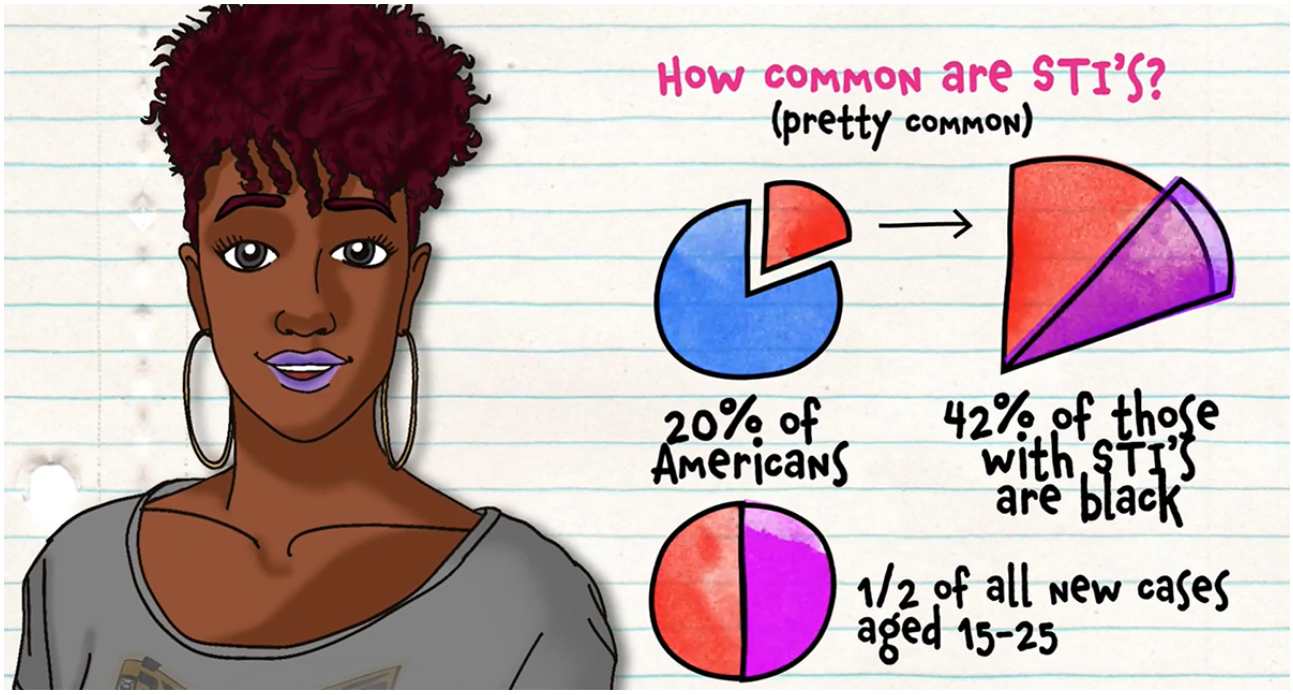

Figure 6. A conversation about HIV and sexually transmitted infection (STI) testing with a doctor.

Data Collection

Data were collected in 2 unique ways. First, all the assessments were self-administered via Qualtrics, which allows participants to complete assessments on their computer, phone, or tablet. Participants completed the baseline and postgameplay assessments during a live Zoom session with the researcher, which ensured that participants could ask questions of the study personnel as they arose. The 1-month and 4-month follow-up assessments were emailed to participants and completed by participants on their own time. Second, recordings of all gameplay sessions allow for the transcription of game content and player interactions during the game for qualitative analysis.

Outcomes

Primary Outcomes

The primary outcome of this study is to evaluate the feasibility and acceptability of a multiplayer game–based intervention designed to increase HIV and STI testing and condom use among Black adolescent girls. Intervention feasibility and acceptability will be examined through the number of sessions completed by participants and participant retention rates throughout the study.

XSL•FO
RenderX

Secondary Outcomes

Our secondary outcome is to increase Black adolescent girls' HIV and STI testing; use of condoms; self-efficacy to use condoms; positive attitudes toward condom use; intentions to use condoms; harm perceptions; HIV, STI, and pre-exposure prophylaxis (PrEP) knowledge; positive sexual norms; sexual communication with partners; and reduced incidence of sexual risk behaviors associated with HIV and STI transmission. We hypothesize that participants in the intervention condition will demonstrate greater improvements in the above outcomes when compared with the control participants. We will also measure whether changes are sustained across the follow-up periods of 1- and 4 months, as well as intervention feasibility and acceptability. Table 1 lists the surveys used to evaluate our secondary aim.

Across all time points, HIV and STI knowledge is evaluated with 12 true or false statements such as "having an STI like herpes can put a person at greater risk for getting HIV" or "chlamydia and gonorrhea cannot be cured," and recoded as correct or incorrect. The 12-item assessment is based on the validated 45- and 27-item HIV- and STI-Knowledge Questionnaires [45,46] and is available in Multimedia Appendix 1 [45,46]. Participants have the option to select "I don't know," which is scored as incorrect. A cumulative knowledge score will be created for each participant, with a maximum score of 12. CUSES (Condom Use Self-Efficacy Scale) is measured with a 10-item adaption of the scale designed by Brafford and Beck [47] and includes questions like "If my partner didn't want to use a condom, I feel confident that I could convince him that it was necessary" and "I feel confident in my ability to put a condom on my partner" to which participants could respond 1 (strongly disagree) to 5 (strongly agree). SRBBS (Sexual Risk Behavior Beliefs and Self-efficacy) is measured with a 27-item Likert scale questionnaire that includes questions like "Most of my friends believe people my age should wait until they are older before they have sex" or "If you decided to have sex, how sure are you that you could have a condom with you when you needed it?" to which participants respond on a 5-point scale [48]. PrEP knowledge and attitudes were assessed with questions regarding participant familiarity with PrEP, whether they would approve of friends or partners taking PrEP, and whether they believed friends and partners would approve if they were to take PrEP. Finally, sexual risk behavior was assessed with self-report questions based on the Youth Risk Behavior Survey [49]. We hypothesize that participants in the intervention condition will have greater changes or improvements in the above outcomes when compared with the control participants and that these changes will be sustained across time points.

Exploratory Outcomes

An exploratory outcome is included to evaluate participants' real-time responses to the game through the content analysis of audio recordings of gameplay sessions. We will investigate participant perceptions of research procedures and game content to analyze suggestions for the improvement of both. An additional exploratory analysis seeks to determine whether there is a relationship between participant responses on the 6-item MEIM-R (Multigroup Ethnic Identity Measure—Revised) and other outcome measures. The connection between ethnic identity and self-esteem, for example, is well known [50]. We will explore whether connection to one's ethnic identity may be a protective factor against sexual risk behavior [38]. Because the exploratory aim concerns implementation procedures and the adaptation and expansion of the game, there are no a priori hypotheses.

Statistical Analysis

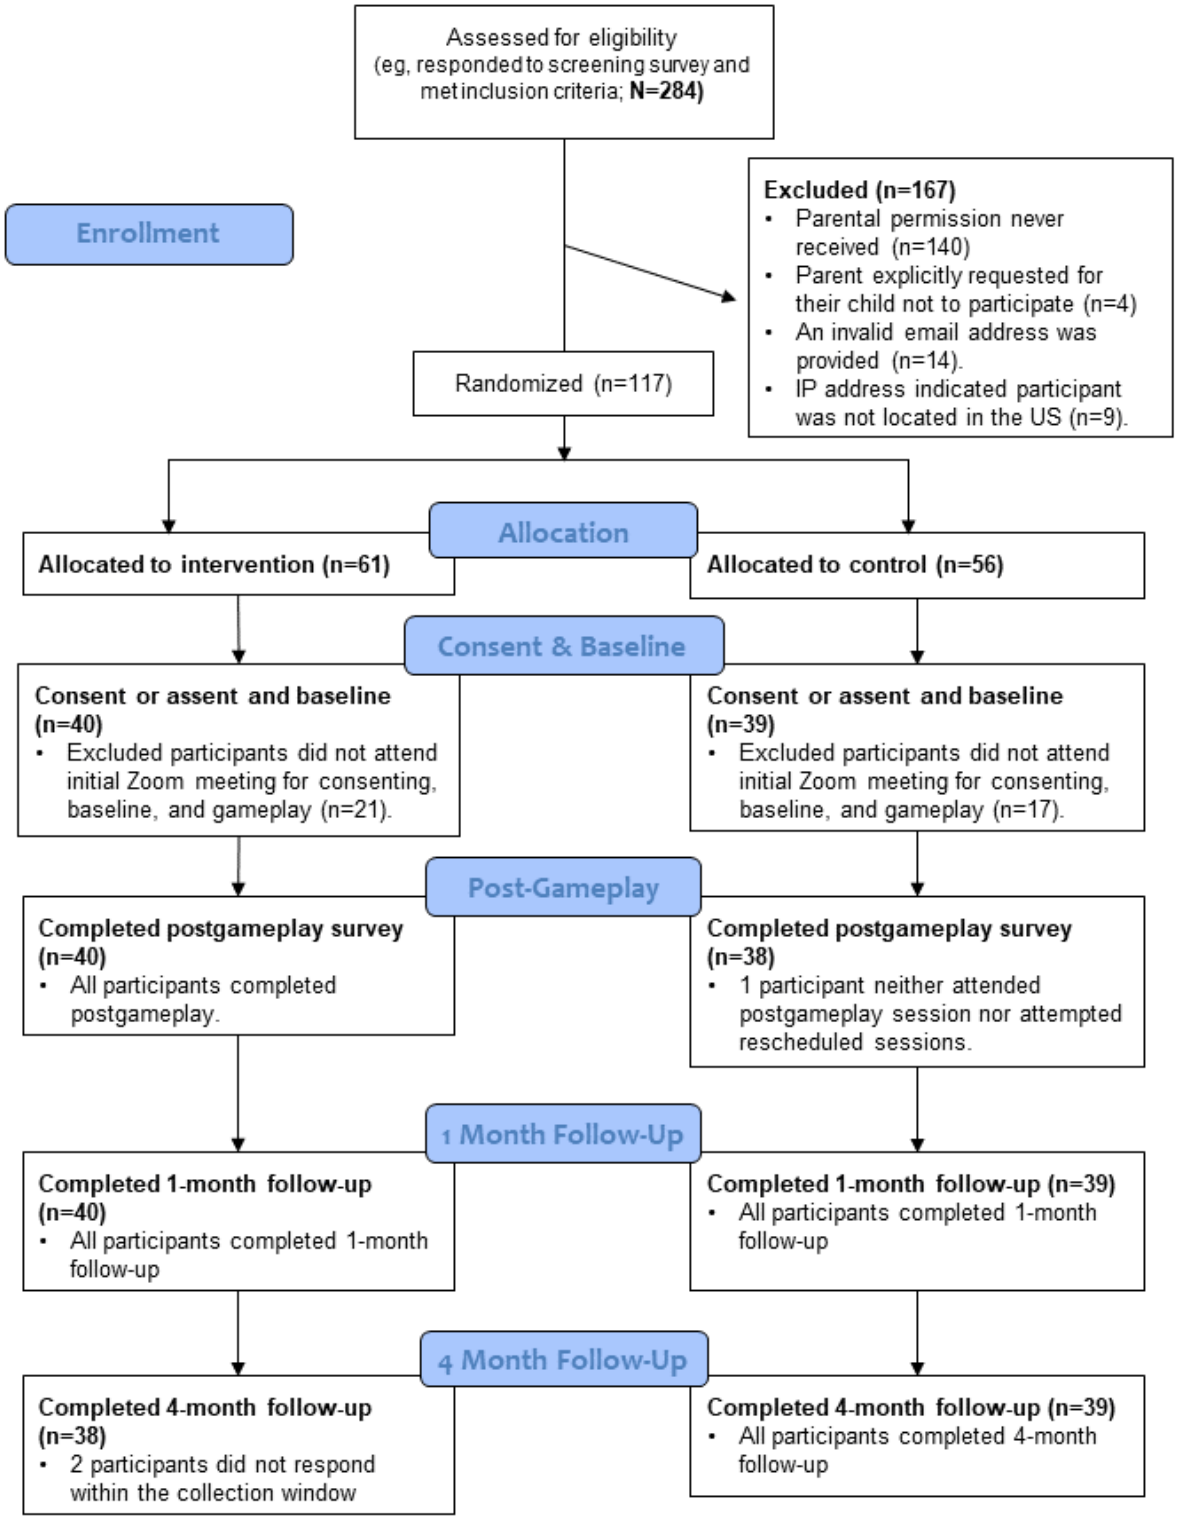
All statistical analyses will be conducted on an intention-to-treat sample using SPSS Statistics (IBM Corp) packages. Baseline characteristics will be analyzed using descriptive statistics. We will use baseline, postgameplay, 1-month, and 4-month data to estimate effect sizes for the primary outcomes. We will test the hypothesis that individuals who play *InvestiDate* will report more HIV and STI testing and communication with partners about testing in comparison to the control condition. We will conduct a longitudinal analysis using a hierarchical linear mixed models approach to compare participants in the intervention group to participants in the control group on reported participant HIV and STI testing from baseline across all follow-up assessments (ie, baseline, 1 month, and 4 months). Hierarchical modeling will allow us to account for the fact that the data are nested, as the participants will play the game in groups. An advantage of mixed models is that participants with missing data need not be excluded as all available data are used in estimating parameters. We will also use logistic regression models to determine if any relevant baseline variables, including ethnic identity, are associated with improvement in reported HIV and STI testing (constructed as a binary outcome [yes or no]). We plan to evaluate the prognostic significance of a small set of predictor variables (eg, attitudes, self-efficacy, ethnic identity, and knowledge) and use them as covariates in the primary analysis. Given the limited sample size (n=79), we anticipate that the power of this study to identify small but significant effect sizes will be low. A strength of this design is that it provides a number of perspectives from which to view treatment effects, including a treatment condition, a control condition, and a follow-up period. The results will inform the sample size calculation for a subsequent larger RCT.

Qualitative Analysis

The transcripts and chat logs from *InvestiDate* gameplay sessions (experimental group only) will be reviewed by members of the research team jointly who will perform data coding. These codes will be created in a step-wise fashion [51], beginning with the creation of an initial code structure from the first 2 transcripts that are independently reviewed by each team member. To enhance interrater reliability, gameplay transcripts will be independently reviewed and coded by each researcher and coding will be compared for agreement. Manual coding will then be electronically applied to the textual data using Dedoose (SocioCultural Research Consultants), a software program designed to facilitate the analysis of qualitative data. Data collected will be used to inform subsequent iterations of the video game, *InvestiDate*, and will similarly be used to provide exploratory evidence for the success of the intervention at achieving primary outcomes such as normalization of

XSL•FO
RenderX

conversations about sex and safe sex practices such as testing and condom use.



Results

Enrollment and Randomization

Overall, 1497 individuals clicked the link to the screening survey. In total, 47.43% (710/1497) of individuals completed the screening questionnaire, 40% (284/710) of which met the eligibility criteria; 9.5% (27/284) of eligible respondents were 18 years old at the time of recruitment, and we received parental consent for an additional 31.7% (90/284) of individuals to participate. Of those 117 prospective participants, 79 (67.5%) girls attended the first gameplay session, consented to participate, and were enrolled. Subsequently, 51% (40/79) of the enrolled participants were randomized into the intervention condition, and 49% (39/79) of the participants into the control condition. Figure 7 shows the CONSORT (Consolidated Standards of Reporting Trials) flow diagram that depicts participant retention at all time points [52]. All 79 participants were enrolled into the RCT between February 2022 and April 2022. All 39 participants in the control condition and 38 participants in the intervention condition completed the final survey in September 2022.

Figure 7. CONSORT (Consolidated Standards of Reporting Trials) flow diagram depicting participant enrollment and retention across all study time points. US: United States.

Sample Demographics

At baseline, there were no significant differences in demographic characteristics between intervention and control condition participants. At baseline, participant ages ranged from 14 to 19 years (mean 16.4, SD 1.23). One participant turned 19 during the week that elapsed between recruitment and the first gameplay session. Although the screening survey excluded participants who identified as having a sexual orientation other than straight (ie, heterosexual), bisexual, or pansexual, at baseline 10.1% (8/79) of participants identified as questioning or unsure, 1.2% (1/79) as queer, and 1.2% (1/79) as asexual, with the remaining 55.6% (44/79) of the participants identifying as straight or heterosexual and 32.9% (26/79) of the participants as bisexual or pansexual.

Discussion

Overview

In this pilot RCT of a multiplayer game–based intervention designed to increase HIV and STI testing and condom use among adolescent Black girls, we enrolled and randomized 79 participants. All participants were recruited through Instagram or Facebook, and there were no significant demographic differences between participants randomized to the intervention and control conditions. Notably, we chose to expand our inclusion criteria from strictly heterosexual-identifying participants to include individuals who identified as bisexual or pansexual in response to high numbers of participants who self-identified as something other than heterosexual. This observation is consistent with recent data from the Adolescent Behaviors and Experiences Survey in which 1 in 5 high schoolers identified as something other than straight or heterosexual [53].

This study protocol offers several strengths and novel strategies that can inform future gender- and culturally tailored HIV and STI prevention interventions as well as inform efforts to collect data for RCTs remotely using extant platforms like Zoom. Our video game intervention specifically addresses the intersectional identities of Black adolescent girls by incorporating the lived experiences of focus group participants into game story lines. In addition, the video game fosters a sense of social support by allowing Black adolescent girls to interact with each other, which is an important protective factor for sexual health [38]. It is among the first targeted interventions that is sex positive and harnesses the power of peer interactions through multiplayer gameplay to deliver HIV and STI prevention material. Because the video game intervention is self-contained, it has the potential to overcome common barriers to existing HIV prevention interventions, including access to adequately trained providers and intervention fidelity. Finally, data were successfully collected remotely during the global COVID-19 pandemic when in-person interactions were restricted. The procedures developed for data collection in this intervention can be adopted and used in other web-based studies involving multiple synchronous participants and may also be useful for the collection of larger nationally distributed samples.

Limitations

There are some limitations to this study protocol. In particular, participants were conveniently sampled through social media advertising, which may have resulted in selection bias. To participate in the study, participants were required to be available for gameplay sessions during weekday evenings, have a strong internet connection, and had to have access to 2 separate internet-capable devices (one to use the Zoom platform and one to play the game). These requirements may have discouraged participants with full evening schedules such as afterschool activities, part-time jobs, or family responsibilities from participating, as well as participants with low socioeconomic status. Finally, although the game was intended to be a social experience, game audio (such as background music and video game character dialogue) made communication between players difficult during many game sequences. Decreased social interaction in the multiplayer game may impact both participant ratings of gameplay satisfaction and acceptability, as well as intervention outcomes. In future iterations, we will examine whether in-person gameplay is more satisfactory than remote play over Zoom.

Conclusions

Black adolescent girls have the highest rates of STI among ethnic minority girls and are more than twice as likely to be diagnosed with an STI than their White peers, but there are very few HIV and STI prevention interventions specifically tailored for this group. This paper describes our protocol for a pilot RCT of a multiplayer game–based intervention designed to increase HIV and STI testing and condom use in Black adolescent girls. The aims of this pilot study are to assess the feasibility, acceptability, and preliminary efficacy of the game intervention. This protocol directly informs the development of a future larger RCT testing the efficacy of the video game intervention, *InvestiDate*, and can serve as an example for other researchers seeking to collect data over Zoom from multiple synchronous participants distributed nationally.

Acknowledgments

This project would not have been possible without our partnership with game prototype developer, PreviewLabs, Inc. The authors would also like to thank our sound engineer, Andrew Schartmann, PhD, who created the *InvestiDate* soundtrack and audio. The authors would like to thank our Board of Advisors and all the focus group participants who contributed to the development of this project, as well as Ms Alex Evans who provided her talents as a voice actor for the game. The study is funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development at the National Institutes of Health (1R21HD098031-01) and is registered as a clinical trial (NCT04108988).

Data Availability

The data generated during this study will be available from the corresponding author on reasonable request.

Authors' Contributions

KH, VW, IO, SH-R, and BS designed the intervention. VW, MB, and BS collected the data. IO, LD, and CSFF contributed to the design and selection of the assessments. VW drafted the manuscript, and IO and KH revised and critically reviewed the

XSL•FO
RenderX

manuscript for important intellectual content. All authors approved the final manuscript as submitted and agree to be accountable for all aspects of the work.

Conflicts of Interest

KH is the principal investigator for this study and has a significant relationship with the video game prototype company, PreviewLabs Inc, that is currently developing the video game intervention based on the findings of this research study. This relationship is extensively managed by KH and her academic institution. All other authors declared no potential conflicts of interest.

Abstract

Background: Accumulating evidence shows that subtle alterations in daily functioning are among the earliest and strongest signals that predict cognitive decline and dementia. A survey is a small slice of everyday functioning; nevertheless, completing a survey is a complex and cognitively demanding task that requires attention, working memory, executive functioning, and short- and long-term memory. Examining older people's survey response behaviors, which focus on how respondents complete surveys irrespective of the content being sought by the questions, may represent a valuable but often neglected resource that can be leveraged to develop behavior-based early markers of cognitive decline and dementia that are cost-effective, unobtrusive, and scalable for use in large population samples.

Objective: This paper describes the protocol of a multiyear research project funded by the US National Institute on Aging to develop early markers of cognitive decline and dementia derived from survey response behaviors at older ages.

Methods: Two types of indices summarizing different aspects of older adults' survey response behaviors are created. Indices of subtle reporting mistakes are derived from questionnaire answer patterns in a number of population-based longitudinal aging studies. In parallel, para-data indices are generated from computer use behaviors recorded on the backend server of a large web-based panel study known as the Understanding America Study (UAS). In-depth examinations of the properties of the created questionnaire answer pattern and para-data indices will be conducted for the purpose of evaluating their concurrent validity, sensitivity to change, and predictive validity. We will synthesize the indices using individual participant data meta-analysis and conduct feature selection to identify the optimal combination of indices for predicting cognitive decline and dementia.

Results: As of October 2022, we have identified 15 longitudinal ageing studies as eligible data sources for creating questionnaire answer pattern indices and obtained para-data from 15 UAS surveys that were fielded from mid-2014 to 2015. A total of 20 questionnaire answer pattern indices and 20 para-data indices have also been identified. We have conducted a preliminary investigation to test the utility of the questionnaire answer patterns and para-data indices for the prediction of cognitive decline and dementia. These early results are based on only a subset of indices but are suggestive of the findings that we anticipate will emerge from the planned analyses of multiple behavioral indices derived from many diverse studies.

Conclusions: Survey response behaviors are a relatively inexpensive data source, but they are seldom used directly for epidemiological research on cognitive impairment at older ages. This study is anticipated to develop an innovative yet unconventional approach that may complement existing approaches aimed at the early detection of cognitive decline and dementia.

KEYWORDS

dementia; mild cognitive impairment; early markers; survey response behaviors; epidemiology

Introduction

Dementia, a syndrome characterized by a progressive cognitive decline that interferes with independent functioning, affects a large and growing number of older adults. With increases in life expectancy in the population, the individual, family, and societal burdens associated with dementia are expected to accelerate rapidly, making the disease one of the major public health challenges of this century [1]. It is increasingly recognized that the identification of preclinical markers that are predictive of the future transition from healthy cognition to dementia is of paramount importance [2,3]. Such markers could allow earlier intervention and even modest delays in disease onset or progression, which would have a substantial impact on incidence rates and health care costs.

Despite existing efforts to discover biomarkers of cognitive decline and dementia [4,5], there is a need to develop and investigate nonbiological, behavioral markers that can be turned to when using biomarkers is impractical [6]. Accumulating research has shown that subtle alterations in daily functioning, for example, telephone or computer use, managing finances, and completing forms, are among the earliest and strongest signals that predict cognitive decline and dementia [4,5,7-9]. Reductions in the efficiency, speed, and consistency of performing these and other cognitively demanding activities can be observed up to a decade before diagnosis [3,7]. Accordingly, recommendations by the US National Institute on Aging and Alzheimer's Association highlight the need to identify and validate new neurobehavioral measures, including assessments of very early deficits in functional performance, that could detect preclinical manifestations of the disease [2,3].

We propose to develop indicators of functioning that can be gleaned from the way older people complete survey assessments, that is, questionnaires and computer-administered assessments. Surveys are ubiquitous in research and clinical practice, and many large-scale national and international longitudinal panel surveys on aging are presently in the field. A survey is a small slice of everyday functioning; nevertheless, completing a survey is a complex and cognitively demanding task that requires attention, working memory, executive functioning, and short- and long-term memory. Research on the psychology of survey methods confirms that answering survey questions requires considerable cognitive effort: respondents are expected to interpret the meaning of each question, retrieve relevant information from memory, integrate it into a summary judgment, and map their judgment onto the provided response alternatives [10]. As a result, examining older people's survey response behaviors, which focus on how respondents complete surveys irrespective of the content being sought by the questions, may represent a valuable but often neglected resource that can be leveraged to develop behavior-based early markers of cognitive decline and dementia that are cost-effective, unobtrusive, and scalable for use in large population samples.

The purpose of this paper is to describe the study protocol of the "Testing Early Markers of Cognitive Decline and Dementia Derived from Survey Response Behaviors" study. The study has the following 3 specific aims:

1. Aim 1 will develop questionnaire answer patterns and para-data indices of potential functional deficits based on survey response behaviors observed in a number of longitudinal aging studies.
2. Aim 2 will evaluate the validity and clinical utility of the indices and synthesize validity results across multiple longitudinal studies using meta-analytic principles.
3. Aim 3 will determine the optimal combination of survey response behavior indices for the prediction of subsequent mild cognitive impairment and dementia onset.

Methods

Overall Design

This study will develop early markers of cognitive decline and dementia from 2 types of indices summarizing different aspects of older adults' survey response behaviors. One category is comprised of indices that can be directly computed from the pattern of answers in questionnaires. These questionnaire answer pattern indices can be generated from participants' responses in a number of population-based longitudinal aging surveys, providing a repository of archival data that allows for predictions of current cognitive function from response behavior data collected many years ago. Examples of these questionnaire answer pattern indices are skipping questions, agreeing or disagreeing with statements regardless of content, errors due to nondifferentiation among questions or response options, or giving contradictory responses. The second category is comprised of so-called para-data indices, that is, auxiliary information unobtrusively collected alongside people's responses in surveys that are collected electronically (eg, on the web). Examples of such para-data indices are participant response times for survey questions, mouse movements, and keystrokes.

Ethics Approval

The study is approved by the University of Southern California Institutional Review Board (UP-22-00147) and the University of Surrey Research Integrity and Governance Office (FHMS 21-22 216 EGA).

Data Sources

Data for Creating Questionnaire Answer Pattern Indices

Existing longitudinal studies on aging are screened to identify data sets suitable for creating questionnaire answer pattern indices. Inclusion criteria are (1) a minimum of 3 waves of data collection (to estimate change over time) in which (2) participants complete a minimum of 40 multi-item rating scale questions at each assessment occasion (to achieve a sufficient

XSL•FO
RenderX

body of questionnaire answers to construct the indices), (3) respondents are 50 years of age or older (studies that include younger participants are truncated or only later waves are used), and (4) availability of objective tests of cognitive functioning. The criteria for inclusion in these studies are intentionally broad to enable the construction and examination of questionnaire answer pattern indices under a wide range of conditions. Excluded are studies that are cross-sectional, focus on younger adults, or administer questionnaires on a single occasion.

Table 1 shows the 15 longitudinal studies that we have identified as of October 2022 as eligible data sources for creating questionnaire answer pattern indices. The combined sample size in these studies is >50,000, including over 300,000 assessment time points. Multiple self-report scales of varying content are administered at each measurement occasion in all studies, including personality, mental health, attitudes, beliefs and values, quality of life, and emotional experience, which are used for generating the questionnaire answer pattern indices. Each study provides multiple cognitive functioning measures at each assessment wave, including the Mini-Mental State Examination [11], the Telephone Interview for Cognitive Status [12], and formal clinical assessments of dementia status.

Table 1. Eligible longitudinal aging studies for creating questionnaire answer pattern indices.

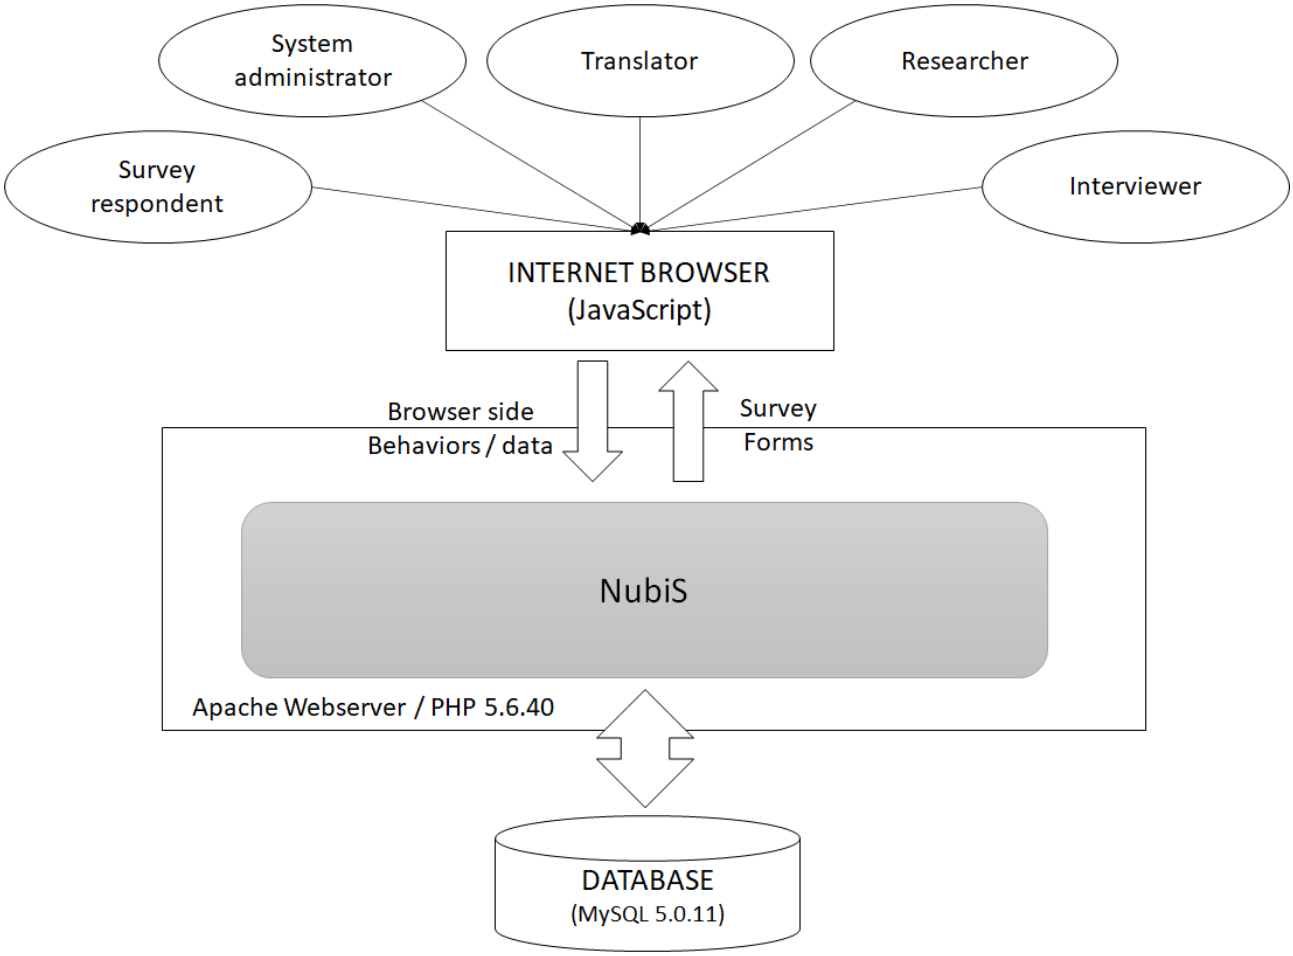
[a]Years indicate the first assessment wave to be used in the analyses.

[b]Minimum number of available individual questions from multi-item rating scales at each assessment occasion.

[c]T indicates that dementia status is ascertained by validated cutoffs from Telephone Interview for Cognitive Status [13,14].

[d]M indicates that dementia status is ascertained by Mini-Mental State Exam cutoffs [15,16].

[e]C indicates that dementia status is ascertained by formal clinical assessment.



Data for Creating Para-Data Indices

To create para-data indices, para-data are identified from the backend server of the Understanding America Study (UAS). The UAS is a probability-based web-based panel launched in 2014 that comprises 10,000 panel members, of whom about 5000 are aged 50 years or older. Panel members are randomly selected through address-based sampling and are compensated based on the estimated time spent on each survey. Panel members without prior access to the internet are provided with a tablet computer and internet access. Since its launch, the UAS has conducted over 400 surveys of varying length. Details about the UAS can be found on the UAS website [17].

Surveys in the UAS are conducted and managed by using an internally developed web-based software called NubiS (Centre for Economic and Social Research, University of Southern California), whose development was co-led by author BO. Figure 1 illustrates the system architecture of NubiS. The software runs on an Apache Webserver 2.4.10 with PHP version 5.6.40 and provides a role-based web interface for user groups such as survey respondents and system administrators. NubiS has the capability to capture and store both survey responses and browser-side behaviors, including mouse clicks, keys pressed, errors, leave, return, or progress in surveys, and user platform information using JavaScript.

XSL•FO
RenderX

Figure 1. The system architecture of NubiS.

There are seven types of raw para-data pertaining to the survey response process on NubiS: (1) "timing" records the time spent per screen, defined as the time from which the server outputs the survey screen to the browser to the moment that the respondent uses the back or next button; (2) "error" records errors detected on the browser side; (3) "key pressed" records keys pressed on the browser side; (4) "mouse click" records mouse clicks or touch events on the browser side; (5) "leave/return to survey" records the leaving or returning to the browser tab that contains the survey; (6) "survey invitation/response" records survey nonresponse and the times of survey invitation, uptake, and completion; and (7) "platform information" records the type of device, operating system, and browser type of the device used by the respondent.

Procedures for Creating Survey Response Behavior Indices

We periodically conduct literature searches in the areas of aging and cognition, psychometrics and survey methodology, computer use behaviors among older adults, and the psychology of survey response to identify publications describing questionnaire answer pattern indices and para-data indices that may be useful for research on cognitive decline and dementia. SAS macros are developed to compute the identified indices. For indices that require different analysis software, like R (R Foundation for Statistical Computing) or M*plus* (Muthén & Muthén), macros are developed to execute these external analysis steps in batch mode from within the SAS environment. The generated indices are matched to the survey waves or scales of each eligible aging study and stored for analysis. As of October 2022, we have identified a total of 20 questionnaire answer pattern indices (Table 2) and 20 paradata indices (Table 3). We will periodically refresh our literature search and update the list of response behavior indices.

XSL•FO
RenderX

Table 2. List of questionnaire answer pattern indices.

Index	Description
Item nonresponse	
• Proportion of skipped items [18]	This index measures the proportion of skipped items in a multi-item survey, which has been suggested to be associated with cognitive functioning [18].
Response styles	
• Acquiescence ("yea-saying") • Disaquiescence ("nay-saying") • Extreme response tendency • Midpoint responses	These indices are based on detecting abnormal response styles to identify respondents with cognitive impairment. Emerging evidence has suggested that certain response styles, such as acquiescence and an extreme response tendency, may be predictive of cognitive impairment or associated with important risk factors for cognitive impairment like low education in older adults [19,20].
Expressions of uncertainty	
• Proportion of "don't know" answers • Response uncertainty parameter [21]	These indices capture the extent to which participants express uncertainty about their answers in the surveys.
Classical Test Theory indices of improbable responses	
• Multivariate outlier rate [22] • Person-total correlation [23] • Psychometric synonyms [24] • Psychometric antonyms [24]	These indices are based on detecting improbable or implausible responses to identify respondents with cognitive impairment. Cognitive impairment has been suggested to result in improbable answers [24].
Item Response Theory person-fit statistics	
• Polytomous l_z index [25] • Normed Guttman errors [26] • *U*3 index [27]	These indices are also designed to detect improbable or implausible response patterns, based on modern test theory approaches.
Random errors or noise in responses	
• Individual test reliability • Inter-item standard deviation [28]	These indices capture unreliable answer patterns to capture random variability in attention or fluctuating cognitive performance.
Response inertia	
• Residual autocorrelation across consecutive responses [29] • Long-string analysis [24]	These indices measure carry-over effects in people's response patterns, which may express an inability to adapt responses to changing question contents.
Response pattern drift within a survey	
• Improvement or worsening in missing, stylistic, outlying, misfitting, or random response patterns within a survey • Change-point analysis of weighted residuals [30]	These indices measure trends in response patterns over the course of a survey. Worsening response behaviors as a participant completes multiple questions in succession may indicate mental fatigue or lower sustained attention ability.

XSL•FO
RenderX

Table 3. List of para-data indices.

Index	Description
Survey completion	
• Time lag from invitation to survey uptake • Time of day survey was taken • Missed survey • Time from uptake to complete the survey	This category of indices measures aspects of survey completion, such as whether a survey is incomplete and the time spent on completing a survey. Emerging evidence suggests that these indices may be predictive of cognitive impairment [31].
Response time	
• Median browser-side response time • Deviations from the median browser-side response time • Variability in response times across questions • Autocorrelation (inertia) of response times across questions • Item response theory person-fit statistics response time patterns • Pause rate (no response for >20 seconds) • Median pause duration	This category of indices measures aspects of response times such as the median response times, variability, and autocorrelations. A growing number of studies suggest that response times and their derived measures may be associated with cognitive impairment [32,33].
Errors and corrective behaviors	
• Proportion of corrected or changed answers • Rate of error messages received (eg, invalid entry) • Rate of “back” button use • Rate of “next” button use without a completed response	This category of indices measures aspects of errors and corrective behaviors in answering web-based surveys.
Mouse and touch efficiency	
• Number of mouse clicks per page (median) [34] • Variability of mouse clicks across screens [34] • Total pixel count (inefficiency in movement: “wandering around on screen”) [34]	This category of indices measures aspects of mouse clicks and inefficiencies in mouse movement behaviors.
Keystrokes	
• Median time between keystrokes (for text entries) [34] • Variability of time between keystrokes (within a text entry) [34]	This category of indices measures temporal rhythms of keystrokes from keyboard entries by respondents for survey questions.

Data Analysis Procedures

Validity and Clinical Utility of the Proposed Indices

We will conduct in-depth examinations of the properties of the generated questionnaire answer pattern and para-data indices for the purpose of evaluating their concurrent validity, sensitivity to change, and predictive validity in each study, as well as the replicability and robustness of their performance across different studies and survey contents. We first evaluate the cross-sectional correlations between the survey response behavior indices and cognitive functioning scores. We then evaluate each generated index for its sensitivity to change in 3 aspects, including the average rate of change with age (ie, whether an index reflects a decline in performance with age), differential change with age (ie, the extent to which some people change more rapidly than others with age), and correlated changes (ie, the extent to which changes in an index correlate with changes in a cognitive test score). In addition, we evaluate prospective relationships between the generated indices and subsequent changes in cognitive functioning measures. We examine the lagged effects between the indices and subsequent cognitive test scores across the measurement occasions in each study. We also test the ability of the survey response behavior indices at baseline (ie, the first measurement occasion) to predict the later onset of dementia in time-to-event (survival) analyses. To ensure robustness and replicability of the variables’ performances, we repeat the analyses across all eligible longitudinal aging studies. As for the paradata indices, we repeat the analyses for different surveys in the UAS.

Synthesis of Indices Across Studies

Methods of individual participant data meta-analysis are used to analyze and aggregate results across different studies. These methods have been considered state-of-the-art for study comparison and integration, and the research team has successfully implemented them in prior research projects [35,36]. Given that the different panel studies vary in data structure (eg, number and spacing of measurement occasions) and do not administer exactly the same instruments (eg, cognitive functioning tests), we do not harmonize the data across studies or combine them into a single large data set. Instead, analyses are first carried out separately for each data set (ie, for each study) using identical data-analytic models. The resulting effect sizes are then synthesized across data sets using meta-analytic techniques. This method preserves the heterogeneity of effect sizes across studies, and, because it synthesizes effect sizes without directly pooling data into a single data set, it can accommodate the integration of results from diverse studies. Thus, individual participant data meta-analysis enables us to generate a cumulative evidence-base

XSL•FO
RenderX

of the performance and validity of the survey response behavior variables with great efficiency.

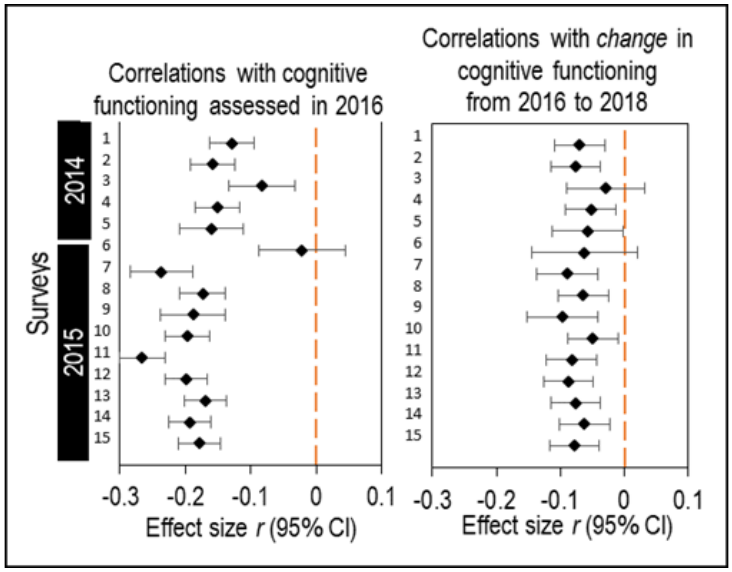
Selection of the Optimal Combination of Indices

We use feature selection methods to determine the optimal subset of survey response behavior indices that are most predictive of subsequent dementia onset when combined with each other. Feature selection is a machine learning technique that is particularly well-suited for determining those indices that jointly optimize a prediction equation for individuals while identifying and discarding those indices that are irrelevant or provide redundant predictive information. Among the multiple approaches considered, we use a regularized survival modeling method that uses a path-based algorithm for the Cox proportional hazards model, regularized by elastic net penalties, to rank and select the most predictive indices [37]. The model penalizes the regression coefficients of the survival model, effectively causing many coefficient estimates to shrink to zero. The predictive power of each index is then ranked based on shrinkage speed, with the slowest shrinking index having the strongest predictive power. Overall model accuracy is assessed with common measures of model performance such as sensitivity, specificity, and area under the receiver-operating curve.

Results

As mentioned in the previous section, we will have identified 15 longitudinal ageing studies as eligible data sources for creating questionnaire answer pattern indices by October 2022 (Table 1). We have identified a total of 20 questionnaire answer pattern indices (Table 2) and 20 paradata indices (Table 3). We have conducted a preliminary investigation to test the utility of the questionnaire answer pattern indices for the prediction of cognitive decline and dementia. The tested indices included the proportion of skipped items [18], the multivariate outlier rate [22], the normed Guttman errors [26], the inter-item standard deviation [28], and the person-total correlation [23] derived from the 2006/2008 waves in the Health and Retirement Study (N=12,554). Survival analyses (using the Fine and Gray competing-risk model [38]) were used for each index to examine whether it predicted dementia onset in the subsequent 8 years, while statistically controlling for age and education and while taking death into account as a competing event. Dementia status was ascertained using the criteria by Langa and Weir, which categorize respondents as cognitively normal, cognitively impaired (not dementia), or having dementia. The classification is based on cognitive test scores with cutoffs calibrated against in-person clinical assessments in the Aging, Demographics, and Memory Study [13]. It is not a clinical diagnosis but has proven useful for research purposes. As shown in Table 4, the hazard rates of dementia onset are between 1.52 and 2.25 times as high in respondents with questionnaire answer patterns that suggested cognitive problems (highest tertile) as for those in the lowest tertile (P<.001 for each index), and the middle tertile fell between the lowest and the highest. Details on the results of these analyses have been published elsewhere [39].

To assess the predictive power of the para-data indices, we derived participants' response times to survey items in 15 UAS surveys that were fielded from mid-2014 to 2015. We examined whether they were predictive of subsequent cognitive functioning measured in 2016 and of cognitive function change from 2016 to 2018. The response times to UAS survey items were log-transformed to reduce skewness. Cognitive functioning was evaluated by using the verbal analogies test, an executive functioning and analogical reasoning task with good specificity and sensitivity in discriminating normal controls from probable dementia patients. The analysis included 3829 UAS panelists 50 years and older and examined both zero-order associations and associations controlling for age and education. As shown in Figure 2, longer response times on 14 of the 15 surveys were significantly correlated at the 0.05 level with lower subsequent cognitive test scores in 2016 as well as with worsening cognitive functioning from 2016 to 2018. The significance and direction of these associations did not change after controlling for age and education.



Notably, these early results are based on only a subset of questionnaire response patterns and para-data indices but are suggestive of the findings that we anticipate will emerge from the planned analyses of multiple behavioral indices derived from many diverse studies.

Table 4. Hazard ratios (95% CI) for associations between selected questionnaire answer pattern indices and subsequent dementia risk in the Health and Retirement Study (N=12,554).

Tertile for each variable	Proportion of skipped items	Multivariate outlier rate	Normed Guttman errors	Interitem SD	Person-total correlation
Low	Reference	Reference	Reference	Reference	Reference
Middle	1.34 (1.15-1.56)	1.38 (1.12-1.71)	1.43 (1.18-1.76)	1.28 (1.05-1.57)	1.40 (1.14-1.71)
High	1.52 (1.24-1.86)	2.25 (1.84-2.75)	2.09 (1.73-2.53)	1.93 (1.61-2.34)	2.03 (1.68-2.46)

Discussion

This paper describes the protocol of a multiyear research project that aims to develop early markers of cognitive decline and dementia from survey response behaviors. The project plans to develop 2 types of indices, known as questionnaire answer pattern indices and paradata indices, summarizing different aspects of older adults' survey response behaviors. The project will examine the psychometric properties of the created indices and create predictive models of cognitive decline and dementia using the indices. Preliminary results are suggestive of the predictive power of survey response behavior indices for forecasting cognitive decline and dementia. To the best of our knowledge, this study is the first multiyear funded project aspiring to develop nonbiological early markers of cognitive decline and dementia from large-scale survey response behavior data at older ages.

If successful, the study may open novel opportunities for advancing research on health care for cognitive decline and dementia. Indices derived from survey response behaviors that could serve as preclinical markers of cognitive decline could greatly enhance the usefulness of questionnaires collected in large-scale surveys for epidemiological research on the risk and protective factors of dementia. Questionnaires are also routinely collected in medical care settings, and it is possible that survey response behavior indices extracted in these settings could potentially supplement information from standardized cognitive tests. In clinical trial research, the Food and Drug Administration recommendations for early-stage Alzheimer disease trials encourage the development of novel approaches for the evaluation of preclinical functional deficits [40], and response behavior indices extracted from questionnaires administered in clinical trials might potentially supplement core clinical measures that serve as trial endpoints. Furthermore, the survey response behavior indices may be useful as a proxy for cognitive impairment in aging survey research where standardized cognitive functioning measures are not assessed.

Survey response behaviors are a relatively inexpensive data source, but they are seldom used directly for epidemiological research on cognitive impairment at older ages. This innovative yet unconventional approach may complement existing approaches aimed at the early detection of cognitive decline and dementia.

Abstract

Background: In the veteran community, chronic pain is particularly prevalent and often debilitating. Until recently, veterans with chronic pain were offered primarily pharmacological intervention options, which rarely suffice and can also have negative health consequences. To better address chronic pain in veterans, the Veterans Health Administration has invested in novel, nonpharmacological behavior interventions that target both pain management and chronic pain–related functional issues. One approach, acceptance and commitment therapy (ACT) for chronic pain, is supported by decades of efficacy evidence for improving pain outcomes; however, ACT can be difficult to obtain owing to issues such as a lack of trained therapists or veterans having difficulty committing to the time and resources needed for the full clinician-led ACT protocol. Given the strong ACT evidence base combined with access limitations, we set out to develop and evaluate Veteran ACT for Chronic Pain (VACT-CP), an online program guided by an embodied conversational agent to improve pain management and functioning.

Objective: The aims of this study are to develop, iteratively refine, and then conduct a pilot feasibility randomized controlled trial (RCT) of a VACT-CP group (n=20) versus a waitlist and treatment-as-usual control group (n=20).

Methods: This research project includes 3 phases. In phase 1, our research team consulted with pain and virtual care experts, developed the preliminary VACT-CP online program, and conducted interviews with providers to obtain their feedback on the intervention. In phase 2, we incorporated feedback from phase 1 into the VACT-CP program and completed initial usability

XSL•FO
RenderX

testing with veterans with chronic pain. In phase 3, we are conducting a small pilot feasibility RCT, with the primary outcome being assessment of usability of the VACT-CP system.

Results: This study is currently in phase 3; recruitment for the RCT began in April 2022 and is expected to continue through April 2023. Data collection is expected to be completed by October 2023, with full data analysis completed by late 2023.

Conclusions: The findings from this research project will provide information on the usability of the VACT-CP intervention, as well as secondary outcomes related to treatment satisfaction, pain outcomes (pain-related daily functioning and pain severity), ACT processes (pain acceptance, behavioral avoidance, and valued living), and mental and physical functioning.

Introduction

Background

Among the most complicated medical conditions to manage, chronic pain refers to pain lasting longer than 3 to 6 months that persists beyond the healing of an initial injury or disease; in fact, it can often last for years or decades [1,2]. Chronic pain is a highly prevalent problem in the United States, with 50 million (20.4%) American adults experiencing daily chronic pain [3]. Military veterans aged ≥20 years are at a particularly high risk because they are 11.4% more likely to have chronic pain than nonveterans of the same age [4]. American veterans, with higher rates of chronic pain and more severe pain than nonveterans, are substantially affected in terms of general functioning and well-being [5-7]. In an effort to reduce chronic pain in this population, pharmacological treatments such as long-term opioid therapy were routinely prescribed and considered standard of care for chronic pain [8]. However, although patients with chronic pain report some relief from short-term use of opioids, there are concerns about long-term opiate use [9], which can lead to substance use and abuse, as well as death [10,11].

To adequately address chronic pain, it is imperative to look beyond pharmacological treatments and encourage the use of behavioral approaches that can enhance self-management of chronic pain. Over the past decade, the Veterans Health Administration (VHA) has strongly promoted a holistic approach to chronic pain treatment that promotes behavioral, therapeutic, and holistic interventions for pain management [12]. Research has shown that addressing factors promoting resilience and psychological well-being can be particularly helpful for individuals with chronic pain [13]. One promising therapeutic framework for pain that emphasizes behavior change and promotes resilience is acceptance and commitment therapy (ACT) for chronic pain, which focuses on mindfulness, value-based goal setting, and psychological flexibility [14]. More than 15 randomized controlled trials (RCTs) to date have shown greater efficacy of ACT for chronic pain than cognitive behavioral therapy, educational and support control groups, medical treatment as usual, or a waitlist control [15,16]. For veterans specifically, ACT for chronic pain has shown effectiveness in improving functioning [17], pain interference, pain-related anxiety, and depression [18].

ACT, similar to other behavioral approaches, requires considerable support from both the health care system (in terms of clinician training and appointment availability) and the patient (in terms of time and effort needed to complete the full treatment protocol). Even when veterans are interested in behavioral interventions for their chronic pain, they may not find it easily or locally accessible. Behavioral treatment for chronic pain requires considerable clinician time and training and, as a result, is less accessible to veterans who are not close to a large Veterans Affairs (VA) medical center. In fact, fewer than half of the veterans diagnosed with chronic pain receive mental health treatment [19], and half of VA facilities do not have any pain-focused behavioral therapy services [20].

To bridge this access gap, technology-assisted pain management interventions are increasingly appealing because remote treatment options can improve the VHA's ability to reach patients, are cost-effective, and can increase overall clinical impact [21,22]. Web-based behavioral interventions are relatively easy to implement across clinical settings after initial development, compared with in-person interventions, because they do not require training new practitioners to implement a treatment or monitor treatment fidelity [23,24]. In addition, online interventions have the potential to reach many veterans with chronic pain in their homes because 85% of veterans report having access to the internet in their homes [25].

Recent systematic reviews have concluded that technology-delivered ACT is both feasible and effective in managing chronic pain [26]. However, although technology-supported health care interventions are increasing in popularity and are often noninferior to in-person treatment, sustained engagement in these treatments continues to lag [21]. Research has suggested that existing online interventions can increase engagement by adding in more interactive, personalized, and user-tailored feedback [27]. For years, developers of online pain self-management systems have also reported that users become most engaged when the systems provide intelligent responses to the user's input information related to their pain experiences, concerns, goals, and target behaviors [28]. It should be noted that very few online interventions are able to provide this level of interaction between

XSL•FO
RenderX

the user and the system, and even fewer evaluate the impact of personalized features on health outcomes [29] or sustained engagement [23,30]. Consequently, there is still room to improve online pain treatment by developing and testing a more user-centered, interactive, and engaging online pain management experience.

One way to increase engagement with online behavioral interventions is by using embodied conversational agents (ECAs), which are computer-animated characters that simulate interactive dialogue with patients [31]. An ECA can act as a responsive, humanistic, and nonjudgmental coach to guide patients through treatments such as health behavior change interventions, social skills training, and mindfulness-based stress reduction [32-35]. Interacting with ECAs that guide behavior interventions has been associated with positive outcomes such as higher use of stress management skills [33] and healthier eating behaviors in older adults [35]. Clinical trial participants—in particular, individuals with lower levels of health literacy [31]—have also expressed greater satisfaction with interventions that use ECAs than with educational content delivered by other means [33]. By using an ECA as a digital coach for delivering module-based ACT for chronic pain, we aim to provide a fully remote, accessible, and engaging option for at-home pain treatment for veterans with chronic pain.

Objectives

We are conducting a 3-phase project that will culminate in a pilot feasibility RCT of ECA-delivered ACT for chronic pain. The online program, Veteran ACT for Chronic Pain (VACT-CP), will use a weekly 7-module protocol to guide veterans with chronic pain to decrease behavioral avoidance and increase pain acceptance and valued living to improve their functioning. Using the principles of user-centered design, the aims of this research project are to (1) develop the VACT-CP system with feedback from mental health and other clinical professionals who treat chronic pain; (2) assess the usability of the VACT-CP system via iterative usability testing and development from veteran feedback; and (3) assess the usability of the complete VACT-CP website, as well as describe differences between the VACT-CP group and a waitlist plus treatment-as-usual (WL+TAU) control group on secondary outcomes related to treatment satisfaction, pain outcomes (pain-related daily functioning and pain severity), ACT processes (pain acceptance, behavioral avoidance, and valued living), and mental and physical functioning.

Methods

Phase 1: Consultation, Development, and Gathering Provider Feedback

Objective

The aim in phase 1 was to gather qualitative feedback on the VACT-CP system from 10 to 12 chronic pain clinical care providers, as well as identify barriers and facilitators for VACT-CP referrals and implementation in the VA Bedford Healthcare System.

Participant Recruitment

In phase 1, we conducted semistructured interviews with clinical care providers (n=10) at the VA Bedford Healthcare System, whose work is at least partially related to issues of chronic pain. Participants were recruited using flyers posted around the facility in areas that serve veterans with chronic pain as well as snowball recruitment methods. To ensure a representative mix of clinical care pain providers, we aimed to recruit 2 to 3 psychologists, 2 to 3 nurses, 2 to 3 physicians, and 2 to 3 psychiatrists. The inclusion criteria were as follows: (1) currently working at the VA Bedford Healthcare System or one of its affiliated community-based outpatient clinics in a clinical capacity and (2) currently seeing veterans to assist in their management of chronic pain. The exclusion criterion was any cognitive or physical impairment (eg, auditory or sight issues) that would interfere with aspects of study participation that require using a computer or giving verbal feedback.

Provider Feedback Session Procedure

Interested individuals were briefly screened by telephone for eligibility and scheduled for their hour-long session. After providing informed consent, eligible participants completed a quantitative survey and a qualitative interview. The quantitative survey included a brief (5-minute) questionnaire related to their work background and individual demographics. The qualitative interviews were audio recorded for formative assessment of the potential benefits, concerns, and institutional VHA dissemination issues for the VACT-CP intervention using a semistructured interview guide and a *think-aloud* strategy for intervention review.

Measures

The demographics questionnaire included basic, nonidentifying information, including participant age, ethnicity, race, and education. The work history survey included questions created specifically for this study related to working with patients who have chronic pain, including the provider's current position, past experiences as a health or mental health provider specific to working with patients with chronic pain, length of time in their current position, past specialized training on treating chronic pain, and information related to making any prior referrals to online or technology-mediated health interventions or resources. The qualitative interview included open-ended questions related to palatability of the intervention; feasibility of engagement with veterans with chronic pain; interest in, or potential concerns regarding, referring veterans to such a program; and reactions to a short walk-through of the intervention. Questions about palatability were based on the "organizational perspective" components of the Practical, Robust Implementation and Sustainability Model [36] (Multimedia Appendix 1).

Data Analysis Plan

After data collection, we used provider feedback to (1) understand the acceptability and potential usability of the platform in other settings (eg, at the veteran's home), (2) examine provider attitudes toward the VACT-CP system, (3) address any technological or system-specific concerns, and (4) modify potential plans for the future VACT-CP phase 2 usability

XSL•FO
RenderX

assessment. Modifications to the interface and protocol were based on (1) acceptability and feasibility of the VACT-CP platform and potential treatment components and (2) qualitative feedback obtained from providers. Individual qualitative interviews will be analyzed at the end of the full study via the consensual qualitative research (CQR) approach. The initial codebook will be used by 2 to 3 coders throughout the data analysis process to foster multiple perspectives until consensus is reached among the coders about the meaning of the data. In addition, at least 1 auditor will check the work of the primary team of coders and serve to minimize potential bias.

We will report the frequency of emerging domains and themes. Themes will then be categorized according to the following CQR groupings: general (include all or all but one of the cases), typical (include more than half of the cases up to the cutoff for general), and variant (at least 2 cases up to the cutoff for typical). We will use these data to discuss broader scientific and implementation-related barriers and facilitators for interventions for patients with chronic pain within the VA system. Full data for this phase will be analyzed at the end of the completed study.

Phase 2: Veteran Usability Assessment

Objective

The objective in phase 2 was to conduct an iterative usability assessment by pilot-testing VACT-CP components, including the format, digital ECA guide (*Coach Anne*), and system via field-based iterative usability testing (3 waves; n=4-5 per testing wave, total goal: N=12-15).

Participant Recruitment

Veteran participants for phase 2 were recruited through a variety of methods, including through providers who shared information about the study with potential participants, posting flyers throughout the hospital, and sending mailers to veterans who received treatment for chronic pain within the past 6 months as identified via a medical chart review. The inclusion criteria were as follows: (1) veteran aged ≥18 years; (2) current diagnosis of noncancer chronic pain; (3) competent to provide written informed consent; and (4) has a working, high-speed wireless internet connection at home or is willing to access the website at the VA Bedford Healthcare System using a provided laptop computer in a secure space. The exclusion criterion was any cognitive or physical impairment (eg, auditory or sight issues) that would interfere with aspects of study participation that require using a computer or giving verbal feedback.

Usability Testing Procedure

We aimed to have 3 different usability testing waves, with at least 1 week between each wave to allow enough time to iteratively address any functionality issues or concerns with the user interface. The choice of 4 to 5 participants per wave was based on the finding that approximately 80% of usability problems can be detected using a sample of 4 to 5 participants [37]. Usability sessions were conducted remotely using a secure videoconferencing platform or in person at the Bedford VA medical center, if preferred by the participant. The goals of phase 2 were to (1) obtain further feedback on the VACT-CP treatment by gathering information from veterans via usability testing designed to assess interest in, satisfaction regarding, and usability of the online VACT-CP treatment; and (2) iteratively address any technological concerns. We first completed a telephone screen to assess whether veterans were eligible according to our inclusion and exclusion criteria. After the intake assessment, eligible participants were scheduled for a single 2-hour usability testing session. After providing verbal informed consent, participants completed a pre–usability testing survey battery. Subsequently, they were provided with a hyperlink and their precreated account information and asked to complete the first and second modules (combined) of the VACT-CP system, guided by Coach Anne. Participants were instructed to *think aloud* as they completed the module and provide their first reactions to the program. VACT-CP usability was evaluated along four dimensions: (1) usefulness: whether users can successfully complete designated tasks on the website, (2) effectiveness: whether users can accomplish tasks quickly and easily, (3) learnability: whether users meet predetermined site navigation goals within a specified period of time, and (4) satisfaction: how users feel about the website. Objective measures included usability scales related to content, perceived usefulness, visual appeal, and overall usability of the system. A qualitative interview was conducted after the think-aloud session to gather additional feedback, identify which aspects of the program were the most or least helpful, and review any suggested changes. Participants received a US $40 gift card for their 2-hour digital research session.

Measures

Demographics, Functional Health, and Pain Measures

Demographic measures included questions on pain type and duration, age, gender identity, race, ethnicity, and education level. Additional measures will include the Patient Health Questionnaire-9 [38] and Posttraumatic Stress Disorder Checklist [39], as well as pain interference (Brief Pain Inventory) [40] and the Veterans RAND 36-Item Health Survey (VR-36) [41]. These measures will be used to describe the demographic and health-related characteristics of the sample.

Media and Technology Use and Attitudes Scale

The Media and Technology Use and Attitudes Scale [42] is a 16-item measure of attitudes toward technology with a 10-point frequency scale, from 0=never to 10=all the time, that assesses comfort level, attitudes toward new technology, and use patterns for mobile technology. This scale is completed before the VACT-CP interaction session and will be used to describe the technology attitudes and perceptions of the sample.

System Usability Scale

The System Usability Scale (SUS) [43] is a 10-item measure that uses a 5-point Likert scale from 1=strongly disagree to 5=strongly agree to assess the usability of a technology. The SUS, a globally used scale, generates a subjective evaluation score to determine whether the technology system in its current form is sufficiently usable. An SUS score of >68 is regarded as above average usability, and an SUS score of >80 is regarded as high; when people rate a technology product with an SUS score of >80, they are likely to recommend it to friends [43].

XSL•FO
RenderX

Intrinsic Motivation, Usability, and Perceived Usefulness Scales

The usability survey items are adapted from an existing set of usability questions to make the questions specific to the VACT-CP treatment and are informed by the Unified Theory of Acceptance of Technology [44,45] and the Wilson and Lankton [46] model, which combines the Technology Acceptance Model [47] and motivational model of technology acceptance [48]. The survey items assess the following factors: intrinsic motivation to use the VACT-CP system, perceived ease of use, perceived usefulness, and behavioral intention to use the system. Each item is assessed using a 5-point Likert scale, and participants are asked to indicate their level of agreement with each item on a scale from 1=strongly disagree to 5=strongly agree. Scale scores (agreement ratings averaged across items for each construct) are then calculated for each of the following constructs: intrinsic motivation, ease of use, perceived usefulness, and behavioral intention to use the VACT-CP system.

Qualitative Combined Usability and Contextual Interview

Participants were observed while working with the VACT-CP system, including being video recorded and asked questions by an interviewer. The interview guide (Multimedia Appendix 2) includes specific questions related to the different parts of the system (eg, the digital coach design, structure of the modules, and feedback system). In addition, interviewers query participants for feedback or information when participants seem to be confused or report difficulties with the system (eg, What are you trying to get to from this page? and What could be better about how this is set up?). All questions are open-ended and ask about multiple areas of usability and content, such as problems accessing and using the VACT-CP treatment, the perceived usefulness or importance of VACT-CP areas of treatment, and whether the participant would recommend this treatment to a fellow veteran.

Intervention Revision

Between each wave of testing, information specific to usability issues was gathered and analyzed to address any technological issues and revise content. Modifications to the website, module structure, and overall VACT-CP website framework were made between each wave based upon acceptability and feasibility of the online treatment and qualitative feedback obtained from patients.

Data Analysis Plan

Similar to phase 1, the video recordings and notes made during the qualitative portion of user testing will be transcribed and analyzed using Excel (Microsoft Corp). The quantitative data from the SUS and usability survey will be used to obtain scale scores that describe each veteran's general perceptions and opinions of the usability and content of the VACT-CP system. This feedback will then be reported in conjunction with qualitative usability and acceptability data, which will be analyzed using the modified CQR approach also planned for in phase 1. In phase 2, the themes generated by these qualitative data will be used to identify user system issues, general trends in use of the website, content issues, how well users can complete an assigned task on the VACT-CP system, and where they are encountering problems. Using this method, we will classify all general comments regarding usability as necessary to include in iterative development and site changes, whereas variant and typical usability concerns will be discussed within the research group to decide upon potential ways to incorporate this feedback into future intervention refinement. Full analysis of these data is ongoing, although initial general usability issues have been resolved, and suggestions for website refinement have already been integrated into the VACT-CP system.

Phase 3: Small Pilot Feasibility RCT

Objective

We will conduct a stage IB pilot feasibility RCT to assess the usability, feasibility, and acceptability of the VACT-CP system compared with a WL+TAU control group. This will include (1) evaluating the usability of the VACT-CP system; (2) assessing the relative feasibility and acceptability of the VACT-CP intervention procedure and WL+TAU control, including ease of recruitment, retention in each condition, treatment receptivity, attrition and retention in each condition, sustained VACT-CP website use, and the assessment process; and (3) describing changes in pain acceptance, valued living, mental and physical functioning, pain-related interference in daily functioning, and behavioral avoidance for each group. This trial has been registered on ClinicalTrials.gov (NCT03655132).

Participant Recruitment

We aim to recruit and complete baseline assessments for up to 60 participants over 15 months to allow for the required 40 participants to be screened as eligible and successfully randomized. Participants will be screened based on the inclusion and exclusion criteria. The inclusion criteria will include (1) veteran aged ≥18 years; (2) current diagnosis of noncancer chronic pain (as noted in the phase 2 inclusion criteria); (3) has a working, high-speed wireless internet connection at home or is willing to access the website over the 7-week intervention at the VA Bedford Healthcare System using a provided laptop computer in a secure space; and (4) competent to provide written informed consent. The exclusion criteria will include (1) any current or lifetime Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), psychotic disorder; (2) current or recent (within 1 month of study entry) DSM-5 alcohol or drug use disorder; (3) current use of any other chronic pain–related behavioral or psychological treatment; (4) any cognitive impairment that would interfere with study participation; (5) clinically significant suicidality within the past year; (6) presence of any clinical features requiring a higher level of care (inpatient or partial hospital treatment); and (7) any cognitive or physical impairment that would interfere with aspects of study participation that require using a computer and providing feedback. Participants with >1 pain diagnosis or comorbid mental health diagnoses other than those already listed will not be excluded.

RCT Procedures

Potential participants will be prescreened by telephone to determine whether study eligibility criteria are met. Individuals who remain eligible after the telephone prescreen will be

XSL•FO
RenderX

scheduled for a baseline session during which staff will obtain informed consent and confirm clinical eligibility through the Structured Clinical Interview for DSM-5 to assess for potential psychosis, substance use disorders (SUDs), or clinically significant suicidality. Eligible participants will complete self-report measures via an online or mailed paper survey, and after completion of the survey, they will be randomized in a 1:1 ratio into 4 randomly permuted blocks (10 per block) to either the VACT-CP condition or the WL+TAU control condition. Veterans randomized to the VACT-CP condition will receive 7 online weekly modules to be accessed using a desktop or laptop computer within a secure space at the VA Bedford Healthcare System. Veterans in the WL+TAU control group will be provided with a list of common pain resources and encouraged to connect to their local VA pain clinic if interested in pain management care. All participants will complete the 4 surveys. At the conclusion of the study, participants in the WL+TAU condition will be provided with the VACT-CP website as an optional pain management resource, but they will not be asked to use it and will not be followed as research participants. Participants will be compensated US $60 for the baseline assessment (approximately 1 hour), US $40 at the midpoint (week 3; approximately 45 minutes), US $60 at the end of treatment (week 7; approximately 1 hour), and US $40 for the week 11 (1-month follow-up; approximately 40 minutes) for a total possible compensation of US $200.

VACT-CP Treatment Content and Structure

Table 1 shows the treatment components that will be emphasized in the VACT-CP program based on previous manualized ACT for chronic pain treatments and workbooks [15,49-52].

Table 1. Veteran Acceptance and Commitment Therapy for Chronic Pain (VACT-CP) timeline and intervention description.

Timeline	Module focus	Intervention components
Week 1	Introduction to the VACT-CP program	The introductory module assesses the nature of the veteran's pain, past treatments, and experience with acceptance and mindfulness. Coach Anne provides information on ACT[a] and assesses the veteran's values and goals to help them set a weekly goal.
Week 2	Behavioral change and triggers	This module focuses more broadly on pain psychoeducation and pain management. Veterans complete exercises on dealing with cognitive barriers with the goal of changing their own self-identified obstructions to living a meaningful life.
Week 3	Acceptance and mindfulness	This module uses metaphors and a veteran narrative story to explain and explore concepts of acceptance and mindfulness, and the veteran completes an acceptance exercise linked to previously identified values.
Week 4	Cognitive defusion	This module focuses on the ACT concept of cognitive defusion using psychoeducation about the nature of language and cognitive barriers to valued living. Metaphors, mindfulness, and ACT exercises are included.
Week 5	Willingness	This module explains the ACT concept of willingness and discusses willingness to experience discomfort as a means to pursuing important valued living goals. The veteran creates and applies a willingness hierarchy to identify a goal for the week that embodies values-driven willingness.
Week 6	Committed action	This module focuses on the ACT concept of committed action. Coach Anne helps the user to identify personal barriers to committed action and strategies for dealing with these perceived barriers.
Week 7	Valued living wrap-up	The final session provides an overview of ACT processes, a review of goals achieved, and reinforces progress made during the program. This session ends with planning for the "lifelong assignment" of fully engaging in one's life.
Additional modules	Mindfulness exercises module	This module introduces the topic of mindfulness and provides a series of questions to route users to use exercises that align with their goal for the mindfulness experience. This module is accessible any time after completing the first module.
Additional modules	Additional resources	This module provides additional information, links, and resources for care options within the VHA[b] for pain, psychiatric conditions, and physical health management.

[a]ACT: acceptance and commitment therapy.

[b]VHA: Veterans Health Administration.

The 7 online modules that participants will receive as weekly sessions feature Coach Anne as a digital treatment guide (Figure 1). The website is currently only accessible on desktop and laptop computers; it is not available as a mobile-enabled website for mobile phones. Seven modules were chosen, consistent with reviews of module-based online ACT that suggested that 7 to 8 modules are sufficient to allow users to experience all aspects of ACT [26]. All content is presented interactively through text-based 2-way conversations with Coach Anne. Veterans hear what Coach Anne *says* and can respond to her queries using forced-choice text options that will trigger different responses from Coach Anne as the conversation progresses, allowing the system to responsively interact in a personalized manner with the veteran (for an example of our video introduction, refer to Multimedia Appendix 3). The modules also use videos (eg, veteran narratives and metaphors), in-module assessments (eg, values assessments), and interactive exercises for goal setting. Each week, the user is reminded via an encrypted email to complete their next online module.

Once a module has been completed, the next week's module opens 5 days later to allow for more flexible completion of the 7 sessions. Thus, the shortest duration over which a user can complete the VACT-CP protocol is 35 days. The system

XSL•FO
RenderX

prevents the user from completing the next week's module immediately because they must wait 5 days for the next module to open. This was incorporated to provide the user with several days to meet self-created goals, practice skills, and use other resources provided through the website as desired. Participants will be contacted via telephone at week 3 and week 5 to check in on any usability issues and potential concerns, as well as to assess for any possible risk related to mood, physical health, or suicidal ideation. Users can access the website for their entire participation time (11 weeks).

Figure 1. Screenshot of the Veteran Acceptance and Commitment Therapy for Chronic Pain website program.

Measures

Demographics, Functional Health, and Pain Measures

We will use many of the same surveys from phase 2 in our phase 3 data collection, including the Patient Health Questionnaire-9, Posttraumatic Stress Disorder Checklist, Brief Pain Inventory, VR-36, Intrinsic Motivation and Perceived Usefulness Scales [53], and SUS [54]. In addition, we will collect the information encapsulated in the following sections.

Feasibility and Acceptability Measures

Feasibility outcomes will include information on recruitment rates, retention rates within each condition, completion rates, how often each veteran accesses the website, and any reported problems with the website. This information will be collected through open-ended survey items, website data, and through use of a semistructured post–VACT-CP qualitative interview (Multimedia Appendix 4).

Pain-Related Daily Functioning

The Pain Outcomes Questionnaire-Short Form [55] is a 19-item inventory that assesses a patient's ability to engage in functional activities related to daily living that may be affected by pain interference. Each item is rated on an 11-point (0-10) Likert-type scale and yields an overall average score of all 20 items, resulting in a total score between 0 and 10. In addition, the scale contains a pain numeric rating scale item and 5 subscales measuring (1) activities of daily living, (2) negative affect, (3) mobility, (4) vitality, and (5) fear.

Pain Acceptance

The Chronic Pain Acceptance Questionnaire-Revised [56] is 20-item survey measuring recognition that pain does not prevent one from living a valued life. The questionnaire consists of two subscales: (1) activity engagement (11 items), or the degree to which one engages in life activities regardless of the pain; and (2) pain willingness (9 items), or an individual's willingness to experience pain. In addition, a total score is created by summing all items [57]. The scales have shown adequate reliability and validity and are substantially related to the other measures of patient functioning [58].

Valued Living

The Chronic Pain Values Inventory [59] is a 12-item self-report measure of the extent to which a patient is living in accordance with their values in areas such as work, health, and family, and which is related to lower perceived disability and pain-related anxiety, as well as greater reported patient functioning, even in the context of high levels of pain.

Behavioral Avoidance

The Multidimensional Experiential Avoidance Questionnaire (MEAQ) [60] is a 62-item self-report measure of experiential avoidance, including subscales on behavioral avoidance, distress aversion, procrastination, distraction and suppression, repression and denial, and distress endurance. The MEAQ has shown good internal consistency across all subscales, with Cronbach α averaging .83 across multiple samples [60,61].

Patient Satisfaction With Treatment

The Client Satisfaction Questionnaire-8 [62] is an 8-item scale that measures global treatment satisfaction based on perceived treatment quality and effectiveness of the intervention. This scale has been used at mental health and other health centers and has acceptable internal consistency (Cronbach α=.83-.93).

Planned Analyses

Sample Size Considerations

Consistent with the recommended stage model for development of behavioral therapies, the aim of this stage IB pilot feasibility RCT is to inform future treatment development and evaluation. Given that prior investigations of ACT have reported effect sizes in the large-to-medium range, we expect that the VACT-CP intervention will also produce at least a medium

XSL•FO
RenderX

treatment effect. To have a power of 0.80 to detect differences at a 2-tailed α level of .05, a medium effect would require 125 participants. This was beyond the objective and scope of this preliminary stage IB pilot feasibility RCT. A total sample size of 40 (n=20, 50%, per group) is consistent with the recommendation by Rounsaville et al [63] of 15 to 30 participants per condition for stage IB behavioral treatment development. For phase 3, the total goal for enrollment and randomization is 40 participants (n=20, 50%, per group) for the 7-week VACT-CP intervention and WL+TAU control groups. Assuming an attrition rate of 30% after randomization based on past attrition rates for online behavior interventions [30], we plan to enroll up to 60 participants to meet our goal of 40 successfully randomized participants.

Primary Analyses

Usability of the VACT-CP system as assessed through the SUS is the primary outcome for the RCT. Scores for those in the VACT-CP group will be aggregated and described according to these metrics, with an SUS score of >68 interpreted as above average and a score of >80 as high and reflective of a system that participants are likely to recommend to others [64]. We will also describe changes on the Usability Survey Scales from before to after the intervention. Additional feasibility and usability data will be provided by the semistructured qualitative interviews and tracking of any telephone calls or emails to research staff with concerns. Similar to phases 1 and 2, phase 3 analysis of postintervention interview transcripts will use CQR techniques (eg, coding for and extracting major themes) to assess both barriers and facilitators for use of the VACT-CP system, as well as individual demographic user factors that affect use and perceived usefulness. Finally, we will assess intervention feasibility by measuring the proportion of individuals who successfully complete at least 5 (71%) VACT-CP modules of the total 7, which would be slightly above the mean percentage of completed sessions observed in previous online behavior interventions [30].

Secondary Analyses

Secondary exploratory analyses will describe satisfaction with the VACT-CP system and the potential impact of the intervention on treatment outcomes related to pain-related interference in daily functioning and severity (Pain Outcomes Questionnaire-Short Form), pain acceptance (Chronic Pain Acceptance Questionnaire-Revised), behavioral avoidance (MEAQ), valued living (Chronic Pain Values Inventory), and mental and physical functioning (VR-36 Mental Component Score and VR-36 Physical Component Score). On the basis of the intent-to-treat principle, all participants enrolled and successfully randomized will be included in these analyses, and the principal investigator will conduct preliminarily analyses and descriptively report on the pilot RCT outcomes of the VACT-CP intervention to inform further refinements to it. Descriptive measures (means and SDs) will be reported for all outcomes of interest. We anticipate that, for VACT-CP participants, we will observe increases in the mean scores for pain acceptance, valued living, and mental and physical functioning, as well as a decrease in pain-related interference in daily functioning and behavioral avoidance. In addition, we predict that there will be small-to-no changes in mean pain severity levels, given research suggesting that behavior interventions do not change pain levels for participants with chronic pain. Given imprecise estimations owing to the pilot's small sample size and a lack of power, we will not report estimates of effect sizes for these specific predictions. However, we will report descriptive outcomes (means and SDs) between before and after the intervention as well as between the groups and use nonparametric testing to report changes in secondary outcomes at the individual and group levels (pain acceptance, valued living, and mental and physical functioning, as well as pain-related interference in daily functioning and behavioral avoidance).

Ethics Approval

All 3 phases of this study were approved by the institutional review board of the VA Bedford Healthcare System Research & Development Committee in Bedford, Massachusetts, United States (1598754), with initial approval granted in September 2018.

Results

Participant recruitment for phase 3 began in April 2022 and is currently ongoing. We expect that recruitment will be complete by April 2023, data collection completed by October 2023, and primary data analyses completed by late 2023.

Discussion

Potential Applications

Online programs and at-home treatments for chronic pain are increasingly popular, but there is room to improve the breadth and efficacy of remote treatment options and to create a more engaging user experience. The intended outcome product, online VACT-CP, requires this multiphase project to successfully apply user-centered design best practices in developing our proposed intervention. Good usability and acceptability research should highlight the biggest needs for the proposed end product, but we cannot know all requirements before beginning the design processes. Consequently, by having multiple stages of feedback across multiple stakeholder groups, we will be able to develop and continually improve on the initial proposed VACT-CP system. Given the existing research base for our preliminary system, we believe that this online, ECA-delivered intervention may be a promising treatment option for chronic pain for the veteran population.

Limitations and Future Directions

This study includes limitations specifically related to its small sample size and, therefore, generalizability. However, our proposed sample size aligns with prior research on the number of participants needed to assess usability and feasibility. In addition, the format of the website requires a person to have access to a laptop or desktop computer because the current website is not mobile-device enabled. However, as a proof-of-concept design, successful findings from this study could be leveraged to further revise the site to allow for mobile options. In addition, excluding participants with an active SUD is a limitation. This comorbidity is common among veterans

XSL•FO
RenderX

with chronic pain, and this online intervention could potentially assist in both their pain management and substance use owing to the transdiagnostic nature of ACT interventions. However, for this preliminary study, such an exclusion is warranted to ensure that participants are medically stable and not reporting clinical symptoms that would require a higher level of care. In the future, it would be useful to allow participants with an active SUD to participate if interested and as part of their SUD treatment. Finally, this study will include a majority of veterans living in 1 region of the country. Further testing could include multiple sites, including other VA medical centers that serve more rural populations that would potentially benefit from efficacious remotely delivered treatments for chronic pain.

Conclusions

This research project has the potential to create an easily disseminated and highly accessible pain treatment option, VACT-CP. In addition, the online intervention is potentially more engaging, accessible, and cost-effective than other existing versions of ACT for chronic pain. An interdisciplinary research team, comprising experts in ACT interventions, chronic pain, and technology-assisted health care assessment and delivery, will create and refine the VACT-CP system. Multiple stages of testing with veterans will further refine the intervention as well. Overall, it is expected that this 3-phase research project will lead to the development of a veteran-centered pain management website that helps users to better manage pain-related symptoms and focus on valued living domains. This study will provide preliminary feasibility data on whether the VACT-CP system is usable and acceptable. The final online program would allow all veterans with a home computer and internet access the option of an engaging, user-centered pain intervention. The VACT-CP system may also be particularly well received by, and of interest to, patients with chronic pain, given the lasting impact of COVID-19 on increased acceptance of, and interest in, remotely delivered interventions. After completion of this project, we will evaluate whether a future study is warranted in the form of a larger-scale VACT-CP efficacy trial to investigate whether the intervention improves pain-related functioning and quality of life.

Acknowledgments

Abstract

Background: Alzheimer disease and related dementias (ADRD) are increasingly common conditions that disrupt the lives of persons living with dementia and their spousal care partners. At the time of ADRD diagnoses, many couples experience challenges that produce emotional distress and relationship strain. At present, there are no interventions to address these challenges early after diagnoses to promote positive adjustment.

Objective: The study protocol described here is part of the first phase of a larger program of research that aims to develop, adapt, and establish the feasibility of Resilient Together for Dementia (RT-ADRD), a novel dyadic skills-based intervention to be delivered over live video early after diagnosis, with the goal of preventing chronic emotional distress. This study will elicit and systematically summarize perspectives of ADRD medical stakeholders to inform the procedures (eg, recruitment and screening methods, eligibility, timing of intervention, and intervention delivery) of the first iteration of RT-ADRD prior to pilot-testing.

Methods: We will recruit interdisciplinary medical stakeholders (eg, neurologists, social workers, neuropsychologists, care coordinators, and speech language pathologists) from academic medical center clinics in the departments treating persons living with dementia such as neurology, psychiatry, and geriatric medicine via flyers and word-of-mouth referrals from clinic directors and members of relevant organizations (eg, dementia care collaboratives and Alzheimer disease research centers). The participants will complete electronic screening and consent procedures. Consenting individuals will then participate in a 30- to 60-minute qualitative virtual focus group, held either via telephone or Zoom, using an interview guide designed to assess provider experiences with postdiagnosis clinical care and to gather feedback on the proposed RT-ADRD protocol. The participants will also have the

XSL•FO
RenderX

opportunity to participate in an optional exit interview and web-based survey to gather additional feedback. Qualitative data will be analyzed using a hybrid inductive-deductive approach and the framework method for thematic synthesis. We will conduct approximately 6 focus groups with 4-6 individuals in each group (maximum N=30 individuals; until saturation is reached).

Results: Data collection began in November 2022 and will continue through June 2023. We anticipate that the study will be completed by late 2023.

Conclusions: The results from this study will inform the procedures of the first live video RT-ADRD dyadic resiliency intervention focused on the prevention of chronic emotional and relational distress in couples shortly after ADRD diagnoses. Our study will allow us to gather comprehensive information from stakeholders on ways to best deliver our early prevention–focused intervention and gain detailed feedback on study procedures prior to further testing.

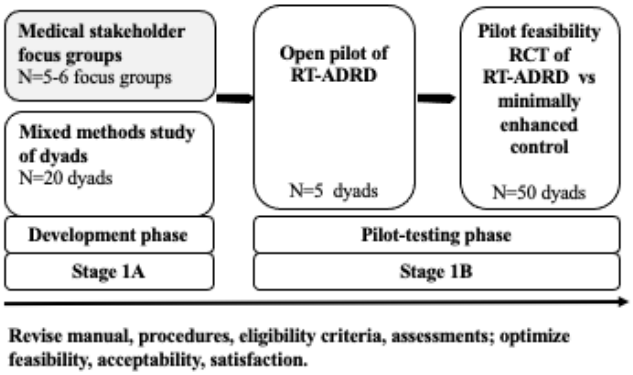
Introduction

Background

Alzheimer disease and related dementias (ADRD) are a common cause of death and disability that have a substantial impact on individuals, families, health care systems, and society. By 2030, over 78 million individuals will be living with ADRD, leading to global health care costs of over US $2.8 trillion [1,2]. There are no available disease-modifying treatments or cures for ADRD [2,3]. ADRD symptoms (eg, forgetfulness, communication challenges, loss of recognition of places, time, and routines) are progressive in nature and continually undermine the independence of persons living with dementia [2]. In the months and years following diagnosis, these symptoms lead to heightened stress, clinically elevated emotional distress, burden, and relationship strain for persons living with dementia and their family care partners—many of whom are spouses or other forms of committed partners [4-7]. The timely diagnosis, care, and management of ADRD is critically important because these can each facilitate positive adjustment and preserve quality of life for couples [8,9].

Recent research advancements have enabled the earlier diagnosis of ADRD, creating the potential to meaningfully engage persons living with dementia in psychosocial interventions early after diagnosis during the "window of opportunity" before cognitive symptoms progress [9]. However, there are no established psychosocial interventions available at the time of diagnosis for persons living with dementia and their partners to support them in developing a shared understanding of the diagnosis, learning to collaboratively address early challenges, expressing personal needs, and collaboratively planning for the future [10,11]. Evidence suggests persons living with dementia and partners are interested in participating in interventions together (ie, "dyadic interventions"), early after diagnosis [10-14], and prior work has demonstrated that dyadic interventions are more effective avenues for promoting positive adjustment than those focused on individuals or care partners alone [15,16]. Dyadic interventions deployed during the later stages of ADRD have demonstrated feasibility and some positive effects on the dyads' relationships [17], including those delivered via telehealth approaches (eg, Zoom; Zoom Video Communications) [18-20].

Early dyadic interventions have the potential to promote positive adjustment to ADRD by improving the dyads' individual and interpersonal *resiliency* (ie, the ability to adjust effectively to significant adversity) [21] and can provide persons living with dementia and their partners with skills and support to actively contribute to care planning, preserve autonomy for persons living with dementia, and help both partners to express their needs and preferences [22,23]. The members of our team have developed dyadic programs with procedures that can be adapted to address the dyads' needs early after ADRD diagnoses. Specifically, the Recovering Together program is a brief dyadic resiliency intervention that demonstrates feasibility and preliminary efficacy at preventing chronic emotional distress in patients and informal care partners (ie, unpaid family members and friends) shortly after intensive care unit admission for acute neurological illnesses (eg, traumatic brain injury and stroke) [24,25]. The Recovering Together program was iteratively developed as part of a larger multidisciplinary partnership with patient–care partner dyads and medical stakeholders involved in patient care [26]. Prior research indicates that psychosocial interventions for ADRD are poorly integrated into medical treatment settings, have inconsistent methods of delivery, and are poorly aligned with participant and medical stakeholder preferences [14,27]. Therefore, there is a missed opportunity to integrate dyadic psychosocial interventions into the postdiagnosis support clinical infrastructure, and to design interventions that consider the perspectives of participants and medical stakeholders involved in patient care. Gathering feedback from individuals who will adopt, deliver, and use interventions is a necessary first step of developing early psychosocial interventions to improve adjustment to ADRD diagnoses for persons living with dementia and their care partners [28,29].



This Study

The purpose of this paper is to describe the protocol for our qualitative focus group study involving ADRD medical stakeholders that will inform the development of the procedures of the first version of a dyadic intervention. The study protocol described here is part of the first phase of a larger 5-year program of research (Figure 1) that aims to use the methodology, program content, and procedures of the Recovering Together program as a basis for developing a novel postdiagnosis dyadic

XSL•FO
RenderX

resiliency intervention for ADRD called Resilient Together for Dementia (RT-ADRD). RT-ADRD will be developed using our team's theoretically and empirically derived framework for transdiagnostic dyadic interventions [30]. Our approach to intervention development will follow the National Institutes of Health stage model for intervention development [31], including the following: (1a) qualitative interviews with dyads and (1b) qualitative focus groups with ADRD medical stakeholders to understand population needs and develop the first iteration of the program; (2) an open pilot study to assess and refine RT-ADRD content and procedures; and (3) a feasibility pilot randomized controlled trial to further refine RT-ADRD content and test feasibility, acceptability, and preliminary efficacy of RT-ADRD relative to a minimally enhanced usual care condition (Figure 1). Through this study, we will gather detailed information from heterogeneous groups of medical stakeholders and develop procedures (eg, recruitment, screening, eligibility, timing of intervention, and intervention delivery) that are feasible, acceptable, and capable of meaningfully improving adjustment to ADRD for persons living with dementia and their partners.

Figure 1. Proposed iterative development of Resilient Together for Dementia (RT-ADRD). RCT: randomized controlled trial. RT-ADRD: Resilient Together for Dementia.

Methods

Ethics Approval

This study was approved by the Massachusetts General Independent Review Board (2022P001510).

Study Design

We will conduct a qualitative focus group study involving medical stakeholders (eg, neurologists, geriatricians, geriatric psychiatrists, social workers, neuropsychologists, care coordinators, and cohabiting speech language pathologists) involved in the care of persons living with dementia around the time of diagnosis (target N=up to 30 stakeholders in up to 6 focus groups). This study is designed to gather ADRD stakeholders' perspectives on the following: (1) postdiagnosis challenges and psychosocial support needs of persons living with dementia and their partners, (2) factors that may promote or inhibit couples' suitability and interest in a postdiagnosis dyadic intervention, and (3) proposed recruitment procedures and ways of optimizing recruitment support from ADRD stakeholders.

Inclusion and Exclusion Criteria

We plan to include up to N=30 adult participants (18+ years old) who are currently employed in 1 of 2 academic health care settings and provide outpatient care for individuals diagnosed with ADRD around the time of diagnoses. Recruitment began in November 2022 and will continue until June 2023. Eligible participants will be (1) fluent in English, (2) willing and able to participate in a live video interview or focus group, and (3) employed in a position relevant to ADRD care. Focus groups will be conducted separately for each of the 2 recruitment sites in order to understand potential differences by clinic setting. Our team will use purposive, convenience sampling from both sites and construct focus groups in an iterative manner based on ongoing data collection and rapid data analysis, consistent with prior studies [32].

Recruitment and Screening

We will recruit participants actively involved in ADRD clinical care from clinics within relevant departments (eg, neurology, psychiatry, and geriatric medicine) at 2 academic medical centers with comprehensive research and clinical programs dedicated to the treatment of ADRD (Massachusetts General Hospital in Boston, MA and Mount Sinai Hospital in New York, NY). We will recruit via flyers, presentations, and word-of-mouth referrals. Interested individuals will respond to a brief survey on a secure Research Electronic Data Capture platform and provide their name, contact information (email or phone number), current employment site, and current position. The survey will also contain an information sheet and form for eligible individuals to provide electronic consent to participate in the study. A research assistant will contact the individual to confirm eligibility and discuss scheduling for a focus group or individual interview. All recruitment, screening, and consent procedures will be performed remotely via telephone, electronic survey, email, and over a live video platform (ie, Zoom).

Data Collection

We will conduct a series of focus groups comprising medical stakeholders. Focus groups will include approximately 4-6 participants to encourage discussion while maximizing participant comfort, consistent with guidelines for virtual focus groups [33]. Stakeholders who are unable to attend the focus group sessions will be invited to participate in an individual interview. Focus groups and individual interviews will last

XSL•FO
RenderX

approximately 30-60 minutes in total. Focus group participants will have the opportunity to participate in an optional exit interview immediately following the conclusion of the focus group to provide any additional information that they did not have time to share or did not feel comfortable sharing in the group setting.

Focus groups will be cofacilitated by a PhD-level clinical psychologist with expertise in qualitative research methods and a trained research assistant. The clinical psychologist will lead the focus group, and the research assistant will provide technical support and document observations using a rapid data analysis template developed by the research team. The rapid data analysis template will be used to inform formal coding and includes observations within key interview domains, poignant participant quotes, researcher reflexivity, and other notes or observations (Multimedia Appendix 1) The clinical psychologist will work to generate information on convergent and divergent perspectives regarding the dyads' experiences early after ADRD diagnoses and feedback surrounding the proposed intervention procedures and content. Exit interviews will be led by trained research assistants and volunteers using a live video conference breakout room tool.

Prior to the focus groups, participants will receive a document with potential discussion topics and guidelines for participating in the focus group with other individuals. The focus group discussion will follow an interview guide with open-ended prompts and questions surrounding domains including the following: (1) perceptions of clinical care early after ADRD diagnosis, (2) feedback on the proposed intervention procedures and content, and (3) ways of maximizing feasibility and acceptability outcomes (Multimedia Appendix 2). The clinical psychologist will follow general prompts with questions and probes to develop a more comprehensive understanding of the participants' perspectives.

Data Analyses

Audio data will be transcribed verbatim using a transcription service and deidentified. Deidentified transcripts will be uploaded into Dedoose software [34] for formal analysis. We will use a combination of deductive and inductive approaches to data analysis for our key research aims. Specifically, our *deductive* approaches will serve as the basis for our interview guide, rapid data analysis template, and coding framework (ie, codebook domains), which will be influenced by (1) prior research on the dyads' early psychosocial challenges and unmet needs following ADRD diagnoses and (2) the findings from on our prior studies focused on dyadic intervention development [35]. For example, we will include prompts in the interview guide that assess perspectives of the proposed delivery context (eg, current available psychosocial resources and ways of screening and referring dyads) on the rapid data analysis template and initial codebook domains.

Following the organization of the initial codebook domains, our approach to data analysis will involve rapid data analysis and be primarily *inductive* in nature. During data collection, our research assistant will document observations using the rapid data analysis template in a generative manner based on focus group discussion. These observations will be used to refine our initial codebook prior to formal data analysis and to assess when thematic saturation is reached [36]. Next, we will analyze the transcribed interviews in a collaborative and iterative fashion guided by the framework method [37]. Members of our research team involved in data analysis will begin with a line-by-line review of transcripts for 1-2 focus groups and openly code any relevant observations. These codes will be organized into categories within the a priori determined domains and refined through team discussion to create a revised codebook that will be used for formal coding in Dedoose. Two members of the research team will then code 25% (n=1-2 focus groups) of the transcripts using the initial codebook and will resolve discrepancies in discussions with the larger research team to refine the codebook. We will ensure a high agreement between the coders before they individually complete the remaining focus group transcriptions. We will then iteratively refine coded data into themes and subthemes within each domain through individual review and team discussions.

Results

This study is funded by the National Institute on Aging grant 1K23AG075188-01A1. Recruitment began in November 2022. Data collection is anticipated to begin in January 2023 and be completed by June 2023, and data analysis is anticipated to be completed by August 2023.

Discussion

ADRD are increasingly common conditions due to the aging population and have a considerable negative impact on persons living with dementia and their spousal care partners. At present, these dyads have little psychosocial support to address postdiagnosis challenges and positively adjust to ADRD and progressive symptoms at the time of diagnosis. Dyads are interested in participating in interventions together early after diagnosis [10-14], and prior research suggests that existing interventions [24,25] can be adapted to effectively and efficiently address the dyads' challenges to promote dyadic adjustment [15,16]. To effectively adapt such programs, it is necessary to first gather comprehensive feedback from individuals who will adopt, deliver, and use interventions [14,27]. This approach can help promote alignment with patient, caregiver, and medical stakeholder perspectives and is recognized as an important step toward optimizing clinical care for ADRD [28,29].

This paper describes a study design that is part of the first phase of a larger project focused on the development of a novel postdiagnosis dyadic resiliency intervention for couple dyads navigating ADRD. We provide details on the study aims and the recruitment, screening, data collection, and data analysis procedures. This information is valuable for future studies involving medical stakeholders treating ADRD shortly following diagnosis and for the development of intervention programs and procedures that are tailored to address the postdiagnosis experience of persons living with dementia and their care partners.

XSL•FO
RenderX

The results of this trial will critically inform the development of the proposed RT-ADRD intervention and procedures. Our findings will also benefit the broader field, as we will gain perspectives to further understand common experiences and challenges before and after ADRD diagnoses. In addition, using direct feedback from a variety of stakeholders, we will be able to highlight commonly identified ways of integrating interventions within the existing clinical infrastructures, as well as areas of disagreement across stakeholder groups and clinic sites. Taken together with feedback obtained from dyads at the time of diagnosis gathered from a separate study, our findings will be used to refine our approach prior to pilot-testing, consistent with the National Institutes of Health Stage Model guidelines [31].

In summary, this study will be the first to gather comprehensive feedback from medical stakeholders on experiences, unmet needs, and perceptions of helpful intervention approaches and procedures for persons living with couple dyads early after ADRD diagnoses. Our findings will inform the design, procedures, and content of the novel Resilient Together for Dementia program, and we will gather feedback to inform subsequent clinical trials and implementation efforts. The results from this study will also have the potential to directly inform other efforts to increase the dyads' postdiagnosis support, with implications for other chronic and progressive neurological conditions.

Acknowledgments

We would like to thank the members of the Massachusetts General Hospital CHOIR lab members and the Massachusetts General Hospital "K club" led by Dr Ana-Maria Vranceanu for their feedback on proposed focus group procedures.

This study was funded by grants from the National Institute on Aging (1K23AG075188-01A1) to SB, and grants from the National Institute of Nursing Research (R01NR019982-01) and National Institute Center for Complementary and Integrative Health (1K24AT011760-01) to A-MV.

Abstract

Background: The psychosocial needs and risks of children with cancer and their families are well-documented including increased risk of parental distress, posttraumatic stress, and anxiety. There is a critical need to provide evidence-based psychosocial care to parents and caregivers of children with cancer. Digital health interventions are important to address many barriers to in-person intervention delivery but are not widely used in pediatric psychosocial cancer care. The COVID-19 pandemic has reinforced the need for flexible, acceptable, and accessible psychosocial digital health interventions. The Electronic Surviving Cancer Competently Intervention Program (eSCCIP) is an innovative digital health intervention for parents and caregivers of children with cancer, delivered through a combination of self-guided web-based content and supplemented by 3 telehealth follow-up sessions with a trained telehealth guide. A Spanish language adaptation of eSCCIP, El Programa Electronico de Intervencion para Superar Cancer Competentemente (eSCCIP-SP), has been developed. The self-guided web-based cores of eSCCIP/eSCCIP-SP are a mix of didactic video content, multifamily video discussion groups featuring parents of children with cancer, and hands-on web-based activities.

Objective: The objective of this study is to test eSCCIP/eSCCIP-SP in a multisite randomized controlled trial, compared to an internet-based education control condition consisting of information specifically focused on concerns relevant to parents and caregivers of children with cancer.

Methods: Using a randomized controlled clinical trial design, 350 eligible parents and caregivers of children with cancer will be randomly assigned to the intervention (eSCCIP/eSCCIP-SP) or an education control condition. Data will be collected at 3 time points: preintervention (prior to randomization), immediately post intervention (after 6 weeks), and at a 3-month follow-up (from baseline). Participants randomized to either condition will receive study material (eSCCIP/eSCCIP-SP intervention or education control website) in English or Spanish, based on the primary language spoken in the home and participant preference.

Results: The primary study end point is a reduction in acute distress from baseline to postintervention, with secondary end points focused on reductions in symptoms of posttraumatic stress and anxiety, and improvements in coping self-efficacy and cognitive coping. An additional exploratory aim will be focused on implementation strategies and potential costs and cost-savings of eSCCIP/eSCCIP-SP, laying the groundwork for future trials focused on dissemination and implementation, stepped-care models, and intervention refinement.

XSL•FO
RenderX

Conclusions: This trial will provide necessary data to evaluate the efficacy of eSCCIP/eSCCIP-SP. This intervention has the potential to be an easily scalable and highly impactful psychosocial treatment option for parents and caregivers of children with cancer.

Introduction

Background

Parents and caregivers of children with cancer are at risk for negative psychosocial sequelae following their child's cancer diagnosis [1-3]; yet, few evidence-based options exist for improving psychosocial outcomes. This is particularly discouraging because the Standards for Psychosocial Care for Children with Cancer and Their Families specifically recommend that parents and caregivers of children with cancer have access to such interventions to decrease the risk of adverse psychosocial outcomes, including acute distress, posttraumatic stress symptoms (PTSSs), anxiety, depression, and decreased family functioning [1,4]. Parent, child, and family-level functioning are closely linked, and parent distress is linked to impaired family functioning and child maladjustment across the cancer trajectory [2,5-8]. Providing evidence-based psychosocial support to parents and caregivers of children with cancer is a clear, actionable strategy to prevent adverse outcomes and improve individual and family functioning following a pediatric cancer diagnosis [9,10].

Individuals identifying as Latinx represent the largest minority group in the United States and are also the fastest-growing segment of the population in the United States, representing 18% of the total population and contributing over half (52%) of the population's growth between 2010 and 2019 [11]. Parents and caregivers of children with cancer, who are of Latinx descent, are at especially high risk for negative psychosocial sequelae because they are overrepresented in the United States in terms of being affected by multiple, negative, systemic, and sociodemographic factors, including low socioeconomic status and limited English proficiency [12]. Socioeconomic status has been found to mediate survival outcomes in pediatric cancer, with worse outcomes for Latinx and racially diverse children [13-15]. Moreover, parents and caregivers of children with cancer of Latinx descent often report high levels of distress following their child's cancer diagnosis [12,13]. Although there is some evidence that culturally adapted interventions are effective in improving health and well-being outcomes for these populations [16-19], cultural and language adaptations of psychosocial evidence-based interventions for the Latinx population are scarce [1,12,20]. As the Latinx population in the United States continues to grow, there is an urgent need to provide evidence-based psychosocial care to this at-risk subset of parents and caregivers of children with cancer.

Access to technology and the internet is widespread in the United States and is often used to seek health care information and support [21,22]. Latinx and non-Latinx populations report internet use at comparably high levels, with recent data showing that 93% of White adults, 91% of Black adults, and 95% of Hispanic adults use the internet [23]. Trends in internet usage over time have demonstrated that the "digital divide" in the United States is shrinking across race and ethnicity, so the need for psychosocial interventions that adapt to this new reality is critical.

Intervention Development and Adaptation

Several studies have laid the groundwork for the proposed randomized controlled trial (RCT). The Electronic Surviving Cancer Competently Intervention Program (eSCCIP) was developed as a brief, psychosocial digital health intervention for parents and caregivers of children with cancer to reduce negative psychosocial sequelae following pediatric cancer diagnosis and improve family functioning [24]. The theory and content of eSCCIP were adapted from 2 prior in-person interventions for parents and caregivers of children with cancer: the Surviving Cancer Competently Intervention Program [25] and the Surviving Cancer Competently Intervention Program—Newly Diagnosed [26]. To provide parents and caregivers of children with cancer with the accessibility and flexibility of a digital health intervention, eSCCIP was initially developed in 2015 using best practice methodology from the digital health literature. In addition to its foundation in both cognitive behavioral and family systems principles, eSCCIP is guided by the Ritterband Behavior Change model for internet interventions, which explains change as occurring through a pattern of unique, nonlinear interactions in 9 steps, including the users, the environment, and the web-based tool [27]. eSCCIP is further guided by the Pediatric Preventative Health Model [28,29], a social ecological model conceptualizing how families should receive psychosocial support based on individual needs, strengths, and risk factors. Following the conceptualization and initial development of eSCCIP, the intervention was refined using think aloud usability testing, collaboration with community stakeholders, and small-scale beta testing [24]. Recent preliminary studies evaluating the eSCCIP intervention have demonstrated high acceptability and feasibility, as well as preliminary evidence of efficacy [30]. Additional revisions and iterations have been made to eSCCIP to modernize and scale up for a larger RCT. To fill a critical need in the field, a Spanish-language adaptation of eSCCIP, El Programa Electronico de intervencion para Superar Cancer Competentemente (eSCCIP-SP) [31], was also developed using

XSL•FO
RenderX

best practices for cultural and linguistic intervention development [32]. Refer to Figure 1 for a visual overview of the eSCCIP/eSCCIP-SP work to date.

Figure 1. Overview of eSCCIP/eSCCIP-SP development. eSCCIP: Electronic Surviving Cancer Competently Intervention Program; eSCCIP-SP: El Programa Electronico de Intervencion para Superar Cancer Competentemente.

Study Objectives

The purpose of this study is to test eSCCIP/eSCCIP-SP in a multisite RCT to build off existent pilot work and establish a strong base for the efficacy of the intervention. With the exception of the present intervention and a web-based adaptation of the Bright IDEAS Maternal Problem-Solving Skills Training Intervention [16,33,34], we are not aware of any additional psychosocial digital health interventions for parents and caregivers of children with cancer, so establishing a strong evidence base for this intervention is both timely and imperative in addressing the psychosocial needs in this population. The specific aims of this study are as follows:

1. Specific aim 1 evaluates the efficacy of eSCCIP/eSCCIP-SP in a multisite RCT comparing eSCCIP/eSCCIP-SP with an education control website in "real-world" clinical settings. The primary hypothesis is that eSCCIP/eSCCIP-SP will be more efficacious than an education control in decreasing acute distress post intervention. A secondary hypothesis is that eSCCIP/eSCCIP-SP will be more efficacious than an education control in decreasing PTSS and anxiety and improving coping self-efficacy and use of positive cognitive coping strategies post intervention.
2. Specific aim 2 describes the patterns of user engagement and identifies clinical and psychosocial factors associated with eSCCIP/eSCCIP-SP treatment gains. A component of this aim is to identify clinical, demographic, and psychosocial protective factors and risks predictive of maximum eSCCIP/eSCCIP-SP participation benefit. Potential differences in outcomes for English-speaking and Spanish-speaking parents and caregivers of children with cancer will also be explored.
3. Specific aim 3 explores preliminary eSCCIP/eSCCIP-SP implementation strategies and costs and cost savings. We will conduct qualitative interviews with oncology health care providers (psychosocial and medical/nursing staff) and intervention participants using the Consolidated Framework for Implementation Research (CFIR) paradigm to identify barriers and facilitators of eSCCIP/eSCCIP-SP uptake and completion. We will also estimate the costs and potential cost savings of delivering eSCCIP/eSCCIP-SP.

Methods

Ethics Approval

The MD Anderson Cancer Center Office of Human Subjects Protection serves as the central institutional review board for this study. Study procedures have been approved (protocol # 2021-0988).

Study Design

This study is a multisite RCT that will enroll participants at 3 geographically diverse pediatric hospitals, which are subsequently anonymized as sites A, B, and C. Participants will be randomized to one of two treatment conditions: (1) eSCCIP/eSCCIP-SP (depending on primary language or preference) or (2) education control.

Randomization

Randomization will be conducted at the family level according to a 1:1 ratio between groups, in permuted blocks of 6, stratified by site and language preference. The study data analyst at site A will use an Excel (Microsoft Corp) spreadsheet with a randomization scheme created by the study biostatistician to randomize families. This spreadsheet will be inaccessible to any members of the study team aside from the data analyst. It is not possible for study telehealth guides to be blinded to the intervention condition because of the in-person contact required for eSCCIP/eSCCIP-SP; however, study investigators and research coordinators (RCs) not involved in intervention delivery will not have access to random assignment information. After randomization, participants will be instructed on the procedures within their assigned group. All outcome measures will be completed directly on the web by study participants, further reducing the risk of bias.

Participants

Participants will be parents or caregivers of a child with cancer who speak English or Spanish between ages 0 and 18 years.

XSL•FO
RenderX

Parents and caregivers of children with cancer must have access to the internet (including access exclusively via cellular data or access via a borrowed institutional device). The only disease-based exclusion criteria are known poor or uncertain prognosis at the time of approach (child not expected to live longer than 6 months). In families with 2 caregivers, both will be eligible to participate in the study, including receiving the intervention and completing study measures; however, 1 caregiver will be asked to identify as the primary participating caregiver at study enrollment.

Sample Size

Based on the power analyses discussed below, 350 parents and caregivers of children with cancer will be recruited to account for a conservative 25% attrition rate. Of note, although multiple caregivers from each family are eligible to participate, the target sample size of 350 parents and caregivers of children with cancer refers specifically to 350 primary participating caregivers from unique families. Data from nonprimary participating parents will be used only for exploratory analyses. Based on the results from pilot studies, we expect approximately 20% of the 350 families recruited to include a second participating parents and caregivers of children with cancer. Recruitment, retention, and engagement strategies have been an explicit focus of previous eSCCIP research, and strategies generated from this research and the literature inform the recruitment plan [35,36]. Recruitment targets are feasible based on the number of children with cancer treated annually at sites A, B, and C (1000 per year across sites), as well as the number of English-speaking and Spanish-speaking parents and caregivers of children with cancer at each site. We expect 40%-50% of the sample to be Spanish-speaking parents and caregivers of children with cancer. Previous eSCCIP studies have had high recruitment rates (64%-70%) [24,36] as well as retention rates of over 70% in eSCCIP pilot work. Estimating 25% study attrition is an appropriately conservative approach; however, recruitment targets will be evaluated frequently and adjusted accordingly if attrition is higher than expected, given previous work.

To specifically address aim 3, parents and caregivers of children with cancer will be identified from each study site using purposive sampling across demographic groups. We will initially target 10 participants from each site (n=30), comprising 6 parents and caregivers of children with cancer (3 English-speaking and 3 Spanish-speaking), 2 psychosocial providers, and 2 oncology providers, but final recruitment will be dependent upon data saturation. We will complete interviews until no new ideas are shared, consistent with best practices for reaching saturation in qualitative research [37].

Study Conditions and Delivery

eSCCIP Intervention

The content of eSCCIP/eSCCIP-SP has 4 web-based, self-directed cores designed for parents and caregivers of children with cancer to complete over 1 month during their child's active cancer treatment (including maintenance therapies) or shortly after completion of treatment. Each core is a unique mix of original video content and web-based activities and is complemented by a brief telehealth follow-up with an eSCCIP-trained clinical interventionist (ie, guide). Cores 1-3 include novel content derived directly from evidence-based cognitive behavioral concepts and family system principles modeled from components of the in-person predecessor of eSCCIP; core 4 is designed as a wrap-up core to summarize intervention content. All cores incorporate family systems theory to maintain an interpersonal focus and normalize the family's experiences. All intervention materials exist in English and Spanish, and telehealth sessions are delivered in English or Spanish, depending on enrollment in eSCCIP or eSCCIP-SP.

Video content falls into two distinct categories: (1) the multifamily video discussion groups, which were initially created for the Surviving Cancer Competently Intervention Program—Newly Diagnosed protocol, consist of recorded and edited conversations between a group of 17 parents and caregivers of children with cancer that serve as a powerful family systems proxy of participants' interaction with other parents and (2) skill-building videos, where foundational cognitive behavioral intervention skills, such as cognitive reframing, are introduced. The multifamily video discussion groups capture themes common among parents and caregivers of children with cancer (eg, anger, guilt, and emotional exhaustion), examples of coping (eg, putting things in perspective), and the impact on the family over time (eg, siblings, grandparents, and thinking about the future). The skill-building videos feature interviews with parents and providers, as well as graphics and narration illustrating foundational intervention skills. Web-based activities provide opportunities for caregivers to practice the skills they have learned.

All web-based activities are securely captured by the program, allowing the guide to view data entered by participants (eg, free text responses) and integrate participant responses into telehealth follow-up sessions. The telehealth follow-ups after cores 1-3 are the only component of eSCCIP that is scheduled with a trained guide. The telehealth follow-up sessions follow a flexible manualized format to ensure standardization across guides and appropriate delivery of key intervention principles.

Education Control

Parents and caregivers of children with cancer randomized to the patient education control condition will be given a unique log-in to access a website with information about psychosocial functioning, coping, and PTSS related to pediatric cancer. This website will be available in both English and Spanish and will consist of information modified from CopingSpace [38], an evidence-informed website developed by Ryan's Case for Smiles, a national organization dedicated to supporting families impacted by pediatric cancer and other chronic diseases. Topics include age-appropriate explanations and coping strategies for children, the siblings' unique experience and needs, warning signs a child is not coping well, techniques to reduce your stress and anxiety, and practical tips for managing meals and family needs. Unlike eSCCIP/eSCCIP-SP, the education control website will not include instruction in the cognitive behavioral skills taught in eSCCIP/eSCCIP-SP nor will it include access to the videos or telehealth follow-up sessions in eSCCIP/eSCCIP-SP. The high-quality information provided to

XSL•FO
RenderX

parents and caregivers of children with cancer makes this a valuable and meaningful comparator condition.

Study Platform

The eSCCIP/eSCCIP-SP and education control programs have been built in the most recent version of the Research Infrastructure Containing e-interventions system developed and maintained by the University of Virginia Center for Behavioral Health and Technology. This platform provides the tools to both deliver robust digital health interventions as well as to manage participants in research trials. The system is designed to support projects that contain protected health information and are subsequently subject to compliance with federal and state regulations regarding data of this type. eSCCIP/eSCCIP-SP has been designed to be delivered as a fully automated program, but also it has the functionality to incorporate human support components (eg, facilitate communication between participant and guide). It includes 4 cores and 3 telehealth visits, with the cores automatically made available to the participant over time. After completion of the first core, the first telehealth visit is scheduled for a time in the upcoming week. The second and third cores are available 1 week after the completion of the previous core and include a subsequent telehealth visit. The fourth and final core concludes the intervention with a review of the program. Participants access the intervention through a secured portal, and all data are captured and maintained consistent with Health Insurance Portability and Accountability Act's guidelines.

Study Procedure

Potential participants will be screened for eligibility using a brief, web-based screening questionnaire that is accessible by direct contact with a member of the study team or through the study interest website. Once screened, an RC will confirm eligibility and instruct participants about the consent process. Web-based consent procedures will be conducted via DocuSign or a similar secure software. Once web-based consent is complete, participants will receive a unique username and password to log onto their randomized condition (eSCCIP/eSCCIP-SP or education control). Study questionnaires will be completed through this web platform. As there are no required components of the education control, automated or RC-directed text and email reminders to use the program will not be required for individuals randomized to the education control.

After completion of the initial web-based assessment battery, participants in the intervention condition will schedule their initial telehealth session using an automated scheduling tool available through the platform hosting eSCCIP/eSCCIP-SP. Participants will be notified that the overview core and core 1 need to be completed prior to the telehealth session. Automated reminders will be sent at regular intervals to encourage participation in study cores. Manual follow-up by RCs will also be initiated in cores that are not completed. Cores will automatically unlock at 1-week intervals, and telehealth sessions will be scheduled directly with the participant. A total intervention completion window of 4-6 weeks will be anticipated by the study team for each participant, building in some additional time for start-up and potential scheduling delays. A similar process has been successfully implemented in eSCCIP pilot studies [24,30]. Because eSCCIP/eSCCIP-SP cores and the education control website are delivered digitally, all parents and caregivers of children with cancer will have convenient access to their respective condition's content anywhere the internet is available.

Treatment Fidelity

The administrative interface of the intervention platform collects several metrics that will be used to record the intervention and monitor participation, including generating a comprehensive activity record of core use (ie, a record of completion of each activity and a record of all free-response answers). Fidelity checklists and session outlines have also been developed for the telehealth follow-up sessions. The designated Fidelity Consultant, a pediatric psychologist with extensive experience delivering psychosocial intervention to families, will watch and code 15% of all telehealth sessions for each guide using the fidelity checklists as a measure of treatment fidelity to strengthen study rigor.

Study Outcomes

Data will be collected at 3 time points: prior to beginning the intervention (T1), postintervention (after 6 weeks; T2), and at 3-month follow-up (3 months after baseline; T3). Outcome measures include the Psychosocial Assessment Tool (PAT) [39,40], the Multidimensional Scale of Perceived Social Support [41], the Kessler Psychological Distress Scale (K-6) [42,43], the COVID-19 Exposure and Family Impact Scale [44], the Coping Self-Efficacy Scale [45], the Cognitive Emotion Regulation Questionnaire [46], Distress Thermometer [47], the Patient-Reported Outcomes Measurement Information System Short Form (PROMIS Short Form v1.0—Anxiety-8a) [48], the posttraumatic stress disorder checklist [49], as data on previous psychosocial service usage. Individuals randomly assigned to the intervention condition will also complete a questionnaire at T3 measuring satisfaction and acceptability with the intervention, which has been used in all prior eSCCIP studies. Measure description and schedule for data acquisition are provided in Table 1.

[k]PCL-5: posttraumatic stress disorder checklist.

[l]eSCCIP: Electronic Surviving Cancer Competently Intervention Program.

Power Analyses and Sample Size Consideration

The primary end point of the study is to compare posttest differences in distress post intervention between intervention and education control groups. In a recent pilot study of 14 participants, we detected a mean change of 1.71 (SD 2.09) in distress on the distress thermometer at 1 month in the English version of the questionnaires. In standardized form, the effect size is 0.82. We do not have an estimate of the impact of the education control group on our primary end point; however, we expect no more than a modest to medium effect (0.2 to 0.5). Therefore, we are planning a sample size to detect a difference in effects between the groups of at least 0.3. Power analyses based on the analysis of covariance (ANCOVA) model and assuming a correlation of at least 0.5 between pretest and posttest scores suggest that a sample size of 350 individual parents and caregivers of children with cancer (175 in each group) can detect a difference of ≥0.3 in standardized mean distress reduction between intervention and education group conditions with a power of at least 80% at the level of significance of .05 and assuming an attrition rate of 25%. Therefore, a sample size of 350 is planned for this study.

Data Quality

Data quality will be monitored throughout intervention implementation and data collection. The research team will routinely generate data quality reports (via built-in functionality) and meet biweekly to review the reports, discuss any identified

XSL•FO
RenderX

issues (eg, missing data), and outline remedial actions. For the education control website, data from CopingSpace.org will be migrated to the same server that will host eSCCIP/eSCCIP-SP for ease of tracking and standardization. Once data collection is complete, a rigorous data cleaning, description, and covariate screening process will be carried out prior to analysis. Data will be first inspected for erroneous, outlying, or potentially high-leverage values, and missing data patterns tabulated and visualized. Data from the 3 recruiting study sites will then be pooled for analyses in 2 different versions of the data set separating participants who provide data for at least 1 measurement visit from participants who provide data at all time points. Multiple imputations will be used to handle missing data, including determination of a primary missing data mechanism, appropriate selection of auxiliary variables (if applicable), and sensitivity analyses to check for robustness of underlying assumptions (eg, MNAR selection models, pattern mixture models) [50]. Efficacy analyses will be carried out for both sets, thus providing a complete picture of whether and how missing data impact analysis results.

Planned Statistical Analyses

Aim 1: Analyses

The primary end point of specific aim 1 is the change in acute distress as measured by the K-6 distress scale over 1 month (immediately post intervention). To test whether eSCCIP/eSCCIP-SP is more efficacious in decreasing acute distress relative to the education control (hypothesis 1), an ANCOVA model will be estimated, which has repeatedly been shown to provide optimal estimate precision, power, and CI coverage among pretest-posttest analysis alternatives in RCTs [51,52]. The ANCOVA model will be used to test for group differences in K-6 distress scores, controlling for preintervention distress scores. Covariates will be incorporated if baseline differences are identified across site-specific, program delivery, and demographic variables. As participants may be nested within providers at each site, we will explore the need for specifying a mixed-effects model, contingent upon the size of the provider effect (eg, design effect, impact on model standard errors) and the number of providers available in the data set. With regard to families with 2 participating parents and caregivers of children with cancer, methodological research has shown poor model performance of mixed-effects dyadic models if the proportion of singletons (dyads with only 1 member) is high, as is expected for this study; therefore, primary analyses will be conducted only on primary participating caregivers [53]. We do not expect treatment effects to differ by dyad status and will test this assumption with data obtained from nonprimary participating parents analyzed in exploratory analyses. Model assumptions will be checked and alternative robust will be methods used, for instance, robust SEs, bootstrapping, or generalized linear models, if applicable [54,55]. Secondary end points (eg, PTSS and anxiety) in specific aim 1 will be analyzed in the same manner. All tests will be 2-tailed at a .05 level of significance; the Benjamini-Hochberg method will be used to adjust for multiple testing [56].

Aim 2: Analyses

Specific aim 2 analyses will further probe the eSCCIP/eSCCIP-SP user experience, intervention effects, and boundary conditions. First, descriptive summaries and data visualizations will be used to explore user engagement variables, such as the number of cores completed. Next, potential risk and protective factors will be examined by introducing interaction effects to the models previously described for specific aim 1, including all primary and secondary end points. Interaction terms will be formed between intervention assignment and each potential moderator variable, tested in separate models under the Benjamini-Hochberg control method. Follow-up inferential and graphical procedures will be used to interpret significant interaction effects [57]. Variables selected as potential moderators are participant characteristics guided by the Behavior Change Model for Internet Interventions (eg, race, gender, and socioeconomic status) and family risk variables guided by the Pediatric Preventative Health Model (eg, COVID-19 Exposure and Family Impact Scale score, PAT baseline score). Of primary importance is the potential moderating effect of intervention language, which will similarly be tested. Additional exploratory analyses will be carried out to answer key auxiliary questions and maximize the use of the data collected. First, we will examine any possible persisting effects of eSCCIP/eSCCIP-SP at the 3-month follow-up time point, based on longitudinal analysis models designed for randomized pretest-posttest-follow-up designs [58]. Similarly, we will also explore whether treatment effects differed between parents and caregivers of children with cancer from families with 1 or 2 participating caregivers, as well as examine trends in data provided by nonprimary participating caregivers.

Aim 3: Analyses

Qualitative interviews will be coded and analyzed using the CFIR framework, a widely used implementation science framework. An initial codebook will be generated using different domains of the CFIR framework, focusing on the constructs within each domain that are most related to the implementation of eSCCIP/eSCCIP-SP (eg, adaptability, cost, patient needs and resources, and self-efficacy). Discrepancies will be identified and resolved by consensus among the investigators. To strengthen the rigor of the analysis, a primary and secondary coder will be assigned as the analysis continues with the secondary coder checking the coding of the primary coder as well as completing a summary of data on each category within that case (group) and across all cases (groups). The case summaries and samples of the coding process will be reviewed in regular meetings of the study team. Through this content analysis process, codes will be transformed into categories and categories into themes according to national standards that identify and refine strategies for the implementation of the intervention. Themes that result from this process will be translated into implementation and sustainability strategies organized around the 5 major domains of the CFIR framework. We will explore intervention characteristics, inner and outer settings, characteristics of individuals, and the implementation process.

XSL•FO
RenderX

The incremental (ie, beyond the cost of an education control website) costs and cost-savings analysis will follow best practices. We will estimate incremental costs associated with eSCCIP/eSCCIP-SP treatment, costs per participant, and marginal costs per unit of acute distress reduction. All costs will be estimated and evaluated in constant dollars using the appropriate index for price adjustment. Those resources that rise at the rate of general inflation will be corrected for inflation with the consumer price index, while medical costs will be adjusted with the medical component of the consumer price index. Due to the efficacy trial nature of this project, we will conduct a partial economic evaluation to document the cost information of the eSCCIP/eSCCIP-SP and estimate a preliminary cost-effectiveness regarding the primary outcome (ie, acute distress reduction). We will evaluate the intervention costs from health care provider perspective; therefore, the nonresearch-related cost/resource will be those health care provider–related ones, which will include intervention labor costs for hourly wages including fringe benefits of delivery staff for a different component of the program (ie, website regular maintenance staff, and telehealth guide). During all phases of development and implementation, we will document what was performed, by whom, the length of execution, and the use of any nonhuman resources. Cost collection instruments will be modified based on the eSCCIP guide/research team templates and behavioral intervention templates. Care will be taken to accurately separate research-based costs (eg, costs of follow-up assessments) from actual worksite program implementation costs. We will estimate separate costs for eSCCIP and eSCCIP-SP to provide the information needed to compare differences and provide evidence for predicting costs based on patients' ethnicity distribution. To capture cost savings from a health care provider's perspective, we will use electronic patient record to track control group patients' related health care service usage, which provides the relevant information to estimate potential cost savings patients in the treatment group could have used if there is no eSCCIP/eSCCIP-SP. A full-scale cost-effectiveness analysis will be out of the scope of this efficacy study. We will calculate incremental cost-effectiveness ratios and will use bootstrapping methods to account for the uncertainty around the incremental cost-effectiveness ratios but recognize that the limited scope of this study: only collecting partial information on program costs, especially on implementation costs [59]. We will calculate net benefits, benefit-cost ratio, and return on investment (return on investment=net benefits/costs×100). Bootstrapping will be used for CIs construction around those measures. Generalized linear models will be applied to estimate the relationship between program incremental costs and the characteristics of participants, providers, and programs. Appropriate link function and distribution family will be chosen to fit the data. A 2-part model will be used to examine and handle sample selection and nonrandom attrition.

Results

This RCT was funded by the National Cancer Institute (1R01CA258668) in March 2022. Recruitment is planned to begin by February 2023 and will continue for 3 years.

Discussion

Principal Findings

This study protocol details an RCT to evaluate the psychosocial efficacy of eSCCIP/eSCCIP-SP, a novel digital health intervention for parents and caregivers of children with cancer. The development of eSCCIP and eSCCIP-SP was thoughtfully guided by the psychology, culturally competent care, and technology literature. Considering the recent and ongoing COVID-19 pandemic, the need for flexible, acceptable, and accessible psychosocial digital health intervention is more apparent than ever before to provide evidence-based psychosocial care for parents and caregivers of children with cancer. We hypothesize that the intervention will be more efficacious than an education control at decreasing negative symptoms of acute distress, anxiety, and PTSS symptoms while demonstrating improvements to coping self-efficacy and positive cognitive coping strategies.

Comparison With Prior Work

Despite the well-documented and established psychosocial needs of parents and caregivers of children with cancer as well as challenges to in-person engagement, exceedingly few digital health options have been evaluated to provide care to this population. To our knowledge, the web-based adaptation of the Bright IDEAS Maternal Problem-Solving Skills Training Intervention [16,33,34] is the only existent psychosocial digital health intervention for parents and caregivers of children with cancer. This intervention provides education to improve problem-solving skills.

The proposed study is innovative for several key reasons. The availability of an evidence-based, psychosocial digital health intervention for parents and caregivers of children with cancer available in English and Spanish is novel, especially given its hybrid format of including both self-guided web-based content and live telehealth sessions with a trained interventionist. This format capitalizes on recommendations from prior electronic adaptations of manualized psychosocial support for parents and caregivers of children with cancer, which has suggested that web-based content may be most effective when combined with in-person contact and support [33]. The eSCCIP/eSCCIP-SP intervention has been rigorously designed and developed and is now ready for large-scale testing. Second, the development of eSCCIP/eSCCIP-SP used a systematic participatory process with multiple groups of stakeholders at all stages of design and initial testing, increasing the likelihood that the intervention is responsive to participant needs and reflects the "true" needs of the target population. In addition to working closely with parents and caregivers of children with cancer, we also partnered with trained medical interpreters and experts in cultural intervention adaptation when developing the eSCCIP-SP. Although this type of participatory research is increasingly important and well used in social and behavioral research, it is not yet commonplace in pediatric psychosocial oncology and further serves to distinguish our tools and approach. Third, the eSCCIP-SP is innovative, given the lack of resources available to the high-risk population of parents and caregivers of children with cancer, who are of Latinx descent, and the potential of the intervention to reduce

XSL•FO
RenderX

systemic health care disparities related to psychosocial services. Fourth, eSCCIP/eSCCIP-SP can be used anywhere with an internet connection (including cellular telephone data access or Wi-Fi) and is adaptable/responsive to devices (eg, mobile phones), decreasing barriers to access and making the intervention highly amenable to eventual broad and rapid dissemination. While delivering web-based psychosocial interventions itself is not altogether novel, these interventions are largely unavailable for parents and caregivers of children with cancer. This is especially timely given the recent rise and acceptability of telehealth and video platforms for health care service delivery during the COVID-19 pandemic. Fifth, we will use an advanced platform to closely track engagement metrics, which will allow us to develop and quickly implement stepped care plans for future implementation studies. This platform has been developed by the Center for Behavioral Health and Technology at the University of Virginia and is used successfully to manage numerous behavioral and psychosocial digital health intervention trials, including large studies in adult oncology and adolescent oncology [60-62].

Limitations

It is possible that the sample of parents and caregivers of children with cancer who opt to participate in our research are self-selected and may not fully represent the population of caregiving individuals of children with cancer. To identify and more broadly implement successful recruitment, retention, and engagement strategies, the primary study team recently published a manuscript describing qualitative data from focus groups and interviews [36]. The sample included past eSCCIP participants and parents and caregivers of children with cancer who were naïve to eSCCIP (but viewed some intervention content prior to participating). By implementing these strategies broadly over the course of the study, a wide range of potentially eligible parents and caregivers of children with cancer will be targeted for inclusion. We will monitor recruitment and enrollment rates closely over the course of the study, adjusting recruitment strategies if indicated. It is also possible, given both the duration of the study follow-up and randomization procedures, that participants may drop out or be lost to follow-up. Efforts by research staff to maintain participation in the study and to obtain postintervention measures for all participants will be made, including participants providing multiple means of contact to aid in follow-up as well as receiving study payments after completion of each data collection time point. In eSCCIP development trials, close tracking and monitoring procedures led to high retention rates for participants who begin the intervention, and the addition of automated reminders and a stepped care approach to communicate with participants will bolster these efforts. The characteristics of completers versus noncompleters will also be examined for systematic differences, and we will use an intent-to-treat design for data analyses.

Second, since the intervention involves an active intervention component, including telehealth follow-up with a trained guide for participants allocated to eSCCIP/eSCCIP-SP, blinding of guides is not possible. However, study team members not involved in intervention delivery will not have access to random assignment information. After randomization, participants will be instructed on the procedures within their assigned group. All outcome measures will be completed directly on the internet by study participants, further reducing the risk of bias.

Finally, it is also important to acknowledge that care at study sites includes access to psychosocial support; however, the use of these services is likely to be equivalent across intervention and control group participants, and no participant in either condition will be discouraged from accessing any available psychosocial support. While usual care may include work with a licensed psychologist, novel aspects of eSCCIP are unique to the intervention and not a component of routine care. We will also collect information on mental and psychosocial health services used by all participants during the study period to understand the context in which eSCCIP/eSCCIP-SP was received and control for other psychosocial services in analyses if indicated.

Dissemination Plan

Data will be disseminated and shared with the scientific community through peer-reviewed publications and academic conference presentations. Furthermore, the results will be shared with participants through annual updates. Continual efforts to disseminate study progress and results are valued to maintain productive and collaborative relationships with institutional care teams and relevant stakeholders. A summary of study results will be submitted to ClinicalTrials.gov within 1 year of the trial's primary completion date.

Conclusions

Despite advances and improved medical outcomes for childhood cancer, parents and caregivers of children with cancer are at known risk for negative psychosocial sequelae, including increased risk for Latinx, Spanish-speaking parents and caregivers of children with cancer [1,2,12]. Established standards of care recommend access to high-quality psychosocial support for parents and caregivers of children with cancer and, while digital health interventions may address many logistical barriers to in-person participation in this population [63], few options exist at this time. The results from rigorous development, refinement, and pilot testing of eSCCIP and eSCCIP-SP have demonstrated the potential to deliver an effective and easily disseminatable intervention, decreasing barriers to care, and improving psychosocial outcomes. Data obtained from this RCT will be instrumental in evaluating the efficacy of the eSCCIP/eSCCIP-SP intervention as an evidence-based tool to support parents and caregivers of children with cancer across the cancer trajectory.

Abstract

Background: As much as 80% of children on the autism spectrum exhibit challenging behaviors (ie, behaviors dangerous to the self or others, behaviors that interfere with learning and development, and behaviors that interfere with socialization) that can have a devastating impact on personal and family well-being, contribute to teacher burnout, and even require hospitalization. Evidence-based practices to reduce these behaviors emphasize identifying triggers (events or antecedents that lead to challenging behaviors); however, parents and teachers often report that challenging behaviors surface with little warning. Exciting recent advances in biometric sensing and mobile computing technology allow the measurement of momentary emotion dysregulation using physiological indexes.

Objective: We present the framework and protocol for a pilot trial that will test a mobile digital mental health app, the *KeepCalm* app. School-based approaches to managing challenging behaviors in children on the autism spectrum are limited by 3 key factors: children on the autism spectrum often have difficulties in communicating their emotions; it is challenging to implement evidence-based, personalized strategies for individual children in group settings; and it is difficult for teachers to track which strategies are successful for each child. KeepCalm aims to address those barriers by communicating children's stress to their teachers using physiological signaling (emotion dysregulation detection), supporting the implementation of emotion regulation strategies via smartphone pop-up notifications of top strategies for each child according to their behavior (emotion regulation strategy implementation), and easing the task of tracking outcomes by providing the child's educational team with a tool to track

XSL•FO
RenderX

the most effective emotion regulation strategies for that child based on physiological stress reduction data (emotion regulation strategy evaluation).

Methods: We will test KeepCalm with 20 educational teams of students on the autism spectrum with challenging behaviors (no exclusion based on IQ or speaking ability) in a pilot randomized waitlist-controlled field trial over a 3-month period. We will examine the usability, acceptability, feasibility, and appropriateness of KeepCalm as primary outcomes. Secondary preliminary efficacy outcomes include clinical decision support success, false positives or false negatives of stress alerts, and the reduction of challenging behaviors and emotion dysregulation. We will also examine technical outcomes, including the number of artifacts and the proportion of time children are engaged in high physical movement based on accelerometry data; test the feasibility of our recruitment strategies; and test the response rate and sensitivity to change of our measures, in preparation for a future fully powered large-scale randomized controlled trial.

Results: The pilot trial will begin by September 2023.

Conclusions: Results will provide key data about important aspects of implementing KeepCalm in preschools and elementary schools and will provide preliminary data about its efficacy to reduce challenging behaviors and support emotion regulation in children on the autism spectrum.

Introduction

Background

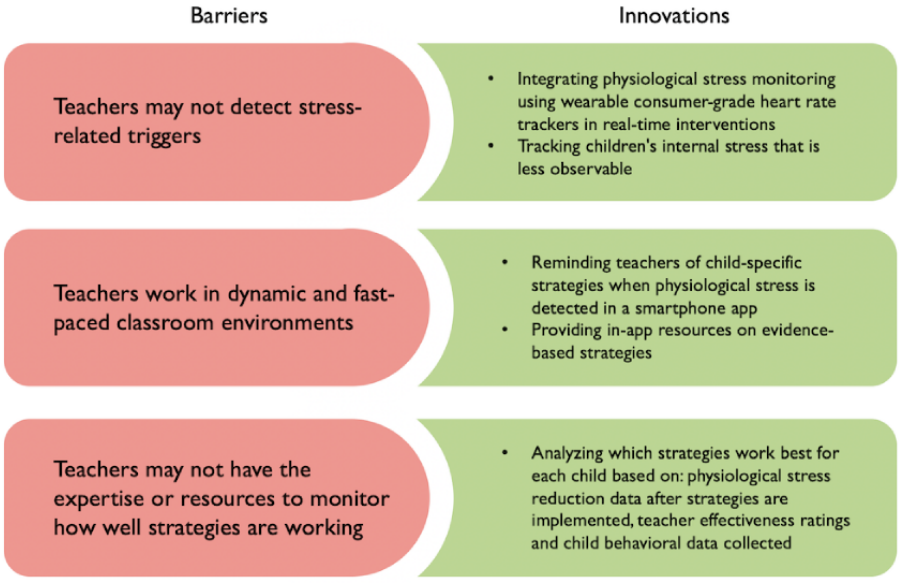
Children on the autism spectrum can exhibit challenging behaviors, such as aggression, self-injury, and property destruction [1-3], which occur in as much as 80% of children [4]. These behaviors can have a devastating impact, negatively affect personal and family well-being [5], contribute to teacher burnout [6], and even lead to hospitalization [7]. Challenging behaviors may stem from a culmination of physiological and psychosocial stress when children are unable to regulate their stress, that is, when they do not have a repertoire of emotion regulation strategies to call on to defuse their stress [8,9]. Emotion dysregulation—difficulties with monitoring, evaluating, and modifying emotional responses to environmental demands [10]—is thought to serve as a mediator between stress and challenging behaviors in autism [11,12]. Consistent with this notion, recent literature has documented that challenging behaviors in children and adolescents with autism spectrum disorder are more likely to surface in response to situations placing demands that exceed their emotion regulation skills [13]. Individuals on the autism spectrum are more likely to experience stressful events compared with their peers owing to their difficulties with communicating, understanding others' behaviors, and responding to demands; sensitivities to sensory stimuli; insistence on sameness; and social expectations that might be perceived as emotionally overwhelming [9]. These difficulties or factors can be particularly pronounced in the school setting [14]. Therefore, these difficulties with emotion dysregulation, in addition to frequently experienced stressors, place children on the autism spectrum at high risk for frequent challenging behavior episodes.

Evidence-based strategies for managing challenging behaviors and supporting emotion regulation in schools include proactive (antecedent) and reactive (consequent) strategies [1,15,16]. Proactive strategies, such as setting routines and tailoring the environmental or instructional design to prevent challenging behaviors, are typically preferred to reactive strategies, such as punishment and planned ignoring [1,15,16]. However, even when proactive strategies are well implemented, challenging behaviors still occur, with parents and teachers often reporting that they occur without warning [11,12]. In children on the autism spectrum, triggers can be difficult to determine even with expertise in functional behavioral assessment (which is not standard training for the teaching force) [17], as children on the autism spectrum often have trouble in communicating their stress [18]. Therefore, it is critical to understand the stress-related triggers that lead to the onset of challenging behaviors. Early detection of rising stress can allow for the implementation of proactive strategies targeting stress reduction or emotion regulation, such as emotion regulation training; mindfulness-based strategies; the prompting of cognitive reappraisal; functional communication training; or other antecedent-based strategies, such as providing access to sensory stimuli or offering choices.

A way to know when a child may be experiencing stress before a challenging behavior, and thus intervene early, is by measuring the physiological state; physiological state is a well-recognized index of stress, which may be captured using many physiological channels, including heart rate (HR) [19-24]. Many theoretical frameworks point to a causal pathway between physiological stress and challenging behavior [8,25-27], and previous studies have shown elevated HR before the onset of a challenging behavior in adults on the autism spectrum [28,29]. In our previous study, we found that there is often a >22% increase in HR in the 58 seconds immediately preceding the challenging behavior and that this increase has moderate utility in predicting challenging behaviors (area under the curve [AUC]=0.72;

XSL•FO
RenderX

P<.001) [30]. We replicated this finding in 2 samples of children aged 8 to 12 years on the autism spectrum, finding that 33% to 36% increase in HR in the preceding 76 to 80 seconds was associated with challenging behaviors (AUC=0.75-0.82). These results were again replicated in another data set including both children and adolescents on the autism spectrum (AUC=0.71) [31]. These studies suggest that responding to early HR increases may be a more direct approach to identifying the need for emotion regulation strategies, which may support the identification of behavioral triggers.



Timely identification of stress may help prevent emotion dysregulation and challenging behaviors. In addition, children on the autism spectrum may be less equipped to deal with this stress, as many have well-documented difficulties in independently using emotion regulation strategies and instead more frequently rely on maladaptive or ineffective strategies, such as rumination or shutting down [32-37]. Thus, difficulty in emotion regulation is likely a mechanism by which stress contributes to challenging behaviors, and teaching emotion regulation is critical. However, there are 3 barriers that limit the use of emotion regulation strategies for managing challenging behaviors in children on the autism spectrum in school settings. First, teachers may not detect children's stress-related triggers or their rising stress, with or without training, as children on the autism spectrum often do not express emotions verbally or in clear, observable ways using nonverbal communication channels [18]. Therefore, the detection of stress by teacher's observation alone may be sometimes ineffective or unreliable.

Second, teachers work in dynamic and fast-paced classroom environments. Even when teachers are sensitive to behavioral triggers and evidence-based behavior plans are in place, teachers have multiple demands on their attention and may not recognize a trigger or recall the best strategies to use with each student in the moment of crisis. In addition, teachers' own stress during episodes may interfere with this recall, as their stress has been found to interfere with delivery of evidence-based practices in schools [38,39]. Therefore, teachers need support to implement emotion regulation interventions with children on the autism spectrum.

Third, teachers may not have the training or resources to monitor how well the strategies are working. Many teachers do not receive training in program monitoring and analysis that is required to refine children's behavioral plans, limiting their ability to make data-informed decisions about which strategies work for a given child. Even when teachers have training in outcome measurement and monitoring, they may be unable to systematically monitor the success of strategies owing to competing demands. They may not have the time, personnel, or technological resources to determine which strategies are the most effective. Our proposed mobile health (mHealth) app, KeepCalm, is designed to address these 3 barriers and reduce or prevent challenging behaviors in children on the autism spectrum (Figure 1; app development and features are described in the *Methods* section).

The KeepCalm app is designed as a real-time electronic clinical decision support tool, otherwise known as a *just-in-time adaptive intervention* (JITAI) augmentation, a term coined in mHealth [40]. JITAI augmentations are intervention supports designed to provide the right type or amount of support at the right time by adapting to a person's changing internal and contextual state (eg, by tracking physiological stress, sleep quality, exercise or activity, temperature, and location). Most JITAI technologies are designed to support the individual client directly (eg, check-in messages and resources for clients with alcohol use disorder, triggered by GPS data showing that they are near a predetermined risk location, such as a local bar) [41]. However, the KeepCalm app is one of the first (also refer to the studies by Juarascio et al [42] and Clausen et al [43]) to support the provider (in this case, teacher or aide) directly, so that they may in turn best support their client (in this case, student).

Figure 1. Barriers and the KeepCalm app's corresponding proposed innovations to be tested.

XSL•FO
RenderX

Objectives

We present the framework and protocol for a pilot randomized waitlist-controlled field trial that aims to examine the implementation of a digital mental health app, the KeepCalm app (refer to the *Materials* section for details about the app), designed for children on the autism spectrum with challenging behaviors of any IQ or speaking ability. Given that >95% of digital mental health apps have not actually been studied [44,45], an overarching goal of the project is to test the KeepCalm app systematically. We expect the KeepCalm app to score high on usability, acceptability, feasibility, and appropriateness. We also predict satisfactory proximal efficacy (>80% clinical decision support success rates and <20% false positive and negative rates), high technical reliability (the removal of artifacts and offline mode activation success), and the use of the KeepCalm app to result in low severity and frequency of challenging behaviors and emotional dysregulation in children on the autism spectrum after the trial relative to baseline.

Methods

App Development Work

We have used user-centered design [46,47] methods to develop the mHealth KeepCalm app by involving key stakeholders in each phase of development and testing [47-49]. As part of the early stages of the project, we have already conducted needs assessments with school personnel and parents to understand their needs in managing children's challenging behaviors and supporting their emotional regulation. We are in the process of completing 5 cycles of rapid cycle prototyping (so far, 4 cycles have been completed, including 2 with the live app prototype). App feedback gathered through this testing has directly informed future app iterations. We have also gathered data showing high usability, feasibility, acceptability, and appropriateness of the KeepCalm app and data from associated HR trackers and accelerometry devices to examine in the context of regulatory and ethical educational frameworks [50]. Alongside this work, we conduct expert advisory board meetings with a board composed of relevant experts in the community (the autism support coordinator from the School District of Philadelphia, teachers, teacher coaches, parents, and adults with autism). The board meets every few months to gather their feedback about and support for every aspect of the project, including app features and design, in-app evidence-based strategy resources, study methods, and recruitment. All previous work will inform the final KeepCalm app to be tested in this pilot randomized waitlist-controlled field trial.

Design

We will conduct a pilot randomized waitlist-controlled field trial of the KeepCalm app (refer to the *Materials* section for details about the KeepCalm app) in which participants will either be randomized to the KeepCalm app for a period of 3 months or will be included in a waitlist and will trial the app for 3 months after an initial 3-month waiting period. In this trial, the KeepCalm app will be tested for usability, feasibility, acceptability, and appropriateness, and we will also collect some preliminary proximal and distal efficacy data to inform a future, fully powered randomized field trial.

Participants and Recruitment

Overall, 20 educational teams comprising a preschool or elementary school student on the autism spectrum, their parent, their teacher, and their aide (if they have one) will be recruited. If a child does not have an aide or their aide declines to participate, their speech therapist, occupational therapist, or another educational team member may participate instead. Therefore, at a minimum, teacher-child or parent dyads will be consented, with some teams forming a triad with an aide or other member of the educational team. Teachers may participate with 1 to 2 of their students on the autism spectrum.

Inclusion Criteria

Children must have an educational classification of autism, verified using the Social Communication Questionnaire [51], a parent-reported measure. They must also exhibit challenging behaviors (ie, behaviors dangerous to the self or others, behaviors that interfere with learning and development, and behaviors that interfere with socialization). Examples include aggression, self-injury, escape behavior, property destruction, loud noises, and rigid or inflexible behavior (if at least one of the challenging behavior criteria mentioned previously applies).

Participants will be recruited from the School District of Philadelphia and private preschools or schools in the Philadelphia area using several recruitment methods including emailing teacher listserves or email lists, through the center participant registry, through the study's expert advisory board, and through projects led by HJN or DM. We will also send Parent Permission-to-Contact forms home from school via students, along with the study flyer. If parents sign the form and send it back to school, we will reach out to them to invite them into the study. We also include a version of the flyer and Parent Permission-to-Contact form in Spanish. We may also use study flyers sent through various relevant organizations and listserves, newsletters, internet postings, social media (Facebook and Twitter), and other recruitment tools as needed, and we may attend parent workshops and autism-related events to recruit participants. If study participation is initiated by parents, after consenting parents, we will send the referral contact forms to schools via parents to recruit the child's teachers or reach out to the schools directly to invite teachers to participate, after obtaining letters of support from school principals or directors, if required. Then, parents and teachers who agree to be contacted will be contacted by the research team to explain the study and invite them to participate. In addition, once teacher consent is completed, classroom aides will also be invited to participate. If no aides are available to participate, we will invite their speech therapist, occupational therapist, or any other educational team member identified by the parent or teacher.

To help characterize the children in the study, we will obtain the child's IQ from their Individual Education Program, if this was derived from a standardized test battery. If such an IQ score is not available on the child's Individual Education Program, the research team will administer the Stanford Binet Abbreviated Scales [52] test battery to obtain an IQ score.

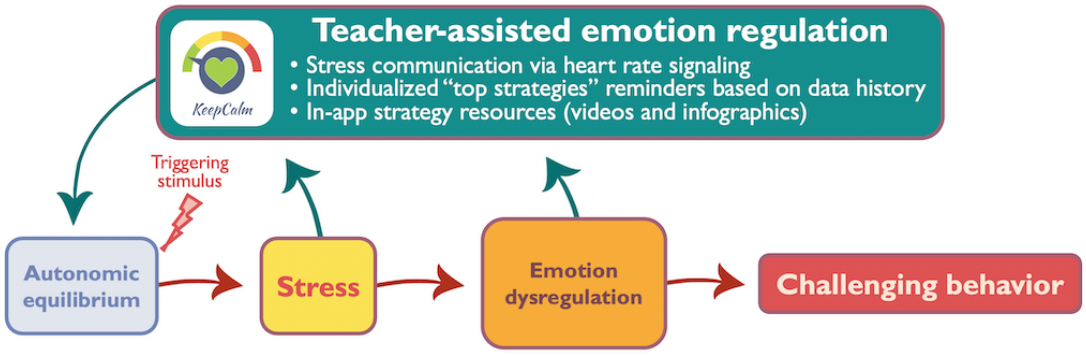
RenderX

Materials

Overview of the KeepCalm App

The KeepCalm app is designed to be an interactive learning and data collection tool to facilitate a team approach to support emotion regulation in students. It integrates wearable HR tracking to identify and alert educators about heightened stress in their students and remind them about evidence-based strategies for de-escalating stress, supporting proactive coping, and preventing challenging behaviors. Refer to Figure 2 for the KeepCalm causal model, which shows that the pathway from stress to challenging behaviors via emotion dysregulation is "rescued" with the KeepCalm app, via teacher-assisted emotion regulation, whereby the teacher supports their student to reattain autonomic equilibrium (ie, physiological baseline or resting state) via stress communication (ie, child HR signaling to teacher), along with individualized recommendations about strategies to keep calm.

The KeepCalm app offers 3 innovations (to be tested) that address the 3 barriers described in the *Introduction* section (Figure 1). First, it incorporates physiological stress data into treatment delivery by capitalizing on recent advances in wearable biosensing [22,53,54]. The selected consumer-grade trackers are accurate [53,55,56] and have high technical reliability [55,57] for measuring HR (beats per minute) and HR variability (interbeat interval), making them inexpensive and scalable alternatives to medical-grade devices. In previous studies, we found that 85% of children on the autism spectrum will wear these trackers without complaint and rate them high on comfort and low on exacerbating sensory sensitivities [55,57].



Second, KeepCalm reminds teachers about child-specific strategies when physiological stress is detected. Computerized clinical decision support systems have been found to be related to higher fidelity in evidence-based practices and better patient outcomes among providers who work in chaotic environments, such as ambulatory clinic staff [58-61]. Despite the promise of this technology, such systems have not been linked with HR monitoring for decision support during behavioral interventions or therapy. The KeepCalm app gives pop-up notifications about top emotion regulation and behavior management strategies identified for each child and contains a comprehensive easy-to-access list of proactive and reactive strategies to support teacher training and ongoing in-class coaching in these strategies by the center's teacher coaches. Additional coaching will be conducted as needed.

Third, it has a feature to track and tailor strategy recommendations based on stress reduction data. The app captures HR data before and after strategy implementation, allowing for calculation of physiological stress reduction based on each strategy. These data allow for the calculation of the "Top 3 Strategies" for each child. These are included in push notifications linked with HR alarms, accessible via an app dashboard, and sent to teams on a daily or weekly basis via email, so that everyone can stay up to date with which strategies work best for each child. Thus, the technology gives teachers a tool to assess strategy effectiveness in restoring emotion regulation. This is adaptive and will allow teachers to tailor future use of strategies, thus supporting personalized treatment.

This app is aligned with the strategic plan of the Interagency Autism Coordinating Committee [62], which calls for maximizing the potential for technology-based intervention supports to improve the lives of individuals on the autism spectrum and developing technology-based treatments deployable in community settings to increase treatment access. In addition, our previous pilot data from parents and children show that they think that an app using HR signaling could be "extremely useful" for managing stress in students on the autism spectrum; they "strongly agree" that such a system would help prevent challenging behaviors, and they "strongly agree" that this offers advantages over current practices [63]. Figure 3 shows the main features and design of the KeepCalm app.

The KeepCalm app offers several features designed to make it easy to know when and how to intervene with children to support their proactive coping and emotion regulation development.

Figure 2. KeepCalm causal model.

XSL•FO
RenderX

Figure 3. KeepCalm app design.

HR Stress Zone Tracking

The KeepCalm app pairs with selected commercially available HR trackers (refer to the *HR Trackers* section) that children wear to allow moment-by-moment physiological arousal tracking by educators. After recording a baseline HR for each child, educators are given pop-up notifications to alert them about moderate stress levels, along with individualized top strategies that can be used to reduce their stress. As HR is an index of stress levels [22-24], an increase in HR may index rising stress in children. HR above baseline (ie, HR at rest) is arranged in a stress zone rainbow in the KeepCalm app, with green representing baseline, yellow representing small increase in HR above baseline (+10%), orange representing medium increase in HR above baseline (+20%), and red representing large increase above baseline (+30%). Educators can track the child's HR, so that they can intervene at moderate stress levels (ie, orange-zone HR) to prevent challenging behaviors associated with high stress levels or HR of approximately 30% above baseline [30] (ie, red-zone HR). In doing so, the educator creates emotion regulation learning opportunities for the child. Increase in HR may occur for other reasons, including increased physical exertion; however, accelerometry data movement thresholds ensure that increases in HR owing to child movement are not reflected in the HR stress zone tracking (refer to the *Offline Mode* section).

Individualized Child Behavior, Skills, Triggers, and Strategies Tracking

The KeepCalm app is designed to help educators and parents track children's individualized education programs in a centralized manner. Teams can create custom profiles for each child for individualized tracking of challenging behaviors, skills, behavioral triggers and antecedents, and strategies for that child and sync data entry across the team.

Top Strategy Notifications

The KeepCalm app offers individualized "top strategy" suggestions from an up-to-date list of evidence-based strategies for supporting emotion regulation and preventing challenging behaviors in children on the autism spectrum. The top strategies are individualized for the child based on previous data collection and HR tracking and sent out when a child enters the orange or red stress zones.

Offline Mode

"Offline mode" is activated when a child's average movement (acceleration) over the past 5 seconds is ≥1 m/s^2. This threshold was selected to screen out the effect of vigorous movement on the top strategy notifications triggered by the child entering the orange or red stress zones.

Evidence-Based Strategy Resources

The app provides resources (infographics and videos) about the implementation of evidence-based strategies to help support emotion regulation and prevent challenging behaviors in children on the autism spectrum. These strategies are based on the research team's comprehensive systematic review of the literature [64].

Day View

The KeepCalm app includes a "Day View" tab with a daily report including 2 versions. The first is a detailed day view that includes each data entry in list and figure format, and the second is a summary day view that includes a narrative description of the day including the top strategies used that day. This downloadable report is autogenerated at the end of each day and sent to the team via pop-up notification to support frequent team communication.

Custom Reports

The KeepCalm app includes a "Reports" tab where teams can produce clear and concise tables and figures to present data about each child's challenging behaviors, skills, behavioral triggers and antecedents and strategies for upcoming education team meetings and to share with parents. These downloadable reports may be used to help with noticing trends and for evidence-based programming to support children's development.

Functional Behavioral Assessment Mode

The KeepCalm app includes a functional behavioral assessment mode to help teams collect data to determine the function of or

XSL•FO
RenderX

reason for new or emerging challenging behaviors, to help decide on strategies for these behaviors. Behavioral analysts can be added to the child's KeepCalm team for easy sharing of functional behavioral assessment data.

Team Messaging

The KeepCalm app offers a team messaging platform to aid team communication, which is important for consistency of strategy use across school teams and at home. Teams can also contact the app development team in real time for troubleshooting.

To sign up to the app, school personnel and parents will enter their name, email, phone numbers, and their child's nickname or ID, so that they can identify the child. Teams will record triggers, behavior and skills, and strategies in the app, and HR and accelerometry data will be recorded from child participants. Only the child's team members and the research team will have access to this information. The app does not collect any other information from participants' mobile devices.

HR Trackers

We will use 2 HR tracker models previously tested for accuracy, reliability, validity, and comfort [55]—the Mio Fuse (Mio Global) wristband and Polar H7 (POLAR) chest strap. These models are highly accurate (correlation with wired electrocardiogram: Mio Fuse: mean r=0.91, 95% CI 0.882-0.929; Polar H7: mean r=0.99, 95% CI 0.987-0.991) [53,56] and reliable (they meet quality thresholds on spike rate—Mio Fuse: 100%; Polar H7: 87.4%-89.4% and sampling fidelity—Mio Fuse: 96.2%-97.1%; Polar H7: 96.6%-100%) [55] for measuring HR and HR variability. We found that children on the autism spectrum rated both devices in the comfortable range [55], and in our pilot study, they were able to wear one of the 2 HR trackers during 5 school days.

Accelerometer

We will also use belt-clip accelerometers (mBient MetaMotionRL or another suitable model) to measure child movement, so that stress zone alerts are not sent out during period of high child movement but instead put the child's notifications in "offline mode" (refer to the *Offline Mode* section for more details). In our pilot study, teachers were asked to use the mBient trackers with child participants during 5 school days.

Measures

Primary Outcome Measures

Usability

Teacher and parent perceptions of usability will be measured using the System Usability Scale [65]. The scale consists of 10 items rated on a 5-point Likert scale ranging from 1 ("Strongly disagree") to 5 ("Strongly agree"). Responses are transformed to obtain a total value from 0 to 100, with higher scores indicating greater perceptions of usability. This scale will be administered at the end of the trial, 3 months after baseline.

Feasibility

Feasibility of the app will be assessed through teacher and parent report using the Feasibility of Intervention Measure [66]. The measure consists of 4 items rated on a 5-point Likert scale ranging from 1 ("Completely disagree") to 5 ("Completely agree"). The score is calculated by summing all items to yield a total score ranging from 4 to 20, with higher scores indicating greater feasibility of the app. Participants will complete this scale at the end of the trial, 3 months after baseline.

Acceptability

Acceptability of the app will be measured through teacher and parent report using the Acceptability of Intervention Measure [66]. The measure consists of 4 items rated on a 5-point Likert scale ranging from 1 ("Completely disagree") to 5 ("Completely agree"). The score is calculated by summing all items to yield a total score ranging from 4 to 20, with higher scores indicating greater acceptability of the app. Participants will complete this scale at the end of the trial, 3 months after baseline.

Appropriateness

Appropriateness of the app will be assessed through teacher and parent report using the Intervention Appropriateness Measure [66]. The measure consists of 4 items rated on a 5-point Likert scale ranging from 1 ("Completely disagree") to 5 ("Completely agree"). The score is calculated by summing all items to yield a total score ranging from 4 to 20, with higher scores indicating greater feasibility of the app. Participants will complete this scale at the end of the trial, 3 months after baseline.

Interview Feedback

Following participation in the study, teachers, aides, and parents will complete a 30-minute interview, where we will gather more context about the usability, feasibility, acceptability, and appropriateness of the KeepCalm app. We will also gather feedback, suggestions, and general impressions about the app. This feedback will also focus on the issue of alarm fatigue, that is, if teachers were overwhelmed, annoyed, or otherwise felt negatively toward the number of notifications received from the app during the day.

Secondary Outcome Measures

Proximal Preliminary Efficacy Outcomes

Clinical decision support success: We will additionally obtain information from teachers to measure the clinical decision support success of the app. This will be calculated from the proportion of alarms and emotion regulation strategy push notifications that result in timely implementation, as measured through in-class observation sessions (if possible, given the COVID-19–related school policies and teacher preferences) and remotely through data entry on the app.

False positives and false negatives: False positives and false negatives will be calculated as the proportion of alarms that appear to not be associated with an oncoming challenging behavior (eg, child movement) or challenging behaviors that occurred without an alarm, respectively. This will be measured through in-class observation sessions (if possible, given the COVID-19–related school policies and teacher preferences) and remotely through data entry on the app.

XSL•FO
RenderX

Distal Preliminary Efficacy Outcomes

Challenging behaviors: Challenging behaviors will be assessed using 3 measures: 2 measuring challenging behavior severity—the School Situations Questionnaire (SSQ [67]), completed by teachers, and the Open-Source Challenging Behavior Scale [68], completed by parents—and 1 measure of challenging behavior severity—the Institute for Basic Research Modified Overt Aggression Scale (IBR-MOAS [69]), completed by teachers and parents.

The SSQ assesses challenging behaviors within the school context. The scale assesses both the presence and the severity of challenging behaviors, with items assessing whether a given behavior occurs for a child and the severity ratings. The scale yields 2 summary scores. The first is the number of problems score, which is a sum of the number of challenging behaviors endorsed, ranging from 0 to 8, with higher scores indicating greater number of problems endorsed. The second is the mean severity, calculated as the mean severity for the items endorsed, ranging from 1 to 9, with higher numbers indicating more severe problems (1-3=mild severity, 4-6=moderate severity, and 7-9=significant severity). Participants will complete this measure at baseline and 3 months after baseline.

The Open-Source Challenging Behavior Scale measures the severity of challenging behavior episodes across contexts (eg, school and home), from the parent's perspective. The scale includes 18 questions rated on a 5-point Likert scale (1=not at all a problem, 2=mild problem, 3=moderate problem, 4=severe problem, and 5=very severe problem). Participants will complete this measure at baseline and 3 months after baseline.

The IBR-MOAS measures the frequency and severity of aggressive behavior episodes. The scale is divided into five subscales: (1) verbal aggression toward others, (2) verbal aggression toward self, (3) physical aggression against other people, (4) physical aggression against objects, and (5) physical aggression against self. Items are rated on frequency on a 5-point Likert scale: never=never happens, rarely=averages about once a year to once a month, sometimes=averages about several times a month to several times per week, often=averages about daily to several times a day, and U=used to happen but not in the past year. For our analyses, we will code U ratings as equivalent to never. Unlike the original Overt Aggression Scale and other modified versions, a weighted scoring system was not used. We will adapt the measure to include other challenging behaviors of interest (eg, escape, climbing furniture, and meltdowns). Participants will complete this measure at baseline and 3 months after baseline.

Emotion dysregulation: Emotion dysregulation will be measured through parent and teacher reports using the Emotion Dysregulation Inventory (EDI), either the original version [70-72] or the young child version [73], depending on the child's age. The scales consist of 30 items (original version) or 22 items (young child version) for raters to indicate how much of a problem certain emotions and behaviors are for the individual, being rated on a 5-point Likert scale ranging from 0 ("Not at all") to 4 ("Very severe"). The EDI produces scores for reactivity (rapidly escalating, intense, and poorly regulated negative affect) and dysphoria (sadness, low positive affect, and unease). Raw scores are summed and converted to standardized scores with clinically elevated cutoffs, based on a large autism sample, and scoring information from a US census–matched sample of 1000 youths provides clinical cutoffs. Participants will complete this measure at baseline and 3 months after baseline.

Technical Outcomes

Artifact removal: The total number of "artifacts"—interbeat HR intervals (also known as RR intervals) >200 ms [55] detected during the testing period will be calculated throughout study participation.

Offline mode activations: The proportion of time for which "offline mode" (refer to the Offline Mode section for more details) is activated over the testing week based on the accelerometry data threshold will be calculated throughout study participation.

Adverse Events

We will use a brief Adverse Events Checklist to be administered to teachers and parents in the treatment group weekly throughout the trial, which may include items related to teachers experiencing stress triggered by monitoring their student's stress levels. This checklist will be reviewed by the expert advisory board for the study before trial commencement.

Ethics Approval

The trial is approved by the University of Pennsylvania institutional review board (829690) and the School District of Philadelphia research review committee (2022-12-1071).

Procedure

The trial is registered at ClinicalTrials.gov (NCT05277194). After screening for eligibility, the 20 teams (at a minimum, teachers-parents and child dyads; at a maximum, teachers-parents and child-aide [or other educational team member] triads) will be randomized to the waitlist (n=10, 50%) or treatment group (n=10, 50%). The treatment (and later, the waitlist) group will use the app for 3 months. After a dyad or triad has signed up for the study, participants will complete a conferencing software-based intake meeting, during which they will be individually briefed about the KeepCalm app and complete the baseline assessments.

School personnel will then complete an in-app training session either remotely or in the classroom, during which they will receive access to the KeepCalm app, HR tracker, and accelerometer. The research team will also show or instruct teachers about how to put the HR tracker and accelerometer on the child or assist or instruct the child in putting them on themselves. Participants will download the app onto their own phones or, if they do not have an iPhone, an iPhone will be lent to them for their participation in the project. A member of the research team will also help the school personnel to customize the app for their student by showing them how to add the child's profile and their triggers, behaviors and skills, and strategies. Standard but editable lists will be programmed into the app for each student, including evidence-based proactive and reactive strategies for reducing challenging behaviors and supporting emotion regulation [64]. All teachers recruited will have had

XSL•FO
RenderX

professional development and in-class coaching in these strategies by coaches in our center. The research team will administer a fidelity assessment tool to teachers to understand their proficiency in implementing these strategies and provide additional coaching or resources for strategies, as needed.

Following this training, school personnel participants will begin testing the app within the classroom. They will initially record at least one baseline HR of the child, which will be used to calibrate the app's stress zone notifications for the child. Baseline HR is recorded over a 5-minute period, during which the child will be engaged in a relaxing activity. We recommend that teachers take 2 to 3 baseline measurements to ensure accuracy. Students will then wear the HR tracker and accelerometer each day during the 3-month testing period. School personnel will be able to track the student's HR and movement; enter child data about triggers and antecedents, challenging behaviors and skills, and intervention strategies; view the daily report; export the child's data; and message others on the student's team. School personnel will receive SMS text message support from the study team during the testing period and will be able to ask questions and troubleshoot any issues that arise during this period. Parents will be able to view the autogenerated daily report for the child, export and build figures of the child's data, access the intervention strategy resources, and use the app's messaging features. The research team will remotely monitor each participant's use of the app during their respective testing period.

Following the app testing period, teachers, aides, and parents will provide feedback about their experience with the app during a brief interview with a member of the research team that will cover various themes including usability, acceptability, feasibility, appropriateness, and any adverse event that may have occurred (the latter will be in addition to the previously mentioned Adverse Events Checklist that will be administered weekly throughout the trial). Measures will be taken at eligibility determination, baseline, throughout the trial, and after the trial as per Table 1. A demographic survey will also be administered at baseline, including a question on the child's current medications, as some are known to affect HR. If possible, given the COVID-19–related school policies and teacher preferences, the research team will perform in-class observations to obtain a first-hand look at the use of the KeepCalm app in the classroom and to track clinical decision support success and false positives and false negatives (as described in the *Measures* section).

Data Analysis

Primary Outcomes

This trial is designed to test usability, acceptability, appropriateness, and feasibility data rather than efficacy; therefore, primary outcome data analyses will use descriptive statistics of the survey measures on usability (System Usability Scale), acceptability (Acceptability of Intervention Measure), feasibility (Feasibility of Intervention Measure), and appropriateness (Intervention Appropriateness Measure) of the KeepCalm app, as outlined in the *Measures* section.

We will also examine usability, acceptability, feasibility, and appropriateness through a qualitative interview and examine barriers to and facilitators of using the KeepCalm app in classrooms with students on the autism spectrum. Audio recordings of the interviews will be transcribed, and all transcripts will be loaded into Dedoose for data management and analysis. Thematic analysis will be guided by an integrated approach that includes identification of a priori attributes of interest (usability, acceptability, feasibility, and appropriateness). This integrated approach uses an inductive process of iterative coding to identify recurrent themes, categories, and relationships in qualitative data. After exploring the data, a comprehensive coding scheme will be developed and applied to produce a descriptive analysis. A team of coders will separately code the transcripts and compare the results to assess the reliability of the coding scheme. Any disagreements in coding will be resolved by team consensus. After the coding scheme is finalized, coders will be required to code 2 transcripts in a row at a high level of agreement with the lead coder (k>0.70) before independent coding of the rest of the transcripts. Following this, the lead coder will code 20% of the transcripts in duplicate for the reporting of interrater reliability.

Quantitative and qualitative data about usability, acceptability, feasibility, and appropriateness will be integrated by examining the qualitative data from the participants who responded in the lowest versus highest quartile on the quantitative measures of each construct. Data analysis will inform our understanding of the usability, acceptability, feasibility, and appropriateness of the KeepCalm app and will provide a list of feature updates to be included in the app before the following fully powered randomized controlled trial.

Secondary Outcomes

To examine technical reliability, we will use descriptive statistics of artifact removal success and offline mode activations. To examine proximal preliminary efficacy, we will use descriptive statistics of clinical decision support success rates and false positive and negative rates. To examine distal preliminary efficacy, we will also conduct a preliminary examination of the efficacy of KeepCalm on challenging behavior (SSQ and IBR-MOAS) and emotion dysregulation (EDI) using an exploratory (underpowered) repeated measures ANOVA to assess the 2 groups (waitlist and treatment) at baseline and posttrial periods. Given the sample size, this analysis will be underpowered.

Power

For the study's pilot randomized controlled trial, the analyses will focus on feasibility, usability, and implementation (descriptive) data but will include some preliminary efficacy inferential analyses. In this study, 50% (10/20) of the teams will be randomized to the treatment condition and 50% (10/20) of the teams will be randomized to the waitlist control condition. The sample size was not based on power analysis but rather a need to obtain pilot data that will support an app for a fully powered trial.

Results

We anticipate that recruitment for the randomized controlled trial will begin in September 2023. The analysis of data will begin following the trial, which we expect to be completed in the second half of 2024. We expect to publish the results of the trial in 2025.

Discussion

In this paper, we described the protocol of an innovative pilot randomized waitlist-controlled field trial to investigate the usability, acceptability, feasibility, and preliminary efficacy of an app to detect and manage challenging behaviors in children on the autism spectrum. We aim to address current barriers that limit the use of emotion regulation strategies with children on the autism spectrum by developing this evidence-based strategy implementation tool based on objective, physiological measurements. This study offers several innovations to be tested. First, it tests an app that integrates physiological stress monitoring, to track children's internal stress that is less observable, with real-time intervention suggestions. Second, the intervention suggestions provided by the app are individualized to each child. It reminds teachers about child-specific emotion regulation strategies and provides in-app resources about evidence-based strategies to help parents and teachers learn strategies that may be more effective to use with the child. Finally, the app will analyze which strategies work best for each individual child based on physiological stress reduction data, teacher's ratings of strategy effectiveness, and child's behavioral data.

The mHealth KeepCalm app is an app designed to target challenging behaviors in children on the autism spectrum using biosensing technology. The main limitation we anticipate facing in this trial is that, owing to the small sample size of only 20 teams, we will lack sufficient power to determine the efficacy of the app in preventing and reducing challenging behaviors. However, this trial will be aimed at gathering usability, acceptability, feasibility, and appropriateness data and information about barriers and facilitators to prepare for a large randomized controlled trial to gather data about effectiveness, which will be conducted later.

We are not aware of any other digital health app for children on the autism spectrum that uses physiological biosensing to monitor physiological arousal and support the implementation

XSL•FO
RenderX

of evidence-based practices for children on the autism spectrum. Although there are many other types of technological innovations to support individuals on the autism spectrum and despite the range of digital mental health apps that are commercially available, there is little evidence about their efficacy [74]. However, as mentioned previously, >95% of them have not actually been studied, and there is a lack of studies in this field regarding efficacy, especially relative to studies of web-based mental health programs [44,45].

Current implementation of strategies to manage challenging behaviors or emotion dysregulation by school teams is limited by difficulties in detecting rising stress levels in children on the autism spectrum who struggle to communicate their emotions, chaotic and stressful classroom environments that make it difficult to recall the best emotion regulation strategies per student, and difficulty in tracking the effectiveness of these strategies for ongoing program refinement. The mHealth KeepCalm app seeks to address these barriers with new biosensing technology and takes a personalized medicine approach to reduce the impact of significant challenging behaviors in children on the autism spectrum.

Acknowledgments

Funding for this study was provided by the National Institute of Mental Health (grant K01-MH12050; principal investigator: HJN). The National Institute of Mental Health had no role in the study design; collection, analysis, or interpretation of the data; writing of the manuscript; or decision to submit the paper for publication. We appreciate the detailed feedback on our funded grant application given by National Institute of Mental Health reviewers (Multimedia Appendix 1).

Data Availability

Data sharing is not applicable to this paper, as no trial data sets have been generated or analyzed at this time. Data that will be collected in the trial described in this paper, which will be published in a future manuscript, will adhere to the established rules set forth by the National Institutes of Health for public sharing of data.

Conflicts of Interest

HJN consults with 2 digital health companies, Songbird Therapy and Pletly. CAM receives royalties from Oxford University Press and is on the scientific advisory board for the Brain and Behavior Foundation. JCM consults with Customer Value Partners, Bridgebio, Determined Health, and BlackThorn Therapeutics; has received research funding from Janssen Research and Development; serves on the Scientific Advisory Boards of Pastorus and Modern Clinics; and receives royalties from Guilford Press, Lambert, and Springer. RSB is the principal at Implementation Science & Practice, LLC. She receives royalties from Oxford University Press and consulting fees from United Behavioral Health and OptumLabs and serves on the advisory boards for Optum Behavioral Health, AIM Youth Mental Health Foundation, and the Klingenstein Third Generation Foundation. All are outside the scope of the submitted work. All other authors have no conflicts of interest to declare.

Abstract

Background: For many older Americans, aging in place is their preferred living arrangement. Minoritized and socioeconomically disadvantaged older adults are up to 3 times more likely to experience disability than other groups, which increases their likelihood of being unable to age in place. Bold ideas to facilitate aging in place, particularly among vulnerable populations, are needed. One such idea is the Unite care model, a community-initiated, academic-supported, cross-sector initiative that combines 2 sectors: housing and health care. The Unite care model colocates a federally qualified health center clinic on an older adult affordable housing campus in Flint, Michigan.

Objective: There are two aims to this study. Aim 1 is to evaluate the implementation of the Unite care model in terms of acceptability, adoption, and penetration. Aim 2 is to determine which older adults use the care model and whether the care model promotes aging in place through risk factor reduction and improvement in the physical and social environment.

Methods: We will assess the care model using a concurrent, exploratory mixed methods design. For aim 1, acceptability will be assessed through semistructured interviews with key stakeholder groups; adoption and penetration will be assessed using housing and health care records. For aim 2, residents residing in the Unite clinic building will participate in structured outcome assessments at 6 and 12 months. Risk factor reduction will be measured by change in systolic blood pressure from baseline to 12 months and change in the physical and social environment (item counts) will also be assessed from baseline to 12 months.

XSL•FO
RenderX

Results: Data collection for aim 1 began in July 2021 and is anticipated to end in April 2023. Data collection for aim 2 began in June 2021 and concluded in November 2022. Data analysis for aim 1 is anticipated to begin in the summer of 2023 and analysis for aim 2 will begin in the spring of 2023.

Conclusions: If successful, the Unite care model could serve as a new care model to promote aging in place among older adults living in poverty and older Black Americans. The results of this proposal will inform whether larger scale testing of this new model of care is warranted.

KEYWORDS

aging in place; stroke prevention; hypertension; blood pressure; social determinants of health; affordable housing; older adults; community-based participatory research; implementation evaluation

Introduction

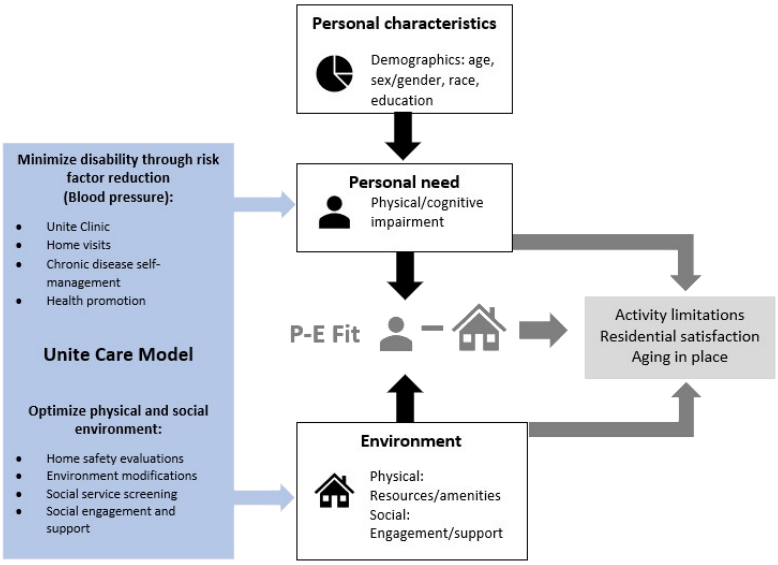
Background

Aging in place, defined as the ability to stay in one's current residence by securing necessary support in response to evolving needs, is overwhelmingly preferred among older adults [1-3]. Aging in place also provides health benefits for older adults [4], via sustaining established social networks and care services [5,6]. Furthermore, aging in place is overwhelmingly favored by policy makers because it may delay or avoid the costly option of institutional care; 1 year of nursing home care costs about US $80,000 [7]. For many older Americans, aging in place is their only option as assisted living facilities require significant out-of-pocket spending. Thus, strategies to support aging in place are critical, particularly among low-income Americans.

Disability is the strongest predictor of nursing home admissions [8]. Over 25% of older adults experience activity limitations and cognitive impairment [9-11]. Disability disproportionately impacts Black people and low-income Americans and negatively impacts aging in place. Minority and socioeconomically disadvantaged older adult populations are up to 3 times more likely than other groups to experience disability [12-14]. Furthermore, Black people have the highest incidence of Alzheimer disease and Alzheimer disease–related dementias (AD/ADRDs) with a 2-fold greater incidence compared with White people [15-19].

Efforts to reduce disability and optimize the environment may help facilitate aging in place. Hypertension is the most important modifiable cardiovascular risk factor [20-24] and a predictor of nursing home admission [8]. Hypertension treatment reduces the incidence of stroke [25] and may reduce the incidence of AD/ADRDs [26], which are the leading causes of disability and strongest predictors for not aging in place [27-29]. Therefore, hypertension treatment, complemented by physical and social environment optimization, may promote aging in place by reducing informal caregiving needs, unmet needs, falls, and disability [30-33].

Unite Care Model



The Unite care model is a community-initiated and led, academically supported, cross-sector initiative that combines housing and health care to promote aging in place by addressing personal needs and optimizing the physical and social environment. The Unite care model includes a federally qualified health center clinic on an older adult affordable housing campus in Flint, Michigan, home to over 700 predominately Black older adults. The Unite clinic is located within the largest older adult congregate housing building, home to about 300 older adults.

The Unite care model is comprised of 3 components: Colocation of a federally qualified health center clinic on the affordable housing campus, home medical visits, and community health worker–supported care. The Unite care model will promote aging in place by optimizing (1) medical care including onsite clinic and home visits; (2) the social environment through clinic referrals for home safety evaluations and facilitating environmental modifications; and (3) the social environment by community health worker–led social engagement and support. Figure 1 depicts this care model. Overall, the Unite care model flips the paradigm that asks the most vulnerable older adults to seek out the medical safety net. Instead, the Unite care model will bring the safety net to older adults to support aging in place.

The Unite care model builds on Community Aging in Place—Advancing Better Living for Elders (CAPABLE), a randomized trial of home occupational therapy and nursing sessions, and home repairs to reduce disability and promote aging in place through physical environmental optimization compared to controls. The CAPABLE group experienced a 30% (4.00 to 2.22) decrease in disability scores compared to controls at 5 months but was not sustained at 1 year [34]. Booster visits, social service screening, and community health worker support were identified by the research team and other researchers as mechanisms that could improve sustainability [34,35]. The Unite care model builds on the CAPABLE trial by expanding the intervention to provide medical care to reduce disability risk factors and community health workers to optimize the social environment.

Figure 1. Unite care model.

Aims and Objectives

This study will evaluate the Unite care model through 2 aims.

- Aim 1: To assess the implementation and impact of the Unite care model in terms of acceptability, adoption, and penetration among key stakeholder groups using an exploratory mixed methods design
- Aim 2: To determine which older adult residents who reside in the Unite clinic building use the Unite care model and whether the model promotes aging in place through cardiovascular risk factor reduction and improvement in the physical and social environment

Methods

Study Design

A concurrent exploratory mixed methods approach will be used to evaluate the implementation of the Unite care model.

Ethics Approval

This study is approved by the University of Michigan Institutional Review Board (HUM00197049).

Study Setting

Flint, Michigan is a community with a large burden of chronic disease and poverty. Flint is recovering from the water crisis, where the city's drinking water was contaminated with excessive levels of lead for over 18 months. Flint has a population of about 80,000, 57% of which are Black; 40% live in poverty and is ranked 80 out of 83 Michigan counties on Robert Wood Johnson Foundation County Health Rankings [36].

The Unite care model takes place at a heavily charity-subsidized older adult (55 years and older) affordable apartment complex in Flint, Michigan. The apartment complex is situated within a broader, informal, older adult housing campus. Within a 3-square mile radius of the apartment complex, an estimated 700 independently living older adults reside at a public housing apartment building, a US Department of Housing and Urban Development senior living building, and single-family homes. About 75% of the older adults are Black, many earning less than US $12,000 annually.

Aim 1: Assessing the Implementation and Impact of the Unite Care Model

Overview

We will determine how much and for whom (ie, adoption and penetration) and how well (ie, acceptability) the Unite care model is implemented. These implementation outcomes are necessary preconditions to understand the effectiveness of the Unite care model [37].

Acceptability

To measure the acceptability of the Unite care model, stakeholders from three different groups: (1) housing and health care administrators, (2) providers, and (3) older adult residents will be recruited to participate in semistructured interviews based on the theoretical framework of acceptability [38], theoretical domains framework, and Proctor's definition of acceptability [37]. Interview guide questions will explore constructs including affective attitude, burden, perceived effectiveness, ethicality, intervention coherence, opportunity costs, and self-efficacy. Interview guides will be tailored to each population, given acceptability is distinct among those who received the care model compared to those who deliver the care model [38]. Sample interview guide questions for each group are shown in Table 1.

Housing and health care administrators (n=9) will be interviewed at the time of the clinic opening (baseline) and again at 18 months. Snowball sampling will be used to identify all key administrators. Providers (n=5) will be interviewed at 12 months and will include Unite clinic staff (nurse practitioner and medical assistant) and housing employees who provide wraparound services to residents (resident wellness director, resident service coordinator, and community health worker). Older adult residents (n=36) will also be interviewed at 12 months. Older adult positive and negative opinion leaders will be purposely sampled across three subgroups: (1) older adult residents who use the clinic (n=12), (2) older adult residents who have

XSL•FO
RenderX

attempted to use the clinic (n=12), and (3) older adult residents who do not use the clinic (n=12). We will identify older adults pertaining to each subgroup based on structured survey responses (aim 2) and notes kept by the research team. Interviews will be conducted in person as possible at a location convenient to the participant, with the alternative of video or telephone calls given the individual's availability, preference, and COVID-19 restrictions. Participants will receive US $40.

Semistructured interviews will be audio recorded, professionally transcribed, and reviewed by the research team for accuracy. We will use ATLAS.ti (ATLAS.ti Scientific Software Development GmbH), a qualitative data analysis and research software, to facilitate qualitative analysis. We will perform direct content analysis using the theoretical framework of acceptability and theoretical domains framework as a template. Two members of the research team will independently code each transcript, compare their coding, discuss discrepancies, and agree on final codes. Several strategies will be used to enhance the reliability and validity of the analysis including member checks, peer debriefing, and concurrent data collection and analysis described below.

Table 1. Overview of aim 1 interviews.

Population	Participants, n	Timeline	Sample questions
Housing and health care administrators	9	• Baseline (clinic opening) • 18 months	• Now, as the Unite clinic is about to open, how are you feeling about participating in this project? (affective attitude) • How has the clinic impacted your daily workload? (burden and barriers)
Providers	5	• 12 months	• How are things going at the clinic? (positive and negative affect) • What do residents say about the clinic? (social norms)
Older adults	36	• 12 months	• How do you feel about the clinic? or What do your friends think about the clinic? (positive/negative affect) • What do you think would happen if you went to the clinic? (outcome expectations)

Adoption

Adoption, defined as the Unite care model uptake by older adult residents, will be quantified by the number of provider home visits and community health worker or resident service coordinator interactions. The number of home visits will be self-reported. Community health worker or residence service coordinator interactions will be sampled daily for 1 week per month via a Qualtrics survey completed by the community health worker. The survey will assess the number of residents served that day as well as the services provided to each resident.

Penetration

Penetration is defined as the proportion of people who participate in a given program. We will explore the role of clinic proximity as a predictor of Unite care model usage. The research team will obtain data from the Unite clinic electronic health record, including patient-level data (addresses, demographics, and comorbidities). Patient addresses will be geocoded using Google's interface to identify if the patient resides on the older adult affordable housing campus and specifically in the Unite clinic building.

The primary outcome is the proportion of older adults who reside on the older adult affordable housing campus who are cared for by the Unite clinic. The research team will make 2 types of comparisons between older adults who reside in the Unite clinic building compared to older adults who reside on the campus but not in the Unite clinic building. First, for measures that can only be defined in aggregate (ie, number of new patient visits), the research team will compare mean per-patient usage measures between populations. Specifically, we will compare the mean of each usage variable divided by the number of patients living in each setting using *t* tests and the proportion of new and return visits using chi-square tests across settings. Second, for measures where individual-level data can define the population at risk (number of missed appointments and appointment timeliness), we will fit appropriate regression models to predict the usage measures (dependent variable) accounting for residence (Unite clinic building vs other older adult campus) and demographics known to predict missed appointments (age, race, and sex), comorbidities and dual eligibility (independent variables).

Integration of Qualitative and Quantitative

The qualitative (acceptability) and quantitative data (adoption and penetration) will be collected and analyzed during the same time. Integration will merge the qualitative and quantitative data after their respective analyses are complete [39]. We will merge the data through narrative integration, whereby the qualitative results are presented followed by the quantitative results and jointly displayed in a table. Conceptually, the research team believes that the Unite care model must be found to be acceptable by stakeholders as a precursor to adoption and penetration. Thus, the qualitative data will be presented first. The research team will also assess the concordance of the data integration. If discordance is identified, additional data may be gathered.

XSL•FO
RenderX

Aim 2: Determining Which Older Adults Residing in the Unite Clinic Building Use the Unite Care Model and Whether the Model Promotes Aging in Place

Overview

We seek to understand the usage of the Unite care model and to assess the impact of the components of the person-environment fit model, hypertension as a predictor of disability, and the environment. This is a prospective observational study with baseline, during, and post-Unite care model initiation assessments.

Study Population Recruitment and Enrollment

Residents of the Unite clinic building (n=300) will be recruited to complete in person, prospective observational assessments in which they will be asked structured interview questions and have their blood pressure taken. Residents will be recruited from building central locations, including community and recreation rooms, in addition to fliers, word-of-mouth, and door-to-door knocking. Recruitment will continue until all residents have been contacted and provided the opportunity to consent or decline. The housing staff will aid the research team in contacting hard-to-reach residents. Residents who do not respond to the research team and housing staff after multiple contact attempts will be considered a decline. We will use our ongoing successful retention strategies, which include maintenance of contact and obtaining alternate contact information, including those of family members, in the event of change in contact information. The assessments will take place in a private space in the Unite clinic building. Participants will be given US $20 at baseline and US $25 for each outcome assessment.

Baseline assessments will begin at the time of the Unite clinic opening, with 6- and 12-month outcome assessments. The assessments will measure resident cognition, activity limitations [40-42], blood pressure, Unite clinic usage, physical [43] and social environment [44], health-related social needs [45], and housing transition information. Blood pressure will be measured by research staff using the OMRON 7 series upper arm blood pressure monitor (OMRON Healthcare, Inc) in accordance with national standards for measurement. Housing status transition will be obtained from the Unite clinic building records including 2 years prior to the start of the Unite care model. Participant responses and blood pressure measurements will be stored in a Research Electronic Data Capture database (Vanderbilt University). Table 2 depicts which measures are assessed at each outcome assessment.

Table 2. Comparison of aim 2 measures by outcome assessment.

	Baseline	6 months	12 months
Sociodemographics	✓		
Comorbidities	✓		
Self-rated health	✓		✓
Activity limitations	✓		
Cognitive impairment	✓		
Unite care model usage		✓	✓
Blood pressure measurement	✓	✓	✓
Physical environment	✓		✓
Social environment	✓		✓
Housing status	✓	✓	✓

Data Analysis

The primary analysis is the change in systolic blood pressure (SBP) from baseline to 12 months. Meta-analyses have found that for a given blood pressure, SBP predicted over 90% of the risk of ischemic heart disease and stroke and that a 2 mm Hg decrease in SBP could reduce stroke and ischemic heart disease mortality [46]. Analysis will fit a linear regression model with the outcome of 12-month SBP, including baseline SBP and a binary predictor of Unite care model patient (yes vs no) as independent variables.

Other secondary analysis end points will include determining whether functional and cognitive limitations are associated with care model usage, change in physical and social environment, and moves out of the Unite clinic building. To determine if functional and cognitive limitations, including activity limitations and AD/ADRD are associated with Unite care model usage, the research team will build a logistic regression model predicting Unite utilization, including age, sex, race, ethnicity, AD/ADRD status, level of functional disability, self-reported health, and baseline hypertension as independent variables. Change in physical and social environment (item counts) will be assessed using a Poisson regression with an outcome of 12-month values, adjusting for baseline values and including an intervention indicator. Moves out of the clinic building will be assessed by comparing moves out of the building in the 2 years prior to the Unite care model compared to year 2 of the Unite care model.

Of the 300 older adults residing in the Unite building, we estimate that 5% will elect not to enroll, resulting in a study population of 285 older adults. We estimate that we will have 89% power to detect a 2-point change in SBP within older adults assuming a mean baseline SBP of 162 mm Hg and SE of change in SBP over time of 10 mm Hg, based on prior data in this

XSL•FO
RenderX

community and community studies [47,48], and a 10% loss to follow-up using an analogous test to our primary analysis. If loss to follow-up increases to 20%, power to detect a 2-point change in SBP would decrease to 85%. The effect may be larger. We will have 100% power to detect a 4-point SBP change if loss to follow-up were 20%.

Overall Assessment of Unite Care Model

After executing these aims, true to our community-engaged approach, our advisory board comprised of older adults, Unite partners (housing and health care), insurance, and local government stakeholders will review the results. Our evaluation of the care model will be holistic and require considerable judgment as no single metric nor combination of metrics is likely to capture the complexities of the initial Unite experience. The panel will then judge whether the Unite care model is sufficiently promising to justify efforts to develop similar models of care.

Results

This study was funded by the National Institutes of Health-National Institutes on Aging in April 2021 and received institutional review board approval from the University of Michigan in May 2021. Semistructured interviews for aim 1 began in July 2021 and are anticipated to end in April 2023, with an anticipated total 45 stakeholders, including administrators, providers, and older adult residents. Structured interviews for aim 2 began in June 2021 and ended in November 2022. For aim 2, at baseline, 265 residents were approached, of which 179 residents enrolled. In total, 149 residents completed 6-month outcomes and 131 residents completed the final 12-month outcome. Data analysis for aim 1 is anticipated to begin in summer 2023; analysis for aim 2 will begin in spring 2023.

Discussion

Anticipated Findings

We anticipate the following outcomes: (1) among older adults residing in the Unite clinic building, those with functional and cognitive limitations (ie, activity limitations, AD/ADRD) will be more likely to use the Unite care model than those without limitations; (2) among older adults residing in the Unite clinic building, those who receive care through the Unite care model will have reduced SBP compared to those who do not receive care through the Unite care model; and (3) Among older adults residing in the Unite clinic building, those who receive care through the Unite care model will have an increase in physical environment modifications and a decrease in social isolation compared to those who do not receive care through the care model.

Strengths and Limitations

The evaluation of the Unite care model is at the intersection of community engagement and implementation science. The Unite care model is a community-led and community-implemented intervention where the academic partners are supporting the initiative by conducting the analysis. Cross-sector collaborations such as Unite where housing and health care are partnering is 1 approach to addressing adverse social determinants of health. Often, investment in 1 sector accrues benefits in another sector while increasing the costs and resource usage in the investing sector [49-51]. In this case, the Unite care model is initiated and led by both housing and health care stakeholders, a cross-sector partnership promoting a shared assessment of value [52]. Multilevel interventions, such as the Unite care model, may interact to create synergistic effects, but rigorous assessments are rarely completed [53,54]. Our robust, holistic assessment of the Unite care model will inform whether larger scale testing of this new care model is warranted.

Potential challenges include recruitment and retention of participants in aim 2. We will employ our long-standing community recruitment and retention practices to reduce this barrier. Another potential pitfall lies in the study duration. The 2-year study timeframe may not be long enough to accrue outcomes of interest including aging in place and change in physical and cognitive impairment. Long-term follow-up of the Unite population could occur in subsequent research.

Conclusions

Understanding the impact of combining older adult housing and health care will inform future cross-sector collaborations. Additionally, overlaying an implementation science-centered evaluation on a community-led initiative is an example of how academic teams can fully support their community partners.

Conflicts of Interest

None declared.

Abstract

Background: Older adults struggle to maintain newly initiated levels of physical activity (PA) or sedentary behavior (SB) and often regress to baseline levels over time. This is partly because health behavior theories that inform interventions rarely address how the changing contexts of daily life influence the processes regulating PA and SB or how those processes differ across the behavior change continuum. Few studies have focused on motivational processes that regulate the dynamic nature of PA and SB adoption and maintenance on microtimescales (ie, across minutes, hours, or days).

Objective: The overarching goal of Project Studying Maintenance and Adoption in Real Time (SMART) is to determine the motivational processes that regulate behavioral adoption versus maintenance over microtimescales, using a *dual process framework* combined with ecological momentary assessment and sensor-based monitoring of behavior. This paper describes the recruitment, enrollment, data collection, and analytics protocols for Project SMART.

Methods: In Project SMART, older adults engaging in at least 30 minutes of moderate-to-vigorous intensity PA per week complete 3 data collection periods over 1 year, with each data collection period lasting 14 days. Across each data collection period, participants wear an ActiGraph GT3X accelerometer (ActiGraph, LLC) on their nondominant waist and an ActivPAL micro4 accelerometer (PAL Technologies, Ltd) on their anterior thigh to measure PA and SB, respectively. Ecological momentary assessment questionnaires are randomly delivered via smartphone 10 times per day on 4 selected days in each data collection period and assess reflective processes (eg, evaluating one's efficacy and exerting self-control) and reactive processes (eg, contextual cues) within the dual process framework. At the beginning and end of each data collection period, participants complete a computer-based questionnaire to learn more about their typical motivation for PA and SB, physical and mental health, and life events over the course of the study.

Results: Recruitment and enrollment began in January 2021; enrollment in the first data collection period was completed by February 2022; and all participants completed their second and third data collection by July 2022 and December 2022, respectively. Data were collected from 202 older adults during the first data collection period, with approximate retention rates of 90.1% (n=182) during the second data collection period and 88.1% (n=178) during the third data collection period. Multilevel models and mixed-effects location scale modeling will be used to evaluate the study aims.

Conclusions: Project SMART seeks to predict and model the adoption and maintenance of optimal levels of PA and SB among older adults. In turn, this will inform the future delivery of personalized intervention content under conditions where the content will be most effective to promote sustained behavior change among older adults.

Introduction

Background

By 2035, the number of older adults is expected to outnumber children for the first time in the United States [1]. As our society ages, strategies are needed to promote the health and well-being among older adults. Physical activity (PA) offers many physical and mental health benefits [2], yet adults aged ≥60 years are the least active and most sedentary segment of the population [3,4]. Accelerometer-derived data suggest that the average older adult engages in no more than 10 minutes of moderate-to-vigorous intensity PA per day [5]. In addition, most older adults spend 60% to 85% of their waking hours (approximately 9.4 hours each day) engaged in sedentary behavior (SB) [6]. Although short-term interventions have increased PA or decreased SB, individuals often struggle to sustain new behavior patterns in the long term [7,8]. The fact that interventions often fail to have enduring effects on long-term behavior change represents a substantial challenge to health promotion in older adulthood.

Limitations of Contemporary Theoretical Frameworks

The lack of sustained intervention effectiveness is partly because health behavior theories that inform interventions rarely address how the changing contexts of daily life influence the processes regulating PA and SB or how those processes differ across the behavioral sequence from adoption to maintenance [9]. These are necessary considerations because (1) PA and SB occur within and across days, with optimal levels of these behaviors ideally maintained across the life span, and (2) these behaviors are partly driven by temporal and situational cues such as location, social context, and affective states that rapidly change over time [10]. Moreover, there is a growing body of research that suggests that different pathways guide behavior adoption and maintenance [11-13]. Thus, there is a critical gap in understanding the factors that drive adoption versus maintenance within the context of PA and SB as dynamic, time-varying behaviors. Understanding microtemporal factors (ie, factors that unfold over minutes, hours, and days) within everyday life and how the temporal dynamics of motivational processes contribute to health behavior adoption and maintenance is essential for developing effective behavioral interventions [14].

Dual Process Models

Dual process models represent a viable framework for investigating microtemporal processes regulating behavioral adoption and maintenance. These models categorize behavioral determinants as either *reflective processes* (intentional, deliberative, slow, and effortful) or *reactive processes* (nonconscious, automatic, fast, and effortless) [15-17]. Reflective processes encompass motivational factors central to many contemporary health behavior theories (eg, attitudes toward a behavior, confidence to perform a behavior, and self-monitoring of goals) [18]. Reflective processes often rely on self-regulation (eg, regulating emotions, coping with stress, managing demands, or exerting self-control) to override a dominant, unwanted behavioral response and translate intentions into goal-directed behavior [19]. Reactive processes represent automatic associations spontaneously activated by stimuli within one's environment (eg, physical location, surrounding people, and affective state) [20,21].

To adopt a new behavior, a person would likely need controlled effort; willpower and ultimately, a conscious decision to replace the habitual, undesired behavior in a given context. The deliberative overriding of cues and the undesired habitual response would require considerable self-control resources and self-regulatory skills [22,23]. Therefore, strong reflective processes are needed when adopting a new behavior [24-26]. However, once a behavior is well learned and automatic, reactive processes likely dominate the motivations underlying the behavior [27,28], thus promoting behavioral efficiency and making long-term continued behavioral engagement more likely [29,30]. Strong reactive processes are likely needed to maintain engagement in a behavior [11,12].

Studying Maintenance and Adoption in Real Time

To address existing knowledge gaps, Project Studying Maintenance and Adoption in Real Time (SMART) was designed to test a dual process model mapping the microtemporal mechanisms regulating PA and SB along the continuum from adoption to maintenance in older adults. To accomplish the overall objective, ecological momentary assessment (EMA) methodology and sensor-based monitoring of behavior will be used to intensively capture motivation and behavior over microtimescales and to examine differences in the microtemporal processes underlying the adoption and maintenance of older adults' PA and SB. Specific research questions to be addressed in this study include the following:

1. To what extent do momentary reflective and reactive motivational processes differentially predict subsequent PA and SB among behavioral adopters and maintainers?
2. To what extent do subject-level patterns in reflective and reactive motivational processes predict behavioral adoption versus maintenance at each wave and across the entire year?
3. How do reflective and reactive motivational processes and behavioral patterns predict change in adopter or maintainer status from wave to wave?

The purpose of this paper is to present the protocol for Project SMART.

Methods

Project Overview

Project SMART is a measurement burst design of physically active older adults living in Guilford County, North Carolina. Participants complete three 14-day data collection periods spaced out over the course of 1 year. For the duration of each data collection period, waist-worn and thigh-worn accelerometers measure participants' PA and SB, respectively. In addition, on days 9 to 12 of each data collection period, participants complete an EMA protocol in which they use a loaned smartphone to answer 10 brief questionnaires per day assessing current behavior, context, feeling states, demands, and motivation to engage in PA and limit SB over the next hour. Figure 1 provides an overview of the study's design and procedures. Project SMART began enrolling participants in January 2021.

Figure 1. Overview of the study design. EMA: ecological momentary assessment.

Target Population and Eligibility

We aimed to enroll 200 older adults who are aged >60 years; living in Guilford County, North Carolina; and currently engage in ≥30 minutes of moderate-to-vigorous intensity PA. Within that sample, we aimed to have approximately 50% (100/200) of older adults classified as PA adopters and 50% (100/200) of older adults classified as PA maintainers through initial and back-end classification (details about the classification are provided in the following sections). We chose minimum levels of PA as the inclusion criteria for behavioral adopters and maintainers rather than levels of SB, because of the relatively high volume and normal distribution of SB in older adults [3,6]. By prioritizing PA adopters and maintainers, we can ensure adequate group numbers, given the frequent low levels of PA among older adults. Adopter or maintainer status classification is repeated at each wave. Exclusion criteria for all participants are the following: (1) unable to speak or read English fluently, (2) functional limitations that prevent older adults from standing or walking on their own for at least 10 consecutive minutes, (3) unable to use a smartphone's basic functions, (4) unable to hear the auditory signal on the study smartphone, (5) planning to move outside of Guilford County within the next year, or (6) a score indicating impaired cognitive status on a consolidated mental status screener [31].

Sample Size, Recruitment, and Retention

Sample estimation was performed using Monte Carlo simulations [32], with the expected parameter values derived from aim 1 and aim 2 models fit using our preliminary data (39 participants; 10 observations/day; 4 days). Although missing data in EMA studies of older adults are typically low (ie, almost 90% of EMA studies in older adults achieve compliance of ≥80%) and our preliminary data showed a 96% EMA compliance rate, we conducted simulations using varying patterns of missingness (0%-30%) at varying likelihoods (5%-80%). If missingness occurs at the highest anticipated limits—70 participants per behavioral status group, providing 5 to 7 observations per day over 4 days—we would still obtain 20 to 28 observations per person at each wave. For the study, α was set at .05, and minimum acceptable power was set to 0.80. Given a maximum sample size of 200 participants per model (with simulation sample sizes ranging from 140-200 participants), we achieved power >0.90 for each outcome. To account for possible attrition of up to 30% in both the PA adopter and maintainer groups, we aimed to recruit 100 PA adopters and 100 PA maintainers.

Recruitment efforts targeted fitness centers and older adult programming available within Guildford County, North Carolina. A recruitment method was the electronic distribution of a brief study description with links to videos posted on

XSL•FO
RenderX

YouTube that further explained the study, showed the necessary study equipment, and addressed frequently asked questions through cooperating organizations' listserves. The second major recruitment method was making in-person announcements at exercise classes geared toward individuals aged ≥60 years. In addition, recruitment efforts were conducted through local media coverage of the study and word of mouth. Depending on the recruitment method, participants' contact information was collected (eg, in-person announcements) or study contact information was provided to individuals.

Owing to the longitudinal nature of this study, retention plans were developed, including (1) obtaining phone numbers, email addresses, and home and mailing addresses of participants and up to 3 other individuals (in case we are unable to reach the participant); (2) scheduling participants for their next data collection period during the current data collection period and providing an appointment reminder card or email after scheduling; (3) sending birthday postcards to participants; and (4) sending study newsletters at 4-month intervals, which are customized to each participant to remind them about their next scheduled data collection period.

Procedures

Interested individuals complete a telephone screening with a research staff member to determine eligibility. Eligible individuals receive additional details about the study and are able to ask any questions to a research staff member. Participants are then scheduled to attend an introductory session. A week before an introductory session, participants receive a link to a questionnaire via email to provide electronic consent for the study and complete a baseline assessment of their motivation for PA and SB, self-reported levels of PA and SB, and demographic and contact information. Participants are asked to complete the baseline assessment before their introductory session.

An introductory session is conducted on day 1. Introductory sessions are conducted every 3 weeks, and as a result, participants are scheduled on a rolling basis. A research staff member meets with individual participants (or participants from the same household) in person on campus, at a community location, or via Zoom (Zoom Video Communications), depending on the participant's preference. Participants meeting via Zoom receive study equipment in person at a community location, or study equipment is delivered to their home. During the introductory session, the research staff member reviews the consent document with the participant and answers any questions. Then, participants are familiarized with the study procedures and trained on 2 accelerometers to be worn for the next 14 days. Accelerometers include an ActiGraph GT3X-BT accelerometer to be worn on their nondominant waist during all waking hours (except when swimming or bathing) to provide a device-based measure of PA and an ActivPAL3 micromonitor to be worn on their thigh during all sleeping and waking hours to provide a device-based measure of SB. Participants begin wearing the activity monitors at the introductory session. Participants are given a sleep and wake time log and an activity monitor log to complete over the 14-day study period. On the sleep and wake time log, participants indicate for each day the time they got out of bed to start their day (ie, wake time) and the time they began trying to fall asleep at the end of the day (ie, sleep time). On the activity monitor log, participants report any waking times during which they were not wearing their activity monitor and a brief explanation of the reason. These logs will be used to validate activity monitor nonwear algorithms.

A week later, on day 8, a research staff member meets the participant or participants again (in person or via Zoom) to train them on how to use a smartphone preloaded with a commercially available, app, MovisensXS, on which they answer brief EMA questionnaires. To ensure that the MovisensXS app is functioning as intended, all participants are loaned a Motorola Moto G Power mobile phone, a compatible device for the MovisensXS app. Participants receive a practice questionnaire at 7:30 PM that same evening to practice accessing the questionnaire and familiarizing themselves with the questions and response formats. The practice questionnaire will not be included in the analytic data set.

On days 9 to 12, participants receive prompts to complete the EMA questionnaire 10 times per day as part of the study procedures. Participants select 1 of 3 EMA prompting schedules for the data collection period based on their self-reported usual wake time. Available EMA prompting schedules deliver questionnaires between 7 AM and 9 PM, between 8 AM and 10 PM, or between 9 AM and 11 PM. Across all prompting schedules, the day is divided into intervals of 1 hour and 25 minutes. Participants receive 1 EMA prompt randomly during each interval. There is an imposed minimum 30-minute buffer period between the random EMA prompts. Participants are alerted to the EMA prompt via an auditory signal. Participants can adjust the mobile phone volume but are encouraged, when able, to have the mobile phone volume turned up to maximum. Upon hearing a prompt, participants are asked to complete a brief EMA questionnaire on the mobile phone. If no entry is made, the app emits up to 3 reminder signals at 5-minute intervals. If a signal occurs during an incompatible activity (eg, driving or sleeping), participants are instructed to ignore it or complete that activity before answering. Each EMA questionnaire contains 20 items and is expected to take 2 to 3 minutes to complete (refer to the *EMAMeasures* section for details). Upon going to bed on day 12, participants will have completed the EMA protocol but continue to wear their activity monitors until waking on day 15.

On day 15, participants return their equipment at an in-person appointment or mail the equipment back to the research team using a prepaid United Parcel Service envelope provided to them. Participants also complete a post–data collection period questionnaire, which assesses life events, affective experiences during movement behaviors, behavior over the data collection period, and feedback about the data collection period.

Study procedures are identical for each data collection period, except that, at the second and third data collection periods, participants are given the option to complete a 1-hour, condensed training session reviewing both the activity monitors and smartphone on day 1 as opposed to 2 separate 1-hour training sessions spaced through the data collection period.

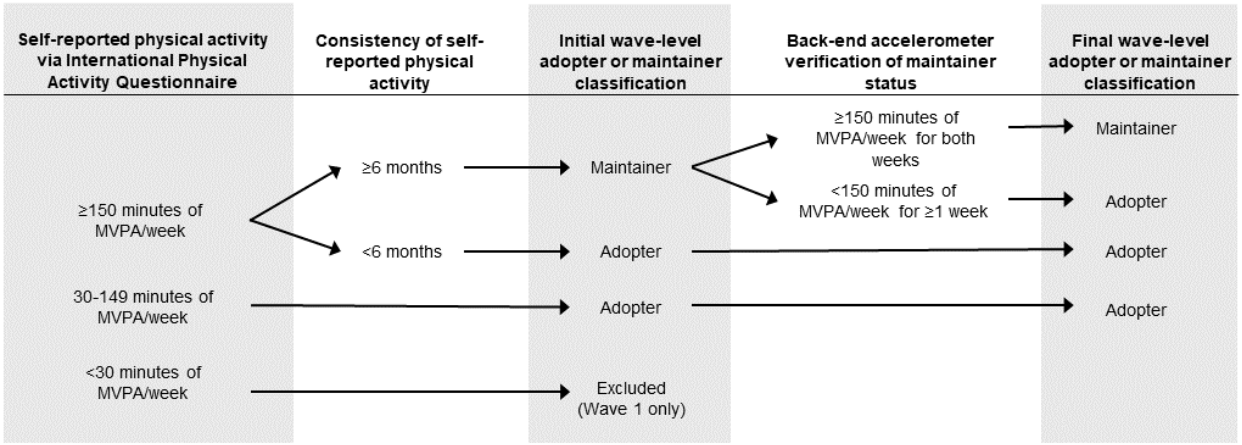
XSL•FO
RenderX

For their participation in the study, participants can earn up to US $100 for each data collection period. Participants are compensated with US $60 for completing the data collection period. If participants answer at least 80% of the questionnaires on the smartphone, they receive US $40 as bonus. If participants complete all 3 data collection periods, they receive US $40 as bonus at the third data collection period. Therefore, participants can earn up to US $340 for this study.

Measures

Adopter and Maintainer Status

Overview



To determine adopter and maintainer status, we use a staged classification model using self-reported behavior initially, with subsequent selective verification via accelerometer. Overall, 2 weeks of accelerometer data will be collected to more reliably differentiate adopters and maintainers, given that self-report measures are subject to recall biases and social desirability [33] and having only 1 week of accelerometer data may not provide an accurate representation of participants' typical levels of PA and SB.

PA Adopter and Maintainer Status

Initial eligibility based on PA level is determined during the telephone screening before study enrollment using items assessing moderate-to-vigorous intensity PA from the International Physical Activity Questionnaire Short Form [34]. Items include the number of days in the past 7 days in which participants engaged in moderate-to-vigorous intensity PA and the typical amount of time spent engaged in that activity on one of those days. Individuals engaging in <30 minutes of moderate-to-vigorous intensity PA over the past 7 days are excluded. Here, 30 minutes was chosen as the minimum level of PA to increase the likelihood of capturing moments of PA during the wave (to minimize the extent to which we have a skewed distribution for data analysis where PA serves as the outcome).

Then, during the administration of the baseline electronic questionnaire, participants will complete the Physical Activity Stage of Change Questionnaire [35], where they indicate whether they are currently engaging in 150 minutes of PA per week and, if so, how long they have been engaging in that level of PA. Individuals indicating <150 minutes of moderate-to-vigorous intensity PA per week will be classified as adopters. Those indicting that they engage in ≥150 minutes of moderate-to-vigorous intensity PA but for <6 months will also be classified as adopters. Those indicating ≥6 months of that PA level will be categorized as maintainers. As overestimation of PA is a common methodological weakness associated with self-reported, retrospective measures of PA [33], PA maintainer status will be confirmed via accelerometry. On the back end of each wave of data collection, maintainer status will be confirmed by examining ActiGraph-derived minutes of moderate-to-vigorous intensity PA during the wave. Participants who meet the 2018 US Federal PA guidelines according to ActiGraph-derived data during both weeks of data collection will remain as maintainers. Those who do not meet 2018 US Federal PA guidelines according to ActiGraph-derived data for one or both weeks are recategorized as adopters. The staged classification model is depicted in Figure 2. This initial and back-end classification will be performed at each data collection period.

Figure 2. Overview of adopter or maintainer classification procedures at each data collection period. MVPA: moderate-to-vigorous intensity physical activity.

SB Reduction Adopter and Maintainer Status

Although our inclusion criteria are based on PA adopter and maintainer status, we also determine SB reduction adopter and maintainer status via the baseline questionnaire before each data collection period using items from the International Physical Activity Questionnaire [34], assessing weekday and weekend-day SB. Those indicating sitting for >8 hours per day will be considered as SB reduction adopters. Individuals indicating sitting for ≤8 hours per day for <6 months are also categorized as adopters; those sitting for ≤8 hours per day for ≥6 months are classified as maintainers. We confirm SB reduction adopter or maintainer status using ActivPAL-derived data and follow similar recategorization procedures for PA. We chose sitting for ≤8 hours per day as the cutoff for adopter or maintainer status because older adults who sit for >8 hours per day have high risk for premature death and other chronic conditions [36].

EMA Measures

EMA measures real-time experiences of reflective and reactive factors (refer to Multimedia Appendix 1 for details about reflective and reactive EMA items). EMA data are stored on the study-provided mobile phone after each entry and uploaded to a secure server when a participant enters a Wi-Fi–enabled area. If a participant does not have access to Wi-Fi, all responses are stored on the mobile phone until uploaded by a research assistant upon completion of the data collection period. All EMA items are either taken directly or modified from established measures. Construct-general (instead of behavior-specific) reflective EMA items begin with the stem, "Right before the phone went off..." to capture momentary reports. Each construct-general reflective factor is assessed using a single item appearing in every EMA prompt. Construct-general reflective EMA items will assess momentary self-efficacy [37], deliberation [38], self-control [39], demands [40], stress coping [41], and emotion regulation [42]. In addition, we also assess behavior-specific reflective factors through EMA. Behavior-specific reflective factors include single-item assessments of intentions, self-efficacy, and planning to engage in PA and reduce SB over the next hour [43,44]. At each EMA prompt, 2 items assessing behavior-specific reflective factors are randomly delivered to participants. Therefore, each behavior-specific reflective factor will be assessed 3 to 4 times per day. Reactive EMA items will assess current positive and negative affect. Positive and negative affect assessments each use a domain-specific approach assessing 5 affective domains; however, each EMA prompt will only contain 3 affect-related items randomly delivered. The average of the available items for each construct will be used to create momentary positive and negative affect composite scores. Additional reactive factors include current functional stability of habits (1 item), physical context (2 items), and social context (1 item) at each EMA prompt [45,46]. Each EMA prompt is date and time stamped to assess the temporal context. Temporal context data will be used to create dummy-coded variables related to the day of week (ie, weekend day vs weekday) and time of day (eg, morning vs other times of day). Participants also self-report their behavior at every EMA prompt (2 items). Each EMA prompt contains 20 items and takes 2 to 3 minutes to complete.

Device-Based PA and SB

The ActiGraph GT3X-BT accelerometer provides a device-based measure of PA. Participants are instructed to wear the ActiGraph device on their nondominant waist during all waking hours. If participants engage in activities where the monitor could get wet (eg, swimming and showering or bathing), they are instructed to remove it. Data are collected in 30-second epochs. The ActiGraph has been used extensively in large epidemiologic studies to assess PA and validated in both laboratory and field settings [3,5]. Existing count-based intensity thresholds inform time spent in specific intensities of PA. The count threshold for moderate-to-vigorous intensity PA (≥2020 counts/min) was designed and validated specifically to assess PA in populations across the adult life span and has been used extensively in epidemiologic studies and intervention trials [3]. PA is operationalized as the total time spent engaged in moderate-to-vigorous intensity PA in the 60 minutes after the EMA prompt. Any occasion where the ActiGraph records 0 minutes of valid wear time in the 60 minutes after the EMA prompt will be considered as nonwear and coded as missing data. Accelerometer recordings will be date and time stamped to link with EMA data.

The ActivPAL3 microaccelerometer provides a device-based measure of SB. Participants will be instructed to wear it on their anterior thigh during all sleeping and waking hours. Participants' ActivPALs are waterproofed using heat-sealed polymer plastic tubing to ensure that wearing it during water-based activities does not damage the monitor. Owing to the placement of the ActivPAL on the thigh, the monitor is better able to detect different postures (ie, sitting, lying, and standing) compared with waist-worn accelerometers such as the ActiGraph [47]. The ActivPAL has been used in large epidemiologic studies and intervention trials and has undergone validation in both laboratory and field settings [4,48,49]. ActivPAL uses proprietary algorithms to categorize behavior in 15-second epochs as time spent in SB. SB is operationalized as total time spent engaged in SB in the 60 minutes after the EMA prompt. Any occasions where the ActivPAL was not worn for the entire 60 minutes after the EMA prompt will be considered as nonwear and coded as missing data.

Data Analysis Plan

Overview

An overview of key study measures and their role in data analysis is presented in Table 1.

XSL•FO
RenderX

Table 1. Overview of key study measures and their role in data analysis.

Construct	Measure	Aim 1	Aim 2		Aim 3
			Hypothesis 2a	Hypothesis 2b	
Reflective factors	• EMA[a] (10 prompts/day)	Predictor	• Stage 1—outcome • Stage 2—predictor	• Stage 1—predictor	Predictor
Reactive factors	• EMA (10 prompts/day)	Predictor	• Stage 1—outcome • Stage 2—predictor	• Stage 1—predictor	Predictor
Physical activity	• ActiGraph GT3X-BT	Outcome	• N/A[b]	• Stage 1—outcome • Stage 2—predictor	Predictor
Sedentary behavior	• ActivPAL3 micro	Outcome	• N/A	• Stage 1—outcome • Stage 2—predictor	Predictor
Adopter or maintainer status	• Initial self-report classification—International Physical Activity Questionnaire • Back-end accelerometer classification—ActiGraph GT3X-BT and ActivPAL3 micro	Moderator	• Stage 2—outcome	• Stage 2—outcome	Outcome

[a]EMA: ecological momentary assessment.

[b]N/A: not applicable.

Aim-1 Analytic Plan

Hierarchical linear modeling [50] will be used to determine the extent to which momentary reflective and reactive motivational processes are associated with subsequent PA and SB in the 60 minutes after the EMA prompt. Separate, 2-level (observations within participants) random effects models will be estimated for both PA and SB, with only 1 reflective or reactive factor tested at a time, resulting in a total of 18 reflective factor models and 10 reactive factor models. Reflective and reactive variables will be person-mean centered at level 1 and grand-mean centered at level 2 to partition variance in outcomes owing to within-subject changes and between-subject differences, respectively [51]. Maintainer status at baseline will be entered as a person-level covariate; both within-level and cross-level interactions with reflective and reactive variables will be tested. In addition, it is not uncommon for PA data to be positively skewed. Should model assumptions concerning normality be violated, we will log transform dependent variables and refit the model or models or shift to hierarchical generalized linear modeling should a non-Gaussian link function be more appropriate [50]. The fixed effects for interactions between maintainer status and reflective and reactive variables on PA and SB will be of primary interest in investigating this aim. It is because of our specific interest in these interactions that we will not include multiple reflective and reactive factors in the same model. Finally, given the number of model parameters to be estimated across all models, we will use false discovery rate to maintain a type-1 error rate within acceptable levels (0.05) while limiting commensurate type-2 error inflation that occurs with other techniques used to control family-wise error rates (eg, Bonferroni correction) [52].

Aim-2 Analytic Plan

Aim 2 is designed to determine the extent to which subject-level patterns in reflective and reactive motivational processes predict behavioral adoption versus maintenance. Analyses for aim 2 will use a novel, 2-stage approach for each hypothesis using the stand-alone program, MixWILD [53]. In stage 1, mixed-effects location scale modeling [54,55] is used to model between-subject and within-subject variability in momentary reflective and reactive motivational processes. With heterogeneous variability, mixed-effects location scale modeling extends the typical hierarchical linear model to allow the incorporation of covariates in the modeling of between-subject and within-subject variability. Thus, we will estimate separate 2-level random effects models, controlling for relevant demographic and temporal covariates (refer to information about covariate screening in the previous section). We will estimate effects of random within-subject means (ie, subject-level average of a given construct based on all available occasions of data—location effect), variance (ie, subject-level degree of intraindividual variability on a given construct across all available occasions of data—scale effect), and slope (ie, subject-level average strength of an association between 2 variables across all available occasions of data). Within-subject mean, variance, and slope random effect estimates generated in stage 1 will be retained for use in the stage-2 analysis.

In stage 2, the within-subject mean, variance, and slope estimates of reflective or reactive variables will serve as predictors of likelihood of categorization as a behavioral adopter or maintainer (coded as 0 or 1, respectively) in single-level logistic regression models [53]. Separate single-level logistic regressions will be tested for each wave and for the entire year,

XSL•FO
RenderX

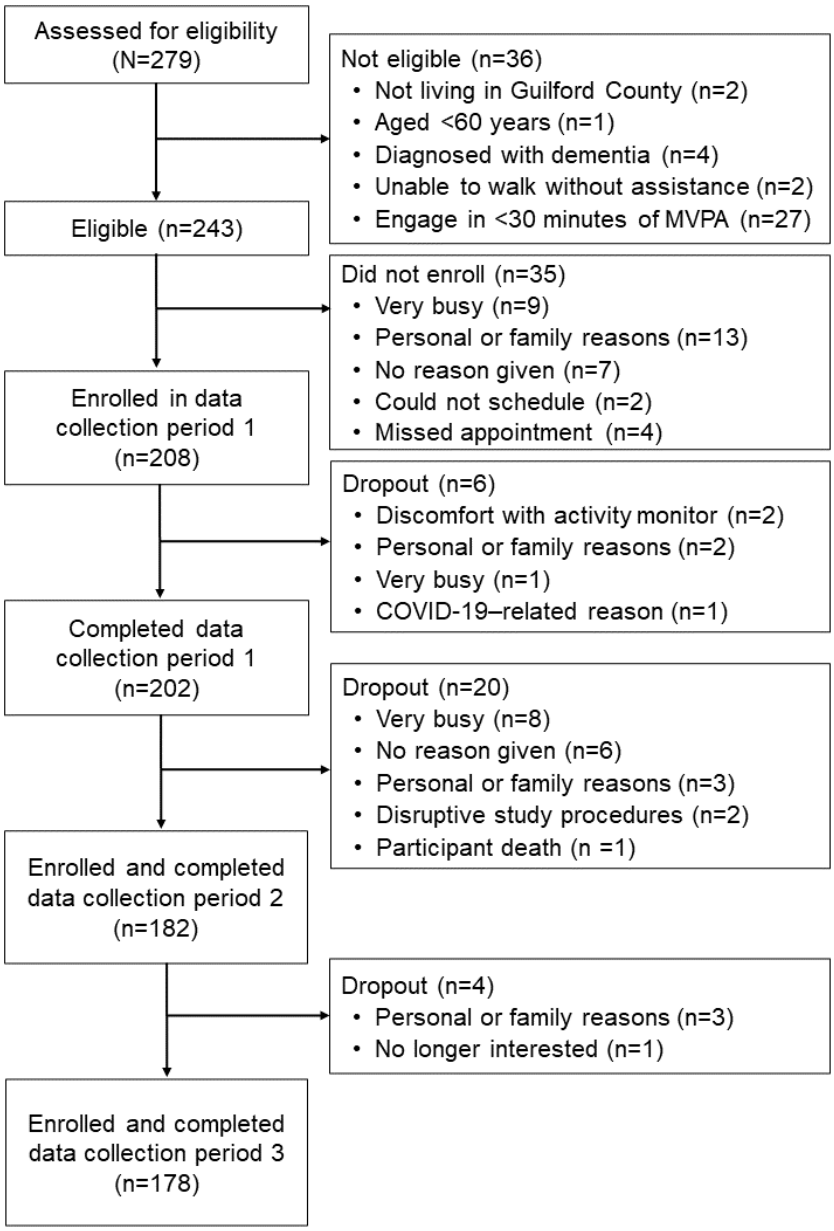
with associated location and scale estimates incorporated as covariates. The dependent variables will be maintainer status at the end of each wave (for single-wave models) and whether participants retained the classification as a maintainer across all 3 waves (year model). In addressing each hypothesis associated with aim 2, model refinement will be informed by the magnitude and significance of individual beta coefficients and the impact on omnibus model performance assessed via change in –2 log likelihood. Final conditional models will be examined for improvement in classification accuracy over null models and for the individual performance of subject-level mean and variance effects in reflective and reactive factors and subject-level slopes regarding associations between reflective and reactive factors and subsequent behavior in predicting maintainer status. Again, we will use false discovery rate in each stage to control type-2 error rates [52].

Aim-3 Analytic Plan

Aim 3 is designed to investigate the extent to which reflective and reactive motivational processes and behavioral patterns predict change in adopter or maintainer status from wave to wave. For this exploratory aim, we will apply latent Markov modeling to examine predictors of individuals' status change over waves (ie, adopter to maintainer or maintainer to adopter) [56]. Specifically, we will estimate adopter or maintainer status using observed status and test whether subject-level mean, variance, and slope random effects generated in aim-2 analysis can be used to predict the likelihood of transitioning from one status category to another. Given the power concerns and the exploratory nature of this aim, we will test each reflective or reactive variable within a separate model.

Ethics Approval

All study procedures were approved by the University of North Carolina Greensboro institutional review board (20-0216) in January 2020.



Results

Funding for Project SMART was awarded in April 2020. Additional COVID-19 protocols were approved by the University of North Carolina Greensboro's Office of Research Engagement in December 2020. Participant recruitment and enrollment began in January 2021. As of February 2022, a total of 202 participants enrolled and completed the first data collection period. As of July 2022, overall, 90.1% (182/202) of participants completed their second data collection period. As of December 2022, overall, 88.1% (178/202) of participants completed the third and final data collection period. Among those who dropped out of the study between data collection period 1 and 2 and between 2 and 3 (n=24), reasons for attrition included no longer being interested in the study (n=1, 4%), personal or family reasons (n=6, 25%), being very busy (n=8, 33%), having found the smartphone protocol to be disruptive (n=2, 8%), or no reason was given as they were unable to be contacted (n=6, 25%). A participant (1/24, 4%) also passed away during a scheduled break from data collection between data collection periods 1 and 2. A flow diagram showing participant progress through the recruitment, screening, enrollment, and data collection processes is shown in Figure 3.

Of those who enrolled in and completed the first data collection period and provided relevant information, most identified as female (female: 142/199, 71.4%; male: 57/199, 28.6%) and White (Asian: 1/199, 0.5%; Black or African American: 47/199, 23.6%; White: 148/199, 74.4%; and ≥2 races: 3/199, 1.5%). The average age of the sample was 69.9 (SD 5.7; range 60-85) years. Most participants were overweight (61/194, 31.4%) or obese (49/194, 25.3%; mean BMI 27.1, SD 5.5 kg/m^2). The median annual income in the sample was US $60,000 to US $79,999. Approximately 22.6% (45/199) of the participants reported <US $40,000, and 21.1% (42/199) reported >US $100,000 as annual income. After back-end classification, approximately two-thirds (127/201, 63.2%) of the sample were classified as PA adopters, and the remaining (74/201, 36.8%) were classified as PA maintainers.

Discussion

Summary

Project SMART will determine the motivational processes that regulate behavioral adoption versus maintenance over microtimescales, using a dual process framework combined with EMA and sensor-based monitoring of behavior. Applying a within-subject approach permits a refined examination of motivation-behavior relations as naturally occur in everyday life across the behavior change continuum. This paper describes our approach to understanding these relations.

Methodological Challenges and Decisions

To enhance the likelihood of capturing moments of PA during data collection periods, this study requires that older adults currently engage in at least 30 minutes of self-reported PA per week. There are many older adults who engage in <30 minutes of self-reported PA per week. An important direction for future studies is to examine the motivational processes at play in inactive and insufficiently active older adults. Such studies would complement the proposed study by identifying microtemporal motivational processes regulating health behaviors among older adults at other key points in the behavior change continuum such as contemplation (ie, intending to change behavior in the next 6 months) or preparation (ie, intending to change behavior in the next 30 days and sporadically engaging in desired health behavior) [57]. Future studies expanding our approach to additional points in the behavior change continuum would enable temporally sensitive and context-sensitive interventions applicable to a wide range of older adults. Minimum levels of PA are used as an inclusion criterion rather than levels of SB because of the relatively high volume and normal distribution of SB in older adults [4,6].

In this study, participants are loaned Motorola Moto G Power mobile phones to complete the EMA protocol. This decision was made for several reasons. First, the MovisensXS app is

XSL•FO
RenderX

available only on Android devices. As most smartphone owners in the United States use an iOS device [58], the research team did not want to exclude a large proportion of potential participants owing to the operating system of the personal device. Second, MovisensXS tests specific devices and operating systems to determine their potential for app performance. The Moto G series of devices has been shown to perform well in executing various features of the MovisensXS app. Furthermore, the MovisensXS app currently requires an operating system of Android 4 or higher. Providing a loaned mobile phone ensures that the recommended operating system is in use and that the device is optimized for performance. Finally, evidence suggests that adults have improved compliance when completing an EMA protocol on a loaned mobile phone as opposed to one's personal device [59]. This may be because participants are more sensitive to novel app-based notifications from a new device as opposed to their personal device on which they may be used to ignoring notifications. In this study, the research team weighed the costs and limitations associated with buying a limited number of devices (n=30) and the benefits associated with optimal app performance. Another important consideration for providing participants with devices is that introducing a novel device may require additional training, depending on the participant population. In this study, because of the need to meet with participants (in person or over Zoom) to train them on wearing the activity monitors, there was a built-in opportunity to train them on the smartphone device as well.

Strength of Project SMART

Previous studies that aimed at understanding the motivational processes regulating movement-related behaviors in older adults have used retrospective or summary-based questionnaires, which may be prone to recall biases and misremembering, to capture typical levels of behavior [10]. Unlike these traditional (between-person) methods, our approach recognizes that movement behaviors change within individuals and across days and that the pattern of variation in movement behaviors may differ between people. Furthermore, this study addresses those methodological weakness by pairing EMA of older adults' current motivation, affect, and contexts with device-based movement behavior. This study capitalizes on the fact that mobile phones have become ubiquitous and easy to use in daily life, even among older adults [60]. Previous studies have documented that smartphone-based EMA studies of movement-related behavior are feasible, acceptable, and valid among diverse groups of older adults [61,62]. However, this is the first known movement behavior EMA study to intensively assess older adults 10 times per day. This study will enhance our knowledge about how EMA can be used among older adults in combination with other types of real-time behavioral measures (ie, accelerometers) to capture momentary, within-day effects of reflective and reactive motivational processes on older adults' PA and SB.

This study will help to generate more definitive conclusions about how reflective and reactive processes operate to influence PA and SB from adoption to maintenance. In addition, this study will not only explore the role of specific levels of constructs (eg, degree of confidence) or the presence of a particular construct (eg, alone vs not alone) but also explore patterns of stability (or instability) in reflective and reactive processes and the influence those patterns have on behavior across the behavior change continuum. This study is a necessary and fundamental step toward refining health behavior theories to predict health behaviors more accurately as they unfold over everyday life [14].

In summary, Project SMART is well suited to address gaps in the current understanding of the motivational processes that regulate movement behaviors along the continuum of adoption to maintenance. By intensively assessing movement behaviors and motivational antecedents, Project SMART aims to generate a great understanding of the within-person, reflective, and reactive motivational processes regulating behavior and thus will provide information to identify intervention targets in the context of everyday life. Specifically, novel intervention approaches such as just-in-time approaches [63] that can respond to participants in real time based on passively collected or participant-reported data may benefit from our more ecologically valid, real-time approach. Ultimately, this study is necessary to develop behavioral interventions that deliver personalized intervention content (eg, motivational messages and prompts to increase PA or reduce SB) under the temporal and contextual contexts when that content will be most effective to promote sustained behavior change among older adults.

Abstract

Background: Young men who have sex with men (YMSM) are the fastest-growing HIV-positive population worldwide. Thailand has the highest adult HIV seroprevalence in Asia; over 25% of men having sex with men in Bangkok are HIV positive. Pre-exposure prophylaxis (PrEP) is an efficacious HIV prevention strategy recommended for all at-risk individuals. PrEP is highly effective when taken as prescribed, but PrEP utilization rate has been low, and adherence is often inadequate.

Objective: We propose to develop and pilot a multicomponent, technology-based intervention to promote motivation to begin PrEP ("uptake") and sustained adherence to PrEP among HIV-negative Thai YMSM. We will adapt an existing 2-session technology-delivered, motivational interviewing–based intervention to focus on PrEP use in YMSM in Thailand. The resulting intervention is called the Motivational Enhancement System for PrEP Uptake and Adherence (MES-PrEP). We will also develop motivational text messaging (MTM) to send two-way motivational messages to promote PrEP use.

Methods: The proposed study includes 3 phases. Phase 1 includes in-depth interviews with HIV-negative Thai YMSM and providers to explore barriers and facilitators of PrEP initiation and adherence, aiming to inform intervention content. Phase 2 consists of adapting and beta-testing MES-PrEP and MTM for functionality and feasibility using a youth advisory board of Thai YMSM. In Phase 3, we will conduct a pilot randomized controlled trial to evaluate the feasibility, acceptability, and preliminary efficacy of MES-PrEP and MTM to increase PrEP uptake and adherence among Thai YMSM. A total of 60 HIV-negative Thai YMSM who have not started PrEP and 60 YMSM who are on PrEP but not adherent to it will be randomized 2:1 to receive MES-PrEP and MTM (n=40) or standard PrEP counseling (n=20). The feasibility and acceptability of the intervention will be assessed through usage patterns and the System Usability Scale. The preliminary impact will be assessed by evaluating the proportion of PrEP initiation and level of adherence to PrEP. Participants will complete the assessments at baseline and at 1-, 3-, and 6-month postintervention. Biomarkers of adherence to PrEP and biomarkers of HIV and sexually transmitted infections will be collected.

Results: Recruitment for this study began in January 2022 for phase 1. Qualitative interviews were completed with 30 YMSM and 5 clinical providers in May 2022. Phase 3, the pilot feasibility and acceptability trial, began in July 2023. Upon project completion, we shall have developed a highly innovative mobile health intervention to support YMSM using PrEP, which will be ready for testing in a larger efficacy trial.

XSL•FO
RenderX

Conclusions: This study addresses a critical problem (ie, high HIV incidence and low PrEP use) among Thai YMSM. We are developing 2 potentially synergistic technology-based, theory-driven interventions aimed at maximizing PrEP use. The proposed project has the potential to make significant contributions to advancing HIV prevention research and implementation science.

Introduction

Overview

Men who have sex with men (MSM) are 19 times more likely to be HIV positive than the general population worldwide, with an HIV prevalence of 20%-30% in many countries [1-4]. New infection rates are particularly high in young MSM (YMSM), whose developmental period is associated with increased risk-taking [5]. Thailand has the highest adult HIV seroprevalence in Asia (1.1% in 2017) [6]. The rate of new HIV infections among MSM dramatically increased in the past 20 years [7], with an HIV prevalence rate reaching 30% and an incidence rate of 12 per 100 person-years among those aged 15-21 years [4]. Effective interventions for this high-risk population are critical to the success of the UNAIDS' Fast Track Strategy—ending the AIDS epidemic by 2030 [8].

Pre-exposure prophylaxis (PrEP) is an efficacious HIV prevention strategy. The Centers for Disease Control and Prevention recommends PrEP for all individuals at substantial risk for HIV infection, including HIV-negative MSM [9]. Despite high levels of efficacy when taken as prescribed, PrEP uptake and adherence have been low [10], with high discontinuation rates reported among YMSM [11,12]. The existing literature suggests that YMSM generally lack awareness of PrEP and their uptake motivation and adherence are often inadequate [13-15]. In Thailand, only 9.3% of MSM who were offered PrEP agreed to take it [16]. Commonly cited barriers to initiating or staying on PrEP have included low self-perceived risk, concerns about medication side effects, concerns about maintaining daily oral PrEP regimen, drug use, and HIV stigma [17-19]. Given this evidence of low uptake and high discontinuance rates of PrEP, effective behavior-change interventions are needed to motivate the uptake of and sustain adherence to PrEP among HIV-negative YMSM in Thailand.

Mobile health (mHealth) interventions for high-risk YMSM have the potential to reduce HIV risk behaviors and increase HIV testing rates [20]. These interventions may be particularly well suited for youth because they tend to use computers, cell phones, and texting very frequently [21,22]. Motivational interviewing (MI) is the only evidence-based behavioral intervention that has demonstrated success across the youth HIV prevention and care cascades [23-25]. MI has been linked with improved medication adherence, decreased depression, and decreased risky sexual behaviors in people living with HIV [26]. Interactive text messaging provides ongoing support to maintain motivation for behavior change. Text messaging has a beneficial impact on antiretroviral therapy adherence and provides ongoing behavioral reinforcement for HIV-positive MSM, and the effect is stronger when combined with other interventions [27,28]. Despite the rapid growth of technology in behavioral health, there have been very few technology-based interventions that have specifically targeted HIV-negative YMSM for PrEP uptake and adherence.

Study Aims

We propose to develop and pilot a multicomponent, technology-based intervention to promote both motivation to begin PrEP ("uptake") and sustained adherence to PrEP. Intervention development and testing will be guided by the framework of the ADAPT-ITT model [29]. First, we will adapt an existing 2-session technology-delivered, MI-based intervention to focus on PrEP uptake and adherence in HIV-negative YMSM through a systematic, multistep process [30]. The resulting brief technology-based intervention will be called the Motivational Enhancement System for PrEP Uptake and Adherence (MES-PrEP). We shall develop and pilot-test motivational text messaging (MTM) to promote PrEP uptake and adherence. These intervention components will be integrated to enhance the impact of MES-PrEP through MTM. Second, we will conduct a pilot randomized controlled trial (RCT) to evaluate the feasibility, acceptability, and preliminary efficacy of an intervention combining MES-PrEP and MTM to increase PrEP uptake and adherence in Thai YMSM. This study will pave the way for the successful scale-up of PrEP implementation among MSM in Thailand.

Theoretical Frameworks of Behavior Change

The Information-Motivation-Behavioral Skills (IMB) model and the Socioecological Model will serve as the conceptual frameworks for developing our PrEP mobile intervention. Both theoretical models have been applied to a variety of health promotion topics, including HIV health behaviors [31-33] and PrEP uptake and adherence [34,35]. Although the IMB model includes only individual-level factors, the Socioecological Model captures individual-, structural-, and social-level factors around PrEP use. The proposed intervention is primarily focused on behavior change at the level of the individual and also addresses structural- and social-level factors, such as HIV stigma and depression as well as access to PrEP. According to the IMB model, behavior change results from the joint function of 3 critical elements: accurate information about risk behaviors (eg, risks of not taking PrEP while engaging in unprotected sex),

XSL•FO
RenderX

the motivation to change behavior, and the perceived behavioral skills necessary to perform the behavior (eg, self-efficacy). For this study, we will develop intervention content to address each core element of the IMB model to facilitate PrEP adoption and adherence among Thai YMSM.

Intervention Components

MES-PrEP Intervention

MES-PrEP is a 2-session computer-delivered intervention. At the start of each session, the participant chooses a preferred character (avatar) who will deliver the intervention in a way that has high fidelity to the most recent edition of MI (MI-3) [36]. The avatar evokes both importance and confidence (key components of readiness or motivation) with MI strategies, such as identifying the pros of behavior change, providing affirmations to reinforce change talk and boost confidence, as well as identifying strengths and resources. MI strategies used within the motivational enhancement system to promote autonomy, boost self-efficacy, and identify social supports are also designed to address HIV stigma and coping. The intervention manages counterchange talk by having the avatar reflect without judgment and providing statements to emphasize autonomy. Importantly, the interactions between the avatar and the participant are synchronous and not reliant on feedback at the completion of the session. Small amounts of education about PrEP are integrated with motivational elements. The intervention is adjusted based on participants' ratings of the perceived importance of and confidence in taking PrEP by routing each participant to different content based on these assessments. For example, participants who perceive initiation of PrEP to be of low importance are branched to decisional balance exercises, while participants who perceive this to be very important receive reinforcement for this perception. Youth, regardless of the level of importance and confidence, are also directed to content designed to explore HIV stigma, including exploration of autonomy, self-efficacy, and social support. Youth are given feedback on their PrEP knowledge assessment followed by information about the protective effect that can result from improved PrEP adherence. Each participant will be asked to set a goal (obtain PrEP prescription, maintain optimal adherence, practice steps, or think about it more), identify possible barriers (eg, concerns around stigma, forgetting, and side effects), and form plans for overcoming these barriers. In the second session (1 month later), participants are assigned to new branches based on whether they felt that they met their goal (reinforcement and plan for continued success), partially met the goal (identifying plans for overcoming barriers), or did not meet the goal. Youth may choose to plan for a new goal or continue the same goal.

MTM Intervention

Text messages are motivational statements promoting the uptake of and adherence to PrEP. We will use LINE for automated but bidirectional MTM to send and receive text messages to promote PrEP initiation and adherence. The program features automatic prompts and response data capturing, requires no internet, and works in the Thai language. The interface program will allow flexibility in the timing and frequency of MTM; message selections from the message libraries; and automatic recording of the message sent, the message received, and whether the message fails. All MTM activities will be performed by an information technologist at the Institute of HIV Research and Innovation. MTM will be sent daily for 1 month, followed by weekly for an additional 5 months (months 2-6) at a time chosen by the participant to promote autonomy. The message content is individualized based on participant responses to the baseline survey. Those participants who indicate that they are "ready" to initiate PrEP and set the goal to take their medications as prescribed will receive MTM to remind them to take PrEP. Those who indicate that they are less ready to take PrEP can choose from alternatives, including taking on-demand PrEP or just thinking about taking PrEP. MTM content for those who are not ready to take PrEP will be individualized based on the participant's choice, that is, a daily message encouraging them to work toward their chosen goal. Participants who are not prescribed PrEP receive daily text messages regarding PrEP effectiveness, HIV risk, and getting prescribed PrEP.

Standard PrEP Counseling (Control Condition)

All study participants will receive one-on-one, face-to-face counseling focused on sexual and behavioral risk assessment for HIV and sexually transmitted infections as well as risk reduction. For those who are at high risk but not yet ready to start PrEP, the focus will be on risk assessment skills or risk perception, awareness of PrEP or postexposure prophylaxis, as well as facilitators and barriers to accessing PrEP. For those already on PrEP, the focus will be on adherence. Counseling is a standard practice within our partner clinics and will last about 15-20 minutes.

Methods

Study Setting

YMSM will be recruited from 2 large clinics in Bangkok, Thailand, to ensure diversity in the respondent population. Thai Red Cross Anonymous Clinic has a large YMSM client population. Over 3500 YMSM (aged 16-25 years) attended this clinic in 2020 [37]. Rainbow Sky Association of Thailand (RSAT) clinic is among the first community-based organizations working to serve key populations in Thailand. RSAT has implemented the Key Population-Led Health Services model since 2015 in a highly populated area in Bangkok to provide HIV-related health services for key populations, including MSM. Annually, approximately 1500 YMSM (aged 16-25 years) have attended the RSAT clinic.

Study Design

There are 3 phases in the study: phase 1 (formative research), phase 2 (intervention adaptation), and phase 3 (pilot RCT).

Phase 1: Formative Research

In-Depth Interviews

We will conduct interviews with 30 HIV-negative Thai YMSM (15 PrEP-naïve YMSM and 15 YMSM on PrEP, including 5 with good adherence) to explore factors related to PrEP uptake and adherence. An interview guide will be created by the investigator team that will provide a general structure for the interview. Based on the IMB model, we will explore their "information" (ie, their knowledge of PrEP and HIV

XSL•FO
RenderX

transmission risk and their perceived advantages and disadvantages of PrEP), "motivation" (ie, attitudes toward PrEP, perceptions of HIV risk, willingness and interest to use PrEP, reasons for accepting or declining PrEP), and "behavioral skills" (ie, specific behavioral skills relevant to PrEP initiation and adherence, facilitators and barriers to PrEP initiation and adherence, reasons for keeping scheduled appointments or filling PrEP prescription, and reasons for discontinuing or restarting PrEP). We will also explore sources of social support and past successes. Responses will be used to broadly inform intervention content (eg, which modules to include in the intervention framework). The responses will also be used for more specific purposes (eg, response options for barriers and identifying sources of social support). We will also prompt the participants for feedback on intervention content (eg, what they would like to know about PrEP) and delivery (eg, how often they would like to receive text messages to help them take PrEP). Interviews will be audiotaped, transcribed, and translated into English by an independent translator. Interviews will last about 30 minutes.

Youth Advisory Board

A youth advisory board (YAB) of 8-10 eligible Thai YMSM will be identified and assembled by Thailand investigators who have strong relationships with medical providers serving YMSM in Bangkok. YAB members will be high-risk YMSM and selected to ensure diversity in age and socioeconomic status. Members will meet quarterly (with additional meetings as needed). The primary role of the YAB will be providing iterative feedback on study materials, recruitment and retention strategies, intervention approach and content, and disseminating study findings. The operational guidelines will follow the best processes for community-participatory research (eg, establishing the YAB's function and promoting empowerment) [38]. Any inconsistencies in feedback will be resolved during the meeting, or if necessary, via discussions with the Thai-US study team. Detailed notes will be taken during meetings. Study materials will be revised based on YAB feedback.

Phase 2: Adapting and Refining MES-PrEP and MTM

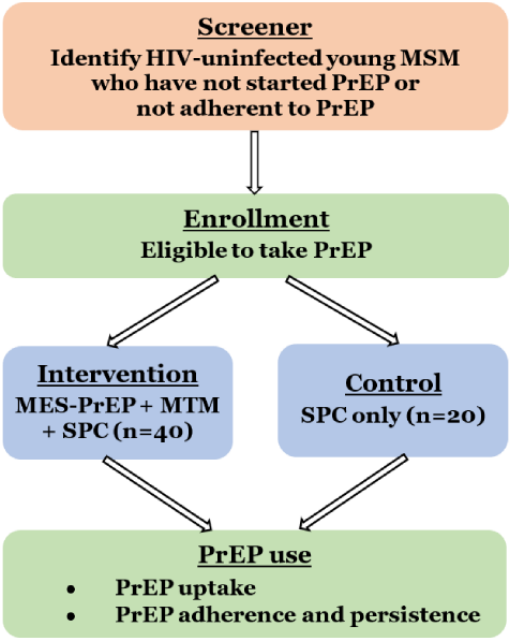
Adapting Motivational Enhancement System for Adherence to Focus on PrEP Uptake and Adherence (Development of "MES-PrEP")

We will build upon existing infrastructure to adapt the 2 components of the intervention (MES-PrEP and MTM) based on responses to interviews. We will use interviews in Phase 1 to adapt the 2-session intervention to promote PrEP. The adaptation process of the Motivational Enhancement System for Adherence will involve two steps: (1) initial programming of sessions of PrEP uptake and adherence intervention in collaboration with the YAB and (2) evaluation of cultural acceptability and intervention content via the YAB and beta-testing. The YMSM will complete 2 MES-PrEP sessions over 1 month.

Developing and Programming MTM

We will use automated, bidirectional ("two-way") MTM via LINE as a tool to support PrEP initiation and adherence [39]. MTM will be developed using information from interviews in Phase 1. Motivational statements promoting PrEP use will be generated from each theme and grouped into one of the 2 MTM libraries—PrEP initiation or PrEP adherence library. Participants will respond to MTM using multiple-choice or open-ended responses, alternated to avoid fatigue. MTM will be sent daily for 1 month, followed by weekly for an additional 5 months (months 2-6) at a time chosen by the participant to promote autonomy.

Beta-Testing of MES-PrEP and MTM



The MES-PrEP system will be beta-tested among 10 HIV-negative Thai YMSM. The youth will complete 2 MES-PrEP sessions over 1 month. Each session will be videotaped. We will also assess the MTM system functionality with the same 10 participants who will receive daily MTM between MES-PrEP sessions, using the 2 message libraries. YMSM on PrEP will receive messages from the PrEP adherence library; PrEP-naïve YMSM will receive messages from the PrEP initiation library. Participants will be asked to respond to the prompt(s). After 24 hours of sending the first text message, the staff will call the participant to check if they have encountered any issues with MTM. A brief face-to-face interview will be conducted to (1) identify and correct any technical or other issues encountered in delivering MTM and MES-PrEP and (2) solicit input on how to refine MTM and MES-PrEP delivery and content.

Phase 3: Pilot RCT Trial

We will launch a pilot RCT (registered with ClinicalTrials.gov registry: NCT05243030) to evaluate the feasibility, acceptability, and preliminary efficacy of MES-PrEP and MTM to increase PrEP uptake and adherence among Thai YMSM. The design is shown in Figure 1. We will enroll 120 YMSM (60 YMSM on PrEP and 60 PrEP-naïve YMSM) from the 2 HIV clinics. The 60 PrEP-naïve YMSM are those who are at high risk and eligible for PrEP but have not decided to start PrEP. We anticipate enrollment of 20 participants per month (for 6 months). Participants will be randomized to receive MES-PrEP and MTM (intervention) versus standard PrEP counseling (control) in a 2:1 ratio, stratified by current use of PrEP (PrEP naive vs PrEP users). The 2:1 allocation was chosen to maximize the collection of feasibility and acceptability data among intervention participants. Separate randomization for YMSM who are currently on PrEP and YMSM who are not starting PrEP will be computer-generated using Qualtrics. The primary outcome will be acceptability, feasibility, as well as PrEP uptake and adherence assessed through Computer-Assisted Self-Interview and Dried Blood Spot testing.

XSL•FO
RenderX

Figure 1. Pilot randomized controlled trial schema. MES-PrEP: Motivational Enhancement System for Pre-Exposure Prophylaxis; MSM: men who have sex with men; MTM: motivational text messaging; PrEP: pre-exposure prophylaxis; SPC: standard PrEP counseling.

Study Sample

YMSM will be eligible based on inclusion criteria consistent with the Centers for Disease Control and Prevention and Thailand National HIV/AIDS Treatment and Prevention Guidelines [40,41], as follows: (1) age between 16 and 25 years; (2) men who report sex with men in the past 12 months; (3) laboratory-confirmed HIV-negative status; (4) self-reported evidence of being at risk for HIV acquisition, including one of the following in the past 6 months: having sex with an HIV-positive partner, having anal sex without using a condom, being diagnosed with a sexually transmitted infection, or having any illicit drug use (eg, amphetamine-type stimulants); (5) able to understand, read, and speak Thai; and (6) either have not started PrEP (group 1: PrEP naive) or currently on PrEP but not adherent to PrEP (taking ≤3 pills/week) in the past month (group 2: PrEP users). Exclusion criteria are as follows: (1) in a mutually monogamous relationship of >6 months with a partner who recently tested negative for HIV, (2) a serious cognitive or psychiatric problem that would compromise the ability to provide informed consent, and (3) currently enrolled in another HIV intervention study.

Sample Size of Trial

We use PrEP adherence as a calculating variable, as it is a primary outcome. Using the G*power 3.2 program (2-tailed *t* test: “difference between 2 independent means” procedure), a set effect size of 0.80 (large), α=.05, power=0.80, and an allocation ratio of 2:1, the calculated sample size is 58, with 39 participants in the intervention and 19 in the control group. To detect a medium effect size in PrEP adherence (set effect size 0.50), a sample of 144 is required (96 participants in the intervention and 48 in the control group). Our proposed pilot RCT is not an efficacy study, and thus, it is not able to achieve full statistical power (to detect a small-medium effect size).

Recruitment and Enrollment Procedures

Young male clients presenting at the 2 study clinics will be prescreened by the clinic service staff based on the study’s eligibility criteria. Potential participants will be referred to trained research staff for more information and the informed consent process. After providing verbal informed consent, the research staff will determine if the youth meets the inclusion criteria. Those who have an HIV-negative status and meet the other inclusion criteria will be invited to join the study. Clinic staff will facilitate the PrEP evaluation, including anti-HIV testing. Those found to have a confirmed HIV-positive status will undergo an evaluation for antiretroviral therapy by clinic staff (standard of care will be provided for HIV-infected youth). The screening visit, enrollment, and baseline assessment should take place on the same day, or failing that, within 1 week. After signed consent is obtained, participants will be asked to provide a phone number or email address and contact information for a family member or friend who can be called in case the participant cannot be reached by phone, email, or text.

Ethics Approval

This protocol was reviewed and approved by the institutional review boards at the University of Massachusetts Chan Medical School in the United States (H00023523) and Chulalongkorn University in Thailand (Med Chula IRB 919/2564).

Results

Recruitment for this study began in January 2022 for phase 1. Qualitative interviews were completed with 30 YMSM and 5 clinical providers in May 2022. Qualitative data analysis has been completed, and the results were used to inform intervention adaptation and refinement. In phase 2, our team developed 2 motivational text message libraries, which contain nearly 100 motivational text messages; these messages were reviewed by the YAB and the investigator team for improvement and

XSL•FO
RenderX

refinement. Our team also developed a 2-session intervention (MES-PrEP) to promote PrEP uptake and adherence using the Computerized Intervention Authorizing Software (CIAS 3.0; Steven Ondersma). Individual YAB members completed one-on-one beta-testing of the intervention components and provided additional feedback to guide refinement. Phase 3, the pilot feasibility and acceptability trial, began in July 2023. The findings will be disseminated to stakeholders and communities of interest using peer-reviewed journals, academic conferences, and other communication channels.

Discussion

Expected Outcomes

We anticipate developing 2 integrated mobile interventions to improve PrEP uptake and adherence among YMSM in Thailand. YMSM are among the most at-risk groups for HIV transmission, yet PrEP use has been low, and adherence is often inadequate. Combining MES-PrEP and MTM may help increase the uptake of and sustained adherence to PrEP among HIV-negative Thai YMSM. We will evaluate the feasibility, acceptability, and preliminary efficacy of an mHealth intervention combining MES-PrEP and MTM. Based on our theoretical models of behavior change, we anticipate that the mHealth intervention will be found to be effective, but this is yet to be determined. Our study addresses major challenges related to PrEP use. If successful, this study will be among the first to identify an mHealth intervention for YMSM in Thailand toward improving PrEP use. Our research is integrated within Thailand's national HIV prevention effort. The commitment and ongoing involvement of the Institute of HIV Research and Innovation at a national level will allow this research to serve as a global model for HIV prevention among at-risk groups, especially for low- and middle-income countries.

Planned Next Steps

The project will be conducted to develop an integrated technology-based intervention for HIV-negative Thai YMSM and prepare for a future large-scale RCT. For a fully powered project, we would propose a multisite study to test the efficacy of MES-PrEP and MTM. We will adopt a type-2 effectiveness-implementation design with dual testing of the intervention's effectiveness in achieving the desired outcomes across the PrEP cascade. Additionally, we will gather information on the implementation of technology-based interventions, including cost analysis to assess the relative cost of implementing the intervention.

Conclusions

This study addresses a critical problem (high HIV incidence and low PrEP use) among an at-risk population (YMSM) in Thailand. We are developing 2 potentially synergistic technology-based, theory-driven interventions aimed at maximizing PrEP uptake and sustained PrEP adherence. Even though Thailand was involved in the world's first PrEP clinical trial (iPrEP) and several PrEP demonstration projects, PrEP uptake and adherence remain low in Thailand. Our study addresses major challenges related to PrEP use. It is responsive to the US Preventive Services Task Force's recommendations that call for research on methods to increase PrEP uptake and adherence [30]. If successful, this study will pave the way for the successful scale-up of PrEP implementation among MSM in Thailand.

Acknowledgments

This research project was funded by the National Institutes of Health (NIH) under grant R34MH124081 awarded to BW and NP. Our team would like to thank Dr Bonita Stanton for her very helpful input on the proposal. The content of this research is solely the responsibility of the authors and does not necessarily represent the official views of the NIH.

Data Availability

The data generated during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

BW, NP, and KM wrote the manuscript and designed the study protocol. BW, NP, KM, RJ, CR, ES, and SN are designing the intervention content. RJ led stakeholder engagement and focus groups. All authors provided input for the protocol design and reviewed the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Chronic pain and early cognitive decline, which are costly to treat and highly prevalent among older adults, commonly co-occur, exacerbate one another over time, and can accelerate the development and progression of Alzheimer disease and related dementias. We developed the first mind-body activity program (Active Brains [AB]) tailored to the needs of older adults with chronic pain and early cognitive decline. Results from our previous study strongly supported the feasibility of conducting AB remotely and provided evidence for improvements in outcomes.

Objective: We are conducting a single-blinded, National Institutes of Health stage-2, randomized clinical trial to establish the efficacy of AB versus a time-matched and dose-matched education control (Health Enhancement Program [HEP]) in improving self-reported and objective outcomes of physical, cognitive, and emotional functions in 260 participants. The methodology described in this paper was informed by the *lessons learned* from the first year of the trial.

Methods: Participants are identified and recruited through multidisciplinary clinician–referred individuals (eg, pain psychologists and geriatricians), the Rally Research platform, social media, and community partnerships. Interested participants complete eligibility screening and electronic informed consent. Baseline assessments include self-report, performance-based measures (eg, 6-min walk test) and objective measures (eg, Repeatable Battery for the Assessment of Neuropsychological Status). Participants are mailed a wrist-worn ActiGraph device (ActiGraph LLC) to passively monitor objective function (eg, steps) during the week between the baseline assessment and the beginning of the programs, which they continue to wear throughout the programs. After baseline assessments, participants are randomized to either AB or HEP and complete 8 weekly, remote, group sessions with a Massachusetts General Hospital psychologist. The AB group receives a Fitbit (Fitbit Inc) to help reinforce increased activity. Assessments are repeated after the intervention and at the 6-month follow-up. Coprimary outcomes include multimodal physical function (self-report, performance based, and objective). Secondary outcomes are cognitive function (self-report and objective), emotional function, and pain.

XSL•FO
RenderX

Results: We began recruitment in July 2022 and recruited 37 participants across 4 cohorts. Of them, all (n=37, 100%) have completed the baseline assessment, 26 (70%) have completed the posttest assessment, and 9 (24%) are actively enrolled in the intervention (total dropout: n=2, 5%). In the three cohorts (26/37, 70%) that have completed the AB or HEP, 26 (100%) participants completed all 8 group sessions (including minimal makeups), and watch adherence (1937/2072, 93.48%, average across ActiGraph and Fitbit devices) has been excellent. The fourth cohort is ongoing (9/37, 24%), and we plan to complete enrollment by March 2026.

Conclusions: We aim to establish the efficacy of the AB program over a time-matched and dose-matched control in a live video-based trial and test the mechanisms through theoretically driven mediators and moderators. Findings will inform the development of a future multisite effectiveness-implementation trial.

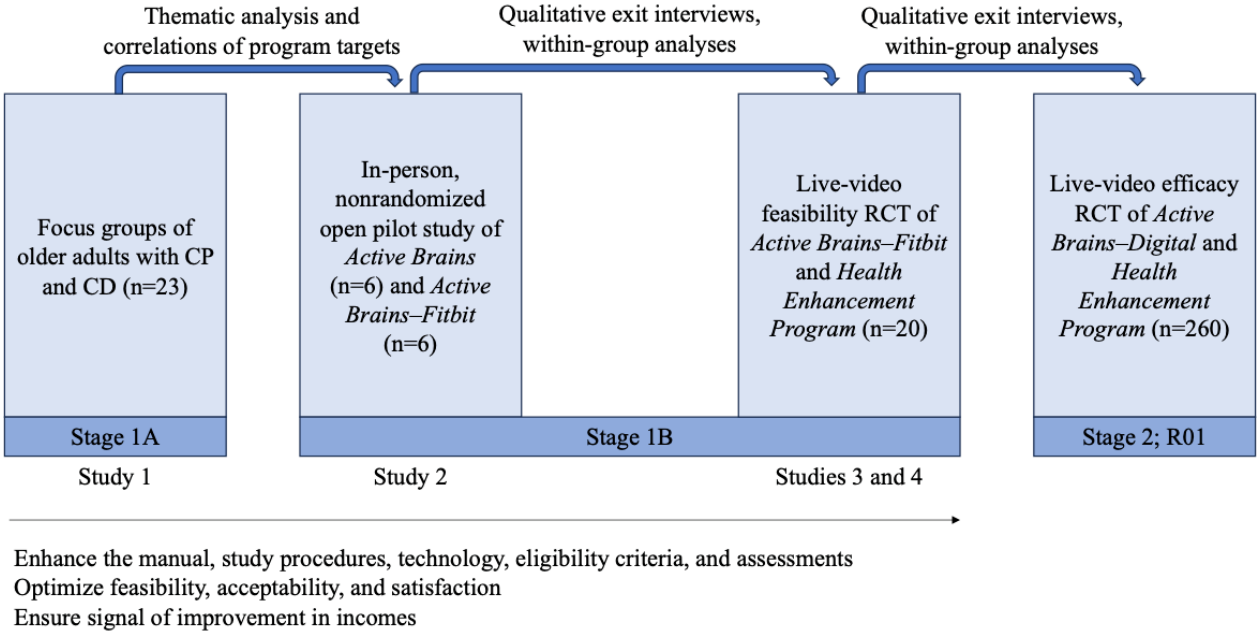
Introduction

Background



Chronic pain (CP; ie, pain lasting ≥3 mo) and early cognitive decline (ECD; ie, subjective cognitive decline [1] or mild cognitive impairment [2]) commonly co-occur among older adults. An estimated 60% to 75% of people aged >65 years report at least some persistent pain [3]. Older adults with CP are twice as likely to also report ECD [4,5]. The presence of both CP and ECD has an even greater negative impact on older adults' physical and emotional functioning than either of these conditions separately [6]. Pain impairs cognitive function, accelerates ECD, and is a modifiable risk factor for developing Alzheimer disease and related dementias [5,7]. In contrast, ECD alters pain perception, reduces treatment compliance, and increases the risk for subsequent disability [8]. Consequently, older adults with CP along with ECD (CP-ECD) can become caught in a *disability spiral* whereby cognitive, physical, emotional, and social functioning are interrelated and progressively worsen over time [9,10]. Addressing this comorbidity in the ECD stage is an unexplored opportunity to stop the disability spiral and potentially slow the transition toward dementia.

The current model of treating the CP-ECD comorbidity is incomplete [11]. Medications have limited efficacy [11-15], increase the risk of adverse events such as falls [16], and have harmful side effects that can impair cognition [17]. Walking interventions provide a safe, nonpharmacological alternative for older adults [18,19], with benefits for both CP and ECD [20-22]. However, older adults with CP-ECD face numerous barriers to walking, including pain misconceptions (eg, *hurt equals harm*), maladaptive thoughts (eg, fear avoidance and pain catastrophizing), and rigid regimens (eg, interferes with life and very difficult to implement) [23-26]. Mind-body interventions can directly address these barriers to sustained walking by teaching evidence-based skills (eg, diaphragmatic breathing and mindfulness exercises) to manage CP-ECD and engage in values-based activities. Older adults have increasingly embraced technologies for health care (known as *digital health*), in part owing to the COVID-19 pandemic [27]. Digital health technologies can enhance the delivery, accessibility (eg, live video), and reinforcement of mind-body interventions (eg, Fitbit [Fitbit Inc] reinforcement of walking goals) to address the CP-ECD comorbidity.

Our interdisciplinary team has iteratively developed the first web-based, mind-body activity program (Active Brains [AB]) aided by a Fitbit to address the CP-ECD comorbidity among older adults [28]. We followed the National Institutes of Health (NIH) Stage Model [29] and used mixed methods to develop and iteratively optimize the program (Figure 1). We conducted and published the following: (1) qualitative focus groups to understand the needs of older patients with CP-ECD and develop AB [28] (NIH stage 1A); (2) a nonrandomized open pilot study with exit interviews to test the feasibility, satisfaction, and preliminary improvements of AB delivered in-person [30] (NIH stage 1A); (3) adaptation of study procedures for fully remote delivery of AB in response to patient preferences and COVID-19 [31] (NIH stage 1A); and (4) a single-blind feasibility randomized clinical trial (RCT) of AB versus an attention-matched education control (Health Enhancement Program [HEP]), both delivered via live video (NIH stage 1B). Results supported the feasibility, acceptability, credibility, satisfaction, and adherence regarding the web-based AB program and study procedures. Signals of improvement were stronger for AB than for the control in multimodal physical function (step count and self-report) and cognitive function (objective cognitive test and self-reported ECD), emotional function (anxiety), pain intensity, and hypothesized mechanistic targets (mindfulness, coping, catastrophic thoughts about pain, and self-efficacy).

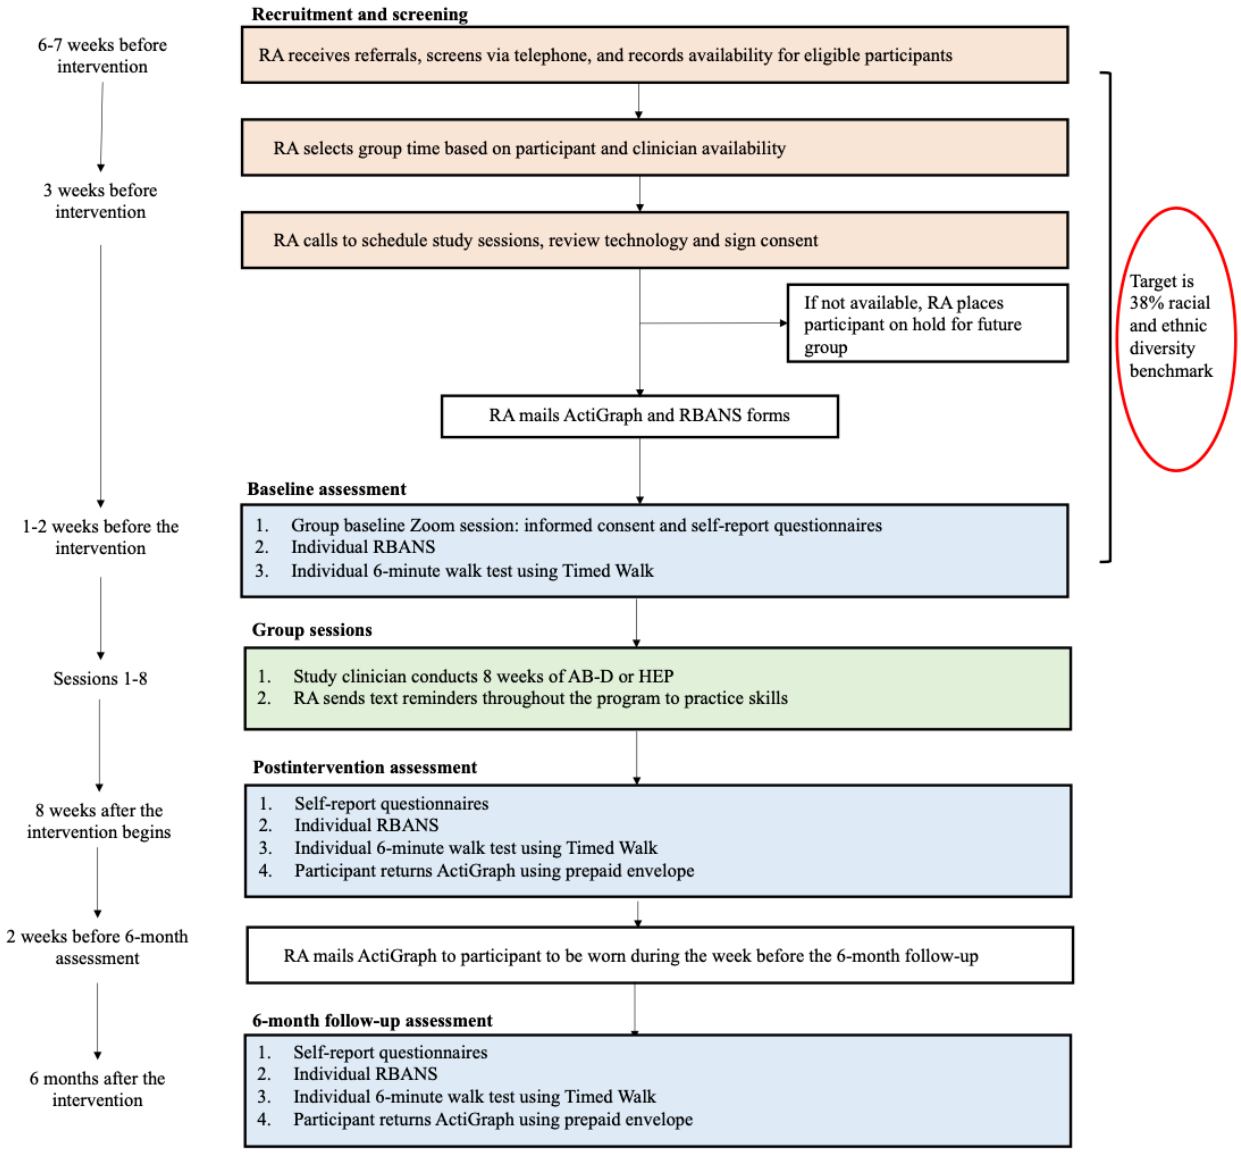
Figure 1. Iterative stages of Active Brains intervention development. The study described in this paper was informed by studies 1 to 4 shown in the figure. CD: cognitive decline; CP: chronic pain; R01: 1R01AG075899-01; RCT: randomized clinical trial.

Objectives

Building on our promising feasibility RCT, we are conducting a web-based RCT of AB versus an attention-matched education control (HEP) in a fully powered study of older adults with CP-ECD (N=260). Randomization is stratified according to ECD type (subjective vs mild cognitive impairment). Our RCT aims to determine the following: (1) efficacy of AB versus HEP on multimodal physical function (coprimary outcomes), cognitive function, emotional function, and pain intensity (secondary outcomes); (2) sustainability of improvements through 6-month follow-up; and (3) mediators (nonadaptive coping, adaptive coping, social factors, and compensatory strategies) and moderators (ECD type, demographics, and clinical variables) of improvement in coprimary and secondary outcomes. To address the lack of diversity in our pilot studies (100% of participants were White) [28,30], our goal is to recruit >38% ethnoracially diverse older adults to align our sample with the US distribution [32]. In this protocol paper, we have described the enhanced methodology, manualized treatments, outcome assessments, current recruitment, and *lessons learned* from the ongoing RCT so far. AB has the potential to be the first evidence-based program for older adults with CP-ECD, with important implications for the prevention of dementia in this high-risk population.



Methods

Overview

We are conducting this single-blind, NIH stage-2, fully powered, parallel-group efficacy RCT of the AB intervention versus the HEP control at the Massachusetts General Hospital (MGH). Figure 2 depicts the study flow and procedural timeline. We followed live video and technology guidelines for older adults with CP and ECD from our previous protocol [31].

Ethical Considerations

The Mass General Brigham institutional review board (IRB) approved all the study procedures (2021P002811).

Participants

Participants are older adults (aged ≥59 y) with self-reported, nonmalignant, musculoskeletal CP (≥3 mo) and ECD (subjective or mild cognitive impairment). Textbox 1 reports full details about the inclusion and exclusion criteria. These eligibility criteria were informed by similar mind-body trials for CP [33,34] and were refined through our previous AB studies [28,30,31,35]. We included older adults with both ECD types (subjective and mild cognitive impairment) because (1) both types increase the risk for dementia among people with CP [7]; (2) our pilot studies included both ECD types, and we did not observe differences in outcomes or skills use [30,35]; (3) it increases generalizability; and (4) it can help to test moderation by ECD type in this fully powered trial.

XSL•FO
RenderX

Textbox 1. Study eligibility criteria and rationale.

Inclusion criteria and rationale

- Aged ≥59 y—population under study
- Have self-identified nonmalignant chronic pain for >3 mo—International Association for the Study of Pain criteria [36]
- Early cognitive decline (subjective or mild cognitive impairment)—both are comorbid with chronic pain and are precursors to dementia
- Telephone Interview for Cognitive Status [37] to confirm the absence of severe cognitive decline that would preclude them from meaningfully engaging with the study
- Functional Activities Questionnaire [38] score <9—to ensure that participants are able to meaningfully engage with the program
- Able to perform a 6-min walk test at an accelerated pace—the Active Brains intervention will involve increasing the number of steps for the coprimary physical function outcome measure
- English fluency and literacy—all measures are validated for use in English
- Ability and willingness to participate and use an ActiGraph watch and smartphone app—the study involves use of multiple technologies, and all participants will receive technological support, but the study requires willingness to learn
- Free of concurrent psychotropic or pain medication for at least 2 wk before initiation of treatment or stable on current psychotropic or pain medication for a minimum of 6 wk and willing to maintain a stable dose—changing pain or psychotropic medication introduces an additional intervention that may act as a third variable

Exclusion criteria and rationale

- Diagnosed with dementia or another neurodegenerative disease—these individuals would require a different intervention
- Diagnosed with a medical illness expected to worsen in the next 6 mo (eg, malignancy)—a serious medical illness may act as a third variable
- Active, untreated serious mental illness or substance use disorder—participant safety
- Current, active suicidal ideation—participant safety
- Started a regular mindfulness practice of ≥45 min/wk in the past 6 wk—treatment involves mind-body techniques, and recent initiation of practice would introduce confounds
- Started a course of cognitive behavioral therapy in the last 3 mo—treatment involves cognitive behavioral skills, and recent initiation of treatment would introduce confounds
- Regular use of a digital monitoring device to monitor step count—treatment confound
- Engage in regular exercise for >30 min/d—treatment confound
- Not at risk for falls assessed by the Stopping Elderly Accidents, Deaths, and Injuries Three Key Questions [39,40] or self-reported clearance by a physician for engaging in light physical activity—to ensure the safety of participants

Recruitment and Screening

We began recruiting participants in July 2022. Older adults with self-reported ECD and CP are recruited from MGH clinics (Pain Clinic, Memory Unit, Multicultural Alzheimer Prevention Program, and Geriatric Medicine Unit) through multidisciplinary clinician–referred individuals (ie, pain psychologists and geriatricians), by distributing our IRB-approved study flyer through hospital-wide emails via the Rally Research web-based platform, and via social media. Our entirely web-based trial enables us to recruit from the local community and nationally (eg, memory cafes and organizations for older adults). Research assistants log all incoming referred individuals in a REDCap (Research Electronic Data Capture; Vanderbilt University) database (for storing protected health information) and a recruitment log (for tracking the flow of referred individuals and contact attempts). Research assistants conduct individual phone screening to provide study details and determine eligibility. We embedded an R code in the recruitment flyer that allows referred individuals to complete the initial eligibility screening on their own via a simple REDCap checklist. Research assistants answer questions about the study and collect information about availability with all eligible referred individuals. Self-reported CP and ECD are confirmed by referring clinicians and a review of the patient's medical records when available. Referred individuals that do not meet the study criteria are offered a resource sheet for CP and ECD developed for older patients. The principal investigator confirms all the screening before enrollment and consults with the interdisciplinary team of psychologists, neuropsychologists, and geriatricians as needed.

Inclusion of Ethnoracially Diverse Older Adults

Our team developed strategies to increase the recruitment and retention of ethnoracially diverse older adults. We included recruitment sites within our institution that serve ethnoracially diverse older patients, including the Multicultural Alzheimer Prevention Program and Senior Health. We have consulted with the MGH Community Access, Recruitment, and Engagement Center about a variety of outreach strategies, which include community talks and presentations, tabling, health fairs, individual meetings, and events. We are prioritizing the recruitment of ethnoracially diverse older adults by using recommendations from the literature. These include, but are not

XSL•FO
RenderX

limited to, the following: (1) developing culturally sensitive and inclusive study materials, (2) exercising flexibility in scheduling and emphasizing study resources to reduce barriers to participation, (3) asking trusted clinicians (ie, physicians, nurses, social workers, psychologists, and medical assistants) and community members to introduce the study to patients, (4) training the staff on culturally sensitive communication and recruitment strategies that focus on building trust and rapport, (5) prioritizing approaching all ethnoracially diverse older patients who present to recruitment sources as feasible, (6) inviting family into the decision-making process and to support participation (eg, reinforce attendance and troubleshoot technology), (7) addressing the stigma associated with CP and ECD, (8) providing tablets and smartphones with data plans to older adults who do not have them, (9) providing one-on-one training to learn technology, and (10) increasing the diversity of study staff [41-45]. If needed, we will expand recruitment to satellite clinics (MGH Dimmock, Chelsea, Revere, and Waltham) and the Boston Medical Center Pain Clinic.

Assessments and Enrollment

Informed Consent and Mailing of Study Materials

After recruiting at least 8 eligible participants (ie, the minimum threshold to start forming a round of groups), research assistants contact each participant to coordinate the informed consent process and mailing of study procedures. A total of 3 weeks before the first AB or HEP session, research assistants conduct 30-minute Zoom (Zoom Video Communications) meetings with participants to: (1) review and sign the electronic consent form, (2) test Zoom and eliminate barriers to web-based participation, (3) download the Timed Walk app [46] (to self-administer the 6-min walk test), (4) schedule the baseline assessments, (5) assess delivery preferences (timing, email, or SMS text) for receiving daily study reminders, (6) collect an address to mail the study materials, and (7) identify a friend or family member to troubleshoot technology if needed. After consent, a research assistant mails the following to each participant: (1) a study welcome letter, (2) a complementary pen and magnet with the study logo and contact information, (3) Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) Update [47] cognitive assessment forms, and (4) a wrist-worn ActiGraph wGT3X-BT (ActiGraph LLC) [48,49] watch and materials (user-friendly instructions and charger) for blinded step count assessment. We provide tablets (to sync watches, respond to surveys, and attend the AB or HEP sessions) to promote equitable participation of older adults who do not own these devices. These participants receive an additional tutorial with a research assistant to set up their tablet. Participants are instructed to leave the study package unopened until the group, baseline assessment Zoom session. So far, all participants have provided informed consent, and all study procedures have been conducted in accordance with our IRB-approved protocol.

Assessments

We selected measures based on the Initiative of Methods, Measurement, and Pain Assessment in Clinical Trials [50] and International Classification of Functioning [51] guidelines for CP clinical trials, our conceptual model [10,52-55], and previous AB studies [28,30]. All outcome measures are assessed at baseline, after the intervention, and at 6-month follow-up. Table 1 reports details about the measures, organized according to construct.

XSL•FO
RenderX

Table 1. Study measures and constructs.

Categories and subcategories	Time points
Demographic factors	
Date of birth, gender, weight, height, handedness, race or ethnicity, marital status, education level, employment status, income, and concurrent medical therapies	Baseline
Clinical factors	
Type of ECD[a] (subjective or objective), pain diagnoses, pain location, length of chronic pain, comorbid medical conditions, current and history of mental health conditions, current pain medication, current memory medication, and current treatments (eg, physiotherapy and occupational therapy)	Baseline
Coprimary outcomes	
Accelerometer (wrist-worn ActiGraph wGT3X-BT)—measures 7-d average step count [48,49]	Baseline, after the intervention, and 6-mo follow-up
6-min walk test using the Timed Walk app—measures the distance walked in meters at a fast pace for 6 min using smartphone GPS [46]	Baseline, after the intervention, and 6-mo follow-up
PROMIS[b] (version 1.2.8b)—measures the level of difficulty with daily function [56,57]	Baseline, after the intervention, and 6-mo follow-up
Secondary outcomes	
Repeatable Battery for the Assessment of Neuropsychological Status—measures 5 cognitive domains (immediate memory, visuospatial and constructional, language, attention, and delayed memory) and global cognition [47]	Baseline, after the intervention, and 6-mo follow-up
Everyday Cognition Scale—measures self-reported cognitive functioning by comparing current performance on cognitive tasks with that a decade ago [58]	Baseline, after the intervention, and 6-mo follow-up
PROMIS Depression (version 1.0.8b)—measures negative mood, views of self, engagement in daily living, and social components [59]	Baseline, after the intervention, and 6-mo follow-up
PROMIS Anxiety (version 1.08a)—measures fear, worry, hyperarousal, and somatic symptoms [59]	Baseline, after the intervention, and 6-mo follow-up
Numerical Rating Scale—measures pain intensity at rest and during activity during the past week [60]	Baseline, after the intervention, and 6-mo follow-up
PROMIS Pain Interference (version 1.0.8a)—measures the consequences of pain on relevant aspects of life, including social, cognitive, emotional, physical, and recreational activities [56,61]	Baseline, after the intervention, and 6-mo follow-up
The Pain, Enjoyment of Life, and General Activity Scale [62]—measures pain intensity and pain interference in the past week	Baseline, after the intervention, and 6-mo follow-up
Mechanisms	
Quota-based pacing—measures the perceived use of quota-based activity pacing using a 4-item scale adapted from the Activity Pacing Questionnaire [63]	Baseline, after the intervention, and 6-mo follow-up
Memory Compensation Questionnaire—measures the use of cognitive compensatory strategies for actual or perceived memory loss [64,65]	Baseline, after the intervention, and 6-mo follow-up
Pain Catastrophizing Scale—measures hopelessness, helplessness, and rumination about pain [66]	Baseline, after the intervention, and 6-mo follow-up
Tampa Kinesiophobia Scale—measures the fear of activity owing to pain or injury [67]	Baseline, after the intervention, and 6-mo follow-up
Pain Self-Efficacy Questionnaire—measures self-efficacy for performing activities of daily living despite pain [68]	Baseline, after the intervention, and 6-mo follow-up
Self-Compassion Scale—measures self-compassion in the face of stressors or challenges [69]	Baseline, after the intervention, and 6-mo follow-up
Measures of Current Status—measures the ability to engage in a series of general coping skills (eg, relaxation, being aware of tension, expressing needs, confidence in coping, and assertiveness) [70]	Baseline, after the intervention, and 6-mo follow-up
Gratitude Questionnaire—measures the ability to experience gratitude daily [71]	Baseline, after the intervention, and 6-mo follow-up
Toronto Mindfulness Scale—measures self-reported state-level mindfulness [72]	Baseline, after the intervention, and 6-mo follow-up
Exploratory	

XSL•FO
RenderX

Categories and subcategories	Time points
Global Cognitive and Social Engagement—measures the perceived engagement in mentally stimulating social and cognitive activities (involving meaning, learning, challenge, and creativity) and passive activities (eg, watching television)	Baseline, after the intervention, and 6-mo follow-up
NIH[c] Toolbox Loneliness Fixed Form Age 18+ (version 2.0)—measures the perception that one is alone, lonely, or socially isolated from others [73]	Baseline, after the intervention, and 6-mo follow-up
PROMIS Satisfaction with Social Roles and Activities (version 2.0.8a)—measures satisfaction with social roles and responsibilities [74]	Baseline, after the intervention, and 6-mo follow-up

[a]ECD: early cognitive decline.

[b]PROMIS: Patient-Reported Outcomes Measurement Information System.

[c]NIH: National Institutes of Health.

[d]OQ: Outcome Questionnaire.

Self-Report Measures

Participants complete the self-report measures via the web-based REDCap platform during a 60-minute group assessment via Zoom. In our previous AB studies, we learned that group assessments allow our research assistants to efficiently provide technical support with Zoom (eg, connectivity issues) and REDCap (eg, accessing or responding to survey questions) for multiple participants simultaneously. To encourage focus and privacy during the self-reports, the Zoom host mutes all participants and asks them to use the chat or *raise hand* function for help. After completing the surveys, participants have the option of remaining on the call to receive additional technological support from the research assistants. Research assistants review all self-reports for missing data and errors that were not prevented by the REDCap response validation features.

ActiGraph wGT3X-BT

During the group baseline (1-2 wk before the first session), participants open their study package and place the ActiGraph watch on their nondominant wrist to measure step count. Participants are instructed to wear the ActiGraph watch daily (except when bathing) until 1 week after the intervention. Participants sync (using the CentrePoint smartphone app) the watch daily and charge weekly. The research assistants review tips to care for their ActiGraph watch, address common misconceptions (eg, no GPS tracking or on or off switch), and encourage them to contact the study staff for technical support. ActiGraph wGT3X-BT is widely used [49] to measure step count and has demonstrated validity in older adults [76]. Participants receive and wear the ActiGraph watch for 1 more week at the 6-month follow-up and return it in a prepaid envelope.

We estimate an average 7-day step count for each participant, measured by ActiGraph wGT3X-BT at baseline, after the intervention, and at 6-month follow-up using an established protocol [30,34,35]. First, we exclude nonwear (no data) or invalid wear days, which is defined as less than 7 hours of wear time during waking hours [77,78]. Next, we exclude the highest and lowest step-total days to prevent very active or inactive days from skewing average step counts. Finally, we average the remaining valid days (minimum days to calculate average count=3).

RBANS Assessment

After the group assessment, participants complete an individual 30-minute RBANS cognitive assessment with trained clinicians via Zoom. The clinician confirms that participants have received the testing materials (RBANS figure copy and coding sheets) and have secured an ideal testing environment. This includes (1) stable connectivity, (2) full-screen Zoom on a tablet or laptop (no smartphone), (3) clear audio, (4) no environmental (phone is silenced and no background activity) distractions, (5) proper lighting, (6) flat surface to write, (7) screen-sharing capability, and (8) privacy for the duration of the test. Following the established telepractice guidelines [79], the clinician shares their screen to show the stimulus book, takes screenshots for scoring, and instructs participants to mail written items (figure drawing and coding) in a prepaid envelope.

The 6-Minute Walk Test

After completing RBANS, the clinician instructs the participant to complete the 6-minute walk test outside, on flat terrain using Timed Walk. Timed Walk is a GPS-enabled smartphone app, which enables users to measure walking distance within a fixed time frame. The 6-minute walk test performed using Timed Walk is a valid performance-based measure of physical function and presents a reliable alternative to traditional laboratory assessments [46]. The assessment period is complete once the participants call the research assistant with their 6-minute walk test score.

Randomization

A week before the first AB or HEP session, research assistants randomize and enroll participants via phone. Participants are randomly assigned in a 1:1 ratio to AB intervention or HEP control to ensure comparability between groups. The unblinded study biostatistician created the randomization schedule with permuted blocks of random sizes and implemented it in REDCap. Randomization is stratified according to ECD type (subjective vs mild cognitive impairment). To maintain single-arm blinding, study staff and materials refer to AB and HEP as AB1 and AB2, respectfully. Without unblinding, research assistants notify each participant about their group assignment, schedule weekly session times, and provide links to the AB or HEP websites. Research assistants review expectations for attending the group sessions, including the

XSL•FO
RenderX

following: (1) timeliness, (2) quiet location, (3) respectfulness of others, (4) no multitasking, (5) wearing the watch, (6) having a pen and the manual ready, and (7) responding to daily smartphone surveys to complete home practice. The research assistant mails a printed copy of the program manual to be received by participants before the first group session. Participants in the AB arm receive a Fitbit to wear, starting after session 1 to ensure that step count assessment remains blind in both groups. Participants are considered to be enrolled after completing session 1 of the AB or HEP arms.

Treatment Arms

Overview

We iteratively developed AB and HEP for the specific needs of older adults with CP-ECD through our previous studies [28,30,31,35]. The control (education only; no skills) is dose-matched and time-matched to the intervention. Both treatment arms are group-based and the intervention is delivered by trained clinicians over 8 weeks (90-min sessions) in addition to patients' usual care. Participants receive both a paper copy of the structured treatment manual and access to a digital copy through the program website. Both manuals refer to ECD as *memory-related problems* because it was preferred by patients who participated in our qualitative focus groups to develop AB. Participants are encouraged to take notes in the treatment manuals during the sessions and for home practice to promote comprehension and retention. Treatment completers are those who complete a minimum of 6 out of 8 sessions. If participants are unable to attend a session, they are offered a 15-minute makeup with the clinician via Zoom to review missed content and address adherence barriers as needed.

AB Intervention

Overview

The AB intervention is a multimodal walking program informed by the fear-avoidance model [10]. It integrates relaxation response [52], mindfulness [53], pain-specific cognitive behavioral [54], and operant and physical restoration elements [55]. AB teaches skills to break the *disability spiral* of worsening cognitive, physical, emotional, and social functioning in response to comorbid CP and ECD [9,10]. AB skills include the following: (1) *walking skills* to gradually increase step count through individualized quota-based pacing and goal setting reinforced by a digital monitoring device (Fitbit) linked to valued activities; (2) *mind-body skills* to reduce reactivity to pain or cognitive symptoms through diaphragmatic breathing, body scanning, and mindfulness exercises; (3) *pain-cognition-behavior* awareness skills to educate on myths about CP and ECD and understand the disability spiral; (4) *cognitive functioning skills* to develop cognitive compensatory strategies and increase intellectual stimulation; and (5) *social-emotional functioning skills* to cope with stress or setbacks and increase social factors (obtaining social support and decreasing isolation) through self-compassion, gratitude, and acceptance (Table 2). The goal is to provide patients with coping skills to manage pain and develop compensatory strategies to improve their physical, cognitive, and emotional function.

Table 2. Session outline for the Active Brains (AB) intervention and Health Enhancement Program (HEP) for older adults with chronic pain (CP) and early cognitive decline.

Session	AB topic	AB skills and session content	HEP topic	HEP session content
1	Taking charge of pain and MRP[a]	Deep breathing	Program overview and CP and MRP	Program goals, understanding CP and MRP, how CP and MRP are connected, and the impact of stress

[a]MRP: memory-related problem.

[b]Stop, Take a breath, Observe with curiosity, Proceed mindfully.

In each session of AB, the clinician and participants review previous session material, discuss home practice, solve barriers, learn educational material, practice program skills and apply them to participants' daily lives, and create an individualized walking plan (eg, "I will walk to the park once per day while calling family then do housework until I hit my daily goal of

XSL•FO
RenderX

1,200 steps.") to achieve their step goal. For home practice, participants execute their walking plan, practice skills for at least 5 minutes per day, and log their adherence via daily SMS text messages sent from Twilio [80]. Participants are encouraged to regularly visit the program website to watch videos that explain core concepts (eg, disability spiral and myths about pain) and listen to clinician-guided recordings of mindfulness skills.

Fitbit and Quota-Based Pacing

Participants randomized to the AB group receive a Fitbit Inspire [81] to wear from the first session through the 6-month follow-up. Fitbit is a user-friendly and commercially available activity watch that enables participants to monitor (updated step count data on the wrist and Fitbit app) and reinforce (motivating reminders to walk and notifications when step goals are achieved) their daily walking. The AB treatment manual contains written instructions and a tutorial video about wearing, charging, and syncing Fitbit daily. Informed by our internal testing, we instruct participants to wear Fitbit on the nondominant wrist below ActiGraph wGT3X-BT and remove Fitbit during activities with repetitive arm movement (eg, gardening and washing dishes) to prevent step count overinflation. To justify wearing 2 activity watches, we explain that ActiGraph is for the research-grade assessment of step count and Fitbit is to reinforce their quota-based pacing plan.

AB participants are taught to increase their daily step count gradually and safely by following evidence-based guidelines for quota-based pacing [55,82]. The research assistant sets each participant's initial goal by calculating a truncated average (removing the highest and lowest observation) step count for valid days (≥7 h/d) measured by Fitbit Inspire during the week after session 1. Each subsequent week, the research assistant updates AB participants' step goal by calculating a weekly truncated average using Fitbit Inspire data synced via the Fitabase web-based platform [83]. AB participants (1) increase their goal by 10% if they achieve their goal, (2) reattempt their goal if they did not achieve their goal for 1 week, or (3) decrease their goal by 10% to 20% if they did not achieve their goal for 2 weeks. Clinicians guide participants in applying AB skills to make the patient's walking plan noncontingent on CP and ECD symptoms or other barriers to achieving their step goal (eg, weather and time). Research assistants routinely monitor ActiGraph and Fitbit adherence using CentrePoint [84] and Fitabase [83] web-based dashboards, respectively. Participants with 24 hours of nonadherence are contacted for reminders and troubleshooting as needed.

Improvements to AB for This Trial

We refined AB based on the results of our pilot feasibility RCT and feedback from participants during exit interviews [35]. First, we streamlined the content in our treatment manual to focus more directly on walking and mindfulness skills. In the updated manual, walking is emphasized as the primary target of AB, and mindfulness is described as a tool to improve coping and support increased activity. Second, we replaced Specific, Measurable, Attainable, Realistic, and Timed (SMART) goals with a simplified walking plan based on feedback from participants stating that the acronym overcomplicated weekly walking goals. Third, we restructured the intervention sessions to incorporate more guided mindfulness practices to support learning before home practice. Similarly, we added structured check-ins at the beginning and summaries at the end of each session to consolidate learning, solve challenges with participants, and encourage skills practice. Fourth, we added information about ActiGraph (for research) and Fitbit (for tracking the daily step goal) to help participants understand the differences between the 2 devices. Fifth, we selected a large font and used a white background with black and dark blue text to maximize contrast, to make the manual more readable for older adults [85]. Sixth, we removed scientific jargon, explained key terms (eg, mindfulness, CP, and ECD) with patient-friendly language, and added figures (eg, to validate that CP-ECD can feel similar to *climbing a mountain* but that gaining AB skills along the way can help). We revised both patient and clinician manuals to ensure that the AB skills are taught to encourage understanding of language in the study outcome measures. Finally, we created animated videos to support the learning of program skills and linked these via a program website throughout the manual.

HEP Education Control

Our previous study provides full details about HEP [31]. Briefly, this time-matched and dose-matched attention control accounts for the effects of time spent, feedback, and support from the study clinician and other group members. It consists of lifestyle education consistent with public health recommendations and standards for health promotion (eg, physical activity, sleep, nutrition, healthy weight, and medical appointments). Our team has successfully used HEP as an active control in multiple previous studies [86-88]. We adapted HEP to include population-specific information about CP and ECD symptoms. Consistent with a similar efficacy trial [89], the HEP participants are instructed to journal for 5-10 minutes per day to match the dose of mind-body skill practice in the AB intervention.

Population-Specific Technology Considerations

Overview

Our web-based trial implements several technological solutions to improve the experience of older participants in our study. The treatment arms are delivered via Zoom, which overcomes cost, transportation, and scheduling as important barriers to care in this population. The ActiGraph watch continuously and passively collects step count, which reduces the burden of assessments. Walking goals are reinforced in real time via Fitbit, which addresses difficulty in planning and initiating behavior change with CP and ECD. To bypass ECD symptoms (ie, forgetfulness, distractibility, and difficulty in planning), participants receive SMS text messages to attend sessions, practice program skills, record home practice, and self-monitor pain interference with daily activities. During enrollment, research assistants help AB participants install a shortcut to our program website on their smartphones to easily access clinician-guided recordings of all mindfulness skills. Our pilot study showed that older adults with CP and ECD benefited from and could use these technologies with high feasibility, acceptability, and satisfaction [35].

XSL•FO
RenderX

Our previous study [31] describes our protocol for teaching older adults about technologies based on the National Council on Aging guidelines [90]. During enrollment, research assistants assess participants' familiarity with technology (eg, experience with Zoom and devices owned), identify individual preferences for remote communication (eg, SMS text, email, or phone), and develop individualized support plans (eg, specific family members who can help). During training sessions, research assistants clarify the value and rationale of each technology, allow time for experimentation, and avoid common pitfalls for communicating with older adults (eg, speaking very loudly or slowly). Our qualitative study has revealed that scheduled, individualized learning sessions; frequent encouragement; and on-call technical support help older participants overcome any initial lack of technological readiness [35].

Informed by *lessons learned* from our pilot RCT, we refined our procedures to further improve participants' experience with technology. First, we streamlined the written materials in the manual and before-treatment packet on wearing, syncing, and charging the watches. Second, we created a demonstration video about wearing and caring for the watches that participants could easily access on the program website. Third, we increased the involvement of family members and friends to help participants troubleshoot challenges with Zoom, email, and responding to SMS text message surveys. Fourth, participants can receive in-person device setup and training with a research assistant during the baseline period (US $10 is provided for travel). Fifth, participants are encouraged to contact the research assistant with technology-related questions and are offered one-on-one appointments when more extensive troubleshooting or training is required.

Treatment Fidelity

We follow the NIH Science of Behavioral Change guidelines to support treatment fidelity [91]. We have developed structured manuals and standard operating procedures that we revised based on the lessons learned after our feasibility pilot study of AB [35] and similar efficacy trials [86]. All study staff meet weekly to discuss participant progress through the study, including session attendance, watch use, home practice adherence, and any deviations from the treatment protocol. All study clinicians are Doctor of Philosophy level clinical psychologists and doctoral-level trainees. The clinicians are directly supervised by the project manager who has extensive training in geriatrics, CP, and mind-body treatments. Following a standardized training protocol, clinicians read selected papers about treating CP and ECD in older adults, listen to audio recordings of the sessions, rehearse the clinician manuals, and colead with a senior clinician before running their first group. Clinicians receive training about adherence to the treatment manual, completion of study forms, assessing participant comprehension, and monitoring the use of skills. During weekly in-person supervision, the clinicians receive feedback about protocol adherence, specific participant or group concerns, and session preparation. All sessions are audio recorded. Clinicians record participant attendance and complete checklists of the content delivered. We will randomly select up to 20% (approximately 40) of these checklists to review. Independent coders will assess each session against a coding scheme to evaluate protocol fidelity, with attention to coder discrepancies. Home practice (eg, step count and skills used) is tracked automatically and reviewed during weekly supervision.

Data Analytic Plan

Power Analysis

Our blinded statistician used SAS (version 9.4; SAS Institute) [92] for the power analysis. Our primary outcome requires clinically important improvements in both functional measures (step count and 6-min walk test) and patient-reported outcome (Patient-Reported Outcomes Measurement Information System Physical Function). Allowing for 20% dropouts, 260 participants recruited (130/group; 104/group completing the study) would provide 92.3% power (Cronbach α=.05; 2 sided) to detect the minimum clinically important difference in step count (1000 steps) [93,94] between the AB and HEP groups in the change from baseline to postintervention assessment. This assumes an SD of 2120, which is the upper 80% confidence limit for the SD observed in our pilot study, as recommended [95]. We also assume 50% correlation between preintervention and postintervention measures. This sample size provides 81.8% power for a difference of 54 meters (the minimum clinically important difference) [96] in the 6-minute walk test (SD 135 based on our pilot data) and >99.9% power for a difference of 5.48 points (minimum clinically important difference) [97] for the Patient-Reported Outcomes Measurement Information System Physical Function score (SD 7.61 based on our pilot data). Assuming a correlation of 0.5 between significant results of step count and 6-minute walk test, the power of the study would be 80.7% (based on simulations) of having a statistically significant result for all 3 coprimary end points.

Data Analyses

Overview

Our blinded statistician will conduct all data analyses using SAS (version 9.4) [92]. We will estimate treatment-dependent changes in primary (objective, performance-based, and patient-reported physical function) and secondary outcomes (patient-reported and objective cognitive function and emotional function). We will follow the intention-to-treat principle and include all randomized participants in our primary efficacy analyses. Data will be analyzed using a shared-baseline, linear mixed model with fully unstructured covariance among repeated measures. The shared-baseline assumption reflects the true state of the population before randomization and has the benefit of adjusting for chance differences at baseline. Linear mixed models with maximum likelihood estimation are unbiased when data are missing at random, conditional on the observed data. If loss to follow-up is strongly treatment-dependent (relative risk >2), we will use perturbed multiple imputation to assess the robustness of estimates from the primary model if data were missing in not-at-random manner.

Aim 1: Efficacy of AB (Baseline to Posttest Period)

We have already established the feasibility benchmarks of the intervention and control [28,30]; therefore, emphasis of this study is on establishing the efficacy of AB. Accordingly, the primary analysis will compare the changes in primary and

XSL•FO
RenderX

secondary outcomes (continuous measures) from baseline to posttest period between the randomized conditions. For each outcome, we will compare the effect of AB versus control on changes from baseline to the posttest period using linear contrasts. With 3 coprimary outcomes, no adjustment for multiple comparisons is needed; therefore, we will use 2-sided tests at $P<.05$ to declare the superiority of AB, maintaining an overall 5% type-1 error at our primary postintervention time point. The success of the trial will be declared if participation in AB is associated with statistically significant and clinically important improvement from baseline to posttest period over participation in control based on the 3 physical function outcomes.

We will conduct several sensitivity analyses to ensure that a conclusion about efficacy is robust to possible deviations from the assumptions of the primary model. Baseline parameters will be included to account for chance differences owing to randomization and to explain the sources of variation in response that are independent of treatment group. We will also use a Wilcoxon rank sum test comparing the change in scores between the 2 groups to avoid any parametric assumptions about the data. All secondary outcome measures will be analyzed using the same shared-baseline, linear mixed model and the same secondary sensitivity analyses. Step-down, Bonferroni-adjusted *P* values will be used to control for multiple comparisons regarding the secondary outcomes.

Aim 2: Sustainability of AB (Posttest Period to Follow-Up)

The same shared-baseline analyses will be used to determine durability (eg, changes between *after the intervention* and *6-month follow-up*) on the coprimary and secondary outcomes. Specifically, the persistence of a benefit from AB at 6-month follow-up will be estimated from linear contrasts of the postintervention period to 6 months least-square means and analyzed as a noninferiority test of durability. Noninferiority of AB in maintaining benefits relative to control will be declared if the lower 1-sided 95% confidence bound for a given coprimary outcome is less negative than each outcome's minimum clinically important difference in favor of control.

Aim 3: Mediation and Moderation

We will explore the extent to which treatment-dependent effects are associated with a priori–defined mediators and moderators. Mediation analyses of postintervention change scores will be conducted following a causal model [98] that extends traditional models for mediation [99,100]. The magnitude of the mediated effect will be estimated as the natural indirect effect, which includes effects mediated by an interaction between the treatment and the mediator [101,102]. This extends the traditional Baron and Kenny method and is equivalent to the analysis of Kraemer et al [103] for the linear models. Tests of significance for natural indirect effect estimates will use 2-tailed *t* tests based on SEs estimated using the delta method. Mediation tests will be conducted separately for changes in outcomes of physical, emotional, and cognitive function and pain intensity. The possible effect of moderators of a beneficial effect of AB will be investigated by adding moderator (eg, gender and subjective vs objective cognitive decline), moderator × treatment, and moderator × treatment × visit interaction terms to the repeated-measures analysis of variance described for aim 1.

Results

The study was funded by the National Institute on Aging in December 2021. The study was approved by the IRB on December 8, 2021. We began recruitment in July 2022. As of March 2023, a total of 201 individuals have been referred and all have been contacted. Of these 201 individuals, we screened 141 (70.1%) and enrolled 37 (18.4%) participants (n=18, 49% in AB and n=19, 51% in HEP) across 4 group cohorts (largest group: n=10, 27%). All (37/37, 100%) participants completed the baseline assessment. Of the 37 participants, 1 (3%) dropped after the first AB session owing to an unrelated psychiatric hospitalization and 1 (3%) dropped after the second HEP session owing to extreme orofacial pain. In the three cohorts (26/37, 70%) that have completed the AB or HEP, 26 (100%) participants completed all 8 of the group sessions (including minimal makeups) and the posttest assessment. Adherence has been high for the Fitbit and ActiGraph watches, with 93.48% (1937/2072) valid days of wear compliance for both devices across the 2 group cohorts. The fourth group cohort is ongoing (9/37, 24%). We plan to complete enrollment by March 2026 and data analyses by February 2027.

Discussion

Significance

Our single-blinded, NIH stage-2 RCT (N=260) is designed to test the efficacy, sustainability, and mechanisms of the AB program in improving self-reported and objective outcomes of physical, cognitive, and emotional function. We anticipate that the results will inform nonpharmacological interventions targeting CP and ECD in older adults. Although most nonpharmacological CP interventions address a discrete pain condition (eg, back pain), we developed our mind-body activity program to address issues that are common across all nonmalignant CP conditions. This is important because most older adults have ≥1 type of pain condition [104]. We are targeting people with both subjective and objective ECD because both are precursors of dementia [1], have similar symptom presentations, and require similar tailoring of skills [105,106]. Our web-based mind-body activity program is grounded in strong theoretical and empirical frameworks [10,52-54], combines mind-body skills with quota-based pacing and engagement in activities of daily living, is delivered in a group format to foster social support, and uses a pacing plan that is tailored to each individual. AB has been iteratively refined using the NIH Stage Model [29] guidelines; follows the Initiative of Methods, Measurement, and Pain Assessment [50] and International Classification of Functioning [51] criteria for CP clinical trials; and has demonstrated excellent feasibility markers and proof of concept [28,30]. The groups conducted so far, although preliminary, show high initial participant retention and adherence to both treatment arms and the study technologies.

This study addresses three key limitations of our pilot studies: (1) recruitment of ethnoracially diverse older adults (38% is the

XSL•FO
RenderX

benchmark [32]), (2) assessment of longitudinal follow-up (6 mo), and (3) enhanced methodology for blinded assessment (ActiGraph) and reinforcement (Fitbit) of our step count coprimary outcome. Testing AB versus the education control will yield critical information about the efficacy and durability of improving multimodal physical function in older adults with CP-ECD. We plan to assess the mechanisms for improving the coprimary physical function and secondary outcomes (cognitive function, emotional function, and pain intensity). We will test mediation through theoretically informed constructs (nonadaptive coping, adaptive coping, social factors, and compensatory strategies). We will also test moderation by type of ECD (subjective and objective) and relevant demographic and clinical variables. The results will inform future trials of AB and targets in psychosocial treatments for CP and ECD to optimize physical, emotional, and cognitive outcomes.

Limitations

Despite our emphasis on refining our RCT methodology, we anticipate several limitations. First, it is challenging to include ethnoracially diverse older adults in clinical trials at our academic medical center. We developed specific strategies to recruit and retain a diverse sample. However, this is our first attempt at implementing these strategies and building trust with new communities of potential participants. Despite plans for future translation studies, the programs are only available in English, which limits diverse groups from participating. Next, we have designed a more *digitally inclusive* trial by providing free tablets, watches, and smartphones with data plans and offering hands-on training to participants who do not have access to or are unfamiliar with these technologies. Some older adults may not be able to meaningfully participate in the web-based group program owing to significant visual, speech, or hearing impairment. In addition, wearing 2 watches may be a burden for some participants. We selected ActiGraph and Fitbit because there were no research-grade accelerometry watches that could remotely toggle between blinded assessment and real-time reinforcement of participants' step count. Our internal testing and the literature [107-109] show that Fitbit tends to overestimate step count relative to ActiGraph, which has made it challenging to set valid and meaningful quota-based step goals during the intervention. Finally, we risk unblinding participants who find our study on ClinicalTrials.gov [110] database or web-based publications.

Conclusions

We aim to establish the efficacy of the AB program over a time-matched and dose-matched control in a web-based trial. Our findings from this trial will be used to inform the development of a future multisite, hybrid, effectiveness-implementation trial. We hope to implement AB in routine care for older adults across medical settings and train different disciplines (eg, nurses, social workers, and peer coaches) to deliver it. We plan to culturally adapt the program, through collaborations with community partners, to increase the generalizability of the program and disseminate it to diverse older adults living in the community. AB has the potential to be an effective, low-cost, and sustainable treatment for older adults with CP-ECD, with important implications for the prevention of dementia in this high-risk population.

Acknowledgments

Abstract

Background: Aging workers constitute a growing population in many countries and form an indispensable and qualified resource, especially in the context of the labor shortage. Despite work's many benefits for individuals, organizations, and societies, it also presents several risks and challenges that may lead to occupational injuries. Thus, rehabilitation professionals and managers working with this emerging and unique clientele during their return to work after an absence often lack the tools and skills to support them, especially in the changing world of work that includes the rise of telework. Indeed, as an increasingly present work arrangement, telework has the potential to be used as an accommodation modality that can facilitate inclusion and healthy participation in the workplace. However, the implications of this topic for aging workers require study.

Objective: This paper presents the protocol of a study that aims to develop a reflective telework application guide to support the accommodation, inclusion, and health of aging workers after an absence from work. Specifically, this study will (1) explore the experience of aging workers, managers, and rehabilitation professionals regarding telework and its impact on accommodation, inclusion, and health; (2) use a validated logic model to design a reflective application guide; and (3) test and evaluate the guide.

Methods: Following a 3-phase developmental research design, individual interviews with aging teleworkers, managers, and rehabilitation professionals will enable the collection of qualitative data to be used in generating a logic model of levers and good practices, leading to the creation of a reflective application guide. Validation of this guide by workers and managers to measure its acceptability and applicability in daily life will precede its implementation.

Results: Data collection began in spring 2023 and initial results are expected in fall 2023. This study aims to generate a concrete tool—namely, the reflective telework application guide—that rehabilitation professionals could use to support managers and aging workers during their return to work through the healthy use of telework. All phases of the study include conducting dissemination activities to share the results of the project and increase its sustainability potential (ie, publication through social networks, podcasts, conferences, and scientific publications).

Conclusions: As the first of its kind, this project aims to produce innovative impacts at several levels, including practical, scientific, and societal impacts. In addition, the results will provide healthy solutions to the labor shortage in a changing world of work, where digital and teleworking are becoming increasingly important.

aging workers; health; intervention; qualitative research; telecommute; telework

Introduction

The number of aging workers (ie, aged 55 years or over [1]) is growing worldwide and forming an indispensable population contributing to economic life, especially in the context of a critical labor shortage. In Canada, this workforce represents more than one-third of the working-age population, almost 40% of whom are active in the labor market [2]. These are the highest proportions that the statistical account of work in Canada has noted. In the United States, the only group of workers on the rise since the mid-1990s are workers over the age of 55 years [3]. Moreover, they represent the group of workers that will grow the most by 2030 [4]. The European Union is also experiencing a similar situation, with a 17% increase in workers aged 55 to 64 years since 2009 [5].

This increase raises awareness of the importance of this group of workers who have specific characteristics differentiating them from other active generations at work. Indeed, this older generation of workers has distinctive values regarding work. For instance, older workers seem less likely than other generations to value the extrinsic advantages of work less than such intrinsic advantages as social contacts, challenges, and opportunities for responsibility [6]. In addition, some authors report that the baby boomer generation (ie, people born between 1946 and 1964 [7]) tends to show the greatest employer loyalty and a lower propensity than younger workers to leave their jobs [8]. These workers are also subject to particular representations by their younger colleagues. The results of a study on stereotypes of older workers show that others generally perceive them as more faithful but less likely to be fast adapters to technology [9].

Although work leads to many benefits for aging workers, such as developing a sense of belonging or ensuring financial security, it also carries risks [10]. Aging workers face higher probabilities of experiencing one or more periods of disability, either due to an occupational injury or a personal medical reason [10]. Moreover, the severity of the injury and the duration of disabling conditions escalate with age [11,12]. Indeed, workers aged 55 years and over are twice as likely as their younger colleagues to have a work-related accident and 6 times more likely than those colleagues to develop a musculoskeletal disorder [11]. Some authors report that gaps between workers' abilities and job demands [13] as well as the decline of certain senses (eg, vision and audition [14]) partly explain these differences. Moreover, a major difference of nearly 100 days exists between the average duration of the disability period following an occupational injury for workers at least 55 years of age and that of younger workers aged 15 to 24 years [15]. Factors related to injury severity, presence of comorbidities, and tissue repair speed may mean longer periods of disability for aging workers [12,16], contributing to a marked increase in their use of rehabilitation services [17].

The increasing rehabilitation needs of aging workers create changes in the profile of the rehabilitation-service clientele [18]. Rehabilitation professionals now work with this emerging population and its distinctive characteristics. Professionals are generally aware of the growing presence of aging workers among the clients receiving their services. Nonetheless, they often do not know how to respond to this singular population in a changing world of work, and most clinical settings have not yet added specific services to meet those needs [18]. In addition, managers need resources to support aging workers in their return to work after an absence. Indeed, a recent scoping review revealed a gap between the needs of aging workers returning to work and the responses from managers [19]. Therefore, developing resources to help rehabilitation professionals support and guide managers and aging workers is essential, considering their singular characteristics.

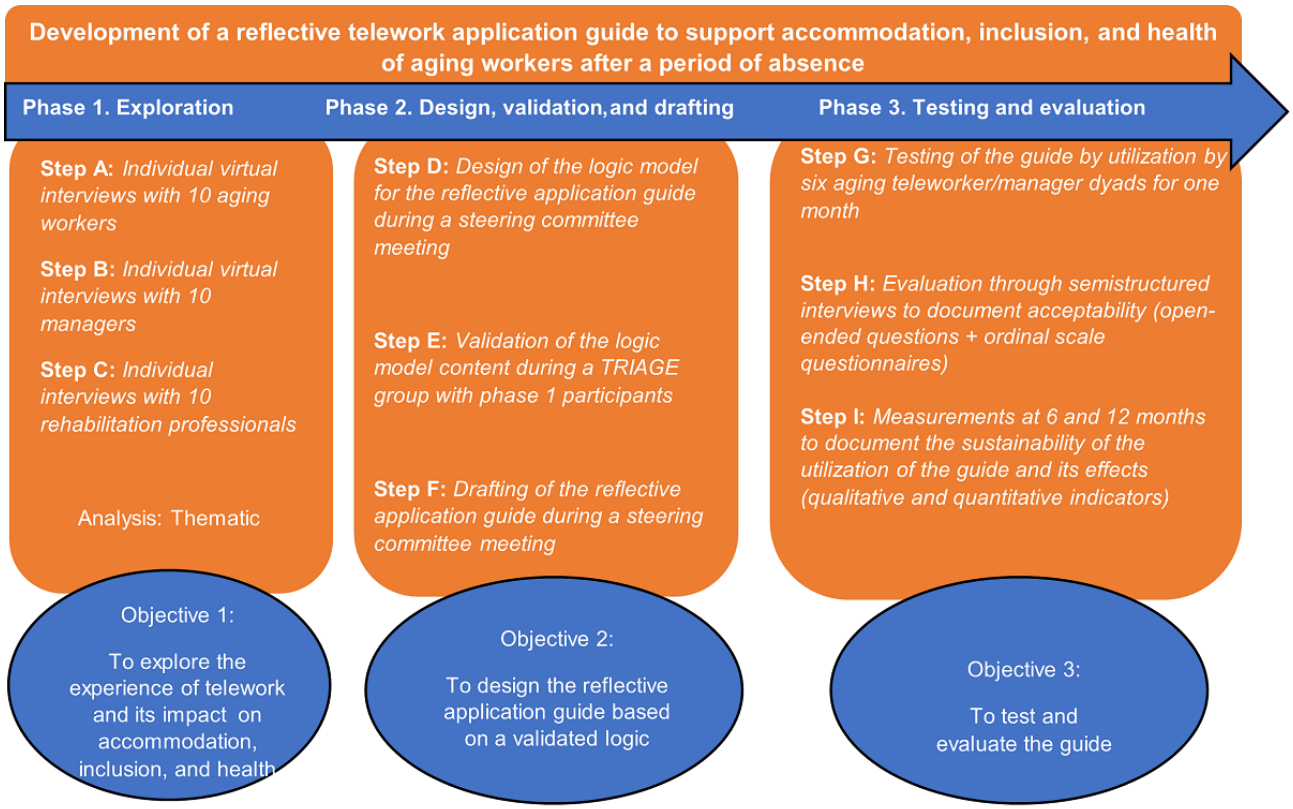
The situation is even more complex because the COVID-19 pandemic fundamentally changed the way many people do their work, forcing a shift to digital work and telework [20,21]. As we emerge from this period of crisis, telework is clearly a work arrangement that will remain [22], with its advantages and challenges. Indeed, the research on telework during the pandemic has exploded, revealing some health benefits for individuals (eg, schedule flexibility [23]) but also challenges (eg, disconnection difficulties [24]) that may specifically impact aging workers' mental health [25]. Other authors report the added value of telework in promoting inclusion and health for all worker populations [26,27], especially such marginalized populations as aging workers. While telework had been an exceptional accommodation for some workers (eg, workers with physical disabilities) from the 1990s until the late 2010s [28,29], workplace stakeholders more widely accept and recognize it now, resulting in less marginalization of workers who benefit from it.

Studies have highlighted the potential of telework as an accommodation for people living with specific health conditions as they feel more able to perform their work while managing their fatigue or pain levels [27,30-32]. Thus, using telework to accommodate individuals who may have challenges performing work in a conventional manner after a period of absence may be of interest. Indeed, this form of work provides "invisibility," ensuring greater equality [26,27] as well as protection against prejudice and discrimination [31,33]. Some exploratory work suggests ways to use telework as a modality to facilitate accommodation, inclusion, and health for unique worker populations, such as people with physical disabilities [20,21] or neurodivergent workers [22]. Nonetheless, to our knowledge, there are not yet guidelines for ensuring a healthy application of telework for aging people. Recent research results have suggested that telework is particularly challenging for aging workers [34]. How can we ensure that this work arrangement promotes the accommodation, inclusion, and health of this workforce?

To optimize the contribution of all available people and reduce the labor shortage while promoting the principles of equity, diversity, and inclusion in the workplace, addressing this

XSL•FO
RenderX

contemporary issue is important. Developing innovative tools to guide the healthy use of telework among aging people who have experienced an absence and improving knowledge about the use of telework as an accommodation modality for aging workers could help equip the rehabilitation professionals who support managers and workers in the trajectory of rehabilitation, return, and stay at work.



This study aims to develop a reflective telework application guide to support the accommodation, inclusion, and health of aging workers after an absence. Specifically, this study (1) explores the telework experience of aging workers, managers, and rehabilitation professionals; (2) designs the reflective application guide on the basis of a validated logic model; and (3) tests and evaluates the guide.

Methods

Design

This project will proceed according to a developmental research design [35] that includes a steering committee comprising 8 stakeholders (researchers, workers, managers, and rehabilitation professionals). Such a design engages researchers and participants in a reflective process as, together, they seek solutions to an issue. It enables the production of useful and accurate knowledge that corresponds to stakeholders' realities [36]. Therefore, this study will focus on aging workers who have returned to work after an absence during the past 2 years and experienced telework as an accommodation modality. Managers and rehabilitation professionals will also participate in the study to provide other perspectives. The research involves the following three phases: (1) exploration; (2) design, validation, and drafting; and (3) testing and evaluation. Figure 1 shows the phases of the research leading to the development of the reflective guide.

Figure 1. Phases, steps, and objectives of the research project. TRIAGE: technique for research of information by animation of a group of experts.

Procedure, Participants, and Analysis

Phase 1

This phase will address objective 1 in 3 steps.

Overview

Recruiting all participants in this study will occur through social media announcements and contacts with clinical settings and organizations within the research team member networks. We will use a purposive sampling method to recruit participants and a maximum variation sampling strategy to select them [37]. Recruiters will ensure diversity in terms of gender, age, and employment sector.

Step A

A 60-minute individual web-based interview with 10 aging workers, respectively, will address various themes (eg, work practices, life role balance, feeling inclusion and satisfaction at work, and perceived health status) using a pretested interview guide. Eligibility to participate will depend on candidates being at least 55 years of age and having experienced telework as an

XSL•FO
RenderX

accommodation modality upon returning to work after an absence during the previous 2 years.

Step B

A 60-minute individual web-based interview will occur with each of the 10 managers working with aging workers, addressing themes similar to those in step A with an emphasis on management practices and using an equivalent pretested interview guide. Managers will have accommodated at least one aging worker with telework after an absence during the previous 2 years.

Step C

A 60-minute individual web-based interview will occur with 10 rehabilitation professionals, respectively. Recruits will be working in occupational rehabilitation (ie, occupational therapists, physiotherapists, and psychologists). Each interview will address themes similar to those in step A, emphasizing rehabilitation practices and using an equivalent pretested interview guide. Eligible rehabilitation professionals will have accompanied at least one aging worker returning to work through telework after an absence during the past 2 years.

A member of the research team will conduct all interviews, digitally audio-recording each. Based on the available literature [38,39], a total of 30 participants should enable reaching content saturation. A questionnaire will collect sociodemographic data (eg, age, gender, marital status, employment experience, and health status) for each participant.

Analysis

Following the transcription of interviews, 2 research team members will analyze the data using an inductive posture and a 5-step thematic-analysis strategy [40]: (1) repeated readings of the data corpus to enable researchers to develop a sense of immersion; (2) initial coding with descriptive codes assigned to the units of significance found in the corpus; (3) units of meaning transformed into meaningful expressions of participants' perspectives; (4) synthesis of expressions allowing the organization of the data in a general structure; (5) back and forth between the raw data and the general structure, allowing clarification and interpretation of the data while respecting participants' perspectives. The 2 coders will first analyze each transcript individually, then compare their structure of codes and generate a new, improved version. This process prevents the analysis from reflecting a single person's perspective and ensures interjudge agreement. The research team may produce several versions of the structure until the team agrees on a structure that most accurately reflects the data. QDA Miner software will support the analysis process.

The researchers expect that the results obtained in this phase will enable generating various elements, such as questions to ask, factors to consider, levers, good practices, and obstacles to avoid, to promote the accommodation, inclusion, and health of aging workers returning to work after an absence.

Phase 2

This phase will address objective 2 in 3 steps.

Step D

Identified Phase 1 elements will support designing the logic model of a reflective telework application guide for aging workers and their managers. The logic model will present the goals, supporting theories, components, sections, and expected outcomes of its use [41]. Some authors have suggested the added value of creating a logic model in the process of developing a new tool, especially because this preliminary step facilitates communication between the actors involved and promotes their common understanding of the tool to be developed [41,42]. The steering committee will develop this logic model using a co-construction approach during a working day.

Step E

Validation of the logic model will involve a 120-minute web-based group using the "technique for research of information by animation of a group of experts (TRIAGE)" [43,44], namely, a group of 8 participants in Phase 1. The TRIAGE technique allows structuring discussions between participants to obtain a consensus on specific ideas while encouraging the emergence of new ones [44]. Two research team members will facilitate the group. Various indicators of validity related to logic models (ie, relevance and clarity) will be documented [41] with a pretested guide. Data analysis related to the validation of the logic model will occur during the session (in situ), consistent with the TRIAGE technique [44].

Step F

Based on this validation of the logic model, the steering committee will create the first version of the complete guide during a second working day.

Phase 3

This phase will address objective 3 in 3 steps.

Step G

This phase aims to test and evaluate the guide with respect to the accommodation, inclusion, and health of aging workers. It will determine whether users of the guide consider it appropriate, particularly in terms of acceptability [45] and satisfaction. We will invite 6 teleworker-manager dyads to familiarize themselves with the guide and use it in their daily work for a month.

Step H

Following this trial period, the perceptions of the dyads will be collected in a semistructured interview to document various indicators of acceptability (eg, affective attitude, perceived effectiveness, and opportunity costs [45]), and satisfaction regarding accommodation, inclusion, and health. Qualitative open-ended questions will support this purpose ("Which barriers to the use of the guide have been faced?" "How much has the guide facilitated a sense of inclusion at work?") along with quantitative closed-ended ordinal scale questions ("What is your level of satisfaction regarding the use of the guide?"). A thematic analysis strategy [40] will support analyzing qualitative data, and descriptive statistical analysis (eg, frequency, means, and SDs) will enable quantitative data analysis [46].

XSL•FO
RenderX

Step I

Finally, applying the same measures to the same participants in step G will occur at 6 and 12 months to document the sustainability of the guide's use and its effects on the accommodation, inclusion, and healthy work participation of aging workers.

Ethics Approval

This study obtained ethical approval from the Ethics Committee of the Centre intégré universitaire en santé et services sociaux de la Capitale-Nationale (project 2023-2805) and the Human Research Ethics Committee of the Université du Québec à Trois-Rivières (project CER-23-298-10.01)

Results

Data collection began in spring 2023 and initial results are expected in fall 2023. This study aims to produce a concrete tool, namely, a reflective telework application guide for short-term use by rehabilitation professionals, managers, and aging workers, to improve the implementation of telework as an accommodation modality to support the inclusion and health of aging people in their return to work after an absence. The guide will also serve to influence policy makers regarding telework. Since rehabilitation professionals and managers are often poorly equipped to respond to such a unique population, the results should propose guidelines for using telework to return to work.

To share the results of the project and increase its sustainability potential, the steering committee will organize several dissemination activities, either during the project or at its end. The researchers will frequently post the study's progress on social media and in a newsletter. We will record a podcast with a researcher, a worker, a manager, and a rehabilitation professional to publicize the guide and its potential utilization. We will invite various stakeholders in the world of work (ie, unions, insurers, and employer and worker associations) to listen to this podcast. Also, we will submit the results for publication in scientific journals and presentation at international scientific conferences. To ensure rigor in the dissemination of results, we will follow the Standards for Reporting Qualitative Research (SRQR) [47]. Finally, we will promote the use of the guide to government authorities.

Discussion

Overview

This study will create a reflective telework application guide through a rigorous, multistep research process involving various work-related stakeholders. This study constitutes a first of its kind and is highly relevant, especially in the context of the labor shortage and the recent major changes in the world of work. To our knowledge, there are no tools, guidelines, or "best practices" for rehabilitation professionals, managers, or workers to use to ensure a healthy application of telework, specifically for the aging population. This project is particularly innovative on several levels. On a *practical level*, the guide represents a concrete tool that rehabilitation professionals, managers, and aging workers can use upon returning to work after an absence. This study's *research* contribution is to pave the way for other projects aimed at developing innovative and effective solutions in promoting the accommodation, inclusion, and health of aging workers after an absence. Finally, on a *societal level*, the study results will help to explain the influence of telework on the health and inclusion of aging workers and encourage people to use the guide to promote healthy participation in telework.

Conclusion

This paper presents a research protocol to develop a reflective telework application guide with its basis in scientific and experiential knowledge. The results of this study will lead to implications at practical, scientific, and societal levels. Moreover, the results of this study should pave the way for further studies and interventions to ensure aging workers' healthy work participation.

Acknowledgments

This study will be carried out with the help of research grants from the Quebec Network for Research on Aging (a Thematic Network funded by Fonds de recherche du Québec-Santé) and the Social Sciences and Humanities Research Council (grant 892-2022-2010).

Abstract

Background: In Finland, at least 1 in 4 residents will be >75 years of age in 2030. The national aging policy has emphasized the need to improve supportive services to enable older people to live in their own homes for as long as possible.

Objective: This study aimed to develop a preventive health screening procedure for home-dwelling older adults aged 75 years to enable the use of clinical patient data for purposes of strategic planning of supportive services in primary care.

Methods: The action research method was applied to develop the health screening procedure with selected validated health measures in cooperation with the local practicing interprofessional health care teams from 10 primary care centers in the Social Security Center of Pori, Western Finland (99,485 residents, n=11,938, 12% of them >75 years). The selection of evidence-based validated health measures was based on the national guide to screen factors increasing fall risk and the national functioning measures database. The cut-off points of the selected health measures and laboratory tests were determined in consecutive consensus meetings with the local primary care physicians, with decisions based on internationally validated measures, national current care guidelines, and local policies in clinical practice.

Results: The health screening procedure for 75-year-old residents comprised 30 measures divided into three categories: (1) validated self-assessments (9 measures), (2) nurse-conducted screenings (14 measures), and (3) laboratory tests (7 measures). The procedure development process comprised the following steps: (1) inventory and selection of the validated health measures and laboratory tests, (2) training of practical nurses to perform screenings for the segment of 75-year-old residents and to guide them to possible further medical actions, (3) creation of research data from clinical patient data for secondary use purposes, (4) secondary data analysis, and (5) consensus meeting after the pilot test of the health screening procedure for 75-year-old residents procedure in 2019 based on the experiences of health care professionals and collected research data.

Conclusions: The developed preventive health screening procedure for 75-year-old residents enables the use of clinical patient data for purposes of strategic planning of supportive services in primary care if the potential bias by a low participation rate is controlled.

Introduction

Between the years 2015 and 2050, the number of people aged >60 years will increase globally from 900 million to 2 billion [1]. In Finland, at least 1 in 4 residents will be >75 years of age in 2030 [2]. Health care systems should be realigned to meet the needs of growing older populations and be capable of providing person-centered integrated care that meets the needs of this population segment. Most health systems globally are ill-prepared to address the service needs of older people who often have multiple chronic conditions or geriatric syndromes.

Finland has one of the fastest-aging populations in the world [2]. Finnish aging policy and health and social policy have emphasized the need to enhance support services to enable older people to live in their own homes for as long as possible, even when daily home care support is regularly needed [2-4]. To enhance support for living at home, new effective preventive actions are needed to maintain the functional ability of older adults [2]. Early detection of diseases and efforts to prevent or attenuate the complications of chronic diseases may provide a cost-effective strategy for maintaining the health and functional ability of older adults, although conclusive evidence is still lacking [5-7]. Screening for the subclinical state of a disease has benefitted many asymptomatic patients [8] but applying preventive health screening to old people may be problematic for several reasons such as geriatric disorders with multiple risk factors, having less physiological reserve than younger adults, and having higher comorbidity rate often leading to polypharmacy. In general, older adults are often excluded from clinical trials influencing outcomes measured and reported for evidence synthesis and thus interpreted for medical interventions [8,9]. The abovementioned issues have contributed to the lack of comprehensive health screening procedures suitable for home-dwelling older adults and suitable to be used in clinical practice to guide preventive actions.

Our extensive literature searches did not find any studies reporting preventive comprehensive health screening tools or procedures specifically designed and validated for home-dwelling older adults. Existing age-specific health screening tools are disease or symptom specific (eg, cancer [10], mental disorders [11], frailty [12], cognitive impairment [13], falls [14], and nutritional status [15]) [10-21] and they primarily focus on community settings [17,22-26]. As health systems are becoming increasingly digitalized, screening tools should be suitable for structured and cumulative data recording in electronic patient databases, enabling data-driven management practices and the secondary use of social and health data in the future. The aim of this study was to develop a preventive health screening procedure for home-dwelling older adults aged 75 years to enable the use of clinical patient data for the strategic planning of supportive services in primary care.

Methods

Context of the Study

The Finnish health care and social services system is currently undergoing a major reform [27]. Since the beginning of 2023, these services have been organized by 22 well-being service counties [28,29]. According to the new Act on Organizing Social Welfare and Healthcare [30], the planning and implementation of publicly funded health care and social services in the well-being service counties should be guided by patient data aggregated in care processes. The Act on the Secondary Use of Health and Social Data [31] was enacted in 2019 and states how patient data can be used by service providers for organizing services, planning their equal availability, and optimizing cost-effectiveness [30].

This study was conducted in the Social Security Center of Pori, which was transferred to the well-being service county of Satakunta at the beginning of 2023 (1 of the 22 regional providers of social and health services in Finland) [28,29]. In the Satakunta Wellbeing Service County, institutional care for older residents has been significantly more common than in the rest of Finland. Therefore, the county made a strategic decision in 2019 to find new ways to remarkably reduce the proportion of older residents aged >75 years requiring expensive institutional care (reduction from 9% to 4.5% by 2024) [32]. The goal was for older residents to favor living at home for as long as possible by providing them with new community housing solutions, extending home care into round-the-clock services, and resourcing client-specific home care to support residents in poorer health. This study was started to support the strategic goal of the well-being service county by developing a preventive health screening procedure to identify home-dwelling older adults at risk of impaired health and functional ability.

According to the Finnish legislation, it is mandatory for the well-being service counties to use the Resident Assessment Instrument (RAI) assessment tools [33,34] in assessing the functional capacity of an older person if the person needs regularly provided social services to ensure sufficient care and support [35]. RAI is a comprehensive assessment tool specifically designed for the evaluation of the care needs of vulnerable populations [33,34]. The RAI assessment system consists of several assessment instruments designed for varied care contexts such as nursing home [36], home care [37] rehabilitation [38], palliative care [39], or acute care [40]. In contrast, a preventive health screening assesses home-dwelling older adults' overall potential health risks and can be used for individuals regardless of their service needs.

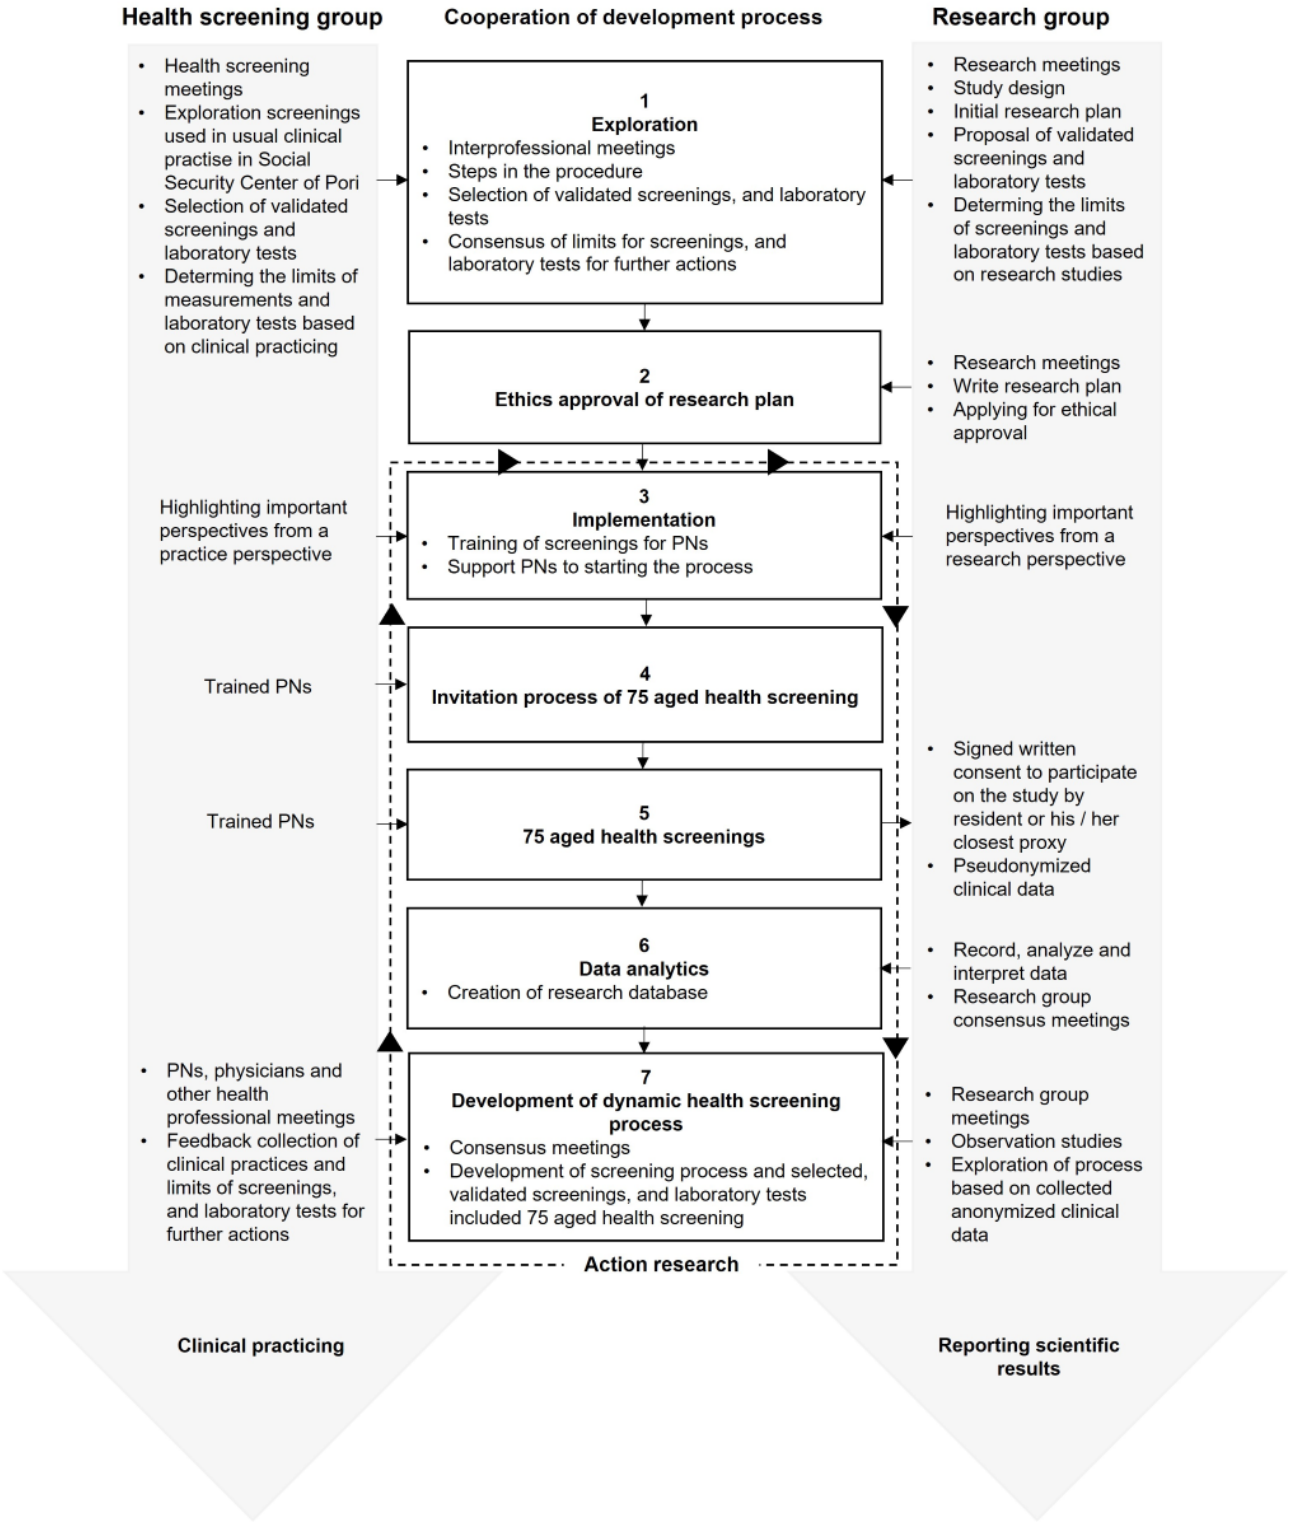
This study included 10 public health care centers from 3 municipalities within the Satakunta Wellbeing County—Pori, Ulvila, and Merikarvia—located in Western Finland, with

XSL•FO
RenderX

99,485 inhabitants, of whom 12% (n=11,938) were ≥75 years in 2020 [41]. Pori Home Care Unit is divided into 3 service areas: North, West, and East. Each service area has 3-4 local public health centers. Every health center has a practical nurse (PN) who is trained in health screening. Health screenings are a publicly funded part of primary care services in Finland [42]. Since the beginning of 2023, well-being service counties have been funded mainly by the government and partly by collecting service fees from service users [28].

Study Design and Method

This study applied the action research method to develop a preventive health screening procedure for home-dwelling older adults aged 75 years [43,44]. The action research method is suitable for identifying problems in clinical practice and developing potential solutions to improve the practice [43]. It involves researchers working with and for people rather than undertaking research on them [43]. The study design was developed in cooperation between the Satakunta University of Applied Sciences, the Social Security Center of Pori, and the University of Helsinki, Finland. Advanced-level nursing students from the Satakunta University of Applied Sciences were also involved in training PNs to conduct health screenings.



Development Process of the Health Screening Procedure

The following were the starting points for the development of the health screening procedure: (1) the screening could be performed every year for a new segment of 75-year-old residents; (2) the health measures included should provide sufficient information about the health status of the home-dwelling residents in this age segment to plan for required health services and be suitable for structured and cumulative data recording enabling data-driven management practices; and (3) the health screening procedure should be dynamic, allowing changes in measures while maintaining comparability between annual cohorts to observe the possible changes in the health status of 75-year-old residents and their service needs over time.

The health screening procedure was developed in 7 steps and close cooperation between the health screening group—comprising the care team personnel from the Social Security Center of Pori—and the research group, comprising the researchers (Figure 1). The health screening group comprised all PNs, their managers (nurses), physicians, and other health care professionals involved in the 10 care centers of the 3 municipalities involved in the study. The research group comprised 3 clinically trained researchers: a physician, a pharmacist, and a clinical physicist.

XSL•FO
RenderX

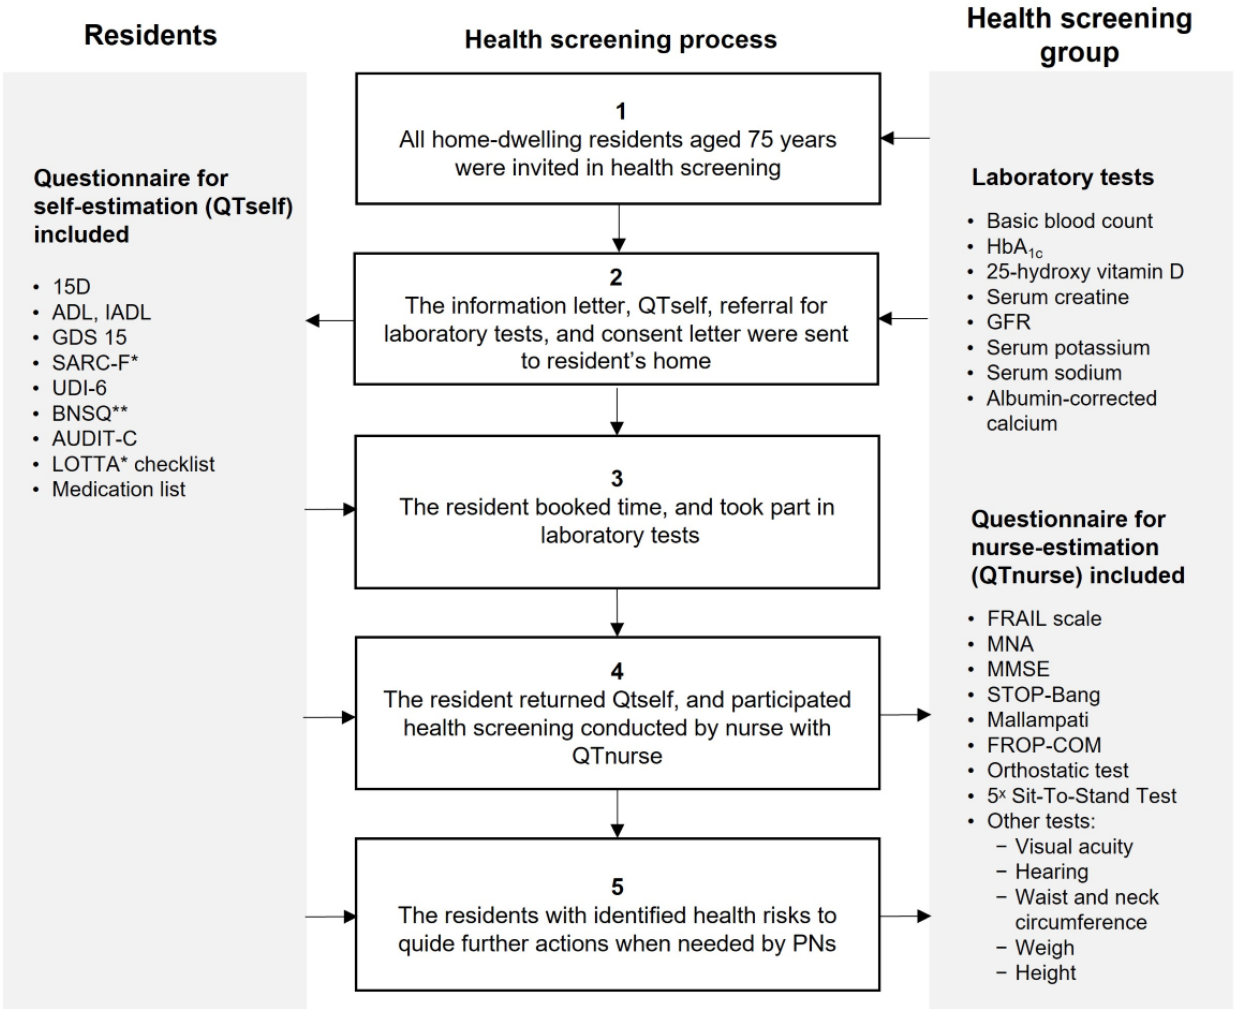
Figure 1. The development process of the preventive health screening procedure for home-dwelling older adults aged 75 years (PORI75) using the action research method [43,44]. PN: practical nurse.

Ethical Considerations

This study was approved by the Ethics Committee of the Hospital District of Southwest Finland (ETMK 58/2019). The research permit was approved by the Social Security Center of Pori, Finland to conduct research at the health center. Informed consent was obtained from each client and their closest proxy before any study procedure was performed. This study was conducted in accordance with the principles of the Declaration of Helsinki.

Inventory of Potential Health Measures to be Included in the Procedure (Step 1)

Meetings between the health screening group, which was familiar with health screenings in practice, and the research group conducting research played a crucial role in developing the health screening procedure (Figure 1). The first step was to



XSL•FO
RenderX

make an inventory of potential health measures to be included in the procedure (research group). The inventory and selection of measures were based on evidence-based, validated, client-oriented measures covering the typical symptoms and conditions in older adults who may influence their functional ability to live at home. Our inventory found the national guide on preventing falls in older adults by the Finnish Institute for Health and Welfare as a useful evidence-based source of measures to be used in our study [45]. The guide presented a holistic approach to factors that have been associated with an increased risk of falls and that are recommended to be screened in older adults. Thus, we drew all the recommended health measures from the guide to form a preliminary set of measures for our health screening procedure.

In cases where a validated health measure recommended by the fall prevention guide [45] was not available in the guide, it was drawn from the National TOIMIA Functioning Measures Database, which is also maintained by the Finnish Institute for Health and Welfare [46]. The TOIMIA Functioning Measures Database is an open-access and free-of-charge database designed for experts and professionals to measure functioning in clinical practice and research. The database contains the basic descriptions of functioning measures, assessments of psychometric properties, and the feasibility of these measurement instruments for different purposes and guidelines and recommendations by experts concerning the measure of functioning in different situations and contexts. The guidelines and measures published in the database have been systematically evaluated by the TOIMIA network of experts with regard to their validity, reliability, and usability for different purposes.

When possible, the health measures used in routine clinical practice at the Social Security Center of Pori were selected for the health screening procedure to minimize additional work for PNs and inconvenience for residents (Figure 2). Laboratory tests were selected to screen for diseases and conditions prevalent in older adults according to the fall prevention guide [45] and to optimize drug treatment.

Figure 2. Description of the developed health screening procedure for 75-year-old residents (PORI75). * LOTTA checklist and SARC-F test were included in 2020. ADL: activities of daily living; AUDIT-C: Alcohol Use Disorders Identification Test—Consumption; BNSQ: Basic Nordic Sleep Questionnaire; FROP-Com: Falls Risk for Older People in the Community; GDS 15: Geriatric Depression Scale; GFR: glomerular filtration rate; HbA1c: hemoglobin A1c; IADL: Instrumental Activities of Daily Living; PN: practical nurse; QTnurse: questionnaire included screenings performed by a health care professional; QTself: questionnaire included screenings suitable for self-assessment; UDI-6: Urinary Distress Inventory; LOTTA: Checklist for Successful Medication Therapy (translated in English). ** The BNSQ questionnaire was included only in 2019, not in 2020.

XSL•FO
RenderX

The cutoff points of the selected health measures and laboratory tests for possible further medical examination to treat the identified health problems were agreed upon in a consensus meeting with the local physicians (Multimedia Appendix 1 shows this in more detail). The criteria for the cut-off points were based on the categorization of internationally validated tests, national current care guidelines [47], and local policies. Consensus was reached when all the local physicians agreed on the cutoff points of the measures and tests in the meeting.

Implementation of the Health Screening Procedure (Steps 2-7)

After consensus was reached between the research group and health screening group on the health measures and laboratory tests included in the procedure, named health screening procedure for 75-year-old residents (PORI75), a study protocol was developed to implement the procedure (Figure 1). The study protocol was evaluated by the Ethics Committee of the Hospital District of Southwest Finland (step 2).

For the implementation of the procedure in steps 3-7, all 75-year-old residents living at home were selected from 10 public health care centers in 3 municipalities within Satakunta Wellbeing Service County and were invited by a postal letter to participate in the health screening by a trained PN (Figure 1). The recruitment process was conducted between June 2019 and December 2020 and invited only those residents who turned 75 years old that year. All residents were given oral and written information about the study protocol prior to consenting. Written informed consent was obtained from all voluntary participants in person or with the help of their caregiver or closest proxy.

PNs were prepared to perform the health screenings for the consented residents of 75 years of age (Figure 1; step 3). During this preparatory phase, PNs were encouraged to comment on the health screening process to the research group to make it fit the usual clinical practice. PNs were trained to identify residents with elevated health risks in the health screening phase and to guide them to refer a health care professional or provider or visit a clinic for further medical examination to manage the problems when needed (Multimedia Appendix 1).

Step 5 was designed for implementing the health screenings using the health measures and tests included in the procedure in step 1 (Figure 1). The aim was to assess the current health status of home-dwelling 75-year-old residents by identifying potential ageing-specific issues for diseases prevalent in older adults as well as their medication-related risks.

In the data analysis step (step 6), the research group created a retrospective pseudonymized research database for the secondary use of the collected patient data (Figure 1). They analyzed the data and interpreted the obtained results to produce information on the health status of the residents and to identify the needs for health service use.

After the first segment of 75-year-old residents screened in 2019, the health screening group and research group conducted regular meetings to further develop the health screening process including the measures and tests used, and shared the preliminary results of the screening (step 7). The research group closely worked with PNs and physicians in consensus meetings to facilitate integration between the steps (steps 3-7) and the tasks of the health care professionals involved. The development of the dynamic health screening process as well as the appropriateness of the selected and validated screening measures is planned to be annually assessed in these consensus meetings (step 7). In addition, the health screening group will share the results of the screening with the steering committee to assess the quality and adequacy of available health services compared to the care and support needs of the home-dwelling older residents. This study was limited to describing the development process of the procedure, and the results of the screenings will be published in several different publications.

Results

Description of the Health Screening Procedure for 75-year-Old Home-Dwelling Residents

The health screening procedure for 75-year-old home-dwelling residents comprised 30 measures and tests divided into three categories: (1) validated self-assessments (9 measures), (2) nurse-conducted screenings (14 measures), and (3) laboratory tests (7 measures; Figure 2). Figure 2 presents the 5-stage process of conducting the measures and tests in practice.

The screenings are divided into 3 blocks, 2 of which are presented in 2 separate questionnaires (Figure 2). In the first block, the questionnaire is named as QTself (questionnaire included screenings suitable for self-assessment at home such as quality of life, functional capability, mood and depressive symptoms, the probability of sleep disorders, alcohol use, inability to urinate, and possible problems and risks in medication use; Table 1). In the second block, the questionnaire is named QTnurse (questionnaire included screenings performed by a health care professional) comprises screenings to be performed by a health care professional, that is, a trained PN. These screenings include frailty, nutritional status, cognition (memory and reasoning), sleep apnea, fall risk, lower body strength, orthostatism (difficulty in achieving stable blood pressure), and other tests such as those for identifying impaired vision and hearing (Table 2). The third block, the laboratory tests, includes the following tests such as basic blood count, long-term blood glucose, vitamin D, serum creatine, glomerulus filtration rate, serum sodium and potassium, and albumin-corrected calcium (Table 3).

XSL•FO
RenderX

Table 1. Health screening procedure for 75-year-old residents: the measures included in the self-assessment instrument (QTself questionnaire) are designed to be used by 75-year-old home-dwelling residents by themselves or with the help of their caregiver or closest proxy.

Test and health measure	Definition and description
ADL, IADL [a,b,c,d]	• ADL [48] is the scale of assessment of daily activities, where the amount of help needed in basic daily activities is scored, and the total of the points describes the amount of help needed by others. • IADL [49] describes the need for assistance in instrumental daily activities.
AUDIT-C [a,b,e]	• Alcohol Use Disorder Identification Test (AUDIT) [50] is a screening instrument for hazardous and harmful alcohol consumption. • (AUDIT-C) [51] questions have been previously validated as a 3-item screening tool for alcohol misuse.
GDS 15 [a,b,f]	• GDS 15 [52] is a validated self-rating depression screening scale for older adults.
BNSQ[g,h,i]	• BNSQ [53] has been used widely in a variety of studies and has proven to be a valid tool for measuring subjective sleep complaints.
15D[i,j]	• 15D [54] is a generic, comprehensive, 15-dimensional, standardized, and self-administered measure of health-related quality of life that can be used both as a profile and single index score measure.
SARC-F[i,k,l]	• The SARC-F [55] questionnaire is a rapid diagnostic test for sarcopenia and covers the following components: Strength, Assistance with walking, Rise from a chair, Climb stairs and Falls.
UDI-6[i,m]	• UDI-6 [56,57] is for assessing the life impact and symptom distress of urinary incontinence and related conditions for both men and women.
LOTTA checklist[i,l,n]	• The LOTTA checklist is a validated self-assessment tool [58] for older adults aged >65 years to identify medication-related risks. The checklist aims to (1) ensure that the medication is being taken as directed, (2) encourage older adults to maintain an up-to-date medication list, and (3) monitor the therapeutic effects of their medication.
Medication list[i]	• A medication list comprises the medicines currently in use and is filled by the older adult themselves or by the closest proxy at home.

[a]A measure included in the fall prevention guide [45].

[b]Measures given in italics are already in use at the Social Security Center of Pori before the PORI75 procedure was established.

[c]ADL: activities of daily living.

[d]IADL: Instrumental Activities of Daily Living.

[e]AUDIT-C: Alcohol Use Disorders Identification Test—Consumption.

[f]GDS 15: Geriatric Depression Scale.

[g]BNSQ: Basic Nordic Sleep Questionnaire.

[h]BNSQ was included only in 2019 and was excluded based on the experiences of its use in 2019.

[i]A measure recommended to be screened in older adults by the fall prevention guide [45] but the measure was retrieved from the National TOIMIA Functioning Measures Database [46].

[j]15D: comprehensive health-related quality of life instrument

[k]SARC-F: Strength, Assistance with walking, Rise from a chair, Climb stairs, and Falls.

[l]The LOTTA checklist and SARC-F test were included as new measures in 2020.

[m]UDI-6: Urinary Distress Inventory.

[n]LOTTA: Checklist for Successful Medication Therapy (translated in English).

Table 2. The health measures planned to be screened at the nurse's appointment by trained PNs as part of the health screening procedure for 75-year-old residents (QTnurse questionnaire).

Test and health measure	Definition and description
FROP-COM [a,b,c]	• FROP-Com [59] are tools used in the community for the assessment or screening of falls risk.
MMSE [a,d]	• MMSE [60] is a test of cognitive function among older adults.
MNA [a,e]	• MNA [61] is a simple tool useful in clinical practice to measure nutritional status in older persons.
Orthostatic test [a]	• The orthostatic test [62] is used to determine how the position of the body affects the heart rate and blood pressure. Orthostatic hypotension is defined as a decrease in systolic blood pressure of at least 20 mm Hg or in diastolic blood pressure of 10 mm Hg when assuming an upright position.
5×sit-to-stand test[a] (Chair stand, 5 times)	• The 5 times sit to stand test (5×sit-to-stand test) [63,64] is used to assess the functional lower extremity strength, transitional movements, balance, and fall risk in older adults.
FRAIL scale[f,g]	• The FRAIL scale [65] is a screening tool for clinicians to identify frail persons at risk of developing disability as well as experiencing a decline in health functioning and mortality.
STOP-Bang, Mallampati[f,h,i]	• The STOP-Bang [66,67] questionnaire is used to screen patients for obstructive sleep apnea. • The Mallampati [68] score is used to identify patients at risk for difficult tracheal intubation and evaluate obstructive sleep apnea.
Other tests[b] • Visual acuity[a] (random E test) • Hearing[a] (tympanometry) • Weight[a] • Height[a] • Waist circumference[f] • Neck circumference[f]	• Clients are also examined, and the values for disease identification and those necessary for the study are measured.

[a]A measure included in the fall prevention guide [45].

[b]Measures given in italics are already used at the Social Security Center of Pori.

[c]FROP-Com: Falls Risk for Older People in the Community.

[d]MMSE: Mini-Mental State Examination.

[e]MNA: Mini Nutritional Assessment.

[f]A measure recommended to be screened in older adults by the fall prevention guide [45] but the measure retrieved from the National TOIMIA Functioning Measures Database [46].

[g]FRAIL: simple frailty questionnaire; fatigue, resistance, aerobic capacity, illnesses and loss of weight.

[h]The measure is not specific and sensitive for older adults.

[i]STOP-Bang: Score for obstructive sleep apnea, Snoring, Tired, Observed, Pressure, Body Mass Index.

All chosen measures are specific and sensitive for older adults, except the quality of life measure (Comprehensive Health-Related Quality of Life Instrument [15D]) [54] and 2 measures for sleeping disorders (Score for obstructive sleep apnea, Snoring, Tired, Observed, Pressure, Body Mass Index [STOP-Bang] [66,67] and Mallampati [68]). The 15D is a comprehensive health-related quality of life instrument for adults but is not specifically designed for older adults [54]. In the same way, STOP-BANG [66,67] and Mallampati [68] are used to evaluate obstructive sleep apnea in adults but not particularly in older adults.

Table 3. Laboratory tests are included in the PORI75 health screening procedure for 75-year-old home-dwelling residents to screen for diseases prevalent in older adults.

Laboratory tests	Definition and description
25-hydroxy vitamin D[a]	The measurement of serum vitamin level is generally recognized as the clinical standard for the evaluation of vitamin D status.
Albumin-corrected calcium[b]	Total plasma calcium is bound to protein, with albumin being the most abundant binding protein. Albumin-corrected calcium is used as a measure of calcium balance.
Basic blood count[b]	The basic blood count is an important basic laboratory examination that indicates various ways to analyze the condition of the body.
Hemoglobin A_{1c}[b]	Glycated hemoglobin levels are a measure of average sugar levels in the blood and are commonly used in relation to diabetes.
Serum creatinine glomerular filtration rate[c]	A blood creatinine examination is a part of a routine health examination for recognizing kidney damage or the risk of developing kidney disease. Glomerular filtration rate is the measurement used to determine kidney function.
Serum potassium[c]	Serum potassium is a measure of average potassium levels in the blood.
Serum sodium[c]	Serum sodium is a measure of average sodium levels in the blood.

[a]A measure included in the fall prevention guide [45].

[b]A measure recommended to be screened in older adults by the fall prevention guide [45].

[c]A measure recommended to optimize drug treatment.

Performing the Pilot PORI75 Health Screenings in 2019

All residents (n=1104) who turned 75 years old in 2019 and lived at home were sent an invitation letter to participate in the PORI75 health screening (Figure 2, stage 1). Of the invited residents, the participation rate for health screening was 37% (n=415). Among these 415 participants, 407 (98%) gave written consent to be included in the study.

The invitation letter contained a reserved time for the PN's appointment, a request to fill in the QTself questionnaire before the appointment, instructions to book a slot for laboratory tests (Table 3), and an informed consent letter for the study participation (Figure 2, stage 2). The residents were recommended to book an appointment for the laboratory tests no later than 5 days before the PN's appointment (Figure 2, stage 3). They were also asked to return the filled QTself form at the PN's appointment when the PN conducted the health screenings according to the QTnurse form and reconciled the medication list (Figure 2, stage 4). Residents signed the written informed consent during the PN's appointment if they were willing to participate in the study. An appointment took about 2 hours including screening, reconciling the medication list, and recording results in the electronic patient information system. If a PN identified potential health risks based on the predetermined health risk cut-off points (Multimedia Appendix 1), they advised the resident to contact a health care provider for further medical examination to manage the observed health risks (Figure 2, stage 5).

Experiences From the First Pilot-Year Screenings in 2019

The consensus meeting after the pilot screenings in 2019 considered the content of the PORI75 procedure to be appropriate and applicable to a new segment of 75-year-old residents in 2020. The only changes made to the measures were the removal of the Basic Nordic Sleep Questionnaire [53] for measuring sleep disorders from the procedure. This is because the Basic Nordic Sleep Questionnaire [53] lacked an easily applicable and validated scoring method, thus making it difficult for PNs to identify residents at risk. In addition, the following 2 new measures were added to the health screening: a tool (Strength, Assistance with walking, Rise from a chair, Climb stairs, and Falls) for identifying sarcopenia in older adults [55] and a checklist (LOTTA) for assessing medication-related risks and problems [58]. Strength, Assistance with walking, Rise from a chair, Climb stairs, and Falls measure [55] was chosen because sarcopenia may impede daily activities and increase the rate of complications in older persons [69]. The validated LOTTA checklist was nationally launched in Finland in 2020 by the Finnish Medicines Agency [58]. This self-assessment tool for adults aged >65 years aims to identify the potentially harmful risks and problems in their medication use.

Discussion

Principal Findings

The PORI75 preventive health screening procedure was successfully developed and piloted with 75-year-old home-dwelling residents. The procedure includes a coordinated set of health measures covering the most common age-related diseases and other conditions that may affect older adults' functionality and survival at home. The established questionnaires of health measures and laboratory tests enable systematic and structured patient data recording and management, with potential for secondary use in planning preventive services for older adults according to their needs. This aligns with the ongoing social and health care reform goals in Finland [70]. The developed health screening procedure is dynamic and can be expanded and annually supplemented with new health screening data from 75-year-old residents. At the moment, the database includes data from the years 2019-2022. If the number of measures is wanted to be increased, modern pervasive computing technology with sensors could provide

XSL•FO
RenderX

new additions enabling continuous monitoring of selected health functions in home-dwelling older adults [16,17,71].

The final health screening procedure consists of quite a high number of validated measures (n=30 measures), some of which are extensive and time-consuming to apply (eg, quality of life [54] and functional ability [63,64] measures). This increases the workload of the Social Security Center personnel, especially the PNs who perform the measures. However, the majority of the measures (22/30, 73%) were already in use at the Social Security Center before the PORI75 procedure was established. Although these health measures were used in different health care wards and contexts, systematic preventive screening was missing. Of the existing measures, 10 measures were included in the QTnurse questionnaire and 7 in laboratory tests of the PORI75 procedure.

Delegating the task of self-assessment for some measures to the older residents themselves proved to be a feasible practice (9 measures, of which 5 were already applied at the Social Security Center before PORI75). Based on the pilot experiences, 75-year-old home-dwelling residents were able to actively participate in health screening by answering the QTself questionnaire for the chosen measures. As all the residents were interviewed by a PN during their health screening appointment, PNs were able to confirm whether all measures of QTself questionnaire had been completed and what problems the residents may have experienced in filling in their personal information. Thus, we can assume that all residents who consented to fill the QTself questionnaire did so. Unfortunately, the PNs did not keep records of the difficulties the residents may have experienced in completing the QTself questionnaire, so we cannot report these findings. Difficulty in self-completing the questionnaires could have been one of the reasons for not participating in the health screening. These findings suggest the need for making a more detailed analysis of health screening participants and nonparticipants in the future.

The participation rate in the health screening was not very high (n=415, 37%), even though the health screening was provided free of charge for all 75-year-old home-dwelling residents. If the health screening for 75-year-old residents will become a routine practice, it is important to find new strategies to increase the participation rate. Otherwise, the procedure will not reach its primary goal of helping older residents to live at home for as long as possible and lowering the proportion of older residents living in assisted living facilities and nursing homes.

Another consequence of the low participation rate can be biased on estimates for planning social and health services needed for geriatric care. The bias in the allocation of resources can be aggravated by the assumption that many nonparticipants may have had a poorer health status and functional ability than the participants. This will lead to underestimating the resources needed for geriatric care. Therefore, it is important in future studies to investigate the characteristics of health screening participants and nonparticipants to estimate the bias caused by the participation rate. Based on this analysis, a suitable correction should be used in data analysis to consider this potential source of bias that can reflect on health services planning and allocation of resources in the well-being services county. It is also important to understand other complications encountered in the process and to focus on them in future studies. A potential option for increasing the participation rate could be to conduct health screening in connection with emergency department visits. It is important to note that in any case, the health screening is entirely voluntary, and it is everyone's right to choose whether they want to participate.

In Finland, 75-year-old residents or any other segment of older adults do not routinely have PN’s appointments and the related opportunities for preventive health counseling such as those presented here. Systematic health checks are routine in most countries [72] but are more typically focused on specific diseases or symptoms [10-21] or medication management [73]. The PORI75 is a unique and comprehensive health screening procedure for home-dwelling older adults where the effectiveness and cost-effectiveness should be evaluated in future studies when we have gathered sufficient data for statistical analyses. In forthcoming studies, we will evaluate the effectiveness of the health screening by comparing emergency department visits before and after the health screening for both participants and nonparticipants. If the outcomes are positive, the procedure has the potential to be implemented in other well-being services counties, or even nationally in Finland and beyond. As the measures and tests were chosen by the local health screening group based on proposals from the interprofessional research group, consensus meetings with an extended representation should be carried out to confirm the consensus findings.

The PORI75 health screening procedure is still under development. The procedure has been pilot-tested and used in clinical practice at the Social Security Center of Pori as presented in this study. The development continues towards a digital data lake and a template facilitating the use of the data in data-driven management in the regional well-being services county.

Conclusions

The developed preventive PORI75 enables the use of clinical patient data for purposes of strategic planning of supportive services in primary care if the potential bias by a low participation rate is controlled.

Acknowledgments

We are thankful to the Social Security Center of Pori and Satakunta University of Applied Sciences, Finland, for planning and carrying out the PORI75 Study and participating in this research. We would especially like to thank Minna Rajala and Nina Karttunen, Social Security Center of Pori, for their valuable contributions to this study. This research is part of the Data Lake Innovation Testbed for Future Hospital (January 2021 onwards), Ministry of Education and Culture, Finland, and the Future

Hospital Innovation Platform, the Regional Council of Satakunta, ERDF (January 2019 onwards). Otherwise, this research has not received specific grants from funding agencies in the public, commercial, or not-for-profit sectors. Open-access publishing is funded by the Helsinki University Library.

Data Availability

The data that support the findings of this study are available from the Social Security Center of Pori but restrictions apply to the availability of these data, which were used under license for the current study and are therefore not publicly available. Data are, however, available from the patient document archive of Pori Town (arkisto.ter@porinperusturva.fi) based on the Act on the Secondary Use of Health and Social Data upon reasonable request.

Authors' Contributions

JCK, AH, SK, and JP contributed to the study concept and design. JCK, AH, JB, and JP acquired and analyzed the data. JCK, AH, MA, and JP drafted the manuscript. JCK, AH, MA, and JP critically revised the manuscript for important intellectual content. JCK, AH, SK, PH, ALK, JB, MA, and JP read and approved the final manuscript. JCK, AH, and JP contributed equally to this work.

Conflicts of Interest

None declared.
