Data will be independently extracted by a primary reviewer using a data extraction spreadsheet in Excel (Microsoft Corp). A second reviewer will check and confirm all extracted data, with any disagreements reconciled through discussion. The following information will be extracted, and, if needed, the corresponding authors of included studies will be contacted for missing information:

- Publication details, including study authors and publication year
- Study characteristics, including study design, location, and sample size
- Sample population characteristics; for example, age, sex, ethnicity, socioeconomic status, and education
- Characteristics of anxiety exposure or outcome; for example, type of anxiety or anxiety disorder (if applicable), measure to assess anxiety, and age of onset
- Characteristics of alcohol use exposure or outcome; for example, frequency or quantity of use, age of initiation, hazardous or binge drinking, and alcohol use disorder
- Relevant information on the mediators and moderators examined, including the statistical analysis approach used; for example, mediator or moderator classification, assessment of mediator or moderator, single or multiple mediators or moderators assessed, whether confounders were controlled for, and overall strength of effect

Risk of Bias

Studies deemed eligible for inclusion in the systematic review will have their quality and risk of bias assessed independently by 2 reviewers. Disagreements between reviewers will be resolved through discussion and consultation with a third reviewer if required. Appraisal will be done using the Joanna Briggs Institute Critical Appraisal Tools [37]. Both the Checklist for Analytical Cross-Sectional Studies and the Checklist for Cohort Studies will be used to accommodate the different research designs of the included studies. These checklists evaluate the study sample, measurement of exposure and outcome variables, confounding, appropriateness of statistical analysis, and follow-up reporting (cohort checklist only) across 11 questions in the cohort studies checklist and 8 questions in the cross-sectional studies checklist.

Data Synthesis

Overview

A narrative synthesis of individual mediators and moderators from the included studies will be performed, with results

XSL•FO
RenderX

grouped in line with the biopsychosocial model [38]. This model encompasses biological factors like sex and age, psychological factors including cognitive and behavioral facets, and social factors, which encompass an individual's broader environment and the society in which they live. Furthermore, it is likely the relationships between anxiety and alcohol use will change between different groups; therefore, subgroup synthesis is planned for age subgroups (as defined by the World Health Organization), anxiety subgroups (as defined by the DSM-5), alcohol use sub groups broken down by severity (eg, mild, moderate, severe alcohol use disorder), and lastly, population types (eg, college students, veterans, specific cultural groups, etc). The inclusion of these subgroups will be reliant on data within the included studies, and if other key groupings emerge, further sub-group analyses may be conducted. Other information extracted, including publication details, study characteristics, sample population characteristics, and exposure and outcome characteristics, will also be narratively synthesized.

Given the broad inclusion criteria, it is anticipated that there will be high heterogeneity across studies. However, if the available data within the included studies is sufficiently homogenous, a meta-analysis will be conducted, with mediation and moderation analyses synthesized separately. Studies with comparable exposure and outcome measures and comparable mediator and moderator variables will be included in the meta-analysis. The indirect effects of mediation models will be synthesized using the methods defined in Cheung [39]. The synthesis of moderating variables will be dependent on the statistical analysis within individual studies but will include pooled estimates of coefficients.

Confidence in Cumulative Evidence

The cumulative strength of evidence from included studies will be assessed using the GRADE framework [40]. This framework enables a conclusion to be drawn on whether there is high, moderate, low, or very low confidence in the findings.

Results

This systematic review is currently underway. In September 2022, initial database searches identified 7330 unique studies for title and abstract screening. It is anticipated that the review, including data extraction and synthesis, will be completed by December 2023. Upon completion, results will be reported in line with PRISMA and disseminated in a peer-reviewed journal. Before submission, searches will be rerun to capture any additional articles that have been published since the initial database searches.

Discussion

This paper summarizes the protocol for a systematic review and prospective meta-analysis on mediators and moderators in the co-occurring anxiety and alcohol relationship. The review will incorporate studies from a wide spectrum of anxiety and alcohol classifications, including from anxiety symptoms to anxiety disorders and from alcohol use to alcohol use disorders. The biopsychosocial model will be used to synthesize identified factors to determine the distinct roles of biological, psychological, and social mechanisms.

Existing studies often examine a single mediator or moderator, despite evidence of multiple mechanisms contributing to the alcohol and anxiety relationship [12]. In light of this, this review will be the first to consolidate the literature to date on mediators and moderators driving this common comorbidity. Identified mediators and moderators can then be used as targets to develop and refine prevention, early intervention, and treatment approaches for comorbid anxiety and alcohol use concerns. In some cases, the identified mediating and moderating factors may not be modifiable in interventions; nonetheless, synthesizing this evidence will help advance the theoretical basis underlying this common comorbidity. As this review will focus on both the pathway from anxiety to alcohol use and the pathway from alcohol use to anxiety, findings may suggest different prevention and intervention approaches are needed depending on the temporal sequencing of the two disorders. One limitation, however, of the planned review is the inclusion of cohort and cross-sectional studies, which will limit the ability to draw causal conclusions for all results. The inclusion of these study designs is warranted nonetheless, as preliminary searches indicated most mediation and moderation studies for anxiety and alcohol were not longitudinal.

The findings of this review will offer critical insights into the conceptualization of comorbid anxiety and alcohol use, providing a foundation for researchers, clinicians, and policy makers to enhance outcomes in addressing this complex clinical manifestation. These results have the potential to drive advancements in understanding, prevention, and treatment strategies, thereby positively impacting individuals experiencing anxiety and alcohol use concerns.

Acknowledgments

TG (the primary author) is supported by a National Health and Medical Research Council (NHMRC) Postgraduate Scholarship (GNT2013845). NCN is supported by an NHMRC fellowship (GNT1166377). LAS receives salary support from the University of Sydney Faculty of Medicine and Health Fellowship. KP receives salary support from an Australian Rotary Health Royce Abbey Postdoctoral Fellowship. The funders had no role in study design, data collection and analysis, the decision to publish, or the preparation of the manuscript.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Abstract

Background: Nurses comprise over half of the global health care workforce, and the nursing care they provide is critical for the global population's health. High patient volumes and increased medical complexity have increased the workload and stress of nurses. As a result, the health of nurses is often negatively impacted. Wearables are used within the health care setting to assess patient outcomes; however, efforts to synthesize the use of wearable devices focusing on nurses' health are limited.

Objective: The primary objective of our integrative review is to synthesize available data concerning the utility of wearable devices for evaluating or improving (or both) the health of nurses.

Methods: We are conducting an integrative review synthesizing data specific to wearable devices and nurses' health. The research question for this review aims to answer how wearable devices are used to evaluate health outcomes among nurses. We searched the following electronic databases from inception until July 2022: PubMed, Embase, CINAHL, Web of Science, IEEE Explore, and AS&T. Titles and abstracts were imported into Covidence software, where citations were screened and duplicates removed. Title and abstract screening has been completed; however, full-text screening has not been started. Further screening is being conducted independently and in duplicate by 2 teams of 2 reviewers each. These reviewers will extract data independently.

Results: Search strategies have been developed, and data were extracted from 6 databases. After the removal of duplicates, we collected 8603 studies for title and abstract screening. Two independent reviewers conducted the title and abstract review, and after resolving conflicts, 277 full-text articles are available for review to determine whether they meet the inclusion criteria.

Conclusions: This integrative review will provide synthesized data to inform nurses and other stakeholders about the extent of wearable device–related work done with nurses and provide direction for future research.

Introduction

Globally, nurses constitute the largest body of regulated health care professionals and account for the greatest proportion of direct patient care hours [1-3]. Patient volumes and medical complexity have increased due to organizational factors (eg, understaffing) and population aging, increasing the workload and stress of nurses—these are 2 factors known to negatively

XSL•FO
RenderX

influence their overall health, quality of life, and job satisfaction [4-6]. In addition, the physical and psychosocial demands of nursing have resulted in many nurses leaving direct patient care or the profession, increasing the burden of care on an already strained profession [7-9]. The negative consequences on nursing staff are reported to have a spillover effect on patient outcomes, and high-stress environments are known to negatively influence the quality of care by nurses [4,10].

The use of wearable devices is growing among the general public [11]. Wearable devices are small electronic devices that are noninvasive and are attached to a piece of clothing that a person is wearing, worn as a device anchored directly to the body, or attached directly to the skin, and have embedded sensors with wireless mobility (eg, Fitbit tracker and Apple Watch) [12-14]. There is growing interest in the use of wearables in the health care setting to provide data for monitoring and to improve the delivery of care for patients in both outpatient and inpatient settings [15-18].

Another potential application of wearable devices in the health care setting is with the staff providing patient care, including the nursing staff. Some nursing staff are already using wearable devices for personal or work-related reasons, such as physical activity monitoring [19], highlighting the feasibility of collecting wearable data and assessing its utility in informing decision-making about nurses' health. However, efforts to synthesize wearable devices that focus on nurses' health are limited, with previous reviews focused heavily on sleep health [20,21] or those not specific to nursing [22]. Given the increasing popularity of wearables, coupled with the health challenges that nurses are currently facing, conducting a rigorous review of how wearables are being used to assess the health of nurses would provide evidence-based knowledge to inform how to move forward with the use of wearables to address the health of nurses.

Therefore, the primary objective of our integrative review is to synthesize available data concerning the utility of wearable devices for evaluating or improving (or both) the health of nurses. Specifically, we seek to evaluate the frequency of their use and the associations between wearable devices and health outcomes (physical or psychosocial) among nurses. We hypothesize that the current body of literature is suitable for synthesis, though outcomes and devices are heterogeneous.

Methods

Overview

We aim to conduct an integrative review synthesizing all data specific to wearable devices and the health of nurses. We used the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) checklist to guide the reporting of this protocol [23]. For the final manuscript, we will use the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines to guide the reporting of the review [24].

Research Question

The research question for this review aims to determine how wearable devices are used to evaluate health outcomes among nurses. A PICO (population, intervention, control, and outcomes) format was used to guide this study [25], with the population being nurses, the intervention being wearable devices, the control being usual care, and the outcomes being health outcomes (including physical and psychosocial).

Data Sources and Search Strategy

We searched the following electronic databases from inception until July 2022: PubMed, Embase, CINAHL, Web of Science, IEEE Explore, and AS&T. We consulted an academic-affiliated librarian for the literature search. In addition, we will conduct citation tracking for all eligible studies to highlight articles potentially missed by our search strategy. Textbox 1 displays the specific search and MeSH terms used to identify articles during the search with 2 of the databases. Outcome terms were not included in the search strategy to ensure the search was as inclusive as possible, given the exploratory nature of this review.

Textbox 1. Search Strategy for PubMed and CINAHL.

Study Selection and Screening

To be included in this review, studies must meet the following four inclusion criteria: (1) nurses must be in the population studied (>80% of the sample), (2) a wearable device must be included (which the nurses have attached to their clothing, worn as a device anchored directly to their body, or attached directly to their skin, and that has embedded sensors with wireless mobility), (3) there must be a health outcome studied, including physical and psychosocial outcomes, and (4) the study has an observational or interventional design (prospective and retrospective). Studies are excluded if they meet 1 or more of the following exclusion criteria: (1) they do not report on health outcomes, (2) they are specific to nursing students, (3) they use wearable devices with patients, (4) they are not published in English, (5) they are protocols, (6) they are reviews, or (7) they are located only in the gray literature.

Titles and abstracts were imported into Covidence software, where citations will be screened and duplicates removed. Title, abstract, and full-text screening will be conducted independently and in duplicate by 4 reviewers. Cohen κ statistics will be reported to evaluate the interreviewer agreement at different stages. Inclusion and exclusion criteria guide the full-text screening. Cases of disagreement between reviewers regarding study inclusion will be resolved through discussion.

Data Extraction and Analysis

Four reviewers will extract data independently and in duplicate. We will collect citation information, study design and location, recruitment data, sample information, wearable device data, outcome data, and biometric cross-reporting data using an author-developed data extraction form (Table 1). Given the nonsystematic nature of this review, statistical pooling of inferential estimates will not be conducted. We will report measures of frequency and central tendency to describe sample and study characteristics.

Table 1. Data extraction form.

Citation information	Study design and location	Recruitment data	Sample information	Wearable device data	Outcome data	Biometric cross-reporting
First author (year), title	Type of study design, single versus multisite, and type of site	Inclusion and exclusion criteria, time frame, location of data collection	Total sample size, gender and age data, and country	Type and use of wearable device and measures used in reporting	Primary and secondary health outcomes, assessment time points, and key findings	Reporting of biometric wearable sensor data with nurse activities

Results

Search strategies were developed, and data were extracted from 6 databases in July 2022. After the removal of duplicates, we collected 8603 studies for title and abstract screening. Three independent reviewers conducted the title and abstract review, and after resolving conflicts, there were 277 full-text articles to review. The initial title and abstract review had an overall agreement value of 95.7%, resulting in a moderate Cohen κ of 0.43 for interrater reliability [26]. After the full-text articles are reviewed independently for study eligibility by 4 reviewers, data will be extracted. Additional data may be located after we check the eligible article references. All extracted data will be reported using narrative and tabular formats. We will organize the reported data in accordance with 4 key factors: the type of wearable devices, the wearable measures reported, the health outcomes reported, and the methodology used. Considering the size and depth of this review, we will not report on the feasibility or acceptance of wearable devices in nursing. Results are expected to be available in the fall of 2023.

Discussion

This integrative review aims to carefully examine studies available in the global literature that have used wearable devices to improve health among nurses. The goal is to evaluate and inform on the measurement of health outcomes obtained via wearable devices among nurses. These studies will include the results of both descriptive and correlational and interventional studies that tested a wearable device to assess the effect on the nurses' health. Given the importance of physical and psychological health for nurses, we are examining both facets of health. Synthesized results from this review will inform multiple stakeholders, including the nursing workforce, health system administrators, wearable device developers, health insurance companies, policy makers, and mobile health researchers.

As wearable devices continue to evolve rapidly and improve, becoming easier to use while providing richer data sources, it is pertinent that nursing and those supporting their health consider its use and value [27,28]. Using wearable devices for assessing, informing, and providing the information needed to develop healthier behaviors should positively impact the nurses' health and well-being. This should consequently positively affect health care systems that employ nurses, especially in light of nursing labor shortages. Further, the downstream impact of healthy nurses can improve the care and outcomes of the patients they care for in inpatient, outpatient, and community settings.

This work can inform existing movements focused on improving nurses' health; for example, *Healthy Nurse, Healthy Nation*, a program designed by the American Nurses Association Enterprise [29]. The overarching goal of this program, which has existed in the United States since 2017, is to improve nurses' health in the nation. The 6 domains they focus on are activity, rest, nutrition, quality of life, mental health, and safety. Longitudinal data have been collected on hospital workers, including nurses, where several of these domains have been studied, including collecting data on physical and mental health markers, demonstrating how data can be collected over time in

XSL•FO
RenderX

nurses [30]. In addition, several domains, including physical activity and rest, have been studied with nurse shift workers using commercially available sensors, where they found poorer health outcomes in night shift nurses [31]. For the safety domain, wearable devices are already known to assess these areas with other populations (eg, military and construction workers) [32,33].

Using biometric screening and tracking of occupational activities performed by the nurse provides an opportunity to assess which activities may contribute to poor physical outcomes for the nurse [34]. In addition, predictive analytics can provide context for mitigating those occupational activities that put nurses at risk for adverse health consequences [27]. However, obtaining data from biometric monitoring devices is a field that continues to evolve, and methodological specificities of tools used to obtain biometric data must be carefully reported [35].

Nurses comprise over half of the global health care workforce, and the nursing care they provide is critical for the global population's health [3]. Understanding existing work that has been done to date with the use of wearable devices and focused on nurses' health has the potential to inform how to improve the health of the nursing workforce. This integrative review will provide synthesized data to inform nurses and other stakeholders about the extent of wearable work done with nurses and provide direction for future research.

Acknowledgments

The research team thanks Jessica Sender, MA, MLS, for her assistance with the literature search.

Data Availability

The research team will make available all synthesized data within the text of the manuscript or supplemental files. The data used will already be published and available.

Conflicts of Interest

None declared.

Abstract

Background: There is growing literature on the potential of digital technologies for improving access to, ensuring continuity and quality of health care, and to strengthen health systems. Some studies have reported the cost-effectiveness of teledentistry, its reliability for remote dental screening, diagnosis, consultation, and treatment planning. Nonetheless, current evidence suggests that teledentistry implementation faces many challenges and is not yet adopted by dental health care providers (DHCPs). Developing strategies to improve teledentistry adoption requires an understanding of the factors that promote or hinder its successful implementation.

Objective: This systematic review aims to identify and synthetize barriers and enablers to implementing teledentistry as perceived by DHCPs in their clinical practices, using the Theoretical Domains Framework (TDF) and the Capacity, Opportunity, and Motivation Behavior (COM-B) model.

Methods: This protocol follows the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Protocols) checklist. Literature will be searched in the following databases: PubMed, Cochrane Library, Web of Science, CINAHL, Embase, and PsycINFO. We will perform additional searches on Google, Google Scholar, and ProQuest Dissertations & Theses Global, screen the references of the included studies to capture additional relevant studies, and contact the authors of studies if we need more details. We will consider studies using qualitative, quantitative, and mixed methods. There will be no restrictions on the publication date and dental setting. We will include studies published in French, English, and Portuguese. Two independent reviewers will select the study, extract data, and assess methodological quality using the Mixed Methods Appraisal Tool's checklist. Data analysis will include a descriptive and a thematic content analysis. We will synthetize and categorize the barriers and enablers using the TDF and COM-B model and present a narrative synthesis of our results using tables, figures, and quotes.

Results: By March 2023, the literature search has retrieved 7355 publications. We will identify the range of barriers and enablers to implementing teledentistry through DHCPs' perspectives. Considering the critical need for theory-based implementation interventions to improve the use of evidence-informed practices, we will synthesize the factors influencing the adoption of teledentistry based on the TDF domains and the 3 essential conditions predicting behavior change in accordance with the COM-B model. As needed, we will include additional determinants if not included in the TDF. We will conduct some subgroups analyses if studies are sufficient. We expect to complete the review by July 2024.

Conclusions: This review will provide some insights on the determinants of teledentistry implementation as perceived by DHCPs in dental settings. These findings will cater to patients, families, DHCPs, researchers, academic and professional

XSL•FO
RenderX

decision-makers, and policy makers. The results of the systematic review could be used to develop theory-led interventions in improving teledentistry implementation.

Introduction

Oral diseases significantly affect overall health, well-being, and quality of life and cause an increased economic burden at the patient and society levels. The Global Burden of Disease study in 2019 estimated that oral diseases affect close to 3.5 billion people across the world [1]. Despite interventions developed to improve oral health, numerous oral health inequalities persist over time and space with the greatest burden among marginalized people [1,2], resulting in poor oral health status. Considering the social and economic burdens related to oral health diseases and conditions, and their interconnection with some prevalent noncommunicable diseases [3], there is an international movement toward the imperative need to place oral health care within universal health coverage (UHC) and to improve essential oral health care [4], and to identify optimal strategies to improve oral health and oral health-related quality of life. Consequently, digital health tools are a promising means to address peoples' health needs related to expanding UHC [5], in improving access to, continuity of, and quality of care and to strengthen health systems [6,7].

A growing body of evidence reports the potential of teledentistry, at the intersection of dentistry and telecommunications, as highly pertinent to the future of dentistry [8]. Teledentistry aims to use technologies and related services to deliver oral health care. It has proven to be effective and reliable for remote dental screening, diagnosis, consultation, and treatment planning [9,10]. Several reviews have reported the effectiveness and validity of teledentistry for prevention and health promotion and its accuracy for the diagnosis of oral diseases with results that are comparable to those of face-to-face interventions [10-13]. Dental health care providers (DHCPs), patients, and caregivers also have favorable attitudes and good satisfaction regarding digital interventions in dentistry [8]. Teledentistry has the potential to improve patients' experiences [14,15], population health [16-18], DHCPs' experiences [8,19] and to reduce oral care costs [20-22].

While valuable insights to the implementation of teledentistry can be obtained from decision-makers, patients, and caregivers, it is greatly recognized that DHCPs are among the key actors for the successful digital transformation [6,22,23]. As health professionals, DHCPs' clinical acceptance are among the most important influences on the successful uptake, spread, and sustainability of teledentistry [23]. Consequently, DHCPs' behaviors are an important proximal determinant of the quality of care provided to patients [24]. In their position as sources of information and opinion leaders who shape the clinical encounter, they could ensure teledentistry implementation and sustainability [25]. Their perspective is important to increase the expansion of teledentistry implementation and to deliver the right information to the right people at the right time. A better understanding of barriers and enablers that influence DHCPs' behavior is a prerequisite to the successful implementation of teledentistry, as its adoption can help improve the patients' outcomes and experiences.

Despite the promises of teledentistry, some empirical and theoretical studies have shown that teledentistry implementation remains a challenge [23,24,26,27]. Previous studies have reported that teledentistry has not yet been widely adopted by DHCPs [28-30]. The variation in the use of web-based oral health care cannot be explained by clinical factors or technical aspects alone. Structural, organizational, and DHCP- and patient-related factors including the absence of legal regulation of teledentistry, poor internet connection, lack of reimbursement, lack of training, and lack of familiarity with teledentistry [31,32] have been identified as barriers to implementing teledentistry. To maximize teledentistry implementation, it is crucial to understand DHCPs' perspectives and to support them to modify their clinical behavior toward this modality of the delivery of oral health care. Understanding the barriers and enablers to the implementation of teledentistry is imperative to inform the design and the development of successful theory-led interventions, as well as the appropriate educational resources for the future implementation of teledentistry in dental practices.

Currently, there is no strong evidence available to inform decision-making, nor is there a tailored theoretically informed intervention designed to enhance its successful implementation. Systematic reviews offer a way to synthesize the broad range of barriers and enablers reported in the literature and to provide a broader, in-depth understanding of the factors influencing teledentistry implementation. Furthermore, many studies have reported the relevance of a theoretical framework to categorize the factors that influence health care professionals' behaviors, inform the selection of behavior change techniques (BCTs) [24,33], and develop theory-driven and tailored strategies to support the effective implementation of any innovation [34-36]. To our knowledge, there has been no review of available evidence regarding DHCPs' perspectives about the determinants of teledentistry implementation, nor has there been a previous systematic review using a theoretical framework to describe factors that may influence its implementation. This systematic

XSL•FO
RenderX

review, therefore, aims to identify and synthesize barriers and enablers reported by DHCPs to implementing teledentistry in their clinical practices, using the theoretical domain framework and the Capacity, Opportunity, and Motivation Behavior (COM-B) model to determine factors predicting behavior change. This review protocol will address the question: "what are the barriers and enablers to teledentistry implementation that are reported by DHCPs in dental settings?"

Findings from this review will be valuable to inform the designing, planning, and implementation of teledentistry in any dental setting.

Methods

Study Design

The protocol for this review is registered on PROSPERO (CRD42021293376). This protocol has been written in accordance with the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Protocols) checklist [37]. The systematic review will be reported in accordance with the PRISMA checklist [38].

Eligibility Criteria

We will follow the PICOS (participants, interventions, comparators, outcomes, and settings) framework [39].

Participants

We will include studies about the adoption of teledentistry by DHCPs. The DHCPs are dental professionals directly involved in clinical acts with patients. This review will include any dental professionals involved in oral health care. These DHCPs include general and specialist dentists, dental hygienists, dental therapists, dental nurses, dental students, dental hygiene students, and dental therapy students. All specialties in dentistry will be considered (eg, orthodontics, oral medicine, oral pathology, prosthodontics, periodontics, endodontics, pedodontics, and oral and maxillofacial surgery). If other participants such as patients, other health professionals, or managers are involved in a study with these DHCPs, the study will be included.

Intervention

We will include only those studies that use teledentistry for the delivery of oral health care. Teledentistry interventions could be compared to usual or standard dental care or face-to-face dental visits (in-person) or no comparator. DHCPs can use several devices including cell phones, tablets, telephones, computers, personal digital assistants, text messaging, and apps [40-44] to interact with colleagues, other health professionals, or patients. We will include any studies on teledentistry delivered through different modalities such as synchronous (in real time; ie, direct interaction between a person [patient, caregiver, or health professional] and a DHCP) and asynchronous (store and forward; ie, transmission of health information to DHCPs to evaluate a patient's condition or render a service outside of a real-time or live interaction) modalities. These interventions can be delivered through videoconference (eg, Zoom), telephone, websites, or any applications such as WhatsApp or other web-based mechanisms.

Types of Studies to Be Included

We will include all studies with an original data collection. If there are several publications on the same project presenting similar data, we will include only the most recent publication, and if results are complementary and relevant, we will include all of them. We will include quantitative, qualitative, and mixed methods studies.

Outcomes

We will include studies with different synonyms related to teledentistry implementation such as adoption, usage, uptake, readiness, and intent to its use. We will include studies reporting factors that could influence teledentistry implementation as reported by DHCPs; for instance, knowledge, intention, behavior, self-efficacy, satisfaction, skills, social influences, environmental context, and resources. We will include studies where data are collected using a variety of techniques, including individual interviews, focus groups, or questionnaires. We will include studies using validated or nonvalidated measurement tools to collect data. In this review, we will consider an enabler as any circumstance, factor, or variable that positively influences teledentistry implementation. A barrier will refer to any circumstance, factor, or variable preventing teledentistry implementation.

Settings

We will consider all dental settings such as dental offices, community-based care, hospitals, schools, long-term care facilities, nursing homes, home dental care, university, and private or public dental settings. We will consider any geographical setting (eg, rural or urban regions) and any country (low-, middle-, or high-income).

Exclusion Criteria

We will exclude any study using teledentistry only for education, training, and research. Studies may include other participants such as patients and other health care professionals, but DHCPs must be part of the studied population in the methodology, with the possibility to extract information from DHCPs. We will exclude studies that do not have a clear distinction between DHCPs and other participants' findings. We will exclude any study focusing on health care providers other than DHCPs. We will exclude any studies focusing on the features of a platform for teledentistry, or the validity of teledentistry. Studies that are limited to describing the feasibility, usability, or technical evaluation of certain systems, interfaces or platforms will also be excluded. We will exclude editorials, letters, abstracts, reviews, commentary reports, legal issues, protocols, and press releases.

Information Sources and Search Strategy

A health science information specialist will assist us in developing the literature search strategy in PubMed and will translate it after validation and revision in other electronic databases. A second health science information specialist will review the initial search strategy with the Peer Review of Electronic Search Strategies Tool [45]. The main concepts considered in the search strategy are "teledentistry," "telemedicine oral health," or "remote dental care," "remote

XSL•FO
RenderX

oral care," "virtual dental care," or "virtual oral care" and "dental health care providers," "health personnel," or "dentistry." The electronic search will be carried out to identify all relevant studies from the following databases: PubMed, Cochrane Library, Web of Science, CINAHL, Embase, and PsycINFO. We will perform additional searches in Google, Google Scholar, and ProQuest Dissertations & Theses Global. We will screen the references of included studies to capture additional relevant studies.

There will be no restriction on the date of publication of the studies. We will include studies published in French, English, and Portuguese. A draft search strategy for MEDLINE has been developed with the support of a health science information specialist and is available in Multimedia Appendix 1.

Selection Process and Data Collection Process

Data Management

We will import the list of generated references into EndNote X9 (Clarivate Analytics) software. We will identify and remove all duplicates. Retained studies will be uploaded in Covidence [46] for data screening and selection.

Selection Process

Two independent reviewers will select the retrieved studies. They will perform a calibration exercise with 10% of the total number of identified studies to ensure a mutual understanding of the eligibility criteria and to identify areas where further clarification is needed. Following the conclusive pilot test, the 2 reviewers will independently select studies at 2 levels: the first level of selection will be based on the titles and abstracts only (providing codes of "Yes," "No," or "Maybe"), and the second level will concern the full texts. All studies coded as "Yes" or "Maybe" will be further reviewed in full text by both reviewers. We will report the reasons for the exclusion of any retrieved or selected study.

Discrepancies will be resolved though discussion and consensus or with the consultation of a third reviewer. The selection stage will be considered an iterative process, allowing the eligibility criteria to be refined by the research team. We will contact authors for articles that cannot be obtained through institutional holdings.

Data Extraction

Two reviewers will extract the data independently using an Excel (Microsoft Corp) data extraction sheet. A calibration exercise will be independently performed by both reviewers on 5% of the included studies. The data extraction sheet will be modified and revised as necessary during the process of extracting data. Consistent with the abovementioned steps, data charting will be considered an iterative process as the review develops. Any disagreements that arise between the reviewers will be resolved through discussion and consensus, or with the consultation of a third reviewer. The draft extraction form is provided in Multimedia Appendix 2. The following data will be extracted:

- Characteristics of the included studies (eg, title, main author, year of publication, country of publication, language of publication, aims, funding, type of publication, study design, dental care settings, use of a theoretical framework, name of the theoretical framework, methods of data collection, limitations, and conclusions)
- Participant characteristics (eg, profile, sample size, sex, gender, age, general dentist or specialist, type of specialty, type of practice, and region of practice)
- Characteristics of teledentistry (eg, synchronous or asynchronous)
- Study outcomes (eg, knowledge, practices, beliefs, self-efficacy, time, compliance, behavior, teledentistry adoption and use, training, reimbursement, and equipment).

We will contact the authors if we need additional information on the study.

Risk of Bias and Quality Assessment

Two independent reviewers will assess the methodological quality of the included studies using the core quality criteria in the Mixed Methods Appraisal Tool (MMAT) [47]. The MMAT is a reliable tool, and its use has been widely reported in the literature to facilitate the critical appraisal of mixed studies reviews [48-51]. It was first reported in 2009 as a single tool to evaluate the methodological quality of 5 categories of study designs: qualitative studies, randomized controlled trials, nonrandomized studies, quantitative descriptive studies, and mixed methods studies [50]. Further attempts to refine and improve the MMAT led to the development of its current version in 2018, based on the findings from a literature review on critical appraisal tools, pilot and interrater reliability testing, interviews with MMAT users, and the Delphi approach [52]. There are 5 questions each for quantitative and qualitative study designs and 15 for mixed method studies. The answer categories include "yes," "no," or "can't tell" [47]. As required by Hong et al [47], we will present in detail the ratings of each criterion to better inform the quality of the included studies. We will present the overall quality score of the included studies using a descriptor such as an asterisk (*) or the percentage of quality criteria met [49]. For instance, 1 (*) refers to 20% of the quality criteria met, while 5 (*) refers to 100% of the quality criteria met. For mixed methods studies, we will provide 3 scores including one for qualitative, one for quantitative, and one for mixed methods components. The overall quality of the mixed methods study cannot exceed that of its weakest component [49].

We will consider for the included studies the following cutoff: studies with 1 and 2 (*) will be considered as being of low quality, 3 stars as medium quality, and 4 and 5 stars as high quality. Any discrepancy will be resolved through discussion and consensus or with the consultation of a third reviewer.

Data Synthesis

A narrative synthesis will be conducted. We will analyze the data extracted using descriptive statistics (eg, frequencies and percentages). For instance, we will report the types of study designs, type of teledentistry interventions, countries where studies were conducted, and the study characteristics. We will synthesize and map the factors influencing teledentistry implementation in accordance with the theoretical domains of Theoretical Domains Framework (TDF) [53] and the context

XSL•FO
RenderX

of information reported by the authors in order to allocate the factor to the appropriate theoretical domain. The likelihood is relatively low to miss a potential determinant of teledentistry implementation considering the wide range of factors considered within the TDF. We will report any new construct that is not considered in the TDF.

The robust theoretical model of TDF is more appropriate for this review because of its comprehensiveness. It is a promising and useful way of mapping the broad range of factors that influence a range of behaviors. It has been used in the literature to synthesize and classify the different determinants of a behavior and to target the relevant interventions [54,55]. In its original version, the TDF was composed of 12 theoretical domains (eg, knowledge, skills, social or professional role and identity, beliefs about capabilities, beliefs about consequences, motivation, goals, memory attention and decision processes, environmental context and resources, social influences, emotion, and action planning) that were derived from 33 behavior change theories using a process of expert consensus. The domains are considered as potential determinants of behavior and clearly indicated as barriers and enablers or factors positively or negatively influencing the behavior being studied. Some years later, the TDF has been refined and included in its revised version 14 theoretical domains and 84 theoretical constructs that can influence behavioral change [54]. These 14 individual and environmental theoretical domains include knowledge; social or professional role and identity; beliefs about capabilities; beliefs about consequences; skills; goals; optimism; reinforcement; intention; memory, attention, and decision processes; environmental context and resources; social influences; emotion; and behavioral regulation [54] (Multimedia Appendix 3).

Authors of previous reviews on teledentistry implementation have identified several potential factors influencing its implementation such as awareness, attitudes, knowledge, skills, training, lack of reimbursement, lack of infrastructure, self-confidence, organizational difficulty, quality of information, fear, lack of evidence, lack of guidelines, and data security issues [16,30,31,56]. These constructs can fit under the TDF domains of knowledge, skills, beliefs of capacities, beliefs about consequences, reinforcement, goals, emotion, identity and social roles or responsibilities, environmental context, and resources. In a systematic review of reviews on the barriers and facilitators to clinical behavior change by primary care practitioners, the authors have reported that 3 TDF domains were most commonly reported across many reviews, regardless of the type of behavior change and context: knowledge, environmental context and resources, and social influences [57].

Based on this information and our experience in dentistry, the preliminary step of selection of the TDF domains' constructs could include without exhaustivity: procedural knowledge, knowledge, skills, skills assessment, competence, professional identity or role, self-efficacy, beliefs, attitudes, incentives or reimbursement, resources, infrastructures, social norms, fear, stress, and breaking habits.

The domains of the TDF are further mapped in 3 major essential conditions predicting behavior change, which are components of the COM-B model [33]. The COM-B component "Capability" can be psychological or physical and includes knowledge and skills. The component "Opportunity" can be social or physical and could include social influences and environmental context or resources. Finally, the component "Motivation" can be a reflective process, or automatic process and could include intention and emotions. This approach guides the understanding of behavior in all contexts. The COM-B model is a part of the "behavior system," which helps to design interventions [33] through BCTs [58]. According to the analysis of the nature of behavior and the relevant mechanisms to elicit change, the Behavior Change Wheel is a reliable framework that aims to link the determinants of the target behavior to the design and selection of interventions and policies (Multimedia Appendix 4). Considering the critical need for theory-based implementation interventions to improve the use of evidence-informed practices, we will organize the barriers and enablers by these essential conditions, which could be behavioral change components with high potential to improve teledentistry implementation. If possible, we will perform subgroup analysis based on the number of eligible studies with the following variables: age, gender, type of dental professionals (eg, dentists versus dental hygienists), category of dentists (eg, generalist and specialists), type of setting (eg, private or public), and time period (before and after 2020 with the COVID-19 pandemic), and their methodological quality. Results will be reported in tabular form, graphics, and quotes to reflect the extent of included literature.

At the end of the review, we will have an in-depth understanding of barriers and enablers from DHCPs' perspectives as well as the comprehensiveness of TDF domains, constructs, and predicting factors.

Results

As of March 2023, we have updated the search strategy. The search strategy identified 7355 studies. This systematic review will aim to identify and synthetize the barriers and enablers to teledentistry implementation from DHCPs' perspectives. We will present the sociodemographic information or moderators reported by the authors of these studies, which could influence behavior change. Furthermore, possible research gaps may be identified to guide future studies. Our results will be reported in accordance with the PRISMA-P checklist [38]. We expect to complete the review and publish the results within a year of publication of this protocol—around July 2024.

Discussion

Anticipated Findings

This review will identify and synthesize the enablers and barriers influencing teledentistry implementation from DHCPs' perspectives. These factors can represent micro to macro levels of analysis, which will affect implementation success and predict implementation efforts. The TDF, one of the robust and common theoretical frameworks used in implementation science, will allow us to comprehensively classify the range of barriers and enablers related to teledentistry implementation, which could assist later in the development of tailored implementation

XSL•FO
RenderX

interventions [35]. The TDF has also been used as a coding framework for the analysis of barriers in systematic reviews [34,59,60]. However, to our knowledge, its use is limited in dentistry and was not used to synthetize the factors influencing teledentistry implementation as reported by DHCPs. The knowledge of determinants from the TDF and COM-B model will inform the selection of targeted BCTs, which, in turn, can be used to design behavior change interventions to improve the implementation of teledentistry. We will present the strengths and limitations of this review. As such, implications of the review findings for future research, practice, and policy will be discussed and presented.

Conclusions

This systematic review protocol presents the methodological steps aiming to identify and synthetize the barriers and enablers to implementing teledentistry from DHCPs' perspectives using strong theoretical frameworks. The results of this review can be relevant for different knowledge users including patients, DHCPs, researchers, managers, academics, policy makers, and professional decision-makers in regulatory bodies to design behavioral change interventions to improve the success of teledentistry implementation in dental settings.

Acknowledgments

The authors have received the funding from the "Fondation Émile-Beaulieu" from the Faculty of Dentistry, Laval University.

Data Availability

The data sets generated and analyzed during this study will be available upon request to the corresponding author after publication of the review.

Amendments

We will publish any changes to this protocol as amendments on our PROSPERO protocol web page. We will declare any changes and the date of the amendments, including the rationale for them.

Authors' Contributions

PKT conceptualized the study, developed the draft, and wrote the manuscript. PKT, CI, AD, DZ, FB, and FC contributed substantially to writing and editing the manuscript. All authors read and approved the final study protocol.

Conflicts of Interest

None declared.

Abstract

Background: Chronic respiratory diseases (CRDs) may cause reduced oxygen availability to organs and body tissues, leading to an increased risk for ischemic damage, which can result in brain tissue injury. This damage can lead to a myriad of neurological symptoms contributing to cognitive decline. Cognitive interventions may attenuate cognitive deficits in people with CRDs; however, the effects have not yet been systematically summarized in the literature.

Objective: The purpose of this systematic review is to assess the effects of cognitive interventions (including cognitive behavioral therapy and transcranial brain stimulation) on cognitive function (primary outcome), HRQL, self-management, symptoms, physical activity, physical function, ability to complete activities of daily living (ADLs), hospital admissions, functional capacity, functional performance, psychological and social outcomes, exacerbations, healthcare utilization, and survival in individuals with CRDs.

Methods: This review will be conducted in accordance with the Cochrane handbook for systematic reviews of interventions and reported following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. Searches will be performed in MEDLINE, Embase, Emcare, PsycINFO, Scopus, and CINAHL. Articles will be included if they focus on the effects of cognitive interventions on adults with CRDs, are published in peer-reviewed journals, and are written in English, French, or Portuguese. Risk of bias will be evaluated with the Cochrane Risk of Bias 2 tool for randomized controlled trials, and the Risk of Bias in Non-randomized Studies of Interventions tool for nonrandomized studies. Meta-analyses will be performed if at least 2 studies provided sufficient data for a specific outcome. The GRADE (Grading of Recommendations, Assessment, Development, and Evaluation) assessment will be used to evaluate the overall quality of the evidence.

Results: This systematic review was initiated in November 2022 and registered with PROSPERO in February 2023, prior to title and abstract screening. Full-text screening of articles will be completed in June 2023. Data extraction and drafting of the manuscript will occur from July 2023 to August 2023, with expected publication in February 2024.

Conclusions: This systematic review will summarize the effects of cognitive interventions on cognitive function in people with CRDs. It will guide health care professionals in selecting evidence-based strategies to enhance cognitive well-being and overall health outcomes for individuals with CRDs. Additionally, it will identify research gaps and highlight areas for future exploration, supporting researchers in advancing knowledge in this field.

Introduction

Chronic respiratory diseases (CRDs) are the leading causes of morbidity and mortality, contributing to three million deaths per year worldwide and US $170.8 billion in health care–related costs in 2016 [1]. Clinical presentation of CRDs includes both pulmonary and extrapulmonary symptoms, including dyspnea, cough, musculoskeletal impairments, and cognitive decline, ultimately limiting individuals' abilities to engage in activities of daily living (ADLs) [2].

Cognitive decline is reported in 60% of people with CRDs and has been related to a state of reduced oxygen availability in tissues, resulting in an increased demand for oxygen to maintain homeostasis [3,4]. As CRDs progress, physiological changes such as airway obstruction, inflammation, fibrosis, septal thickening, interstitial edema, intra-alveolar exudate, and destruction of alveolar capillaries can reduce airflow and pulmonary gas diffusion. Such changes lead to impaired exchange of oxygen and carbon dioxide, resulting in hypoxemia, hypoxia, and hypercapnia [5,6]. If maintained, hypoxemia can affect the synthesis of neurotransmitters essential for brain function, such as acetylcholine [4], and cause ischemic brain damage [5,6].

Consistent cerebral hypoxia can present as a multitude of neurological symptoms associated with cognitive decline, including deficits related to memory, information processing, language, attention, visuospatial abilities, judgment, and executive functioning [3,7-9]. As a result, an individual's ability to manage their disease, such as medication tracking and symptom monitoring, may be impeded by this cognitive decline [9,10]. Thus, maintaining and improving cognitive status is crucial to help promote disease self-management and independence in individuals with CRD.

Cognitive interventions encompass a range of targeted approaches designed to maintain or improve specific cognitive functions, such as attention, memory, and reasoning [11,12]. These interventions may involve structured training programs, therapeutic techniques, and innovative methods like transcranial brain stimulation (TBS). They are aimed at improving impaired cognitive function, preventing cognitive decline, or preserving the individual's functional level, drawing from diverse theoretical constructs [13]. Previous studies on non-CRD populations have reported improvements in general cognitive functioning, processing speed, and cognitive abilities related to everyday task performance following cognitive interventions [14]. In addition, these interventions have been reported to slow the progression of cognitive decline, particularly in populations with cognitive impairment [15]. However, the literature on the effects of cognitive interventions for people with CRDs is inconclusive, as it is heterogeneous in terms of sample characteristics, interventions, and outcome measures. Several studies, including randomized controlled trials (RCTs) investigating cognitive interventions in patients with chronic obstructive pulmonary disease, have produced inconsistent and variable findings [16-18]. Although there are possible benefits of cognitive interventions in those with CRDs, such as improvements in cognitive function, self-management, health-related quality of life (HRQL), and performance in trained tasks [16,17], overall, no significant improvement has been found related to cognitive performance, healthy lifestyle behaviors, susceptibility to cognitive stress and cognitive performance [16-18]. Consequently, a review is needed to systematically review and summarize the evidence, and establish its quality to help inform clinical practice as it pertains to the use of cognitive interventions in those with CRDs.

This systematic review primarily aims to assess the effects of cognitive interventions (ie, attention, memory, and reasoning on cognitive function) in people with CRDs. The secondary objectives are to summarize the content and structure of cognitive interventions used within this population and their effects on HRQL, self-management, symptoms, physical activity, physical function, ability to complete ADLs, hospital admissions, functional capacity, functional performance, psychological and social outcomes, exacerbations, healthcare utilization, and survival.

Methods

Overview

This systematic review will be conducted according to the Cochrane Handbook for Systematic Reviews of Interventions [19] and reported following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [20]. The protocol was registered in PROSPERO (CRD42023396234).

Search Strategy

The following electronic databases will be searched in June 2023: MEDLINE (1946-Present), Emcare, Embase, CINAHL, PsycINFO, and Scopus. The search strategy was created in consultation with a health sciences librarian at McMaster University and will involve database-specific MeSH terms in combination with keywords (keywords will be consistent across databases). The reference list of the selected studies will be manually searched to identify further relevant articles. The search strategy was validated in MEDLINE, Emcare, and Embase databases by testing whether it could identify 3 relevant articles to be included, previously sought through Google Scholar [16-18].

XSL•FO
RenderX

Eligibility Criteria

Study Design

Studies will be included if they are RCTs, non-RCTs, pre-post study designs, cohort studies, and case-control studies (all published in peer-reviewed journals). Studies will be excluded if they have been published in conference proceedings, magazines, news articles, dissertations, theses, abstracts, and editorials. Systematic, scoping, literature, and narrative reviews will be excluded but their references will be screened for potential articles. Articles that are not written in English, French, or Portuguese will also be excluded.

Population

Studies will be included if they included participants 18 years of age or older (adult participants) with a diagnosis of a CRD (ie, asthma, bronchiectasis, chronic obstructive pulmonary disease, cystic fibrosis, interstitial lung disease, chronic respiratory tract diseases, post–COVID-19 syndrome, tuberculosis, or lung cancer). Studies will be excluded if they include participants whose primary diagnosis is a cognitive disease or participants presenting with complications such as dementia, Alzheimer, psychological disorders (ie, bipolar disorder), stroke, or trauma, resulting in cognitive impairment.

Intervention

Studies will be included if reporting on the effects of cognitive interventions. Cognitive interventions that help improve or maintain cognitive processes or address the impact of cognitive impairment on overall function will be included. These interventions may involve formally structured training in domains such as information processing speed, attention, memory, or problem-solving. The focus should be on improving the reasoning or cognitive process itself rather than developing a specific skill [21]. As per our definitions, cognitive training and cognitive interventions that include cognitive behavioral therapy (CBT) or TBS focused on improving cognition will be included [22-24]. Cognitive training can be defined as nonpharmacological interventions that involve structured and guided training that aims to maintain or improve certain aspects of cognitive function, including attention, memory, and learning [21]. CBT is defined as an intervention that involves increasing participants' knowledge and understanding of the problem (ie, cognitive function, including attention, memory, and learning); identifying and restructuring dysfunctional thinking and maladaptive beliefs; and developing emotional and behavioral compensatory strategies for the core deficits [22]. It is a diverse group of treatments that include cognitive therapy, CBT, acceptance and commitment therapy, dialectical behavior therapy, schema-focused therapy, rational-emotive behavior therapy, mindfulness-based cognitive therapy, metacognitive therapy, cognitive behavioral analysis system of psychotherapy, and cognitive processing therapy [23]. Transcranial brain stimulation is a non-invasive brain stimulation technique that passes an electrical current through the cortex of the brain to alter brain function [24]. It may include transcranial direct current stimulation, alternating current stimulation, and random noise stimulation [24].

Studies that primarily focus on improving and changing behavioral, emotional, or physical outcomes, single-trial training, and interventions implemented in direct combination with another distinct experimental intervention will be excluded [21].

Having a comparator or control group is not a requirement for inclusion in this review. Accepted types of control groups will be no intervention, usual care, sham intervention, another type of intervention, or multidimensional care (cognitive intervention plus another intervention). Control groups involving another type of cognitive intervention will not be accepted, as this will only determine the effectiveness of one intervention versus the other and not whether cognitive interventions are effective compared to no intervention or another type of intervention.

Outcomes

The primary outcome of this study is cognitive function, which encompasses the mental processes involved in acquiring knowledge, manipulating information, and reasoning [25]. This includes the domains of perception, memory, learning, attention, decision-making, and language abilities [25]. Secondary outcomes include HRQL, self-management, symptoms, physical activity, physical function, ability to complete ADL, hospital admissions, functional capacity, functional performance, psychological and social outcomes, exacerbations, health care usage, and survival.

If sufficient data are available from 2 or more studies, subgroup analyses will be performed for the type of CRD and the structure (ie, duration, frequency, and setting) or components of the cognitive intervention. Such analysis will help determine whether patients with different CRDs respond differently to cognitive interventions, or whether there is a difference in outcomes depending on the cognitive intervention structure or components.

Data Management

EndNote reference manager (Clarivate) will be used to filter duplicate studies. Studies will subsequently be imported into Covidence (Veritas Health Innovation), which will be used for further removal of duplicates, screening, and selecting studies. Excel (Microsoft Corp) will be used for data extraction and management.

Selection Process

Abstracts and full-text screening will be pilot-tested by all reviewers with 12 articles to calibrate the selection process and ensure interrater reliability. An 80% or higher agreement will be sought before proceeding with screening [26]. Six reviewers will independently screen titles and abstracts, with each study requiring consensus between 2 reviewers before a final decision to include or exclude the study for the full-text screening is made [26]. Two authors will independently perform the full-text screening process. At any stage of the screening process, if articles do not meet the inclusion criteria or meet any of the exclusion criteria, they will be excluded and reasons for exclusion will be recorded [26]. Disagreements will be resolved through consensus, and if no consensus is reached, a third reviewer will be consulted.

XSL•FO
RenderX

Data Extraction

Two authors will independently extract the data to a predefined data extraction table, including title, authors, year and country of publication, study design, study setting, sample size per group, population (age, gender, chronic respiratory disease, disease severity, and comorbidities) per group, intervention (type, frequency, components, and duration) per group, outcome measures used, the timing of data collection, follow-up times if applicable, adverse events, and results of the interventions or comparator groups (including the mean, SD, and sample size).

Any disagreements on the extracted data will be resolved by discussion, and a third reviewer will be consulted if no consensus is reached. In the case there are missing data, study authors will be contacted by email to request these data. A follow-up request will be sent after 2 weeks, and if there continues to be no response after 2 more weeks, there will be no further attempts to retrieve the data. If the data are reported only in figures and the authors did not provide the requested data, whenever possible WebPlotDigitizer will be used [27].

Risk of Bias Assessment

Risk of bias assessment will be performed independently by 2 authors at a study level using the Cochrane Risk of Bias 2 tool for RCTs (randomization process, deviations from intended interventions, missing outcome data, measurement of the outcome, and selection of the reported result) or the Risk of Bias in Non-randomized Studies of Interventions tool for non-RCTs (bias due to confounding, bias of selection of participants into the study, bias in classification of interventions, bias due to deviations from intended interventions, bias due to missing data, bias in measurement of outcomes, and bias in selection of the reported result) [28,29]. Disagreements will be solved through discussion, and if no consensus is reached, a third reviewer will be consulted.

Data Analysis and Synthesis

Tables will be used to describe the various types of studies, patient populations, characteristics of cognitive interventions and comparators, and outcomes. Meta-analysis will be performed using the Review Manager (version 5; Cochrane) software. If at least 2 studies reported the same outcome, that outcome will be included in the meta-analysis. Results will be reported as mean difference if the studies used the same outcome measures or standardized mean difference if studies assessed the same outcome using different measures. Depending on the level of heterogeneity between applicable studies, a fixed effects or a random effects model will be used for meta-analysis (ie, a high level of heterogeneity between applicable studies would warrant the use of a random effects model). If a meta-analysis cannot be performed, data will be synthesized narratively, explaining the main findings as they relate to the impact of cognitive interventions for people with CRDs.

Quality of Evidence

For the quality of evidence assessment, the GRADE (Grading of Recommendations, Assessment, Development, and Evaluation) system will be used to upgrade or downgrade the evidence [30]. The GRADE assessment will be performed independently by 2 authors and disagreements will be solved through consensus or consulting a third reviewer if a consensus cannot be reached. The domains to be looked at are as follows: risk of bias, imprecision, inconsistency, indirectness, and publication bias. Based on these domains, the quality of evidence will be determined to be high, moderate, low, or very low. The outcome of the GRADE assessment will be presented in a summary of the findings table.

Results

The project was initiated in November 2022. After formalizing the study methods and prior to title and abstract screening, the protocol was registered with PROSPERO in February 2023. Abstract screening is planned to be completed in June 2023 and full-text screening will be completed in July 2023. Data analysis and drafting of the manuscript will occur from July 2023 to August 2023, with expected publication in February 2024.

Discussion

Principal Findings

The beneficial effects of cognitive interventions for healthy individuals and those with various cognitive impairments have been discussed in several studies [14-17]. However, its effects on people with CRDs have never been systematically documented [4,16-18]. To our knowledge, this is the first systematic review focusing on the effects of cognitive intervention in individuals with CRDs. The nature of this systematic review is a strength, as it provides an objective perspective on this topic while minimizing bias, by following established procedures and reporting guidelines. Other strengths include its robust search strategy as demonstrated by searching 6 databases, reporting on the percentage of agreement among reviewers and including a variety of health domains in the secondary outcomes.

One of the predicted limitations of this study is that it will collect data from various study types, not limited to RCTs. This may affect the quality of the literature included in the paper. However, due to the novelty of this rehabilitation topic, there may be a limited number of primary articles (RCTs) available. Despite this limitation, it is still essential to synthesize the current literature on the effects of cognitive interventions for people with CRDs to inform evidence-based clinical decisions and plan future research. Another limitation of the study is the inclusion of articles written only in English, Portuguese, and French. This may exclude relevant data published in other languages. To capture a broader range of articles, future research on this topic should include studies written in other languages. Finally, to ensure a focused and manageable analysis, we have made the decision to include only the most commonly reported forms of cognitive interventions in the literature. This selective approach allows us to streamline our review process and maintain clarity in our findings. Although this decision may exclude certain less frequently reported interventions, it enables us to provide a comprehensive evaluation of the widely recognized and established cognitive intervention techniques.

XSL•FO
RenderX

Conclusions

The systematic review's findings will assist in displaying the effectiveness of cognitive interventions as a potential treatment approach in reducing cognitive deficits in those with CRDs. This innovative field of clinical research is relevant to all health care disciplines as it impacts decisions related to screening and interventions and informs clinical practice for all health care professionals.

Acknowledgments

DB holds a National Sanitarium Association Chair in Respiratory Rehabilitation Research. This proposal was completed as partial credit for coursework at McMaster University toward a Master of Physiotherapy credential. The authors express gratitude to Laura Banfield, McMaster University Health Sciences librarian, for helping in the preparation of the search strategy and to Dr Luciana Macedo for her guidance through the course unit in which this proposal was completed.

Data Availability

All data generated or analyzed during this study will be included in the published manuscript as a supplementary information file.

Abstract

Background: Among the common malignant tumors in men worldwide, the incidence of prostate cancer ranks second to lung cancer. This disease will bring an economic burden to patients and their families and can reduce the quality of life of patients. Researchers have conducted numerous clinical trials on the efficacy and safety of different interventions in the treatment of prostate cancer with traditional Chinese medicine (TCM) combined with standard treatment regimens. However, the currently published clinical trials exhibit inconsistent and irregular reporting of outcome measures.

Objective: The objective of this paper is to emphasize the need for a core outcome set (COS) to facilitate future prostate cancer research, aiming to improve the quality of trials and generate high-quality evidence.

Methods: This mixed methods project has three phases, as follows: (1) a scoping review of the literature to identify outcomes that have been reported in clinical trials and systematic reviews of interventions involving TCM for the treatment of prostate cancer as well as a qualitative component using interviews to obtain the views of patients with prostate cancer, their families, and their caregivers who have a history of TCM treatment; (2) a Delphi survey among stakeholders to prioritize the core outcomes—Participants will include traditional Chinese and Western medicine clinicians in prostate cancer–related directions, nurses, and methodology experts who will participate in 2 rounds of the Delphi method expert consultation to score each outcome in the list of outcome indicators; and (3) a face-to-face consensus meeting to discuss and agree on the final COS for the application of TCM in the treatment of prostate cancer.

Results: The protocol has been registered in PROSPERO (CRD42022356184) before the start of the review process, and we will initiate the review on August 1, 2023; results should be expected by September 1, 2023. The Delphi survey among stakeholders is expected to start in October 2023.

Conclusions: The development of a core outcome set for assessing clinical safety outcomes of prostate cancer in clinical trials of TCM will provide a significant first step to assist Chinese doctors, researchers, and policy makers.

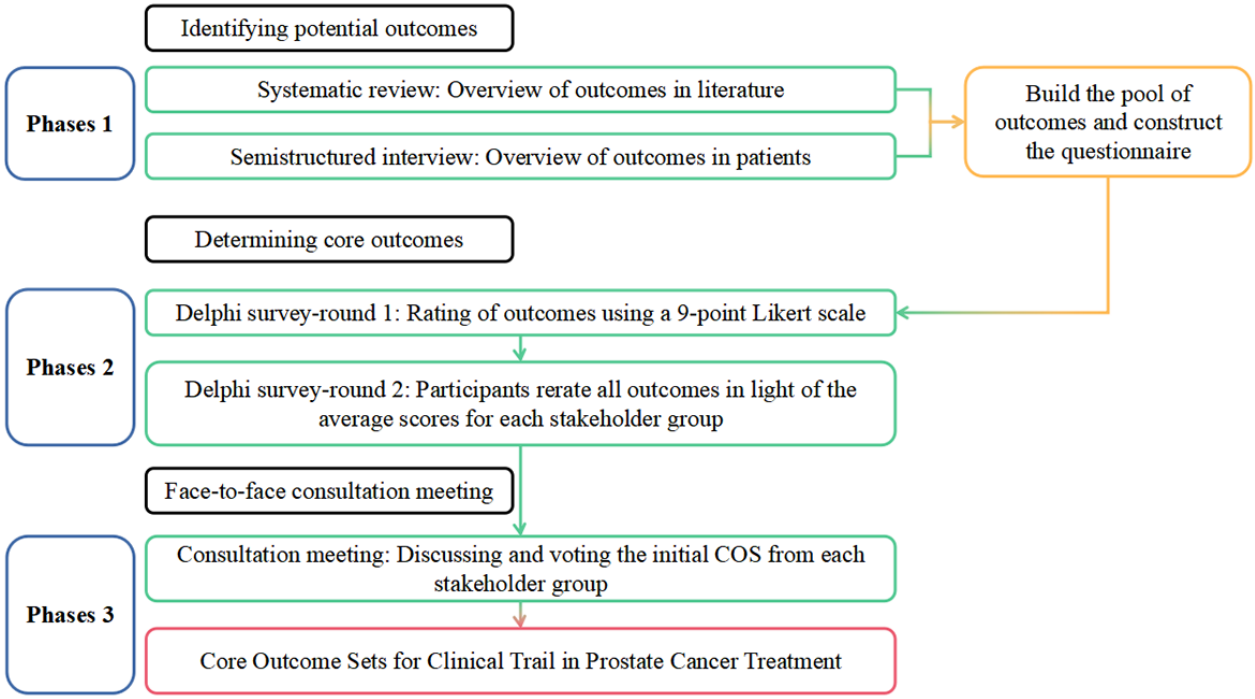
Introduction

Among the common malignant tumors in men worldwide, prostate cancer ranks second to lung cancer in terms of incidence, accounting for 14.1% of the total number of malignant tumors; the mortality rate for prostate cancer is 6.8%, ranking fifth in male cancer mortality, and making it the most common type of cancer in 112 countries globally [1]. According to the new cancer data in China in 2019, the incidence of prostate cancer ranks sixth among men, its mortality rate ranks ninth, and the incidence is on the rise in the country [2]. Some scholars predict that by 2030, prostate cancer will surpass gastric cancer to become the third most common cancer in men [3]. Patients with prostate cancer do not have obvious clinical symptoms in the early stages, 50%-80% of patients are diagnosed at an advanced stage [4], and approximately 80% of patients diagnosed with advanced prostate cancer may develop bone metastasis [5]. Currently, follow-up observation, surgical treatment, endocrine therapy, chemotherapy, external radiation therapy, and seed implantation internal radiation therapy can be used for prostate cancer treatment. Among these options, endocrine therapy—represented by Androgen Deprivation Therapy (ADT)—has become an internationally recognized standard treatment for advanced prostate cancer. The advantage of ADT is that it can significantly delay the progression of the tumor, but the treatment period is not long, usually lasting only 1-2 years. If the treatment time exceeds 2 years, the body will easily develop resistance to ADT, and almost all of patients will progress to castration-resistant prostate cancer in later stages or metastatic castration-resistant prostate cancer [6]. Once the disease progresses to castration-resistant prostate cancer, radiotherapy, chemotherapy, targeted therapy, and other methods are difficult to effectively slow down the progress of the disease; ADT usually produces many adverse reactions [7], reducing the quality of life of patients during treatment [8]. Therefore, modern medicine still has many deficiencies in the diagnosis and treatment of prostate cancer, and there is still a lack of effective treatment methods.

In recent years, with the in-depth understanding of traditional Chinese medicine (TCM) regarding the etiology, pathogenesis, and treatment of prostate cancer, clinical research on TCM for the treatment of prostate cancer at various stages has gradually increased [9,10]. Numerous clinical trials and systematic reviews have been conducted on TCM or integrative medicine for prostate cancer to improve the efficacy and safety outcomes [11-14]. However, due to the lack of guidance on a core outcome set (COS), there is obvious heterogeneity in the selection of outcome measures among different studies. Meanwhile, TCM treatment includes a variety of interventions, such as Chinese medicine decoction, Chinese medicine capsule, Chinese medicine injection, and topical Chinese medicine patch therapy [15,16]. Hence, the complexity and diversity of clinical trials of TCM for prostate cancer makes it even more important to evaluate the efficacy of different interventions. How to select high-quality outcome indicators based on clinical trials is an urgent problem to be solved. A point that cannot be ignored is that the inconsistent and nonstandard reporting of outcome indicators and the status of adverse events is often underestimated or ignored, which may lead to a waste of medical resources, a reduction in clinical treatment efficacy, and an impact on the foundation of clinical trials and evidence-based clinical decision-making.

Therefore, to facilitate future research on TCM treatment of prostate cancer, we need to develop a COS. COS, as an agreed-upon set of standard outcomes for a specific disease or condition, can reduce the risk of reporting bias by prompting researchers to focus their reporting on a more specific set of outcomes that stakeholders agree are best suited to their field [17-19]. There is also the potential to reduce economic waste; improve the utility of randomized controlled trials; facilitate comparison of treatments across different sources of evidence; and aid in the development of systematic reviews, meta-analyses, and evidence-based clinical guidelines through standardized reporting of results in specific areas [20].

Methods



Methods Overview

This COS initiative was registered in January 2022 with the Core Outcome Measures in Effectiveness trial (COMET) initiative. We followed the Core Outcome Set-STAndards for Development [17], the Core Outcome Set-STAndards for Reporting [18], and the Core Outcome Set-STAndardised Protocol items [21] (Multimedia Appendix 1) for developing and reporting this COS. This section describes the 4 phases of the COS development using an international, web-based Delphi study, following the guidelines for a COS development [19]. Figure 1 presents an overview of the 3 phases.

Meanwhile, we will set up a research working group who will be responsible for the planning, guidance, and supervision of the research process of this project. The research group will comprise 5 experts, including 2 TCM or integrated TCM specialists in oncology, a Western medicine specialist in oncology, a nurse, and a methodologist. The Steering Committee will review and confirm the research protocol, identify a list of preliminary results, make decisions in case of confusion, and attend consensus meetings to facilitate the development of the core indicator set.

XSL•FO
RenderX

Figure 1. Overview of the core outcome set (COS) development process.

Ethics Approval

This study has been granted ethics approval by the First Teaching Hospital of Tianjin University of Traditional Chinese Medicine Research Ethics Committee (TYLL2022[K]-21).

Phase 1: Identifying Potential Outcomes

We will identify potential outcomes used in studies evaluating the TCM clinical efficiency and safety in the treatment of prostate cancer by performing a systematic review. A semistructured interview will also be organized to identify outcomes that patients perceive as relevant and important (phase 1).

Identification of Outcomes Through a Scoping Review

A scoping review will be performed following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) checklist. This study protocol was registered in the PROSPERO database (CRD42022356184) before the start of the review process.

We will search 8 databases (PubMed, Embase, Cochrane, Clinical Trials, China National Knowledge Infrastructure, Wanfang Data knowledge service platform, and Chinese Scientific Journal Database), including search terms that encompass TCM and related preparations, prostate cancer, and controlled trials.

The English search strategy is presented in Multimedia Appendix 1. Studies will be included if they meet the following criteria: (1) clinical research (the type of research is not limited); (2) the research participants are patients with prostate cancer; (3) there are clear inclusion and exclusion criteria; (4) the intervention measures are Chinese medicine and Chinese medicine combined with Western medicine treatment, and the control measures are Chinese medicine and Western medicine treatment, a placebo, or blank control; (5) randomized controlled trials that have at least 30 patients in each group, and observational studies with at least 50 patients; (6) for published research, the language is limited to Chinese and English.

Data extraction included the name of the first author, number of participants, outcome measures (including primary and secondary outcomes), the definition of outcome measures, outcome measurement tools, and timing. In addition, the quality of outcome reporting and methodological quality will be assessed. After the data extraction is completed, it is necessary to standardize and merge the outcome index domain or the outcome index. Two researchers will jointly standardize and merge the outcome index domain or the outcome index and reach an agreement through negotiation.

Subsequently, 2 reviewers will independently extract relevant data from the included studies using a standardized data extraction sheet. Information will be extracted regarding the study design, study population, intervention characteristics, reported outcomes, and measurement tools. Disagreement will be resolved through discussion with a third reviewer. Results will include all unique outcomes and a frequency table of the most reported outcomes, sorted per outcome domain [22]. This list of unique outcomes will be presented to the expert panel (phase 2).

Identification of Outcomes Through Semistructured Interviews

It is necessary to consult patients on prostate cancer. Semistructured interviews will be conducted to ensure that certain topics are discussed, while giving the patient the flexibility to delve into details when needed. During patient interviews, information will be collected about health status, previous treatments and expectations, and inconveniences experienced during treatment. Patients aged ≥18 years who were diagnosed with prostate cancer in pathology and regularly

XSL•FO
RenderX

received TCM or integrated Chinese and Western medicine treatment over 3 months and their family members or caregivers will be invited to participate in the semistructured interviews. Informed consent is required to recruit participants to this study. Patients will be assured at the start of the interview that they can choose to opt out at any time during the interview if they feel unable or uncomfortable to complete the interviews. The specific inclusion and exclusion criteria are presented in Textbox 1.

Textbox 1. The inclusion and exclusion criteria for the semistructured interview.

Inclusion criteria

- Patients with prostate cancer (pathological diagnosis according to the national guidelines for diagnosis and treatment of prostate cancer 2022 in China [23])
- Patients ≥18 years of age
- Traditional Chinese medicine (TCM) treatment or integrated TCM and Western medicine treatment ≥3 months
- Patients who signed the informed consent forms

Exclusion criteria

- Patients with a severe mental disease, cancer, and other life-threatening diseases
- Primary malignancies other than prostate cancer
- Participants judged by the investigator to be inappropriate for participation
- The patient refuses to participate in the study

Recruitment of Interviewees

Patient interviews will be conducted in China to ensure that the representative views of patients are included. We plan to interview potential patients in inpatient wards and outpatient clinics of the First Affiliated Hospital of Tianjin University of Traditional Chinese Medicine. There is no strict standard for the sample size of semistructured interviews. To achieve data saturation [24], based on the previous research experience, more than 30 patients will be recruited to ensure obtaining comprehensive results [25,26]. We believe that this sample size will be sufficient to achieve saturation in the semistructured interviews. However, if new viewpoints emerge during the interview, the sample size of the interview will increase. Patients participating in the interviews can complete questionnaires with the help of researchers. To improve the representativeness of the sample in the sample selection process, we will select patients with different ages, disease stages, disease severity, education, occupation, and family income.

Data Collection and Analysis

The questions in the semistructured interviews are as follows:

1. What are the most physiological and psychological effects of prostate cancer on you?
2. What kind of treatment (eg, radical prostatectomy, radiation therapy, and androgen deprivation therapy) have you received after the prostate cancer diagnosis?
3. What therapeutic effect do you want to achieve?
4. What kind of inconvenience does the current Chinese medicine treatment bring to you?
5. Which outcomes are important to you? Which one is the most important?

The patient interviews were audio recorded. After each interview, the recording was transcribed into text and read word by word to form a thematic framework and extract relevant outcome indicators [27]. The outcome indicators were standardized by 2 investigators and compared with the original outcome indicator list formed by the systematic review. If an outcome indicator was judged to be new, it was included in the Delphi survey.

Pooling and Grouping of Study Outcomes

After completing the original list of outcome indicators, according to the recommendations of the "COMET Handbook" [20], the standardized and merged outcome indicators were classified to form a list of outcome indicators of clinical safety outcomes of prostate cancer in clinical trials of TCM. Specific steps for this procedure are as follows:

1. Translating English into Chinese according to the terms formulated by the National Science and Technology Terminology Committee; if there are no relevant terms, 2 researchers will determine the appropriate translation.

2. Extracting the combined results as separate results.

3. Combining overlapping results into one result according to the definition of the result (eg, death, death from any cause, mortality, and total mortality)

4. Discarding results without definition or measurement tools.

5. Classifying the outcomes into different outcome areas according to the classifications developed by the COMET initiative (two researchers will cross-validate the results).

Any inconsistencies will be discussed further by the 2 researchers until a consensus is reached. Next, the results will be formatted as questions and submitted to the Delphi survey [28].

XSL•FO
RenderX

Phase 2: the Delphi Survey

Stakeholders' Involvement

We will invite health industry stakeholders, such as prostate cancer clinicians, senior nurses, and researchers, and evidence-based medicine methodologists, to participate in 2 rounds of the Delphi survey [29]. The inclusion criteria for the participants in the Delphi survey are shown in Textbox 2. There are no exclusion criteria.

Textbox 2. The inclusion criteria for health professionals in the Delphi survey.

Inclusion criteria

- Health professionals with a bachelor's degree or above.
- Health professionals who have at least a senior title or above.
- Clinicians and nurses should have work experience in tertiary hospitals.
- There will be no restriction on the professionals' geographical area.
- The researchers (ie, first author, corresponding author, or other authors) should have published at least one clinical study related to traditional Chinese medicine.

Sampling

There is no consensus on the optimal sample size for the Delphi study, and based on the content of published literature, sample sizes for health professionals typically range from 30 to 120 participants [22,25,26]. In this study, following the research purpose of the project, we adhered to the principles of authority, representativeness, and regionality. We invited about 50 TCM or integrated TCM clinicians, nurses, and methodological experts specializing in prostate cancer–related areas to participate in 2 rounds of the Delphi survey.

Round 1 of the Delphi Survey

The first round of the Delphi survey will include all candidate results and ratings in different outcome areas. The questionnaire will be on a 9-point scale [20], where "1-3" indicates that the result is not important in the COS, "4-6" indicates that the result is important but not critical in the COS, and "7-9" indicates that the result is critical in the COS. At the end of the questionnaire, there will be an open-ended question: "What results do you think are important but not included in the questionnaire?"

Data analysis for the first round of the Delphi survey will include calculating the frequency of response options for each outcome. If no more than 10% of the participants who completed the questionnaire scored an outcome measure of 7-9, that result will be excluded from the second round of the Delphi survey. If participant-recommended results were not included in the first Delphi survey, 2 researchers will determine whether they are new or overlapping with existing outcomes. The new results will be included in the second round of the Delphi survey. Questionnaires for the Delphi law experts were distributed via email or WeChat (a Chinese web-based social software) and returned within 2 weeks.

Data Analysis for Round 1 of the Delphi Survey

We will use Microsoft Excel and SPSS 21.0 software (IBM Corp) and include descriptive analysis of the expert's basic information, including the expert's title, professional field, education, and years of experience, to understand the authority of expert consultation. We will analyze the responses from the first round, calculating the response rate and frequency of response options for each outcome. Moreover, we will analyze the distribution of scores for each stakeholder group. All results will be carried over to round 2 of the Delphi survey.

Round 2 of the Delphi Survey

The second round of the Delphi survey will be sent to participants who completed the first round. In the questionnaire, participants will receive scores from the first round of the Delphi survey and their stakeholder score distribution. They will be asked to rescore the results within 3 weeks. We will send an email or message to the participants, reminding them to complete the Delphi survey by the end of week 2. If the response rate is <80%, we will extend the opening hours of the Delphi survey or invite other eligible individuals to participate in the survey.

Data Analysis for Round 2 of the Delphi Survey

Data analysis for round 2 of the Delphi survey will include response rates; frequency of responses for each outcome option; distribution of scores for each stakeholder group; the outcomes that achieve "consensus in," "consensus out," and "no consensus"; and attrition bias. As shown in Table 1, each outcome will be defined into 3 categories [29]. SPSS 21.0 (IBM Corp) will be used to calculate the positive coefficient, degree of authority, and coordination coefficient of participants to demonstrate the validity of the 2 rounds of the Delphi expert consultation.

Attrition bias resulting from missing data will be determined by calculating the average score for each outcome among participants who completed or did not complete the 2 Delphi survey rounds. The missing data will not be considered if there is no attrition bias. The missing data will be considered as "unclear" if there is an attrition bias or if participants did not score all safety outcomes [30,31].

XSL•FO
RenderX

Table 1. Definition of consensus.

Classification consensus	Criteria	Interpretation
Consensus in	• ≥70% of the participants rated the outcome 7-9 • <15% of the participants rated the outcome 1-3 • The average patient rating is ≥7, regardless of other scores	Outcome is important
Consensus out	• ≥70% of the participants rated the outcome 1-3 • <15% of the participants rated the outcome 7-9	Outcome is not important
Consensus to be further discussed	• All other results	Potentially important outcome

Phase 3: Consensus Meeting

Stakeholder Selection

We will invite experts who have completed the 2 rounds of the Delphi survey to conduct a face-to-face consensus meeting to discuss and vote on the final core set of outcomes; this core set of outcomes consists of the outcomes that were initially included and excluded from the 2 rounds of the Delphi survey. At this stage, we will invite members from systematic review groups, clinical guideline developers, health care workers, and journal editors; we will also invite patients and caregivers to participate in the meeting. The inclusion criteria for health professionals are shown in Textbox 3. There are no exclusion criteria.

Textbox 3. The inclusion criteria for health professionals in the meeting.

Inclusion criteria

- Health professionals with a bachelor's degree or above.
- Health professionals who have a senior title or above.
- Clinicians and nurses should have work experience in tertiary hospitals.
- Researchers who have conducted systematic reviews of prostate cancer in the past 10 years.
- Journal editors should have at least 3 years of work experience.
- Policy makers should have at least 5 years of work experience.
- There will be no restriction on the professionals' geographical area.

Sampling

Based on the published literature, there is no clear calculation method for the number of participants in consensus meetings [20]. However, to gather input from different stakeholders and improve consensus, we need to invite 20 professionals and 2-3 patients to participate.

Consensus Meeting Process

Participants who have participated in the 2 rounds of the Delphi survey will be requested to attend a web-based questionnaire meeting. In the consensus meeting, we will report the results of round 2 of the Delphi survey for health professionals and the results of the survey for patients. The outcomes labeled as "consensus out" by all stakeholders will be excluded. The outcomes labeled "consensus in" by all stakeholders will be sent to the Steering Committee and participants on the day preceding the consensus meeting.

In the consensus meeting, if participants disagree with an outcome that has achieved "consensus in" by all stakeholders to be included in the COS, they will further discuss it. Outcomes that do not reach a consensus will be individually addressed. Then, all participants in the consensus meeting will be anonymously asked to vote on these outcomes as "controversial" or "no consensus" outcomes. Any outcomes that receive votes from ≥ 70% of the participants will be included in the final COS.

Results

The protocol has been registered in PROSPERO; we will initiate the review on August 1, 2023, and results should be expected by September 1, 2023. At the time of the revised submission, the systematic reviews have been completed. The Delphi survey among stakeholders is expected to start in October 2023. We will publish our results through TCM-related associations and the COMET platform to promote recognition and application of the core indicator set in a wider range.

The finished COS will follow the recommendation of recent studies on dissemination strategies [30-32]. Each participant of the COS will be asked to implement the COS in their future clinical trials about the application of TCM in prostate cancer treatment and recommend this COS to their colleagues and other potential researchers. We will communicate our results via peer-reviewed publications, conference presentations, professional societies, and our institution's social media platforms. We will post our final COS information on the COMET website.

Discussion

Constructing a core indicator set for the treatment of prostate cancer with TCM can improve the clarity of clinical research outcomes, thereby reducing the risk of publication bias and facilitating horizontal comparisons between different research results.

Prostate cancer is one of the most common malignant tumors affecting male individuals worldwide, posing a threat to patients' health and quality of life [1,33]. However, currently published clinical trials focusing on TCM treatment for prostate cancer have encountered problems related to inconsistent and nonstandard reporting of outcome indicators [11-13].

Of note, there are certain limitations to this study. For instance, due to literature search strategies or language restrictions, it is possible that not all relevant clinical trials have been included in our analysis. Additionally, although we strive to fully adopt the views of multiple stakeholder groups, some biases may still be present.

This protocol design establishes a comprehensive review of both international and Chinese literature by conducting semistructured interviews, Delphi surveys, and a consensus meeting to fully adopt the views of multiple stakeholder groups, which can ensure the feasibility and promotion of the COS in future clinical studies. The development of a COS ensures the consistency of reporting clinical study outcomes for prostate cancer in the future, assisting in reducing reporting bias. This allows for easier comparison and integration of results from different clinical trials in the future, improving the value of these clinical studies and minimizing the waste of research resources.

Acknowledgments

This study was supported by the National Natural Science Foundation of China (81603438), the Natural Science Foundation of Tianjin (19JCZDJC37000), and the Scientific Research Plan project of the Tianjin Municipal Education Commission (2020KJ163).

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

XL and HT designed this project and wrote the manuscript; YZ and RM arranged the figures and tables. CW and YJ contributed to reviewing and editing the paper. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Electronic nicotine delivery systems (ENDS), commonly called e-cigarettes, have been examined in clinical studies for their effects on tobacco smoking cessation. In the past 2 years, a dozen or more systematic reviews on ENDS and cigarette smoking cessation have been published that present differing conclusions and recommendations on the use of ENDS.

Objective: Our umbrella review aims to synthesize the findings from current systematic reviews to investigate the quit rates and the percentage of participants abstinent from cigarette smoking using ENDS. Additionally, we will examine the quit rates with ENDS in comparison to other established cessation treatments.

Methods: The search will retrieve systematic reviews that include both clinical trials and experimental studies on the use of ENDS for smoking cessation. We will also include nonrandomized cohort studies that track ENDS use and the subsequent abstinence from smoking. Databases searches will be conducted in Embase, Scopus, PubMed, and 7 additional registries. Secondary searches will include reference checking, citation chasing, and consultations with topic experts. Two reviewers will perform a title and abstract exclusion followed by a full-paper inclusion process. Data extraction will be conducted by 1 reviewer and completely checked by a second reviewer. Each systematic review will be assessed by 2 reviewers for methodological quality using AMSTAR2 (A Measurement Tool to Assess Systematic Reviews, version 2) and for reporting bias using categories from the Centre for Evidence-Based Medicine's Catalogue of Bias. Unreported discrepancies between the protocol and the published review will be identified.

Results: The umbrella review started on March 1, 2023. At the time of publication, the study selection was being conducted and the pilot testing of the data extraction and bias assessment forms were in progress. The review is expected to be completed by December 31, 2023, followed by the submission of the review for journal publication. A second-order meta-analysis will calculate the range and average of quit rates for ENDS. A vote counting of the direction of effect, based on quit rates, will be used to present the relative effectiveness of ENDS for smoking cessation compared to other cessation treatments (including no treatment). A citation matrix will list primary studies with their bias ratings from all the systematic reviews. The effect of overlapping studies between the systematic reviews will be calculated using the corrected coverage area analysis. A sensitivity analysis will examine the impact of the intensity of cessation treatment on quit rates. Depending on the availability of data, subgroup analyses will be conducted based on participants' gender, age, prior quit attempts, and nicotine dependence. The strength or weakness of the evidence synthesis will be assessed using a stratification of evidence technique. Reporting bias will be presented with a tabulation of bias indicators. Publication bias will be assessed.

Conclusions: The use of ENDS for smoking cessation is a highly controversial subject. Through an exhaustive synthesis of the available data, we will present the quit rates of cigarette smoking cessation obtained with ENDS and how they compare to quit rates obtained from other established cessation treatments. The critical quality and bias assessment of the systematic reviews will indicate the most reliable sources to inform treatment considerations and policy development.

Introduction

e-Cigarettes, termed electronic nicotine delivery systems (ENDS), were invented in 2003 to be a cigarette cessation device [1]. The substantially reduced toxicant profile of ENDS compared to cigarettes [2,3] has motivated researchers to investigate its potential for supporting cigarette smoking cessation. As the number of clinical studies piled up, the first systematic review on ENDS for smoking cessation was published in 2014 by the Cochrane Group [4], and 21 systematic reviews were published by 2017 [5]. Even after excluding studies with a cessation outcome of less than 6 months' duration, the number of primary studies included in 2 current systematic reviews was 61 and 64, respectively [6,7]. Our preliminary search in PubMed for systematic reviews published since 2021 retrieved 20 potential publications.

Another systematic review is unlikely to make a significant contribution until more experimental studies are published. Our purpose for conducting an umbrella review is to provide the widest overview of the clinical evidence on the use of ENDS and their impact on cigarette smoking abstinence for an audience of researchers and clinicians highly polarized over the use of ENDS [8-10]. An umbrella review systematically searches and retrieves systematic reviews, critically appraises them, and synthesizes their results [11].

We have 4 research questions: 2 focus on cigarette smoking abstinence outcomes, and the other 2 focus on the quality of the evidence. These questions are as follows:

1. Are ENDS more, less, or equally effective in quit rates (ie, the percentage of participants who abstained from smoking), compared to other cigarette smoking cessation treatments?

2. What is the range of quit rates with ENDS in absolute numbers?

3. How weak or strong is the evidence base on the effectiveness of ENDS for smoking cessation?

4. Is reporting bias present in systematic reviews of ENDS for smoking cessation?

Methods

Structure of Review

Our protocol has been designed with reference to the Methods for Overviews of Reviews (MOoR) framework [11,12]. It has 20 steps with 54 substeps. Our protocol is reported based on the checklist provided in the recently published Preferred Reporting Items for Overviews of Reviews (PRIOR) statement by Gates et al [13]. It consists of 27 main items, 46 in total, and is specifically designed for health care interventions.

The population, intervention, comparator, and outcome (PICO) criteria below define the scope of our umbrella review for evidence on cigarette smoking cessation or abstinence with the use of ENDS. These criteria are as follows:

- Population: adults who formerly smoked and currently use ENDS or clinical trial participants who smoked cigarettes at baseline before using ENDS.
- Intervention: personal use of ENDS or ENDS use in a clinical trial.
- Comparator: cigarette smoking cessation treatments, including no treatment.
- Outcome: (1) quit rates, that is, the percentage of participants who abstained from smoking or quit smoking and (2) the quit rate with ENDS compared to other cessation treatments.

Search and Selection Processes

Database search sources will include Embase (Ovid), Scopus (Elsevier), PubMed, Cochrane Database of Systematic Reviews, PROSPERO, and Epistemonikos. For grey literature, database search sources will include MedNar, National Technical Information Service, WorldWideScience, and Open Grey.

The search parameters include keywords related to the intervention (eg, "cessation" OR "quit" OR "abstinence"), ENDS (eg, "e-cigarettes" OR "electronic nicotine" OR "electronic cigarettes" OR "vaping" OR "vape"), and the study design (eg, "systematic review"). The search fields include title, abstract, and keywords. A filter for systematic reviews will be applied, whenever available. One researcher will review the applicable keywords, fields, and filters specific to the database. Syntaxes will vary by database. The search syntaxes for each database will be recorded with a screenshot, counted, and dated; the retrieved records will be downloaded into an EndNote library. The library will be deduplicated, and the count will be recorded. The publication date starts from 2021 for 2 reasons. First, current systematic reviews are most likely to include the most recently published primary studies. Second, a preliminary scoping search was conducted to explore the possibility of an umbrella review study, and it retrieved 20 potentially eligible systematic reviews published from 2021, which is a substantial number for inclusion in an umbrella review.

Two researchers will independently screen the records by title and abstract (or summary). They will include the systematic reviews that cover the PICO components. Discrepancies will be resolved through discussion and referred to the project leader for a final disposition, if necessary. The interrater agreement and the count of excluded studies will be reported.

The next stage of the selection process is a full-paper review. Two reviewers will independently examine each study for

XSL•FO
RenderX

inclusion and exclusion based on the criteria presented in Table 1.

Industry-funded studies, if any, will be discussed separately from the analyses.

Two researchers will independently evaluate the reviews for inclusion. Discrepancies will be resolved by discussion, and if unresolved, will be referred to the project leader for a final disposition and recorded for interrater reliability. All systematic reviews excluded during the full-paper examination will be listed, along with the reason for exclusion, in an appendix.

In a second round of searching, the systematic reviews selected for inclusion will be citation chased (snowball search) in Google Scholar by 2 researchers who independently examine the title and abstract of the papers. The selected papers will be downloaded and organized as a separate group within the library. Discrepancies between the 2 retrievals will be resolved through discussion or referred to the project leader for a final disposition, and the interrater agreement will be reported. Systematic reviews retrieved from this search will be selected using the criteria for full-paper review. The completed full-paper search will be reviewed by 2 topic experts, who will provide recommendations for any additional publications.

Table 1. Inclusion and exclusion criteria.

Criteria	Inclusion	Exclusion
Article type	Systematic review	All other study designs
Language	English, French, Italian, and other languages that may be translated	Reviews without an English abstract or summary
Publisher	Academic journals, government reports, and medical organizations	Predatory journals (not indexed in PubMed or Directory of Open Access Journals)
Primary study designs	Clinical trials, experimental studies, observational cohort studies, and randomized or nonrandomized studies	Cross-sectional studies, surveys, case studies, and qualitative studies
Population	Adults who use ENDS[a], who smoke, or who have stopped smoking cigarettes	Youth or participants who did not smoke before using ENDS
Data	Quit rates with ENDS and comparison of quit rates with ENDS and with other treatments	Reduction of cigarette use and dual use of ENDS and cigarettes
Duration of cessation	Explicitly defined	Duration not specified
Bias assessment of primary studies	Individual primary studies assessed using any method	No bias assessment of individual primary studies
Analysis or synthesis method	Meta-analysis and tabulation of quit rates across primary studies	Solely narrative or descriptive

[a]ENDS: electronic nicotine delivery systems.

Data Collection

The data extraction and quality assessments of a systematic review and its supplementary materials will be conducted simultaneously.

Data extraction will be performed using a prespecified data extraction form covering bibliographic information; funders; locality and setting; databases searched and dates; inclusion and exclusion criteria; outcome definition; primary studies with their bias assessments; data analyses (including sensitivity analyses); meta-analyses; any subgroup analyses; and the conclusion, quoted directly from the study. The specific items for data extraction will be identified by the research team. The form will be pilot-tested by the research team on 3 reviews and revised as needed. Data collection will be conducted by 1 researcher, and a second reviewer will cross-check the data extractions.

In cases where data items are missing, we will contact the author. Reviews lacking multiple data items may be excluded at this stage of the umbrella review. Any studies excluded for missing data items will be reported.

Quality Assessment

After completing the data extraction, the 2 reviewers will independently complete the AMSTAR2 (A Measurement Tool to Assess Systematic Reviews, version 2) checklist [14] to assess the overall confidence in the results of the review as high, moderate, low, or critically low. The research team will decide in advance which of the 16 domains will be designated as noncritical weaknesses or critical weaknesses. The rating assigned to these domains will be used as a proxy for assessing the risk of bias, with higher ratings indicating a lower risk of bias. Discrepancies in scoring will be discussed and referred to the project leader for disposition, if necessary. The interrater reliability will also be reported.

After completing the data extraction and the AMSTAR2 checklist, 2 reviewers will independently assess each review for reporting bias. Reporting bias will be identified by the following indicators: spin bias of nonsignificant findings, omitted findings, one-sided reference bias, framing by over- or underemphasis of outcomes, overreliance on *P* values, and data discrepancies [15]. The reporting of the review will be compared to its protocol or trial registration, and any deviations will be noted. Any indicators of reporting bias will be verified by the project leader.

XSL•FO
RenderX

Before conducting the syntheses, we will conduct a sensitivity analysis to examine the overlap of primary studies across the systematic reviews. Analyzing overlaps is critical because they can result in certain studies being overweighted in the analysis. Currently, there is no one standard method in an umbrella review to correct or weight the meta-analysis for the overlap of primary studies across reviews [16]. Based on its long-term use and validation, we have selected the corrected covered area (CCA) [17]. The formula is CCA=(N-r)/(rc-r) where N is the total number of publications, r is the number of index studies, and c is the number of reviews. To calculate the CCA, a citation matrix of primary studies will be tabulated, and it will be included in our published review. The CCA score is classified as slight (0%-5%), moderate (6%-10%), high (11%-15%), and very high (>15%). The CCA analysis will be conducted with the 5-step process developed by Hennessy and Johnson [18].

The CCA score will inform the selection of systematic reviews for the meta-analyses using the decision tool developed by Pollock et al [19]. We will include the highest rated review by AMSTAR2 score where the reviews have a higher level of overlap. If a 90% overlap in primary studies is found among 3 or more reviews, they will be included together in a subgroup analysis.

Before conducting the syntheses, the primary study data items will be tracked across the reviews to identify any data discrepancies. Data discrepancies will be corrected by examining the primary study. This process constitutes data cleaning.

Results

Overview

The umbrella review started on March 1, 2023. At the time of publication, the study selection was being conducted and the pilot testing of the data extraction and bias assessment forms were in progress. The review is expected to be completed by December 31, 2023, followed by the submission of the review for journal publication.

The search and selection results will be reported with the PRIOR diagram.

A table of review characteristics will display pertinent information, data, and the AMSTAR2 ratings. Comprehensive review tables and the AMSTAR2 scoring will be presented in supplementary materials.

A citation matrix will present all the primary studies included in the systematic reviews and will list the bias rating given to the primary study by each review.

Analyses of heterogeneity across systematic reviews will be conducted on inclusion and exclusion criteria and the comparator used (eg, other cigarette smoking cessation treatments or no quit intention).

A check for publication bias based on quit rates will be conducted if there are 10 or more reviews with meta-analysis data available. A funnel plot will be graphed and analyzed.

Depending on the availability of data in the systematic reviews, we will conduct sensitivity analyses on 3 effect modifications related to smoking cessation: nicotine dependency, prior quit attempts, and treatment intensity (eg, counseling vs no support). A total of 3 data points will be required to conduct the analysis. If an effect modification is reported in fewer than 3 reviews, the findings will be presented in a narrative summary.

Planned Syntheses—Quit Rates and Comparative Quit Rates of Cessation Treatments

For the first research question, which pertains to the relative effectiveness of ENDS compared to other methods (including no method), we will conduct a vote counting of direction of effect for each individual cessation treatment.

For the second research question, which pertains to the quit rate for ENDS, we will conduct a second order meta-analysis by combining the odds ratios for quit rates obtained from various systematic reviews. The data from the meta-analyses in the reviews will be converted to odds ratios by using the conversion formulas listed by Fusar-Poli and Radua [20] in cases where they were not computed as such.

Each of the syntheses conducted for the 2 cessation questions will be tested with 3 sensitivity analyses: length of cessation (any vs >6 months vs longer durations), the AMSTAR2 rating (high rating vs all others), and the inclusion or exclusion of industry-funded primary studies in the systematic review.

For each of the cessation analyses, a subgroup analysis by gender and age will be conducted, where feasible.

Planned Syntheses—Quality of Evidence

For the third research question, which focuses on the strengths or weaknesses of the evidence, we will evaluate the strength of the evidence base by conducting a stratification of evidence with the criteria published by Fusar-Poli and Radua [20]. This method rates a meta-analysis as convincing, highly suggestive, suggestive, weak, or nonsignificant, as stratified by the number of cases, the P values, the I^2 values, and biases. The method will require a slight adaptation to suit the requirements of an umbrella review.

For question 4, which is related to reporting bias, we will tabulate the number of incidences identified for each reporting bias indicator (as described above), grouped by review and for each bias indicator.

Additional Items

To assess the overall confidence in the findings of the umbrella review, a scoring system will be used based on the number of study designs included and their AMSTAR2 rating, with a modification of the GRADE (grading of recommendations, assessment, development, and evaluations) system.

The “Discussion” section will include a summary of the main findings, any contradictory findings between the systematic reviews, limitations of the systematic reviews, limitations of the umbrella review, recommendations for future research, and the relevance of the findings to clinicians and policy makers.

All deviations from this protocol will be documented and justified in the published study.

XSL•FO
RenderX

Discussion

Regarding the projected quit rates for smoking cessation, we expect them to be low, which unfortunately is the case for all cigarette smoking cessation treatments.

Our umbrella review will be subject to limitations. First, we will have a small research team of 4 members. Fortunately, the team has expertise in systematic and umbrella reviews with decades of research experience on ENDS. Regarding staffing constraints, we are well aware from prior experience that the identification of reporting bias is time intensive, but in our estimation, it is absolutely essential for credibility in our highly contested field.

Our dissemination plans are also subject to funding limitations. As a minimum, we will publish our umbrella review in an open-access journal and produce a white paper in plain language with infographics and post it on our research unit's website. We will also submit it for conference presentations after publication if team members are available. Low-cost avenues of knowledge translation will be considered as time permits.

The methods and processes specified in this protocol are all aimed at achieving one goal: to identify data on the effectiveness of ENDS for cigarette smoking cessation. Our purpose is to provide clinicians, policy makers, and individuals who smoke with the published evidence, enabling them to make evidence-informed decisions. With 15 or more systematic reviews published in just the past 2 years on ENDS for cigarette smoking cessation, the literature is ripe for an umbrella review.

Acknowledgments

This investigator-initiated study is sponsored by ECLAT Srl, a research-based spin-off company of the University of Catania, with the help of a grant from the Foundation for a Smoke-Free World, Inc—a US nonprofit 501(3)(c) private foundation (no grant number was assigned). The funders had no role in the design of the study; the collection, analysis, and interpretation of data; or the writing of the manuscript.

The contents, selection, and presentation of facts, as well as any opinions expressed in this systematic review are the sole responsibility of the authors and under no circumstances shall be regarded as reflecting the positions of the Foundation for a Smoke-Free World, Inc.

Data Availability

All data will be available in the systematic reviews. For Open Science, the completed data extraction forms, the AMSTAR2 checklists, and bias reports will be uploaded to Zenodo.

Authors' Contributions

RO and RP were in charge of the study conceptualization, writing the original draft, as well as reviewing and editing the final draft. RP was responsible for funding acquisition.

Conflicts of Interest

RO is supported by a contract with ECLAT Srl. ECLAT Srl has received funding from the Foundation for a Smoke-Free World. RP has received grants from U-BIOPRED and AIR-PROM, Integral Rheumatology & Immunology Specialists Network (IRIS), Foundation for a Smoke-Free World, Pfizer, GlaxoSmithKline, CV Therapeutics, NeuroSearch A/S, Sandoz, Merck Sharp & Dohme, Boehringer Ingelheim, Novartis, Arbi Group Srl, Duska Therapeutics, Forest Laboratories, and Ministero dell'Universita' e della Ricerca (MUR) Bando PNRR 3277/2021 (CUP E63C22000900006) and 341/2022 (CUP E63C22002080006), funded by NextGenerationEU, the European Union (EU) economic recovery package. He is the founder of the Center for Tobacco Prevention and Treatment (CPCT) at the University of Catania and of the Center of Excellence for the Acceleration of Harm Reduction at the same university. He receives consultancy fees from Pfizer, Boehringer Ingelheim, Duska Therapeutics, Forest Laboratories, CV Therapeutics, and Sermo Inc. He is being paid textbook royalties from Elsevier. He is also involved in a patent application for ECLAT Srl. He is a pro bono scientific advisor for Lega Italiana Anti Fumo (LIAF) and the International Network of Nicotine Consumers Organizations (INNCO). He is Chair of the European Technical Committee for Standardization on "requirements and test methods for emissions of electronic cigarettes" (CEN/TC 437/WG4).

Abstract

Background: Military trauma teams are commonly operating in civilian hospitals during peacetime; in a war situation they must adjust their practices to the austere conditions. Simulations can replicate austere conditions to allow training in a safe environment that tolerates errors. Gamification, understood as the use of game elements to motivate and engage learners in nongame contexts, is gaining interest in medical education and military training. Applying game elements in the design of military trauma management simulations has the potential to provide learners with active learning opportunities and prepare them for providing medical services under austere conditions. Although gamification is known for its engaging and motivational benefits, there are controversies about its pedagogical value. The controversies can be attributed to the fact that various gamification strategies may consist of a different combination of game elements, leading to different outcomes.

Objective: This systematic review aims to understand how game elements are used in the design of simulations in military trauma management training and their reported outcomes.

Methods: We have designed a search strategy for the purpose of the review. Two researchers will independently assess the identified studies based on the defined inclusion and exclusion criteria. The selection process will be represented using a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. The search will be repeated and updated as necessary prior to publication of the review. Two reviewers will independently extract and manage the data for each of the articles using a structured data extraction form. Any disagreement that arises between reviewers will be resolved through discussion, and a third review author will be consulted when needed. We are going to conduct a thematic synthesis of the extracted game element descriptions. The results are going to be presented in a diagrammatic or tabular form, alongside a narrative summary. The quality of the studies will be assessed.

Results: We implemented and tested the developed search strategy in May 2023. We retrieved 1168 study abstracts, which were reduced to 630 abstracts after deduplication. We have piloted the screening on 20% (126/630) of the identified abstracts in groups of 2 reviewers.

Conclusions: Although gamification has the potential to motivate learners in various ways, there is a lack of understanding about specific game elements and how they can inform instructional design in different contexts. Our findings will increase the understanding of how game elements are used in the design of simulations in military trauma management training and, thus, contribute to more effective development of future simulations.

Introduction

Background

Trauma injury is one of the leading causes of death in Western countries and is a significant threat to public health [1]. Hemorrhage is the leading cause of preventable death in both military and civilian trauma [2]. In many nations, including Sweden, trauma team members work in both civilian and military settings, with military trauma teams commonly operating in civilian hospitals during peacetime [3]. Usually, the multidisciplinary trauma team consists of a variety of specialized health care professionals who collaborate with first responders and medics. Trauma patient outcomes are highly impacted by the performance of trauma teams, requiring a combination of technical and nontechnical skills. In a war situation, the trauma teams must adjust their practices to the austere conditions outside the fully equipped civilian hospital, operate with reduced numbers of team members, and deal with significantly higher numbers of patients than they might be accustomed to.

Prehospital trauma care differs significantly between a civilian and a deployed setting [4]. In the latter, resources in terms of personnel and equipment are limited, and there is a risk that multiple injured casualties can overburden the capacity of the resources. In the deployed setting the environment may hinder the provision of trauma management, due to challenging weather conditions and darkness. The environment may be hostile with the risk of gunfire hindering immediate patient care [5,6]. Additional tactical considerations may limit the possibilities for providing equipment and resources, as well as evacuating the patients requiring further care.

According to a recently published study [6], research and education may overlook the conditions of a truly austere environment. Health care professionals should be adequately trained to use a wide range of skills in environments with constrained resources in contemporary conflicts. Training does not stop at medical personnel but extends to the soldiers who are often the first responders. All combatants should be familiar with tourniquets and basic life support techniques. However, the learning opportunities to practice such skills are limited, due to the lack of exposure to trauma patients in austere conditions. In most cases, military medical personnel receive training in civilian settings for the tasks they will face in conflict. Simulation training has the potential to support the training and amend this imbalance [3].

Simulation can replicate austere conditions and allow the training in a safe environment that tolerates errors [7]. Simulation may refer to various technologies, from virtual reality equipment to mannequins and field exercises. Some simulation types can be resource-intensive regarding cost, facilities, faculty time, and the alignment of curricular and learners' schedules while others can provide more flexibility and scalability [8]. Different simulation technologies can be used to train different competencies in trauma [9]. A previous study [10] identified examples of emerging technologies used for trauma training that have the potential to support the education and training toward challenges that civilian trauma teams face when moving to an austere environment. Examples included virtual reality, virtual reality combined with haptics and manikins or requiring special equipment, virtual patients, and gamification.

Gamification is gaining interest in medical education [11] and military training [8,12]. Gamification is a strategy in simulation design understood as "the use of game mechanics as a further dimension... in an endeavor to nudge participants to perform certain actions, by adopting a playful attitude" [13]. For instance, the learner might be required to solve a problem under time pressure, compete or collaborate with other users, and earn points or badges [14].

Incorporating game elements in health professions education can increase motivation and improve learning outcomes, specifically when employing game elements that promote learning behaviors and attitudes [15]. Applying game elements in the design of military trauma management simulation has the potential to provide learners with active learning opportunities to prepare for providing medical services under austere conditions [12].

Previous work analyzing game elements in health care education, as well as in education in general, has led to frameworks that can support the design and evaluation of gamification design in learning environments [14,16]. Although gamification is known for its engaging and motivational benefits, there are controversies about its pedagogical value [13,15]. The controversies can be attributed to the fact that various gamification strategies may consist of a different combination of game elements, leading to different outcomes [17]. Although gamification has the potential to motivate learners in various ways there is a lack of understanding about specific game elements and how they can inform the instructional design in different contexts [17].

Aim

This systematic review aims to understand how game elements are used in the design of simulations in military trauma management training and their reported outcomes. Our research questions are:

1. What game elements are used in the design of educational simulations in the context of military trauma management?
2. How are the identified game elements used?
3. What is the purpose of using game elements in the designing of educational simulations in military trauma management?
4. What outcomes are reported related to the game elements?

XSL•FO
RenderX

Methods

Inclusion and Exclusion Criteria

We will include both qualitative and quantitative empirical and design studies that address different types of simulation interventions, identified in our previous study [10], which incorporate game elements. Game elements will be identified using published gamification frameworks [14,16]. We will include game elements that support the education and training of military trauma management. The simulation interventions of the studies included should have an educational purpose in the context of military trauma management. Studies in which participants are passively observing rather than actively interacting with the intervention will be excluded. Studies that are using interventions primarily for patient education, rehabilitation, telementoring, treatment, surgical assistance, or planning are not within the scope of this review. We will exclude studies where the training only focuses on individual body parts. We will exclude studies that gamification is only used for assessment unless the assessment has an educational purpose and is not intended to assess the outcome of the study. Table 1 outlines our inclusion and exclusion criteria.

Table 1. Inclusion and exclusion criteria.

Criteria	Include	Exclude
Context and participants	All participants that are receiving training in the context of military trauma management. Participants are military medicine service providers (physicians, nurses, health care–qualified soldiers) at all stages of education. Included are also military personnel without health care qualifications who are trained to perform lifesaving procedures under combat conditions. Included are also health care personnel receiving military medicine education which requires immediate response and collaboration under austere conditions.	• Studies involving only civilian health care professionals without a clear link to military—for example, residents in an emergency medicine program participating in a gamified trauma simulation.
Education and training	All forms of learning opportunities both implemented in formal curricula and one-time educational events with the intention to gain knowledge, skills or improve attitudes.	• Scenarios where the gamified simulation is used merely as a form of outcome measurement and the educational impact of the assessment itself is not considered. • Simulations containing game elements with planned therapeutic health effect—for example, in treatment of posttraumatic stress disorder; those that aim to be used for diagnostic purposes or as motivational elements to improve compliance with treatment regimen. Excluded are also studies that are using interventions primarily for patient education, rehabilitation, telementoring, treatment, surgical assistance, or planning.
Trauma	Scenarios in which people were physically injured and require stabilizing, time-critical decisions with incomplete information, performance of concurrent medical aid tasks, multidisciplinary management, and collaboration. Both simple (one body system) and complex injuries (more than one body system) are included.	• We exclude psychological trauma without physical injuries that required immediate attention. • We also exclude studies that focus only on individual injured body parts without considering the context of the injury.
Simulation	Empirical or design studies including a simulation modality such as virtual and mixed reality, virtual worlds, digital and non-digital games, interactive scenarios such as virtual patients, mannequins, part task trainers, artificial wounds and cut suits, standardized patients, and deliberately designed realistic field exercises employing role-playing.	• Studies where participants are passive observers without interacting in the simulation.
Game element	At least one game element is included in the simulation as defined by Maheu-Cadotte et al [14]. We will also include studies with game elements going beyond the classification framework by Maheu-Cadotte et al [14] provided the activity or feature is explicitly and detailed enough described as designed to introduce game elements into the simulation. The included simulations must have an interactive plot as a game element.	• Simulations, where the plot is in the form of a case vignette without interactive unfolding during the intervention, are going to be excluded.

Search Methods for Identification of Studies

We will explore the databases or search engines Medline (Ovid), PubMed, IEEE Xplore, ERIC, Web of Science, and ACM Digital Library CINAHL with the help of librarians at Karolinska Institutet. We will include all articles regardless of publication language.

XSL•FO
RenderX

Searching Other Sources

For all included studies, we will search reference lists and conduct author and citation searches. We will search the lists of references of other systematic reviews that are identified while running our electronic searches.

Selection of Studies

We will import all references identified to the Rayyan open-source web system. Two researchers will independently assess the identified studies based on the inclusion and exclusion criteria. Any disagreements will be resolved through discussion between the 2 reviewers. If no agreement can be reached, a third author will be consulted. The selection process will be represented using a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram, including the actual number and the inclusion and exclusion criteria of each stage of screening [18]. The search will be repeated and updated as necessary prior to publication of the review.

Data Extraction and Management

Two reviewers will independently extract and manage the data for each of the articles using a structured data extraction form. The data extraction process will be piloted among the researchers. Any disagreement that arises between reviewers will be resolved through discussion and if needed mediation of a third review author. If any articles are in a language the authors are not familiar with, the text in a non-English language will be first automatically translated by an artificial intelligence–powered translation tool (DeepL; DeepL SE), and if needed, a researcher native to the language will be consulted. We deem this strategy to be sufficient as we aim to analyze the manifest presentation of game elements and are not investigating the latent, culture-based, meaning of game elements. The data extraction form will be based on our previous systematic review [19] and will include extraction categories such as research aim, learning objectives, setting, subject, group of learners, instruments used for assessment if any, outcome of the intervention, and will be extended by fields such as type of simulation, game elements, type of trauma, and austere factors. To answer the second and third research questions, qualitative data (ie, text passages describing the game element design and purpose and images like screenshots showing game elements) will be extracted for thematic synthesis. To provide answers to the first and fourth research questions, we will extract data based on prespecified categories, inspired by the identified gamification frameworks and former systematic reviews [14,16,19]; the data extraction form corresponding to these topics is enclosed in the Multimedia Appendix 1.

Data Analysis, Synthesis, and Reporting

A qualitative data analysis combined with a thematic data synthesis will be conducted. In particular, the extracted data will be synthesized following the processes outlined by Thomas and Harden [20]. First, the data are going to be coded in a reductant way to encapsulate the meaning of the extracted text. Codes will be developed from the text and extend and modify prespecified codes adopted from the identified gamification frameworks [14,16]. Next, descriptive themes are going to be established to unify codes that have been identified in more than one study. In the third and last stage, analytical themes will be generated; this step will aim to interpret the identified descriptive themes in a way that can support answering of the research questions. The data synthesis will be performed by the first author (NS) and will be discussed and reviewed by all authors. The results are going to be presented in a diagrammatic or tabular form, alongside a narrative summary.

Quality Appraisal

The quality of studies will be assessed with the use of the Medical Education Research Study Quality Instrument (MERSQI) [21] and the grid suggested by Côté and Turgeon [22].

Results

We implemented and tested the developed search strategy in May 2023. We retrieved 1168 study abstracts, which were reduced to 630 abstracts after deduplication. We have piloted the screening on 20% (n=126) of identified abstracts in groups of 2 reviewers. Our search strategy may be found in Multimedia Appendix 2.

Discussion

Anticipated Findings

Gamification has the potential to motivate learners in various ways, and it is showing promising results in improving forward combat casualty care performance in a simulated tactical environment [23,24]. The effectiveness of games as instructional tools has been debated over the years as there is a lack of understanding about specific game elements and how they can influence the reported outcomes. A recent systematic literature review about the application of virtual reality and haptic interfaces for civilian and military open trauma surgery training reports mixed and poor-quality evidence about their realization in education [25]; we envision that an enhanced understanding of game elements in educational simulations would inform the design of educational technologies and simulations.

Our starting point to interpret and configure the game elements is based on existing frameworks to understand gamification as a concept [14,16]. Several definitions exist for gamification, with the most widespread definition to be from Deterding et al [26] as the use of game elements in nongame contexts. In this protocol, we use a relatively new definition proposed by Pfeiffer et al [13] that emphasizes the principle of nudging [27] the participants with playful elements to engage in simulation, and therefore it can be understood as a tool for triggering positive behaviors towards learning.

We acknowledge that our backgrounds may influence the data analysis and synthesis. NS and AAK have a background in health informatics and research interests in educational technologies, specifically virtual patients; CS is a military surgeon and researcher in surgical education; and KK has a background in interaction design, technology-enhanced learning, and medical education.

XSL•FO
RenderX

Limitations

A potential limitation of the upcoming systematic review might be that evidence published in gray literature is not going to be retrieved; we might therefore overlook evidence about gamification applications that have not been reported in peer-reviewed journals. Additionally, we may not retrieve papers that did not include keywords that we have a priori associated with game elements. To control this challenge, we have collaborated with a team of professional librarians to design a complex search strategy and will hand-search references in included studies.

Conclusions

To our knowledge, this is going to be the first systematic review to explore game elements in the design of educational simulations in the context of military trauma management. Our findings will increase the understanding of how game elements are used in the design of simulations in military trauma management training and by that hopefully contribute to more effective development of future simulations.

Acknowledgments

The authors would like to acknowledge Jonas Pettersson, Anja Vikingson, and Narcisa Hannerz at Karolinska Institutet Biblioteket (university library) for their support in designing the search strategy and retrieving the articles.

This study is financially supported by the Swedish Armed Forces.

Abstract

Background: An increasing interest in machine learning (ML) has been observed among scholars and health care professionals. However, while ML-based applications have been shown to be effective and have the potential to change the delivery of patient care, their implementation in health care organizations is complex. There are several challenges that currently hamper the uptake of ML in daily practice, and there is currently limited knowledge on how these challenges have been addressed in empirical studies on implemented ML-based applications.

Objective: The aim of this systematic literature review is twofold: (1) to map the ML-based applications implemented in health care organizations, with a focus on investigating the organizational dimensions that are relevant in the implementation process; and (2) to analyze the processes and strategies adopted to foster a successful uptake of ML.

Methods: We developed this protocol following the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines. The search was conducted on 3 databases (PubMed, Scopus, and Web of Science), considering a 10-year time frame (2013-2023). The search strategy was built around 4 blocks of keywords (artificial intelligence, implementation, health care, and study type). Based on the detailed inclusion criteria defined, only empirical studies documenting the implementation of ML-based applications used by health care professionals in clinical settings will be considered. The study protocol was registered in PROSPERO (International Prospective Register of Systematic Reviews).

Results: The review is ongoing and is expected to be completed by September 2023. Data analysis is currently underway, and the first results are expected to be submitted for publication in November 2023. The study was funded by the European Union within the Multilayered Urban Sustainability Action (MUSA) project.

Conclusions: ML-based applications involving clinical decision support and automation of clinical tasks present unique traits that add several layers of complexity compared with earlier health technologies. Our review aims at contributing to the existing literature by investigating the implementation of ML from an organizational perspective and by systematizing a conspicuous amount of information on factors influencing implementation.

Introduction

Rationale

After a period of so-called artificial intelligence (AI) winter, AI has re-emerged into the scientific and public consciousness by virtue of new technological breakthroughs and marketed solutions [1]. Recent machine learning (ML) applications have expanded the frontiers of AI. In this scenario, finding an operational definition of AI and ML is challenging. While the term AI has been embraced for regulatory purposes [2], various technical domains view it as a descriptor for the latest advancements in computer science. Consequently, as AI becomes more pervasive and integrated into mainstream applications, experts gradually disassociate it from its original designation [3]. ML instead refers to the subset of AI encompassing all the non–knowledge-based techniques that automatically learn from data without being explicitly programmed [4,5]. Recent advances in ML promise remarkable improvements in medical diagnosis and prognosis [6,7], generating tremendous enthusiasm surrounding these innovations. The use of ML in clinical environments has hitherto experienced diverse adoption patterns, with the field of radiology raising considerable attention due to the notable capability of ML (in particular, deep learning [DL]) models to extract valuable information from medical images [7]. Other clinical areas are also a fertile environment for ML-based applications, as their outcome prediction capabilities are expected to help health care systems improve the quality of care and use resources more accurately and efficiently [8].

Regulatory science has tried to keep up with these advances by adopting a permissionless innovation approach with low barriers for the entry of new algorithms [9]. Despite the European Union and the United States regulating AI with distinctiveness [10], regulatory approaches to ML are still under definition, ultimately impacting on the access strategies of developers [11] and contributing to delaying the deployment of ML in clinical practice and in specific settings.

Previous literature has well documented the implementation of expert systems and knowledge- or logic-based applications [12], all included in the definition of AI proposed by the High-Level Expert Group on Artificial Intelligence appointed by the European Commission [13]. Instead, ML-based applications assumed a prominent role only recently, thanks to greater data availability and computing capabilities [14]. Nevertheless, due to the incremental complexity of ML-based applications [12], their incorporation into health care processes is fraught with different challenges that need to be organically steered by various stakeholders [15]. ML-based applications that encompass the characteristics of autonomy, inscrutability, and learning [16] hence need further investigation from the implementation science community.

Recent scholarly contributions have shown that a theoretical understanding of the dimensions and dynamics associated with the implementation of AI in health care organizations is still in its infancy [14]. Empirical knowledge about the implementation of AI comes mostly from systems with a low level of autonomy and learning (ie, knowledge-based applications) and looks at either clinical effectiveness, technical efficiency, or regulatory and legal issues of such technologies, overlooking the organizational aspects [17]. For this reason, our work focuses exclusively on non–knowledge-based ML, namely tools that use some form of either supervised or unsupervised learning, and not on traditional knowledge-based AI algorithms.

Research on ML implementation has been predominantly conceptual in nature, with the identification of distinguishing issues in the development and dissemination in clinical practice, such as the opacity or black-box effect, and concerns surrounding equity, data privacy, and security [7,18]. Conversely, the consequences that such characteristics have on the implementation of ML in health care organizations have been poorly investigated empirically. A recent scoping review by Chomutare and colleagues [19] adopted a mixed deductive-inductive approach to extract barriers and facilitators to the implementation of ML and map them onto the Consolidated Framework for Implementation Research (CFIR) [20], identifying generalizability, interoperability, and data quality as the main barriers and engagement in the implementation process as the main facilitator [19]. However, additional inquiry is needed to gauge whether the current body of empirical studies of ML adequately acknowledges distinguishing implementation challenges such as trust and explainability and to analyze which implementation strategies have been adopted to address them.

Objectives

Given the potential disruptiveness of recent developments of ML in health care and the lack of knowledge about how to overcome the organizational challenges associated with their implementation, our research objectives are to identify and explore cases of real-life implementation of ML within health care organizations as documented in the literature and to synthesize the processes adopted to foster a successful implementation of ML. We plan to conduct a systematic literature review with the following goals in mind:

1. To examine the stages and characteristics of implementation processes described in empirical studies on ML under the lens of implementation science, namely the scientific study of methods to promote the uptake of evidence-based innovations into routine practice [21]. Specifically, the CFIR will be adopted as a practical theory-based guide for assessing the implementation outcome and complemented with implementation considerations associated with the distinctive features of ML.
2. To analyze the observed or suggested determinants of successful uptake of ML, thereby identifying the implementation processes and strategies currently adopted by health care organizations.

Methods

Study Design

This systematic review protocol follows the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) statement [22,23] and was registered within the PROSPERO (International Prospective Register of

XSL•FO
RenderX

Systematic Reviews) on March 3, 2023 (registration number 403873).

Eligibility Criteria

This review will be focused on studies that investigate aspects related to the implementation of ML-based applications in health care organizations. For the purposes of this review, by implementation, we define the "active and planned effort to mainstream innovation within an organization" [24], while the term "health care organization" refers to entities that deliver health services, including hospitals (general, community, teaching, or research hospitals), outpatient centers, and primary care and public health facilities. Studies will be selected based on the eligibility criteria described below and summarized in Textbox 1.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Study design: empirical studies based on implementation research designs (experimental or quasi-experimental, observational, hybrid, and simulation study designs)
- Intervention: implementation of machine learning (ML)–based applications including considerations on the inner setting and/or implementation process domains
- Stakeholder groups: ML-based applications used at least by health care professionals
- Settings: hospitals, outpatients, and other community care settings

Exclusion criteria

- Study design: effectiveness research study designs, literature reviews, commentaries, editorials, opinion articles, study protocols, studies collecting perceptions on implementation, and unrelated to specific ML-based applications
- Intervention: implementation of knowledge-based applications
- Stakeholder groups: ML-based applications targeting patients and other nonclinical stakeholders (eg, caregivers, policy makers, and regulators) only

Study Design and Publication Type

We will select peer-reviewed empirical studies documenting the implementation of ML-based applications, thereby including experimental or quasi-experimental, observational, hybrid, and simulation study designs [25]. In the context of implementation research, experimental studies typically aim to evaluate the impact of specific strategies to improve implementation, whereas observational designs examine the implementation in service delivery using approaches that are quantitative, qualitative (eg, semistructured interviews with involved end users), or mixed methodologies. We will also consider hybrid designs, which blend the components aimed at testing clinical effectiveness with those that analyze the implementation process by investigating potential barriers and facilitators to the implementation and assessing outcomes such as adoption, reach, acceptability, and fidelity [26]. We will exclude comparative effectiveness study designs (such as randomized controlled trials that only aim at generating clinical evidence and do not imply organization-wide implementation), as well as nonempirical designs, including editorials, commentaries, opinion articles, and other published reviews of the literature. Works based on surveys and interviews with subject matter experts will be excluded if they broadly investigate issues concerning the adoption of ML-based applications and do not report on the implementation process of specific technologies in a given organizational setting.

Intervention

Studies will be considered eligible if they analyze the implementation of tools based on ML in health care organizations and discuss the associated processes, context, barriers, or facilitators. As part of ML, we will include both DL techniques, unanimously considered as a subset of ML [5], and natural language processing models when based on ML. The latter, by their very nature, do not necessarily involve learning techniques. However, DL techniques have been widely used to overcome the limitations of symbolic approaches applied to natural language processing, and most of its recent development is unanimously attributed to DL approaches [27-29].

Based on the constructs of the updated CFIR [20], only articles including considerations on either the inner setting in which the innovation has been adopted or the activities and strategies being used to implement the innovation will be included. Studies only focusing on the clinical implications of the implementation or based on logic- and knowledge-based applications (expert systems) will be excluded.

Stakeholder Groups

We will include studies focused on ML-based applications available for use by health care professionals. Applications used by patients, caregivers, health care administrators, and policy makers will only be included if they are also used by clinicians and other health care professional groups.

Setting

We will include studies with a spotlight on the implementation of ML-based applications in clinical practice, biomedical research, and public and global health, as per the classification provided by the European Parliament [30]. All possible organizational settings related to these practices will be considered, including inpatient units, emergency departments, outpatient settings, and primary care. ML-based applications used in administrative settings will be excluded.

XSL•FO
RenderX

Time Frame

Considering the rapid evolution and changes in ML-based applications, we will only consider studies published in the past 10 years (since 2013).

Information Sources

Literature searches were conducted in MEDLINE (PubMed), Scopus, and Web of Science and replicated in top-tier management journals (ie, Academy of Management Journal, Organization Science, MIS Quarterly, Journal of Management Studies, Organization Studies, and Academy of Management Annals). In addition, the reference list of all included studies and of the reviews identified will be scanned to ensure that any relevant work is captured. Gray literature was not considered.

Search Strategy

The search strategy was developed, including a combination of keywords around four main concepts: (1) AI, (2) implementation, (3) health care, and (4) study type.

The list of search concepts and associated terms used is provided in Textbox 2.

The exact search stream was developed by the research team following an iterative process. The general term "artificial intelligence" has been used to encompass studies that address the terms AI and ML as synonymous. The search strategy was initially finalized for PubMed and then adapted to the syntax and subject headings of the other databases. The initial search was performed in April 2023.

Textbox 2. Concepts to be used to define the search string.

Main search concepts, to be combined using "AND"

- Artificial intelligence
- Implementation
- Healthcare
- Study type

Search concepts synonyms, to be combined using "OR"

- Artificial Intelligence, Machine Learning, Deep Learning, Natural Language Processing
- Implementation, Adoption, Diffusion, Uptake
- Healthcare, Health*, Therap*, Patient*, Clinic*, Care, Professional, Medic*, Doctor, Hospital, Life Science, Pharma
- Empirical, quantitative, trial, qualitative, interview*, case stud*, case report, field stud*, field research, mixed-method*, mixed method*, focus group*, observational stud*, hybrid design, hybrid stud*, trial

Study Records

Data Management

The records retrieved from the literature search were uploaded and merged into RefWorks, a reference management tool that simplifies the process of research and collaboration among the review team. Duplicates were removed, and the identified list of records was extracted into an Excel (Microsoft Corp) spreadsheet for title and abstract screening.

Selection Process

A total of 2 researchers (VA and LMP) screened the first 100 retrieved articles based on titles and abstracts. Interrater agreement was measured using kappa statistics [31]. Once aligned on the eligibility criteria, the remaining papers were screened independently by the review team (VA and LMP) based on titles and abstracts. Disagreement over final inclusions was solved with a third researcher (FP). Studies deemed eligible for full-text reading will be assessed in depth (VA, LMP, and FP). Disagreements will be solved by dialogue with 2 other researchers (GC and AC). The entire research team will read all the studies eventually included in the analysis.

Data Collection Process

The data collection process will be performed by 3 reviewers (VA, LMP, and FP). Data will be extracted using an ad hoc Excel (Microsoft Corp) spreadsheet, preliminarily developed by the research team. To ensure consistency across reviewers, the extraction sheet will be tested by each reviewer and possibly recalibrated before starting the data collection process. Disagreements will be resolved by discussion, and 1 of 2 arbitrators (GC and AC) will adjudicate unresolved disagreements. Information on the implementation process of ML-based applications will be collected, as specified in the following section.

Data Items

Data items to be extracted from the selected studies will include the following fields, based on preexisting, established classifications or schemes, where possible:

1. Demographic information: study identifiers, authors, journal outlet, publication year, and keywords.
2. Methodology: study design.
3. Setting: country, organizational setting (eg, hospital inpatient, emergency department, and primary care), organizational nature (eg, public and private), and unit of implementation of the ML-based application.
4. Implementation stages: stages of the implementation process described in the study, adapted based on Aarons et al [32].
5. Intervention: name and description of the ML-based application, level of integration with other technologies, main practice (ie, clinical practice, biomedical research,

XSL•FO
RenderX

public and global health, and health care administration) [30], steps of the clinical workflow impacted by the ML-based application [33], ML capabilities (eg, recognizing sounds vs images vs texts) [34], type of learning system (ie, supervised vs unsupervised vs semisupervised learning) [35,36], level of autonomy that the ML-based application foresees (from data presentation only to full autonomation following the classification by Bitterman and colleagues [37]), underlying data fed in the ML-based application (ie, quantity, quality, and data inputs), and previous evaluation of effectiveness [14].

6. Individuals: actors involved in the development and implementation of the ML-based application.
7. Inner setting: factors related to the organizational context in which the innovation is implemented, including both persistent general characteristics of the organization and properties specific to the delivery of the innovation. These include implementation capacity and readiness, as well as ML-specific domains such as the consideration of ethical concerns [38] and computational resources (ie, any references to the availability of substantial computing power, either proprietary or through cloud-based analytics, and organizational policies or strategies that have favored data storage and processing) [39].
8. Outer setting: considerations on the setting in which the inner setting exists, such as legislative, regulatory, accreditation, and reporting authorities and aspects [40], partnerships and connections with external entities, and external pressure from either social movements, peer organizations already adopting the technology, or benchmarking metrics [20].
9. Implementation process, including activities and strategies used to implement, assimilate, and routinize the innovation, encourage participation, and collectively discuss the success of the process.
10. Barriers and facilitators explicitly cited in the study.
11. Outcomes: observed, measurable outcome domains and metrics associated with the implementation process.

Data Synthesis

A narrative analysis will be adopted to synthesize the findings from the included studies, as the characteristics of the implementation processes will be tabulated and summarized through descriptive statistics according to the implementation-science domains selected for data collection. Given the objectives of this systematic review, the wide variety in the study designs and outcome domains considered, and the prospected predominance of qualitative studies, no quantitative synthesis of the results will be performed.

Results

The systematic review is ongoing. As of June 1, 2023, we have finalized the identification of records and the title and abstract screening of the 3520 records that met our search criteria. A full-text review is currently underway and will be completed by September 2023. After data synthesis, we plan to disseminate the study results by submitting the corresponding manuscript to a peer-reviewed journal in November 2023.

Discussion

ML-based applications have proliferated exponentially in recent years and demonstrated to have high potential both to streamline the clinical workflows and to improve patient outcomes. Yet, available studies have focused mainly on the technical components of ML-based applications and on their clinical efficacy, while the organizational preconditions or determinants needed to facilitate or sustain their implementation have been overlooked, emphasizing the need to identify effective strategies and foster the use of theories, models, and frameworks to facilitate implementation [41].

Therefore, our research will systematically review and synthesize the evidence of empirical studies reporting on implemented ML-based applications that are used in the real world. To comprehensively investigate implementation factors at the organizational level, ML-based applications that impact the activities of health care professionals at large will be considered.

In this context, the domains of the updated CFIR will be used as a practical tool to guide the data extraction and interpretation of the organizational factors that drive implementation, adopting the theoretical lens of implementation science. As such, we expect that our review will contribute to the field of implementation science research, a field that seeks to systematically close the gap between what we know and what we do (ie, the know-do gap) [21], adding insightful knowledge to the implementation science literature on ML.

The strengths of our prospective literature review are that it will follow a standardized methodological approach by adhering to systematic review guidelines (ie, PRISMA statements and checklist for systematic reviews) [42] and that it will aim at systematizing a conspicuous amount of information on factors influencing implementation. On the contrary, potential limitations lie both in language barriers, as only articles published in English will be scrutinized, and on the exclusion of the gray literature.

This work is part of larger research whose overarching aim is to develop a conceptual framework for the implementation of ML in health care organizations in an effort to support the adoption and deployment of health care innovations. In perspective, the theoretical basis of this work will therefore pave the way for the later conceptualization of an implementation framework that will stem from the available implementation science frameworks, but will be tailored to also account for the distinctive features of ML. This process will be additionally informed by the engagement of expert stakeholders employed in health care organizations, who will provide qualitative inputs based on their real-life experience with ML to fine-tune and finalize the framework. All in all, starting with the current review, the aim of our research is twofold: building a practical tool for health care practitioners while transitioning toward the use of ML-based applications within their organization, while also contributing theoretically to management and innovation theories.

Acknowledgments

This systematic review will be performed within the Multilayered Urban Sustainability Action (MUSA) project, funded by the European Union, NextGenerationEU, under the National Recovery and Resilience Plan Mission 4 Component 2 Investment Line 1.5: Strengthening of research structures and creation of R&D "innovation ecosystems" setup of "territorial leaders in R&D."

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed for this research protocol. All data extracted from the literature and generated during the prospective systematic review will be included in the published article or made available upon request.

Authors' Contributions

GC and AC conceived the initial concept for the review. VA, FP, and LMP generated the first draft of the manuscript. VA and LMP carried out the search strategy and initial screening of the records. All authors contributed to developing the data extraction form and revised and approved the final version of this manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Countries and health systems have had to make challenging resource allocation and capacity-building decisions to promote proper patient care and ensure health and care workers' safety and well-being, so that they can effectively address the present COVID-19 pandemic as well as upcoming public health problems and natural catastrophes. As innovations are already in place and updated evidence is published daily, more information is required to inform the development and implementation of policies and interventions to improve health and care workforce capacity to address the COVID-19 pandemic response.

Objective: The objective of this protocol review is to identify countries' range of experiences with policies and management interventions that can improve health and care workers' capacity to address the COVID-19 pandemic response and synthesize evidence on the effectiveness of the interventions.

Methods: We will conduct a living systematic review of quantitative, qualitative, and mixed methods studies and gray literature (technical and political documents) published in English, French, Hindi, Portuguese, Italian, and Spanish between January 1, 2000, and March 1, 2022. The databases to be searched are MEDLINE (PubMed), Embase, SCOPUS, and Latin American and Caribbean Health Sciences Literature. In addition, the World Health Organization's COVID-19 Research Database and the websites of international organizations (International Labour Organization, Economic Co-operation and Development, and The Health System Response Monitor) will be searched for unpublished studies and gray literature. Data will be extracted from the selected documents using an electronic form adapted from the Joanna Briggs Institute quantitative and qualitative tools for data extraction. A convergent integrated approach to synthesis and integration will be used. The risk of bias will be assessed with Joanna Briggs Institute critical appraisal tools, and the certainty of the evidence in the presented outcomes will be assessed with the Grading of Recommendations, Assessment, Development and Evaluation.

Results: The database and gray literature search retrieved 3378 documents. Data are being analyzed by 2 independent reviewers. The study is expected to be published by the end of 2023 in a peer-reviewed journal.

Conclusions: This review will allow us to identify and describe the policies and strategies implemented by countries and their effectiveness, as well as identify gaps in the evidence.

KEYWORDS

COVID-19; health and care workforce policy; health and care workforce capacity; management interventions; SARS-CoV-2; pandemic

Introduction

Health systems worldwide have been challenged by the COVID-19 pandemic, which affected about 670 million people as of May 2023 [1]. The need for the health and care workforce (HCWF) to be adaptable and flexible in the face of constant change was emphasized, as almost all countries affected by the pandemic faced a surge in reported cases and disruptions of essential health services [2].

The pandemic resulted in a high incidence of SARS-CoV-2 infections and deaths among health and care workers (HCWs); increased workload (accentuated by absenteeism and quarantine); and exposure to work-related health hazards and their consequences, including fatigue, psychosocial stress, despair, violence, and a shortage of personal protective equipment, among others [3,4]. Moreover, it highlighted preexisting weaknesses in health and care systems and services, such as a shortage of HCWs, as well as other sorts of imbalances that are long-standing challenges observed in almost every country [5].

A recent study concerning HCWs' perceptions of government responses, support, and the impact of their measures on public and private health sectors identified dissatisfaction in most cases [6]. Particularly, they were discontent with the lack of health system organization; unequal distribution of support across health facilities; and the perception of government policies as disorganized, confused, and even contradictory [6]. Countries and health systems had to make challenging resource allocation and capacity-building decisions to promote proper patient care, ensure staff safety and well-being, and innovate to address the pandemic as well as upcoming public health problems and natural catastrophes. The widespread and far-reaching repercussions of this pandemic and other recent crises signal an urgent appeal to leaders and health and care systems around the world to be better prepared. Specifically, there should be clear and comprehensive disaster response management strategies [7] and a strong public health system, with HCWs who are fit for the purpose, well supported, better protected, and provided with decent working conditions.

The World Health Organization (WHO) has made an effort to synthesize high-quality, timely evidence and contribute guidance to inform the decision-making process. Their aim is to "assist health managers and policy-makers at national, subnational, and facility levels in designing, managing and preserving the workforce necessary to manage the COVID-19 pandemic and maintain essential health services" [8]. With the development of the epidemic, innovations are already in place and updated evidence is published frequently; however, more information is required to inform the development and implementation of policies and interventions.

Hence, we intend to conduct a living systematic review (LSR) to identify the range of experiences across countries with various policies and management interventions that can improve HCWs' capacity to address the COVID-19 pandemic response, gather and synthesize evidence on the effectiveness of the interventions, and identify gaps and maintain the currency of the evidence.

Methods

Study Design

An LSR is a systematic review that is regularly updated, adding pertinent new information as it becomes available and serving as a crucial connection between health research findings and evidence-based health care decision-making [9].

With the current LSR (registered at PROSPERO; CRD42022327041 [10]), we intend to address the following review question: What strategies and policies have been adopted by countries to improve HWCs' capacity to address the COVID-19 pandemic and how effective have they been?

An LSR is particularly appropriate to address this review question given that the issue under analysis is a priority for decision-making, the level of uncertainty in the existing evidence is high, and emerging evidence might impact the conclusions of a traditional systematic review. Most methodological guidelines still do not address the specificities of LSRs. Therefore, the proposed LSR will be conducted by adopting and adapting the Joanna Briggs Institute (JBI) methodology for mixed methods systematic reviews [10].

Eligibility Criteria

The eligibility criteria for this LSR are as follows:

- Types of study: This review will include quantitative, qualitative, and mixed methods studies and gray literature (technical and political documents). Quantitative studies will include observational (eg, case-control, cohort, and cross-sectional), experimental, and quasi-experimental studies. Advocacy materials, opinion letters, news releases, editorials, and opinion documents will be excluded from the review but can be used to discuss the findings.
- Interventions: This review will consider countries' range of policies and management interventions implemented to improve HCWF capacity to address the COVID-19 pandemic response, including the following domains: supporting and protecting health workers; strengthening and optimizing health workforce teams; and increasing capacity, strategic health worker deployment, and

XSL•FO
RenderX

system-level human resources for health interventions as proposed by the WHO interim guide [8].

- Participants: The review will consider studies that address policies or management interventions implemented by countries regarding HCWs, hereby understood as all health-related occupations in the health and social sectors of employment, those working in health facilities offering all levels of care, and various employment settings.
- Context: This review will consider studies that investigate the range of interventions in different countries, whether implemented at supranational, national, or state levels.

Search Strategy

The search strategy will aim to identify both published and unpublished studies. Search terms (preferably Medical Subject Headings [MeSH]) will be used to search the databases. To search relevant documents in databases that do not index using MeSH terms, we will use other thesaurus databases (eg, Descritores em Ciências da Saúde and Emtree) and the entry terms for each relevant keyword combined using the Boolean commands AND, OR, and * to capture various terms of the same word or expression (Multimedia Appendix 1).

The search of all data sources will be conducted by 1 researcher. After this process is complete, a second researcher will select a random sample of the databases to be used in a quality check. The reference list of all studies selected for critical appraisal will be screened for additional studies. Researchers from ongoing studies might be contacted to request preliminary or unpublished data to complete the publicly available data.

Studies published in English, French, Hindi, Portuguese, Italian, and Spanish will be included. The initial literature review will include studies published from January 1, 2020, to March 1, 2022. Since this systematic review is an LSR, monthly updates will be run for electronic databases. Studies identified will be incorporated in the review or noted in the "What's new" section and included in the updates. Gray literature and international organizations or databases on workforce will be updated every 3 months.

The databases to be searched are MEDLINE (PubMed), Embase, SCOPUS, and Latin American and Caribbean Health Sciences Literature. Sources of unpublished studies and gray literature to be searched are the WHO's COVID-19 Research Database [11] and the websites of international organizations: International Labour Organization [12], Economic Co-operation and Development [13], and The Health System Response Monitor [14].

Study Selection

We will use EndNote Web (Clarivate) to collect, organize, and manage references retrieved from the searches of the different databases.

Data on eligibility will be collected through Rayyan (Rayyan Systems Inc.) [15]. Inclusion and exclusion criteria will be first applied to the abstracts of the retrieved documents. In case no abstract is available, the criteria will be applied either to the executive summary or the introduction of the documents. Titles and abstracts of the initial searches will be screened, and if eligibility criteria are met, the documents will be selected for full-text analysis. An initial pilot test will be performed in this phase ("Title+Abstract phase") by reviewers until a sufficient level of agreement is reached. After that, the remaining publications will be divided between the reviewers. In this second phase, the eligibility criteria will again be applied to the full text independently by 2 researchers. If the text meets the criteria, we will then extract relevant data from the document to answer the research question. The reviewers are expected to collaborate whenever questions or doubts arise, and a third reviewer will be consulted in case of disagreement. κ statistics, sensibility, and sensitivity will be computed to assess interreviewer agreement and the quality of this process [16]. The inclusion of studies will be described according PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) recommendations, including the number of documents retrieved; identified as duplicates; screened for abstract; excluded and the reason for exclusion; and included during full-text analysis and the number of documents for data extraction [17].

Risk of Bias and Quality Assessment

If the inclusion criteria are met, the documents will be selected for full-text analysis. In this phase, the eligibility criteria (as well as the exclusion criteria) will be again applied, and if they are met, we will then use the JBI critical appraisal tools (CATs) to assess the risk of bias in the included studies [18]. Quantitative and qualitative studies selected for retrieval will be assessed by 2 independent reviewers for methodological validity prior to inclusion in the review using the standardized critical appraisal instrument from JBI SUMARI; these instruments are designed to be study specific and facilitate cross-study comparisons. We have selected the following appraisal tools: randomized controlled trials, cohort studies, case-control studies, economic evaluations, qualitative studies, as well as text and opinion.

According to the assessment, we will then categorize the study into low, medium, and high quality, as follows:

1. Each item in the CAT has 4 options of answer (yes, no, unclear, or not applicable), to which we will assign the following points: yes=2 points, no=0 points, unclear=1 point, and not applicable=missing value and will not be considered for scoring.
2. We will compute a score per study by adding the points of each item.
3. For each CAT, the maximum score will be computed by multiplying the total number of items by the maximum score in each item (as detailed in Table 1.
4. Low quality is set at ≤quartile 2 of the maximum score, medium quality is set between quartile 2 + 1 and quartile 3, and high quality is set as ≥quartile 3 + 1. In case an integer value was not obtained, the next integer value was set as a cut-off.

XSL•FO
RenderX

Table 1. Critical appraisal tool (CAT) scores (adapted from Fronteira et al [19]).

CAT	Items	Maximum score	Quality and score range		
			Low	Medium	High
Checklist for Analytical Cross-Sectional Studies	8	16	≤8	9-12	≥13
Checklist for Case Control Studies	10	20	≤10	11-15	≥16
Checklist for Cohort Studies	11	22	≤11	12-17	≥18
Checklist for Prevalence Studies	9	18	≤9	10-14	≥15
Checklist for Qualitative Research	10	20	≤10	11-15	≥16
Checklist for Quasi-Experimental Studies	9	18	≤10	10-14	≥15
Checklist for Randomized Controlled Trials	13	26	≤13	14-20	≥21

The level of bias will be considered in the synthesis of the results on the evidence found. The CATs will be applied by 2 reviewers. The critical appraisal results will be reported in a narrative form and in a table. All studies, regardless of the results of their methodological quality, will undergo data extraction and synthesis (when possible).

The quality of the evidence supporting study findings regarding the outcomes of the policies and management interventions implemented by countries will be analyzed using the GRADE (Grading of Recommendations, Assessment, Development and Evaluation) approach developed by the GRADEpro Working Group [20].

Data Extraction and Synthesis

Data will be extracted from the selected documents, including bibliographic information (author, year, location, and setting), study design type, interventions type, country, level or location, sector and actors involved, participant profession, sample size, delivery model, outcomes, and implementation context according to the data extraction instrument (Multimedia Appendix 2). The reviewers will use electronic forms adapted from the quantitative and qualitative tools for data extraction from the JBI Manual of Evidence Syntheses [21].

Study data will be collected and managed using REDCAP (Research Electronic Data Capture; Vanderbilt University) tools hosted at Universidade Estadual do Rio de Janeiro, Instituto de Medicina Social; the REDCAP form was specifically developed for the study design (quantitative or qualitative) [22,23]. The quantitative data will then be converted into "qualitized data." This will involve transformation into textual descriptions or narrative interpretation of the quantitative results in a way that answers the review questions.

The primary outcomes to be considered are HCWF availability, distribution, performance, efficiency, productivity, retention, protection, working conditions, and satisfaction. Additional outcomes cover absenteeism, deaths, infection, cases of violence and harassment, turnover, intention to leave, workplace hazards, financial protection, service delivery disruptions or disrupted access to essential health services (continuity of treatment of chronic diseases), and coverage. Furthermore, additional outcomes not mentioned here can be added during the LSR.

This review will follow a convergent integrated approach according to the JBI methodology for mixed methods systematic review using JBI SUMARI that "refers to a process of combining extracted data from quantitative studies (including data from the quantitative component of mixed methods studies) and qualitative studies (including data from the qualitative component of mixed methods studies) and involves data transformation" [24]. It is recommended that quantitative data be "qualitized," as codifying quantitative data is less error-prone than attributing numerical values to qualitative data [10] by assembling the qualitized data with the qualitative data. Assembled data are categorized and pooled together based on similarity in meaning to produce a set of integrated findings in the form of a line of action statements. This transformation leads to the creation of qualitative categories, which can be compared with other qualitative observations to identify patterns or discrepancies, thus extracting additional information from the quantitative data and validating its interpretation.

We will be grouping the findings in each specific policy and intervention domain per type of intervention and outcome. For each outcome, we will summarize the study type and method in selected studies, intervention context, population, outcomes, and risk-of-bias assessment results. We will discuss the body of evidence for each policy and intervention domain, the type of intervention and outcome, and the overall quality of the evidence by using the risk assessment results and GRADE recommendation system.

The type of quantitative synthesis of data will be determined by evidence for a prespecified comparison, the completeness of the reported outcome, differences in the effect measures, bias in the evidence, clinical and methodological diversity, and statistical heterogeneity.

Results

The database and gray literature search retrieved 3378 documents. Data are being analyzed by 2 independent reviewers. The results are expected to be published in a peer-reviewed journal by the end of 2023.

Discussion

Expected Findings

The COVID-19 pandemic has revealed significant vulnerabilities and challenges within global health and care systems, particularly in terms of HCWF capacity and resilience. Policies

XSL•FO
RenderX

and management interventions implemented to improve the HCWF's capacity to address the COVID-19 pandemic response have been discussed in different studies [25-30]. For example, one study suggested methods to measure and improve the resilience and preparedness of countries to face the pandemic through timely and responsive strategies for crisis management to mitigate negative impacts on public health, economies, and societies [30]. It has also been identified that failures in the management of the pandemic with regard to ensuring workers' well-being can result in exacerbated inequality and highlight the importance of politics in countries, where political authority also shapes decision-making processes [29]. In addition, sound leadership and ownership lead to the successful execution of initiatives and overall preparedness. The adaptability of health services plays a crucial role in achieving positive outcomes [31]. However, only a few studies have mentioned the outcomes of the interventions and addressed it in a systematic manner [27].

To the best of our knowledge, this is the first LSR that represents a comprehensive examination of policies and management interventions across 4 levels—individual, management, organizational, and system—in the context of pandemics. The study design; the incorporation of scientific, technical, and political documents; and the use of a framework are strengths of this review, as they offer a broad perspective on the identities of the interventions implemented (encompassing information that, by its nature, does not make it into scientific documents). This presents an objective view of the topic while minimizing biases by following established procedures and reporting guidelines. Other strengths include the robust search strategy, which includes published and unpublished literature in 6 languages across 5 databases and the websites of international organization. In addition, we will report the percentage of agreement between reviewers.

On the contrary, the limitations of this systematic review may include publication bias, as studies with favorable outcomes are more likely to be published, resulting in an overrepresentation of effective interventions. In the context of a pandemic, policies and strategies to enhance the HCWF are also rapidly evolving. In addition, the impact of the pandemic may evolve over time, making it difficult to assess the long-term effects and sustainability of the proposed policies and strategies.

Conclusions

This review can shed light on measures to improve the HCWF; the results can guide policy makers in developing evidence-informed policies and strategies that optimize the HCW response to future pandemics. Findings can inform future policy decisions and resource allocation. In addition, by conducting an LSR that incorporates the latest evidence, health care systems can respond more swiftly to the changing demands of HCWs. Furthermore, identifying gaps in knowledge can contribute to the development of a research agenda to inform the development of policies and strategies related to the HCWF.

Acknowledgments

This living systematic review (LSR) is part of a group of LSRs [19,32,33] developed in response to the World Health Organization's call.

This study was funded by the Solidarity Fund, through a grant administered by the World Health Organization.

Centro de Estudos, Pesquisa e Desenvolvimento Tecnológico em Saúde Coletiva (CEPESC) provided management and administrative support.

Portuguese Fundação para a Ciência e Tecnologia provides funds to Global Health and Tropical Medicine (GHTM), Instituto de Higiene e Medicina Tropical, Universidade Nova de Lisboa (IHMT/UNL; GHTM UID/04413/2020).

Data Availability

The database of the living systematic review is available upon request from the authors.

Authors' Contributions

APCdO designed the study, oversaw all stages of its implementation, was the chief writer of the PROSPERO protocol registration, and contributed to the writing of this manuscript. MDP and PF were major contributors to the design of the project. PF wrote the first draft of this manuscript, and MLG conducted the final checklist verification. RC was the librarian advisor for this project. All authors contributed to the methodological discussions. All authors read and approved the final manuscript. The authors alone are responsible for the content of this protocol.

Abstract

Background: Heat waves significantly impact ecosystems and human health, especially that of vulnerable populations, and are associated with increased morbidity and mortality. Besides being directly related to climate-sensitive health outcomes, heat waves have indirectly increased the burden on our health care systems. Although the existing literature examines the impact of heat waves and morbidity, past research has mostly been conducted in high-income countries (HICs), and studies on the impact of heat waves on morbidity in low- or middle-income countries (LMICs) are still scarce.

Objective: This paper presents the protocol for a systematic review that aims to provide evidence of the impact of heat waves on health care services in LMICs.

Methods: We will identify peer-reviewed studies from 3 online databases, including the Web of Science, PubMed, and SCOPUS, published from January 2002 to April 2023, using the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) guidelines. Quality assessment will be conducted using the Navigation Guide checklist. Key search terms include *heatwaves*, *extreme heat*, *hospitalization*, *outpatient visit*, *burden*, *health services*, and *morbidity*.

Results: This systematic review will provide insight into the impact of heat waves on health care services in LMICs, especially on emergency department visits, ambulance call-outs, hospital admissions, outpatient department visits, in-hospital mortality, and health care operational costs.

Conclusions: The results of this review are anticipated to help policymakers and key stakeholders obtain a better understanding of the impact of heat waves on health care services and prioritize investments to mitigate the effects of heat waves in LMICs. This entails creating a comprehensive heat wave plan and ensuring that adequate infrastructure, capacity, and human resources are allocated in the health care sector. These measures will undoubtedly contribute to the development of resilience in health care systems and hence protect the health and well-being of individuals and communities.

Introduction

The world is facing significant climate change with a variety of impacts, especially from rising temperatures and more frequent heat wave episodes. Globally, the annual average temperature has been rising since the beginning of the 20th century, and it is now higher than the 1901 to 2000 average [1]. Global warming as a result of the continuous increase in greenhouse gas production has contributed to heat waves with increasing frequency, severity, and duration [2]. Moreover, the effects of heat waves are aggravated by rapid urbanization, population growth, and the urban heat island effect [3]; more than half of the world's population lived in urban settings in 2017 [4]. The Intergovernmental Panel on Climate Change (IPCC) has projected that global warming of 1.5 °C could be reached in the 2030s if countries do not adhere to the Paris Agreement and do not create a mitigation action plan [5,6]. Major heat wave events have caused widespread casualties and strain on health care systems worldwide. The impacts were observed during the 2003 European heat wave, with the deaths of an estimated 72,000 people, and the 2010 Russian heat wave, with 56,000 deaths [7]. The number of deaths is projected to increase in the future, with 250,000 additional deaths per year between 2030 and 2050 [8]. An extended time-series study demonstrated increased risks of mortality of 5.1%, 2.9%, and 5.5% for every degree rise in temperature above the identified threshold for London, Budapest, and Milan, respectively [9].

Heat waves are generally defined as prolonged periods of exceptionally high or extreme temperatures and are characterized by the magnitude, duration, severity, and extent of the event [10,11]. Up to now, there has been no agreed definition of a heat wave, as the best definition would largely depend on the specific climatic zone of a geographical area, time trends, and individual acclimatization [12]. The unavailability of a unified global index further complicates research that seeks to compare results [12] and discuss patterns, trends, and impacts [13] for the development of health warning systems. The World Meteorological Organization and the Centre for Research on the Epidemiology of Disasters define heat waves as 2 or more consecutive days of temperatures exceeding the local region's given temperature or a percentile threshold [14-16]. A heat wave index (HI) can be defined using temperatures alone or in combination with other meteorological factors, such as humidity and wind speed, for a specified duration, ranging from 1 to several consecutive days [10,13]. Some researchers prefer to use daily mean temperature [17], while others have used daily maximum and apparent temperature [18] to understand the exposure relationship. For instance, Kent et al [12] and Zhang et al [19] found a relative mean temperature HI was the most predictive of adverse heat-related health effects compared to other HIs. According to Wu et al [20], the diversity in heat wave definitions could lead to uncertainty of approximately 22% in predictions of mortality risk.

An increase of 1 °C in temperature above a city-specific threshold is a serious public health concern due to increased mortality and hospital admissions [21-23]. Health effects following heat waves are usually acute, ranging from immediate effects to effects that persist until 7 days later [24,25]. Heat waves have been linked directly to multiple medical conditions, such as heat-related illnesses [26], accelerated complications and deaths from cardiorespiratory and renal diseases, endocrine disorders, food and waterborne diseases, vector-borne diseases [27], accidents [28], increased preterm births [12], and many more. Furthermore, morbidity and mortality in urban areas are higher due to the urban heat island effect [29,30]. On the other hand, improvements in living conditions, urban green space, and awareness of heat waves [31] have been shown to reduce the adverse health effects.

Heat waves will create a surge in demand for health care services and subsequently increase the burden on these services at all levels, including primary care, elective admissions, and intensive care. This includes increased ambulance call-outs, slower response time [32], increased emergency and outpatient department visits [33], increased hospitalization [34], shortages of medicine, and ultimately increased health care expenditures, both direct and indirect [35]. Even though a few previous studies found that emergency hospital admissions were lower compared to mortalities during heat waves [36,37], the number of excess emergency department visits can still be high and thus impose an extra burden on health care services. For instance, during heat wave events in California in 2006, an excess of 16,166 emergency department visits was documented [38]. Health care systems will be under pressure with high bed occupancy rates and constrained resources, which may ultimately affect the care plans of patients [39] and lead to greater economic costs [40].

The effects of heat waves are more pronounced in vulnerable groups. Numerous systematic reviews have examined the effects of heat waves on older people [31]; children [41,42]; men and women [43]; pregnant women [44]; people with chronic conditions, such as mental illness [45,46], cardiovascular disease [47-50], and kidney disease [51]; people experiencing homelessness; people with low socioeconomic status and poor access to green areas [52]; and people in certain occupational sectors, such as agriculture, forestry or fishing, construction, and manufacturing [53]. Reviews that examined the impact of heat waves on health services in low- or middle-income countries (LMICs) are still scare [52,54], with the majority concentrating on high-income countries (HICs) [34] or a combination of LMICs and HICs [55,56]. Moreover, LMICs have limited access to health care systems, lack of adequate infrastructure, and a lower allocation of gross domestic product (GDP) to health care [52]; they also have more vulnerable populations due to low adaptive capacity to heat waves [57-59], lower socioeconomic status, and lack of cooling facilities such as air-conditioning in homes [60,61].

Thus, it is necessary to understand the specific, isolated impact of heat waves on health care services in LMICs in order to ensure adequate preparedness, health promotion, and risk management and allow preventive measures to be carried out effectively to protect vulnerable people from the harmful effects of extreme weather, as highlighted by the World Health Organization and the US National Climate Assessment Program 2014 [62]. Moreover, previous research in China has demonstrated that public health divisions and clinical divisions were unprepared to act confidently in facing challenges related to climate change due to lack of logistical support, capacity

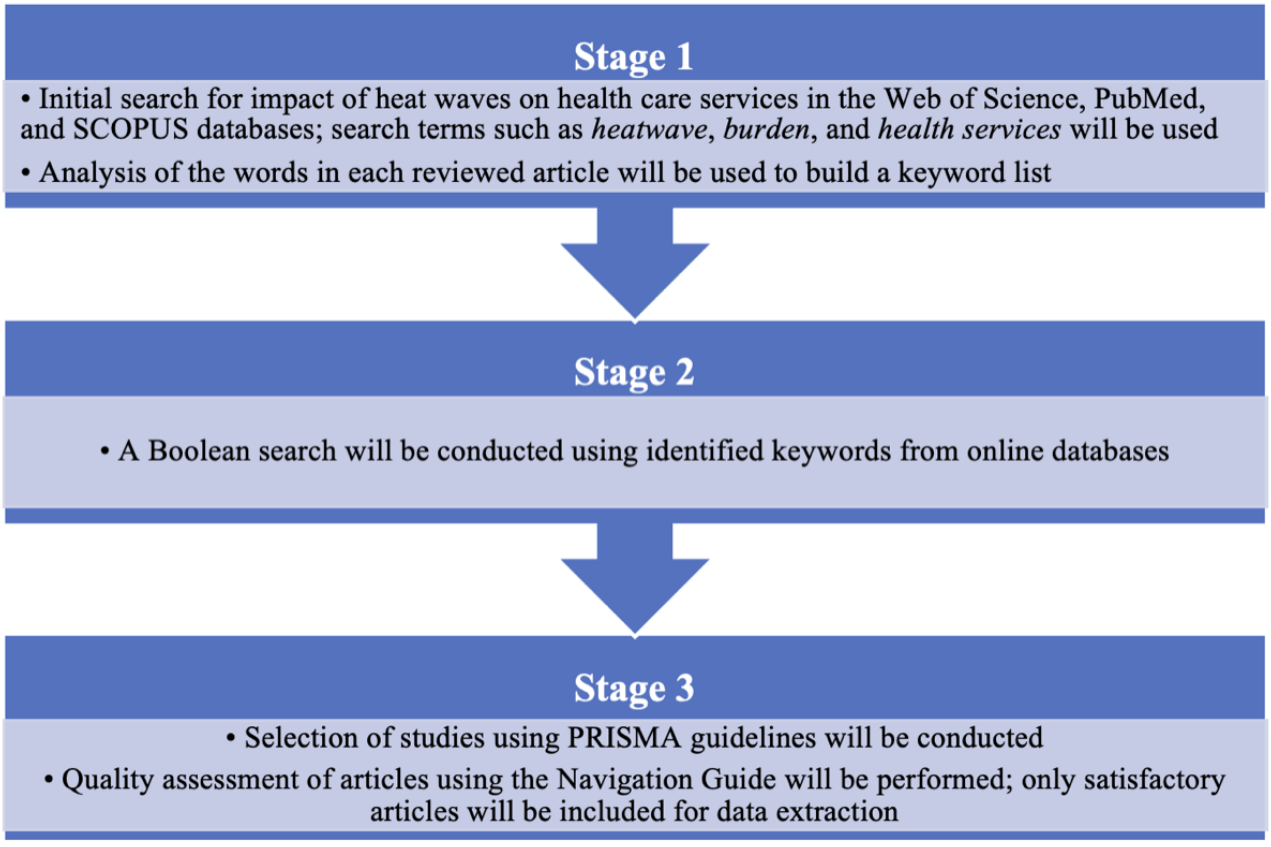
building, and funding [27,63]. The enhancement of health care services ultimately aims to reduce morbidity and mortality arising from heat wave exposure.

This systematic review aims to evaluate the impact of heat waves on health care services in LMICs. Moreover, this study aims to identify critical research gaps in the existing literature for future research and to aid in the dissemination of important research findings to policymakers and relevant stakeholders for strategic policy planning and implementation.

Methods

Protocol Registration

This study has been registered with the international Prospective Register of Systematic Reviews (PROSPERO; CRD42022365471). This paper presents a protocol for a systematic review of literature reporting on the impact of heat waves on health care services, particularly in LMICs.



Identifying the Research Question

The main research question is "How do heat waves place a burden on health care systems, particularly in LMICs?" The specific questions are (1) "What are the impacts of heat waves on health care systems—emergency department visits, hospital admissions, outpatient department visits, ambulance call-outs, in-hospital mortality, and health care operational costs?" and (2) "What are the risk factors involved?"

Search Strategy

A comprehensive literature search of electronic databases for peer-reviewed literature published between January 2002 and April 2023 will be conducted on the Web of Science, PubMed, and SCOPUS using a common search strategy. The process of the review started in March 2023 and is currently still in the screening phase. This process involves a 3-stage protocol, as depicted in Figure 1, using the Boolean operators "AND" and "OR." A search strategy combining MeSH terms and keywords that will be used in the 3 online databases is described in Multimedia Appendix 1. As a preliminary search, these keywords will be used on each database using the following search terms: ("heat wave" OR "extreme heat" OR "heat wave") AND ("hospitalization" OR "hospital admission") OR ("morbidity" OR "heat-related illness") OR "ambulance" OR "outpatient visit" OR "emergency department" OR "health services."

Figure 1. Schematic flow chart of the systematic review process. PRISMA: Preferred Reporting Items for Systematic reviews and Meta-Analyses.

Selection of Eligible Studies

To increase the feasibility of this review, studies that have been published during the past 20 years will be included. Subsequently, eligibility criteria will be developed using the PECO (population, exposure, comparison, and outcomes) analytical framework, as detailed in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria, developed using the PECO (population, exposure, comparison, and outcomes) analytical framework.

Inclusion criteria

- Population: The general population of low- or middle-income countries (LMICs) that are affected by heat waves and seek treatment in health care services, regardless of their age, gender, location, or ethnicity. The International Monetary Fund definition of LMICs will be used [64,65]; the list of included countries is provided in Multimedia Appendix 1.
- Exposure: All studies related to heat waves will be included, regardless of their definition of a heat wave.
- Comparison: The same population at a time they are not exposed to a heat wave event or a comparable population that are not exposed to a heat wave event.
- Outcomes: Health care services, including ambulance-call-outs, emergency department visits, outpatient department visits, hospitalization, and in-hospital mortality.

Exclusion criteria

- Population: Morbidity and mortality outside of health care services (ie, hospitals, outpatient clinics, and ambulance dispatches); populations in high-income countries
- Exposure: No definition of heat wave provided; studies on ambient temperature that do not examine heat waves; studies on cold temperatures

All observational studies on heat waves will be included. Intervention studies (eg, randomized controlled trials, single-arm studies), case reports, guidelines, book chapters, commentaries, reviews (eg, systematic reviews, scoping reviews), editorials, protocols, short communications, guidelines, surveillance studies, qualitative research, and non-English publications will be excluded. The full text of selected studies is required to be retrievable for further review. The epidemiological measures must be reported as relative risks, odds ratios, or incidence rate ratios with the 95% CI.

Study Selection Process

Before starting the screening process, a standardized questionnaire for study selection will be developed based on the predetermined eligibility criteria followed by a training session at each level of screening to ensure high interrater reliability (>75% agreement).

Eligible articles will be exported into EndNote X9 (Clarivate) for data management, which will include identifying and removing duplicates, by one reviewer. Subsequently, the data will be exported into Covidence (Level 10) for screening and data extraction. All attempts will be made to obtain the full text of selected articles, including web searching, engaging with the University Teknologi Mara librarian, or, if necessary, contacting the author.

After removing all duplicate articles, 2 reviewers will examine the eligibility of the articles in a 2-stage process. During the first screening, the list of titles and abstracts in the search results will be evaluated for relevancy. In the second screening, potentially relevant full-text papers will be reviewed according to the eligibility criteria. Articles that do not fulfill the criteria will be excluded from the study. Three reviewers will independently execute both stages of study selection, and cross-validation will be conducted for any potential disagreements. Cross-validation will be used to analyze inconsistencies in the list of included and excluded studies. In the event of a disagreement, a fourth reviewer will be assigned before considering the involvement of a fifth verifier. All disagreements will be resolved through discussion, and agreement will be assessed using the κ statistic, with a value of more than 0.8 considered good agreement.

The selection process will be conducted following the PRISMA-P (Preferred Reporting Items for Systematic reviews and Meta-Analyses protocol) checklist [66]. We expect that this systematic review will be completed in December 2023.

Data Items and Data Abstraction Process

Three independent reviewers will perform data abstraction to ensure high interrater reliability and minimize error. Prior to this process, a standardized data collection form will be pilot-tested by 3 independent reviewers. Any discrepancies identified will be resolved by a fourth and fifth reviewer.

Data items will include all relevant information on (1) study characteristics (author, publication year, study design, study location, study years); (2) exposure definition; (3) population characteristics (study population geographical area, vulnerability factors such as age, gender, medical conditions), (4) measures of exposure and outcome, (5) confounders, and (6) effect estimates and outcome characteristics (ambulance call-outs, emergency department visits, outpatient department visits, and in-hospital admissions).

Charting the Data

A data charting form will be used to capture all relevant information for each included study in the review. This process will be conducted by 2 independent reviewers. A thematic analysis approach will be used to identify the key concepts from the full-text articles and code them into non–mutually exclusive themes. All relevant articles will be coded manually in the spreadsheets and presented in the evidence table. The third reviewer will verify the charted data.

Critical Appraisal

Overview

The included papers will be assessed in accordance with the Navigation Guide, which provides criteria for evaluating the quality of systematic reviews of environmental health observational studies in order to minimize the risk of bias (RoB) and maximize transparency [67]. The assessment will be

XSL•FO
RenderX

conducted in three stages: (1) individual study RoB assessments, (2) assessment of the overall quality of the evidence across all included papers, and (3) rating of the overall strength of the evidence across studies. This process will be independently conducted by 2 reviewers and followed by discussion to reach agreement on ratings. Whenever there is disagreement, a third reviewer will be called in for further discussion on the appraisal.

RoB Assessment

The quality of the individual studies will be assessed using the Office of Health Assessment and Translation (OHAT) RoB assessment tool to examine internal validity and whether the study's design and execution jeopardized the validity of the association between exposure and outcome [68]. This tool was adapted from several guidelines, such as those of the Agency of Health Care Research and Quality [69], the Navigation Guide [70] and the Cochrane Handbook [71]. Since OHAT does not specifically consider time-series environmental health study design, 2 subject-matter experts will modify some of its domains according to our research questions. The RoB domains that will be used are selection, confounding, exposure assessment, outcome assessment, selective reporting, conflict of interest, and other possible bias. The overall rating will be categorized as "definitely low," "probably low," "probably high," or "definitely high."

Assessment of Overall Quality of Evidence Across All Included Papers

Based on the Navigation Guide, the certainty of evidence will be assessed using the Grading of Recommendation Assessment, Development and Evaluation (GRADE) system for each exposure outcome. The body of evidence will be initially graded as moderate based on priority criteria in human observational evidence [67] and then downgraded according to 5 domains (individual study limitations, inconsistency of results, indirectness of evidence, imprecision, and publication bias) and upgraded based on 3 domains (dose-response gradient, large magnitude of effect, and confounding). The final assessment will be as "high," "moderate," "low," or "very low" [72].

Rating of Overall Strength of Evidence Across Studies

The Navigation Guide further outlines four considerations when rating the overall strength of evidence across studies [67], which include (1) the quality of the body of evidence, (2) the direction of effect estimates, (3) confidence in the effect estimates, and (4) any other attributes that might affect certainty. The rating will be either "sufficient," "limited," "inadequate," or "evidence of lack of effect." The final rating will indicate the level of certainty of effect [70].

Ethical Approval

Formal ethical approval is not required as this study does not use primary data.

Results

We anticipate publishing the systematic review by May 2024. To enhance the transparency and clarity of the results and provide a comprehensive overview of the results obtained from each database during preliminary screening, we present our current results in Table 1, which includes a few examples.

Table 1. Characteristics of the studies during preliminary screening.

Title	Year	Journal name	Database	First screening	Second screening	Reason for exclusion
"Cause-specific risk of hospital admission related to extreme heat in older adults" [73]	2014	*JAMA*	SCOPUS	Included	Excluded	Conducted in high-income country
"Increased risk of emergency hospital admissions for children with renal diseases during heatwaves in Brisbane, Australia" [74]	2014	*World Journal of Pediatrics*	SCOPUS	Excluded	N/A[a]	Conducted in high-income country
"The effects of heatwaves on human morbidity in primary care settings: a case-crossover study" [75]	2022	*Scholarly Community Encyclopedia*	Web of Science	Excluded	N/A	Short communication
"The burden of extreme heat and heatwave on emergency ambulance dispatches: A time-series study in Huainan, China" [76]	2016	*Science of the Total Environment*	PubMed	Included	Included	N/A
"Burden of non-accidental mortality attributable to ambient temperatures: a time series study in a high plateau area of southwest China" [77]	2019	*BMJ Open*	PubMed	Included	Excluded	Mortality outside health care services

[a]N/A: not applicable.

Descriptive Analysis

A narrative report will be produced to summarize the extracted data related to the research questions in the final review. The results will be presented in the final evidence tables; Figures 2, 3, and 4 represent samples of these tables, which include the following information: (1) the study characteristics, including author, publication year, study design, study location, the years the study covers, and the definition of a heat wave; (2) population characteristics and vulnerability (ie, risk factors), including age, gender, race, location (urban vs rural); (3) type

XSL•FO
RenderX

of disease according to body system, such as cardiovascular disease, respiratory disease, and renal disease, which will be presented in the effect estimates sections of the tables in Figures 3 and 4; and (4) the burden on health care services, including ambulance call-outs, emergency department visits, outpatient department visits, hospital admissions, in-hospital mortality, and health care operational costs.

Figure 2. Sample table for characteristics of articles selected for the study.

Author (ref)	Location (country)	Study design and period	Target population	Heatwave definition and matrices	Statistical analysis	Adjustment for confounding factors	Health care service outcome

Figure 3. Sample table for impact on hospital admissions.

Reference (location)	Heat wave definition and matrices	Effect estimates	Vulnerable groups	Summary

Figure 4. Sample table for impact of heat waves on other health care services.

Impacts and reference (location)	Heat wave definition and matrices	Effect estimates	Vulnerable groups	Summary
Emergency ambulance call-outs				
Emergency department visits				
Outpatient department visits				
In-hospital mortality				
Health care expenditures				

Statistical Analysis

This study will not conduct a meta-analysis of the results due to the heterogeneity of outcome measures. Hence, only descriptive thematic analysis will be performed. Nevertheless, the RoB assessment will be performed using SPSS (version 27; IBM Corp) for categorical outcomes, which will be presented as frequencies and percentages.

XSL•FO
RenderX

Discussion

Principal Findings

It is anticipated that the strain on health care systems will increase significantly if heat wave events rise in frequency, length, and severity. This review's findings are expected to demonstrate that heat waves significantly increase ambulance call-outs, emergency department visits, hospitalization, outpatient department visits, and in-hospital mortality, as well as health care operational costs. Previously, Campbell et al [78] found that ambulance call-outs increased by 34% during extreme heat waves, 10% during severe heat waves, and 4% during low-intensity heat waves. Davis and Novicoff [79] found significantly increased risk for emergency department visits and hospitalization for White and Black people, as well as men and women aged 20 to 49 years, with a variety of presentations, including diabetes, pregnancy complications, poisoning, and traffic crashes, [80] in addition to common presentations such as renal disorder [81,82], cardiovascular disease, respiratory disease [83,84], mental disease [85], and heat-related illness [86].

To our knowledge, this study will be the first to review the impacts of heat waves on health care systems in LMICs and thus fill a knowledge gap. Since the impact of heat waves is more pronounced in LMICs due to their inadequate infrastructure, low access to health care [52], and dense populations of vulnerable people [87], it will be beneficial if LMICs can identify temperature thresholds and vulnerable groups in their region so that targeted interventions can be implemented effectively. Moreover, morbidity indicators such as ambulance call-outs, hospital admissions, and emergency department visits should be used during heat wave impact assessments and the development of early warning systems. Wang et al [88] recommended examining ambulance dispatch data to develop a real-time surveillance heat health warning system that would allow early detection of residents' health demands and health status in a region. Toloo et al [89] demonstrated that the implementation of an early warning system can be cost-effective and reduce mortality and ambulance call-outs. Indeed, many HICs have developed and implemented heat health action plans [90,91]. However, Ahmedabad, India, has become the first South Asian city to develop and implement an early warning system and heat preparedness plan based on collected evidence, such as an analysis of local temperature and mortality data and surveys of the population vulnerable to heat. Nevertheless, evaluation and continuous improvement are still ongoing [92].

The findings of this review also could assist public health and health care systems in allocating resources effectively, such as by allocating more GDP to health care, improving existing infrastructure [26], increasing human resources, and promoting health. Apart from this, health care workers must be provided with adequate training and updates on the latest information or guidelines related to heat waves [16]. Enhanced diagnostic accuracy and speed, followed by immediate treatment, is vital for hospitals and other community medical institutions in order to reduce morbidity and mortality [26]. Lastly, understanding the impact of heat waves on health care services underscores the need for climate change mitigation and adaptation, such as increasing the resilience of health care systems and being responsive to the effects of heat waves [93,94].

Among the limitations that we expect in this review are the inability to access full texts and some of the articles not being in English. This could limit the overall findings of the review. Secondly, during our search, we found numerous articles that examined the impact of ambient temperature on health care services but few that examined the impact of heat waves. In fact, some of the articles did not provide a definition of a heat wave. This might be due to underrepresentation of some LMICs [95], which will further limit the findings of the review. However, we believe that this finding could encourage these countries to participate and conduct more research on this topic, as well as highlight to HICs that funding to these countries is necessary for them to conduct more research.

Conclusion

Undeniably, heat waves pose a significant health risk to individuals and the community. Therefore, understanding the burden on health care services due to exposure to heat waves is of paramount importance as heat waves are becoming more frequent and increasing in intensity. This proposed systematic review is expected to provide a better understanding of the impact of heat waves on health care systems in LMICs; this will be critical for optimal planning, preventive activities, policymaking, and climate action. By prioritizing this understanding and disseminating this information to policymakers and relevant stakeholders, we can better protect individuals' and communities' health and well-being, as well as construct a more resilient health care system in the face of climate change.

Abstract

Background: Feeding intolerance (FI), frequently resulting from gastrointestinal immaturity, is prevalent among premature infants. Current practices are gradually prioritizing nonpharmacological treatments, such as massage or "Tui na," considering the potential side effects of prolonged medication use. Pediatric Tui na, a specialized massage therapy based on traditional Chinese medicine, has been widely studied for treating FI in premature infants. However, to our knowledge, no systematic review specifically focusing on the effectiveness and safety of traditional Chinese medicine–based pediatric Tui na for FI in premature infants has been published yet.

Objective: This study aims to develop a protocol for a systematic review and meta-analysis for evaluating the safety and efficacy of pediatric Tui na for premature infants with FI.

Methods: We will perform a comprehensive search in the following databases: Springer, Cochrane Library, Embase, MEDLINE, Clarivate Analytics, Physiotherapy Evidence Database (PEDro), CINAHL, PubMed, Scopus, World Health Organization (WHO) International Clinical Trials Registry Platform, and Chinese biomedical databases (Wanfang database, the China National Knowledge Infrastructure, Chinese Scientific Journals Database, and Chinese Biomedical Literature Databases), limited to studies published in Chinese and English languages between January 2000 and January 2023. The search strategy will use MeSH (Medical Subject Headings) terms and database-specific keywords. A total of 2 independent reviewers will initially screen the studies based on titles and abstracts, followed by a full-text evaluation of the eligible studies. Studies will include any nonrandomized controlled trials, nonrandomized clinical studies, randomized controlled trials, and quasi-experimental studies wherein the treatment group involves premature infants with FI given pediatric Tui na. Primary outcomes will be necrotizing enterocolitis, gastric residual volume, emesis, and stool blood. Secondary outcomes will be abdominal distension weight gain, time to achieve full enteral feeding, any adverse effects associated with pediatric Tui na, and length of hospital stay. The Cochrane Collaboration Risk of Bias Tool will be used to assess the risk of bias and methodological quality. Funnel plots will be used for evaluating publication bias. Meta-analysis will be conducted using the Review Manager software (version 5.4; Cochrane Collaboration). Subgroup analyses will be considered according to treatment received, country or setting, sex, and birth weight of premature infants (if heterogeneity is high, $I^2 \geq 50\%$).

Results: This is a systematic review and meta-analysis protocol, so the results are not yet available. The protocol has been registered with PROSPERO (CRD42023390021). We are currently in the study selection phase. Results are expected to be completed by the end of 2023.

XSL•FO
RenderX

Conclusions: Following this protocol, a comprehensive and rigorous literature synthesis will be developed to assess the impact of pediatric Tui na treatment on premature infants with FI, enabling the determination of its efficacy and safety.

Introduction

Feeding intolerance (FI) is usually a consequence of gastrointestinal immaturity and commonly occurs in premature infants [1]. It typically presents as increased gastric residual volume (GRV), abdominal distention, vomiting, stool blood, and emesis [2], affecting 33.8%-53.45% of premature infants in China [3]. Furthermore, there is an association between high GRV and increased morbidity of necrotizing enterocolitis (NEC) [4,5]. These gastrointestinal immaturity–associated intestinal system problems can affect the nutritional intake and gut morbidity of premature infants, leading to several complications such as prolonged hospitalization and weight loss, and even increased mortality [6,7], thus placing a heavy burden on health care services.

There is no ideal or effective treatment available for FI as its pathobiology remains to be fully understood and identified [8-10]. Previous guidelines and studies have primarily focused on pharmacotherapies for managing FI [11]. However, long-term use of medications such as erythromycin, probiotics, metoclopramide, and cisapride has been reported to be associated with many adverse effects (AEs), including neurological disorders and cardiovascular dysfunction [12-16], leading to a greater expenditure of time and money and posing a significant burden on patients [10]. Consequently, current guidelines and practices increasingly focus on nonpharmacological treatments such as massage or Tui na [4,17]. Pediatric Tui na, based on the principles of the meridian theory [18] of traditional Chinese medicine (TCM) [19], is widely used as a complementary and alternative medicine in East Asia [20-23]. It treats a range of pediatric diseases by applying various manipulations on the body surface, including pressing, kneading, circling, nipping, and pushing [24,25]. Studies have indicated that Tui na and other similar touch therapies can regulate hormones such as cortisol and dopamine and accelerate blood and lymphatic circulation, thereby improving the function of the gastrointestinal system [3,21,22,26-29]. Many studies [24,25,29-32], especially those conducted in China, have explored pediatric Tui na as a treatment for FI in premature infants. However, the results of these studies are inconsistent. For instance, several investigations [24,25,30] have indicated that pediatric Tui na provides significant benefits to premature infants with FI, including improved weight gain; reduced time to achieve full enteral feeding; reduction in GRV, emesis, and abdominal distention; and a notable reduction in the average length of hospital stay. However, Liu and Zhang [31] did not find any significant difference between the control group and the pediatric Tui na group in terms of weight gain or the time required to return to birth weight (P>.05). Additionally, a meta-analysis [33] suggested that massage benefits premature infants with FI. However, this analysis was limited to studies published in Persian and English. Furthermore, it primarily evaluated the effects of massage on GRV and did not specifically address the efficacy and safety of pediatric Tui na regarding intestinal function and other FI-associated factors in premature infants. Therefore, despite the research mentioned above, to our knowledge, no studies have specifically addressed the safety and efficacy of pediatric Tui na in premature infants with FI, highlighting a gap in understanding its role as a nonpharmacological treatment for these infants. Moreover, no published systematic review, meta-analysis, or review protocol focusing on TCM-based pediatric Tui na for premature infants with FI is yet available.

Considering the high heterogeneity of previous studies and their varying outcomes, as well as the absence of any comprehensive evidence on this subject, it is crucial to assess the effectiveness and safety of pediatric Tui na for premature infants with FI. We intend to conduct a systematic review and meta-analysis to enhance the current evidence base on the effectiveness of pediatric Tui na for FI in premature infants. To ensure the most comprehensive data collection, minimize publication bias, and summarize the currently available evidence, we will conduct electronic searches for studies published both in English and Chinese.

Methods

Overview

The protocol for this review has been registered with the National Institute for Health Research (PROSPERO 2023 CRD42023390021) [34]. This protocol will be reported and conducted according to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Extension for Protocols) 2015 guidelines [35] and the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analysis) guidelines [36].

Study Selection Criteria

The eligibility criteria of studies will be presented in the PICOS (Patient, Intervention, Comparison, Outcome, and Study) design framework [37,38].

Types of Studies

The following types of studies will be included: (1) any nonrandomized clinical studies, nonrandomized controlled trials,

XSL•FO
RenderX

randomized controlled trials, and quasi-experimental studies, wherein the treatment group involved premature infants with FI who received pediatric Tui na; (2) interventional studies, retrospective or prospective observational studies, or case series; and (3) studies that reported and included data associated with specific primary (NEC, GRV, emesis, abdominal distension, and stool) and secondary outcomes (weight gain, time to achieve full enteral feeding, length of hospital stay, and any AEs associated with pediatric Tui na). Single-case reports will not be included.

Participants

On the basis of any definition of FI, we included studies in which premature infants received pediatric Tui na to prevent or treat FI. We will identify prematurely born infants as per the definition of the World Health Organization (WHO); this includes infants born within 259 days from the first date of the mother's last menstrual period or before 37 full weeks of gestation [39].

Intervention

We will include all trials evaluating pediatric Tui na intervention for FI.

Comparison

We will include studies with different control interventions, such as placebo and other currently used interventions (eg, physiotherapy, acupuncture, gentle touch, and medication), and those without any control group.

Outcomes

Emesis, NEC, GRV, and stool blood will be included as primary outcomes. Any AEs associated with pediatric Tui na, abdominal distension, time to achieve full enteral feeding, length of hospital stay, and weight gain will be included as secondary outcomes.

Search Strategy

A comprehensive search will be performed in the following databases: Springer, Cochrane Library, Embase, MEDLINE, Clarivate Analytics, Physiotherapy Evidence Database (PEDro), CINAHL, PubMed, Scopus, WHO International Clinical Trials Registry Platform, and Chinese biomedical databases (Wanfang database, the China National Knowledge Infrastructure, Chinese Scientific Journals Database, and Chinese Biomedical Literature Databases), limited to studies published in Chinese and English languages between January 2000 and January 2023. The database searches will include only studies published in peer-reviewed journals and reporting results within their full text. Experts will be consulted for including additional studies. With inputs from the principal investigator of the study, an experienced librarian at Nanjing University of Chinese Medicine will design and carry out a comprehensive literature search. For searching publications on the safety and effect of pediatric Tui na on premature infants with FI, we will use controlled vocabulary and keywords. Table 1 shows the search strategy for the PubMed database.

Study Selection

The retrieved literature will be imported into Endnote X9 (Clarivate Analytics); duplicate literature will be removed. A total of 2 authors will independently screen the titles and abstracts. Studies not meeting the inclusion criteria will be excluded. To seek full-text copies of studies or clarification of methods or results, study authors will be contacted through email if required. The latest or most comprehensive literature information will be extracted if multiple articles report the findings of the same study. Figure 1 shows the flow diagram for study selection.

XSL•FO
RenderX

Figure 1. Flow diagram for study selection.

Methodological Quality and Risk of Bias Appraisal

A total of 2 researchers will evaluate the quality of the literature using the quality evaluation method of the Cochrane Collaboration System evaluator manual on the following 6 aspects [40]: concealment of the allocation scheme, generation of a random allocation scheme, complete data results, selective reporting results, blinding method, and other risks of bias.

Data Extraction

A total of 2 independent reviewers will extract information using a predesigned form after identifying the studies to be included. The form will include data on the following aspects:

1. Identification information (first author, publication year, study design, country, and setting)
2. General information (study type, country, sample size, number of centers, and study design)
3. Participants (weight, sex, and age of premature infants)

XSL•FO
RenderX

4. Interventions (pediatric Tui na, type of pediatric Tui na, pediatric Tui na technique, pediatric Tui na position selection, and frequency and duration of sessions)
5. Comparator (if available, treatment details, including dosage, name, course, and frequency)
6. Outcomes (safety, efficacy data, and time points for each measurement)

If any information is missing or there is a need to seek further clarification, we will attempt to contact the corresponding authors.

Assessment of Reporting Bias

We will use funnel plots to detect publication bias in the overall estimate and Egger and Begg tests to examine the funnel plot asymmetry. Symmetry and asymmetry in the funnel plot indicate low and high risks of reporting bias, respectively.

Data Synthesis

Meta-analyses or descriptive analyses will be performed as per the measurement results, heterogeneity levels, and intervention measures. Conversely, we will report quantitative research results descriptively. Continuous variables will be analyzed according to mean differences and 95% CIs. Dichotomous variables will be assessed using risk ratios. Standardized mean differences and 95% CIs will be calculated if the outcome measure scales differ. Heterogeneity assessments will be performed within each pairwise comparison by the Cochran *Q* test and the I^2 statistic. Negative I^2 values will be treated as 0%, indicating no heterogeneity. I^2<50% indicates low heterogeneity, while I^2≥50% indicates high heterogeneity [41]. For sensitivity analysis, the results will be compared with those of other meta-analysis models, which would exclude trials with a high risk of bias and include fixed-effects models. We will perform a meta-analysis using a random-effects model if at least two included trials are found to be sufficiently homogeneous for the aspects of the comparator, outcome measurement, and study design. For performing the meta-analysis, the Cochrane Collaboration's software Review Manager (version 5.4) will be used. Subgroup analyses will be considered according to the treatment received, country or setting, sex, and birth weight of premature infants (if heterogeneity is high, I^2≥50%).

Dissemination

This meta-analysis and systematic review will be submitted to a peer-reviewed journal. The findings are expected to shed some light on the efficacy and safety of pediatric Tui na for premature infants with FI.

Results

This is a systematic review and meta-analysis protocol, so the results are not yet available. This protocol has been registered with PROSPERO (CRD42023390021) on February 8, 2023 [34]. We are currently in the study selection phase. Results are expected to be completed by the end of 2023.

Discussion

This study aims to conduct a systematic review and meta-analysis of relevant research articles to comprehensively summarize the current evidence regarding the efficacy of pediatric Tui na for premature infants with FI. Pediatric Tui na, originated in China over 2300 years ago, was first recorded in *Wushierbingfang* (*Prescriptions for Fifty-two Diseases*) [42]. It is a commonly used, convenient, noninvasive, and cost-effective intervention therapy suitable for children [43]. Xie et al [44] reported that working on specific acupoints of the skin surface in pediatric Tui na can improve the gastrointestinal function of children. Xiao et al [24] and Chen [29] have reported that pediatric Tui na can accelerate gastrointestinal tract maturity, promote intestinal evacuation, and increase gastrointestinal motility in premature infants, thus alleviating FI. Although many clinical trials [24,25,30-32] have evaluated pediatric Tui na for treating FI in children, its efficacy and clinical evidence have not yet been established. The current clinical guidelines in China recommend massage therapy for treating FI in premature infants [17]. Despite being a TCM-based approach, pediatric Tui na is currently not included in the guidelines for treating FI in premature infants. This omission has prevented it from being widely and successfully adapted as a potential treatment for FI in premature infants. This study will be the first to evaluate the effect and safety of TCM-based pediatric Tui na for FI in premature infants by objectively synthesizing the currently available publications.

Some limitations should be considered in this systematic review. First, it will consider only studies published in Chinese and English, which could introduce potential language bias, resource constraints, difficulty locating non-English studies, and the possibility of bias in data extraction and analysis. Second, the specific focus of our research question might restrict the number of eligible studies for inclusion in the proposed review. Nonetheless, our objective is to extract valuable insights from the available evidence to offer preliminary guidance for current FI practices and future research. To stay updated with new evidence, we plan to conduct updates to the systematic review and meta-analysis every 3 years.

This protocol intends to aggregate current research, provide greater insights into the efficacy and safety of pediatric Tui na for FI, and offer a comprehensive assessment of the evidence for pediatric Tui na treatment of FI in premature infants for health care providers worldwide. Additionally, it will lay the groundwork for future research in pediatric Tui na and serve as a reference for the potential inclusion of pediatric Tui na in the treatment guidelines for premature infants with FI.

Acknowledgments

This study was supported and funded by the Youth Program of the National Natural Science Foundation of Nanjing University of Chinese Medicine (NZY81704138). We would like to extend our sincere gratitude to Yufeng Zhang, Youxin Sui, and Kaiyue Han for their invaluable contributions during the writing of this paper. Their expertise and insights greatly enhanced our work.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

ZB and MW wrote the original draft of the manuscript. YT and XL curated the data. ZB and XL analyzed the data. YT reviewed and edited the manuscript. MW contributed to project administration and supervision.

Conflicts of Interest

None declared.

Abstract

Background: Applications of artificial intelligence (AI) are pervasive in modern biomedical science. In fact, research results suggesting algorithms and AI models for different target diseases and conditions are continuously increasing. While this situation undoubtedly improves the outcome of AI models, health care providers are increasingly unsure which AI model to use due to multiple alternatives for a specific target and the "black box" nature of AI. Moreover, the fact that studies rarely use guidelines in developing and reporting AI models poses additional challenges in trusting and adapting models for practical implementation.

Objective: This review protocol describes the planned steps and methods for a review of the synthesized evidence regarding the quality of available guidelines and frameworks to facilitate AI applications in medicine.

Methods: We will commence a systematic literature search using medical subject headings terms for medicine, guidelines, and machine learning (ML). All available guidelines, standard frameworks, best practices, checklists, and recommendations will be included, irrespective of the study design. The search will be conducted on web-based repositories such as PubMed, Web of Science, and the EQUATOR (Enhancing the Quality and Transparency of Health Research) network. After removing duplicate results, a preliminary scan for titles will be done by 2 reviewers. After the first scan, the reviewers will rescan the selected literature for abstract review, and any incongruities about whether to include the article for full-text review or not will be resolved by the third and fourth reviewer based on the predefined criteria. A Google Scholar (Google LLC) search will also be performed to identify gray literature. The quality of identified guidelines will be evaluated using the Appraisal of Guidelines, Research, and Evaluation (AGREE II) tool. A descriptive summary and narrative synthesis will be carried out, and the details of critical appraisal and subgroup synthesis findings will be presented.

Results: The results will be reported using the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analyses) reporting guidelines. Data analysis is currently underway, and we anticipate finalizing the review by November 2023.

Conclusions: Guidelines and recommended frameworks for developing, reporting, and implementing AI studies have been developed by different experts to facilitate the reliable assessment of validity and consistent interpretation of ML models for medical applications. We postulate that a guideline supports the assessment of an ML model only if the quality and reliability of the guideline are high. Assessing the quality and aspects of available guidelines, recommendations, checklists, and frameworks—as will be done in the proposed review—will provide comprehensive insights into current gaps and help to formulate future research directions.

Introduction

Rationale

Artificial intelligence (AI) has become a hot topic in biomedical and clinical routines in the past decade [1,2]. In fact, an increasing number of scientific publications suggest algorithms and AI models for target diseases and conditions [3]. The application of AI in health care ranges from medical image analysis to text mining, targeting prognosis, diagnosis, event and outcome prediction, and treatment [1]. The number of scientific contributions in peer-reviewed journals focusing on AI applications in medicine is also highly increasing [4,5].

The comparison of algorithm performance for a target condition has become a common way of presenting and evaluating machine learning (ML) models. The diversity of ML models leads to competition and fast progress. However, the current situation leaves health care providers unsure about which ML model to use given multiple alternative models for a specific target [6] and the "black box" nature of ML [7]. Moreover, the fact that studies do not use guidelines consistently in developing and reporting AI models poses another challenge in trusting and adapting models for practical implementation [8-10].

In fact, guidelines and recommended frameworks for developing and reporting AI studies have been published by different experts and work groups to facilitate reliable assessment of model validity and consistent interpretation [11-14]. In addition, the authors have proposed recommendations for the evaluation of AI studies [15-18]. This review protocol describes the planned steps and methods of a future review that aims to synthesize evidence regarding the quality of available guidelines and frameworks developed to facilitate AI applications in medicine and summarize their content.

Objective

The systematic review will address the following scientific questions:

- What are the available guidelines and frameworks with regard to predictive AI model development and reporting in medicine?
- What are the main aspects (target or purpose) of the available guidelines and frameworks?
- What is the quality of the available guidelines with respect to the Appraisal of Guidelines, Research and Evaluation (AGREE II) domains?
- What are the reported implementation challenges in the available guidelines?

Methods

Eligibility Criteria

All guidelines, standard frameworks, best practices, checklists, and recommendations will be included, irrespective of the study design. Studies will be limited to English and to the time period between database inception and June 2023 (the time of data collection).

Search Strategy and Information Sources

This protocol adheres to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 [19]. A systematic literature search will be commenced using Medical Subject Headings (MeSH) terms and keywords for medicine, guidelines, and ML (Table S1 in Multimedia Appendix 1). The initial search will be conducted on 3 web-based repositories: PubMed, Web of Science, and EQUATOR (Enhancing the Quality and Transparency of Health Research). The EQUATOR network is a global initiative working toward improving the value of research by promoting robust reporting guidelines [20]. A Google Scholar search will also be performed to identify gray literature. References in selected literature will be scanned, and relevant papers will be included after discussion among the reviewers.

After the comprehensive search, all bibliographic information will be uploaded to a web-based systematic review tool (Rayyan) and afterward processed with CADIMA [21] for further screening and preliminary analysis.

Study Selection

After removing duplicate results, a preliminary scan for titles will be done by 2 reviewers. After the initial scan, the reviewers will rescan the selected literature for abstract review, and any incongruities about whether to include the article for full-text review will be resolved by the third reviewer based on the predefined criteria.

Data Extraction, Collection, and Management

Once the selection process has been finalized, relevant information from the selected literature will be extracted by the 2 reviewers independently using a predefined information extraction sheet. At this stage, discrepancies will be resolved by the third and fourth reviewers.

The information extraction sheet will be designed to collect relevant information such as study characteristics (authors, year of publication, study type, aspect, specific disease or condition focused, and standard followed) from selected literature for further synthesis. "Study type" in this context refers to whether the study is a guideline, a framework, a suggestion, a checklist, a best practice, or a recommendation. The term "aspect" entails the purpose for which the guideline or the framework is primarily designed. Guidelines or frameworks could be designed for different purposes. For instance, if a guideline is developed to elaborate on or declare how ML studies should report their findings, the aspect or purpose will be a "reporting aspect." If, however, the guideline emphasizes the ethical dimension of ML in medicine, the aspect will be referred to as "ethical aspect." A study can have multiple aspects (sometimes a guideline or a framework could be about both the development and reporting procedures and sometimes only the reporting or the development procedure), and it will also be extracted under the "aspect" category. The column "specific disease or condition focused" refers to whether the guideline or framework is subject to or validated for a specific disease or condition. Sometimes, researchers suggest customized and focused guidelines for a specific condition. Based on the predefined data extraction Excel (Microsoft Corp) sheet, 2 reviewers will extract the data

XSL•FO
RenderX

independently, and any sort of discrepancy will be discussed with the 3rd and 4th reviewers after every 10 extractions. The data extraction template is presented in Table 1.

Table 1. Data extraction template.

Sections	Description
Section 1: study characteristics	
First author's name	For example, John Smith
Year of publication	For example, YYYY
Title	The title of the study
Journal	The name of the journal. For example, scientific reports
Country of first author	For example, United States of America
Section 2: research questions	
Type of outcome	Provide a description about the study whether it is a guideline, standard framework, recommendation, checklist, best practice, or expert opinion.
Aspect	Provide the primary purpose for which the guideline or the framework is designed. For example, reporting, development, ethics, and governance.
Standard followed	Provide a description of the standard followed during the development of the proposed guideline or framework. For example, the EQUATOR[a] network.
Guidelines and frameworks with regard to predictive artificial intelligence model development and reporting in medicine	Provide a description of the content and domain of the guideline or framework.
The quality of the available guidelines	Provide a quantified quality assessment of the identified guidelines based on AGREE II[b] assessment.
Reported gaps in the available guidelines	Describe the reported gaps and implementation challenges.
Specific target domain	Provide information if the guideline or framework is designed for a specific disease domain.

[a]EQUATOR: Enhancing the Quality and Transparency of Health Research.
[b]AGREE II: Appraisal of Guidelines, Research, and Evaluation.

Quality and Risk of Bias Assessment

The quality of identified guidelines will be evaluated using the AGREE II tool [22]. AGREE II assesses the quality of guidelines in terms of the methodological rigorousness and transparency of the guideline development process [22]. It consists of 23 key items organized within 6 domains (scope and purpose, stakeholder involvement, rigor of development, clarity of presentation, applicability, and editorial independence) and 2 global rating items for overall assessment. As recommended by the AGREE II user manual, 4 appraisers will individually appraise the selected guidelines and frameworks, and the percentage of quality will be calculated based on the ratings of each quality domain [22]. Other frameworks and best practices proposed by researchers will be systematically summarized.

Analysis

A descriptive summary and narrative synthesis will be carried out, and the details of critical appraisal and subgroup synthesis findings will be presented. This systematic review will present the list of available guidelines, frameworks, suggestions, checklists, best practices, or recommendations for developing and reporting AI studies in medicine and assess the quality of the guidelines and discuss the aspects.

Results

We anticipate finishing the systematic literature review by November 2023. The expected result from this review will explore and highlight the quality of the available guidelines and point out the existing gaps. Furthermore, the synthesis from the checklists and recommendations will provide a comprehensive set of standardized tools.

Discussion

Guidelines are important sets of instructions that facilitate transparent and reproducible scientific processes [23]. The potential benefits of guidelines are, however, only as good as the quality of the guidelines themselves. This protocol describes the setup of a systematic review to identify available guidelines, frameworks, best practices, and recommendations for developing and reporting AI studies in medicine. The review will assess the quality of guidelines, summarize the gap in guidelines, and identify critical considerations in the application of AI in medicine. As the search is limited to English due to resource limitations, there might be language bias, indicating that some important studies conducted in different languages might be missed. Thus, conclusions should be drawn carefully.

Abstract

Background: Gestational weight gain (GWG) exceeding the recommendations of the Institute of Medicine (in the United States) is associated with numerous adverse maternal and infant health outcomes. While many behavioral interventions targeting nutrition and physical activity have been developed to promote GWG within the Institute of Medicine guidelines, engagement and results are variable. Technology-mediated interventions can potentially increase the feasibility, acceptability, and reach of interventions, particularly for pregnant women, for whom integration of interventions into daily life may be critical to retention and adherence. Previous reviews highlight GWG self-monitoring as a common intervention component, and emerging work has begun to integrate digital self-monitoring into technology-mediated interventions. With rapid advances in technology-mediated interventions, a focused synthesis of literature examining the role of digital self-monitoring tools in managing GWG is warranted to guide clinical practice and inform future studies.

Objective: The proposed review aims to synthesize the emerging research base evaluating digital GWG self-monitoring interventions, primarily focusing on whether the intervention is effective in managing GWG. Depending on the characteristics of the included research, secondary focus areas will comprise intervention recruitment and retention, feasibility, acceptability, and differences between stand-alone and multicomponent interventions.

Methods: This protocol was developed following the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines for systematic review protocols. The proposed review would use a planned and systematic approach to identify, evaluate, and synthesize relevant and recent empirical quantitative studies (reported in English) examining the use of digital weight self-monitoring tools in the context of technology-mediated interventions to manage GWG in pregnant US adults, with at least 2 instances of data collection. Literature eligible for inclusion will have a publication date between January 2010 and July 2020. The Effective Public Health Practice Project Quality Assessment Tool for Quantitative Studies will be used to assess the methodological quality of included studies across various domains, and results will be synthesized and summarized per the synthesis without meta-analysis guidelines.

Results: The initial queries of 1150 records have been executed and papers have been screened for inclusion. Data extractions are expected to be finished by December 2023. Results are expected in 2024. The systematic review that will be generated from this protocol will offer evidence for the use of digital self-monitoring tools in the management of GWG.

Conclusions: The planned, focused synthesis of relevant literature has the potential to inform the use of digital weight self-monitoring tools in the context of future technology-mediated interventions to manage GWG. In addition, the planned review has the potential to contribute as part of a broader movement in research toward empirically supporting the inclusion of specific components within more extensive, multicomponent interventions to balance parsimony and effectiveness.

Introduction

Background

Gestational weight gain (GWG) is currently assessed by comparison to recommendations provided by the Institute of Medicine (IOM) [1]. These guidelines are based on prepregnancy BMI, such that GWG falling below the recommended range is considered "inadequate," and GWG above the recommended range is considered "excessive." Excessive gestational weight gain has demonstrable associations with adverse maternal and infant health outcomes, such as pregnancy complications (eg, hypertension and preeclampsia) [2-4], postpartum weight retention with implications for long-term maternal obesity [5], large-for-gestational-age [2,3,6], macrosomia [6], cesarean delivery [2,3,6], elevated child BMI [5,7,8], among others.

Recent systematic reviews have primarily supported health behavior change (eg, diet or physical activity) to reduce the prevalence of excessive GWG [9-13]. However, these multiple review papers have described concerns about the generalizability of findings due to the inclusion of studies characterized by small sample sizes, low participant recruitment and retention, lack of diversity, or a lack of information about these areas [10,11,14-17]. Moreover, the prevalence of excessive gestational weight gain remains high, with nearly half (48%) of pregnant women in the United States reporting weight gain above the recommended ranges across categorizations of prepregnancy BMI [18-20]. A recent meta-analysis of GWG-focused interventions during pregnancy [21] reflected a notably nonrepresentative sample (over 80% White women). Homogenous samples such as these call for researchers to assess how specific interventions have addressed acceptability, feasibility, and effectiveness for certain subpopulations. Notable efforts to recruit and test different lifestyle intervention strategies to modify GWG in diverse populations have been successful through a consortium model [22].

As new technologies emerge, technology-mediated interventions have been proposed as a potential solution for expanding the reach and scope of behavioral and interpersonal (eg, provider-directed) interventions [12,23-25]. Internet websites, text messaging, and smartphone apps have been identified as accessible resources for a diverse population of racial or ethnic and socioeconomic groups [24,26], and other potential methods may include activity and lifestyle tracking technologies such as wearable devices or scales with Bluetooth or other wireless capabilities. For example, a technology-based intervention that incorporated skills training, prompts, personalized feedback, counseling, and peer support via text messaging, health coaching phone calls, and Facebook group involvement was noted to be a significant improvement over usual care concerning managing weight during pregnancy for urban mothers with low-income [27,28]. Such findings underscore the importance of health education and awareness around GWG outcomes for low-income women [29] and the need for complex intervention development that is adequately informed by and responsive to the risks and needs of the target population [30].

Recent reviews have specifically examined the impact of technology-supported lifestyle interventions on GWG and postpartum weight retention [31-34]. Lau et al [31] determined e-based lifestyle interventions to be acceptable among pregnant populations, calling for future work to optimize intervention components. Mertens et al [32] focused mainly on randomized controlled trials (RCTs) using telecoaching or feedback (eg, via SMS or app) that was responsive to participants' self-monitoring, with some evidence of optimization for GWG. In their review of exclusively digital health interventions (for managing GWG, improving diet, or increasing physical activity), Rhodes et al [33] highlighted that while self-monitoring components were not universally included among the effective interventions, 7 out of 11 interventions did use some self-monitoring component, revealing a potential avenue for a more nuanced understanding of the impact of specific mobile health (mHealth) approaches in managing GWG. The results indicate that in the context of marked heterogeneity in outcomes studied, digital interventions did not demonstrate evidence of effectiveness for managing GWG, highlighting that different types (ie, subareas) of digital approaches may show differing levels of effectiveness [33]. Furthermore, findings of a meta-analysis determined e-Health technology exposure was associated with a nonsignificant effect on weight management during pregnancy but in postpartum, there was a statistically significant weight reduction [34].

Technological or digital interventions may provide feasible solutions for adapting to unique life circumstances and needs [35]. However, a more focused assessment of the degree to which specific technological approaches are feasible, acceptable, and effective are essential prerequisites [36]. Despite the generally broad availability and accessibility of mobile phone technology among women in the United States [37], there are significant considerations for addressing participation barriers associated with technology, such as rural versus nonrural users, inconsistent data plans, and device sharing [38,39]. Consequently, specific characteristics and components of interventions (eg, social media versus smartphone apps or responsive wearable devices) may dictate accessibility and constrain the reach of digital approaches [40,41].

Given the high overall rate of mobile phone ownership and use and qualitative data suggesting that pregnant women desire personalized mobile tools for healthy lifestyle behaviors in pregnancy [42], mHealth interventions represent a unique

XSL•FO
RenderX

subclass of interventions distinct from other technology-based interventions [43]. Consistent with this sentiment, the World Health Organization, in their guideline on digital interventions to strengthen health systems, specifically addressed "targeted client communication for behavior change" as a context-aware recommendation for the use and development of mHealth technologies (eg, text messaging, interactive content such as apps, games, and social media, wireless devices) [44]. Pregnancy-related smartphone apps are the largest category of medically related apps, and smartphone apps with interactive capability are the most popular and well-liked [45]. While many smartphone apps advertise themselves as focused on GWG self-monitoring, a recent review highlighted that only a small percentage provided all of the key features of GWG monitoring (ie, tracking tools and guidelines or recommendations) [46].

A systematic review examining weight self-monitoring in nonpregnant populations seeking weight loss or management noted that the use of weight self-monitoring differs considerably between studies concerning aspects such as frequency, tools used, instructions provided, and role of weight self-monitoring (ie, as the only intervention versus as one part of a multicomponent intervention) [47]. Overall, across studies, participants perceived weight monitoring positively and feasibly. However, Zheng et al [47] highlighted the variability and inaccuracies that may present with self-report assessments of weighing behavior and weight and joined a broader call for more objective assessment methods. Moreover, the use of "smart" (ie, cellular-connected) scales tied to personalized feedback has been associated with weight loss, adherence to weight self-monitoring, and decreases in caloric consumption in comparison to a waitlist control group [48]. Thus, digital health approaches to weight self-monitoring have the potential to address the need for objectivity and improve adherence while maintaining the feasibility associated with self-monitoring.

Notably, the goals of pregnant individuals engaged in a GWG management program may differ considerably to those seeking weight loss or management outside of pregnancy. This highlights the need to closely examine and understand the impact of weight self-monitoring in this unique population. While a systematic review has been conducted to investigate the effect of routine weighing during pregnancy as a standalone intervention to manage GWG, this review (which included only 2 published RCTs) included both self-weighing and clinician weighing, was unable to identify any studies using digital health approaches to weight self-monitoring, and ultimately failed to support the effectiveness of weight monitoring for GWG management [49]. In a subsequent comment, the authors acknowledged that while the systematic review results were inconclusive, research in this area continues to accumulate [50,51]. In sum, though digital approaches provide a method to maintain benefits previously observed across pregnant and nonpregnant populations (about weight monitoring) while also increasing feasibility and adherence, uncertain quality of consumer-facing options (ie, publicly available smartphone apps) and a rapidly evolving research base highlight the need to evaluate the potential role of digital self-monitoring tools for the management of GWG.

Thus, the proposed review aims to summarize and synthesize the emerging research base evaluating digital GWG self-monitoring interventions for managing GWG during pregnancy. The primary outcome focus of this systematic review is GWG because prior RCT methods targeting nutrition or physical activity have yielded promising but modest effects on the reduction of GWG by about 20% [11]. There is a need to identify more effective and sustainable approaches to intervention delivery.

Objectives

Overview

The proposed review would aim to answer the following research questions relating to interventions, including a digital GWG self-monitoring component with a primary or secondary focus on the management of adult GWG.

Primary Focus

- How effective are interventions, including digital self-monitoring tools, in the management of GWG?

Secondary Foci

- Are interventions including digital GWG self-monitoring components associated with increased retention of participants in comparison to usual care or other care in control groups?
- Are interventions including digital GWG self-monitoring components associated with indicators of feasibility and acceptability among participants?
- Are there differences in the effects of standalone digital GWG self-monitoring interventions compared to multicomponent interventions, including digital GWG self-monitoring components?
- How diverse are the samples used to study GWG self-monitoring with digital components?

Methods

Study Designs

This protocol followed the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines for developing systematic review protocols (the PRISMA-P checklist is provided herewith). Studies will be selected according to the following criteria. The proposed review would include RCTs, feasibility trials, acceptability trials, pilot studies, nonrandomized trials, and controlled before-and-after studies. The proposed review will consist of studies examining adult pregnant individuals (18 years or older, as adolescent growth and development may further complicate the measurement of GWG and associated recommendations). It will include studies that examine individuals with chronic conditions, diseases, or disorders, as long as the primary or secondary outcome relates to GWG. Studies will be selected for inclusion in the proposed review only if at least 2 time points of data are available (ie, no studies that report only on cross-sectional data would be included). Additionally, though no restrictions will be placed on the length of follow-up for outcomes, follow-up data will be reported if available.

XSL•FO
RenderX

Interventions

Of interest in the proposed review would be mHealth interventions for the management of GWG, which include a digital weight self-monitoring component (eg, mobile app weight tracker). For the proposed review, interventions will be considered "mHealth" if the primary components of the intervention is delivered via a wireless device (eg, tablet, iPad, wearable device, and wireless scale) or mobile telephone (eg, cell phone, smartphone, and mobile website), and would be considered to have a weight self-monitoring component if they require the user to enter their weight, whether these data are collected automatically or input manually by the user. However, interventions that do not require any interactional component (ie, do not use the advanced functionality in mobile or wireless devices, eg, appointment reminders and static informational websites accessed via mobile devices) would not be considered mHealth interventions. Given the proposed review's focus on a descriptive (rather than reductive) summary of the extant literature on the use of digital self-monitoring technologies in interventions for the management of GWG, studies with any comparison group are eligible for inclusion, as are studies with no comparison group.

Evaluation Outcomes

In the proposed review, included studies would have an outcome relating to GWG as the primary study outcome (ie, interventions that attempt to prevent excessive GWG or promote adequate GWG within IOM guidelines). For the proposed review, GWG would be considered to be reflected by the total weight gain from pre- or early pregnancy to the time of delivery, the rate of weight gain per week from pre- or early pregnancy to the time of delivery, or the IOM categorization of the adequacy of pregnancy weight gain. Secondary study outcomes (if provided) would include physical activity or exercise behaviors (measured indirectly via self-reported or directly via activity tracker data reflecting frequency, intensity, or duration), diet or eating behaviors or diet quality (measured via self-reported dietary intake records or food frequency questionnaires, reflected as nutrient or energy intakes or as evaluation of dietary quality in comparison to established guidelines, eg, Healthy Eating Index-2015), sleep behaviors (measured indirectly via self-reported or directly via activity tracker data reflecting duration or quality), or psychosocial well-being or mood (measured via self-report surveys).

Exclusion Criteria

The proposed review will be restricted to studies conducted within the United States, given how guidelines for GWG vary considerably between countries [52]. We will include papers reported in English only, though a list of possibly relevant titles in other languages will be provided as a supplemental resource. Inclusion and exclusion criteria are summarized in Textbox 1.

Textbox 1. Inclusion or exclusion criteria.

Included criteria

- **Paper type:** Randomized controlled trials, feasibility trials, acceptability trials, pilot studies, nonrandomized trials, and controlled before-and-after studies
- **Sample:** Adult pregnant individuals 18 years or older, with or without chronic health conditions
- **Outcomes:** Primary or secondary outcomes relate to gestational weight gain
- Additional psychosocial or behavioral outcomes, including physical activity or exercise, diet or eating, sleep, or well-being or mood
- **Study timespan:** Longitudinal or prepost designs, with or without postpartum follow-up period
- **Intervention:** mHealth interventions focused on managing gestational weight gain; primary components of the intervention are delivered over the wireless device or mobile telephone; participants are required to monitor weight (either automatically or via manual entry)
- **Comparison:** Studies with and without intervention comparison groups (eg, waitlist control group, treatment-as-usual, no comparison group)
- **Study location:** Conducted in the United States
- **Language:** English

Excluded criteria

- **Paper type:** Qualitative studies, studies that do not contain an intervention component
- **Sample:** Adolescent pregnant individuals, nonpregnant individuals
- **Outcomes:** No outcomes relating to gestational weight gain or gestational weight gain was not measured
- **Additional outcomes:** Not applicable, if other outcomes are collected, they will not be reported (eg, blood pressure and blood glucose)
- **Study timespan:** Cross-sectional studies
- **Intervention:** No digital weight self-monitoring component; no interactional component; static informational websites
- **Comparison:** Not applicable
- **Study location:** Conducted outside of the United States
- **Language:** Languages other than English (list of possibly relevant titles published in other languages will be included as a supplemental resource)

Search Strategy

Electronic databases will be searched for literature published between January 2010 and July 2020 (to encompass the past decade given the rapid and ongoing development of digital health technology): PubMed or MEDLINE, Web of Science, Google Scholar, CINAHL, Academic Search Complete, PsycINFO, Embase. Both keywords and MeSH (Medical Subject Headings) terms relating to GWG, eHealth, mHealth, and variations of these terms. Boolean logic (ie, use of AND Mesh OR) will be implemented where appropriate.

Reference lists of studies initially selected for the review and lists of studies citing the studies originally chosen for the review will be assessed to identify additional studies that may meet eligibility criteria. Additionally, studies included in extant systematic reviews relevant to the proposed review will be evaluated against the proposed eligibility criteria. Finally, authors of registered protocols (for which published works summarizing results cannot be located) will be contacted to solicit any unpublished or unfinished work that may be incorporated into the narrative synthesis.

A university librarian with content coverage in public health provided preliminary consultation in developing the search strategy to ensure it captured all relevant terms. An example of the PubMed database search strategy is provided in Multimedia Appendix 1. It will be amended for other search engines to use database-specific or -compliant subject headings and keywords (ie, controlled vocabularies).

Data Management

Excel (Microsoft Corp) will be used to review literature search result lists. These results from all searched databases will be combined, and duplicate entries will be removed. The process will be described using a PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analysis) flow diagram. A checklist based on the inclusion and exclusion criteria will be created to facilitate the initial title screening of papers. Further, 1 reviewer will independently screen titles. In total, 2 reviewers will screen the abstracts associated with the resultant list of relevant titles to identify studies for which the entire text will be reviewed. The Kappa statistic will be used to assess the inter-reviewer agreement on this list before pulling the selected studies' full text. Finally, studies for which full text is reviewed will be independently assessed for inclusion by 2 reviewers, with any discrepancies brought to a third reviewer for additional feedback to reach a consensus on the final list of included studies.

Quality Assessment

The Effective Public Health Practice Project Quality Assessment Tool for Quantitative Studies will be used to assess the methodological quality (indicated as “strong,” “moderate,” or “weak”) of selected studies in each of the following areas: study design, analysis, withdrawals and dropouts, data collection practices, selection bias, invention integrity, blinding as part of a controlled trial, and confounders. Both reviewers will conduct quality assessments, and any discrepancies will be brought to a third reviewer for additional feedback to reach a consensus on quality evaluation. Additionally, these ratings will be presented in a tabular format to aid in contextualizing the narrative summary. Ratings over 2 SDs below the mean quality assessment rating will be excluded from any synthesis of outcome data.

Data Extraction and Synthesis

Descriptive details of interventions, including details of this study (setting and length), participant characteristics, the overall role of digital self-monitoring technology in the intervention, features of technology used in the intervention, description of any other intervention components, and outcomes will be extracted for narrative synthesis. Further, 2 reviewers will independently extract relevant information. Disagreements on the categorizations for selected studies will be discussed, and a third reviewer will be consulted as necessary until a consensus is reached. See Multimedia Appendices 2 and 3 for the data extraction tool and variables of interest.

A summary of findings and evaluation of the strength of the body of evidence will be provided in accordance with the synthesis without meta-analysis guidelines [53] in narrative and tabular format based on the outcomes reported in the studies reviewed, along with an indication of the quality of the studies as indicated by the Effective Public Health Practice Project Quality Assessment Tool. For continuous outcomes (eg, total GWG, rate of GWG per week), means and SDs would be used for comparison purposes. For categorical outcomes (eg, adequacy of GWG according to IOM guidelines), relative risk or odds ratios would be used for comparison purposes. If at least 2 studies are available examining intervention impact on pregnant women categorized as “overweight” or “obese” based on currently used BMI categorizations, a separate narrative synthesis section would evaluate intervention use and outcomes in this subpopulation.

Results

The research protocol was registered with PROSPERO (CRD42020204820), on September 29, 2020. The initial queries resulting in 1150 total records have been screened. Data extractions are expected to be finished by December 2023. The systematic review generated from this protocol will offer evidence for using digital self-monitoring tools in the management of GWG. The research to practice translation may have implications for OB or GYN care by summarizing the feasibility and acceptability of digital self-monitoring tools for GWG. The results will be disseminated through a peer-reviewed publication, expected in 2024.

Discussion

Principal Results

While advancements in intervention science have primarily supported the use of behavior change techniques (eg, physical activity and diet changes) for the management of GWG from the perspective of efficacy, much uncertainty remains regarding their broader feasibility and acceptability, as well as their impact on related health outcomes (eg, pregnancy and birth complications), constraining evidence for more general effectiveness. However, the continuing and rapid development

XSL•FO
RenderX

of new intervention approaches, particularly in the area of weight self-monitoring mHealth technology (given its accumulated support in nonpregnant populations), necessitate an updated and focused systematic review to more specifically address the potential of digital weight self-monitoring technology to address current gaps in feasibility, acceptability, and broad reach of interventions for managing GWG. If the proposed review finds that digital weight self-monitoring components are associated with desirable GWG outcomes or with improvements or maintenance of health behaviors (secondary outcomes), this would suggest that digital weight self-monitoring is an essential and necessary component of technology-mediated interventions focused on GWG.

Comparison With Prior Work

While previous reviews have examined effectiveness in the broadly defined use of e- and mHealth technologies to intervene concerning a variety of pregnancy health outcomes, limited consideration of such aspects as acceptability, feasibility (eg, retention), participant perceptions, and unique features specific to digital self-monitoring interventions uniquely positions the proposed review as both an extension of prior work and a much-needed reorientation toward a more practical understanding of the utility of digital self-monitoring tools for GWG management.

Limitations

The proposed review would include non-RCT studies, which may reduce the number of included studies with a comparison group and limit the conclusions that can be drawn regarding the impact of digital GWG self-monitoring interventions. Further, much of the research conducted to date (as suggested by previous reviews) has occurred with mostly White pregnant individuals. Consequently, any systematic reviews focusing on this body of literature will likely have limited applicability for Black, indigenous, or other racial or ethnic minority groups [54]. Given the notion of the "digital divide," it is possible that larger socioeconomic systems may dictate access to specific technologies.

Similarly, digital weight self-monitoring tools are primarily designed from a personal behavior change perspective. Thus, research captured in the context of the proposed review may not reflect how sociocultural systems (eg, familial or cultural context, interpersonal relational dynamics) may shape individuals' perceptions of and engagement with the apps. Finally, the authors acknowledge that their socioeconomic positions, racial or ethnic identities, and life histories may constrain the degree to which they can recognize, acknowledge, and consider the unique contexts and barriers experienced by socioeconomically, racially, ethnically, and culturally diverse pregnant women who do and do not engage with pregnancy weight management interventions.

Conclusions

The proposed review could help identify the degree to which digital GWG self-monitoring (as reflected by published empirical studies) can impact the prevalence of healthy GWG and the degree to which participants find the interventions feasible and acceptable. Furthermore, identifying effective strategies within interventions can inform future intervention research and, in the long term, individualized selection of efficacious interventions (and their constituent components) in clinical practice settings.

Acknowledgments

JM and AAD wrote this protocol, and JM conducted initial searches.

Data Availability

Data sharing does not apply to the above-described protocol, as no data sets were generated or analyzed in the production of the protocol. The proposed data set described in the protocol would consist of information gathered primarily from published research. Any additional data generated during the proposed systematic review (eg, quality ratings for specific papers) will be described as appropriate within the paper describing the review results. Any data not related will be available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: There is a tendency nowadays to restore large defects in primary dentition with pediatric crowns instead of conventional restorations. Thus, understanding the factors contributing to the survival or failure of dental crowns in pediatric dentistry is essential for optimizing treatment outcomes.

Objective: The primary objective of this protocol is to outline the methodological approach for analyzing data from observational studies and randomized controlled trials to investigate reasons for the failure of dental crowns in primary teeth and to compute their survival and failure rates.

Methods: A comprehensive literature review will be performed in electronic databases, including PubMed (MEDLINE), Cochrane, Embase, and Web of Science. As per predefined inclusion criteria, we will include observational studies (prospective clinical studies) and randomized clinical trials that have an English abstract and involve children aged 1-10 years undergoing crown restorations. Two independent reviewers will independently screen all retrieved records and full-text articles and extract data. The study's methodological quality will be appraised using suitable tools. Assessments of publication bias will be performed using funnel plots. The findings will be described qualitatively for the systematic review. If possible, a meta-analysis will be performed to estimate failure rates by dividing the number of failures by the total exposure time. A Poisson regression model, assuming constant event rates, will be used to compute 3-year and 5-year survival proportions. The Pearson goodness-of-fit statistics will be used to assess the heterogeneity of the model. A P value <.05 will be considered significant. All analyses will be performed using R Statistical software (version 4.1.2; R Core Team).

Results: This systematic review and synthesis aim to assess the survival and failure rates of dental crowns in pediatric dentistry. By following this rigorous methodology, we seek to provide valuable insights into the factors contributing to the success or failure of these restorations. The results of our full review will have implications for pediatric dentists, researchers, and policy makers, helping to improve dental care for children.

Conclusions: This systematic review protocol helps in establishing a thorough approach for reviewing failures in pediatric crowns. By following this methodology, standardization and transparency of the process as well as accountability for the stated methods and outcomes will be ensured. The findings of this review and analysis will provide useful data on the survival of crowns to pediatric dentists and researchers.

Introduction

Apart from maintaining space for permanent teeth, primary teeth serve important functions in mastication and speech development [1-3]. Structural damage to primary teeth caused by caries, bruxism, and other parafunctions, such as jaw clenching and tooth grinding, are relatively common presentations in pediatric dentistry. In 2010, it was shown that untreated caries in deciduous teeth affected 9% of the global population or 621 million people worldwide [4]. Furthermore, the prevalence of bruxism could be in the range of 3.5% to 40.6% among children and adolescents [5]. This high prevalence of caries and structural damages caused by caries and other parafunctions warrant restorative interventions that are safe and effective in the long term [4,5].

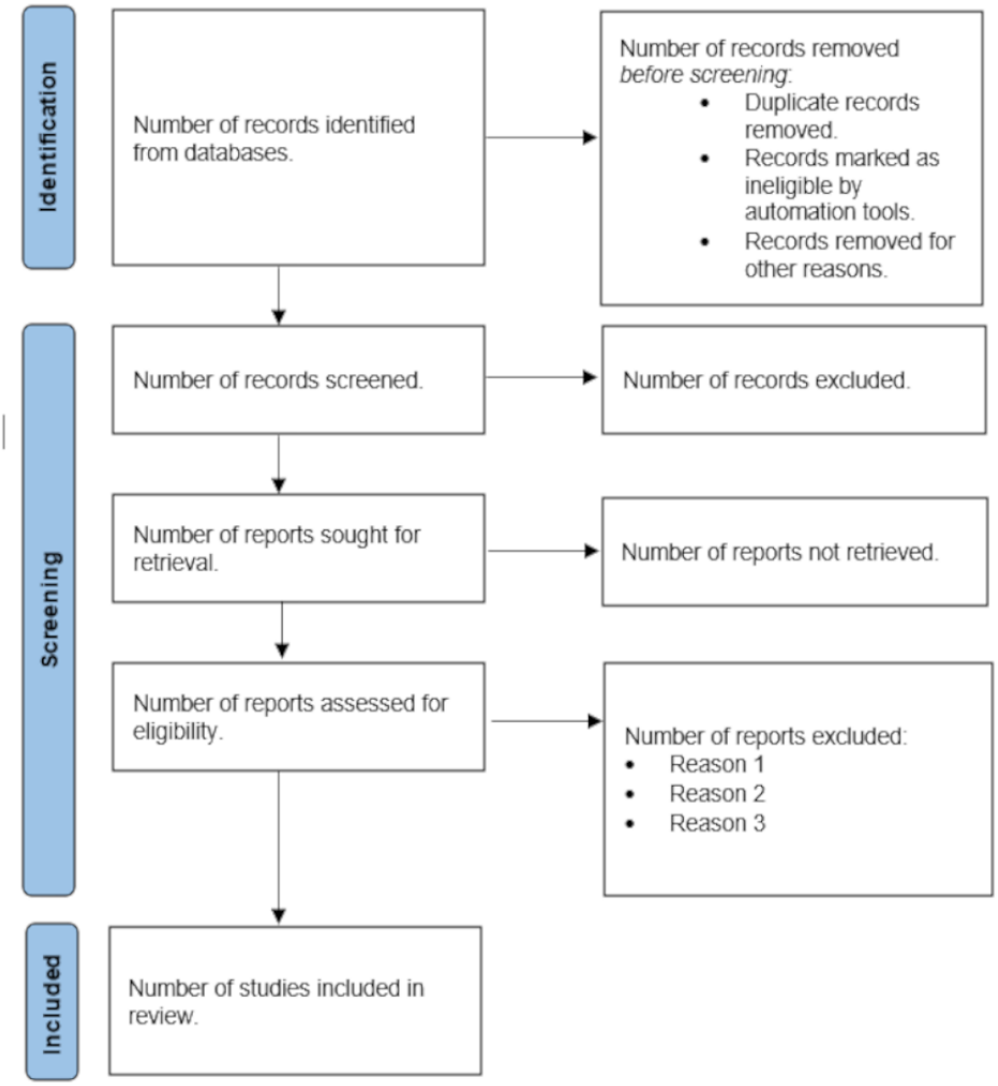
Pediatric dental crowns are commonly used as a restorative measure to preserve the tooth's functionality and prevent premature loss. Several materials, such as stainless steel, zirconia, composite resins, and polycarbonate materials, have shown satisfactory properties for fabricating dental crowns [6-8]. Despite advancements in dental materials and techniques, crown failures do occur, leading to potential complications and the need for further interventions [9].

Although secondary caries seem to be a common reason for the failure of these crowns, several other biological and technical factors also contribute to the failure of crowns [9]. Several studies have investigated the outcomes and success rates of dental crowns in pediatric dentistry, but there remains a lack of comprehensive synthesis and analysis regarding the specific reasons for crown failure. Therefore, conducting a systematic review and meta-analysis to pool and analyze available evidence on the reasons for crown failure in pediatric patients will provide valuable insights into this important clinical concern.

The objective of the systematic review and meta-analysis proposed in this protocol is to comprehensively analyze the reasons for the failure of crowns in primary teeth. By synthesizing existing evidence, we aim to identify the common causes of failure, assess their prevalence, and explore potential risk factors associated with crowns in primary teeth.

Methods

Protocol Registration and Reporting Information



This protocol is registered in the PROSPERO database (CRD42023442266) and has been written according to the MOOSE (Meta-Analysis Of Observational Studies in Epidemiology) and the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols) guidelines [10,11].

Data Sources, Search Terms, and Search Strategy

Under the supervision of the principal investigator, we will conduct a systematic search of electronic databases, including Cochrane, Embase, PubMed (MEDLINE), and Web of Science to identify relevant articles published up to the date of our search. The search strategy will be developed using appropriate keywords and Medical Subject Headings terms related to “child,” “children,” “toddler,” “crowns,” “pediatric dentistry,” and “treatment failures.” Additionally, we will manually search the reference lists of selected articles and relevant systematic reviews to identify any additional studies. The searches will not be limited by historical time constraints. The search strategy will be considered adequate to reduce the risk of selection and detection bias. The search results will be exported to Zotero, where duplicates will be excluded. Included studies will be manually searched to select other relevant studies. A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1) will be reported to describe the study selection process.

XSL•FO
RenderX

Figure 1. Conceptual PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram for identification of studies via databases and registers.

Inclusion and Exclusion Criteria

We will include clinical studies, randomized controlled trials (RCTs), and prospective longitudinal studies (nonrandomized clinical studies and cohort studies) that meet the following criteria: (1) evaluate crown restorations in pediatric patients aged 1-10 years, (2) report reasons for crown failure or complications, and (3) have abstracts available in English. Qualitative interviews, quasi-experimental studies, single-case studies, and series of single-case studies will be excluded. Furthermore, studies without sufficient data on the survival of crowns or duplicate publications will be excluded. Secondary caries, endodontic complications, and periodontal pathology will be considered biological complications in this analysis. The technical complications to be considered in this analysis will include fractures of the crown (not the tooth itself), loss of retention, debonding, and occlusal wear. Data based on conference abstracts and dissertations will not be included.

Data Extraction and Analysis

Two independent reviewers will screen the articles for eligibility; they will extract data and assess the quality and risk of bias of the included studies. Any discrepancies will be resolved through discussion or consultation with a third reviewer. The extracted data will include study characteristics, sample size, patient demographics, types of materials, reasons for failure, and reported complications. A narrative synthesis will be performed to summarize the findings, and if feasible, a meta-analysis will be conducted to calculate pooled estimates of the prevalence of restoration failures in pediatric dentistry.

Assessment of Methodological Quality

The risk of bias in the included RCTs will be systematically assessed using the RoB 2 (Risk of Bias 2) tool developed by the Cochrane Collaboration [12]. Using this tool, 2 independent reviewers will evaluate the various domains of bias in RCTs, including randomization, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective reporting, and other sources of bias. Each included RCT will be assessed for risk of bias in accordance with the domains specified by the RoB 2 tool, and an overall risk of bias judgment (low, some concerns, or high) will be assigned to each trial [12]. Furthermore, a checklist proposed by Moga et al [13] will be adapted for assessing the risk of bias in prospective clinical studies. Only studies with a moderate or low risk of bias will be included in the current

XSL•FO
RenderX

analysis. Although this tool was originally developed for case series, a modification of this tool has been adapted previously for assessing the risk of bias in studies that have a missing comparator [14]. Using this tool, seven domains will be assessed for risk of bias (Table 1) and an overall risk of bias judgment (high risk of bias, serious risk of bias, low risk of bias, or no information) will be assigned to each study [13,14].

Table 1. Risk of bias domains to be assessed for prospective clinical studies. Assessments will be reported as high risk of bias, serious risk of bias, low risk of bias, or no information [13,14].

Domains	Assessment item
Domain 1	Study design
Domain 2	Study population
Domain 3	Interventions
Domain 4	Outcome measures
Domain 5	Statistical analysis
Domain 6	Results and conclusion
Domain 7	Competing interests

Assessment of Publication Bias

To enhance the transparency and accuracy of the findings, assessments of publication bias (less likelihood of publishing studies that failed to show statistical significance) using funnel plots will be undertaken in the evaluation of the survival and failure rates of dental crowns in pediatric dentistry. If present, publication bias will be reflected as an asymmetry in the funnel plot [15,16].

Meta-Analytic Approach

For the purposes of quantitative analysis, survival will be defined as a number of crowns that were in situ, regardless of complications (technical and biological), which include secondary caries, marginal integrity, marginal discoloration, and loss of anatomical form along with surface roughness, endodontic complications, loss of retention, and fractures. Failure rates resulting from biological and technical failures will be calculated by dividing the number of failures by the total exposure time. Exposure time for each included study will be calculated by taking the sum of exposure time for all fixed dental prostheses. A Poisson regression model will be used to analyze the calculated rates. Survival proportions for 3 years and 5 years will be estimated with an assumption of constant event rates. The Pearson goodness-of-fit statistics will be used to assess the heterogeneity of the model. A P value <.05 will be considered significant. All analyses will be performed using R Statistical software (version 4.1.2; R Core Team).

Results

Overview

The search and screening for the systematic literature review are anticipated to be finished in October 2023. Data extraction, quality appraisal, and subsequent data synthesis began in October 2023. The review is expected to be completed by November 2023, and attempts to publish the study results will be made in December 2023.

Protocol Amendments

If this protocol is substantially amended after an initiation that may impact the conduct of the study (including eligibility criteria, study objectives, study design, study procedures, and analysis), then an amendment will be agreed upon by all collaborators prior to the implementation and will be documented in a later report.

Discussion

Key Findings

This planned systematic review and meta-analysis will systematically identify the common causes of failure, assess their prevalence, and explore potential technical and biological factors associated with crown failures in pediatric patients. Furthermore, a meta-analysis will be attempted, if feasible; a Poisson regression model, assuming constant event rates, will be used to compute 3-year and 5-year survival proportions. The findings of the systematic review and meta-analysis will assess the quality of available studies and provide important insights for methodological aspects of future research. Thus, the findings of this review and its quantitative assessments could inform researchers and clinicians.

Comparison to Previous Research

Chisini et al [9] reported a systematic review on survival and reasons for failure of primary teeth restorations [9]. This systematic review included data from 31 studies conducted between 1996 and 2016 [9]. However, this review looked at all restorative materials used in pediatric dentistry and was not restricted to crowns on primary teeth. Apart from this study, a systematic analysis of the technical and biological factors affecting the survival of crowns for primary teeth has been scanty. Our review will analyze pediatric crowns only and, therefore, will add valuable insights for understanding the technical and biological factors contributing to the success or failure of crowns for primary teeth.

Limitations

Although it has been suggested that researchers must include unpublished literature in meta-analyses and systematic reviews,

XSL•FO
RenderX

the inclusion of data from unpublished studies can itself introduce bias [17]. Thus, data from unpublished studies and non–peer-reviewed literature (eg, reports) will be excluded. However, assessments of publication bias will be performed using funnel plots [15,16]. Despite this potential limitation, the findings of the proposed systematic review and meta-analysis will contribute to the existing body of knowledge by identifying common causes of failure, highlighting potential risk factors, and guiding future research and clinical practice to improve the success rate of crowns in children with structural damage of the primary teeth.

Conclusions

This systematic review and meta-analysis protocol is designed to provide a comprehensive assessment of the common causes of crown failures in primary teeth, explore associated technical and biological factors, and estimate survival proportions over 3-year and 5-year periods. Although building upon the existing body of knowledge, the proposed study distinguishes itself by focusing on the unique challenges and intricacies of crown failures in primary teeth. By systematically identifying factors influencing crown outcomes, our findings will inform dentists in clinical practice about possible causes of pediatric crown failures, helping to minimize these potential failures. This study will also guide future research efforts to improve material properties to increase the clinical longevity of these pediatric crowns.

Data Availability

All data generated or analyzed during the systematic review and meta-analysis proposed herein will be made available as supplementary files as part of any forthcoming publications.

Abstract

Background: Digital health literacy is considered a health determinant that can influence improved health and well-being, health equity, and the reduction of social health inequalities. Therefore, it serves as an asset for individuals to promote their health. However, low digital health literacy is a major problem among forced migrant populations. They do not always have the capacity and skills to access digital health resources and use them appropriately. To our knowledge, no studies are currently available to examine effective interventions for improving digital health literacy among forced migrant populations.

Objective: This paper presents the protocol for a systematic review that aims to assess the effectiveness of digital health literacy interventions among forced migrant populations. With this review, our objectives are as follows: (1) identify interventions designed to improve digital health literacy among forced migrant populations, including interventions aimed at creating enabling conditions or environments that cater to the needs and expectations of forced migrants limited by low levels of digital health literacy, with the goal of facilitating their access to and use of eHealth resources; (2) define the categories and describe the characteristics of these interventions, which are designed to enhance the abilities of forced migrants or adapt digital health services to meet the needs and expectations of forced migrant populations.

Methods: A mixed methods systematic review will be conducted according to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist. The research will be conducted in an iterative process among the different authors. With the help of a medical information specialist, a specific search strategy will be formulated for the 6 most relevant databases (ie, MEDLINE, Embase, CINAHL, Web of Science, Academic Search Premier, PsycINFO, and the Google Scholar search engine). A literature search covering studies published between 2000 and 2022 has already been conducted. Two reviewers then proceeded, individually and independently, to conduct a double selection of titles, abstracts, and then full texts. Data extraction will be conducted by a reviewer and validated by a senior researcher. We will use the narrative synthesis method (ie, structured narrative summaries of key themes) to present a comprehensive picture of effective digital health literacy interventions among forced migrant populations and the success factors of these interventions.

Results: The search strategy and literature search were completed in December 2022. A total of 1232 articles were identified. The first selection was completed in July 2023. The second selection is still in progress. The publication of the systematic review is scheduled for December 2023.

XSL•FO
RenderX

Conclusions: This mixed methods systematic review will provide comprehensive knowledge on effective interventions for digital literacy among forced migrant populations. The evidence generated will further inform stakeholders and aid decision makers in promoting equitable access to and use of digital health resources for forced migrant populations and the general population in host countries.

Introduction

Overview

Forced migration is a growing global phenomenon. It is defined by the International Organization for Migration [1] as "a non-voluntary, coerced and suffered migratory movement, caused by various factors, but involving the use of force, coercion." According to Keely and Kraly [2], the reasons for forced migration include wars and armed conflicts, persecution and violence, human rights violations, climate change, natural disasters, and famine. In 2021, there were approximately 1 billion migrants worldwide, accounting for 1 in 7 people in the world [3,4]. Of this population, 82.4 million are forced migrants [3]. An estimated 48 million are internally displaced, 26.4 million are refugees, and 4.1 million are asylum seekers [3]. On host lands or countries, migrants often live with minimal public services and face many complex problems [5]. Due to a lack of regular migration status, stigmatization, xenophobia, racism, discrimination, language and cultural barriers, as well as low income levels, forced migrants have limited access to social and health services and health promotion interventions [6-8]. All these difficulties negatively affect their physical and mental health and well-being and make them more vulnerable [6,9].

The use of information and communication technologies (ICTs) for health, called digital health or eHealth [10,11], could be a promising avenue to address the challenges faced by these forced migrant populations, including internally displaced persons, refugees, asylum seekers, and economic, political, or climate migrants [2,12-17]. Indeed, digital health technologies could play an important role in preventing and promoting the health and well-being of forced migrant populations [18,19]. Chae et al [20] and Wang and Yu [21] explain that forced migrant populations use digital technologies as tools or sources of health information to circumvent barriers in host countries. For example, the internet is regularly used as a cost-effective or free alternative route to search for web-based health information [20]. The study by Chae et al [20] found that about 3%-6% of surveyed women of Korean descent living in the United States used the internet as their primary source for health information. Accessing health information via the internet can also overcome language barriers by using either the language of the country of origin or the language of the host country [21].

Smartphones and digital platforms are digital solutions that could help forced migrant populations understand and connect with complex health systems in host countries [12,17,22]. These digital tools allow these populations, who are unfamiliar with the organization of health systems in host countries, to find doctors, clinics, and hospitals [17]. They also facilitate access to health services, including appointment scheduling and geolocation, especially those in close proximity to their living environment [17]. For example, digital platforms like the Ssyla Digital Therapy Platform, an initiative based in the United Kingdom, connect refugees and migrants to a global network of mental health therapists [12].

In the face of various stressors and challenges experienced by migrants in host countries, digital technologies are resources contributing to improving their well-being. Digital forced migrant resilience was repeatedly linked to social ties [17,23]. Social networks are digital spaces for forced migrant populations to strengthen and create cultural ties (or shared identities) and gather emotional and social support [23]. Connecting with members of their community who are already settled in the host country strengthens feelings of security and trust, belonging to a community, social inclusion, a sense of value, recognition of social status, and nondiscrimination [23]. In addition, contact via mobile phone and social media with family and relatives back home is an important social support for forced migrants, allowing them to overcome physical barriers as well as feelings of social isolation and manage stress [17,24].

Although ICTs have many opportunities and benefits, there are barriers that could prevent forced migrant populations from accessing and using digital health technologies. The first level of difficulties faced by forced migrants is accessing digital media and equipment (eg, internet, computers, tablets, and phones, as well as necessary infrastructure). For example, asylum seekers in Australia were unable to access the internet due to the unaffordable cost or unavailability [25]. Afghan migrants in Iran could not access mobile devices and networks due to infrastructure and legal restrictions [26].

The second category of barriers faced by forced migrants is related to their ability to use available digital health resources. Forced migrants with adverse personal characteristics (eg, advanced age, cognitive impairment, lack of experience, and lack of digital skills) face more barriers to using the internet and apps [27]. For example, older migrants whose health is deteriorating face more barriers to internet use than their healthier counterparts. According to Kouvonen et al [27], the most frequently mentioned challenges were that these digital

XSL•FO
RenderX

tools were too complicated or difficult to learn and they presented security challenges.

Finally, the third category of barriers faced by forced migrants is related to their ability to search, find, understand, evaluate, and use health information via the internet. Indeed, language barriers, the complexity of the organization of health systems in host countries, and certain medical terminologies limit access to web-based services for forced migrant populations [28-31]. Moreover, faced with the flood of information on social media, forced migrants do not always have the skills to assess and differentiate between reliable and unreliable health information [32]. This category of barriers is also observed in the general population of the host land or country [33].

Thus, low digital health literacy is an important issue among forced migrant populations [29,34]. Norman and Skinner [35] define digital health literacy as "the ability to search, find, understand and evaluate health information from numerical, electronic sources and use the information to make decisions about one's health." In the face of constant digital evolution and the increasing complexity of society and health care systems, forced migrants require additional skills, such as the ability to recognize information needs, trust web-based health information, and interact with the digital health system to improve their health and well-being [36]. To do so, several authors [37-39] indicate that there is a need to conceptualize digital health literacy by considering dimensions such as context (eg, the ability to recognize the existence of an information need and trust web-based health information) and the interactions between migrants and the digital health system. Low levels of digital health literacy could lead to poor health and well-being outcomes [40]. In addition, they may exacerbate disparities (or digital inequalities) in accessing and using digital health services (or digital exclusion), and above all, they may contribute to health inequalities between communities [33]. Low levels of digital health literacy are not conducive to health equity.

To address these major challenges, many initiatives aimed at promoting better health behaviors among forced migrant populations have been developed by different actors [13,37,40]. A comprehensive understanding of these interventions to support digital health literacy among forced migrant populations and their effectiveness is essential to enable policy makers to develop programs and interventions tailored to their needs. However, to our knowledge, there is limited literature on interventions favorable to the digital health literacy of forced migrant populations, which underscores the interest in a research protocol for a mixed methods systematic review.

Objectives

The overall aim of the systematic review is to assess the effectiveness of interventions aimed at improving digital health literacy among forced migrant populations. To achieve this general objective, 2 specific objectives are pursued, as follows:

- Identify interventions designed to improve digital health literacy among forced migrant populations, including interventions aimed at creating enabling conditions or environments that cater to the needs and expectations of forced migrant populations limited by low levels of digital health literacy, with the goal of facilitating their access to and use of eHealth resources.
- Define the categories and describe the characteristics of these interventions, which are aimed at improving the abilities of forced migrants or adapting digital health services to meet the needs and expectations of forced migrant populations limited by low levels of digital health literacy.

Methods

Reporting Standards

This systematic review protocol uses the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocol) checklist [41]. The systematic review will be conducted by a research team in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist for systematic reviews [42].

Eligibility Criteria

Eligibility criteria will be based on the PICOS (population, intervention, comparison, outcomes, and study design) model [43] and are described in Table 1. To be selected for review, studies should target forced migrant populations, including internally displaced persons; refugees; asylum seekers; as well as political, economic, and climate migrants. In addition, all studies on interventions related to the theme will be included (ie, if they focus on interventions aimed at digital health literacy among vulnerable migrant populations). As for the types of studies, there will be no restrictions. All quantitative empirical studies, qualitative or mixed methods studies, and studies with or without a control group will be included without distinction. We will consider only studies published in English or French. This systematic review will cover the period from 2000 to 2022. Frank [44] introduced the concept of "digital health" in the early 2000s. We will exclude editorials, commentaries, conference abstracts, protocols, and test recordings.

XSL•FO
RenderX

Table 1. Eligibility criteria based on the PICOS (population, intervention, comparison, outcomes, and study design) model [1,2,45].

PICOS model categories	Description

Population (P)	• The population consists of forced migrant populations, including internally displaced persons, refugees, asylum seekers, as well as political, economic, and climate migrants. It should be noted that forced migrant populations research is challenged by the diversity of terminology and definitions used [2]. For the purposes of this systematic review, we will rely on definitions from the International Organization for Migration [1] glossary, as follows:
	  ◦ Internally displaced persons are "persons forced to flee or leave their homes or places of habitual residence within their own country, including as a result of or to prevent the effects of conflict, violence, human rights violations or natural or man-made disasters" (free translation) [1].
	  ◦ Refugees (convention 1951) means to refer to any "person who, owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and who is unable or, owing to such fear, does not want to claim the protection of this country" (free translation) [1].
	  ◦ Asylum seeker refers to a "person seeking international protection. In countries with individualized examination procedures, the asylum seeker is a person whose asylum application has not yet been the subject of a final decision by the potential host country. Not every asylum seeker is necessarily recognized as a refugee at the end of the process, but every refugee has initially been an asylum seeker" (free translation) [1].
	  ◦ Migrants include all persons who leave their place of habitual residence to settle, temporarily or permanently, either in another region within the same country or in another country, thus crossing an international border, and for various reasons [1]. When people move in search of a better life or work, we speak of economic migration. In addition, when they migrate to escape persecution due to their political opinions, it is referred to as political migration [1].
	  ◦ Climate migration means to refer to any "movement of a person or group of persons who, essentially for reasons related to a sudden or gradual change in the environment as a result of climate change, are forced to leave their place of habitual residence, or leave it on their own initiative, temporarily or permanently, to go elsewhere in the territory of a state or across an international border" (free translation) [1].
	• All studies on interventions related to promoting digital health literacy among forced migrant populations will be included.

Intervention (I)	• All studies on interventions related to promoting digital health literacy among forced migrant populations will be included. • All types of interventions will be considered and classified according to the "Behaviour Change Wheel" model [45]. Indeed, this model makes it possible to systematically characterize interventions aimed at modifying or changing behavior at the individual, organizational, and societal levels.
Comparative (C)	There will be 2 types of comparisons: • A specific intervention to promote digital health literacy in forced migrant populations, compared to no specific intervention or usual services. • A specific intervention to promote digital health literacy in forced migrant populations, compared to any other intervention, to promote digital health literacy in these populations.

Outcomes (O)	The following elements will be examined:
	• Categories: the following categories will be reviewed:
	  ◦ Level of intervention: individual, group, or mixed
	  ◦ Mode of design: theory, evidence, or none
	  ◦ Targeted behavior: opportunities, motivations, attitudes, and abilities or skills
	• Characteristics of interventions: interventions will be classified according to the following 9 functions of an intervention (ie, types of interventions) based on the model proposed by Michie et al [45]: education, persuasion, incentive, coercion, training, restriction, environmental restructuring, modeling, and empowerment.
	• Results and success factors of interventions: outcomes related to behavior change, self-care behaviors, and resolution of health problems through interventions will be examined along with their success factors. We will also explore outcomes related to access to basic health information and improved quality of life through digital health technologies.

Study design (S)	• As for the types of studies, there will be no restrictions. All quantitative empirical studies, qualitative studies, or mixed methods studies, and studies with or without a control group will be included without distinction.

XSL•FO

Review Question

The review question for this systematic review is the following: what are some effective interventions to improve digital health literacy among forced migrant populations, including internally displaced persons, refugees, asylum seekers, as well as economic, political, and climate migrants?

Search Strategy

The search strategy will be developed by a research team in collaboration with a librarian from Laval University (FB), who specializes in medical information and is experienced in systematic reviews. The research will be carried out in an iterative process between the different authors. First, the systematic literature search will be conducted in the following relevant bibliographic databases: MEDLINE (OVID), Embase, CINAHL, Web of Science, Academic Search Premier, and PsycINFO. We will also search the Google Scholar search engine. The search terms used will be based on a combination of 2 key concepts, which are "Digital Health Literacy" and "forced Migrant Populations." Research terms for each of these concepts will be developed from the literature and thesauri. Specific details of the strategies will be presented in the form of tables. Then, the search results will be imported to the web-based collaboration tool Covidence (Veritas Health Innovation) [46], a review management software, where duplicates will be removed using the automation function. Missing duplicates will be removed manually.

Study Selection and Extraction

The selection of studies will be done in Covidence [46]. Individual reviewers from the research team will perform a double selection of titles and abstracts, then the full text of relevant studies. After study selection, data will be extracted by a reviewer and validated by a senior team member, using an extraction grid designed and pilot-evaluated by the research team. Conflicts or discrepancies will be resolved through discussion and consensus within the research team.

Bias or Quality Assessment

Quality assessment is used to describe the selected articles and to interpret the data in the synthesis [47]. In this review, the quality of studies will be assessed using the Mixed Methods Appraisal Tool (MMAT). This tool will make it possible to simultaneously evaluate the different types of studies selected, whether qualitative, quantitative, or mixed [47].

Data Synthesis and Analysis

To synthesize the data, we will use narrative synthesis as a method, regardless of the type of study (eg, quantitative, qualitative, or mixed). We will provide a descriptive synthesis of the results of the included studies. A narrative summary of the main results will be produced. Outcomes related to behavior change, self-care behaviors, and health problem–solving (as a result of using the interventions) and the success factors of these interventions will be presented. Additionally, we will present the results related to access to basic health information and improved quality of life through digital health technologies.

Ethical Considerations

Ethics approval is not required for this systematic review, as it does not require primary data collection. The protocol will be registered with the International Prospective Registry of Systematic Reviews [48]. The results of this systematic review will be disseminated through publication in an academic journal and scientific conferences.

Results

The search strategy was completed in December 2022. The literature search identified 1232 studies. The first stage of study selection was completed in July 2023. A total of 82 studies were retained for the second selection, which is still in progress. Publication of the paper is scheduled for December 2023.

Discussion

The Main Contributions of This Systematic Review

Although literature reviews on health literacy interventions among migrants exist, they have not explicitly included studies on digital health literacy interventions among forced migrants. Fernández-Gutiérrez et al [49] published a systematic review in 2018 that focused solely on health literacy interventions among migrants and included only 9 studies and targeted health care professionals, including nurses. In 2022, a systematic review published by Fox and colleagues [50] on the same topic reviewed the existing literature documenting randomized controlled trials, including 23 articles. To our knowledge, there is no mixed methods literature review on the subject. Our review is the first attempt to examine interventions to improve digital health literacy among forced migrant populations and their effectiveness and challenges.

Potential Impact and Future Directions

Digital health literacy or eHealth literacy refers to the basic skills required for individuals to take advantage of digital technologies for the benefit of their own health [51]. The importance of these skills is well established for populations with low digital health literacy, such as forced migrants [52]. These skills enable forced migrant populations to promote their own health and well-being. Because of their vulnerability, it is essential to support the development of the skills needed to search, find, understand, and especially, critically evaluate health information among forced migrant populations. Thus, these populations represent important targets for the development of interventions conducive to their digital health literacy as well as the evaluation of the effectiveness of these interventions. This research aims to provide a synthesis of knowledge and generate evidence that will guide effective interventions promoting digital health literacy and the use of eHealth among forced migrant populations.

Determining the level of digital health literacy in forced migrant populations and associated factors contributes to the development of effective and innovative interventions that meet the needs of these populations [28]. Based on the socioecological model [53], 4 factors are identified: individual, interpersonal, community, and societal. The literature shows that there is

XSL•FO
RenderX

considerable variability in the methodology of digital health literacy assessments in forced migrant populations [28]. Chesser et al [28] indicate that some of these measurement tools used for evaluation have inherent limitations. The wide variability in intervention designs to support digital health literacy in forced migrant populations could be explained by the variety of measurement tools and the plurality of associated factors. They also explain why some interventions are more effective than others. There is, therefore, a need to comprehensively understand and highlight effective interventions that support digital health literacy among forced migrant populations and the factors that these interventions have addressed. Mixed methods will be used in this systematic review to provide a broader and more comprehensive picture of the existing literature on effective interventions for improving digital health literacy in forced migrant populations.

Conclusions

The results of this systematic review will provide a comprehensive picture of effective interventions that promote digital health literacy among forced migrant populations. They will share knowledge and evidence on digital health and the use of eHealth among the forced migrant populations with different stakeholders. This evidence and knowledge, in turn, will aid decision makers in promoting equitable access to and use of digital health resources among forced migrants and the general population in host countries.

Acknowledgments

The authors would like to acknowledge all the individuals who were consulted or involved in the course of this study.

Data Availability

Data relating to the search strategy for this review are available in Multimedia Appendix 1. All data generated or analyzed during this study (including the PRISMA [Preferred Reporting Items for Systematic Reviews and Meta-Analyses] flow chart) will be included as multimedia appendices. Databases created during the data extraction process will be available upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Cellulitis is defined as an infection of the skin that is usually characterized by localized but poorly demarcated areas of erythema, swelling, and pain. Erysipelas is a subtype of cellulitis that is characterized by a more superficial infection, often involving the face. Because gram-positive bacteria are the most common infective agent, beta-lactam antibiotics such as cephalosporins are commonly used. However, guidelines and physician preference vary widely as different antibiotic options and routes of administration exist, in addition to the fact that most cases are treated empirically without microbiological lab guidance. This lack of standardization in evidence, guidelines, and physician practice prompted this systematic review and meta-analysis of both randomized trial data and cohort studies to aggregate the currently available evidence for the optimal routes of antibiotic administration in cellulitis treatment.

Objective: The primary objective of our review is to compare the efficacy of oral versus intravenous antibiotic administration for cellulitis infections, thereby providing clinicians with evidence-based guidelines for treatment.

Methods: We will search MEDLINE, Embase, and CENTRAL through Ovid as well as Web of Science and CINAHL for all available literature comparing different routes of antibiotic administration in the treatment of cellulitis and erysipelas. We will perform title and abstract as well as full-text screening in duplicate according to the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analyses) guidelines and then extract the relevant data using a prepiloted data sheet. The primary outcome for our review is the duration of infection resolution, and secondary outcomes such as incidence of sepsis, mortality, hospital admission, and Clostridium difficile infection. We will assess the risk of bias in our included studies using the RoB 2.0 (revised tool for Risk of Bias in randomized trials) and ROBINS-I (Risk of bias in non-randomized studies for interventions) tools, with a final quality assessment using the GRADE (Grading of Recommendations, Assessment, Development, and Evaluation) framework and a sensitivity analysis to examine heterogeneity.

Results: We will publish the final results of our systematic review in a peer-reviewed academic journal. This project received no funding or financial assistance. Data analysis is currently underway, and the results are expected to be submitted for publication in late November 2023.

XSL•FO
RenderX

Conclusions: To our knowledge, this will be the most up-to-date review of the best available evidence comparing different routes of antibiotic administration for cellulitis. Because of the vast selection of antibiotic options available and the empirical nature of the treatment, we anticipate heterogeneity within our data but nonetheless hope to provide aggregated evidence on the efficacy of intravenous versus oral administration of antibiotics in cellulitis treatment. We hope the results from this study will better inform physician practices in the future for cellulitis infections.

KEYWORDS

antibiotics; cellulitis; infection; intravenous; oral

Introduction

Cellulitis is defined as a bacterial infection of the skin, usually involving the epidermal and dermal layers, with occasional involvement of the subcutaneous fat and lymphatic tissues. It is commonly characterized as poorly demarcated but localized swelling and pain, most often in the lower limbs [1]. Erysipelas is a subtype of cellulitis where the infection is more superficial in the epidermal layer and is often referred to by its clinical name when it affects the face or legs. The presentation of cellulitis also varies in severity and in bacterial species. Most patients only have mild systemic symptoms such as fevers, with only around 10% of hospitalized patients experiencing severe complications such as sepsis and necrotizing fasciitis [1,2]. However, around 18% of initial antibiotic treatment still fails. The most common causative agents include beta-hemolytic streptococci, such as group A and group G, as well as *Staphylococcus aureus*. The presence of methicillin-sensitive versus methicillin-resistant species of *S aureus* is also crucial in directing antibiotic treatment [2]. However, because of the nonsterile site of cellulitis infection with the presence of numerous commensal bacteria, empiric treatments are usually started without specimen collection. Microbiological studies are often only conducted in a research setting, to a limited effect, as the presence of commensal colonies can often confound the culture results. In rare cases, through opportunistic infections, fungal species can be implicated as well [3].

Based on the prominent bacterial species possibly found in common cellulitis infections such as beta-hemolytic streptococci and staphylococci, gram-positive antibiotics covering these organisms have been the empiric drug of choice [3,4]. However, a wide range and different classes of antibiotics are available to fill this demand, and there have been no cohesive guidelines for standardization. Beta-lactam inhibitors such as penicillin or different generations of cephalosporins such as cefazolin, cephalexin, or ceftriaxone have been commonly used. Other classes of antibiotics such as macrolides, doxycycline, and clindamycin have all been used and reported in the literature [3]. Additionally, antibiotics used for the broader coverage of methicillin-resistant *S aureus*–related cellulitis also vary, from vancomycin to trimethoprim-sulfamethoxazole or clindamycin. These antibiotics all differ in their efficacy and side effect profiles, such as *Clostridium difficile* risks. This lack of standardization and reliance on physician preference points to the need for evidence-based reviews for the optimal treatment of cellulitis [3-5]. These antibiotic options also differ in their routes of administration, with some available in both oral and intravenous (IV) routes, while other antibiotics can only be administered through one of the options. Because of its potential involvement in deeper layers of skin, topical antibiotic administration is unlikely to show efficacy against the infection. Despite some evidence showing that oral therapies are at least as effective as IV administration, some guidelines still recommend the IV routes for high-risk patients, such as those with obesity or venous stasis [3,6].

It is for these reasons mentioned above that we have decided to perform this systematic review. The primary objective of our review is to compare the efficacy of oral versus IV antibiotic administration for cellulitis infections, thereby providing clinicians with evidence-based guidelines for treatment.

Methods

Overview

This systematic review and meta-analysis will be conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analyses) guidelines [7]. This protocol is also registered with PROSPERO (International Prospective Register of Systematic Reviews; registration ID CRD42023413590). Any major changes to this protocol will be reported within the final review itself.

Search Methods

We will conduct a systematic search of MEDLINE, Embase, and CENTRAL through Ovid, as well as CINAHL and Web of Science, from inception to February 2023. We will also use medical subject headings terms, when possible, for broad inclusion of studies. Examples include “erysipelas.tw,kf.” and “(antimicrob* or antibiotic*).tw,kf.” A detailed sample search strategy for MEDLINE through Ovid is outlined in Multimedia Appendix 1. We will not have any language restrictions on the data in our search. The bibliography of previous literature and systematic reviews will also be hand-searched for relevant or potentially missed articles.

Eligibility Criteria

Types of Studies

We will include parallel group randomized controlled trials (RCTs) as well as both prospective and retrospective cohort studies. Studies with skin and soft tissue infection as its main focus and cellulitis as one of its subgroups will also be included in the review. Case control, case series, and case reports will

XSL•FO
RenderX

be excluded. Studies focusing on other skin conditions such as necrotizing fasciitis with noncellulitis sources will also be excluded. The detailed inclusion and exclusion criteria are organized into a table format in Table S1 in Multimedia Appendix 2.

Types of Participants

Our review will focus on all adult patients (aged 18 years or older) who were diagnosed with cellulitis or erysipelas in any health care setting. Cellulitis diagnostic criteria are based on individual studies.

Type of Intervention

We will include all studies comparing oral versus IV administration of antibiotics for the treatment of cellulitis. The antibiotic agent does not have to be the same across the different treatment groups within the study, nor does it have to be from the same class. For example, if a study compares IV cephalosporin versus an oral macrolide, it will be included in our analyses. Studies comparing antibiotics against placebos or other types of alternative treatments will be excluded. We are only focusing on antibiotics; hence, other rarer causes of cellulitis such as fungal infections will be excluded.

Outcomes

The primary outcome of our review will focus on the duration of infection resolution, which may vary across studies and may need to be adjusted based on our included articles' definition of infection resolution. Our second outcomes include incidence of severe systemic infection or mortality, patients' quality of life (QOL) as measured by QOL scores based on each included study, incidence of adverse events such as nausea and vomiting, length of hospitalization for inpatients or number of hospitalizations for cellulitis in studies measuring outpatients, and incidence of *C difficile* infection.

Study Screening

A total of 2 independent authors will perform title and abstract screening individually and in duplicate using Covidence, a web-based systematic review tool [8]. If both reviewers are in agreement, a study will move on to full-text screening. Any conflicts between reviewers will be resolved through discussion involving a third author. Full-text screening will also be conducted in the same manner. If a full text cannot be found on publicly available domains, attempts will be made to reach out to the authors for a potential copy of the article with relevant data.

Data Collection

All data will be collected using a priori developed data collection sheet within Excel (Microsoft Corp), with 2 reviewers working independently and in duplicate, resolving conflicts through discussion and third-party arbitration. The prepiloted forms will be tested using 10 of the first included studies. For any full texts that are not available in the public domain or databases and for any missing data, we will attempt to contact the authors for further clarification and assistance.

Risk of Bias Assessment

The risk of bias (RoB) assessments of each analyzed study will be performed by 2 independent reviewers in duplicate. The RoB of RCTs will be assessed through RoB 2.0, a revised tool to assess RoB in randomized trials [9]. The reviewers will assess bias across the 5 outlined domains: bias arising from the randomization process, from deviation from intended interventions, from missing outcome data, from the measurement of outcomes, and from the selection of reported results. The overall RoB will be compiled using the calculation algorithm provided within the tool.

For cohort studies, the ROBINS-I tool will be used, which is a tool for assessing RoB in nonrandomized trials for interventions [10]. The 7 domains included in the assessment include bias from confounding, from selecting patients into the study, from classification of intervention, from deviations from intended intervention, from missing data, from the measurement of outcomes, and from the selection of reported outcomes. The overall risk will also be calculated using the algorithms provided within the tool itself.

Data Items

Our prepiloted data extraction form will include the following data items:

- Bibliometric data: authors, year of registration, trial registration number, and digital object identifier.
- Methodology: number of participating centers, location of the study, method for blinding, randomization methods, treatment setting (inpatient vs outpatient), and follow-up duration.
- Baseline data: total sample size, mean age, sex with number of female patients included, comorbidities, choice of antibiotic, route of administration, frequency and duration of administration, daily and cumulative dosage, and species of organisms identified if performed.
- Outcome data: duration to infection resolution, duration to symptom improvement, incidence of severe infection, mortality, QOL scale and respective score, length of hospitalization, incidence of adverse events, and incidence of *C difficile* infection.

Statistical Analysis

We will first provide a comprehensive qualitative synthesis of all of the included studies, summarizing their characteristics and findings in organized text and table format in accordance with the PRISMA reporting guidelines.

If there are sufficient similar studies that will be meaningful for an aggregate analysis, we will perform meta-analyses for a weighted effect of the interventions across different studies. We will conduct our quantitative analysis using the computer program Review Manager (RevMan, version 5.4; Cochrane) [11]. We will use a random-effects model, and in cases where the heterogeneity cannot be explained, we will perform a sensitivity analysis using a random-effects model as well. For continuous outcomes such as duration of infection resolution and length of hospitalization, a mean difference with a 95% CI will be used. For dichotomous outcomes such as mortality or

XSL•FO
RenderX

incidence of severe infection, a Mantel-Haenszel odds ratio with 95% CIs will be used. If the events are rare, a Peto odds ratio will be used instead. If there are not enough meaningful data for meta-analysis for any particular outcome, we will qualitatively describe the results across studies.

The heterogeneity of the included studies will be assessed using a combination of visual inspection of the forest plots along with the I^2 statistic according to the Cochrane Handbook. We will consider an I^2>50% to be seriously heterogeneous and an I^2>75% to be very seriously heterogeneous.

In the case of missing data, we will attempt to contact the authors of the original study. Missing SDs will be inputted using methods outlined in the Cochrane Handbook for Systematic Review of Interventions using correlation coefficients.

Regarding the overall assessment of the quality of evidence included in the review, 2 independent reviewers will perform the GRADE (Grading of Recommendations, Assessment, Development, and Evaluation) analysis [12]. Any discrepancies will also be resolved through discussion.

Ethical Considerations

Ethics approval is not applicable to this study as this is a review study and no original data pertaining to humans or animals will be collected. No individual patient data are collected and all research data collected from original studies will remain anonymized.

Results

We will share the results of this study through peer-reviewed academic publications and conference presentations. We will continue to perform updating the searches in all databases every 2 months for any new data to be included in the systematic review. This project received no funding or financial assistance. Data analysis is currently underway, and the results are expected to be submitted for publication in late November 2023.

Discussion

This protocol outlines the planned systematic review and meta-analysis to compare the efficacy of oral and IV antibiotic administration in the treatment of cellulitis. Because of the vast selection of options available to physicians and the lack of quality evidence or rigorous reviews, there has been significant variation between guidelines and physician preferences. Some antibiotics may be available for both IV and oral administration, while others may only be suitable for one of the routes. Therefore, we also hope to aggregate the evidence from the literature first and then elucidate the indications for the usage of either route of administration, potentially also comparing their usage for similar infection profiles to assess their efficacy.

Our review will have several strengths and weaknesses. In terms of strengths, we will not be placing any language or time restrictions in our search strategy to ensure broad inclusion of all currently available evidence. We will also include both prospective and retrospective cohort studies in addition to RCTs to increase our pooled sample size. As a weakness, the quality of our meta-analysis may be limited by our inclusion of cohort studies, which is inherently weaker on the hierarchy of evidence with a potentially higher RoB. However, to mitigate this, we will analyze RCTs and cohort studies in separate pools, as well as using tools such as RoB 2.0 and ROBINS-I to rigorously assess the quality of the included studies based on the Cochrane Handbook. We will also conduct a subgroup analysis with only high-quality evidence and compare those with the pooled results. Additionally, because of the variations that exist within guidelines and physician practices, we also expect potentially significant heterogeneity between our included studies. We will assess this heterogeneity quantitatively and report on it in our final review. An additional limitation of our review is that, despite placing no language restrictions, the databases searched are primarily Western, English-based databases, meaning additional non-English data may be missed. We are only focusing on adults aged 18 years or older; hence, the value of this study for patients aged 18 years or younger may be limited.

There have been several attempts at assessing the different routes of antibiotic administration for the treatment of cellulitis. Brindle et al [3] conducted a systematic review on cellulitis treatments with the route of administration as a subfocus, finding that there are only a few low-quality randomized trials comparing the different routes, showing no difference between IV and oral treatments. Cross et al [6], with their primary focus on the duration of therapy, arrived at a similar conclusion. This study hopes to build upon these previous findings, as we have the routes of administration as our primary comparison [6]. We will also include observational studies and place no language barriers in our inclusion criteria, with the hope that it could provide additional valuable data upon Brindle et al's [3] and Cross et al's [6] conclusions on oral and IV treatments being equivalent. We hope the results of this study will inform the future prescribing practice of physicians treating cellulitis, especially in deciding oral versus IV treatments. This would not only benefit the patients but also help control the widening spread of antibiotic resistance in the community.

Acknowledgments

The authors received no funding or financial assistance for the drafting of this paper. All data from the included studies will remain anonymized, and the privacy of the individual subjects will be respected.

Data Availability

Data sharing is not applicable to this article, as no data sets were generated or analyzed during this study.

Authors' Contributions

RY, JJ, YW, and WH were responsible for the inception of the project, including this protocol for the planned systematic review, and made significant contributions to the writing and revision of the manuscript. YJ, EQ, and CY made significant contributions to the drafting of the protocol as well as its revision before submission. CJ, MW, KX, XZ, and YJ made contributions to drafting the final manuscript, substantially reviewed it, and assisted in its final revision.

Conflicts of Interest

None declared.

Abstract

Background: Gestational weight gain (GWG) is a crucial determinant of maternal and child outcomes yet remains an underused target for antenatal interventions in low- and middle-income countries (LMICs).

Objective: This systematic review aims to identify and summarize educational, behavioral, nutritional, and medical interventions on GWG from randomized controlled trials conducted in LMICs.

Methods: Randomized controlled trials that documented the effects of antenatal interventions on GWG in LMICs will be included. The interventions of interest will be educational, behavioral, nutritional, or medical. A systematic literature search will be conducted using PubMed, Embase, Web of Science, CINAHL (Cumulative Index to Nursing and Allied Health Literature), and the Cochrane Library from the inception of each database through October 2022 (with an updated search in January 2024). A total of 2 team members will independently perform the screening of studies and data extraction. A narrative synthesis of all the included studies will be provided. The risk of bias will be assessed using the Cochrane Risk of Bias tool. The certainty of the evidence for each homogeneous group of interventions will be assessed using the GRADE (Grading of Recommendation, Assessment, Development, and Evaluation) approach. A narrative synthesis of the included studies will be conducted to summarize mean differences (with 95% CIs) for continuous outcomes and risk ratios, rate ratios, hazard ratios, or odds ratios (with 95% CIs) for dichotomous or categorical outcomes. Available information on the costs of interventions will also be summarized to facilitate the adoption and scale-up of effective GWG interventions.

Results: The development of the research questions, search strategy, and search protocol was started on September 20, 2022. The database searches and the importation of the identified records into Covidence were performed on October 7, 2022. As of September 2023, the title and abstract screening was ongoing. The target completion time of this systematic review is April 2024.

Conclusions: Without effective interventions to manage GWG, the potential to improve maternal and child health through optimal GWG remains unrealized in LMICs. This systematic review will inform the design and implementation of antenatal interventions to prevent inadequate and excessive GWG in resource-limited settings.

Trial Registration: PROSPERO (International Prospective Register of Systematic Reviews) CRD42022366354; https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=366354

Introduction

Gestational weight gain (GWG) refers to the gain in body weight during pregnancy. GWG can be measured as total weight gain over the course of pregnancy or the rate of weight gain over a specific period (eg, in a week or in a month). The National Academy of Medicine, formerly the Institute of Medicine (IOM), recommends that women with underweight, normal weight, overweight, and obesity before pregnancy gain, respectively, 12.5 to 18 kg (0.44 to 0.58 kg/week in the second and third trimesters), 11.5 to 16 kg (0.35 to 0.50 kg/week), 7 to 11.5 kg (0.23 to 0.33 kg/week), and 5 to 9 kg (0.17 to 0.27 kg/week) [1]. Weight gain below or above these thresholds is considered inadequate or excessive GWG.

GWG is an important determinant of short- and long-term maternal and child health. On the one hand, pregnant women who gain inadequate gestational weight have elevated risks of small-for-gestational-age births [2], preterm birth [2], low birthweight [3], and infant mortality [4]. On the other hand, pregnant women with excessive GWG experience higher risks of macrosomia [2], large-for-gestational-age births [2], maternal morbidity [5], postpartum weight retention [6], and an increased risk of overweight and obesity among their children [7]. In addition to the critical impacts of GWG on pregnancy outcomes, maternal weight can also be monitored and feasibly modified during pregnancy. Therefore, GWG is a critical indicator for monitoring the overall health of the pregnancy and an important target for antenatal care [1].

Exceptionally high levels of inadequate GWG have been documented in low- and middle-income countries (LMICs). We previously reported that the mean levels of GWG were well below the IOM recommendation in almost all low- and middle-income world regions [8]. The regional level of GWG is particularly low in sub-Saharan Africa and South Asia, both of which meet only around 60% of the IOM recommendation [8]. In the meantime, an emerging burden of excessive GWG has become of concern in LMICs, as several countries in sub-Saharan Africa have over 15% of pregnant women gaining excessive GWG [9]. This concerning trend of excessive GWG may be a consequence of and further compounded by the nutrition transition to Westernized diets, sedentary lifestyles, and the rising prevalence of overweight and obesity [10-12].

Previous interventions on GWG were conducted primarily in high-income countries, often focusing on preventing excessive GWG through lifestyle interventions on dietary intake and physical activity [13-17]. In low- and middle-income settings, the effects of various interventions on inadequate GWG are unclear, and interventions to prevent excessive GWG are scarce. As a result, GWG remains severely underused in antenatal monitoring and intervention in LMICs. An evidence synthesis of interventions for GWG management will fill this critical gap and guide the design and implementation of culturally appropriate and context-relevant interventions on GWG in resource-limited settings.

This systematic review aims to identify and summarize educational, behavioral, nutritional, and medical interventions on GWG from randomized controlled trials (RCTs) in LMICs. This review will provide critical information to inform the design of antenatal interventions or intervention packages aimed at helping pregnant women prevent inadequate and excessive GWG.

Methods

Research Question

What are the effects of antenatal interventions (eg, educational, behavioral, nutritional, and medical) on GWG in LMICs?

Eligibility Criteria

Inclusion Criteria

The inclusion criteria were as follows:

1. RCTs, which could be individually randomized, cluster randomized, or have a mixture of individual and cluster randomization.
2. Participants were pregnant at enrollment or enrolled before pregnancy and followed up in pregnancy.
3. Studies conducted in a low-income, lower-middle-income, or upper-middle-income economy defined by the World Bank country classification for the 2023 fiscal year.
4. Interventions provided to women during pregnancy. The intervention could be educational, behavioral, nutritional, or medical. This scope of the interventions is based on the conceptual framework provided by the IOM guidelines regarding the determinants of GWG [1]. Examples of potential interventions include counseling about healthy eating, physical activity, or overall lifestyle; nutrition education on dietary intake; counseling on gestational weight management; anti-infectious regimen; single or multiple micronutrient supplementation; and macronutrient and food supplementation.
5. GWG was included as one of the study outcomes. GWG could be quantified by any metrics, including (but not limited to) total GWG in absolute amount, GWG z-score or adequacy ratio based on references or recommendations, and weekly or monthly rate of GWG. We will include GWG outcomes calculated based on body weights objectively measured by study teams.
6. The intervention could be provided alone or in combination with a cointervention that was similar across study arms.
7. At least 1 arm in the study did not receive the intervention of interest.

XSL•FO
RenderX

8. No restrictions will be placed on the year or sample size of the study.

Exclusion Criteria

The exclusion criteria of the studies included:

1. Studies that did not report GWG as 1 of the study outcomes.
2. Studies that used body weight measures based on self-reports or medical record abstraction due to the concern of measurement error.
3. Studies conducted exclusively among women with pre-existing health conditions, such as anemia, human immunodeficiency virus infection, or diabetes. However, studies restricted to women with underweight and women with overweight or obesity will still be included.
4. Observational studies (eg, cohort, case-control, and cross-sectional studies).
5. Interventional studies that did not use individual or cluster randomization.
6. Editorials, commentaries, opinions, or review papers (these will, however, be used to identify relevant original studies).
7. Studies reported in languages other than English.

Information Source

We will conduct the literature search using PubMed, Embase, Web of Science, CINAHL (Cumulative Index to Nursing and Allied Health Literature), and the Cochrane Library from the inception of each database through October 2022. Our search covers the 3 databases (ie, MEDLINE, Embase, and the Cochrane Library) recommended by the Cochrane Handbook for Systematic Reviews of Interventions [18]. We will also review the references of the previous systematic reviews of a similar topic to locate additional studies.

Search Strategy

We developed the PubMed search strategy first and then translated the search strategy into the syntax appropriate for the other databases. The search strategies for different databases are provided in Multimedia Appendices 1-5. We examined the sensitivity of the search strategies by confirming that several sentinel papers were identified. The initial search occurred on October 7, 2022, and an updated search will be conducted in January 2024.

Data Management

We will use EndNote (version 20; Clarivate Analytics) to store the records retrieved from the databases. We will then import the records into Covidence (Veritas Health Innovation), an internet-based program that facilitates the streamlined management of systematic reviews. Duplicate records will be detected and removed first by EndNote and then by Covidence.

Selection of Studies

A total of 2 team members will independently screen the titles and abstracts of the identified studies based on the eligibility criteria, and 2 team members will then independently review the full texts of the remaining studies to confirm final eligibility. Disagreements between reviewers will be resolved by discussion or by a third reviewer, when necessary, at both the stage of title and abstract screening and the full-text screening. The interrater agreement will be quantified by calculating the raw percentage of agreement and the Cohen κ coefficient. Specific reasons for study exclusions will be documented and summarized using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [19].

Data Extraction

We will conduct data extraction using the extraction function in Covidence. A total of 2 reviewers will independently extract the data of the retained studies using a data extraction form that will be pilot-tested on 5 randomly selected studies. Disagreements in the extracted information between reviewers will be resolved by discussion or by a third reviewer. We will extract the following information: study reference, setting and country of the study population, calendar year of intervention, randomization approach, sample size (number of clusters for each group, and number of participants in each group), sample characteristics (eg, age and socioeconomic status), timing and duration of intervention, description of the intervention, control, primary and secondary study outcomes, approach to defining and measuring GWG, main findings (with point estimates and measures of variance), and cost of the intervention (if available). If a publication is missing or unclear on any important study detail, we will contact the corresponding authors of the studies to obtain the information. Multiple reports of a single study will be collated as additional results may be provided in different reports. The data extraction tables are provided in Multimedia Appendices 6 and 7.

Risk of Bias Assessment

A total of 2 reviewers will independently assess the risk of bias, and any disagreement will be resolved by discussion and by a third reviewer when necessary. We will use version 2 of the Cochrane risk-of-bias tool (RoB 2) [20], which considers the following 5 domains: bias arising from the randomization process, bias due to deviations from intended interventions, bias due to missing outcome data, bias in the measurement of the outcome, and bias in the selection of the reported results. For cluster-randomized trials, we will additionally consider bias from the timing of identification and recruitment of individual participants in relation to the timing of randomization [21]. Each domain will be judged as “low risk of bias,” “high risk of bias,” or “some concerns.” We will consider a study to be of low risk of bias if all domains are judged to have a low risk. We will consider a study to be of high risk of bias if at least 1 domain is judged to have a high risk or ≥3 domains are judged to have some concerns. We will consider a study to have some concerns if 1 or 2 domains are judged to have some concerns, but none of the domains is judged to have a high risk [20]. We will summarize the risk of bias assessment in tabular form and present the judgment for each domain with a justification [20].

Data Synthesis

A narrative synthesis of all included studies will be presented in the data extraction tables shown in Multimedia Appendices 6 and 7. Effect estimates for continuous outcomes will be expressed as mean differences (with 95% CIs) comparing the intervention group with the control group. Effect estimates for dichotomous and categorical outcomes will be expressed as risk

XSL•FO
RenderX

ratios, rate ratios, hazard ratios, or odds ratios (with 95% CIs), comparing the intervention group with the control group. In addition to the narrative synthesis, we will conduct meta-analyses if a consistently defined intervention-outcome effect was reported in at least 3 studies.

Assessment of Certainty of Evidence

The overall certainty of the evidence for each reasonably homogeneous group of interventions will be assessed using the Grading of Recommendation, Assessment, Development, and Evaluation (GRADE) approach, which considers the risk of bias, publication bias, imprecision, inconsistency, and indirectness [22-27]. The strength of the overall evidence will be judged as high, moderate, low, or very low [22].

Registration and Reporting

This protocol was registered with PROSPERO (International Prospective Register of Systematic Reviews). The registration ID is CRD42022366354. In the event of protocol amendments, the date of each amendment will be accompanied by a description of the change and its rationale on PROSPERO. We prepared this protocol following the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) [28]. We will report the systematic review following the Cochrane Handbook for Systematic Reviews of Interventions [18] and the PRISMA guidelines [19].

Results

We started the development of the research questions, search strategy, and search protocol on September 20, 2022. On October 7, 2022, we performed the searches of all databases based on the search strategies and imported the identified records into Covidence. As of September 2023, the title and abstract screening was ongoing. We identified 33,664 nonduplicate records from all databases. As of September 25, 2023, a total of 8958 (26.6%) records had received 2 votes, and 8351 (24.8%) records had received 1 vote. The target completion time of this systematic review with the complete paper is April 2024.

Discussion

GWG has critical implications for the short- and long-term health of the mother and the child. Adequate GWG supports the growth and development of the fetus, while both inadequate and excessive GWG lead to adverse outcomes. LMICs have exceptionally high levels of inadequate GWG [8] and an emerging burden of excessive GWG [9]. Previous interventional studies on GWG were predominantly in high-income countries, with a focus on the prevention of excessive weight gain through dietary and physical activity interventions. Due to differences in stature, body composition, dietary practice, food environment, access to obstetric services, and other contextual factors, the effective and appropriate interventions on GWG differ between high-income countries and LMICs. There is, however, a limited understanding of the effective GWG interventions in low- and middle-income contexts. This systematic review will fill this knowledge gap and provide an updated evidence base to guide future interventions on GWG in resource-limited settings.

Food insecurity, inadequate dietary intake, and maternal undernutrition are the main nutritional contributors to inadequate GWG [1]. It is critical to ensure appropriate energy, macronutrient, and micronutrient intake to meet maternal and fetal needs during pregnancy [29]. Several nutritional interventions have been proposed or evaluated to accommodate the increased maternal nutritional needs during pregnancy [30]. Besides nutritional interventions, previous studies in sub-Saharan Africa also suggest alarmingly poor knowledge and practice of gestational weight management among pregnant women [31-33] and antenatal health care providers [34] in LMICs. Therefore, educational and behavioral interventions also hold promise for achieving optimal GWG for pregnant women in resource-limited settings.

In a recent systematic review and meta-analysis, Teede et al [17] evaluated the effects of antenatal lifestyle interventions pertaining to dietary intake and physical activity on GWG based on randomized trials in high-income countries and LMICs from 1990 to 2020. It was reported that, compared to routine antenatal care, overall lifestyle intervention (–1.15 kg; 95% CI –1.40 to –0.91 kg), lifestyle interventions on diet (–2.63 kg; 95% CI –3.87 to –1.40 kg), lifestyle interventions on physical activity (–1.04 kg; 95% CI –1.33 to –0.74 kg), and lifestyle interventions on dietary intake with physical activity (–1.35 kg; 95% CI –1.95 to –0.75 kg), were all associated with lower total GWG [17]. The review focused on lifestyle and behavioral interventions, and few included trials were from LMICs. Our systematic review will complement this work by covering all types of antenatal interventions with an explicit focus on low- and middle-income settings.

This systematic review will have several important strengths. First, we will cover the full spectrum of potential educational, behavioral, nutritional, and medical interventions that have shown promise in previous RCTs. Therefore, this review will contribute useful information to the design of antenatal intervention packages that seek to combine multiple forms of evidence-based interventions. Second, we will consider all metrics of GWG, including total GWG as an absolute value, GWG adequacy ratio based on references and recommendations, and weekly or monthly rate of GWG. As a result, this work will be informative for a nuanced understanding of the potential mechanisms of how different interventions affect the accrual of gestational weight. Finally, we plan to extract available information on the costs of the interventions that will facilitate the adoption and scale-up of effective GWG interventions. Potential limitations of this systematic review include the restriction to studies published in English and the expected heterogeneity of interventions and GWG metrics to be identified from the literature, which may make meta-analyses infeasible.

Without effective interventions to prevent both forms of inappropriate (inadequate and excessive) GWG, the potential to improve maternal and child health through optimal GWG remains unrealized in LMICs. This systematic review will provide a comprehensive and updated body of evidence that will contribute to the design, implementation, and scale-up of practical, effective, and cost-effective antenatal interventions or integrated intervention packages that help pregnant women in LMICs achieve optimal GWG.

Abstract

Background: Hemin is a commonly used drug in the treatment of acute attacks of porphyria, due to its capability of restoring normal levels of hemoproteins and respiratory pigments. In addition, this drug has demonstrated the capacity to induce the heme oxygenase (HO) enzyme. At the moment, there are 3 known HO isoenzymes in mammals: HO-1, HO-2, and HO-3. The first of these shows cytoprotective, antioxidant, and anti-inflammatory effects. Currently, medicines used in inflammatory disorders have increased toxicity, especially over longer time frames, which highlights the need to investigate new, safer options. Indeed, the current nonclinical evidence demonstrates the potential that hemin has a significant anti-inflammatory effect in several animal models of inflammation-related diseases, such as experimental colitis, without significant side effects. However, the underlying mechanism(s) are still not fully understood. In addition, past nonclinical studies have applied different therapeutic regimens, making it relatively difficult to understand which is optimal. According to the literature, there is a lack of review articles discussing this topic, highlighting the need for a summary and analysis of the available preclinical evidence to elucidate the abovementioned issues. Therefore, a qualitative synthesis of the current evidence is essential for the research and medical communities.

Objective: This systematic review aims to summarize and analyze currently available nonclinical data to ascertain the potential anti-inflammatory effect of hemin in animal models.

Methods: Throughout the development of this protocol, we followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) protocol. The comprehensive search strategy will be carried out in MEDLINE (PubMed), Web of Science, and Scopus without any filters associated with publication date. Only in vivo, nonclinical studies that evaluated the potential anti-inflammatory effect of hemin will be included. The evaluated outcomes will be the observed clinical signs, inflammatory and other biochemical markers, and macroscopic and microscopic evaluations. To analyze the potential risk of bias, we will use the risk of bias tool developed by the Systematic Review Centre for Laboratory Animal Experimentation (SYRCLE).

Results: Currently, it is not possible to disclose any results since the project is still in initial steps. More specifically, we are currently engaged in the identification of eligible articles through the application of the inclusion and exclusion criteria. The work was initiated in April 2023, and it is expected to be finished at the end of 2023.

Conclusions: Concerning the major gap in the literature regarding the underlying mechanism(s) and treatment-related properties, this systematic review will be essential to clearly summarize and critically analyze the nonclinical data available, promoting a clearer vision of the potential anti-inflammatory effect of hemin.

KEYWORDS

hemin; inflammation; animal models; nonclinical studies; in vivo

Introduction

Hemin, or ferriprotoporphyrin IX chloride, is an iron-containing metalloporphyrin that has been commonly used in clinical practice for several decades in the treatment of acute attacks of hepatic porphyria [1,2]. The development of porphyria is closely related to deficiency in the heme biosynthesis pathway, resulting in a lack of heme, which is necessary to produce several hemoproteins. In addition, heme precursors, which are directly and indirectly toxic to the human body, can also accumulate [3,4]. Treatment with hemin shows the capability of reducing heme deficiency by suppressing delta-aminolaevulinic acid synthase activity. Furthermore, this treatment also promotes the reduction of porphyrins and toxic precursors of heme [4,5]. Once hemin restores the normal levels of hemoproteins and respiratory pigments, the biological disturbances observed in patients with porphyria are attenuated [4,5].

However, the administration of hemin can also induce the expression of the heme oxygenase (HO) enzyme, which is known as a rate-limiting enzyme for heme catabolism and is responsible for the production of biliverdin, free iron, and carbon monoxide [2,6,7]. Currently, there are 3 identified HO isoenzymes in mammals: HO-1, HO-2, and HO-3 [2,6]. HO-1 is expressed as a response to tissue damage and demonstrates cytoprotective action capable of inhibiting the inflammatory response and oxidative stress [8]. On the other hand, the HO-2 and HO-3 isoenzymes are expressed constitutively in tissues involved in heme catabolism, which regulates the normal functioning of cells [7,9]. Considering the nonclinical evidence currently available, it has been suggested that HO-1 concentration and HO-1 mRNA are significantly elevated in cases of inflammation, such as in active ulcerative colitis [2,6,10]. In fact, through histological studies, it has been observed that HO-1 expression occurs mainly in macrophages; however, it can also be found in epithelial cells when there is an inflammatory response [11,12]. The capability of hemin to induce the expression of HO-1 makes it an interesting drug to evaluate for use in inflammatory-related diseases to ascertain its anti-inflammatory effect.

Considering the high toxicity of commonly used drugs for inflammation-related diseases, especially over the longer term, it is essential to investigate safer approaches that have comparable efficacy [13]. Several nonclinical studies have demonstrated that hemin is a significant anti-inflammatory without relevant side effects, highlighting it as a new potential pharmacological approach for the future. Considering the vast number of therapeutic regimens adopted in nonclinical studies, different animal models of disease, and different evaluated outcomes, it is essential to perform a review to clearly analyze and criticize the current evidence. Thus, this project will aim to develop a systematic review of the potential anti-inflammatory effect of hemin by summarizing and analyzing the nonclinical data currently available.

Methods

Overview

This protocol follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guideline [14]. During the development of the systematic review, 2 authors from the research group will be responsible for all steps concerning the selection of studies, including the title and abstract screening and assessment of study eligibility, as well as the data extraction process. In case of discrepancies during these steps, a third reviewer will be included to make a final decision. The project is currently ongoing, having been initiated in April 2023 with an anticipated completion date at the end of 2023.

Eligibility Criteria

Studies will be included for further analysis if they meet the follow PICOD (population, intervention, comparator, outcomes, study design) eligibility criteria:

- Population: Studies that use rodent models of inflammatory-related diseases. There will be no limitations in terms of species, strain, age, sex, or body weight since the purpose of this study is to analyze and synthesize all nonclinical data available.
- Intervention: Studies that administer hemin at any dosage, frequency, or treatment duration and with any route of administration in animal models of inflammatory-related diseases will be included, while studies that combine hemin treatment with another active drug or drugs will be excluded to clearly evaluate hemin's anti-inflammatory effect, excluding potential bias related to the use of other medicine.
- Comparator: Studies will be included if they have a nonexposed control group that is treated with any other pharmacological molecule, or even a placebo or usual care.
- Outcomes: All biochemical markers related to inflammation, with and without hemin treatment, will be analyzed. Studies with no relevant reported outcomes or that evaluate hemin administration for diseases as part of a summary of product characteristics will not be included.
- Study design: Only analytic, experimental, in vivo, nonclinical studies will be included.

Furthermore, studies written in languages other than English will not be included.

RenderX

Information Sources and Search Strategy

The biomedical electronic databases used for the highly sensitive search strategy will be MEDLINE (PubMed), Web of Science, and Scopus. The search will not be limited in terms of publication date. A comprehensive search strategy will be developed using descriptors related to 3 key terms: *hemin*, *inflammation*, and *nonclinical study*, as well as their synonyms, combined with the Boolean operators "AND" and "OR" to identify and select the eligible studies. The search strategies adopted for each biomedical electronic database are available in Multimedia Appendix 1.

Study Selection

Upon the application of the comprehensive search strategy in each database, the retrieved articles will be exported from the MEDLINE (PubMed), Web of Science, and Scopus databases to a systematic reviews web application (Rayyan QCRI; Rayyan). The first step will be to detect and exclude duplicates, and afterward the titles and abstracts will be analyzed by 2 independent reviewers in order to select relevant and potentially eligible studies according to the inclusion and exclusion criteria. After this process is completed, the same 2 independent reviewers will assess the full text of each study, deciding whether the article is eligible or not considering the inclusion and exclusion criteria. In case of discrepancies and lack of consensus between the 2 reviewers in these steps, a third reviewer will be included to make a final decision. The process of selection will be summarized using a PRISMA flowchart.

Data Collection Process

Upon selection of eligible studies, the 2 independent reviewers will extract them to a standardized data extraction document in Excel (Microsoft) that will be developed to extract the data of interest, including article identification (authors' names and year of publication), animal-related parameters, disease-related parameters, hemin treatment conditions, and outcomes of interest. Once again, in case of discrepancies between the reviewers, a third reviewer will be included to make the final decision. The data of interest will be extracted from the text, graphs, and tables from each included article.

Data Items

Population

We will only consider studies based on animal models, and the data of interest to be extracted will be related to species, strain, sex, age, and body weight.

Intervention

We will only consider studies that administer hemin to the subjects. The parameters of interest will be dosage, frequency of administration, route of administration, and duration of treatment.

Comparator

We will not consider any comparator-related parameters.

Outcomes

The data concerning the outcomes will be related to observed clinical signs (dichotomous measures), inflammatory and biochemical markers (continuous quantitative measures), macroscopic evaluation (dichotomous measures), and microscopic evaluation (dichotomous measures).

Study Design

Throughout the analysis of the in vivo nonclinical studies, the data of interest to be extracted will be related to identification of inflammatory-related diseases, their severity, and their chronicity.

Risk of Bias Assessment

The potential risk of bias will be identified and analyzed using the risk of bias tool of the Systematic Review Centre for Laboratory Animal Experimentation (SYRCLE) [15]. For each study, each component of the SYRCLE tool and the global study rating will be graded as low, moderate, or high. The final grade will be also decided considering an average of all individual components. The reporting quality and the risk of bias assessments will be independently performed by 2 different reviewers, after the data collection process is completed. Any disagreements will be discussed and arbitrated by a third reviewer.

Registration and Reporting

This systematic review protocol has been registered in an international prospective register of systematic reviews (PROSPERO CRD42023406160). Throughout the development of this systematic review, any potential modification of the protocol will be reported.

Results

Currently, the project has included 50 of the 1110 retrieved articles for qualitative synthesis based on the established inclusion and exclusion criteria. The data of interest are being carefully extracted by the 2 independent reviewers. The work is being performed by a pharmacologist team without any external funding and was initiated in April 2023. It is expected to be finished at the beginning of 2024.

Discussion

Current systematic reviews make it is possible only to determine that there is substantial variability in protocols for treatment with hemin, such as the dose, frequency of administration, and duration. However, even with different therapeutic regimens, this drug has shown a significant anti-inflammatory effect, mainly related to its capability to induce HO-1 without any relevant side effects.

It is clear that the majority of pharmacological approaches used in chronic inflammatory-related diseases aim to induce and maintain a remission phase in patients [13]. However, these approaches normally have several side effects, especially considering the long time frame of the treatment regimens, which can significantly decrease the overall quality of life of patients [13]. Thus, it is essential to investigate safer pharmacological tools, either by developing new drugs or by repurposing already accepted and extensively studied ones. Hemin is one of the latter, and it represents an interesting

XSL•FO
RenderX

pharmacological approach to treatment of inflammatory-related diseases, considering its efficacy and safety over the short or long term. Indeed, several nonclinical studies have already demonstrated that hemin has a significant anti-inflammatory effect in different contexts, such as in inflammatory bowel disease [2,6,16,17], kidney dysfunction [18-20], sepsis [21-23], arthritis [24,25], pancreatitis [26-28], cardiac infarction [29], and airway inflammation [30-32].

We emphasize a major limitation regarding the methodology of this project, which is the absence of clinical evidence. Indeed, it would be interesting to analyze clinical data regarding the potential anti-inflammatory effect of hemin; however, the number of studies is relatively small and there have been no clinical trials on this topic. Therefore, we only considered nonclinical in vivo studies, since this approach allowed for the most controlled environment possible.

In conclusion, the main findings from this project may have a pivotal role in the research and medical communities, since we will summarize and discuss, for the first time, preclinical evidence regarding the potential anti-inflammatory effect of hemin. Indeed, considering the need to investigate safer pharmacological approaches for inflammatory diseases, this review should highlight an interesting new tool for future consideration, revealing its efficacy and safety as demonstrated in animal models.

Acknowledgments

Abstract

Background: Resistance training has been consistently shown to have multiple health benefits, especially for patients who have undergone bariatric surgery. Patients who have undergone bariatric surgery are recommended to participate in resistance exercise; however, protocols and guidelines for resistance training remain poorly implemented.

Objective: This is a protocol for a systematic review and possibly a meta-analysis that will synthesize evidence of the effects of resistance exercise on changes in body composition, muscular strength, overall weight loss or maintenance of weight loss, and quality of life in patients after metabolic and bariatric surgery (MBS). The findings of this study may provide practice recommendations for resistance training among patients who have undergone MBS.

Methods: We registered this systematic review on PROSPERO (CRD42023464928) on September 18, 2023. A systematic search of electronic databases (Embase, PubMed, Scopus, Web of Science, and CINAHL) was conducted on studies published from January 1, 1991, to May 15, 2023, to identify English-language human studies on adult patients who have undergone MBS that include a resistance training intervention and describe outcome measurements of body composition or strength. Screening will be performed using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, and relevant data elements will be extracted.

Results: Searches and screenings commenced in May 2023. Data extraction and analyses will be completed by the end of December 2023, after which findings will be synthesized and reported by the end of March 2024.

Conclusions: This systematic review will summarize the evidence regarding resistance training in patients after MBS. The findings from this systematic review and possible meta-analysis may provide practice recommendations for resistance training protocols in this patient population and identify characteristics of protocols with the best adherence and outcomes. With these results, we anticipate that we will gain a deeper understanding of the role of resistance training after MBS.

Introduction

Obesity negatively affects nearly every organ system. Since the National Institutes of Health published a statement on gastrointestinal surgery for severe obesity in 1991, metabolic and bariatric surgery (MBS) has been extensively studied over the last 30 years. Surgical procedures as well as perioperative protocols continue to evolve. The benefits and favorable outcomes of MBS have been consistently proven to be durable for up to 20 years after surgery. These outcomes include greater than 60% excess body weight loss (%EBWL); superiority over diet, exercise, and other lifestyle interventions in attaining significant and durable weight loss; improvement in obesity-related comorbid conditions such as glycemic control in type 2 diabetes mellitus [1], obesity-associated cancers [2], and nonalcoholic steatohepatitis [3]; and improvement in quality of life and overall mortality [2,4]. The evidence has been so robust that the American Society for Metabolic and Bariatric Surgery and the International Federation for the Surgery of Obesity and Metabolic Disorders have convened to produce a joint statement on the current available scientific information on MBS in 2022, which has expanded the indications for MBS to include individuals with a BMI ≥35 kg/m^2, regardless of the presence, absence, or severity of comorbidities; individuals with metabolic disease and a BMI of 30-34.9 kg/m^2; individuals in the Asian population with a BMI ≥27.5 kg/m^2; and appropriately selected children and adolescents [4].

To augment the health benefits of MBS, patients who have undergone bariatric surgery are recommended to participate in regular physical activity [5], although the recommended guidelines remain somewhat nonspecific. The American College of Sports Medicine recommends the same amount of physical activity for both individuals with obesity and patients who have undergone bariatric surgery [6]. Patients who have undergone MBS may require different recommendations than those who have not undergone surgery, as patients after MBS consume what is considered a very low-calorie diet and experience large and rapid weight loss. The rapid weight loss is not only fat mass, but it has been shown to also be fat-free mass, including muscle mass, which is associated with a decrease in muscle strength [7,8].

Resistance training is defined as a form of physical activity that is designed to improve muscular fitness by exercising a muscle or a muscle group against any external resistance [6]. This can include modalities such as machines, free weights, bands, and body weight movements. Resistance training should be implemented to mitigate sarcopenia or skeletal muscle loss, which has in turn been shown to improve strength in patients who have undergone MBS [9-11]. Resistance exercise has been proven to have many benefits. It may assist in the prevention and management of type 2 diabetes by decreasing visceral fat and improving insulin sensitivity [12,13]. It improves physical performance, movement control, walking speed, functional independence, cognitive capabilities, and self-esteem [13,14]. It has also been shown to improve balance and reduce the risk of falls in older adults, which may be a major cause of morbidity and death [15]. Therefore, muscle mass and strength are arguably the most crucial elements of body composition, given their contribution to independence and longevity.

Studies have shown that maintenance of (and in some cases gains in) muscle strength occurred in the context of massive lean body mass loss in patients who have undergone MBS [5,9,10]. The implementation of effective resistance training programs specifically designed for patients who have undergone MBS could help this patient population with favorable body recomposition by increasing fat loss while retaining and even building lean mass, bone mass, and muscular strength. Efforts toward creating specific recommendations for resistance training protocols in patients after MBS have been made based on a systematic review by Morales-Marroquin et al [16]. However, this review was small and based on 9 randomized controlled trials. The effects of resistance exercise in patients after MBS have not yet been assessed through meta-analysis.

With the new 2022 statement on the expansion of patients who should be considered for MBS in mind, the population of patients who have undergone MBS will likely continue to increase, necessitating clearer recommendations and practice guidelines for resistance training in this population.

This study aims to be the largest and most comprehensive systematic review of resistance training protocols and their effects on patients who have undergone MBS with regard to body composition, muscular strength, and relevant health outcomes. More importantly, it also aims to review which protocols have superior adherence and compliance after the implementation of resistance training. Lastly, we hope to offer practice recommendations for resistance training protocols that can be applied in this patient population with the ultimate goal of long-term healthy weight loss and weight maintenance.

Methods

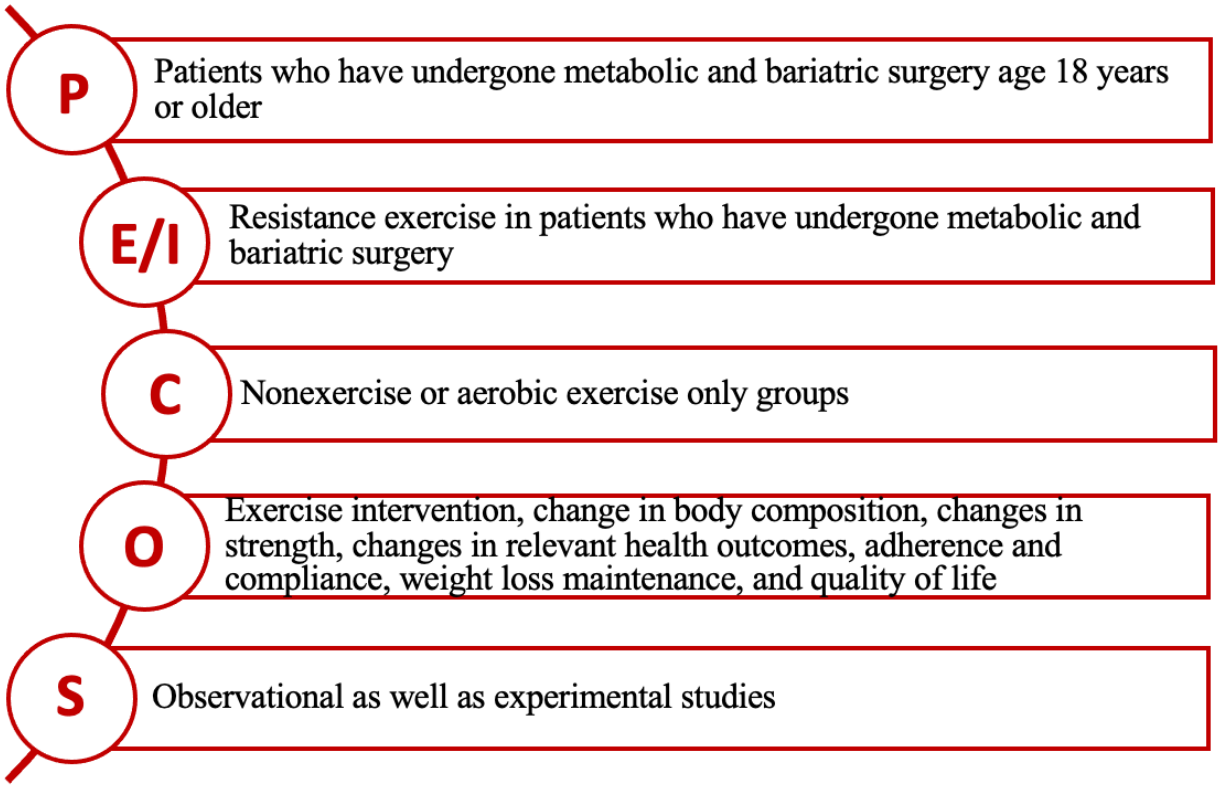
Ethical Considerations

As this study does not have the direct involvement of human participants, an institutional ethical review will not be warranted. However, to adhere to a strict methodology, the protocol of this systematic review and meta-analysis has been registered on PROSPERO (CRD42023464928) [17]. PROSPERO is an international database of prospectively registered systematic reviews, which provides a unique permanent registration number to the protocol that prevents duplication, thereby reducing reporting bias.

Review Question

Our review question is as follows: “What are the effects of resistance training on patients after MBS? Additionally, which resistance training intervention demonstrated the most improvement regarding body composition and relevant health outcomes, and which intervention had the best adherence?”

Inclusion and Exclusion Criteria



The PECOS (Population, Experiment, Comparator, Outcome, Study Design) framework was used to formulate eligibility criteria for this systematic review and meta-analysis [18]. Case series, case-control studies, retrospective and prospective cohorts, and randomized and nonrandomized clinical trials will

XSL•FO
RenderX

be eligible for inclusion. Studies published in other languages, case studies, editorials, posters, abstract-only studies, conference proceedings, animal studies, and reviews will be excluded. Studies that do not include resistance training as a component of the exercise intervention or those without quantitative data on outcomes of interest will also be excluded. We will use the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist.

Study eligibility criteria in the form of PECOS criteria are as follows (Figure 1): we will include studies with adult patients aged 18 years or older; individuals who have undergone MBS, including the following procedures—Roux-en-Y gastric bypass, sleeve gastrectomy, biliopancreatic diversion with duodenal switch, single anastomosis duodenal-ileal bypass with sleeve gastrectomy, gastric band, or revisional bariatric surgery; and those who have undergone a resistance exercise intervention; studies that include outcome measurements of body composition or strength; and articles that were published in English and were performed on humans. We will exclude studies that were not performed on adult human participants, are not in English, included patients who have not undergone MBS, did not include body composition or strength components as outcome measures, and had no resistance exercise component in the intervention.

Figure 1. PECOS (Population, Experiment, Comparator, Outcome, Study Design) framework of the study.

Informational Sources and Search Strategy

A systematic search of bibliographical electronic databases was conducted on studies published from January 1, 1991, to May 15, 2023, to identify English-language human studies. A comprehensive search and article retrieval strategy was planned by the study's investigators, guided by a library subject matter expert, to find potentially relevant articles in the following databases: Embase, PubMed, Scopus, Web of Science, and CINAHL. In accordance with the search development and optimization method proposed by Bramer et al [19], the search strategy was developed in Embase and then translated into the syntax of each of the other databases. The search strategy was optimized for each database using a thesaurus, free-text search terms, as well as Medical Subject Headings terms. Informed by the PECOS framework (Figure 1), search strings for each database were developed iteratively and revised as new search terms were discovered. The search strategy will be peer-reviewed by a second research librarian using the Peer Review of Electronic Search Strategies (PRESS) 2015 Evidence-Based Checklist [20].

Multimedia Appendix 1 includes the full search strategy in detail. Keyword criteria included combinations of the following words and phrases: bariatric surgery, gastric bypass, sleeve gastrectomy, gastric band, biliopancreatic diversion with duodenal switch, resistance training, and weight lifting. We will include studies on humans and in English from all geographical locations.

Screening

All records or articles will be imported into an intelligent, systematic review tool called Rayyan (Rayyan Systems Inc) for screening. After the deduplication, all records will be assessed by 2 independent reviewers to check for inclusion and exclusion criteria (Figure 1). Titles, abstracts, and full texts of articles will be screened in a systematic and sequential manner. All reasons for exclusion will be documented at each step of screening. A

XSL•FO
RenderX

PRISMA flow diagram will be used for describing the study selection process [21].

Data Extraction and Main Data Elements

A total of 2 reviewers will independently extract the relevant data elements from the eligible full texts of the articles and record these variables in a standardized code book. A double extraction method will be used to ensure accuracy and completeness. After data extraction, disparities will be resolved by consensus and discussion with the third reviewer, or a "tiebreaker." Attempts to contact the corresponding authors of the included articles will be made if more information about the individual study's data is needed. The following data elements will be extracted: (1) study title; (2) study author; (3) year; (4) evidence level; (5) quality score; (6) study design; (7) sample size; (8) sex (menopausal status, if in female individuals); (9) age; (10) geographic location (country); (11) operation (Roux-en-Y gastric bypass, sleeve gastrectomy, gastric band, revision bariatric surgery, biliopancreatic diversion with duodenal switch, or single anastomosis duodenal-ileal bypass with sleeve); (12) exercise intervention (type of exercise training [resistance, resistance + aerobic, aerobic only, or none]), postoperative initiation of intervention, frequency (days per week and minutes per session), intensity (sets and repetitions), and the duration of program (weeks or months); (13) exercise setting (supervised, nonsupervised, individual, group, and combined); (14) diet (protein intake); (15) key findings; (16) changes in body composition (%EBWL, total body weight loss [%TBWL], fat mass, fat-free mass, muscle mass, strength, and bone density); (16) how changes in body composition were measured; (17) how strength was measured; (18) changes in relevant health outcomes (heart disease, diabetes mellitus, obstructive sleep apnea, and osteoarthritis or degenerative joint disease); (19) measure of nonexercise physical activity; (20) adherence or compliance; (21) weight loss maintenance; (22) quality of life; (23) self-esteem; (24) habitual physical activity; and (25) length of follow-up.

The primary outcomes of interest in this study are changes in body composition (%EBWL, %TBWL, fat mass, fat-free mass, muscle mass, strength, and bone density). The secondary outcomes of interest include (1) relevant health outcomes (heart disease, diabetes mellitus, obstructive sleep apnea, and osteoarthritis or degenerative joint disease), (2) adherence and compliance, and (3) quality of life and self-esteem.

Quality or Risk of Bias Assessment

For the quality assessments of the included studies, the National Heart, Lung, and Blood Institute quality assessment tool will be used. A total of 2 reviewers will assess the quality of the full texts and will perform scoring independently. The kappa statistics will be calculated to measure the interrater agreement. The National Heart, Lung, and Blood Institute tool has 14 items in the checklist (Figure 2) to evaluate all essential components of original research studies. Quality will be rated as poor (0-4 out of 14 questions), fair (5-10 out of 14 questions), or good (11-14 out of 14 questions) as guided by the tool.

Figure 2. National Heart, Lung, and Blood Institute health quality assessment tool for observational, cohort, and cross-sectional studies.

NIH National Heart, Lung, and Blood Institute

Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies

Criteria	Yes	No	Other (CD, NR, NA)*
1. Was the research question or objective in this paper clearly stated?			
2. Was the study population clearly specified and defined?			
3. Was the participation rate of eligible persons at least 50%?			
4. Were all the subjects selected or recruited from the same or similar populations (including the same time period)? Were inclusion and exclusion criteria for being in the study prespecified and applied uniformly to all participants?			
5. Was a sample size justification, power description, or variance and effect estimates provided?			
6. For the analyses in this paper, were the exposure(s) of interest measured prior to the outcome(s) being measured?			
7. Was the timeframe sufficient so that one could reasonably expect to see an association between exposure and outcome if it existed?			
8. For exposures that can vary in amount or level, did the study examine different levels of the exposure as related to the outcome (e.g., categories of exposure, or exposure measured as continuous variable)?			
9. Were the exposure measures (independent variables) clearly defined, valid, reliable, and implemented consistently across all study participants?			
10. Was the exposure(s) assessed more than once over time?			
11. Were the outcome measures (dependent variables) clearly defined, valid, reliable, and implemented consistently across all study participants?			
12. Were the outcome assessors blinded to the exposure status of participants?			
13. Was loss to follow-up after baseline 20% or less?			
14. Were key potential confounding variables measured and adjusted statistically for their impact on the relationship between exposure(s) and outcome(s)?

Statistical Plan

The first results of all the finally included studies will be described succinctly in the form of a summary table. The pooled estimates with a 95% CI will be generated using the Comprehensive Meta-Analysis software (version 3.0; Biostat). A random-effects model will be used to calculate pooled estimates, as this is a more robust estimate regardless of heterogeneity [22]. Cochran Q and I^2 statistics will be used as indicators of heterogeneity. If enough studies are available in subgroups, then further analyses based on moderator variables, such as sociodemographic variables, country, and type of intervention, will also be conducted. Sensitivity analysis will be conducted to identify studies that may severely affect the pooled prevalence. A funnel plot and Egger linear regression test will be used to assess publication bias [23]. The significant level will be set as 2-sided and $P<.05$. Forest plots will be used to present the data.

Data Analysis and Presentation

We will present the extracted data in tabular form and as a systematic summary as required. A data extraction form will be developed before article analysis. The table will report the extracted variables as listed above in the *Data Extraction and Main Data Elements* section. If the findings are poolable, quantitative analysis will be conducted.

Our meta-analysis plan is as follows: the number of studies with positive, null, or negative findings will be presented. Effects of resistance exercise on changes in body weight, fat mass, lean body mass, muscle strength, quality of life, changes in health outcomes, and adherence will be examined using random effects models. The Comprehensive Meta-Analysis software will be used to analyze the data. The mean (SD) of the absolute change in the intervention and control groups will be reported. Pooled-effect estimates (effect size) will be expressed as the weighted mean difference (MD) between exercise and control groups for the outcomes listed above and as the weighted standardized MD for changes in the outcomes. $P<.05$ will be considered statistically significant. Heterogeneity will be assessed using I^2, with values interpreted as low at 25%, moderate at 50%, and high at 75%. The τ^2 and test of homogeneity will also be reported. Prediction intervals (PIs) will be calculated using the formula 95% PI = MD ± 2 τ^2. To identify sources of heterogeneity, sensitivity analyses with the one-study-removed procedure will be performed. Publication bias will be assessed with a visual inspection of the funnel plot and Egger regression test.

The reason a meta-analysis is a possibility and not definite is because we do not yet know if the group of studies will be sufficiently homogenous in terms of subjects involved, type of intervention (eg, resistance training), outcome, and the type of effect measure reported in each study to provide a meaningful summary. In other words, if studies are too heterogeneous to be comparable, the true effects in meta-analytical evidence may be obscured. It is possible to produce a narrative synthesis (systematic review) of the entire pool of studies and perform quantitative analysis (meta-analysis) only on the randomized controlled trials.

Results

The search for this systematic review commenced in May 2023. Data extraction and analyses will be completed by the end of December 2023, after which findings will be synthesized and reported by the end of March 2024. The plan for dissemination, however, is to publish the review's findings in a peer-reviewed journal and present findings at high-level conferences to share knowledge to help establish specific resistance exercise protocols in patients after MBS. A timeline is provided in Table 1.

Discussion

Overview

Our proposed systematic review will be a comprehensive review that synthesizes the effects of resistance training on the health outcomes of patients after MBS. We anticipate that this study will demonstrate the benefits of resistance training on weight loss, weight maintenance, increased strength, increased bone density, maintenance of lean muscle mass, and improvement in comorbid conditions. In addition, we anticipate there will be

XSL•FO
RenderX

an improvement in mental health, self-esteem, and quality of life.

The results of our review will be used to design resistance training protocols that may be prescribed to patients after MBS for optimal weight management and strength gains, as this population is at high risk of fat-free mass loss due to their very low-calorie diets and rapid weight loss. This will subsequently improve longevity in this patient population, as age-related sarcopenia, fragility, and increased risk of falls and fractures have high mortality rates [13]. Lastly, the results of this study will generate pertinent considerations for future research to continue improving the knowledge available on the benefits and application of resistance training in patients after MBS. If results from the review are suitable for pooling, this will be the largest review with quantitative analysis specific to resistance training protocols in patients after MBS.

Ultimately, the optimal protocol for resistance training is the one the patient will adhere to. Even with a clearly superior protocol, if the adherence rate is low, it will be of minimal benefit to the patient. According to a review by Bellicha et al [24], most patients do not reach the recommended levels of physical activity after bariatric surgery. A recent systematic review by Bond et al [25] demonstrated that participants who were assigned to the exercise interventions achieved only modest weight loss after 12 months, although none of the exercise interventions aligned with the 250-300 weekly minutes of moderate-intensity physical activity recommended by the American College of Sports Medicine and the 2018 physical activity guidelines for the management of obesity and prevention of weight recurrence. This study also showed that adherence rates were only reported in 2 studies [25]. The ideal protocol will look different for all patients; however, this study may provide further insight on which protocols have the highest adherence rates and what the characteristics of those protocols are. We will distinguish if there are differences in supervised versus nonsupervised sessions as well as individual versus group settings. Studies have shown that a critical component of sustained weight loss includes a sense of "reinvention" and an identity shift to a new lifestyle after successful weight loss [26,27]. Whatever the superior protocol is, it must be sustainable and habit-forming for patients who have undergone MBS.

Limitations

This systematic review will have limitations. There will be a degree of heterogeneity among the studies selected due to the variability of the research methodologies, settings, exercise interventions, diets, and outcome measurements. There is an inherent risk of reviewer bias, which will be mitigated by the use of tools for assessing risk of bias. We will attempt to minimize the bias in this review by following strategies: (1) we will perform a sensitivity analysis to examine if overall findings are sensitive to the exclusion of a study with low quality or a risk of bias; (2) we will ensure transparency on the methods; (3) at every stage of the systematic review, we will solicit inputs from subject matter experts; and (4) we will perform a risk of bias assessment in each study using the standardized tools. There is also a risk of missing pertinent literature on our research topic. A medical librarian at the first author's home institution was consulted and assisted in developing a broad search strategy to maximize the likelihood of identifying relevant articles. Additionally, many aspects related to resistance training are fully subjective, and many outcomes are not reflected in a continuous mathematical figure. There is a chance that any recommendations made after this study may not be statistically significant, but the goal is to perform as comprehensive a review on multiple study methodologies as possible and to report on multiple outcomes of interest that may potentially guide protocols in the future.

Dissemination Plan

The findings from this systematic review will be disseminated through a peer-reviewed journal article and presentations at academic conferences.

Conclusion

This study will provide a comprehensive review of the effects of resistance training in patients who have undergone MBS and will include data on outcomes regarding changes in body composition, strength, relevant health outcomes, adherence, and quality of life. This research will hopefully lead to the development of optimal resistance training practice recommendations for this patient population. This study may also shed light on a resistance training protocol that is best for adherence and long-term weight loss maintenance. With these results, we hope to provide a deeper understanding of the role of resistance training after MBS.

Acknowledgments

The authors would like to thank Ana Carroll and Aidy Weeks, Health Sciences Librarians at the Kirk Kerkorian School of Medicine at University of Nevada Las Vegas (UNLV) Library, for their help in suggesting search terminology and more efficient ways to search databases.

The publication fees for this article were supported by the School of Medicine Library Open Article Fund.

Abstract

Background: Hypertension is one of the most prevalent medical conditions that arise during pregnancy, resulting in maternal and neonatal complications. Mobile health (mHealth) has emerged as an innovative intervention for delivering maternal and child health care services. The evidence on the effectiveness of mHealth interventions in improving the health outcomes of pregnant women with hypertensive disorders is lacking. Therefore, there is a need for evidence synthesis using systematic review methods to address this evidence gap.

Objective: This review aims to determine the efficacy of mHealth interventions in improving maternal and neonatal outcomes among pregnant women with hypertensive disorders. The review will answer the following research questions: (1) What are the types of mHealth interventions used in pregnant women with hypertensive disorders? (2) Are the various mHealth interventions effective in improving maternal and neonatal health outcomes, health behaviors, and their knowledge of the disease? and (3) Are mHealth interventions effective in supporting health care providers to make health care decisions for pregnant women with hypertensive disorders?

Methods: This review will include randomized controlled trials, nonrandomized controlled trials, and cohort studies focusing on mHealth interventions for pregnant women with hypertensive disorders. Studies reporting health care providers use of mHealth interventions in caring for pregnant women with hypertensive disorders will be included. The search strategy will be tailored to each database using database-specific search terms. The search will be conducted in PubMed-MEDLINE, ProQuest, CINAHL, Scopus, Web of Science, and CENTRAL. Other literature sources, such as trial registries and bibliographies of relevant studies, will be additionally searched. Studies published in English from January 2000 to January 2023 will be included. A total of 2 review authors will independently perform the data extraction and the quality appraisal. For quality appraisal of randomized controlled trials, the Cochrane Risk of Bias 2 tool will be used. The Risk of Bias in Nonrandomized Studies of Interventions (ROBINS-1) tool will be used for nonrandomized controlled trials, and the Critical Appraisal Skills Programme checklist for

XSL•FO
RenderX

cohort studies will be used. Any disagreements between the 2 reviewers will be resolved through discussion and a third reviewer if required. A meta-analysis will be performed based on the availability of the data.

Results: As per the protocol, the study methodology was followed, and 2 independent reviewers conducted the search in 6 databases and clinical registries. Currently, the review is in the full-text screening stage. The review will publish the results in the first quarter of 2024.

Conclusions: The evidence synthesized from this systematic review will help guide future research, support health care decisions, and inform policy makers on the effectiveness of mHealth interventions in improving the maternal and neonatal outcomes of pregnant women with hypertensive disorders.

Introduction

Background

Hypertensive disorders of pregnancy (HDP) complicate 5% to 10% of pregnancies, leading to maternal, fetal, and neonatal morbidity and mortality [1]. According to American College of Obstetricians and Gynecologists guidelines, hypertension in pregnancy is classified as chronic or preexisting hypertension, gestational hypertension, preeclampsia or eclampsia, chronic or preexisting hypertension with superimposed preeclampsia-eclampsia, mild hypertension, and severe hypertension [2]. Globally, the incidence of hypertensive disorders during pregnancy had a 10.92% increment from 16.30 million (95% uncertainty interval [UI] 13.56-19.42 million) to 18.08 million (95% UI 15.26-21.11 million) in the last decade from 1990 to 2019. Regionally, the highest incidence of HDP in 2019 was detected in South Asia (3.84 million, 95% UI 3.16-4.62 million), followed by western sub-Saharan Africa (3.71 million, 95% UI 2.64-3.63 million) and eastern sub-Saharan Africa (3.12 million, 95% UI 2.64-3.63 million), respectively. Conversely, Australasia (30,110, 95% UI 23,080-38,670), Oceania (37,060, 95% UI 29,640-46,290), and Central Europe (78,060, 95% UI 64,040-94,230) had the lowest incidence estimates. There were approximately 27,830 deaths due to hypertensive disorders during pregnancy in 2019. Countries with low sociodemographic and human development indexes have an increasing burden [3]. According to the World Health Organization (WHO), maternal mortality remains “unacceptably high” worldwide every day, with some 830 women dying from a preventable cause of pregnancy or childbirth-related complications [4]. Most of these deaths (94%) that occurred in low-resource settings could have been prevented. High blood pressure during pregnancy is a major complication that accounts for nearly 75% of maternal deaths [5]. Therefore, tackling hypertension during pregnancy is an important global public health concern to date.

Some of the significant risk factors for HDP include a higher BMI, anemic conditions, and poor education. Maternal age, primiparity, multiple pregnancies, HDP in a previous pregnancy, gestational diabetes mellitus, preexisting hypertension, preexisting type 2 diabetes mellitus, preexisting urinary tract infection, a family history of hypertension, type 2 diabetes mellitus, and preeclampsia are possible nonmodifiable risk factors [6]. HDP was also associated with poor maternal, perinatal, and neonatal outcomes, especially in pregnant women with preeclampsia and eclampsia [7]. A higher burden of stillbirth was found in multiparous women with HDP [8]. A systematic review and meta-analysis reported that pregnant women with chronic hypertension showed high pooled incidences of superimposed preeclampsia (25.9%), cesarean section (41.4%), preterm delivery (28.1%), low birth weight (16.9%), neonatal unit admission (20.5%), and perinatal death (4%) [9]. Therefore, the identification and management of HDP should take priority in pregnant women to avoid preventable deaths and morbidities among mothers and their babies.

There is a moderate quality of evidence that recommends antihypertensive therapy for the management of HDP [10]. Single interventions are not likely to significantly reduce pregnancy-related mortality and morbidity. Instead, improving the overall quality of antenatal care across the health care system is required [11].

An innovative health intervention increasingly being used and tested in maternal and child health is mobile health (mHealth). mHealth refers to “the use of wireless and mobile information and communication technologies to support health and health care” [12]. Globally, mobile phone use is continuously expanding [13]. The International Telecommunication Union reported that about 4.9 billion people were using the internet in 2021. This has increased by 17% since 2019 [14]. The portability, instantaneous access, and direct communication capabilities of mobile technology enable prompt dissemination of health information, which improves medical and public health practices cost-effectively [15]. These qualities characterize mHealth, which enables better health care access and facilitates improved delivery of health care services. In the face of this technological reality, mHealth plays an innovative role in the delivery of health care. However, though the global use of mHealth is increasing, the effect it has on the improvement of outcomes is still unknown [16]. Although current evidence suggests that telemonitoring provides benefits for managing

XSL•FO
RenderX

patients at high risk for HDP, more research is needed to prove its safety and effectiveness [17].

Aim

This review aims to collate relevant data and provide evidence related to the effectiveness of mHealth interventions in improving maternal and neonatal outcomes among pregnant women with hypertensive disorders. This review will also identify the evidence gap in mHealth for antenatal care, which will guide further research, support health care professionals in their practice decisions, and inform policy makers as well as other stakeholders to implement changes in the health care system.

Methods

Overview

The systematic review protocol was designed based on the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 checklist [18]. The review has been registered in PROSPERO (CRD42022321686). The review will be conducted in accordance with the *Cochrane Handbook for Systematic Review of Interventions* [19].

Study Eligibility Criteria

The inclusion and exclusion criteria for the review are given in Textbox 1.

Textbox 1. The inclusion and exclusion criteria.

Inclusion criteria

- Randomized controlled trials, nonrandomized controlled trials, and cohort studies
- Studies with the population of pregnant women with hypertensive disorders (chronic hypertension; gestational hypertension; preeclampsia-eclampsia; chronic hypertension with superimposed preeclampsia; and the "hemolysis, elevated liver enzymes, low platelet count" syndrome) and health care providers using mobile health (mHealth) in providing care for pregnant women with hypertensive disorders
- mHealth interventions that use mobile technology, such as mobile phones, personal digital assistants, and other wireless devices such as wearables and tracking sensors, to support the health of pregnant women with hypertensive disorders and health worker decisions
- Studies with a control group receiving standard care, no intervention, other forms of digital interventions, antenatal counseling, dietary plans, yoga, and any form of breathing exercises
- Maternal mortality, maternal morbidities, perinatal death, and neonatal morbidities; knowledge of the disease and its management; and health behaviors such as early identification of warning signs
- English language
- Conducted between January 2000 and January 2023
- All settings across the globe

Exclusion criteria

- Noninterventional observational studies
- Other high-risk pregnancies, such as gestational diabetes; pregnant women with autoimmune diseases, fibroids, and thyroid disorders; and postnatal women with hypertensive disorders
- Nonmobile digital devices such as desktop computers, which are used for health management information systems and electronic health records
- Studies without comparison groups
- Outcomes other than health outcomes, such as the usability or feasibility of mHealth interventions
- Languages other than English

Search Methods for Identification of Studies

A search will be conducted in the following databases: PubMed-MEDLINE, ProQuest, CINAHL, Scopus, Web of Science, and CENTRAL by 2 independent reviewers (TP and AD). Medical Subject Headings (MeSH) terms, subject headings, and keywords will be searched electronically in all fields. Search strings will be developed using database-specific filters and tailored to each database using the search given in Multimedia Appendix 1.

Searching Other Sources

Additionally, ClinicalTrials.gov, the Clinical Trial Registry of India, and the WHO International Clinical Trials Registry platform will be searched for unpublished and ongoing trial reports. The reference list of retrieved articles will also be searched.

Data Management

Selection of Studies

The first stage of the screening process will involve 2 authors who will independently screen the titles and abstracts of the included studies (TP and AD). They will independently scrutinize the studies for inclusion and exclusion criteria with a prespecified form. For studies with insufficient data in the abstract, the full text will be retrieved and assessed for eligibility. If there is any disagreement between the 2 authors, they will discuss it, and if needed, the third author (ML) will be asked for an opinion. If any inexplicit data are found or any

XSL•FO
RenderX

data are missing, then the authors of the corresponding study will be contacted.

Data Extraction

Data will be extracted independently by 2 authors (TP and AD) using a standard data extraction form developed by the review authors (BN and JS). The variables recorded will be the authors' name, publication year, study period, journal of publication, the country where the study was performed, participant age, sample size, variables adjusted for in the analysis, and findings. The data extracted from each included study will be based on the following: type of mHealth interventions used, outcomes assessed, funding source, type of publication, source of the study if not published, and other study details necessary for risk of bias assessment. Disagreements will be resolved by discussion with the third author (JN).

Quality Appraisal

A total of 2 review authors (TP and AD) will independently assess the risk of bias in studies. The authors will independently assess randomization sequence generation, treatment allocation concealment, blinding, completeness of outcome data, selective outcome reporting, and other sources of bias for randomized controlled trials using the Cochrane Risk of Bias 2 tool [19]. The Risk of Bias in Nonrandomized Studies of Interventions (ROBINS-1) tool will be used to appraise the quality of nonrandomized controlled trials [20]. The Critical Appraisal Skills Programme checklist for cohort studies will be used [21]. We will resolve disagreements, if any, by discussing them with the third author to reach a consensus.

Data Synthesis and Analysis

Statistical analysis will be performed by SN and RN, referencing the *Cochrane Handbook for the Systematic Review of Intervention*. If there are adequate data, a meta-analysis will be performed using a random-effects model. Categorical data will be summarized using the odds ratio, relative risk, or hazard ratio. Continuous data will be summarized using the standardized mean difference. A forest plot will be generated. Sensitivity analysis will be performed if applicable.

Assessment of Heterogeneity and Bias Reporting

A funnel plot and Egger test will be performed to assess publication bias. When data from included studies can be pooled, statistical heterogeneity will be assessed by visual inspection of forest plots using the chi-square test and the I^2 statistic.

Subgroup Analyses

Trial characteristics (participants, design, interventions, outcomes, and risk of bias) will be examined, and based on them, subgroup analysis will be performed.

However, if we are not able to perform a meta-analysis due to insufficient studies or heterogeneity, the findings will be reported descriptively.

Ethical Considerations

The systematic review will be done using previously available data and will not include any personal information about individual participants. As a result, permission from a research ethics committee is not required.

Results

As per the protocol, the study was conducted following the methodology according to the *Cochrane Handbook for Systematic Review of Interventions*. A total of 2 independent reviewers conducted the search in the following 6 databases: PubMed-MEDLINE, ProQuest, CINAHL, Scopus, Web of Science, and CENTRAL. Additional sources, such as clinical trial registries (ClinicalTrials.gov, the Clinical Trial Registry of India, and the WHO International Clinical Trials Registry), were searched using the search strategy developed by the team. Currently, the review is in the full-text screening stage, and data collection is ongoing. The findings of the review will be published in the first quarter of 2024.

Discussion

Overview

This review is designed to evaluate the effectiveness of mHealth interventions on maternal and neonatal health outcomes among pregnant mothers with hypertensive disorders.

mHealth interventions are implemented and researched extensively. Evidence from systematic reviews shows that mHealth interventions are effective in increasing the use of antenatal and postnatal care, including attendance at antenatal and postnatal care check-ups, facility-based deliveries, and skilled attendance at birth and vaccination rates [22]. Conversely, another systematic review and meta-analysis concluded that most studies conducted in low- and middle-income countries are of poor methodological quality, and few have evaluated impacts on patient outcomes [23]. Therefore, there is a need for a rigorous systematic review that addresses health end points as primary or secondary outcomes and includes recent studies and rigorous study designs that are considered the gold standard components to determine an intervention's effect, that is, a randomized controlled trial. Apart from health outcomes, evidence also indicates that health workers can be empowered to accept and use mHealth in circumstances where it is appropriate for their requirements, workload, training, and abilities [24]. In turn, mHealth may provide health care professionals with skills and confidence when technology is viewed as beneficial and simple to use in settings that encourage acknowledgment from clients, peers, or superiors.

The review will enable the critical appraisal and synthesis of evidence on the use of mHealth interventions among pregnant women with hypertensive disorders. As there is a rapid increase in technological development and the relative newness of mobile apps as a tool for health care providers in the management of hypertensive disorders during pregnancy, more primary research has been published [25]. Therefore, the evidence pointing toward the use of these services must be put together, which will help in formulating local policies that can be generalized and promulgated for use in all health care settings and communities. Additionally, the extent to which clear conclusions can be drawn

XSL•FO
RenderX

about the usefulness of mHealth interventions in terms of health outcomes may be limited. However, this review will provide clarity on the existing evidence and its implications for health care providers.

Limitations

The possible limitations might be the inclusion of nonrandomized controlled trials and cohort studies that may not provide a strong evidence base. However, we planned to include those in this review as we do not intend to miss any available evidence. The strength of the evidence depends on the quality of the involved studies. The publication bias of the included studies might affect the results, but they will be reported. Meta-analysis and meta-regression may not be possible due to different methodological approaches in varying studies; however, subgroup analysis will be done.

Conclusion

The review results will highlight the available evidence on mHealth apps and their effectiveness in terms of maternal and neonatal health. The review results provide directions for further practice and further research in this area. It will inform policy makers and those in the hospital and community settings to implement mHealth interventions at the local level as well as scale up to a wider population.

Abstract

Background: Trauma-induced coagulopathy (TIC) is a common and potentially life-threatening coagulopathy as a result of traumatic injury, characterized by abnormal blood clotting and bleeding. Although several treatments have been proposed for TIC, their effectiveness and safety remain unclear. Further, numerous systematic reviews and meta-analyses on trauma have been conducted; however, to our knowledge, there is no systematic review and meta-analysis that specifically focuses on TIC management. Therefore, a comprehensive synthesis of the available evidence on interventions for TIC is needed.

Objective: This systematic review and meta-analysis aim to evaluate the effectiveness and safety of interventions for the management of TIC.

Methods: We will conduct a systematic review and meta-analysis of randomized and nonrandomized controlled trials as well as observational studies regarding severe trauma in patients with TIC. The interventions will include administration of coagulation factor concentrates, tranexamic acid, and blood component products. The control group will be managed with an ordinal transfusion or administered placebo. The primary outcome will be in-hospital mortality. We will search the electronic databases of MEDLINE (PubMed), Web of Science, and the Cochrane Central Register of Controlled Trials. Two reviewers will independently screen the titles and abstracts, retrieve the full text of the selected articles, and extract essential data. We will apply uniform criteria for evaluating the risk of bias associated with individual randomized controlled trials and nonrandomized trials based on the Cochrane risk-of-bias tool. Risk ratio values will be expressed as point estimates with 95% CIs. Continuous variables will be expressed as the mean difference along with their 95% CIs and *P* values. We will assess the strength of evidence using the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) approach. This review will be the first systematic review and meta-analysis providing information on the effectiveness and safety of interventions for the management of TIC, including the administration of coagulation factor concentrates, tranexamic acid, and blood component products. Ethics approval and patient consent were not required for this study protocol, as we conducted a systematic review and meta-analysis of publicly available data, without any direct involvement of human participants.

XSL•FO
RenderX

Results: We will summarize the selection of the eligible studies using a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. The results will be presented in a table summarizing the evidence. The results of the meta-analysis will be depicted using figures and forest plots.

Conclusions: This systematic review will provide updated information on the efficacy and safety of using coagulation factor concentrates, tranexamic acid, and blood component products for patients with TIC. To our knowledge, there is no systematic review and meta-analysis that specifically focuses on treatments for TIC.

Introduction

Trauma remains a major cause of death globally [1]. Death during the early phase of trauma is primarily attributable to uncontrolled bleeding, which is exacerbated by trauma-induced coagulopathy (TIC) [2-4]. Pathophysiology and clinical aspects of TIC comprise blood loss, consumption of coagulation factors, dilution, and fibrinolytic activation [2-5]. TIC correlates with an increased demand for massive transfusion as well as higher mortality. Thus, effective treatment of TIC is crucial for decreasing deaths following trauma [3-5]. Although the conceptual definition of TIC was proposed by the International Society on Thrombosis and Haemostasis, the clinical definition of TIC has not reached a consensus [3].

Randomized controlled trials (RCTs) have investigated the effectiveness of transfusion, administration of coagulation factor concentrates, and tranexamic acid for hemostasis following severe trauma [5-12]. Several systematic reviews and meta-analyses have also been conducted based on these studies [13-15]. However, the inclusion criteria for these reviews were mostly for trauma with severe bleeding or traumatic brain injury with severe consciousness disturbance, and they were not focused on patients with TIC. We speculate that the effectiveness of interventions for coagulation abnormalities is greatest in patients with TIC.

In addition, the administration of tranexamic acid for severe trauma has been investigated by large RCTs, and it is now globally used for early-stage trauma management with a proven lifesaving benefit [6,8,16]. Furthermore, a meta-analysis has indicated the beneficial effect of tranexamic acid on trauma [15]. Tranexamic acid is a potent antifibrinolytic agent, and its clinical effectiveness demonstrated in previous RCTs is presumably based on this antifibrinolytic effect. Therefore, tranexamic acid administration is likely to be more effective for severe trauma with TIC. However, the inclusion criteria of these RCTs and the meta-analysis were not focused on patients with TIC [6,8,15].

To our knowledge, there is no systematic review and meta-analysis specifically focusing on treatments for TIC. From late 2010 to 2020, RCTs investigating the efficacy of coagulation factor concentrates for TIC were published [5,11,12,17]. Due to the small number of RCTs and the biased setting of open-label interventions in these RCTs, observational studies continue to provide novel and helpful insights [18-20]. Therefore, a comprehensive synthesis of the available evidence on interventions for the management of TIC is needed. This is the first systematic review and meta-analysis aimed at evaluating the effectiveness and safety of interventions for TIC, including the administration of coagulation factor concentrates, tranexamic acid, and blood component products.

Methods

Protocol Registration

The study protocol was registered in the University Hospital Medical Information Network (UMIN000057146). This systematic review and meta-analysis will be reported according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines.[21]

Database Search

To retrieve relevant articles, we will perform a literature search of the following electronic bibliographic databases: MEDLINE (PubMed), Web of Science, and the Cochrane Central Register of Controlled Trials. We will examine the references cited in relevant articles to ascertain whether additional studies can be found. The details of the search strategy are available in Multimedia Appendices 1-3.

Study Types

We will include controlled trials (including RCTs and other controlled trials) and observational studies published until December 17, 2022. Studies will be excluded if they do not clearly report the population, treatment, or outcomes of interest. Animal studies will also be excluded. Grey literature, such as conference proceedings and abstracts, will be included. If 2 or more studies are published using the same or overlapping cohorts, the one with the most recent or larger cohort will be included. Only articles published in English will be included.

Study Population

We will include patients with severe trauma and TIC admitted to the hospital. However, there are no international diagnostic criteria for TIC. Therefore, we will include patients with some abnormalities in coagulation or fibrinolysis upon admission to

XSL•FO
RenderX

the hospital as patients with TIC and collect the definition of abnormality in coagulation or fibrinolysis in each study.

Intervention and Control

Intervention types will include the supplementation of coagulation factor concentrations, such as prothrombin complex concentrate (PCC), fibrinogen concentrate, tranexamic acid, and blood component products during the acute phase of trauma. The control group will be managed with an ordinal transfusion or administered placebo. We will not restrict our review to the product type and amount or the timing of the administration of coagulation factors.

Outcomes

The primary outcomes will be all-cause mortality and the quantity of transfusion. The secondary outcomes will be thrombotic events (ie, deep venous thromboses, pulmonary embolism, myocardial infarctions, and strokes), length of intensive care unit stay, and hospital stay.

Study Selection

Citations will be stored, and duplicates will be removed using EndNote Software (Thomson Reuters). Rayyan software will also be used for the systematic review process [22]. The titles and abstracts of studies retrieved using the search strategy will be screened independently by 2 reviewers (YI and YT) to identify studies that potentially meet the inclusion criteria. The full texts of these potentially eligible studies will be retrieved and assessed independently by 2 reviewers (YI and YT). Any disagreement about the eligibility of studies will be resolved through consultation with a third reviewer (MH).

Data Extraction

Using a standardized prepiloted form, data from the included studies will be extracted to assess the quality of the studies and methods of data synthesis. The extracted information will include data on the following variables: study setting, study population, baseline characteristics of the participants, details of the interventions and control conditions, study methodologies, outcomes, and assessments of the risks of bias. Two independent reviewers (YI and YT) will independently extract the data, and discrepancies will be resolved through discussion with a third author (MH). Missing data will be obtained through requests from the authors.

Assessment of Risk of Bias in Individual Studies

Two independent reviewers (YI and YT) will assess risk of bias in individual studies as well as the methodological quality of the articles, and disagreements will be resolved by discussion with a third reviewer (MH). We will apply uniform criteria for evaluating the risk of bias associated with individual RCTs based on the tool for assessing risk of bias in randomized trials [23]. Each study will be assessed for (1) random sequence generation, (2) allocation concealment, (3) blinding of participants and personnel, (4) blinding of related outcome assessment, (5) incomplete outcome data, (6) selective reporting, and (7) other bias. We will also use the "Risk Of Bias In Non-randomised Studies – of Interventions" tool for individual nonrandomized studies [24].

Data Summary

We will perform a meta-analysis when data are available in 1 or more trials according to the Cochrane Handbook for Systematic Reviews of Interventions. For binary variables, values for the risk ratio or odds ratio will be expressed as a point estimate with 95% CIs. Continuous variables, such as the length of intensive care unit stay, will be expressed as their mean difference with 95% CIs and *P* values. If quantitative synthesis is not appropriate for a particular outcome, we will provide a qualitative summary.

Data Synthesis

We will provide estimates of the findings from the included studies according to a random effects model. A random effects model incorporates statistical heterogeneity and provides a more conservative estimate of the pooled effect size compared to a fixed effects model. We will not perform any multiple imputations for missing data, data synthesis, or analysis of randomized trials. All statistical analyses, including risk of bias within studies or across studies, will be performed using Review Manager (RevMan; version 5.4; Cochrane Collaboration 2019) [25]. The level of statistical significance will be set at $P<.05$.

Assessment of Heterogeneity

Statistical heterogeneity will be assessed using the Mantel-Haenszel χ^2 test and I^2 ($I^2>50\%$=significant heterogeneity) [26]. The presence of clinical heterogeneity will be considered in the decision to conduct a quantitative synthesis of data or perform sensitivity analyses.

Sensitivity Analysis

We will examine the robustness of this meta-analysis by conducting a sensitivity analysis according to the different components of the Cochrane risk of bias tool. We will also perform sensitivity analyses by excluding studies in which the overall risk of bias is high or unclear.

Subgroup Analysis

Subgroup analyses will be performed according to the type of coagulation factors, type of trauma (traumatic brain injury will be separately investigated), timing of administration, or type of coagulopathy by each clinical criterion.

Assessment of Reporting Bias

To assess publication bias, we will create funnel plots for mortality.

Rating the Strength of Evidence Using the GRADE Approach

Two authors (YI and YT) will assess the strength of evidence independently using the GRADE (Grading of Recommendations Assessment, Development and Evaluation) approach [27]. The quality of evidence will be assessed for each outcome and categorized as high, moderate, low, or very low according to the GRADE approach.

XSL•FO
RenderX

Patient and Public Involvement and Study Dissemination

Patients and the public were not involved in the design of this protocol. Our findings will be presented at relevant scientific conferences and disseminated through publication in peer-reviewed journals.

Ethical Considerations

Approval from an ethics committee was not required because in this study, we conducted a systematic review and meta-analysis of publicly available data, without any direct involvement of human participants.

Results

We will summarize the selection of eligible studies using a PRISMA flowchart. The results will be presented in a table summarizing the evidence. The results of the meta-analysis will be depicted using figures and forest plots.

Discussion

The use of a coagulation factor concentrate enables a rapid and strong supply of coagulation factors and is recommended in patients with severe trauma in recent international guidelines [28]. Recently, RCTs on the use of fibrinogen concentrates in patients experiencing trauma have increased [5,10-12,29,30]. As per a meta-analysis conducted in 2020 [14], fibrinogen concentrates do not decrease the mortality rate. However, the inclusion criteria in this study did not focus on patients with TIC [14]. A meta-analysis of PCC administration focused on patients with Prothrombin Time-International Normalized Ratio >1.5 was reported in 2021 [13]. In this study, PCC was shown to reduce the mortality rate compared with fresh frozen plasma alone. Although platelets play a fundamental role in hemostasis and have a close counteraction with coagulation factors [2], the effectiveness of early supplementation of platelets for trauma is poorly investigated [31]. Tranexamic acid is now proven to be beneficial for life-threatening conditions [6,8,16] and is recommended by European guidelines [32] with high-quality trials. However, the studies mentioned above were not focused on patients with TIC. TIC is present in up to 25%-35% of patients experiencing trauma upon admission to the emergency department and is associated with a poor prognosis [4,33-35]. Therefore, we speculate that the intervention's effectiveness in addressing coagulation and fibrinolysis abnormalities is greatest in patients with TIC, and a systematic review and meta-analysis focused on the management of patients with TIC is needed.

This study will be the first endeavour to undertake a systematic review and meta-analysis on the effectiveness of early interventions for the management of TIC, involving the provision of coagulation factors and the administration of tranexamic acid. Patients with TIC, who represent a substantial subpopulation with severe and high mortality rates, require special attention [2]. Determining the effectiveness of treatments for this cohort of patients would yield significant advantages. In addition, further studies on interventions that influence the coagulation-fibrinolytic system, such as the use of coagulation factor concentrates and tranexamic acid, may offer more precise insights into their effectiveness in patients with TIC, as opposed to those without TIC. Additionally, this study may facilitate further research focused on assessing the diagnostic measures of TIC and thresholds of abnormal lab data for defining TIC by collating existing studies. As such, our findings will contribute to the current knowledge on the treatment of TIC.

Acknowledgments

This publication is part of the research project of the Scientific and Standardization Committee on Disseminated Intravascular Coagulation of the Japanese Society on Thrombosis and Hemostasis. It has been financed by the Department of Emergency Medicine in Hokkaido University Hospital in Japan and is funded by a research grant program by the Japanese Society of Thrombosis and Haemostasis.

We would like to thank Editage for English language editing.

Authors' Contributions

MH, Y Sakamoto, SK, YE, Y Seki, and KO were guarantors and contributed to the conception of the study. The manuscript protocol was drafted by YI and revised by MH. The search strategy was developed by all authors and will be performed by YI and MH. YI and YT will independently extract data from the included studies, assess risk of bias, and complete the data synthesis. MH will arbitrate in cases of disagreement and ensure the absence of errors. All authors have approved the publication of this protocol. YI was responsible for the funding acquisition.
The Scientific and Standardization Committee on Disseminated Intravascular Coagulation (DIC) of the Japanese Society on Thrombosis and Hemostasis sponsored and funded this study.

Abstract

Background: Globally, among all the vector-borne diseases, mosquito-borne diseases are responsible for a substantial number of cases and deaths and amount to an economic cost of US $12 billion per year. However, there is a dearth of systematic research conducted on the economic burden of mosquito-borne diseases. To address the lack of comprehensive information on this topic, a systematic review will be conducted to synthesize evidence for informing targeted policies and strategies addressing this growing burden and for better financial protection of households.

Objective: The systematic review aims to review the economic burden of mosquito-borne diseases in low- and middle-income countries (LMICs). The review estimates the total cost, which is the compilation of both the direct costs and indirect costs. Additionally, it reports cost estimates per disease, country, and patient. The review outcome will also discuss the impact of the economic burden in terms of out-of-pocket expenditure, catastrophic health expenditure, impoverishment, and gross domestic product impact due to mosquito-borne diseases in LMICs.

Methods: Systematic searches will be conducted in PubMed (MEDLINE), Ovid Embase, Scopus, the cumulative index of nursing and allied health literacy, and Cochrane CENTRAL. Additionally, websites of the World Bank, World Health Organization, and Asian Development Bank as well as grey literature (eg, Malaria No More and the Ministry of Health websites) will be searched to gather comprehensive information on the topic and identify studies published in the English language. The titles and abstracts will be independently screened by 2 reviewers, followed by a full-text review against the inclusion criteria. Disagreements will be resolved through discussion with a third author. The methodological reporting quality of the studies will be evaluated using the Larg and Moss checklist, Cochrane risk-of-bias tool for randomized trials, and the Consensus on Health Economic Criteria. Data will be extracted using a standardized data extraction form.

Results: The protocol was registered in PROSPERO (CRD42023427111) prior to the initiation of the search strategy. The review is currently ongoing and will synthesize information from the identified studies through a process involving structured screening, data extraction, and critical appraisal in the form of tables and a narrative summary of studies reporting the economic burden incurred due to mosquito-borne diseases in LMICs.

XSL•FO
RenderX

Conclusions: This review seeks to report the economic burden of mosquito-borne diseases. It will act as evidence for policymakers to prioritize their decisions regarding containing the prevalence of mosquito-borne diseases and the means to lowering the incidence of diseases spread by mosquitoes.

Trial Registration: PROSPERO CRD42023427111; https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=427111

KEYWORDS

cost of illness; economic burden; out-of-pocket expenditure; OOPE; mosquito-borne diseases; vector-borne diseases

Introduction

Background

Vector-borne diseases are diseases transmitted to humans by vectors (eg, aquatic snails, mosquitos, fleas, blackflies, ticks, lice, sandflies, triatome bugs, and tsetse flies) infected either with viruses, parasites, or bacteria. These account for greater than 17% of all infectious diseases and play a huge role in the economic and disease burden. Among these vectors, mosquito-borne diseases are responsible for almost 700 million cases and more than a million deaths each year. The most important mosquito vectors are *Aedes*, *Anopheles*, and *Culex*, which are responsible for the diseases chikungunya, lymphatic filariasis, dengue, Rift Valley fever, Zika, malaria, yellow fever, West Nile fever, and Japanese encephalitis [1,2].

Every year, more than 1 million people die after contracting a mosquito-borne disease. The US Centers for Disease Control and Prevention reported that more than 1 million people die because of malaria in a year. The pace of infection dissemination has substantially increased during the past few years [3]. It has been estimated that 3.4 billion people are in danger of contracting malaria, which is spreading in 97 countries [4]. The frequency of dengue has increased 30-fold over the past 50 years, and the disease has begun to move from urban to rural areas [5]. As stated by the World Health Organization, there are 50 to 100 million cases of dengue, an arboviral disease, per year [6]. *Aedes albopictus* and *Aedes aegypti* are the primary vectors of dengue [7]. Yellow fever has a high fatality rate, and many patients need supportive care to manage the fever, respiratory failure, and dehydration [8]. Around 10,000 people every year die from Japanese encephalitis, predominantly in Asia [9].

The estimated total economic burden of lymphatic filariasis was US $5.8 billion annually [10]. For the period 2011-2020, the total productivity loss was US $10.5 billion, and for 2021-2030, the anticipated loss is US $13.8 billion [11]. Dengue fever was reported to have a US $8.9 billion yearly global cost in 2013 [12]. The estimated socioeconomic impacts of Rift Valley fever ranged from US $5 million to US $470 million [13]. It has been estimated that the Zika virus costs the global economy a total of US $8.9 billion [14]. In 2016, the total cost of malaria worldwide, including both government and out-of-pocket expenditure (OOPE), was US $4.3 billion [15]. Mosquito-borne diseases contribute to acute and long-term complications, thus affecting the gross domestic product (GDP) of a country.

Nations suffer the loss of billions of dollars annually by investing in treatments for mosquito-borne diseases. For example, households lose an estimated 25% of their income to OOPE for treating malaria, treatment-related travel, and other diagnosis-related expenses, which amount to an average cost of US $3 per case [16]. Most low- and middle-income countries (LMICs) have many cities with high-density populations in urban areas that are associated with poor hygiene and poor water quality, which are characteristics that lead to increased mosquito breeding and the rapid spread of mosquito-borne diseases. Most LMICs have limited universal health coverage (UHC) due to low public health investments, resulting in a substantial proportion of the population being exposed to OOPE, with some of these populations experiencing catastrophic health expenditure and impoverishment.

A preliminary systematic search of the PROSPERO (International Prospective Register of Systematic Reviews), PubMed (MEDLINE), Cochrane Database of Systematic Reviews, Joanna Briggs Institute (JBI) Evidence Synthesis, and Epistemonikos databases identified no published or ongoing systematic reviews on the topic. Systematic reviews on the economic burden of individual diseases (eg, dengue and malaria) have been conducted previously [15,17-19]. However, these reviews have either focused on a specific country or a specific disease and did not consider other mosquito-borne diseases. To fill this information gap, a systematic review of the literature on the economic burden on households and countries due to mosquito-borne diseases in LMICs will be performed. The primary objective is to synthesize available evidence on costs (direct medical, direct nonmedical, and indirect), resources used, and health care expenditure due to mosquito-borne diseases in LMICs. Financial protection is at the core of UHC, as outlined in Sustainable Development Goal 3.8.2 related to indicators of financial hardship, such as catastrophic health expenditure and poverty impact [20]. The review will help to evaluate currently available evidence on OOPE, catastrophic health expenditure, impoverishment, and GDP impact due to mosquito-borne diseases in LMICs. Hence, our review findings will be crucial toward framing targeted policies focusing on increased prevention and health protection strategies to address the growing burden of mosquito-borne diseases in LMICs.

Operational Definitions

The following are operational definitions pertinent to the systematic review:

- Chikungunya: “Chikungunya fever is an acute febrile illness caused by an arthropod-borne alphavirus, Chikungunya

XSL•FO
RenderX

virus (CHIKV). The virus is primarily transmitted to humans via the bite of an infected *Aedes* species mosquito" [21].
- Dengue: "Dengue (break-bone fever) is a viral infection that spreads from mosquitoes to people. It is more common in tropical and subtropical climates" [6].
- Lymphatic filariasis: "Lymphatic filariasis, often known as elephantiasis, is a human infection that is caused by the transmission of parasites called filarias through mosquitoes, including those of the genus *Culex*, which is widespread in urban and semi-urban areas" [22].
- Rift Valley fever: "Rift Valley fever is a neglected, mosquito-borne and direct contact viral zoonosis associated with significant morbidity, mortality and an expanding geographical scope" [23].
- Yellow Fever: "Yellow fever (YF) is a viral acute hemorrhagic illness caused by infected mosquitoes of the flavivirus family" [24].
- Zika: "Zika is spread mostly by the bite of an infected *Aedes* species mosquito (*Ae. aegypti* and *Ae. albopictus*). These mosquitoes bite during the day and night" [25].
- Malaria: "Malaria is a parasitic infection transmitted by the *Anopheles* mosquito that leads to acute life-threatening disease and poses a significant global health threat" [26].
- Japanese encephalitis: "Japanese encephalitis (JE) is a vector-borne disease caused by the Japanese encephalitis virus (JEV), which is a single-stranded ribonucleic acid (RNA) virus belonging to the genus *Flavivirus* (Flaviviridae family) and is closely related to the West Nile encephalitis virus" [27].
- West Nile fever: "West Nile fever is an acute febrile illness associated with malaise, rash, headache, myalgia, and lymphadenopathy. Infection involves a bird-mosquito-human cycle" [28].
- Economic burden: "Economic burden captures the economic impact of a disease or illness of interest on both the health sector and non-health sectors at both microeconomic and macroeconomic levels. Economic burden is defined by cost-of-illness studies that estimate direct and indirect costs due to disease" [29].
- Direct costs: "Direct costs are defined as costs related to the use of resources due to either the disease or its treatment. Direct costs include costs to the health care system (direct medical costs) and costs to social services and to patients themselves or to their relatives (direct non-medical costs)" [30].
- Indirect costs: "Indirect costs or loss of production are defined as costs that occur to society related to loss of production, due either to the disease or its treatment" [30].
- Catastrophic health expenditure: "Population with household expenditures on health greater than 10% of total household expenditure or income" [31].
- Financial hardship: "Households incur 'hardship financing' when they are exposed to a less stable or worsened financial state brought about by additional costs/losses due to borrowing or selling assets" [32]. "Out-of-pocket (OOP) health care payments financed through borrowings or sale of household assets are referred to as distressed health care financing" [33].
- Impoverishment: "Impoverishment occurs when a 'non-poor' household becomes 'poor' after paying for health services" [34].

Review Question

The systematic review seeks to determine the economic burden associated with mosquito-borne diseases in LMICs by answering the following questions: (1) What are the direct and indirect costs associated in treating mosquito-borne diseases in LMICs? (2) What is the impact of the economic burden in terms of OOPE, catastrophic health expenditure, impoverishment, and GDP due to mosquito-borne diseases in LMICs? (3) What is the per patient cost involved in the treatment of mosquito-borne disease? The review will also aim to present evidence across specific mosquito-borne diseases and across all specific LMICs.

Methods

Reporting

The PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) was used to develop the protocol and will follow the JBI protocols for economic evaluations [35,36]. The final systematic review will be undertaken using the JBI methodology for economic evaluations and reported as per PRISMA 2020 guidelines [37,38].

Inclusion Criteria

Participants

This review will consider studies that include patients of all age groups who are affected with mosquito-borne diseases and residing in LMICs.

Conditions

This review will focus on studies that report the costs of the population affected with chikungunya, lymphatic filariasis, dengue, Rift Valley fever, Zika, malaria, yellow fever, West Nile fever, and Japanese encephalitis.

Contexts

This review will include studies conducted in any setting and in any geographical location in LMICs as per the World Bank criteria (Multimedia Appendix 1). For the current 2024 fiscal year, low-income economies are defined as those with a gross national income per capita of US $1135 or less in 2022, and lower middle-income economies are those with a gross national income per capita between US $1136 and US $4465, as calculated using the World Bank Atlas method. Annexure provides the list of LMICs included in the review [39].

Study Designs

This systematic review will consider study designs published in English that involve full or partial economic evaluation, which may include cost analysis, cost comparison, cost of illness or economic burden, cost effectiveness, cost utility, cost benefit, and cost minimization studies. All studies that focus on the economic burden of vector-borne diseases spread by mosquitos in LMICs will be included as per the World Health Organization's definition.

XSL•FO
RenderX

Exclusion Criteria

The following studies were excluded from review: (1) studies with costs pertaining to the comorbidities associated with mosquito-borne illnesses; (2) studies that only report utilities, quality of life, and patient-related outcomes without costs; (3) editorials, methodological articles or commentaries, and reviews (however, the bibliographies of systematic reviews will be used to identify relevant studies to be included); (4) studies conducted in high-income countries; and (5) studies published in a language other than English.

Outcomes

The outcomes of this review will consist of metrics relating to cost components that contribute to the economic burden of mosquito-borne diseases.

Measures of Costs

Cost outcomes will be expressed as total costs per patient, per country, and per disease as per the data available in the included studies. Costs will be categorized as direct or indirect as per the availability of the data.

Measures of Resource Use

The costs associated with clinical outcomes (recovery, morbidity, and mortality) will be measured in terms of the total number of units of resources used. Resources used will be measured in 3 categories. Direct medical resources include consultations, number and length of outpatient visits, hospitalization days, provider services, devices, drugs, supplies, procedures (laboratory and clinical), and investigations. Direct nonmedical resources include the number or duration of services (housekeeping and administration), transportation, accommodation, food, clothing, overhead costs, waiting time, and property losses. Indirect resources include the number of days or hours of work lost due to the disease and productivity loss by patients and their caregivers due to morbidity, disability, or premature death.

Measures of Health Care Expenditure

Health care expenditure includes costs reported in terms of OOPE and the percentage of the population exposed to catastrophic health expenditure, financial hardship, impoverishment, and GDP impact.

Search Strategy

The first step is to develop a search strategy that will include combinations of medical subject heading (MeSH) terms and free texts. Search terms will be developed for the domains, mosquito-borne diseases (conditions), costs (outcomes), and LMICs (contexts). The search terms for mosquito-borne diseases will include the following MeSH terms: “chikungunya,” “lymphatic filariasis,” “dengue,” “Rift Valley fever,” “Zika,” “malaria,” “yellow fever,” “West Nile fever,” and “Japanese encephalitis.” The MeSH terms for the costs will include “economics,” “cost,” and “cost analysis.” The MeSH term for the LMICs will be “developing countries.” The search filters for costs and LMICs were adapted from Canada’s Drug and Health Technology Agency search filters database [40] and the School of Health and Related Research LMIC filter [41], respectively.

These search terms will be combined using the “OR” and “AND” Boolean operators. “OR” will be used to combine search terms within a particular domain, and “AND” will be used to combine different domains. In the next step, the search strategy used in PubMed (MEDLINE) will be peer reviewed following the Peer Review of Electronic Search Strategies 2015 guideline statement [42]. After the search strategy is peer-reviewed, corrections will be made for any suggestions or errors. Once the search strategy is updated, the same will be replicated in all other databases included. No specific date range will be applied (Multimedia Appendix 2).

The search strategy will include databases such as PubMed (MEDLINE), Ovid Embase, Scopus, the cumulative index of nursing and allied health literacy, and Cochrane CENTRAL. Additionally, the websites of the World Bank, World Health Organization, and Asian Development Bank will also be searched. Grey literature will also be identified through a manual search of relevant organizations working in the field, such as Malaria No More, and Ministry of Health websites.

Study Selection

All references retrieved through searches will be imported into Zotero and duplicates will be removed. Following a pilot test to check for interrater reliability, titles and abstracts will be screened by 2 independent reviewers for assessment against the inclusion criteria for the review. Potentially relevant studies will be retrieved in full, and their citation details will be imported into Covidence software [43]. The full text of selected citations will be assessed in detail as per the inclusion criteria by 2 independent reviewers (VL and NC). Reasons for the exclusion of full-text studies that do not meet the inclusion criteria will be recorded and reported in the systematic review. Any disagreements that arise between the reviewers at each stage of the study selection process will be resolved through discussion or adjudication by a third reviewer (SK).

The results of the search and study selection and inclusion process will be reported in full in the final systematic review and presented in a PRISMA flow diagram [38].

Assessment of Methodological Quality

The methodological quality of the included studies will be individually evaluated by 2 authors (VL and NC) and then reviewed independently by 2 other authors (SK and AR). When necessary, the authors of the included papers will be contacted for clarification on any missing information or additional data. The tools used will include an adapted checklist by Larg and Moss [44] for cost of illness studies, the Cochrane risk-of-bias tool (RoB 2) [45] for randomized controlled trials, and the Consensus on Health Economic Criteria [46] for economic evaluation studies. Data extraction and synthesis will be applied to all studies, regardless of their methodological quality.

Data Extraction

Data extraction will be performed in Excel (Microsoft Corp) using a standardized form (Multimedia Appendix 3). The form will be pilot tested by 3 independent authors (VL, NC, and SK)

XSL•FO
RenderX

and reviewed by 2 additional authors (AR and DJ). It will then be used to collate relevant information from the included studies and will be tested by all authors. Data extraction will be performed by 3 independent authors (VL, NC, and SK), and any disagreements will be resolved through discussion with a senior reviewer (AR or GT). Where required, authors will be contacted for any missing or additional information.

Data Synthesis

The studies selected for review will be presented in tables and a narrative summary. The summary will evaluate and compare the methods and primary outcomes across the studies and will be organized according to the country where the study was published, timing, intervention type, economic evaluation type, and the methodology used. The studies will be categorized according to the kind of economic assessment conducted, sources of data, effect size of the intervention, resources usage, costs, epidemiological data, and effectiveness estimates. Further, to facilitate comparison of the studies, they will be summarized in a table. The table will facilitate the collection of information on the year of analysis, currency, type of intervention, and costs reported by the authors of the studies. A table named "characteristics of the included studies" will be created to present the methodological features of the studies included in the review.

For comparison across studies, all costs will be converted into a single currency (USD) and reference year (2022) using the cost calculator provided by the Campbell and Cochrane Economics Methods Group and the Evidence for Policy and Practice Information Centre [47].

Results

The protocol has been registered in PROSPERO. The systematic review is self-funded and was started on May 20, 2023. A systematic search was conducted without any restriction on time period by adapting search filters for economic evaluations from Canada's Drug and Health Technology Agency search filters database and the School of Health and Related Research LMIC filter in May 2023. The title and abstract screening of 13,444 studies was conducted, and 267 studies met the criteria for full text review. Data extraction is currently underway. After data synthesis, we intend to disseminate the results through the submission of a manuscript to a peer-reviewed journal by November 2023. The systematic review conducted as per this protocol will present the results evaluating and comparing the methods and primary outcomes across the included studies and will be presented in the form of tables and a summary.

Discussion

Overview

Mosquito-borne diseases pose a significant economic burden in LMICs. Irrespective of age, race, and income level, anyone can become affected by these diseases. The systematic review will comprehensively synthesize all the existing literature on the economic burden of mosquito-borne diseases and will provide an estimate of their total economic burden. The gap in the existing literature [15,17-19]—that studies have concentrated only on either a specific disease or a specific country—will be addressed in this review. The review's findings will compile the direct and indirect costs associated with treating mosquito-borne diseases. Also, it will offer estimates on the total economic burden caused by mosquito-borne diseases in specific LMICs. Furthermore, the review will determine the disease contributions in the accumulation of economic burden specific to LMICs, as well as per patient cost estimates involved in the treatment of mosquito-borne diseases.

Due to the low number of populations with health care coverage, OOPE has increased considerably in LMICs. This has significantly increased the economic burden on individuals living in LMICs. The outcome of the review will help governments and international bodies to prioritize decisions about how to contain the prevalence of mosquito-borne diseases and inform actions to lower the incidence of diseases spread by mosquitoes.

The most significant limitation of this systematic review will be the necessity that each study included in the review be a full-text, primary study, as conference abstracts will be excluded. Another limitation will be that only studies in English will be included. However, we do not foresee any issues due to these limitations since conference abstracts provide limited information with regard to the methods of economic burden estimation and do not provide sufficient information for conducting a proper critical appraisal using standard tools. Also, the review will not include studies regarding the prevention of mosquito-borne diseases. Studies published in regional language databases, for example Spanish and Chinese language databases, will be excluded; however, this will not have a large impact on the number of studies that will be excluded due to this criterion.

Conclusion

The purpose of this review is to explore the extent of the literature available on mosquito-borne diseases in LMICs. As reported in the literature, given that the burden of mosquito-borne diseases in LMICs is high, a comprehensive review will help to explore the economic burden associated with these diseases in this context. The review outcome will reveal the economic burden caused by mosquito-borne diseases in specific countries and LMICs on the whole. Further, based on the available studies, the review will also identify specific diseases that are increasing the economic burden of individual LMICs. The review will help to evaluate the currently available evidence on OOPE, catastrophic health expenditure, impoverishment, and GDP impact due to mosquito-borne diseases in LMICs. Hence, our review findings will help frame targeted policies focusing on decisions for containing the prevalence of mosquito-borne diseases and inform a means to lower the incidence of diseases spread by mosquitoes. The review will also guide future researchers in designing country-specific studies by choosing an appropriate mosquito-borne disease that increases the economic burden. Also, based on the findings of our full economic evaluation study, future researchers can engage in treatment-based cost-effectiveness studies based on country-specific treatment protocols.

Acknowledgments

Though the review is self-sponsored, we are thankful to the chief librarian of the Health Science library at Kasturba Medical College (KMC), Manipal, India, for giving us access to various library resources that helped us in conducting the review. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Data Availability

Our review is ongoing; therefore, we do not currently have a data set to share. As our study period ends in November 2023, we can share the data with the readers on request thereafter.

Conflicts of Interest

None declared.

Abstract

Background: The effects of reinforcement are still controversial in bariatric surgery, and variations may exist in using this technique.

Objective: This protocol describes a study that aims to survey the views of bariatric surgeons on reinforcement techniques and evaluate the effects of applying reinforcement techniques in sleeve gastrectomy (SG) and Roux-en-Y gastric bypass (RYGB).

Methods: This study is composed of 2 parts. Part 1 will investigate the differences of using reinforcement techniques among surgeons worldwide who perform SG or RYGB through a survey. The survey will be conducted by email and social media. Part 2 will evaluate the safety and effectiveness of using omentopexy or staple line reinforcement in SG and RYGB by systematic review and meta-analysis. In this part, literature searches will be performed in English databases, including CENTRAL, EMBASE CINAHL, Web of Science, and PubMed, and Chinese databases, including Wanfang, China National Knowledge Infrastructure, Database of Chinese Technical Periodicals, and Chinese Biological Medicine, from their establishment to November 2023. Randomized controlled trials and case-control studies will be included. The primary outcomes are rates of postoperative bleeding and gastric leakage. The secondary outcomes include anastomotic stenosis, surgical site infection, reoperation, estimated intraoperative blood loss, operative time (minutes), length of hospital stay (days), overall complications, and 30-day mortality. The meta-analysis will be conducted using RevMan 5.4 under the random-effects model, as well as through extensive subgroup and sensitivity analyses. *P* values <0.05 will be considered statistically significant. This study was registered with PROSPERO (Prospective Register of Systematic Reviews) in accordance with the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols).

Results: The results of this study will be published in a peer-reviewed journal. The web-based survey and initial title or abstract review of papers identified by the search strategy will be completed in November 2023. The second round of title or abstract review and downloading of the papers for full-text inclusion will be completed in January 2024. We aim to complete data extraction and meta-analysis by February 2024 and expect to publish the findings by the end of March 2024.

Conclusions: This study aims to investigate the impact of reinforcement techniques on reducing the incidence of postoperative complications in SG and RYGB procedures and provide assistance for standardizing the procedures of SG and RYGB operations for bariatric surgeons.

Introduction

The prevalence of obesity is steadily rising globally, resulting in a decline in the quality of life of those affected and an increase in mortality rates [1-3]. Various methods are available for managing obesity, including behavioral therapy, pharmacological therapy, and bariatric surgery. Metabolic bariatric surgery has long-lasting weight loss effects, and its positive impact on the treatment of obesity-related comorbidities (eg, hypertension, type 2 diabetes, and obstructive sleep apnea) has also been observed [4,5].

Roux-en-Y gastric bypass (RYGB) and sleeve gastrectomy (SG) are the most frequently performed bariatric surgeries [6,7], which typically involve the use of reinforcement techniques to reduce potential postoperative complications, such as gastroesophageal reflux, gastric leakage, and food intolerance. There are variations of reinforcement techniques used by different surgeons and in different countries [8-11], which can be categorized by material (eg, seamguard, peri-strips, fibrin sealant, absorbable polymer membrane, medtronic), suture methods (eg, oversew, burying, and whole layer continuing), the degree of reinforcement (partial or full), and types (staple line reinforcement or omentopexy). These variations may be related to differences in the effectiveness of reinforcement techniques in SG and RYGB, which make it a challenge to decide if a reinforcement technique is needed and which one is most appropriate for the patient (Table 1). For example, in terms of SG operations, 4 systematic reviews [12-15] reported that staple line reinforcement did not have any clear benefit concerning gastric leakage rate, overall morbidity, and mortality rate, while 3 other systematic reviews [16-18] found that staple line reinforcement overperformed in reducing the rate of gastric leakage and bleeding compared to no reinforcement. With regard to RYGB, a meta-analysis of 3 randomized controlled trials found a reduction in the rate of leakage in participants with staple line reinforcement [19], whereas another systematic review demonstrated that the rate of gastric leakage was no different with or without staple line reinforcement [20].

Apart from staple line reinforcement, omentopexy is another type of reinforcement technique, which uses sutures to fix the rest of the stomach to the free edge of the greater omentum [21]. The effect of SG with omentopexy on the rate of postsurgery complications was investigated in 3 systematic reviews [22-24], which reported inconsistent results. Of the 3 reviews, 2 [22,24] suggested that SG with omentopexy outperforms SG without omentopexy in reducing gastrointestinal adverse reactions (eg, nausea, reflux, and vomiting), while in terms of reducing gastric leakage, they showed the opposite effects. Opposing results were also observed in 2 reviews [23,24] in terms of the length of hospital stay.

According to Table 1, we found that previous systematic reviews of reinforcement techniques either focused on a single type of operation (SG or RYGB) or a single type of reinforcement technique (staple line reinforcement or omentopexy), and the design of the included studies was also relatively simple. Thus, an up-to-date and comprehensive meta-analysis and systematic review is needed to fill the gaps and confirm the effect of reinforcement techniques in SG and RYGB. Therefore, a web-based survey to ascertain the variations in the utilization of reinforcement techniques among surgeons worldwide who perform SG or RYGB will be performed in this study, which aims to elucidate the necessity and rationale for conducting the ensuing meta-analysis and systematic review. The goal of these analyses is to investigate the impact of reinforcement techniques on reducing the incidence of postoperative complications in SG and RYGB procedures.

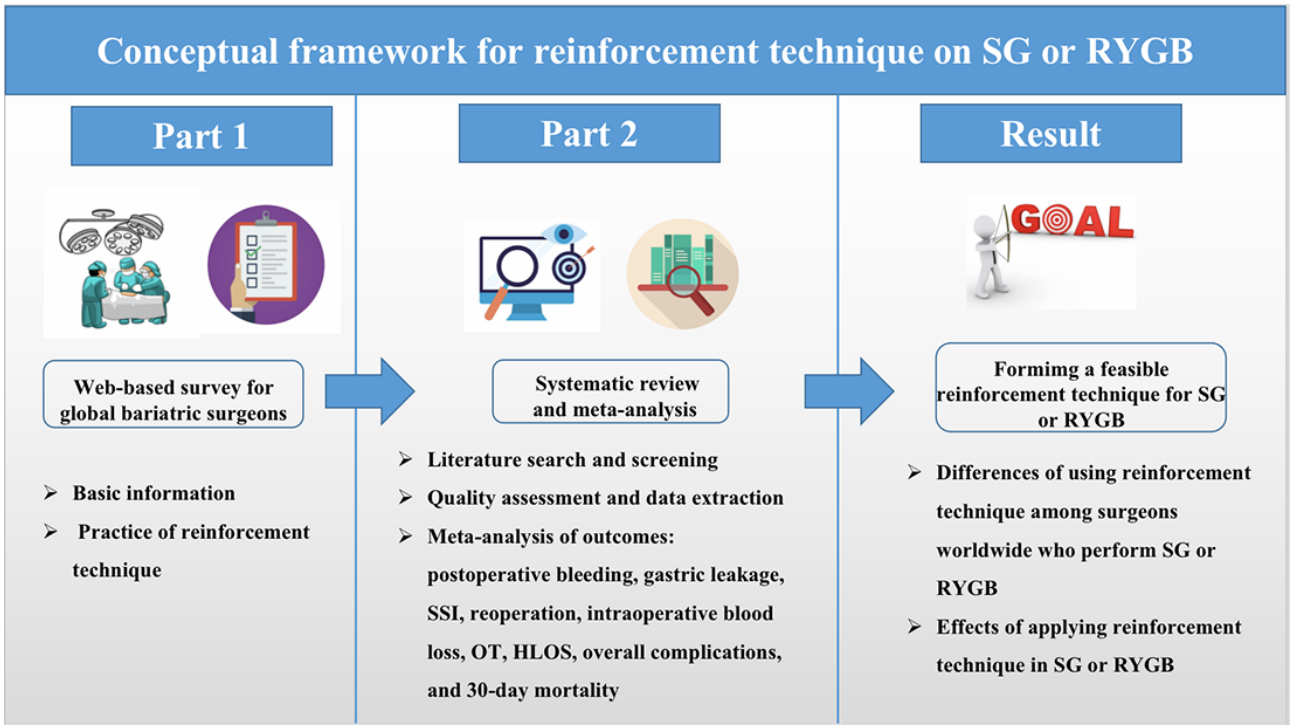
Methods

This study consists of 2 parts. Part 1 aims to survey global bariatric surgeons via the web and part 2 aims to perform a systematic review and meta-analysis. The specific procedures are illustrated in Figure 1.

XSL•FO
RenderX

Figure 1. Conceptual framework. HLOS: hospital length of stay; OT: operative time; RYGB: Roux-En-Y gastric bypass; SG: sleeve gastrectomy; SSI: surgical site infection.



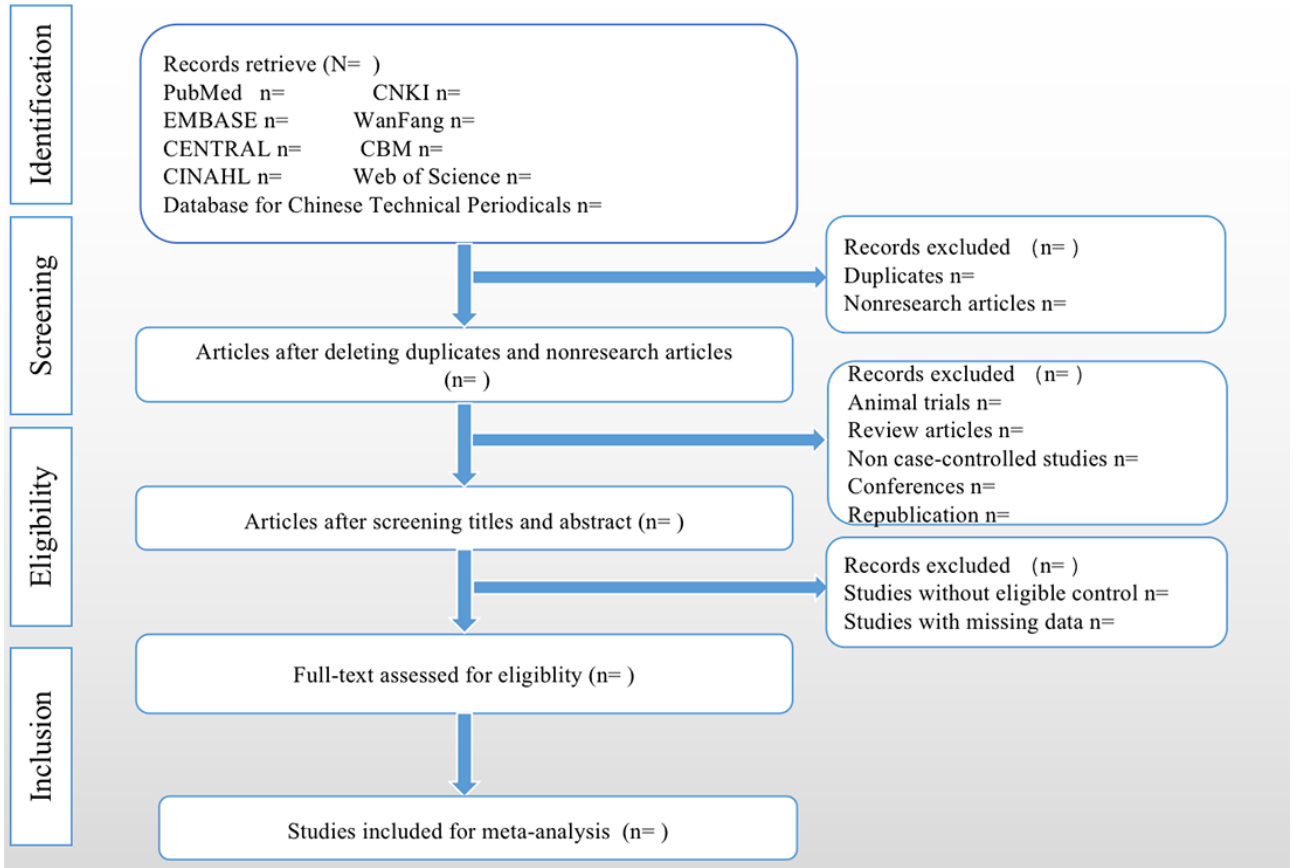


Figure 2. PRISMA flow chart of study.

Part 1: Web-Based Survey for Global Bariatric Surgeons

A global survey will be conducted using Questionnaire Star to collect basic information and differences in the use of reinforcement techniques among bariatric surgeons from October 30, 2023, to November 30, 2023. The survey includes 6 questions inquiring about basic information, including age, sex, work experience in bariatric surgery, time required for per SG or RYGB surgery (minutes), country, and institution.

XSL•FO
RenderX

Additionally, 11 questions pertain to information on reinforcement, including whether to perform SG with staple line reinforcement, the degree of staple line reinforcement in SG, forms of staple line reinforcement in SG, whether to perform SG with omentopexy and their reasons, the degree of omentopexy in SG, whether to perform RYGB with staple line reinforcement and their reasons, the degree of staple line reinforcement in RYGB, and forms of staple line reinforcement in RYGB. The survey will be sent to surgeons through social media (eg, WeChat, Meta) and email. The email addresses of possible surgeons who have published articles in either one of the official journals of The International Federation for the Surgery of Obesity and Metabolic Disorders and the American Society for Metabolic and Bariatric Surgery, namely *Obesity Surgery* and *Surgery for Obesity and Related Diseases*, in the 3-year period from 2020 to 2022 will be captured and used. Only responses from surgeons who perform SG or RYGB will be eligible in later analysis. The survey is shown in Multimedia Appendix 1.

Part 2: Systematic Review and Meta-Analysis

This systematic review and meta-analysis has been registered on PROSPERO (Prospective Register of Systematic Reviews) with the registration number CRD42022376438. The protocol is reported in accordance with the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 [25], which includes the search strategy, eligible criteria, study selection, data extraction and quality assessment, statistical analysis, subgroup analyses, sensitivity analyses, and publication bias.

Eligibility Criteria

Eligible studies have to meet all of the following inclusion criteria:

1. Population: studies in which all patients underwent SG or RYGB.
2. Intervention: studies in which the intervention was SG or RYGB with omentopexy or staple line reinforcement.
3. Comparison: studies in which the comparison was SG or RYGB without omentopexy or staple line reinforcement.
4. Outcomes: studies that reported at least one of postoperative bleeding and gastric leakage assessment as primary outcomes and secondary outcomes including surgical site infection, reoperation, estimated intraoperative blood loss (milliliters), operative time (minutes), length of hospital stay (days), overall complications, and 30-day mortality. Overall complications are defined as the incidence of peritonitis, abdominal abscess, puncture hernia, intraperitoneal hernia, intestinal adhesion, and gastroesophageal reflux.
5. Study design: randomized controlled trials (RCTs) and case-control studies (CCSs).

Studies will be excluded if they are animal trials or noncontrol studies or do not report sample size and outcome.

Search Strategy

Searching work will be conducted by 2 researchers (YX and JW) in November 2023. English databases, including CENTRAL, EMBASE CINAHL, Web of Science, and PubMed, and Chinese databases, including Wanfang, China National Knowledge Infrastructure, Database of Chinese Technical Periodicals, and Chinese Biological Medicine, will be searched. The elements like titles, abstracts, and keywords in a combination of medical subject headings (MeSH) terms and free text terms will be searched to ensure an accurate and comprehensive study. The following MeSH and free text terms will be used: gastric bypass, sleeve gastrectomy, omentopexy, and reinforcement. There is no restriction on language and publication date. The detailed search strategy for PubMed is shown in Table 2.

Table 2. Search strategy for PubMed.

Search	Query
1	(((gastric bypass[Title/Abstract]) OR (sleeve gastrectomy[Title/Abstract])) OR (SG[Title/Abstract] OR (RYGB[Title/Abstract])
2	(((omentum*[MeSH Terms])) OR (omentopexy[Title/Abstract])) OR (reinforce*[Title/Abstract])
3	(((gastric bypass[Title/Abstract]) OR (sleeve gastrectomy[Title/Abstract])) OR(SG[Title/Abstract] OR (RYGB[Title/Abstract]) AND (((omentum*[MeSH Terms])) OR (omentopexy[Title/Abstract])) OR (reinforce*[Title/Abstract])

Study Selection and Data Extraction

The literature management software Endnote X9 will be used to retrieve studies and exclude duplicates. The studies' contents and abstracts will be independently reviewed by 2 authors (YX and JW) according to the precise search strategies after they initially screened the studies that satisfy the inclusion criteria. Data extraction from the included studies, including authors, country, sample size, gender, race, time frame, other comorbidities, type of bariatric operations, reinforcement technique, and reported outcomes, will be collected and managed in Excel (Microsoft Corp; see Multimedia Appendix 2 for a sample table). The full text will then be read by 2 authors (YX and JW) to further determine suitability for inclusion. Any disputes will be settled through discussions or consultation with a third author (HZ).

Quality Assessment

Quality assessment will be performed based on the study design of the included studies. For RCTs, the Cochrane Risk of Bias tool [26] will be used, which focuses on 6 domains, including randomization, allocation concealment, application of blinding, integrity of the outcome data, selective reporting, and other biases. For CCSs, the quality of the included studies will be assessed by the Newcastle-Ottawa Scale (NOS) [27], which includes the appropriateness of the case and control, representativeness of the case, selection of the control, comparability of the case and control in the design, and

XSL•FO
RenderX

statistical analysis of exposure factors. The top score of the NOS is 9, and the higher the score, the higher the quality. Quality assessment will be done by 2 researchers (YX and JW). Any disagreements will be resolved through discussion or consultation with a third researcher (HZ).

Statistical Analysis

This study will use RevMan 5.4 software (Cochrane) for meta-analysis with the random effects model. We will use odds ratios as the effect measure for dichotomous variables (eg, postoperative bleeding, gastric leakage assessment, and reoperation), and mean differences for continuous variables (eg, estimated intraoperative blood loss, operative time, and length of hospital stay). All effective measures will be accompanied by their corresponding 95% CI. Heterogeneity will be evaluated using the Q test method, which calculates χ^2 and I^2 values. $P<0.05$ will be considered statistically significant.

Subgroup Analyses

The following predefined subgroups will be analyzed: study design of the included studies (RCTs or CCSs), age (≤65 years or >65 years) [28], gender (woman or man), type of bariatric surgery (SG or RYGB), materials of staple line reinforcement (eg, seamguard, fibrin sealant, absorbable polymer membrane), suture methods (eg, oversew, burying, whole layer continuing), the degree of reinforcement (partial or full), and the type of reinforcement (staple line reinforcement or omentopexy).

Sensitivity Analyses

Sensitivity analysis will be performed to assess the robustness of the findings using the leave one out approach [17], and studies involved in this meta-analysis will be removed in turn. Sensitivity analyses on the quality and sample size of the included studies will be conducted as well, and the meta-analyses will be repeated after excluding studies whose sample sizes are <5 or those with 3 domains rated as high risk for RCTs or with a NOS score <5 for CCSs.

Publication Bias

Publication bias in this study will be assessed using a funnel plot. A Begg test [29] and Egger test [30] will be performed using the Stata 15 software (StataCorp) to evaluate the statistical significance of the publication bias.

Ethical Considerations

The web-based survey has obtained ethics approval (2023-S-25). As for systematic reviews and meta-analyses, ethics approval is not required because the data used are derived from published papers. Informed consent was not applicable.

Results

The results of this study will be published in a peer-reviewed journal. The web-based survey and initial title or abstract review identified by the search strategy will be completed in November 2023. The second round of title or abstract review and downloading of the papers for full-text inclusion will be completed in January 2024. We aim to complete the data extraction and meta-analysis by February 2024 and expect to publish the findings by the end of March 2024.

Discussion

Principal Findings and Implications

Obesity is a disease caused by excessive accumulation of body fat due to the imbalance between energy intake and consumption [31], which is defined as a body mass index above 30 kg/m^2 [32]. According to the World Health Organization, more than 1.9 billion people worldwide were overweight in 2016, and more than 650 million had obesity [33]. Bariatric surgery associated with a reduction of obesity-related comorbidities has been gradually recognized globally [34,35]. However, the application of reinforcement techniques in SG or RYGB bariatric surgery remains a challenge for surgeons. In this study, we aim to investigate the opinions of bariatric surgeons on reinforcement techniques using web-based surveys and to evaluate the effectiveness of reinforcement techniques in reducing postoperative complication rates by meta-analyses and systematic review. To our knowledge, few studies have investigated the impact of different reinforcement techniques (staple line reinforcement or omentopexy) on 2 types of bariatric surgery (SG or RYGB) and included 2 study designs (RCT or CCS); these represent the strengths of our study. We will also perform subgroup analysis according to study design, age, race, type of bariatric surgery, materials of staple line reinforcement, suture methods, the degree of reinforcement, and types of reinforcement techniques. Our research will fill previous gaps and help standardize SG and RYGB procedures for bariatric surgeons and other researchers.

Limitations

Our study has several limitations. First, given the broad inclusion criteria, there may be high heterogeneity among the included studies. We will minimize the potential heterogeneity by performing subgroup and sensitivity analyses. Second, due to language limitations, we will only search English and Chinese databases. We will search for references included in studies to reduce the issue of incomplete inclusion of literature due to language limitations. Third, we are aware that the email addresses obtained from the studies may include authors who are not bariatric surgeons. Therefore, we have indicated on the questionnaire that participants must be bariatric surgeons for subsequent questions to be answered.

Conclusions

The web-based survey is designed to reveal variations in reinforcement techniques used by bariatric surgeons in SG and RYGB procedures, while the meta-analyses and systematic review are expected to shed light on the effectiveness of these techniques in reducing the incidence of postoperative complications.

Acknowledgments

This project was funded by the Chengdu High-level Key Clinical Specialty Construction Project and Chengdu Medical Research Project (grant 2022188) and the Project of Chengdu Municipal Health Commission (grant 2022188).

Data Availability

The data sets generated and analyzed throughout the study will be provided as supplementary files in a peer-reviewed journal. Additionally, detailed descriptions and comprehensive analyses of the data will be included to enhance the understanding of the research findings for the bariatric discipline.

Authors' Contributions

HZ and YL conceptualized the study. YX performed the formal analysis. YX and JW carried out the investigation. HZ designed the methodology. YL supervised the study. HZ and YX performed the validation. HZ performed the visualization. YX wrote the original draft. YX, JW, HZ, and YL reviewed and edited the manuscript.

Abstract

Background: Traditional health care systems face long-standing challenges, including patient diversity, geographical disparities, and financial constraints. The emergence of artificial intelligence (AI) in health care offers solutions to these challenges. AI, a multidisciplinary field, enhances clinical decision-making. However, imbalanced AI models may enhance health disparities.

Objective: This systematic review aims to investigate the economic performance and equity impact of AI in diagnostic imaging for skin, neurological, and pulmonary diseases. The research question is “To what extent does the use of AI in imaging exams for diagnosing skin, neurological, and pulmonary diseases result in improved economic outcomes, and does it promote equity in health care systems?”

Methods: The study is a systematic review of economic and equity evaluations following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) and CHEERS (Consolidated Health Economic Evaluation Reporting Standards) guidelines. Eligibility criteria include articles reporting on economic evaluations or equity considerations related to AI-based diagnostic imaging for specified diseases. Data will be collected from PubMed, Embase, Scopus, Web of Science, and reference lists. Data quality and transferability will be assessed according to CHEC (Consensus on Health Economic Criteria), EPHPP (Effective Public Health Practice Project), and Welte checklists.

Results: This systematic review began in March 2023. The literature search identified 9,526 publications and, after full-text screening, 9 publications were included in the study. We plan to submit a manuscript to a peer-reviewed journal once it is finalized, with an expected completion date in January 2024.

Conclusions: AI in diagnostic imaging offers potential benefits but also raises concerns about equity and economic impact. Bias in algorithms and disparities in access may hinder equitable outcomes. Evaluating the economic viability of AI applications is essential for resource allocation and affordability. Policy makers and health care stakeholders can benefit from this review’s

XSL•FO
RenderX

insights to make informed decisions. Limitations, including study variability and publication bias, will be considered in the analysis. This systematic review will provide valuable insights into the economic and equity implications of AI in diagnostic imaging. It aims to inform evidence-based decision-making and contribute to more efficient and equitable health care systems.

International Registered Report Identifier (IRRID): DERR1-10.2196/48544

KEYWORDS

artificial intelligence; economic evaluation; equity; medical diagnosis; health care system; technology; systematic review; cost-effectiveness; imaging exam; intervention

Introduction

Traditional health care systems encounter a multitude of challenges that have persisted for decades. These challenges include patient diversity, the vast geographical areas they are often required to cover, and the ever-present financial constraints that limit their capacity to deliver optimal care [1]. However, in recent years, the advent of artificial intelligence (AI) has introduced a transformative dimension to health care, showing immense potential in mitigating these challenges [2,3].

AI, a multidisciplinary field, integrates computer science and engineering to generate intelligent machines skilled in emulating human cognition and problem-solving [4]. Its subfield, machine learning, refines algorithms through the extensive analysis of data sets, thus enabling decision-making and predictions across various contexts [5,6]. An advanced offshoot, deep learning, has found particular prominence in medical imaging, bolstering the system's capacity for human-like reasoning [7]. Within health care, AI technologies serve critical roles in enhancing the accuracy and efficiency of disease detection, segmentation, and classification in medical imaging [8]. These advancements contribute to improved clinical decision-making, cost reduction, and error mitigation [9].

Nevertheless, there are pressing concerns that must be urgently addressed to maximize the clinical use of AI in health care. Methodological limitations, such as the lack of transparent algorithms and insufficient validation studies, risk hindering the wider adoption and efficacy of AI systems in clinical settings [10,11]. Moreover, the issue of data set bias warrants immediate attention; many of the data sets currently used for training and validating AI models are inherently skewed toward specific ethnic or demographic groups [12]. This imbalance may result in algorithms that are less effective or even misleading when applied to populations not adequately represented in the training data, thereby perpetuating existing inequalities in health care outcomes [13]. Such weaknesses not only constrain the clinical impact but could also exacerbate existing health disparities by delivering suboptimal or biased care [14].

Health equity refers to the principle that everyone should have equal access to health care and the opportunity to attain the best possible health, regardless of personal characteristics such as race, ethnicity, gender, socioeconomic class, or other factors that can contribute to health disparities [15]. Moreover, it is crucial to acknowledge that even when data related to equity or social determinants of health are incorporated, they can inadvertently introduce biases into algorithms if not adequately integrated and interpreted [16]. Recently, AI has gained significant attention due to its equity implications, underscoring the imperative to promote population well-being while taking into account differences in gender, race, and socioeconomic status, as evidenced by multiple sources [17-19].

Brazil, a large upper-middle–income country, has the world's largest free public health care system, which is relied upon by the majority of its population. However, several socioeconomic barriers hinder access to diagnoses in impoverished and remote areas. Digital health initiatives, including AI-powered clinical decision support systems, have proven effective in reducing health disparities and facilitating access to services [20]. To tackle these challenges, the Brazilian Ministry of Health's Support Program for the Institutional Development of the Unified Health System (in Portuguese, "Programa de Apoio ao Desenvolvimento Institucional do Sistema Único de Saúde", known as PROADI-SUS) supports a collaborative project named "Banco de Imagens" (Bank of Images) to create a nationwide cloud-based repository of medical images, as well as to develop and validate AI algorithms to assist in disease diagnosis. Currently, clinical validation is underway for performance assessment of diagnostic decision-support algorithms, specifically engineered to address conditions of Brazilian public health importance. These algorithms target dermatological lesions such as melanoma, radiological markers indicative of pulmonary tuberculosis, and volumetric alterations in cerebral computed tomography scans for the evaluation of conditions, including microcephaly, brain atrophy, and hydrocephaly. To ensure the effectiveness and accessibility of these AI algorithms, the clinical validation process also aims to measure the economic and equity impact of implementing these technologies in real-world.

Hence, this protocol outlines a systematic literature review that aims to investigate the economic performance or viability of using AI in diagnostic imaging exams, particularly for skin, neurological, and pulmonary diseases. The review will also assess the possible equity outcomes of this intervention in health care systems. The research question guiding this review is "To what extent does the use of AI in imaging exams for diagnosing skin, neurological, and pulmonary diseases result in improved economic outcomes, and does it promote equity in health care systems?" A preliminary search for existing systematic reviews on this topic has been conducted in databases such as PubMed and PROSPERO, and no identical review to the proposed study was found.

XSL•FO
RenderX

Methods

Overview

The study is designed as a systematic review of economic evaluations, which will be reported in accordance with the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist [21]. To ensure good reporting practices for economic evaluations, the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) tool [22] will be used along with the CHEERS (Consolidated Health Economic Evaluation Reporting Standards) checklist [23]. Additionally, we will adhere to guidelines provided by Preferred Reporting Items for Systematic Reviews and Meta-Analyses with a Focus on Health Equity (PRISMA-E) for conducting equity-focused systematic reviews [24]. The research question was structured following the population, intervention, comparison, and outcomes structure, as shown in Table 1.

Table 1. Population, intervention, comparison, and outcomes (PICO) structure for the systematic review of global economic evaluations and equity studies in the use of artificial intelligence (AI) in medical diagnosis of people with skin, neurological, and pulmonary diseases.

Acronym	Description	Criteria
P	Population	Patients screened for pulmonary, neurological, and cutaneous diseases, considering the entire world population, regardless of the income and development of that country
I	Intervention	Use of AI for diagnostic decision support in any type of imaging exam
C	Comparison	Conventional or human-based diagnostic methods
O	Outcomes	Full economic evaluations, such as cost-effectiveness, cost-usefulness, cost-benefit, or cost-minimization. We will assess changes in patient outcomes related to health care access and demographic factors like age, gender, race, and income, with a focus on equity.

Eligibility Criteria

Publications on economic evaluations or equity in diagnostic imaging use AI-based tools will be included. The thematic focus will align with the specialization areas of the Bank of Images project, particularly emphasizing conditions of critical importance to public health. These include (1) dermatology, specifically melanoma and skin carcinomas; (2) neurology, targeting disorders with notable radiological findings; and (3) pulmonology, concentrating on conditions such as tuberculosis, lung consolidation, pleural effusion, atelectasis, pneumothorax, mediastinal widening, lung edema, lung opacity, lung lesion, lung cancer, other pleural diseases, and lung nodules. Detailed inclusion and exclusion criteria, encompassing language and publication year, are provided in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for the systematic review of global economic evaluations and equity studies in the use of artificial intelligence in medical diagnosis of people with skin, neurological, and pulmonary diseases.

Inclusion criteria

- Article type: Original articles reporting economic evaluation or equity. Cost-effectiveness, cost-usefulness, or cost-benefit or cost-minimization analysis will be considered as economic evaluation studies. Regarding equity, the authors will analyze reported improvements or declines in patient outcomes based on access to health care and demographic indicators such as age, gender, race, and income level.
- Study object: Use of artificial intelligence–based tools in diagnostic imaging exams in dermatological, pulmonary, and neurological fields.
- Language: There will be no restrictions based on language.
- Year of publication: There will be no restrictions based on year of publication.

Exclusion criteria

- Article type: Partial economic evaluations, such as cost analysis, cost-description studies, and cost-outcome descriptions. Regarding equity, we will exclude studies that stratify the study sample into a homogeneous population, not representative of the general population.
- Study object: We will exclude studies that focus on other medical fields, such as heart diseases, breast cancer, and diabetes. Also, validation studies of artificial intelligence will be excluded.

Information Sources

We will conduct a search in the PubMed, Embase, Scopus, and Web of Science databases and perform supplementary searches to locate references cited in the retrieved articles.

Search Strategy

We will define a customized search strategy for each database, using terms related to AI, relevant diseases or health conditions as aforementioned, economic evaluations, and equity. Separate searches will be conducted for each field of medicine, as well as a general search without a specific field. The final search terms are provided in Tables S1-S4 in Multimedia Appendix 1.

Data Management

We will use an Excel (Microsoft) spreadsheet to manage and organize records and data throughout the review process.

XSL•FO
RenderX

Selection Process

The Rayyan platform (Qatar Computing Research Institute) will be used for article selection, with duplicates excluded by the platform and documented accordingly.

The selection process will consist of 2 phases. In the first phase, 2 researchers will independently evaluate and select articles. Researchers GOS and RML will evaluate titles and abstracts related to the neurological and pulmonary fields, while researchers GOS and BCRSF will assess titles and abstracts related to the dermatological field. Researchers GOS and RdMC will review titles and abstracts from the additional search that encompasses various fields of medicine.

In the second phase, the selected articles from the first phase will undergo full-text review. Researchers GOS and RML will evaluate full texts related to neurological and pulmonary fields, while researchers GOS and BCRSF will evaluate full texts related to the dermatological field. Researchers GOS and RdMC will review full texts resulting from the general search. Any disagreements will be resolved by a third researcher (RdMC for searches in neurological, pulmonary, and dermatological fields, and RML for the general search).

After the search strategy is completed, the authors will compile the final list of publications using EndNote software (version X9.3.3; Clarivate).

Data Collection Process

After completing the article selection process, 2 researchers (GOS and RdMC) will collect the variables of interest for the systematic review from each publication with available data. A pilot form will be used to collect data from a subset of studies, following which data will be collected independently. The extracted data by each researcher will be compared and merged into a single Excel spreadsheet.

Data Items, Outcomes, and Prioritization

List 1 registers the variables that will be collected from each study: ID, publication title, year of publication, publisher, authors, URL, type of study, language, time horizon, place of study, study population, study perspective, corresponding author's contact, brief summary, objectives, methodology, sample size, statistical significance, applied AI, outcome measures, such as incremental cost-effectiveness ratio (ICER), cost-benefit, QALY (quality adjusted life years), applied model, sensitivity analysis, demographic characteristics of participants, health indicators of subpopulations, access to health services, measures of equity such as odds ratio and relative risk, direction of effect (favorable or not), first analysis of methodological quality, conflict of interest, funding, transferability of results, observations.

Risk of Bias in Individual Studies and Transferability

The quality of the methodology evaluation will be assessed using the CHEC (Consensus on Health Economic Criteria) checklist [25], which includes a question on distributional effects to evaluate the equity aspects of economic evaluation studies. For selected studies that are not economic evaluations but were chosen for their equity results, the EPHPP (Effective Public Health Practice Project) quality assessment tool for quantitative studies [26] will be used to assess the risk of bias. The Welte checklist [27] will be used to evaluate the transferability.

For the CHEC checklist, points will be awarded for each of the met criteria, totaling a total of 20 items for evaluation. The point will not be awarded if the criterion is not fully met. A percentage value will be calculated based on the number of points awarded divided by the total points on the checklist multiplied by 100.

Regarding the EPHPP tool, each section will be assigned a rating of 1 (strong), 2 (moderate), or 3 (weak). At the end, a global score will be calculated according to the ratings evaluated for each section where, 1 when there is no section as weak, 2 when there is at least 1 weak section, and 3 when there are at least 2 or more weak sections.

For the Welte checklist, points will be awarded according to the following criteria: perspective (2 points), discount rate (2 points), addressing medical costs (2 points), absolute and relative prices in health care (1 point), clinical practice variability (1 point), incidence and prevalence (1 point), mix of cases (1 point), life expectancy (1 point), productivity and lost work time (1 point), making a total of 12 points. Studies that obtained a result greater than or equal to 10 points will be considered transferable.

Data Synthesis

We will create summary tables that include descriptive data from the studies, such as sample size, methods, cost-effectiveness rates, and other results. Information related to the country and health care system, year of publication, as well as the quality of methods and potential conflicts of interest, will be used to categorize results. Relevant findings from the studies will be summarized in the text. The main outcomes that we will focus on are (1) ICER, a cost-effectiveness measure that compares 2 health interventions; (2) cost-benefit results, an economic evaluation that compares the costs and benefits of a technology expressed in monetary units; and (3) equity results for studies that report them.

The methodologies used in the studies will be analyzed, and their robustness will be discussed. To facilitate comparisons between studies, all reported currencies will be converted to US dollars and adjusted for inflation using the US Consumer Price Index (CPI).

Meta-Bias

We will consider the potential for meta-bias resulting from the selective reporting of studies and outcomes, where negative results are often omitted from publication. To mitigate this issue, we will conduct funnel plot analyses to identify possible asymmetries, particularly in the context of cost-effectiveness outcomes. This is crucial as non–cost-effective results may be underreported in the literature.

Results

This systematic review began in March 2023 and has been registered with PROSPERO under registration number CRD42023407755. The literature search identified 9,526 publications and, after full-text screening, 9 publications were included in the study. Data summarization is currently

XSL•FO
RenderX

underway. We plan to submit a manuscript to a peer-reviewed journal once it is finalized, with an expected completion date in January 2024.

Discussion

Principal Findings

The systematic review presented in this protocol aims to address the use of AI in imaging exams for the diagnosis of skin, neurological, and pulmonary diseases. Considering the challenges faced by traditional health care systems, such as patient heterogeneity, geographic disparities, and financial constraints, the integration of AI technology offers a promising avenue to enhance health care delivery [1-3]. This systematic review seeks to synthesize existing evidence to cost-evaluate AI-driven diagnostic interventions and their potential impact on promoting equitable health care.

The inclusion of AI algorithms in health care has shown promise in various domains, particularly in medical imaging analysis. AI can assist in the detection, segmentation, and classification of medical images, potentially improving clinical decision-making and reducing diagnostic errors [8,9]. Moreover, AI has the potential to streamline health care processes, minimize costs, and facilitate earlier disease identification, which is of utmost importance in the context of skin, neurological, and pulmonary diseases [9].

Equity concerns in the implementation of AI-based tools for diagnostic imaging exams have gained significant attention in recent years. While these technological advancements hold immense promise for enhancing health care outcomes, they also carry the risk of exacerbating existing disparities in access to high-quality care. A major concern revolves around the potential for bias in AI algorithms, which could disproportionately affect marginalized and underrepresented patient groups. If AI systems are not adequately trained on diverse data sets, they may exhibit biases related to race, gender, or socioeconomic status, leading to inaccurate diagnoses or recommendations for specific demographic segments. Furthermore, the significant costs of adopting AI technologies could create disparities in access, favoring well-funded health care institutions over underresourced ones. Additionally, the digital divide, wherein not all communities are afforded equal access to essential technology and infrastructure, can further compound inequities in AI-supported diagnostic imaging. Addressing these challenges in an effective manner is crucial for the equitable distribution of AI's benefits in health care, ensuring that they reach all patient demographics irrespective of their socioeconomic or cultural backgrounds [1-3].

The measurement of the economic impact of AI-based tools in diagnostic imaging holds profound significance for several reasons. First, a comprehensive understanding of this impact enables health care systems to allocate their resources more judiciously, ensuring that investments yield tangible benefits and lead to cost savings. Also, AI has the potential to optimize the use of resources and, in turn, reduce the overall expenses associated with health care delivery. Moreover, assessing the economic viability of AI tools plays a pivotal role in determining their affordability and accessibility. By discerning their cost-effectiveness, it becomes feasible to identify potential obstacles to access and devise strategies that guarantee the availability of state-of-the-art health care to all individuals, regardless of their income or geographic location. Finally, identifying AI applications with the most promising economic potential can guide investment decisions, foster innovation, and expedite the development of tools that have a positive impact on patient care.

As with any systematic review, certain limitations are anticipated. One potential limitation is the availability and quality of the included studies. Variability in study designs, data sources, and methodological approaches may present challenges in synthesizing findings and drawing conclusive results. Regarding the topic of AI, as it is a recent object of study and because terms are delimited into 3 medical areas (dermatological, neurological, and pulmonary), there may be a shortage of available primary studies. This can limit the ability to perform robust statistical analyses or draw definitive conclusions. Publication bias is also recognized, in which researchers tend to publish only positive results. Furthermore, some technologies developed in specific contexts (eg, high-income or White-majority countries) may not be applicable in other realities or countries.

Conclusions

The findings of this systematic review will hold significant implications for policy makers, health care practitioners, and researchers. By comprehensively evaluating the economic performance and equity outcomes of AI use in diagnostic imaging for skin, neurological, and pulmonary diseases, we aim to provide valuable insights into the integration of AI into clinical practice. These insights can inform evidence-based decision-making, potentially leading to more efficient and equitable health care systems.

Acknowledgments

The project is sponsored by Hospital Israelita Albert Einstein in partnership with the Brazilian Ministry of Health through the Support Program for Institutional Development of the Unified Health System (PROADI-SUS; NUP 25000.161106/2020-61). We would like to acknowledge the funding provided by the PROADI-SUS Banco de Imagens project, a collaboration between Hospital Israelita Albert Einstein and the Brazilian Ministry of Health (NUP 25000.16110/2020-61). The authors wish to express their heartfelt gratitude to individuals whose contributions were essential to the success of this project, including Pedro Vieira Santana Netto and the PROADI-SUS Banco de Imagens team, Leandro Seiti Anazawa, Luis Gustavo Nascimento de Paula, Tayna Gomes de Souza Bandeira, Renato Tanjoni, and their teams, as well as Edna's team of librarians.

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Authors' Contributions

GOS is the primary author of the systematic review, with assistance in research and protocol writing. RdMC is the secondary author and researcher of the systematic review, who provided support in research and protocol writing. RML and BCRSF are also secondary authors and researchers of the systematic review. ETR provided technical support throughout the protocol and systematic review processes. JPQdP supervised the project and critically reviewed the systematic review protocol. LRC is the main author of the systematic review protocol, responsible for project administration and supervising the systematic review.

Conflicts of Interest

The authors are participants in the Brazilian Ministry of Health through the Support Program for Institutional Development of the Unified Health System (PROADI-SUS) Banco de Imagens project, a collaboration between the Brazilian Ministry of Health and Hospital Israelita Albert Einstein, aimed at enhancing public health in Brazil.

Abstract

Background: Canada is one of the world's most ethnically diverse countries, with over 7 million individuals out of a population of 38 million being born in a foreign country. Immigrant adolescents (aged 10 to 19 years) make up a substantial proportion of newcomers to Canada. Religious and cultural practices can influence adolescents' sexual attitudes and behaviors, as well as the uptake of sexual and reproductive health (SRH) services among this population. Adolescence is a time to establish lifelong healthy behaviors. Research indicates an alarming gap in adolescents' SRH knowledge, yet there is limited research on the SRH needs of immigrant adolescents in Canada.

Objective: The purpose of this study is to actively engage with immigrant adolescents to develop, implement, and evaluate a mobile health (mHealth) intervention (ie, mobile app). The interactive mobile app will aim to deliver accurate and evidence-based SRH information to adolescents.

Methods: We will use community-based participatory action research to guide our study. This research project will be conducted in 4 stages based on user-centered co-design principles. In Stage 1 (Empathize), we will recruit and convene 3 adolescent advisory groups in Edmonton, Toronto, and Vancouver. Members will be engaged as coresearchers and receive training in qualitative and quantitative methodologies, sexual health, and the social determinants of health. In Stage 2 (Define and Ideate), we will explore SRH information and service needs through focus group discussions with immigrant adolescents. In Stage 3 (Prototype), we will collaborate with mobile developers to build and iteratively design the app with support from the adolescent advisory groups. Finally, in Stage 4 (Test), we will return to focus group settings to share the app prototype, gather feedback on usability, and refine and release the app.

Results: Recruitment and data collection will be completed by February 2023, and mobile app development will begin in March 2023. The mHealth app will be our core output and is expected to be released in the spring of 2024.

Conclusions: Our study will advance the limited knowledge base on SRH and the information needs of immigrant adolescents in Canada as well as the science underpinning participatory action research methods with immigrant adolescents. This study will address gaps by exploring SRH priorities, health information needs, and innovative strategies to improve the SRH of immigrant adolescents. Engaging adolescents throughout the study will increase their involvement in SRH care decision-making, expand efficiencies in SRH care utilization, and ultimately improve adolescents' SRH outcomes. The app we develop will be transferable to all adolescent groups, is scalable in international contexts, and simultaneously leverages significant economies of scale.

adolescent health; health promotion; immigrants; information needs; mHealth; sexual and reproductive health; access to care

Introduction

Background

Canada is one of the world's most ethnically diverse countries, with over 7 million individuals born in a foreign country [1]. Globally, Canada has one of the highest percentages of immigrants, who comprise 21.9% of the total population [2]. Of all these newcomers, approximately 34% are under the age of 25, with over 60% of immigrant youth coming from Asia, the Middle East, and Africa [1]. Given these statistics, understanding health care service information needs and utilization by immigrant adolescents is vital for health care planning, policy, and delivery. Adolescence is a critical period in the transition from childhood into adulthood, during which young individuals aged 10 to 19 years undergo substantial physical, psychological, social, and emotional changes [3]. Adolescents are a vulnerable population because of their age-related psychosocial and biological changes and the challenges associated with navigating these changes [4]. As part of this development, it is common for adolescents to explore their sexual identities and feelings through sexual experimentation [5]. Depending on their knowledge about sexuality and social support, some may experience unintended consequences, such as unplanned pregnancy and sexually transmitted infections (STIs). Neglect of adolescents' sexual and reproductive health (SRH) needs can affect their physical and mental health, future employment, economic well-being, and ability to reach their full potential [6-8]. A small but growing body of literature suggests that immigrant youth lack SRH knowledge, use fewer sexual health services, and receive fewer sex education resources than nonimmigrant youth [9-11]. This difference appears to be heavily influenced by religious and cultural practices [12]. Immigrant families from Southeast Asia and the Middle East have diverse cultural and religious views on dating, relationships, adolescent sexuality, gender roles and identity, and sexual orientation [13]. Studies have shown that many immigrant adolescents find it challenging to balance family expectations, cultural standards, and religious demands; dissonance can cause internal and external conflict [13-15]. In addition, many adolescents experience intergenerational conflict, a competition between their own values and those of elders of the community [16].

Despite the large number of immigrant adolescents in Canada, there is limited research on the SRH of this population. COVID-19 pandemic–driven changes in how services are provided, such as limiting in-person care and deferring new and walk-in patients, have created barriers for adolescents to access confidential SRH information and services. Individuals may want to avoid obtaining in-person care during this time to reduce the risk of viral transmission. Hence, it is imperative to promote and adopt innovative approaches such as digital health (mobile apps, information through SMS text messaging) to deliver culturally appropriate SRH and sexuality education to immigrant adolescents in Canada. Beyond pandemic concerns, there is evidence to suggest that mobile apps have the potential to promote adolescent health [17]. This study will address these gaps by exploring the SRH priorities and health information needs of immigrant adolescents and will develop an interactive sexual health promotion mobile app for immigrant adolescents in Canada.

SRH Needs of Adolescents

The transition from adolescence to adulthood is complex, as new responsibilities materialize and confidence and independence emerge [18,19]. Yet, teens often have inadequate knowledge about the consequences of unprotected sex and are novices when it comes to implementing safe sex practices. These consequences include unwanted pregnancy, complications of unsafe abortion, and STIs [11]. In addition, due to fear, stigma, and confidentiality issues, many do not reveal their SRH problems and underutilize the health care services they need [9]. SRH is an important aspect of adolescent health and well-being, and it interconnects with various physical and mental health issues [20-22].

Globally, the SRH needs of adolescents have been largely unmet and pose a significant threat to the health and well-being of adolescents [9,23-25]. They are biologically more vulnerable to infections, more susceptible to peer pressure, developmentally more disposed to risk-taking, and lack the skills and confidence to negotiate safer sexual practices. STI rates among Canadian adolescents are on the rise [24-28]. Studies on adolescent SRH have found that the unintended teenage pregnancy rate is rising again in Canada [29]. The Canadian Community Health Survey reported that almost 15.5% of Canadian youth are at high risk of unintended pregnancy due to the nonuse of contraceptives [30,31]. The consequences of teenage pregnancy include anemia, hypertension, renal disease, eclampsia, and depressive disorders [29]. Research has found that adolescent mothers experience more mental health problems and higher rates of postpartum depression than women aged 25 and older [32]. Moreover, children of teenagers are more likely to have low birth weights and experience associated health problems [29]. Studies highlight an alarming gap in the sexual health knowledge of adolescents in Canada despite their completion of sexual education requirements in school [27,33-36]. Studies also found that sexually active Canadian teenagers commonly engage in risky sexual behaviors, including unprotected sex, multiple sexual partners, and intercourse before 15 years of age [35,37,38]. Moreover, many Canadian youths do not consider themselves at risk for HIV/AIDS, and their overall knowledge base about the disease has declined over the last 2 decades [9,39,40].

Mobile Phone–Based App to Increase Awareness and Uptake of SRH Services

Mobile app platforms have the potential to advance SRH. Nearly 100% of youth in Canada aged 15 to 24 years use the internet

XSL•FO
RenderX

daily or own a smartphone [41]. The use of mobile technology for health promotion offers privacy [42-47], access to personalized information [42,44,46,48], and convenience [42,47,49], making it a valuable way to provide accurate information about sexual health to adolescents [43-48]. Furthermore, young people are responsive to and excited about using new technologies for SRH promotion [42,45,50,51]. Innovative ways to deliver sexual health information are more important than ever before due to the impact of the COVID-19 pandemic on access to SRH services globally [52]. The absence of adolescent SRH services from "essential" health services during COVID-19 amplifies the potential role of technology to meet the SRH needs of vulnerable groups like adolescents. Amid the pandemic, technology has largely provided the means to support the recalibration of health systems, service provision, and information delivery [53]. Just as digital behavior changes, campaigns on hand washing, social distancing, and wearing masks have supported the pandemic response, we can digitally connect with young people to support their access to SRH information and services during times of social isolation and crisis. Although there are many mobile apps addressing SRH worldwide, we could not locate any research on co-designing a mobile app to improve immigrant adolescent SRH in Canada. Research has demonstrated that access to socially inclusive and culturally relevant SRH information significantly improves SRH knowledge and communication skills with partners and parents, improves contraceptive knowledge and use, and reduces risk-taking sexual behaviors by young people [15,27,54]. Therefore, the aim of this study is to engage immigrant adolescents in developing, implementing, and evaluating a mobile health (mHealth) app that will deliver evidence-based SRH information to this population.

Methods

Theoretical Framework

Intersectionality places an explicit focus on differences among people and seeks to illuminate various interacting social factors that affect human lives, including social locations, health status, and quality of life [55]. Intersectionality asserts that people are often disadvantaged by multiple interlocking sources of oppression (ie, their race, class, gender identity, sexual orientation, religion, and other identity markers) [56]. The intersection of race, gender, age, and socioeconomic status may pose barriers to young immigrant populations seeking SRH education and services. This framework will help us understand these differences, considering gender, race, class, sexual orientation, and migration histories, as they impact immigrant adolescents seeking SRH services.

Study Design

A community-based participatory action research (CBPAR) framework will guide our study [57-61]. CBPAR is a context-specific process driven by participants that requires innovative methodological approaches [62,63]. The principal outcome of this adolescent-partnered project is to develop an mHealth intervention that responds to SRH needs. Incorporating the end users' voices into the design and development of these interventions is crucial, as it has been noted that few mobile interventions are truly effective and scalable [64-66]. A user-centered co-design approach will increase the likelihood that adolescents will use the app and that it will be scalable and transferable to other contexts. Our goal for this engagement approach is to create an environment that supports the metacriterion of respect, trust, legitimacy, fairness, competence, and accountability in the development of knowledge [66]. This project will have 4 stages based on user-centered co-design principles [67].

Key Stages of the Research Project

Stage 1: Empathize

For a user-centered design, it is important that we engage the people for whom we are planning to design the product. Therefore, we will first develop and convene adolescent advisory groups (AAGs) in Edmonton, Toronto, and Vancouver. These cities have the highest percentages of immigrant populations from all geographic locations [2,68]. Having a multisite project will help ensure that the app will reach and be disseminated to immigrant adolescents across Canada. The AAGs will participate actively throughout the project (ie, in data collection, data analysis, mobile app development, gathering feedback on app usability, and knowledge mobilization). AAGs will be informed through our national environmental scan of youth advisory groups [69]. To recruit adolescents for the AAGs, we will hire 3 research assistants (RAs) (one at each site) who are skilled in research methods and have substantial youth facilitation expertise and experience working with diverse communities. Peer RAs will also collaborate with RAs to facilitate the recruitment of participants for AAGs. AAG members will be recruited from immigrant communities, public agencies, community and recreation centers, and immigrant service agencies. Participants aged 12 to 19 years from diverse ethnic backgrounds will be invited to participate in the AAG. Based on the developmental stage of young people, particularly in terms of physiological, psychological, and social development processes, we anticipate that it might be hard for younger adolescents to share common "cultural" beliefs and values. In addition, older teens may not allow young adolescents to share their thoughts and may dismiss younger teens. To provide equal opportunity for all to participate, we will create 2 separate groups. Adolescents aged 12 to 15 years will be placed in 1 group, and adolescents aged 16 to 19 years will be in a separate group. We anticipate that a reasonable target size of between 8 and 12 adolescents will create meaningful engagement [65,69] and that we will meet for 2 hours via Zoom or Google Meet every 2 months for approximately 18 to 24 months. To foster meaningful engagement, AAG members will receive training in qualitative and quantitative methodologies, sexual health, and the social determinants of health (see Multimedia Appendix 1).

Stage 2: Define and Ideate

Overview

To explore the experiences, information needs, and challenges of immigrant adolescents related to SRH and how to address these challenges, we will conduct qualitative individual interviews or focus groups (FGs) following the CBPAR

XSL•FO
RenderX

methodology [59,60]. SRH is a sensitive topic, and adolescents sometimes feel uncomfortable discussing their SRH needs in front of others. Participants comfortable with FGs will be invited to FGs. If participants are not comfortable, they will be invited for individual interviews.

Participants

We will recruit immigrant adolescents aged 12 to 19 years who were born in a country other than Canada and who immigrated in the last 10 years or are part of a second-generation cohort. We will focus on this age group because we aim to understand the factors in early and late adolescence that predispose young people to subsequent sexual health risks. In addition, adolescents aged 12 to 19 years are generally mature enough to participate in individual interviews or FGs [70-72].

We will use a multifaceted, community-based strategy to recruit immigrant adolescents from diverse ethnic groups. Public, community, and immigrant service agencies will support participant recruitment. In addition, social marketing campaigns (eg, Instagram advertising as well as posting of study ads by youth and health-oriented organizations) and snowball sampling will be used to recruit participants. Peer RAs and graduate RAs hired as part of this project will also assist with recruitment. We will also include non-English speaking participants. Our peer RAs are bilingual, and we will hire multilingual graduate RAs for this project who speak Canada's most common languages other than English to provide safe interpretation services for participants who do not speak English fluently.

We will conduct between 20 and 25 individual interviews or 3 to 4 FGs in each city. The participants for FGs will be divided into 2 groups (12 to 15 years and 16 to 19 years) to ensure that our data also capture the SRH needs of younger teens. The individual interviews or FGs will occur in person or over Zoom. The final sample size will be based on data saturation [73]. Individual interviews and FGs will be consistent in their delivery. Discussion topics will focus on issues related to SRH, sexual orientation, gender identity, sexual health history, dating and relationship experiences, source of information about SRH, cultural relevance and trustworthiness of those sources, challenges to receiving SRH information and services, and familiarity with SRH mobile apps and websites. We will conduct separate FGs for male and female participants and a mixed-gender FG based on participants' comfort and availability. Transcripts will be digitally recorded and transcribed verbatim by a professional.

Data Analysis

In accordance with CBPAR, we will use the DEPICT (dynamic reading, engaged codebook development, participatory coding, inclusive reviewing and summarizing of categories, collaborative analyzing, and translating) model for participatory analysis (Multimedia Appendix 2) [74]. Data analysis will occur in four stages: (1) conversations will be digitally recorded and transcribed verbatim by a professional transcriptionist; (2) 2 graduate RAs, peer RAs, and 2 members of the research team will read transcripts in detail several times; (3) the nominated principal applicant and the principal applicant will lead the team in conducting open coding of all transcripts and then group codes into preliminary themes using thematic analysis [75]. The themes will be presented to the larger investigator team and AAGs for feedback and additional comments, which will then be incorporated into the analysis; and (4) themes across cases will be grouped into an organizational framework. To achieve reliability and validity and to ensure rigor, we will employ verification strategies that will identify when to continue, stop, or modify the research process. Verification strategies will include (1) methodological coherence, ensuring congruence between the research questions; (2) appropriate sampling to ensure efficient and effective saturation of categories with optimal quality; (3) collecting and analyzing data concurrently; (4) developing a coding system that will be discussed and verified with research team members and AAG members; (5) keeping a detailed audit trail and field notes [76]; and (6) member checks. Then, we will share the transcripts, results, analyses, and reports with participants so they can review and provide feedback on the results and analyses. NVivo software (version 12; QSR International) will be used to manage the data analysis process.

Stage 3: Prototype

Informed by the Stage 2 findings and with integrated, continuous input from the AAGs, we will develop a prototype of a mobile app to house SRH content. The content of the app will stem from two primary sources: (1) evidence-based resources such as the Society of Obstetricians and Gynecologists of Canada, the Public Health Agency of Canada, and the World Health Organization; and (2) themes and experiences generated from individual interviews and FGs in Stage 2. The app will include age-specific information separately so that adolescents of different age groups can easily navigate the information related to them. In addition, information related to accessing SRH services will also be provided to connect adolescents to SRH services in their community.

The AAGs and peer RAs will work with the app developer to iteratively revise and build the app to address questions of clarity, potential sources of bias or marginalizing design elements, ease of use, relevance, and other factors determined by the AAGs. The app will use an internal analytics system to run analysis on user demographics, feedback, and content views to gather information on how the app is being used. The app content will be approved by team members who have expertise in SRH to ensure evidence accuracy and appropriate evidence interpretation. We will initially develop the interventions in English only to consolidate the findings and best practice functionality. Once the app has demonstrated usability and effectiveness in English, we plan to apply for new funding to translate the app content into languages used by immigrant communities.

Stage 4: Usability Testing of Mobile App Prototype

At the end of the project, we will run several FGs to evaluate the usability, acceptability, and effectiveness of the app; seek further input for refining it; evaluate the effectiveness of the project; and seek direction for future research. For usability testing of the app, we will conduct (1) 6 FGs with 5 to 10 immigrant adolescent participants (n=30-60) in Edmonton, Toronto, and Vancouver (2 FGs in each city) and (2) 3 FGs

XSL•FO
RenderX

with 5 to 8 service providers, policy makers, and members of the communities' informal support channels (n=15-20).

At the start of each FG, participants will be asked to download the app and use it on their own. Then, the researcher will begin the FG. Semistructured FGs will focus on questions about the app informed by a systematic search of over 180 usability evaluations [77]: participants' views, their preferences regarding receipt of health information, useful attributes, unhelpful elements, perceptions of the utility to improve adolescent's SRH, and recommended revisions and additions. Each aspect of the app (eg, narrative, visual appeal, audio appeal, health information, engagement, and interactivity) will be explored in the FGs. Interviews will be audio recorded, transcribed verbatim, and thematically analyzed [75]. We will integrate these findings into the app. The final version will then be disseminated using established social media platforms, such as TikTok, Twitter, and Instagram. The AAG members and peer RAs will participate in dissemination activities. The app will be available for free download on the Apple App Store and Google Play. In the future, we will conduct pragmatic trials to evaluate the app's effectiveness in improving SRH outcomes for adolescents.

App Sustainability

This study will develop a holistic, prescriptive model that can be used to ensure the sustainability and scalability of mHealth apps in the public health care sector in Canada and other countries. Our long-term community partners in all 3 cities will support the sustainability of the app. These organizations will host the app, as they need an evidence-based tool to help immigrant adolescents increase their awareness and uptake of SRH services to improve SRH outcomes.

Ethics Approval

This study received ethics approval from the University of Alberta Ethics Board (Pro0013664).

Results

Recruitment and data collection will be completed by February 2023, and we will begin co-designing the mobile app in March 2023. We expect to share a prototype of the app, gather feedback on its usability, and then refine and release the app in the spring of 2024. We will engage immigrant adolescents and service providers as partners in the development of the mobile app to ensure that immigrant adolescents are aware of this tool and will use the app, helping contribute to positive SRH outcomes. This study will also evaluate the usability of the mobile app. In the future, we will conduct pragmatic trials to evaluate the effectiveness of the app in improving the SRH outcomes of adolescents.

Discussion

Expected Findings

This study aims to develop a mobile SRH app designed by and targeted to immigrant adolescents in Canada. Our exciting and novel adolescent-engaged methods and mobile app have the potential to rapidly address the unmet SRH needs of immigrant adolescents and to improve the SRH of immigrant adolescents across Canada. This app is important because it allows immigrant adolescents to independently access resources related to SRH and mitigates the impact of familial bias on teens' ability to seek out such information. Further, young people are very comfortable utilizing mobile apps. This engaging modality will make it easier for immigrant adolescents to learn about safe SRH practices and may support them in having the knowledge and motivation to access services. The expected outputs of this study include:

- We will be able to identify the SRH needs of an underresearched population (ie, immigrant adolescents) in Canada.
- Voices of the full spectrum of gender diversity (including transgender and gender nonconforming adolescents), cultural knowledge, and agency will inform the mobile app.
- An innovative, adolescent-centered knowledge translation tool (ie, the mobile app) will be developed to help improve the SRH of immigrant adolescents in Canada.

The potential impact of this mobile app development includes increasing SRH knowledge and awareness, access to SRH services, and the use of contraception while decreasing unintended pregnancies and the need for abortion among adolescents. Our overall program of research is to build upon the active engagement of immigrant youth to develop, evaluate, and implement innovative and evidence-based digital knowledge translation tools and to build the resilience that immigrant youth need to successfully integrate into Canadian society. This research epitomizes creativity and innovation by merging the arts, sciences, and the engagement of youth in research.

Conclusion

Targeting adolescents and using engaging modalities has a strong potential to effectively increase their involvement in SRH care decision-making, expand efficiencies in SRH care utilization, and ultimately improve adolescents' SRH outcomes. We will disseminate the mobile app, along with other findings of our study, via community symposiums; public training sessions in Edmonton, Toronto, and Vancouver; and a website hosted by the University of Alberta Faculty of Nursing. Our findings will also be presented at academic conferences and published in open-access, peer-reviewed journals, advancing the body of knowledge on immigrant adolescents' SRH needs.

Acknowledgments

This study is funded through the Canadian Institutes of Health Research (CIHR), Early Career Investigator Grant in Maternal, Reproductive, Child & Youth Health (RES0053962). WVN is supported as an Applied Public Health Chair of the Public Health Agency of Canada and CIHR (2014-2024, CPP-329455107837).

Data Availability

The data generated during this study are not publicly available yet because data collection is ongoing, and results have not yet been analyzed. However, data collection materials are available from the corresponding author upon reasonable request.

Authors' Contributions

SM designed the study protocol and wrote the initial manuscript draft. All authors made substantial contributions to revising the initial manuscript and read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Digital health technologies have the potential to transform health care services to be more cost-effective, coordinated, and accessible on equal terms for entire populations. In the future, people will be assisted by such technologies to monitor their health status, take preventive measures, and have more control of their health situation. An increase in digital supplementation or substitution of physical care visits can potentially add value to patients and care providers by increasing accessibility, safety, and quality of care. However, health care organizations struggle with the challenges of developing and implementing digital health technologies and services in practice. As a response to this, we have developed a national multidisciplinary research school to increase competence and capacity for research on the development, implementation, and dissemination of digital health technology solutions. The overall aim of the research school is to increase national competence and capacity for the development, implementation, and dissemination of digital health technology to increase the preparedness to support and facilitate the ongoing digital transformation in the health care system.

Objective: The purpose of this paper is to outline the protocol for the development and implementation of a national multidisciplinary doctoral education program of health innovation supporting digital transformation in the health care system.

Methods: A national multidisciplinary research school for health innovation was planned in collaboration between 7 Swedish universities and their partners from industry and the public sector. The research school will run over 6 years, of which 5 years are dedicated for the doctoral education program and 1 year for the project start-up and closing. In this paper, we outline the methodological approach of the research school; the combining of knowledge and expertise of the universities that are important to run the research school; the jointly formulated research-oriented and societally relevant research focus, goals, and objectives for the research school; the established and developed relationships with partners from industry and the public sector for joint research training projects; the forms of collaboration in the research school; and the format of the doctoral education process.

Results: The research school was funded in December 2021 and started in March 2022. The research school starts with an initiation period from March 2022 to December 2022 where the infrastructure and the action plans to run the school are set up. The PhD projects start in January 2023, and these projects will be completed in 5 years. Additional activities within the research program are doctoral courses, networking activities, and dissemination of results.

Conclusions: The network of several partners from industry, public sector, and academia enables the research school to pose research questions that can contribute to solving relevant societal problems related to the development, evaluation, implementation, and dissemination of methods and processes assisted by digital technologies. Ultimately, this will promote innovation to improve health outcomes, quality of care, and prioritizations of resources.

Introduction

Background

Health care systems around the globe are facing major challenges and need to adapt to changes in demographics and patient needs, transitions from hospital care to home care, limitations in recourses, and requirements for reducing costs while maintaining and improving the quality of care [1,2]. One of the most important resolutions to support and facilitate this ongoing transformation of the health care system is through digitalization [3,4]. Advances in digital health technologies could both reduce costs and revolutionize health care. However, the uptake of health and welfare technology is often slow and with variable results [5]. Thus, the success of digitalization places great demands on the health care system and requires specific competences and close collaboration with industry and universities.

The Sustainable Development Goals for health and well-being lay out ambitious targets for disease reduction and health equity for 2030 [6]. Health systems are highly labor intensive, and health care providers and professionals play a key role in transforming the health care system to achieve these goals. However, an effective health care delivery system also depends on the coproduction with patients [7,8]. In Sweden, the health care reform *God och nära vård* (Good and close care) emphasizes the role of the patients as an active agent in their own care and the health care systems need to revise the focus of care processes, from organizational perspectives to the care pathways of patients [9]. Swedish health care has historically invested in emergency hospitals and specialist care rather than primary care and home care. This has resulted in a health care system that, in international comparison, is of high quality in terms of medical results, but has poor results in continuity, patient participation, and accessibility [9-11]. Thus, a transition of focus of care from organization to patient-provider relationship perspectives, from being reactive to proactive, from being fragmented to coherent, and from seeing patients as passive recipients to becoming active actors is desirable [9]. To be able to respond to these new demands and expectations, educational, research, and innovation initiatives need to address the ongoing digital transformation of health care, to ensure health care professionals can make use of such opportunities [12,13].

The definition and meaning of digitalization are broad and can, in the health care context, be understood as the use of a variety of converging digital tools and systems, such as wireless sensors, information systems, social networking, and mobile connectivity in health-related products and services, that is, a technology-based intervention that aims at maintaining or promoting health, well-being, quality of life, or increasing efficiency in the service delivery system of welfare, social, and health care services, while improving working conditions of the staff [14]. Digital health technologies will, in the future, increasingly enable people to better monitor their health status, take preventive measures, and take more control of their health situation. Such supplementation or substitution to physical care visits can potentially create value to patients and care providers by increasing accessibility, safety, and quality of care [15]. However, many health care systems struggle with the aspiration to stimulate the development and implementation of digital health technologies and services, as part of an undertaking to improve and evaluate health system performance [16,17]. A major challenge when it comes to the use of digital innovations for the transformation of health care is the dissemination and implementation in practice and to make sure it results in actual improvement and value for patients and the health care system [18,19]. The prolonged time for translating research into practice needs attention and improvements to be based on increased influence from patients, clients, and practitioners [20]. There is scarce evidence about how digital health technologies are implemented in health care practice and how they improve health care and health outcomes in patients [18,21]. Given this context, there is a need for additional educational offerings and research about the benefits of the process of digitalization of health services and how they outweigh efforts made and investments in costs [22]. This points to a need to advance theory and empirical evidence on coproduction requirements of digital technologies in the health care sector and opportunities to bring together insights from research on technological development and existing knowledge about innovation, implementation, and improvement science.

As a response to this challenge, we have developed and recently established a national multidisciplinary research school for health innovation in collaboration between 7 Swedish universities and their partners from the industrial and public sectors. The ambition of the research school is to strengthen the national capacity for health care improvement through digital health innovation and to significantly increase competence in the industrial and public sectors. Through enhanced collaboration across academic, industrial, and public sector partners, the overall purpose of this research school is to increase national competence and capacity for the development, implementation, and dissemination of digital health technology to increase the preparedness to support and facilitate the ongoing digital transformation in the health care system.

The intention of the research school is for all partners to benefit from each of the specializations, positions, and expertise, to create a multidisciplinary learning environment with added value for the doctoral students, the involved researchers, and partners. Through this environment, the participating partners

XSL•FO
RenderX

will develop expert competence in areas directly relevant for their business and increased capacity for research and development in the long term. Additionally, access to and broadening of already existing networks and international collaborations will increase.

Aim

The purpose of this paper is to outline the protocol for the development and implementation of a national multidisciplinary doctoral education program of health innovation supporting digital transformation in the health care system.

Methods

Research School Approach

The research school will use a coproduction approach [23] as a theoretical and methodological starting point. Coproduction is proposed as a means to deal with different forms of uncertainty and the complex nature of problems, both in the present and in the future. The approach is value driven and built on principles of shared power and reciprocal exchange between diverse stakeholders. Coproduction processes can harness the synergistic effect of collaborations and offer insights into experience, inspiration, values, goals, and shared vision among stakeholders. This project further involves creating permanent structures for coproduction through building a network for communication of results and impacts, strengthening translation of the knowledge generated in the research school into practice.

A collaboration network of universities, companies, and public sector organizations in Sweden was established during 2019-2021 (prephase) to create a closer connection between research, higher education, health services, and industry through the formation of a research school. The process started and formed the basis for a 2-year coproduction prephase that resulted in a structure and guidelines for running the research school. During the 2-year coproduction prephase, the 7 universities met biweekly, with workshops and meetings being held with companies, regions, and municipalities in several stages to explore what values were of importance for them. This prephase also aimed to narrow down which collaborators were potential participants in the research school. Letters of intent were written with those who were interested in joining the research school, and at a later stage final agreements were written.

The research school runs over 6 years (between 2022 and 2027), of which 5 years are dedicated for the doctoral education program and 1 year for the project start-up and closing. In the following section, we outline the approach and structure of the research school. First, we present the combining of knowledge and expertise of the universities that are important to run the research school. Second, we describe the jointly formulated, research-oriented, and societally relevant research focus, goals, and objectives for the research school. Third, we describe the established and developed relationships with partners from industry and the public sector for joint research training projects. Finally, we present the forms of collaboration in the research school and the format of the doctoral education process.

Combining of Knowledge and Expertise From the Universities to Run the Research School

The 7 universities committed to the research school formation all have research specializations related to the area of digitalization in health care, in different academic disciplines. The 7 universities together have 16 doctoral education programs in different subject areas related to the intention of the research school (Table 1); 9 of these doctoral programs are connected to the theme “Supporting real-world implementation,” 4 are connected to the theme “Developing valuable digital technologies,” and 3 are connected to the theme “Coordinating and optimizing the innovation process.” Some of the universities have doctoral education programs in more than 1 subject area. Accordingly, the universities contribute to the research school with doctoral education programs in different subject areas which, based on both similarities and differences, create unique perspectives to the 3 overall themes in the research school. This will make the scope of the research school broad and allow for cutting-edge research on different multidisciplinary aspects of health innovation. An important value is that the universities contribute to lectures, seminars, and supervision held by leading national researchers. Thus, the 7 universities collaborating on this effort are, in terms of areas of strength, both supporting and complementing each other.

Table 1. Contributions and scientific position of the participating universities.

Participating university/institute	Subject areas	Theme contributions[a]	Research specializations	Research initiatives and centers	Innovations centers[b]
Blekinge Institute of Technology	Applied health technology	Technologies	Gerontechnology	SNAC[c]	Health Technology Research Lab
Halmstad University	Information technology, innovation science, health, and lifestyle	Technologies, implementation, and innovation	Health innovation and information-driven care	RFI[d], CAISR Health[e], and IDC[f]	Leap for life
Jönköping University	Health and care science, welfare and social science, disability research	Implementation	Quality improvement, innovation, and leadership in health and welfare	Jönköping Academy for Improvement in Health and Welfare	—[g]
Mid Sweden university	Health science, quality management	Implementation	Rehabilitation science and quality technology and management	—	—
Mälardalen University	Health and welfare, embedded systems, innovation, and product realization	Implementation and innovation	Medical and health technology for diagnosis and prevention	Embedded sensor systems for health plus	—
University of Skövde	Health science, information technology	Technologies and implementation	Health in the digital society	INFINIT[h] and DHEAR[i]	—
University West	Work-integrated and workplace learning, production technology	Implementation and innovation	Work-integrated learning	LINA[j] and LOV[k]	Health Academy West

[a]Technologies (Developing valuable digital health technologies), implementation (Supporting real-world implementation), innovation (Coordinating and optimizing the innovation process).

[b]The 7 universities have a history of research and education in complementary areas relating to health innovation. A distinguishing feature of this research and education is a high degree of collaboration and coproduction with industries and public sectors and strategic ambitions that combine goal setting for achieving both scientific excellence and value creation in society. Each university has specific research areas and specializations that position them nationally and internationally, and that contribute in different ways with relevant and specialized input to the 3 research themes of the research school (Table 2). The intention of the research school is to benefit from each of the specializations, positions, and expertise, and thereby create a multidisciplinary learning environment with added value for the doctoral students, the involved researchers, and partners.

[c]SNAC: Swedish National Study on Ageing and Care.

[d]RFI: research for innovation.

[e]CAISR Health: Center for Applied Intelligent Systems Research Health.

[f]IDC: information-driven care.

[g]Data not available.

[h]INFINIT: Research directed towards the generation, quality assurance, analysis and visualization of data using information technology systems and models.

[i]DHEAR: Digital Health Research.

[j]LINA: learning in and for the new working life.

[k]LOV: learning and caring for sustainable health.

Table 2. Themes of health innovation for successful transformation of the health care system.

Theme	Focus
Developing valuable digital technologies	Focus on the coproduction of digital technologies that address the needs of stakeholders and users, and can be adopted easily in practice
Supporting real world implementation	Focus on the coproduction of theoretical and applied knowledge on challenges and opportunities of implementing digital technologies in health and welfare
Optimizing adoption and diffusion of health innovations	Focus on the coproduction of improvement processes in health and welfare transformation

Research Focus, Goals, and Objectives for the Research School

In designing the research school, a multidisciplinary approach is taken to integrate theoretical, empirical, and experiential knowledge from the 16 doctoral education programs at the 7 participating universities relating to the entire health innovation pathway. By combining the 16 doctoral education programs the aim is to integrate research of different content, from different perspectives, supported by unique specializations and methodological competencies. Based on several discussions and multidisciplinary workshops between the universities, 3

XSL•FO
RenderX

overarching and interdependent themes of digital innovation for successful transformation of the health care system are defined (Table 2) for the research school: (1) Developing valuable digital health technologies, (2) Supporting real-world implementation, and (3) Coordinating and optimizing the innovation process (Table 2).

The studies within the themes will focus on 6 identified overarching research questions to which the doctoral projects relate and contribute with new knowledge:

- How health innovations can be developed, implemented, and evaluated to provide various actors with knowledge and support to achieve high-quality services and improved health outcomes for user groups? (Themes 1 and 2)
- How user and stakeholder needs and involvement can be applied to overcome barriers in the coproduction of health innovations—in the spectrum from problem elicitation to implementation? (Themes 1 and 2)
- How knowledge and understanding from private and public stakeholders can improve the capacity for quality improvement and innovation in health and welfare? (Themes 2 and 3)
- How can the multidimensional effects and values of innovations in health and welfare be evaluated on individual and system levels? (Themes 2 and 3)
- How health innovations can be integrated into business models and long-term strategies within private and public sectors? (Themes 1 and 3)
- How private and public partners can collaborate to implement digital technologies for sustainable adoption and diffusion within health and welfare? (Themes 1-3)

The most important goal of the research school is the opportunity for participating partners to create expert competence in areas directly relevant for their business. The more long-term goal for the partners is to increase competence and capacity for research on the development, implementation, and dissemination of digital health technology solutions.

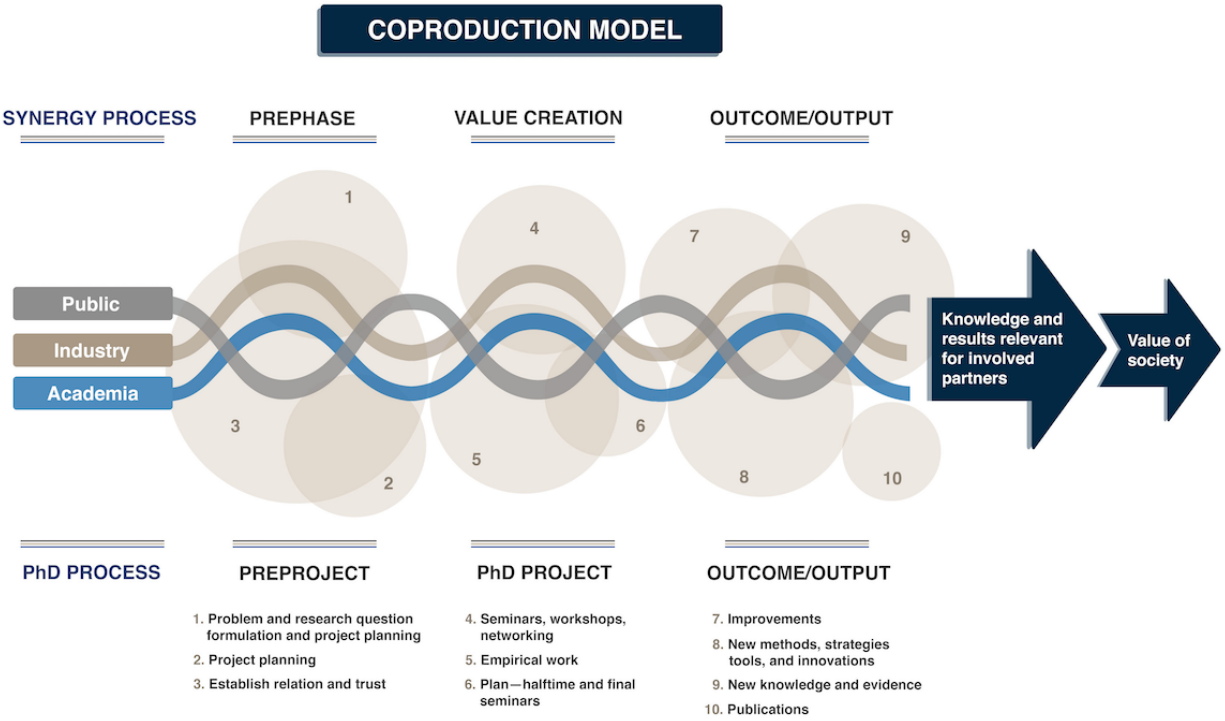
Established Relationships With Partners From Industry and the Public Sector for Joint Research Training Projects

In the research school formation, it was decided that all doctoral students should be employed by the partner industry or public sector organization, and that at least one senior mentor should be tied to the project. The partners could then choose whether to have additional members active in the research school network.

An essential part of the uniqueness of the research school is related to both industry and public sector being part of the constellation. It is otherwise difficult for the public and private sectors to get access to each other's needs and demands, which is crucial for both parts to be successful in the digital transformation of health care. By having these different types of organizations represented in the research school network, activities can focus on raising important questions related to the challenges of working within this sector.

Every company will contribute with their specific expertise in their area, which brings a variety of perspectives to the 3 overall themes in the research school and increases the relevance and impact of the research. Some companies are well established within the health care sector, whereas others see this as an opportunity to gain insights into a new market area. The public partners (regions and municipalities) participating in the research school contribute with contextual competence and understanding of the needs, problems, and challenges they face in their operations. In total, the research school comprises partners from 10 companies and 10 public sector organizations, besides the 7 universities.

Further, the research school establishes a network to create personal relationships between the companies' strategic functions (eg, research and development, managerial levels) and customer representatives (eg, managers of strategic and care departments in the public sector), which are functions that do not often meet in business relation procedures. The research school thereby creates opportunities for participants to discuss common challenges from a strategic or managerial point of view. Integrating these activities within the research school will facilitate learning opportunities for the doctoral students, who are likely to become valuable resources in the companies' and public organizations' future strategic work. The partners are responsible for aligning the research questions with challenges relevant to the industry, regions, and municipalities. Their commitments are both to their research project and to that of the research school and they will take part in annual network meetings, providing study visits and contributing to the management of the research school.



Forms of Collaboration Within the Research School

Overview

The research school will follow an established process of working in coproduction (Figure 1), which means that researchers and partners come together to share and create knowledge that can be used to face the current digital challenges in health care, while increasing capacity to problem solving in the future. The coproduction approach intends to support learning across partners with the purpose to create new practices for research collaboration that better address real-world problems and mirror the complexities we are facing regarding digitalization in health care.

XSL•FO
RenderX

Figure 1. Coproduction model in the research school.

The model presented in Figure 1 is inspired by Sannö's model [24] and illustrates how value can be developed throughout the research school process, from the preproject initiatives taken to connect interested parties to a research school, through finding the common themes, needs, and contexts that such a research school wishes to address, and then to actual implementation of the project. The model describes our 2 main processes, both the individual PhD process and the synergy process between partners, within the research school.

Initially, different partners come together to jointly discuss the real-world problem, discuss the key assumptions, prerequisites, purposes and rules of the collaboration, and build trust. In relation to the PhD process, the doctoral students and their supervisors and mentors jointly formulate the problem and research questions as well as design the project. Following this, the value-creation chain for the research school starts, where all partners are engaged in mutual learnings in seminars, workshops, and networking activities. Thus, new knowledge and results for all involved partners are discussed and transferred between partners and integrated to reach new and more comprehensive knowledge in relation to the problem. The doctoral students work on their dissertation project, conduct joint courses within the research school, and participate in seminars and other research activities, in addition to the requirements of their respective doctoral education program. Finally, the comprehensive and solution-oriented knowledge, results, and publications generated in the research school are evaluated in terms of their relevance and impact in relation to the problem being addressed and converted into improvements, new methods, solutions, strategies, and innovations of relevance for included partners.

One of the main tasks of the research school is to arrange joint activities for all partners in the research school, to provide a learning environment focusing on relevant topics related to the scope, the research themes, and the overall research questions of the research school (Table 3).

The aim of the activities is to enrich the progress and training for the doctoral students, as well as strengthening collaboration and coproduction between participating organizations. The legitimacy and relevance of the activities are ensured by creating learning meetings and a learning organization where all participants are actors in the process. Common research questions and results are expected to arise as an outcome of all the different types of activities performed in the research school. The doctoral students' contribution to a common area of knowledge, in this case related to the 3 themes of the research school, will highlight the expertise that is developed through the research school. By emphasizing the multidisciplinary perspectives that are combined and encouraging contribution to an increased understanding of other perspectives, the knowledge that is created between the different projects goes beyond the scope of the individual project. This is where interesting aspects arise, such as potential synergies and contradictions. To enable impact of this approach, it is of importance to involve both supervisors and mentors, as well as other organization representatives, to take an active part in the research school activities.

XSL•FO
RenderX

Table 3. Types of joint activities for all partners in the research school.

Activity	Format	Content	Purpose
Seminars and networking activities	Two-day network activities every 6 months for all participants of the research school (ie, doctoral students, supervisors and mentors, academic stakeholders, company and public organization representatives) ambulating between the participating universities.	Activities will range from lectures to sharing progress reports, seminars, workshops, and study visits. Activities will be designed to meet the partner's needs and focus on the 3 research themes of the research school.	To give stakeholder groups a chance to meet in various constellations, to identify, develop, and share both specific and generic commonalities and knowledge development.
Doctoral students' network	Several meetings per year with physical meetings specifically targeted to the doctoral students concurring with international conferences, the joint network days, and the doctoral courses. Digital meetings will be held in between to facilitate continuity in interaction.	Activities will circle around doctoral education domain–specific topics and the 3 themes of the research school and will form a tight constellation among the doctoral students.	To enrich the doctoral students at both a professional and a private level, aiming for connections for future collaborations.
Supervisors and mentor activities	Several meetings per year concurring with the joint network days.	Activities will be in a workshop format and include supervisors and mentors from both university and partners.	To delve into the role as supervisor and mentor, coproduction experiences, scientific course development, and questions on dissemination and impact.

International Collaborations

For the research school to be successful it needs to be grounded in international state-of-the-art science and based on cooperative research involving international collaborations. The universities and many of its researchers have established international partners and ongoing research based on existing international networks. The same applies to most of the business and public partners. It is one of the goals of the research school to deliver added value to participating organizations by accessing new, and broadening already existing, networks and striving to further enable and broaden international collaborations. Another goal will be to strive for an understanding of what kind of mechanisms the partners need to be aware of when approaching new markets or diffusing research results and health innovations internationally. The research school will work in several ways to address the internationalization goals. To navigate and receive the best knowledge exchange and outcomes from international collaborations, doctoral students, their supervisors, and the partners need an intercultural and multidisciplinary competency, which will therefore be included as part of the research school's network activities. The joint network's meetings and specific seminar sessions will address the topic, and relevant guest speakers will be invited. Another approach will be to encourage and support international mobility, such as study visits to international universities, research institutes, or companies suitable to the contexts of the student's projects. The students will also be encouraged to participate in international conferences or longer stays at international research institutes, companies, or universities. If possible, a larger group of participants from the research school should aim to jointly attend, thus make a significant impact on the content of a relevant international conference.

Organization and Management

As the research school is a collaboration between numerous partners from industry, academia, and public organizations, appropriate project organization and management are crucial to achieve targeted outcomes and set goals for the doctoral students as well as research and educational environments of the participating universities and industry and public partners (Table 4). The management structure aims to strengthen the dialog and transparency between groups and boards when devising, implementing, and assessing strategies and goals in the research school.

XSL•FO
RenderX

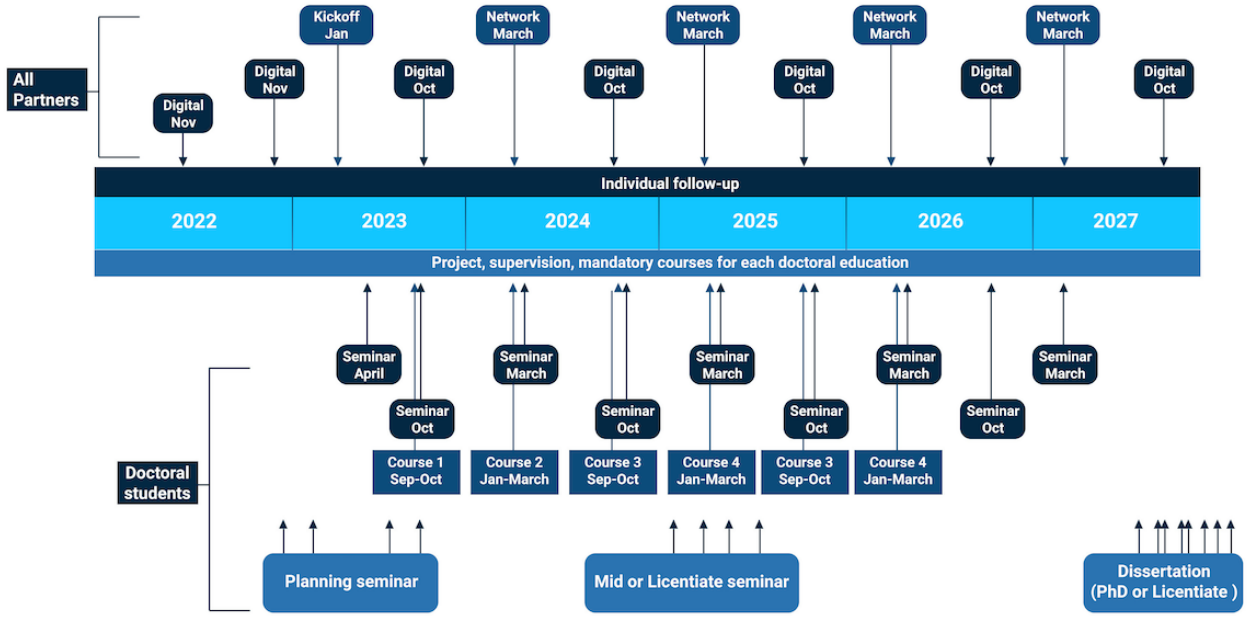
Table 4. The format, role, and purpose of different groups in the research school.

Group	Format	Role	Purpose
Steering group	Twice per year	Oversees that the research school's goals and outputs are achieved and suggests actions if required	To provide strategic development advice for the management group and provide support, guidance, and oversight of the progress and direction of the research school
Management group	Every week in the initial phase (first year) and thereafter every second week	Manages all organizational and scientific processes	To coordinate all partners and ensure that the goals of the research school can be achieved at high quality and have an impact
Operational group	Every second week	Executes all activities, such as reports, budget follow-up, routine setup, and communication	To ensure quality control processes and goal fulfillment
Supporting staff	Continuous	Runs local budget administration, local communication, local doctoral student administration, and coordination of tasks related to partner organizations	To assist in execution and securing alignment with the local routines, regulations, and organization of the universities
Scientific advisory board	Once per year. Includes 5-7 senior researchers	Provides advice and support to the management team in scientific issues related to needs, relevance, development, content, focus, and aggregated results and synergies	To represent the themes of the doctoral program
Stakeholder advisory board	Once per year. Includes 5-7 stakeholders	Provides support and guidance by contributing with expertise and experience-based knowledge and skills relevant to the projects	To identify and support opportunities for synergies, dissemination, and implementations

Format of the Doctoral Education Process

Credits for the Doctoral Program

A PhD degree in Sweden requires 4 years of full-time studies and a total of 240 higher education credits. At least half of these credits should be connected to the thesis. The doctoral students within the research school must acquire their PhD degree within 5 years of studies, of which 80% are spent on their studies and the remaining 20% on ordinary organization-specific work tasks.



The students within the research school will follow the rules and regulations applied to the respective doctoral education, as specified in the general syllabi. Students participating in the research school, however, can specialize and receive significant added value through the research school activities and the large collaborative network that they are a part of (Figure 2). The research school organizes regular network activities for students, supervisors, and industry and public organization partners, in the form of networking days, consisting of lecturers, seminars, workshops, and study visits. The activities focus to a large extent on creating a collaborative environment between these stakeholders, and facilitate discussions supporting the common goals, challenges, commonalities, and state-of-the-art related to digitalization in the health and health care sectors. This approach should lead to a close contact network between the doctoral students, the cluster of supervisors, partner representatives, and the project organization, which can form support structures related to the doctoral education programs and foundations for further collaboration in other forms. It is, however, important that students participating in the research school are not added an extra amount of workload compared with the fellow doctoral students at their doctoral education programs. Therefore, the supervisory role within the research school is important so that research school activities can be acknowledged as results within the doctoral education, and that compulsory elements in the doctoral education are not duplicated in the research school.

In the doctoral education process, there are several checkpoints (Figure 2). These will be followed up by the research school management group, although formally administered by the university doctoral education. After being admitted to 1 of the doctoral education programs, an individual study plan will be drawn up within the first 3 months and will thereafter be updated once a year. This is the formal document explaining the progress of the student throughout the doctoral education program, and its role and use are highly regulated in the Swedish Higher Education Act (Högskoleförordningen 1993:100). The student's research proposal plan is also finalized within the first 3 months and revised continuously as the project progresses.

The doctoral students present their project progress on at least three occasions within their doctoral education program (ie, a research proposal seminar, a midterm seminar, and a dissertation seminar), and in at least two other occasions during network activities in the research school (at doctoral and joint network activities; Figure 2). The presentations during network activities have specific focus on the impact of results in the own (or other) organizations or society.

XSL•FO
RenderX

Figure 2. Format of the doctoral education process.

Recruitment and Admission of Students

The research school has 2 admissions. The research school allows for a total of 10 industrial doctoral students and 10 doctoral students from regions and municipalities that are publicly funded in the first admission. A potential second admission will add another 10 industrial doctoral students, and again matched by an equal number of students from public sector organizations.

To be admitted to the research school, the doctoral student will be assessed and able to qualify in accordance with the general syllabi at the doctoral education program at the university where the student is to be enrolled. Further, the student will have their employment at the participating company or public sector organization. The doctoral students can be someone already employed at the company but can also be a new recruitment for the specific project. In cases of new recruitments, the recruitment process will be led by the company or public sector organization, with support from the local research school manager and potential supervisors of the admitting university.

The doctoral student will be enrolled in the doctoral education program with the most suitable subject area related to the project. The admitting university is responsible for the administration related to the enrollment of each doctoral student and for making suitable supervisors available for the project.

Supervision of Doctoral Students

Each doctoral student has a main supervisor, 1 or 2 assistant supervisors from the universities, and a mentor from the organization where they are employed. If applicable, an assistant supervisor can be affiliated to 1 of the other participating universities to build relations between universities, ensure valuable knowledge transfer, and enrich the project. All supervisors are expected to participate in the research school activities. Mentor candidates from the participating organizations (both business and public) who have a PhD degree and are interested in becoming supervisors will be offered the chance to enroll and participate in the respective university's supervisory education courses. This education is part of the quality assurance of graduate education and a requirement for being eligible as an academic supervisor.

The team of academic supervisors plays a continuous quality control role in the doctoral student's educational process, including the study design, empirical and analytical work, research article production, thesis development, and participation in doctoral education courses and research school activities. The supervisory team and the doctoral student agree on the individual study plan, set up milestones, and supervision arrangements including regular and formal progress meetings. The supervision arrangements are formally and regularly followed up within the organization for each doctoral education at each university. It is also reviewed yearly by the project coordinator of the research school, through the individual study plan for the doctoral students and through dialogs with the doctoral students and supervisors.

It is of importance that supervisor roles in the research school are diversely represented with regard to gender and ethnicity. A broad representation will add value to the doctoral students' perspectives and to the discussion during network activities. It will be the role of the management group to lift these aspects in relation to supervisor appointments.

Doctoral Courses

All doctoral educations require a specific amount of compulsory and elective courses, although the number of credits varies between different doctoral educations. The elective courses are chosen to optimize the students' competence in relation to project needs and interests and should provide a knowledge depth in the field. Students participating in the research school will be offered several small courses (2.5 ETCS credits each) for their elective credits, which are specifically tailored to the research school agenda (Textbox 1).

XSL•FO
RenderX

Textbox 1. Selective courses for elective credits.

Related to content/research focus:

- Health innovations, application, and value (2.5 credits)
- Coproduction in research and practice (2.5 credits)
- Needs-driven implementation, innovation, and quality improvement (2.5 credits)

Related to skills and abilities:

- Communication of research and value (2.5 credits)
- Academic writing (2.5 credits)
- Ethics in coproduction of health innovations (2.5 credits)

The first course (ie, Health innovations, applications, and value) brings up aspects of innovation with specific relevance to the health and health care context. All courses offered in the research school are developed in collaboration between different universities and disciplines and involve listening to collaborating partners to gather needs. Because of the limited space for further elective courses within the doctoral education programs, further needs for developing shared multidisciplinary knowledge among doctoral students will be accomplished through other research school activities.

Ethical Considerations

All data and personal data, for both the research school and the separate doctoral projects, will be handled in accordance with the European General Data Protection Regulation (EU) 2016/679. Ethical approval will be obtained from the Ethical Board in Sweden for each doctoral project where this is applicable.

Some ethical considerations could be important to reflect on. For example, ethical challenges can arise in coproduction projects when different perspectives, ambitions, and priorities from stakeholders meet. In the research school, each doctoral project involves 1 doctoral student from either company/region or municipality, 2 supervisors from 1 or 2 universities with expertise in different areas, and 1 supervisor or mentor from either company/region or municipality. The coproduction approach highlights the importance of respecting the perspectives and values of all stakeholders involved in a project [23]. However, while acknowledging that a researcher's main goal may be to get the results published in scientific journals, it is also necessary to understand that this is not always the goal for other partners. Thus, in each project it is essential to discuss how these issues should be handled to address transparency and common understanding in relation to goals, expectations, and ambitions.

Results

The research school was funded in December 2021 (Knowledge foundation dnr: 20210047). The research program started in March 2022 and is progressing according to the time plan presented in Figure 3. Briefly, the research school was started between March 2022 and December 2022. During this period, we had set up its infrastructure and the action plans to run the school. Thereafter, the PhD projects will be executed, and these projects will be completed in 5 years. The first group of students have been admitted during autumn 2022 and spring 2023 (in total 15 students). The first results from the PhD projects are expected in 2024 and the first dissertation is expected to be produced in 2026. Additional activities within the research program will include doctoral activities (eg, courses, seminars), networking activities, and dissemination of results.

To achieve the overall goal, expected outcomes are stated, which contribute to desired impact for the participants involved. To allow for an overview of desired impact and expected outcomes for the different stakeholders in the project, these are presented from the perspective of doctoral students, university and industry, region, and municipalities (Figures 4-6). In the figures outputs, measurable results are also stated.

Discussion

Expected Findings

The research school is a collaborative network of higher education institutions and stakeholders from the public and private sector across Sweden. The universities all have a strategic focus on different aspects of health innovation, which together forms a unique constellation of complementary competencies around this topic. By tradition, the health sciences field has extensive experience of collaborating with public sector partners, whereas the engineering and computer sciences field often has more experience in working with industrial partners. By bringing these 2 groups together, the research school is expected to provide a multifaceted added value to the participating partners [25], involving the following:

- Close collaboration with industry or public sector organizations through supervision, project implementation, and research school activities.
- Forming a network with other universities with similar or complementary positioning in the field.
- Facilitation of discussions and plausible collaboration between scholars from different subject areas within the universities (different academic environments).
- Strengthening multidisciplinary research related to health innovation, thus increasing the positioning of the

XSL•FO
RenderX

universities, as well as the national academic capacity, in this field.
- Ensuring research of high relevance to industry and public sectors.
- Development of doctoral education programs by integrating industrial doctoral students as well as public sector students.

The benefits of achieving these aspects through an industrial research school are several, and at different systemic levels. For example, the involved academic staff at each university will collaborate closely with the doctoral students and their mentors, which will bring interorganizational and intersectoral understandings and competencies. By developing a better understanding of the health care sector, the shared experiences and perspectives will broaden the horizon and understanding for different research approaches, as well as contextual perspectives [26]. These competencies will be further brought into the research environments and doctoral education programs at each of the universities through the doctoral students, supervisors, and local project coordinators, who act as carriers of this knowledge.

By meeting supervisors from the different participating universities, the research school will facilitate development of supervisory skills, in terms of both insights from adjacent knowledge areas and pedagogic exchange [27]. These aspects of the supervisory role are important to focus on research school activities, to ensure goal fulfillment and relevance related to the supervisors. By being part of a national initiative, rather than a local research school, this effect will have a greater diffusion and impact beyond the academic, business, and public organizations involved in the research school. Further, all involved participants will improve their understanding of the benefits of the synergistic effects resulting from the interaction between academia, industry, and public sector in collaborative development and innovation, as well as the challenges of working interorganizational, which will be problematized within the research school. Another important aspect of the universities' participation in this research school is related to the capability of keeping up with state-of-the-art within this field. The rapid development of technology and the need for digital technology implementation in the public sector make this industry move very fast [16,28,29]. There is a risk that universities will not be able to keep up with the pace, unless being involved in such development projects. By identifying projects that are of high relevance for industry, research, and public sector, we can ensure that competence and collaborations are being established to continuously keep partners in the forefront of the development. The long-term collaborations formed through the research school also form a great platform for other possible collaborative activities. There are many diverse forms of partnerships between the industrial sector and academia, and the interaction taking place within the research school will open up for new forms of collaborations (eg, student projects in educational programs at the university, a broad pallet of different types of professional research projects, educations for lifelong learning, larger consortiums that strengthen the international positioning within the field, and long-term strategic partnerships).

Despite increased recognition of coproduction in research, there are still demands on research to show its values in practice [23,30]. There is a diversity of coproduction models [31], and how different stakeholders conceptualize, understand, and use research in practice. Most coproduction models that are described and investigated in the scientific literature focus on the collaboration between researchers and users such as health care professionals, citizens, patients, and service users [31], not involving stakeholders from industry. There is evidence that coproduction can lead to benefits and practice change, but there is still a knowledge gap on the success and impact of coproduction between stakeholders from universities, companies, and public actors. Thus, the learnings from this research school are of importance and can tell us something about how coproduction can lead to benefits, value, usability, uptake, and practice change.

Conclusions

The research school will contribute to a strong development of competence for industry; solve research questions relevant for academia, public sector, and industry; and build stronger ties between the participating organizations promoting value creation, increased competitiveness, and the potential for future collaboration within and outside of the research school partner network. The forms of collaboration between the health care sector, industry, and academia fostered through the research school is vital to build increased competence and to promote knowledge generation and innovation. This requires multidisciplinary constellations that combine the technological development with research and innovation related to stakeholder values and implementation. Succeeding in bringing these perspectives together is a necessity if this advantage in competence is to be applied within the life science sector.

Acknowledgments

We are grateful to the people, from the universities, companies, regions, and municipalities, who participated in the discussions about the application for the research school in health innovation. There were several meetings and workshops discussing research schools' topics, design, and implementation involving the following staff members of the participating universities in addition to the authors of this protocol: Anderberg Peter (Professor in Applied Health Technology, Blekinge University), Lena-Karin Erlandsson (Professor in Occupational Therapy, Halmstad University), Fristedt Sofi (Associate Professor in Applied Gerontology, Jönköping University), Gellerstedt Martin (Professor in Public Health, Skövde University), Landstad Bodil (Professor in Health Science, Mid University), Lindén Maria (Professor in Health Technology, Mälardalen University), Lindgren Eva-Carin (Professor in Sport Science, Halmstad University), Mårtensson Anna-Maria (Coordinator, Halmstad University), Ramstrand Nerrolyn, (Professor, Orthopaedic Technology, Jönköping University), Roxberg Åsa (Professor in Nursing, University West), Svensson Ann (Professor in Informatics, University West), and Åhlfeldt Rose-Mharie (Assistant Professor in Informatics, Skövde University).

Abstract

Background: Innovative approaches are needed to address the self-management needs of youths with osteogenesis imperfecta (OI) transitioning into adult-oriented health care systems. Using a sequentially phased research approach, the goal is to design, develop, and test the usability of an innovative eHealth program called "Teens Taking Charge: Managing OI Online," hereafter named "Teens OI." This program seeks to optimize self-management, facilitate a successful transition to adult care, and address a critical gap in the quality of care for youths with OI.

Objective: The study objectives are to (1) design and develop an English and French version of the Teens OI and (2) test the usability of the Teens OI in terms of efficiency, effectiveness, and satisfaction from the perspectives of youths with OI and their parents.

Methods: A user-centered design is presently in progress to design and develop Teens OI. A "Website Design and Development Council" (ie, Council) has been convened, with 20 youths and parent dyads recruited and global experts surveyed at an international meeting. With unanimous support from the Council, usability testing of the Teens OI will ensue in 4 iterative cycles with 32 youth-parent dyads. All sociodemographic and usability metrics will be descriptively analyzed. All recorded interview and focus group data are analyzed using content analysis techniques involving an iterative process of data reduction, data display, conclusion drawing, and verification.

Results: As of December 2022, an 8-person, interdisciplinary Teens OI council, comprising 4 health care professionals, 3 youths and young adults with OI, and 1 parent, has been convened to oversee the design and development of Teens OI. Two cycles of interviews have been conducted with 10 youths with OI with or without their parents (n=6) from December 2021 to September 2022. Data analysis has been in progress since April 2022. Aim 2 is ethically approved and will commence following the completion of content development, expected by late July 2023. Preliminary analysis indicates that the following topics need to be prioritized for the youths: mental health, pain, accessibility, medical care, education, community, and parental care.

Conclusions: The proposed study will design and develop a self-management and transitional care program for youths with OI in partnership with patients, caregivers, and health care professionals. This study leverages youths' openness to adopt eHealth technologies to meet their needs and has the potential to actively engage them to autonomously manage their lifelong conditions, and facilitate a successful transition to adult health care. Finally, the proposed study will also address a critical gap in the quality of care and the growing concern that the OI population transitioning from pediatric to adult care is at risk of various adverse events associated with the transition.

KEYWORDS

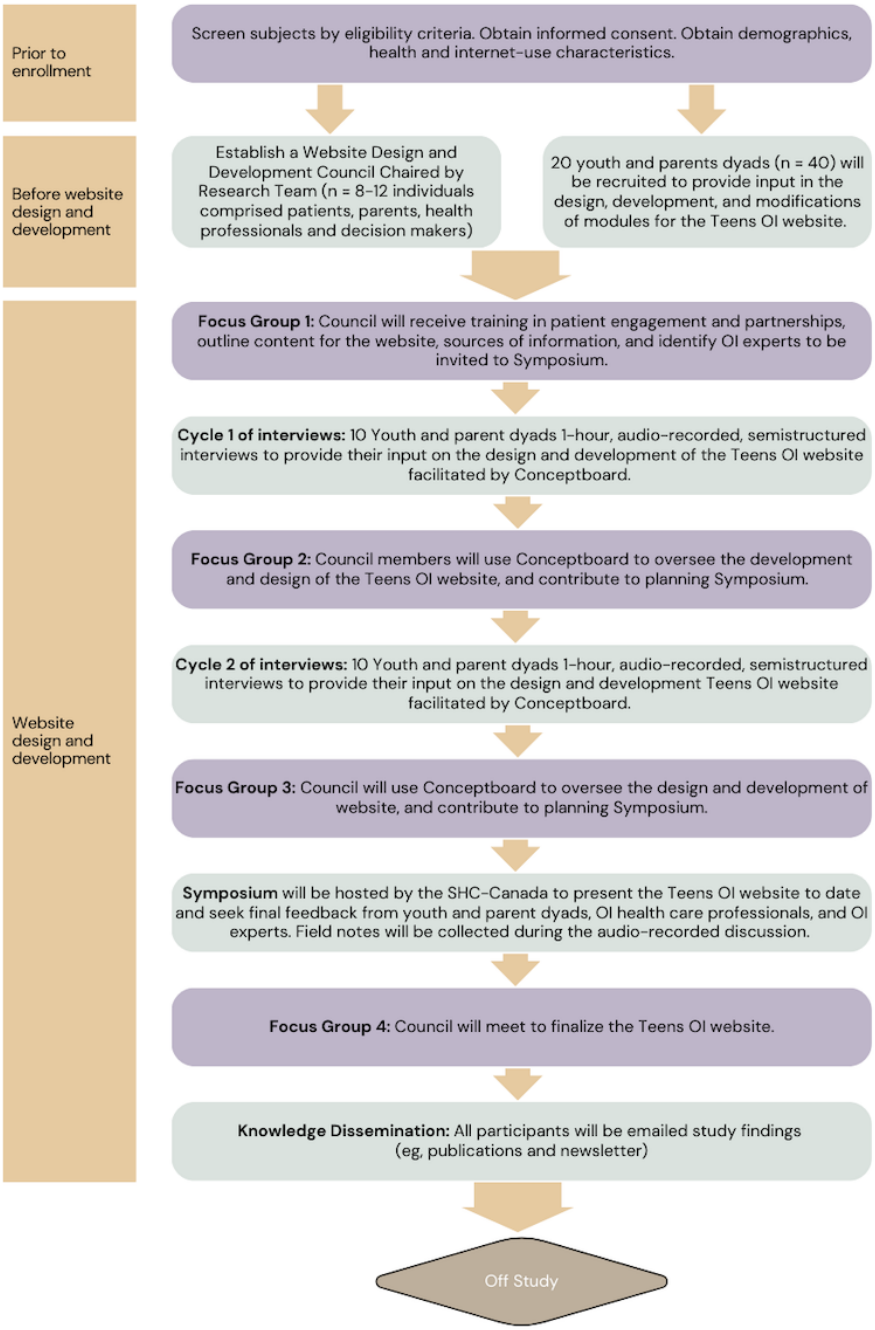
eHealth program; osteogenesis imperfecta; self-management; youth; transition of care

Introduction

Background

There is a critical demand for effective self-management and transitional care programs to optimize the quality of care and quality of life of youths and young adults with rare diseases worldwide. Transition is "the purposeful, planned movement of adolescents and young adults with chronic physical and medical conditions from child-centered to adult-oriented health care systems" [1]. Barriers impede a successful transition [2], leading to adverse events for the transitioning youths [3-8]. eHealth offers an innovative approach to address the self-management needs of transitioning youths [9,10]. Self-management is "the interaction of health behaviors and related processes that patients and families engage in to care for a chronic condition" [11]. In a burgeoning field, self-management interventions, delivered over the internet, can improve selected outcomes in certain childhood illnesses [9]. One promising program is Teens Taking Charge. Our team aims to develop this program for youths with osteogenesis imperfecta (OI). Our preliminary work showcases the critical need and motivation of youths with OI, their parents, and clinicians to engage in such a program [12-18] while addressing the global gap in OI self-management and transitional care programs [12,14,16-19]. Priority topics include a description of OI [16]; self-management of symptoms such as pain [20-22] and constipation [23]; coping with isolation, feeling different, and fear of fractures [24]; need for social support [24,25]; preparing for the transfer and navigation of the adult health care system [16-18]; managing costs [26]; and understanding the clinical manifestations of OI in adulthood [27].

"Teens Taking Charge" is a promising self-management and transitional care program available for youths with OI. Stinson et al [28] designed and developed "Teens Taking Charge," which is currently available for youths with juvenile idiopathic arthritis (JIA), cancer, hemophilia, or organ transplants. These multilayer programs contain self-guided, interactive, multicomponent modules that consist of disease-specific education, self-management strategies, and social support. To help encourage healthy behavior among youths, 2 modules specifically target parents. Recent findings from the 10-site, randomized controlled trial in the United States, using an "active" control group (n=144), supported a modest benefit for pain and quality of life for the Teens JIA group (n=145) [29]. The program is now publicly available and being adapted for use in Ireland [30]. Pilot randomized control trial studies suggest design feasibility, program benefits, and significant improvements in disease-specific knowledge (P=.004), self-efficacy (P=.007), and transition preparedness (P=.046) than the control group (n=13) [31-33]. The pilot testing of "Teens Cancer" is presently in progress.



To our knowledge, there are currently no eHealth interventions designed for youths with OI and their parents, resulting in unmet needs. The typical clinical appearance of youths with OI, a rare genetic disorder (1:10,000), is bone fragility [34]. In North America, the largest cohort of pediatric patients with OI (n=400) is followed at Shriners Hospitals for Children-Canada (SHC-Canada; ie, the study site of this protocol). The health care team is internationally acclaimed for establishing the worldwide standard of care, pioneering the treatment, and testing its effectiveness. Despite these accolades, ongoing multistakeholder service evaluations conducted at the study site have identified a critical need to develop a self-management and transitional care program delivered over the internet [12,14,16-18].

Study Goals and Aims

With multistakeholder input from patients, families, clinicians, and the greater OI community, our research team seeks to design, develop, and test the usability of Teens Taking Charge: Managing OI Online (Teens OI). This study protocol incorporates the preliminary work led by the research team. The approach is modeled after similar and successful approaches conducted with youths with JIA [29,30,32,35], hemophilia [31,36,37], cancer [38,39], and solid transplant [33,40,41]. A sequential phased approach of (1) needs assessments [14,16] (completed), knowledge syntheses [17,18,24,25,27,42,43] (completed), and preliminary symptom assessments [22,23] (completed); (2) program design, development, and usability testing [28,31,41] (this protocol), and (3) feasibility testing and outcome evaluation [32] (future research) has been adopted. The program design, development, and usability testing have 2 study aims. Aim 1 consists of designing and developing an English and French version of the Teens OI program (Figure 1). Aim 2 entails testing the usability of Teens OI in terms of (1) efficiency, (2) effectiveness, and (3) satisfaction, including perceived ease of use (ie, error prevention, other outcomes, information needs, and memorability), and perceived usefulness (ie, learnability, competency, performance speed, flexibility, and customizability) from the perspective of youths with OI and their parents (Figure 2).

Figure 2. Study schema: Teens OI Phase II. OI: osteogenesis imperfecta; SUS: System Usability Scale.

Preliminary Work for Aims 1 and 2

The preliminary work conducted for aim 1 consisted of needs assessments, knowledge syntheses, and the hiring of a former patient to inform the development of Teens OI. A usage-focused evaluation of the OI transitional care program at the study site revealed the need for a web-based self-management program [14]. Efforts to advance this mandate by the study site included the hiring of Chougui, a former patient and young adult with OI who is now a doctoral student in psychology, as a research team member since 2015. Chougui has contributed to drafting the preliminary content of Teens OI and creating varying transition-related tools [17,18,20,25-27,42]. The drafts have been informed by our completed study on self-management [16] and varying knowledge syntheses [17,18,24,25,27,42,43] and preliminary symptom assessments [22,23].

The preliminary work conducted for aim 2 has consisted of 4 qualitative usability studies conducted with 56 English-speaking and 26 French-speaking youths with JIA (n=19) [28], cancer (n=24) [38], hemophilia (n=18) [31], or transplant (n=21) [41], and one of their respective parents, to determine the usability of the user interface and content areas and refine the prototype accordingly using 2-4 iterative cycles. Youths and parents provided similar as well as differing suggestions on how to improve the website's user interface and usability. Participants reported suggestions for minor prototype changes across all 4 programs. They also responded positively to the website's content, use, appearance, and theme; indicated that the program was easy to navigate and understand; and perceived the program as helpful and acceptable. Many participants responded that the interactive features made them feel supported and "not alone" in their illness and that they felt enriched by their experience. No major differences between English- and French-speaking participants were found. Usability themes that arose from the 4 studies were: (1) aesthetics, (2) content and features, (3) functionality, (4) understandability, (5) comprehensiveness, (6) quality and credibility, (7) sociability, (8) intent for future use, (9) user satisfaction, and (10) overall impression [44]. Members of the research team have extensive training and experience designing, developing, and testing innovative eHealth technologies [28,31,38,41,45].

Methods

Aim 1

Study Design, Setting, and Context

A user-centered design is presently being conducted at SHC-Canada, a bilingual (French and English),

university-affiliated orthopedic hospital, inviting input on a global scale. Adoption of a user-centric design and a "user experience of websites" conceptual framework [46,47] will guide the collaborative and participatory design and development of Teens OI, addressing prior limitations including developing eHealth interventions without explicit theoretical frameworks, using single measures with limited end user input, and neglecting environmental factors [48]. By partnering with the end users (ie, youths with all OI Types and their parents) from study onset [49], we will lay the foundations for an effective eHealth program and ensure the content and format of the program are relevant, acceptable, and culturally sensitive [16,35,39,40,50]. Aligned with Shriners' Mission and FOCUSED philosophy of care [51,52], we are seeking to close the transitional care gap encountered by youths with OI and their families, improve the quality of health care services, and help youths and their families better manage OI. Our analysis of all education material for patients with OI at SHC-Canada revealed the dearth of resources available, targeting solely the parents of patients with OI [53]. Hence, our team has partnered with the end users from the study onset with the goal of introducing a series of eHealth programs to complement our existing health care services and enhance the global reach of Shriners [12,54].

Participants

A "Website Design and Development Council" (ie, Council) has been convened. Membership comprises patients, parents, health professionals, and decision makers (n=8-12) from the study site and the greater OI community. Maximum variation sampling techniques were used to recruit 20 youth-parent dyads from SHC-Canada over 5-10 cycles. The inclusion criteria consisted of (1) youths between 12 and 21 years of age; (2) youths receiving OI care at the study site; and (3) both youths and parents able to speak and read English or French. The exclusion criteria excluded youths if they had major cognitive impairments or comorbid medical or psychiatric illnesses that may impact their ability to understand and use the program. The power of the maximum variation sampling technique used lies in selecting information-rich cases for in-depth study, which maximizes variation and diversity. The variability affords a more comprehensive understanding of the many diverse experiences that will enhance the design and development of Teens OI and the transferability of the proposed eHealth platform. While a sample size of 20 youths and parent dyads was proposed, the sample size was tentative and may change based on achieving data saturation and the desire for a diverse sample (eg, cultural, linguistic, OI type, and severity of disability) [55,56]. About 150 eligible patients with OI were followed at the study site. Our experiences suggest there is substantial interest in study participation, with over >90% of participation rated as experienced at the study site [22]. Our youths and their parents remain concerned about their impending transition and welcome the proposed support [12,14,16].

Recruitment

A multipronged approach was used to announce the study and commence recruitment (Multimedia Appendix 1). To protect the families' privacy, the health care team assisted by identifying, screening, and approaching the families to determine if they were interested in hearing more about the study. If the patients express interest in hearing more about the study, their names and contact information are provided to the clinical research coordinator, who approaches the patients, provides a verbal and written explanation of the study, and, if agreeable, obtains written informed consent for study participation and audio-taping. Parents consent for their child to participate, and they consent for themselves to participate. Youths aged 12-13 years, provide assent and youths aged 14-21 years provide consent (Multimedia Appendix 2). Each study participant receives a copy of the consent. The health care professionals consider patients' health status and interest in participating in the study during regularly scheduled clinic appointments and in-patient visits. The recruitment method will be supplemented, if needed, by sending a study postal information letter, signed by their medical doctor and principal investigator, inviting them to participate at home.

Procedures

The Council will oversee the design and development of Teens OI using Garrett's Theory of User Experience [47]. Garrett proposed the following 5 different planes of a website that affect the user experience: surface, skeleton, structure, scope, and strategy, which have been used for understanding and improving youths' exposure to internet-delivered interventions [46,47]. The Council will receive training in patient engagement and partnerships, which includes topics of cultural competency [57], mutual respect, and inclusivity [58]. Conceptboard, a centralized hub for content and ideas for visual projects, will be used to facilitate the web-based, real-time, collaborative design and development of Teens OI with the global OI community and eliminate social distancing barriers due to COVID-19 [44]. Varying data will be collected in English and French by conducting youths' and their parents' interviews and focus groups; hosting 2 symposiums at SHC-Canada; presenting ongoing work; soliciting input from OI experts; and surveying the OI community using Qualtrics. Presently, we foresee 12 interactive, multicomponent modules adapted from Teens JIA [28] being designed for our diverse English- and French-speaking populations. Although draft modules have been created, we will inquire about topics and create, modify, or eliminate draft modules as needed. Other features such as multimedia (eg, video and audio) and other interactive, technological features (eg, discussion boards, animations, quizzes, stories of hope, and video clips) will be designed and developed with input from the end users.

Instrumentation, Interview, Focus Group, and Symposia Guides

Guided by Garrett's 5 planes contributing to users' experiences of websites [47], interview guides (Multimedia Appendix 3) outlining the procedures, questions, and probes have been created to guide discussions of website development and design, user experiences, and tools to solve related problems (1-2 cycles per plane). While each plane will be addressed individually, the discussion will naturally combine all planes. Field notes and feedback from the first cycle of interviews and focus groups will inform the discussion for subsequent cycles of data

XSL•FO
RenderX

collection. With 117 user experience instruments available, the Council will decide on the quantitative metrics of the design and development of Teens OI [59]. One sociodemographic survey will be used to collect demographic, health, and internet-use characteristics [12,16].

Data Management, Analysis, and Interpretation

All survey data are being descriptively analyzed using SAS (version 9.4; SAS Institute Cary). Observations, field notes, and transcribed data will be imported into NVivo (version 12; QSR International Pty Ltd) for data management and analysis. The qualitative data are analyzed using content analysis techniques involving an iterative process of data reduction, data display, conclusion drawing, and verification [60]. All data will be analyzed and triangulated in each of the 5 planes, fostering the process of "building from the bottom to the top" and "moving from abstract to concrete," allowing for refinement of Teens OI between each cycle within each of the 5 planes [47]. Individual and aggregate comparisons and contrasts of subgroups (eg, parent or youth [22,61,62]; English or French; OI Types and disability severity) are lending insight into how to synergize results and establish consensus with participants and the Council to maximize the inclusivity of Teens OI. An audit trail, composed primarily of methodological and analytical documentation, will be kept to permit the transferability of this innovative process [63]. Unanimous support from the Council to proceed to Aim 2 will be sought.

Aim 2

Study Design, Setting, and Context

A user-centered, mixed methods, concurrent design will be used to test usability. Usability testing is critical to ensure content relevancy; determine if the eHealth program is easy to use and efficient to complete; and confirm the end user product acceptability [28,31,38,41,45]. Using varying data sources, the usability testing will ensure the end users are able to access, understand, and use the Teens OI content and that the Teens OI can be delivered in an efficient, effective, and satisfying manner. The study setting and context will be the same as in aim 1.

Participants

Maximum variation sampling techniques will be used to recruit up to 32 youth-parent dyads from SHC-Canada. The inclusion and exclusion criteria will be the same as described in aim 1. Usability testing produces informative results with small sample sizes [64], with 80% of usability problems detected with 4 or 5 participants and 95% of problems identified with 9 participants [65,66]. Previous usability studies of Teens Taking Charge included sample sizes of 18 [31], 19 [28], 21 [41], and 37 [38]. Iterative rounds of testing with 8 youths per round will be conducted until 95% of usability issues have been determined.

Recruitment

The process for recruitment will be the same as that in aim 1.

Procedures

The usability testing will occur in 4 iterative cycles to assess the user performance and level of satisfaction of Teens OI and determine the need for refinement after each cycle. Consenting participants (8 in each of the 4 cycles) will complete a sociodemographic questionnaire, followed by a one-on-one observation recorded with Morae 3.3 (TechSmith Corp) usability software, and a semistructured interview with the research assistant (RA). Participants will access the website via a laptop computer for use at the point of care. Morae, activated at the beginning of instruction, will be used for the automatic recording of user performance and level of satisfaction. Once the automatic recordings have begun, the RA will direct the participants to the main navigation menu and prompt them to select one of the modules of interest to them. The RA will use a standardized script to instruct participants to select one or more key features or functions within the selected module. Participants will be encouraged to "think aloud" and comment on any difficulties, as they explore various features and functions within each module and complete various usability tasks (eg, select a module from the main navigation menu, click on a video, and complete an exercise). Scripted instructions will continue until the participant has viewed all of the modules or shows disinterest in exploring further. After each cycle iteration, changes to the website will be made accordingly, and usability testing will continue until no further significant issues have been identified. Participants will be instructed that they can stop participating in the study at any time. They will also have opportunities to debrief, ask questions, offer feedback, and receive assistance as needed. During the testing, the RA will also record their observations and take field notes. It is anticipated that the interviews will take 45-60 minutes, with length varying depending on the participants' schedules and interests.

Measures and Standardized Scripts

Guided by the Health IT Usability Evaluation Model (Health-ITUEM) [67,68], standardized scripts outlining the procedures, questions, and probes will be adapted from previous Teens Taking Charge research and used [28,31,38,41]. Usability surveys will also be used [69,70]. The sociodemographic survey in aim 1 will be used [12,16].

Data Management and Analysis

All sociodemographic data will be imported into SAS 9.4 for descriptive statistical analysis. Recorded Morae data will be downloaded, coded, and analyzed using descriptive statistics. Observations, field notes, and transcribed data will be imported into NVivo 12 for data management and analysis. The qualitative data will be analyzed using content analysis techniques involving an iterative process of data reduction, data display, conclusion drawing, and verification [60]. All data will be analyzed in 2-4 cycles to allow for prototype refinement between each cycle. Teens OI will also be compared to other OI websites using relevant evaluation indexes from the Alexa website ranking system [71] and Google Analytics [72]. An audit trail, composed primarily of methodological and analytical documentation, will be kept to permit the transferability of this innovative process [63]. As a benchmark of success, the team will strive to resolve 95% of problems, and have mean System Usability Scale and Health Information Technology Usability Evaluation Scale scores of 70% corroborated with positive findings.

Ethics Approval

This minimal-risk study has received feasibility, scientific, and administrative approvals from the Department of Research Programs at SHC International Headquarters and ethical approval from the institutional research ethics board (phase 1: A04-B31-21B, and phase 2: A10-B97-22B). Most participants for study inclusion (n=150) have been followed at the study site for several years, with follow-up visits at least biannually. The burden is relatively small, with no additional visits required for participation. While study participation is not associated with a greater risk than expected or encountered in daily life, distress from discussing self-management needs or preparing for transitioning into the adult health care system may occur. If periods of increased distress arise for the participants, data collection sessions will be postponed and resumed at a later time. Similarly, at any time during or after the study, the participants are free to decline to answer any question that makes them uncomfortable, to stop the interview, or to withdraw from the study. Instructions on how to withdraw are also provided to the participants and their parents during the informed consent discussion. If our team is experiencing any problems during the course of study, we will revisit as a team to strategize, offer solutions, or allocate resources as deemed necessary. Presently, the alternative to participating in the study is to not participate and to seek information and support for self-management and transition from published materials available for free or for purchase (eg, books), attend caregiver programs that exist in the community, or seek help from physicians, mental health practitioners, or other allied health care providers that exist in the community. If a potential participant screens out or does not want to participate but requests information about resources, we will refer the individual to the OI clinical team with their permission.

Knowledge Dissemination

The research team is actively presenting the research in progress at varying meetings to share and solicit input from the global OI community. Preliminary findings have been presented at 2 international meetings [73,74] and awarded a New Investigator Award. Feedback received is being shared and discussed with the Advisory Council, which may influence the research process, including data analysis, interpretation, and discussion of findings, or the content creation process of Teens OI. The findings will be subsequently published in peer-reviewed journals and mobilized via the global community network through social media, newsletters, and community, and academic events.

Results

Aim 1 received ethical approval on June 28, 2021. As of December 2021, an 8-person, interdisciplinary Teens OI council, comprised of 4 health care professionals (nurse practitioner, care coordinator, nurse, and social worker), 3 youths and young adults with OI, and 1 parent, has been convened to oversee the design and development of Teens OI. Two cycles of interviews have been conducted with 10 youths with OI with or without their parents (n=6) from December 2021 to September 2022. There have been no withdrawals. Attrition rates, including dropouts and those lost to follow-up, may range from 10% to 15% (which is similar to Teens JIA [32] and considered low compared to other internet-based studies in adolescents (0-28, mean 14.3) and adults, in which higher dropout rates were found [9,32]). Data analysis has been in progress since April 2022. Aim 2 is ethically approved and will commence following the completion of content development, expected by late July 2023. Preliminary analysis indicates that the following topics need to be prioritized for the youths: mental health, pain, accessibility, medical care, education, community, and parental care.

Discussion

Principal Findings

The survival of youths with chronic health conditions into adulthood has created a critical demand for effective self-management and transitional care programs to optimize the quality of care and quality of life of children with rare diseases worldwide. SHC-Canada, internationally acclaimed for establishing the worldwide standard of care for children with OI, is of no exception. Ongoing, multistakeholder evaluation of transitional care services at SHC-Canada has identified the need for a web-based self-management program to better prepare patients with OI and their families for transition into the adult health care system. Preliminary work consisting of needs assessments, knowledge syntheses, and symptom assessments has ensued to inform the creation of such an evidence-based program with priority topics identified. A long-standing partnership with Stinson, who has led similar studies (registered on clinicaltrials.gov) with youths with arthritis (ID NCT01572896), cancer (ID NCT02299219), hemophilia (ID NCT01477437), and organ transplants, has subsequently catalyzed our efforts to offer Teens OI. Collectively, our interdisciplinary research team is uniquely positioned to address the transitional care gap in the OI community. Our team has led studies of self-management and transitional care in OI [14,16-18] and begun developing eHealth innovations (ie, OI Good to Go Passport [17] and Sisom OI [47]). However, the need for this Teens OI is global. After presenting our in-progress work at 2 international OI meetings [73,74], there is a global request to merge our efforts, knowledge, and expertise. To further catalyze efforts and mobilize the community to enhance the paucity of resources available for this rare disease patient population, we encourage interested individuals, patient organizations, and institutions from the public, private, and industry sectors to express their interest and reach out to the team. A significant amount of content needs to be created amidst the dearth of evidence available in OI, especially tailored to the youth audience. We welcome the sharing of resources, especially any gray source material (eg, pamphlets, policies, tools, pictures, graphics, videos, or teaching materials), to determine how to ideally integrate into Teens OI and to recognize the contributions of others. Moreover, translators will be needed to render Teens OI accessible to communities unable to comprehend English or French and to collaborate on tailoring Teens OI to the respective languages, cultures, and contexts.

XSL•FO
RenderX

Troubleshooting

Due to COVID-19 restrictions imposed at the study site related to large crowd gatherings, our research team opted to solidify global input on our in-progress findings at 2 international OI meetings to date [73,74]. This warranted an ethical amendment allowing us to survey the global OI community with questions generated from our in-progress design analysis [73]. Once large-scale, in-person meetings are reconvened, the research team will host a symposium related to self-management and transitional care at the study site to further inform the content creation process. Software restrictions in the study have precluded the use of Conceptboard. Hence, this innovative feature permitting real-time, collaborative design and development of Teens OI with the global OI community was not used. Rather, design features are transferred to PowerPoint slides shared via Microsoft Teams in individual or focus groups for feedback.

Strengths and Limitations

A rigorous and innovative approach is being used to design, develop, and test the usability of Teens OI. This self-management and transitional care program will be designed, developed, and tested in partnership with youths with OI, their parents, and the greater OI community. This user-centric approach will advance the neglected OI field of research, align with the mission and philosophy of care (FOCUSED) of the study site, and capitalize on youths as early adopters of eHealth technologies to meet their needs. Findings will generate the provision of the Teens OI eHealth prototype, which will be ready for feasibility testing and outcome evaluation. The development of Teens OI will address a critical gap in the quality of care and our growing concerns that the OI population transitioning from our study site and other pediatric hospitals is at risk of various adverse events in terms of morbidity, mortality, social, educational, and vocational outcomes. Moreover, this research program will address a serious lack of health care resources designed with patients to improve the quality of care and life. Finally, actively engaging our patients in the provision of their care is their fundamental right, and it is our duty as health care professionals to offer these quality services. Presently, the findings generated from this study will be primarily derived from English- and French-speaking youths, parents, and clinicians. Efforts are in place to seek evidence (eg, documents, videos, and input) from the global community to guide the design and development of content. While the participants are from varying ethno-cultural backgrounds, they are primarily from Canada and treated at a study site internationally renowned for the treatment of OI. The transferability of the Teens OI prototype will need to be assessed and tailored to other contexts accordingly.

Acknowledgments

We would like to thank all participants, Shriners, and the greater OI community for their ongoing support. This project was awarded a SHC Development Grant (Multimedia Appendix 4). AT is the recipient of a Junior 1 Research Scholar Award (2019-2023) from the Fonds de recherche du Québec - Santé (FRQS).

Data Availability

Congruent with the study site policies, any unique research resources developed through SHC-sponsored research will be available to individuals upon request from any research team member. These resources may include consent forms, instruments, interview guides, databases, coding frameworks, methods, the Teens OI prototype, and dissemination material. These resources will be available for research purposes to qualified individuals within the scientific and OI communities through academic and nonacademic publications and consultations.

Authors' Contributions

AT and JS conceived and wrote the initial protocol. KT, FR, RH, KC, SA, TP, MB, ND-O, and L-NV reviewed, edited, commented on, and finalized the awarded protocol and study materials and will be contributing to the content development of Teens OI. SA and LMNP are research staff coordinating, collecting, and analyzing data. LMNP is coordinating the design and development of Teens OI. RPDS is a postdoctoral fellow collects and analyzes data as part of her training. AT wrote the manuscript. All authors reviewed, edited, commented on, and approved the final manuscript.

Abstract

Background: Patients with colorectal cancer (CRC) receiving chemotherapy often experience psychoneurological symptoms (PNS; ie, fatigue, depression, anxiety, sleep disturbance, pain, and cognitive dysfunction) that negatively impact both patients' and their caregivers' health outcomes. Limited information is available on PNS management for CRC patient and caregiver dyads.

Objective: The purposes of this study are to (1) develop a web-based dyadic intervention for patients with CRC receiving chemotherapy and their caregivers (CRCweb) and (2) evaluate the feasibility, acceptability, and preliminary effects of CRCweb among patient-caregiver dyads in a cancer clinic.

Methods: A mixed methods approach will be used. Semistructured interviews among 8 dyads will be conducted to develop CRCweb. A single-group pre- and posttest clinical trial will be used to examine the feasibility, acceptability, and preliminary effects of the intervention (CRCweb) among 20 dyads. Study assessments will be conducted before (T1) and after intervention (T2). Content analysis will be performed for semistructured interviews. Descriptive statistics will be calculated separately for patients and caregivers, and pre-post paired *t* tests will be used to evaluate treatment effects.

Results: This study was funded in November 2022. As of April 2023, we have obtained institutional review board approval and completed clinical trial registration and are currently recruiting patient-caregiver dyads in a cancer clinic. The study is expected to be completed in October 2024.

Conclusions: Developing a web-based dyadic intervention holds great promise to reduce the PNS burden in patients with CRC receiving chemotherapy and their caregivers. The findings from this study will advance intervention development and implementation of symptom management and palliative care for patients with cancer and their caregivers.

Trial Registration: ClinicalTrials.gov NCT05663203; https://clinicaltrials.gov/ct2/show/NCT05663203

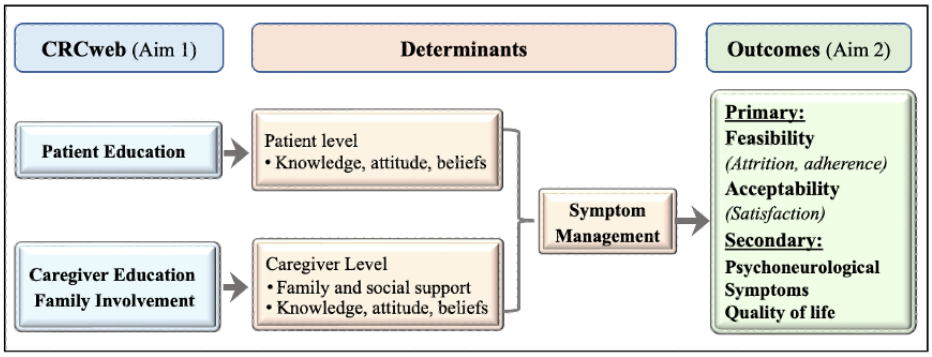
Introduction

Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer-related deaths in the United States [1]. Patients with CRC receiving chemotherapy often experience severe and distressing psychoneurological symptoms (PNS) that include fatigue, depression, anxiety, sleep disturbance, pain, and cognitive dysfunction [2-5]. When these multiple co-occurring symptoms are undertreated, they negatively affect functional status, survival rates, and quality of life (QOL) of patients and decrease health outcomes (eg, QOL and mood) of their family caregivers (hereafter "caregivers," defined as family members or significant others identified by the patients as their primary source of emotional and physical support) [6-8]. Current interventional studies in context of CRC are mainly focused on CRC screening and treatment regimens [9,10]. Limited information is available on symptom management for patients with CRC and their caregivers, which underscores the critical need to develop an innovative and effective intervention to manage PNS for patient and caregiver dyads.

Evidence has shown that PNS may share similar mechanisms, such as increases in proinflammatory responses or neurotransmitter alterations, which partially explains why they cluster together [11,12]. Our prior work shows that depression and fatigue are core symptoms within PNS networks and that PNS are highly interconnected with each other over time, suggesting that symptom management for these clustered symptoms may decrease multisymptom burden at the same time [13]. Moreover, addressing multiple symptoms simultaneously is cost-effective as shown in prior research [14,15]. Although interventions have been developed for managing single symptoms (eg, pain and fatigue) [16,17], little is known about multiple PNS management.

Among current interventional programs, psychosocial strategies that decrease stress and improve psychosocial adaptation for individuals have demonstrated the potential of alleviating PNS as a cluster [18-22]. One evidence-based psychosocial intervention, the FOCUS program (ie, Family involvement, Optimistic attitude, Coping effectiveness, Uncertainty reduction, Symptom management), has shown to improve multiple co-occurring symptoms including PNS for patients with heterogeneous cancer diagnoses (eg, breast cancer and advanced CRC) and their caregivers [23-25]. However, FOCUS has several notable limitations, including an in-person delivery format that is costly and time-consuming. It is also not specific to PNS management and does not target patients with CRC receiving chemotherapy.

In addition, patients with CRC are facing unequal access to palliative care and disparities in treatment [26]. Prior studies reported that patients with CRC on Medicare and living in rural areas were more likely to experience severe symptom burden and treatment disruptions compared with those on private insurance and living in urban areas [27,28]. A technology-based approach (eg, web program) using computers and mobile devices allows high flexibility and accessibility for disproportionately affected patients with CRC and caregivers, especially during and after COVID-19, and minimizes the cost of the intervention in hectic and costly cancer clinics [29,30]. Therefore, developing a web-based dyadic intervention holds great promise to reduce PNS burden for both patients and their caregivers as well as to advance intervention development and implementation in cancer palliative care and health equity.



To our knowledge, there is no current web-based dyadic intervention for PNS management among patients with CRC and their caregivers. Therefore, the aims of this study are to (1) develop a web-based dyadic intervention to manage PNS for patients with CRC receiving chemotherapy and their caregivers (CRCweb) and (2) evaluate the feasibility, acceptability, and preliminary effects of CRCweb among patient-caregiver dyads in a cancer clinic.

Methods

Conceptual Model

Leveraging the FOCUS program [23-25] and health education theory [31], we developed a web-based dyadic intervention model (Figure 1). The FOCUS program provides the rationale for psychosocial education (eg, coping strategies) [32] and family involvement and support by including family members in the care process and educating families to cope with multiple demands [33]. Health education theory provides the basis for enhancing the patient-caregiver communication process and working in team science [31]. We hypothesize that the CRCweb intervention will enhance PNS management by reducing symptom burden and increasing QOL through improving psychosocial education and family involvement and support for patients with CRC receiving chemotherapy and their caregivers.

Figure 1. The web-based dyadic intervention model (CRCweb).

XSL•FO
RenderX

Design

The proposed study will be conducted in 2 phases—CRCweb development in phase 1 and a pilot clinical trial in phase 2. A mixed methods approach will be used. In phase 1, we will determine tailored content through qualitative interviews with patient-caregiver dyads, develop a web-based program prototype, and test program usability and refine the program to yield a final version of CRCweb. In phase 2, we will conduct a single-arm, pre- and posttest clinical trial to evaluate the feasibility, acceptability, and preliminary effects of the intervention on PNS and QOL among patient-caregiver dyads in a cancer clinic.

Participants and Settings

In phase 1, we will recruit 8 patient-caregiver dyads; in phase 2, we will recruit 20 dyads. The inclusion criteria for patients will be age ≥18 years, diagnosed with CRC (any cancer stage), life expectancy >12 months, receiving active chemotherapy, self-reported at least 2 PNS (based on the symptom measures' cutoff scores described in Table 1), identified primary caregiver, access to the internet, and fluent in English. Patients who have a Karnofsky Performance Scale score of <50 will be excluded. The inclusion criteria for caregivers will be age ≥18 years, primary caregiver, self-reported at least 2 PNS (based on the symptom measures' cutoff scores described in Table 1), access to the internet, and fluent in English. Caregivers who have severe diseases such as cancer and heart disease will be excluded. Patients will be recruited at the Gastrointestinal Oncology Clinics of Emory Winship Cancer Institute.

Table 1. Measurements.

Outcome and variable	Time point[a]	Description
Primary outcomes		
Feasibility		
Attrition	T2	• Attrition is measured by the number of patients and caregivers who drop out before completing the intervention. We will consider the intervention to have low attrition if >80% dyads remain enrolled.
Adherence	T2	• Adherence is measured by the number of modules completed for dyads. It is determined by high adherence if dyads complete >80% of the modules.
Acceptability		
Satisfaction	T2	• Participant satisfaction with CRCweb is assessed by the 8-item Client Satisfaction Questionnaire (Cronbach α=.93; 8-item; 4-point Likert) among patients and caregivers at the end of the intervention.
Secondary outcomes[b]		
Intervention effect		
Psychoneurological symptoms	T1, T2	• Fatigue: 20-item Multidimensional Fatigue Inventory. A cutoff score of ≥43.5 indicates moderate-to-severe fatigue. • Depression: 8-item Patient Health Questionnaire. A cutoff score of ≥10 indicates clinically significant depression. • Anxiety: Spielberger State Anxiety Inventories. A cutoff score of >32.2 indicates high levels of state anxiety. • Sleep disturbance: Pittsburgh Sleep Quality Index (PSQI). PSQI score of ≥5 indicates a significant level of sleep disturbance. • Cognitive dysfunction: Attentional Function Index (AFI). AFI score of <5 indicates a significant level of cognitive dysfunction. • Pain: Brief Pain Inventory. A cutoff score of ≥4 indicates moderate to severe pain.
Quality of life	T1, T2	• The Short Form-12 consists of 12 questions about physical and mental health as well as overall health status. It is scored into 2 components: physical component score (PCS) and mental component score (MCS). Higher PCS and MCS scores indicate a better quality of life.

[a]T1: before intervention, at baseline; T2: after intervention.

[b]The details for the measures can be found in Multimedia Appendix 1.

Ethics Approval

The study was approved by the institutional review board at Emory University (STUDY00004750) and registered at the ClinicalTrials.gov (NCT05663203). Participants will be recruited from May 2023 to August 2024 at the Emory Winship Cancer Institute. The research staff will screen eligible patients in the electronic health record system (Epic); they will then reach out to health care providers at the clinic who will confirm eligibility and suitability and give permission for the research staff to reach

XSL•FO
RenderX

out to the patient-caregiver dyads to assess their interests. If the research staff find that both patients and caregivers are interested, they will explain the study to dyads and obtain dyads' written informed consent in person at the clinic.

Phase 1—CRCweb Development

Semistructured Interviews

We will conduct semistructured interviews with patient-caregiver dyads using an interview guide developed from the existing literature that includes open-ended questions and probes. Dyads (n=8) will be asked about their needs for the intervention, perspectives, and suggestions for a web-based intervention to manage their symptoms, what they like and do not like about the proposed CRCweb intervention components (ie, family involvement, symptom management, and coping effectiveness) and delivery mode (eg, doses and intervals), and what modifications they would recommend being made. The interview will last 30 to 45 minutes and be conducted by the principal investigator (PI) in a private conference room at the clinic or in a Zoom meeting based on the dyad's preference. All interviews will be audio recorded and transcribed, and field notes will be taken to capture nonverbal expressions.

Development of a CRCweb Prototype

We will develop the CRCweb prototype and deploy it to Amazon Web Services (AWS) at Emory. AWS at Emory is a certified cloud service provided by AWS. A technology expert (WC) who has developed several rigorous web programs such as TCOLA (a technology-based CRC support program for Asian American women) will provide technical support. Two full-stack web designers will develop the CRCweb prototype (in 4-6 months). We will also collaborate with Health Information Technology Core at Emory University School of Nursing for the web program development. The research team will review the CRCweb prototype to provide feedback and make modifications.

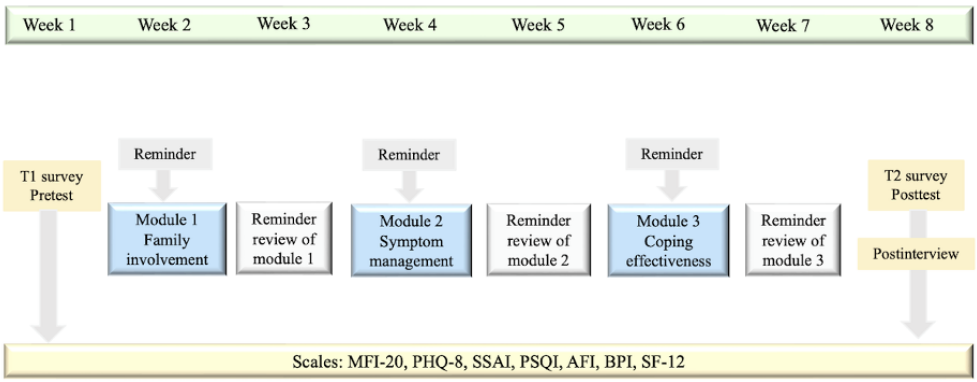
Usability Testing

After the CRCweb prototype is developed, we will ask 4 patient-caregiver dyads to use the CRCweb prototype and provide feedback about the usability of the program [34]. Semistructured interviews (30-45 minutes) will probe for participants' experiences with using CRCweb (eg, design, navigation, structure, and language). Interviews will be recorded and transcribed; field notes will capture dyads' interactions with the program and document problems with using the websites. Five clinicians or researchers in oncology area will serve as content experts and provide feedback on the program. Feedback will guide the refinement of the CRCweb program, yielding a final version that will be used in the clinical trial.

Phase 2—Pilot Clinical Trial

We will conduct a single-arm, nonrandomized, and nonblinded pre- and posttest clinical trial among patients with CRC receiving chemotherapy and their caregivers (n=20 dyads). Primary outcomes (feasibility and acceptability) will be assessed at the completion of intervention among patients and caregivers. Secondary outcomes (PNS and QOL) will be assessed at baseline (T1, before intervention) and 8 weeks (T2, after intervention) for patients and caregivers. We will collect quantitative assessment data on internet-accessible devices via REDCap self-administered surveys. We will avoid collecting symptom data at the acute symptoms stage (within 1 week after chemotherapy administration) to reduce measurement bias. Additionally, semistructured formative evaluation interviews will be conducted after the intervention among these participants regarding their experiences and suggestions on the intervention to inform the future refinement.

Intervention



CRCweb is designed to create opportunities for patients and caregivers to obtain information and interact with each other. Patient-caregiver dyads (n=20) will participate together in an 8-week CRCweb intervention using assigned accounts and passwords to access to CRCweb with the help of the research staff. An introductory video (5 minutes) on the CRCweb page will teach patients and caregivers how to use CRCweb and navigate the websites. Dyads can use the program at any time and any place during the 8 weeks. They are encouraged to log on the program using their own devices and complete modules together, sitting side by side if possible. Three modules (ie, family involvement, symptom management, and coping strategies) are selected because they are more relevant to symptom management. Each module will be presented 2 weeks apart to enable dyads to absorb the information sequentially and practice the module's principles before moving to the next module. The content of modules is shown in Table 2. Each module has 4 sections: video-enhanced lectures (10-20 minutes) and audio-enhanced texts, resources and web links, assignments, and evaluations. The video-enhanced lectures and audio-enhanced texts contain the same contents, allowing users to acquire the material according to their own learning styles. Modules include relevant resources and web links (eg, organizations, guidelines, and support services) for those who want additional information and resources. The modules for patients and caregivers are the same except tailored resources and web links. Assignments encourage dyads to practice learning skills and activities, discuss the symptoms and their effects on their daily lives, and brainstorm strategies to minimize the negative effects. After each module, a self-evaluation survey (score range 0-10) assesses the dyad's learning. If they receive a score 0 to 5, a reminder message appears suggesting they take more time in the next week to review the module; if the score is 6 to 8, they can use the same amount of time next week to review the module; and if the score is 9 to 10, they are ready to move to the next module. We will track website activity data (eg, number of logins and time spent on the site) to assess if patients and caregivers engage in the learning modules. Additionally, we will send them weekly emails or SMS text messages to remind them to complete modules and surveys. The intervention flow is shown in Figure 2.

XSL•FO
RenderX

Table 2. Module content.

Module and goal	Content
Family involvement	
Promoting open communication	•Discuss benefits of open communication versus concealment •Emphasize the importance of communication •Encourage open discussion of concerns •Use "I" statements to express feelings, use humor •Encourage sharing perspectives on any issues, concerns, or feelings •Address issues or concerns and reassure feelings
Encouraging mutual support and teamwork	•Discuss that cancer can affect both patient and family, making mutual support essential •Recognize the contributions of both members of the dyads and encourage the expression of appreciation
Identifying family strengths	•Help patients and family members identify individual and family strengths •Keep up positive outlook and face challenges together
Introducing family to information and resources	•Identify resources for the family to manage the recurrent illness •Give names and contact numbers of support groups for patients with colorectal cancer and their family
Symptom management	
Assessing symptoms	•Assess symptoms experienced by patients and their caregivers •Talk about the most severe, frequent, or distressed symptoms •Discuss effects of treatment on family relationships and the importance of caregiver's health
Teaching self-care strategies	•Review patients' and their caregivers' symptom management and learn symptom management strategies •Provide information, guidelines, resources, and support services
Establishing realistic and short-term goals	•Set up easy goals to achieve for symptom management •Document and monitor symptoms, write symptom diary
Coping effectiveness	
Dealing with overwhelming stress	•Encourage day-to-day efforts to cope •Allow opportunities to discuss death and dying issues or concerns
Encouraging healthy coping and lifestyle behaviors	•Discuss benefits of active versus passive coping strategies •Educate about the importance of healthy lifestyle behaviors for patients and family members: eating and exercise, sleep and rest patterns, use of chemical substances, and support networks
Helping caregivers manage the demands of illness	•Encourage caregivers to accept offers of help from others •Help caregivers identify activities to restore their mental and physical energy (eg, hobbies and recreational activities)

Intervention Fidelity

The PI will check CRCweb login information every Friday and send the reminder nudge messages with a checklist to patient-caregiver dyads who have not completed the modules and surveys. Given competing demands on patients and caregivers, we allow them to use CRCweb in their available time and limit the time of learning modules (less than 1 hour per week).

Measurement

A demographic questionnaire will be used to collect information such as age, gender, race or ethnicity, marital status, education, employment status, exercise, income, insurance, and dyadic relationships. Medical records will be reviewed for patients' disease and treatment information, such as cancer sites, cancer stage (TNM, tumor-nodes-metastasis), treatment types, chemotherapy regimens and cycles, surgery, and radiotherapy. The measures that include primary outcomes (ie, attrition, adherence, and satisfaction) and secondary outcomes (ie, PNS and QOL) are shown in Table 1. As indicated, all the instruments are valid and reliable.

Data Analysis

In phase 1, content analysis will be used to analyze the qualitative data [35,36]. Coding will be conducted by 2 researchers (including the PI) with backgrounds in cancer and qualitative methodology. The NVivo software (QSR International Pty Ltd) will be used to support data analysis, which is completed in four steps:

1. Data preparation [37]: 2 researchers read the transcripts together to get a sense of the whole picture; they identify key topics and storylines and categorize informational content (eg, patients' perspectives).
2. Writing memos: using the transcripts and filed notes, 2 researchers write analytic memos and a brief case description of each participant.
3. Coding [38]: 2 cycles of coding will be used. The PI uses a priori codes from the literature and clinical practice to create a codebook. The first cycle includes codes developed a priori coding, descriptively, and in vivo [38]. The second researcher reviews the coding scheme and provides feedback; the PI revises the codebook by adding or combing codes. Once the first cycle of coding is completed, 2 researchers review the findings and develop larger categories of data using pattern coding and theoretical coding [38]. The second cycle will be used to organize and group codes that are similar or shared common characteristics.
4. Categorizing and connecting: 2 researchers construct tables and matrices to organize, condense, and display the codes and data samples into categories; all researchers help search for patterns, trends, and paradoxes across all participants and then summarize the descriptions and develop the themes [39].

In phase 2, quantitative data will be analyzed using SPSS Statistics (version 27.0; IBM Corp). Descriptive analyses will be conducted to determine the frequencies, percentages, means, and SDs of major variables. Feasibility of study attrition and adherence will be assessed by calculating attrition rates, identifying reasons for refusal, and assessing completeness of the data. Accessibility of participant satisfaction will be evaluated by calculating descriptive statistics to summarize responses to the poststudy evaluation items. Pre-post paired *t* tests (and nonparametric equivalents as needed) will be used to evaluate the changes between secondary outcomes (PNS, using the same calculating methods as described in our previous publication [13]) from pre- to postintervention stages for patients and caregivers. We will use dyadic analyses because of the increasing evidence that patients' and their family caregivers' responses to illness are interrelated [14]. Time and level (ie, patient vs caregiver) will be treated as within-subject variables to control for the interdependent nature of the data. The main effect by time will be examined to determine the overall effect of intervention on PNS for patient-caregiver dyads as a unit (average scores across dyads) [40]. We will also analyze time-by-level interactions to determine if there will be a differential effect of the intervention on patients' and caregivers' outcomes [14]. As needed (for an adjusted analysis), potential covariates (eg, age, insurance, and income) will be included in the planned models as appropriate. Additionally, qualitative data from postintervention interview will use the same analysis as in phase 1. Convergent parallel analysis will be used to compare and merge the quantitative and qualitative data when they have been completed [41]. We will discuss areas of convergence or divergence between the quantitative and qualitative results to refine the intervention.

Results

Given that it is a study protocol, we do not yet have any results to report from the study. This study was funded in November 2022. As of April 2023, we have obtained institutional review board approval and completed clinical trial registration, and we are currently recruiting patient-caregiver dyads at a cancer clinic. The study is expected to be completed in October 2024. Expected results will be published in spring 2025.

Discussion

To our knowledge, this study is the first to develop and evaluate a web-based dyadic intervention to manage PNS for patients with CRC during chemotherapy and their caregivers. The findings from this study will advance intervention development and inform implementation in cancer symptom management and palliative care.

There are several strengths that may enhance its impact. First, we develop and test an intervention to manage multiple co-occurring symptoms or symptom cluster (ie, a PNS cluster) for patients with CRC and their caregivers. Existing interventions have focused on managing single symptoms such as pain and fatigue, but interventions for a PNS cluster are still in early infancy [42]. Our program is designed to help improve PNS management for patients with CRC and their caregivers by providing dyads with information and support through educational sessions (eg, family support, symptom management, and coping) that are tailored to fit the needs of dyads.

XSL•FO
RenderX

Second, we will develop and evaluate a web-based intervention (CRCweb) that is accessible to patients and caregivers who may experience disparities in symptom management and palliative care. More than 76% of underserved populations have a smartphone or computer device that could provide access to web-based interventions [43]. Symptom management interventions have typically been delivered in person (eg, FOCUS), resulting in many barriers to participation (eg, long distance, limited provider availability, and high costs) [14]. In-person interventions can be problematic for patients and caregivers who tend to have many competing commitments and for providers who have limited time in clinic [44]. Web-based interventions have produced improvements in symptom management for patients with cancer and caregivers in several clinical trials [40,45-47], and the use of technologies and telemedicine has significantly increased during and after the COVID-19 pandemic [48]. A web-based dyadic intervention program may enhance feasibility and acceptability relative to in-person interventions by avoiding interruptions to treatments and reducing financial burden for patients and their families [49].

Third, we will evaluate the feasibility, accessibility, and preliminary effects of the intervention (CRCweb) to improve both patient and caregiver outcomes (eg, adherence, symptoms, and QOL). It is essential to focus on both patient and caregiver outcomes because caregivers experience increasing symptoms and distress while caring for patients [50]. To date, limited research has focused on symptom management and palliative care of both patients with CRC and caregivers. The proposed study will address the urgent need to develop a dyadic intervention to improve health outcomes for patient with CRC receiving chemotherapy and their caregivers and accelerate the development of palliative and psychosocial cancer care.

The study also has several potential pitfalls that should be considered. First, the study might have potential selection bias because the inclusion criteria are speaking English and the access to the internet using smartphones or computers. We estimated 10% to 20% of patients who may be interested in the study without mobile devices or internet access. We will provide them with smartphones and data plans. In addition, we will develop the web program in different languages in the future. Second, there might be attrition rate among participants due to treatment burden (eg, chemotherapy) or other issues. We developed several strategies for participant retention. (1) We planned a recruitment strategy that follows recommended guidelines [51] for recruiting and retaining seriously ill patients and underserved populations in longitudinal research and focuses on enrolling interested, completely informed participants. (2) We will train research staff to establish rapport from the time of initial contact and demonstrate rapport and flexibility throughout all study activities. (3) We will send reminder emails or SMS text messages to participants to complete intervention modules and surveys every week. (4) We will minimize participant burden through web-based data collection, limiting the number of measurements, and allowing flexibility in learning modules. (5) Participant concerns will be responded to immediately, within reason. (6) To promote retention between data collections, we will send “thank you” notes, birthday cards, and holiday greetings. (7) We will reimburse each dyad member for participating in the study (eg, US $25 per person for interview, US $50 per person for clinical trial using a prorated incentive plan that reimbursements are disbursed at weeks 1, 5, and 8).

The brevity of the intervention and delivery via web-based format enhance dissemination possibilities. Results from this proposed study may lead to advances in translation into clinical practice. For future research, we may develop a web-based multilevel interventions that include more levels (eg, clinician team, clinic, local, state, and nation level), conduct larger and multicenter interventions (eg, cluster randomized clinical trials), and implement the web-based intervention program in multiple clinical sites nationally and internationally (eg, effectiveness-implementation hybrid design). In addition, we will incorporate potential biomarkers along with interventions to further understand the effects of the interventions. The ultimate goals will be to develop the web-based dyadic intervention (CRCweb) program and disseminate and translate it into clinical settings. The website will become publicly available to equip patients and caregivers with tools to better manage their multiple co-occurring symptoms and improve QOL.

In conclusion, developing a web-based dyadic intervention holds great promise to reduce PNS burden and improve QOL for patients with CRC receiving chemotherapy and their caregivers. The findings from this study will advance intervention development and implementation in cancer symptom management and palliative and psychosocial care as well as accelerate the transformation of technology-based programs into clinical practice.

Acknowledgments

The study was supported by the Oncology Nursing Foundation Research Grant (2022 RE03). The authors also appreciate the support from Emory University School of Nursing and Winship Cancer Institute.

Data Availability

Data sharing is not applicable to this protocol paper as no data were generated or analyzed. The data set generated and analyzed in the interview and clinical trial will be shared with other users only under a data sharing agreement that provides a commitment to the following: (1) use of these data for research purposes only and not for the purposes of identifying individual participants, (2) the securing of the data and any copies (soft or hard) generated from these data using secure filing and appropriate secure computer technology, and (3) destroying or returning the data after analyses are completed. The PI (YL) will coordinate requests

XSL•FO

Abstract

Background: Participating in an adequate amount of physical activity to acquire health benefits is challenging for people with spinal cord injury (SCI) due to personal and logistic barriers. Barriers in the built and social environments may include lack of transportation, lack of accessible facilities or programs, and lack of training among fitness personnel. Low self-efficacy, lack of self-regulation skills, and improper outcome expectations are examples of personal barriers. Current approaches to investigating physical activity programs in people with SCI have been limited to traditional “one-size-fits-all” design, which has yielded low adherence rates, high dropout rates, and participants not maintaining physical activity levels at follow-up.

Objective: The primary aim of this study is to test the feasibility of a tele-exercise program that applies an adaptive intervention design for 30 adults with SCI, targeting increases in adherence to the exercise program and physical activity participation.

Methods: The Sequential Multiple Assignment Randomized Trial for Home-based Exercise and Lifestyle Tele-Health (SMART-HEALTH) is a 12-week, home-based, movement-to-music (M2M) program. The goal of a SMART-designed study is to develop an adaptive intervention that modifies support provisions based on response levels. In SMART-HEALTH, 2 groups of participants will undergo 3-week and 6-week asynchronous M2M interventions in the first phase. Participants who did not achieve the desired adherence rate (≥95% of video watch minutes) will be rerandomized into M2M Live (switch) or individualized behavioral coaching (augmented with the asynchronous M2M program). The study will primarily assess rates of recruitment or enrollment, adherence and retention, timing to identify nonresponders, and scientific outcomes (eg, physical activity and exercise self-efficacy). The study will qualitatively evaluate the acceptability of the study using semistructured interviews among participants who complete the 12-week intervention.

Results: Recruitment procedures started in June 2022. All data are expected to be collected by September 2023. Full trial results are expected to be published by March 2024. Secondary analyses of data will be subsequently published. Results will include exercise adherence rates; changes in self-reported physical activity levels and blood pressure; and changes in secondary conditions including pain, sleep, and fatigue. Thematic analysis of semistructured interviews will include results on participant enjoyment and acceptability of SMART-HEALTH and inform modifications for future delivery of the program.

Conclusions: This study will strengthen our understanding of the potential benefits of the tele-exercise intervention for people with SCI and build upon adaptive intervention design and its delivery strategies that aim to increase adoption and sustainable

XSL•FO
RenderX

exercise behavior. This pilot trial will inform future SMART-designed studies and provide new and innovative strategies for investigating intervention effects on physical activity behavior in the SCI population.

KEYWORDS

exercise; physical activity; spinal cord injury; adaptive intervention

Introduction

Approximately 302,000 individuals in the United States are living with spinal cord injury (SCI) [1]. Substantial evidence supports the benefits of exercise training for improving health and functional outcomes and managing the risk of chronic disease and secondary conditions related to the SCI (eg, cardiometabolic disease, obesity, and depression) [2-8]. Despite the benefits, people with SCI engage in considerably lower levels of exercise and physical activity participation compared with the general population of adults and individuals living with other health conditions [4,9,10]. This may have resulted from a multilevel of barriers that people with SCI experience with exercise and physical activity participation in the community (eg, a lack of accessible facilities or options, knowledgeable instructors, transportation, or social support) [9].

Furthermore, people with SCI, who initiated engaging in an exercise behavior, often have varying rates of success in standardized exercise interventions, which have been designed using a traditional "one-size-fits-all" approach (ie, exercise group vs control) [11,12]. Previous studies have often demonstrated low levels of adherence to exercise programs, high dropouts, and a large portion of the sample not continuing exercise behavior throughout the follow-up [13-15]. In addition, home-based exercise programs are a desirable approach for overcoming barriers and facilitating full participation that could be of great assistance to people with SCI. Tele-exercise programs are potentially more cost-efficient and convenient (ie, do not require transportation or large travel times) than programs offered in the community, making it easier to reach larger groups of people with SCI [16]. Collectively, these findings suggest that the design of future home-based exercise training studies should be more targeted and tailored interventions for people with SCI.

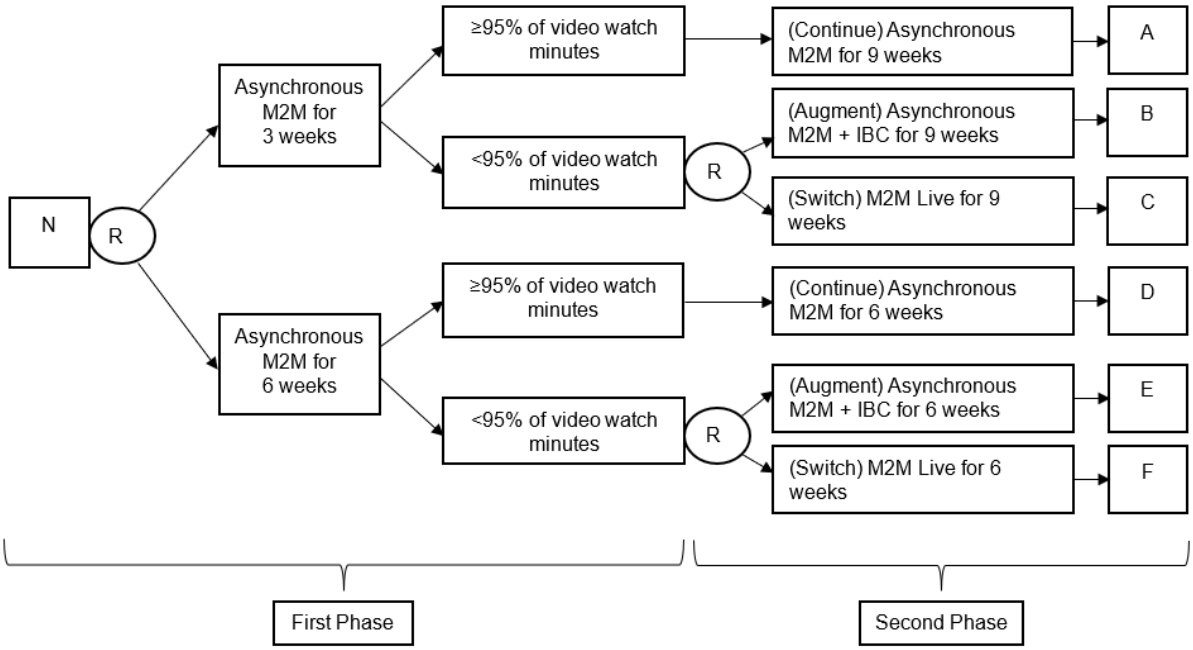
Adaptive interventions provide a flexible treatment regimen based on the participant's evolving status and specific needs, previously used in healthy behavior promotion research (eg, smoking cessation and weight loss) [17-20]. Sequential Multiple Assignment Randomized Trial (SMART) is an experimental design that enables investigators to answer whether, when, and how to alter treatment intensity and type to build an evidence-based adaptive intervention [21]. The use of the SMART design has the potential to optimize the design and delivery strategies of an exercise promotion intervention for maximizing adherence to the program in people with SCI; yet we are unaware of exercise interventions applied and tested this design for people with SCI.

We further note the importance of embedding behavioral approaches to increase physical activity in people with SCI. Based on prior research [22], the study design and delivery are grounded in social cognitive theory (SCT) [23,24], which has been used successfully to improve many health behaviors, such as diet and exercise adherence, in individuals with SCI. The main concept of SCT is the interplay between personal, environmental, and behavioral factors [25]. Outcome expectations [26-29], self-efficacy [28,30-32], social support [26,28,30,31], and self-regulation [26,31,33] are key constructs of SCT that have been associated with changes in various health behaviors in past studies, including several studies involving a broader group of people with mobility disability [27,30,33,34].

We propose a pilot, 2-phase SMART examining the feasibility of a 12-week tele-exercise intervention for improving adherence to the program and physical activity behavior in 30 adults with SCI, named the Sequential Multiple Assignment Randomized Trial for Home-based Exercise And Lifestyle Tele-Health (SMART-HEALTH). The applied exercise intervention is a novel movement-to-music (M2M) video program that incorporates enjoyable movement routines accompanied by music to improve cardiovascular capacity, muscular strength and endurance, balance, and range of motion. Evidence supports the efficacy of M2M in enhancing functional mobility (the timed up and go and 6-minute walk test) among adults with multiple sclerosis [35]. Also, 1 ongoing tele-exercise trial is testing the effectiveness of the M2M video program that includes >400 adults with physical disabilities (NCT03024320) [36]. The modified and scaled-up M2M program was delivered at a state-of-the-art exercise facility for people with disabilities (Lakeshore Foundation). This program integrates the principles of SCT through weekly newsletters that contained educational information aligned with the key constructs of SCT (self-efficacy, outcome expectation, knowledge, self-regulatory strategies, facilitators, or barriers) for promoting and maintaining behavior change.

The primary aim of this study is to assess the feasibility of the 12-week tele-exercise intervention with the SMART design application. The assessment of the feasibility focuses on recruitment or enrollment, adherence, and retention rates, resources and management issues, timing to identify nonresponders, and adverse events (AEs). The secondary aim is to qualitatively assess the acceptability of the SMART-HEALTH intervention. Acceptability will be assessed qualitatively via thematic analysis of semistructured exit interviews conducted at 3 months from baseline, with participants who complete the pilot study. The tertiary aim is to estimate average intervention effects and variability on the

XSL•FO
RenderX



scientific outcomes (eg, video watch minutes, self-reported vs objectively measured physical activity) to determine effect sizes and potential for a larger trial. The information yielded by such a feasibility study will be critical for designing larger-scale projects that can establish the actual efficacy and effectiveness of the future SMART-HEALTH study.

Methods

Study Design

This pilot study applied a 2-phase SMART design. Thirty adults with SCI will be randomized with equal probability into 1 of 2 asynchronous, M2M exercise programs (using prerecorded videos) at the first phase of the intervention. The exercise minutes of the pre-recorded videos are set to progressively increase from 30 to 150 minutes per week throughout the 12 weeks. The response assessment will be administered at weeks 3 (group 1) and 6 (group 2) based on the predetermined adherence criteria to the intervention (average of 95% video watch minutes, ranging from 29 minutes to 143 minutes). Participants who meet or exceed the criteria will be considered as responders and continue the asynchronous program for the entire intervention period, whereas those who did not meet the criteria (nonresponders) will be rerandomized with equal probability into either synchronous, instructor-led M2M exercise program (ie, switch to M2M Live group) or behavioral coaching with asynchronous M2M exercise program (ie, augment with individual behavioral coaching; IBC). The study flow diagram includes the details of the interventions offered in each arm (Figure 1).

Figure 1. Sequential Multiple Assignment Randomized Trial for Home-based Exercise and Lifestyle Tele-Health (SMART-HEALTH) study design for people with spinal cord injury. IBC: individualized behavioral coaching; M2M: movement-to-music intervention; N: sample; R: randomize.

Ethics Approval

Ethics approval was obtained from the institutional review board (IRB) of the University of Alabama at Birmingham on March 10, 2021 (IRB-300006746), and registered at ClinicalTrials.gov (NCT04726891). Informed consent will be obtained from all participants prior to the research activities. For privacy and confidentiality protection, all data will be collected and stored on a secure, web-based database application, referred to as Research Electronic Data Capture (REDCap; Vanderbilt University). Participants will receive up to US $160 of monetary incentives using direct deposit in a reloadable debit card (ie, ClinCard). This includes US $25 for baseline assessments, US $60 for weekly post workout surveys (US $5 for each survey×12 surveys), US $50 for post intervention assessments, and US $25 for an exit interview at the end of the 12-week intervention.

Eligibility Criteria

The inclusion criteria are (1) age 18 years and older; (2) diagnosis of a traumatic SCI that occurred more than 12 months before enrollment; (3) ability to use the arms to exercise (ie, complete [C5 and below] or incomplete paraplegia and tetraplegia); (4) willingness and ability to participate in a 3-month home-based exercise program and study procedures (eg, having internet access, not having visual impairment that prevents watching exercise videos on a computer screen, having complete assessments available, ability to wear an accelerometer, and willingness to undergo multiple randomizations); (5) being physically inactive (defined as ≥150 minutes of moderate-to-vigorous intensity activities in a typical week) [37], and (6) having 1 or more affirmatives on the Physical Activity Readiness Questionnaire for Everyone (PAR-Q) [38] or physician approval for undertaking exercise training for those with 2 or more affirmatives on the PAR-Q. More than 1 affirmative on the PAR-Q indicates that the participant is at more than minimal risk for exercise-related complications, and therefore, physician approval will be required prior to enrolling such participants in this study. Exclusion criteria are (1) history (<6 months) of cardiovascular or pulmonary disease; (2) any unstable medical condition that is likely to compromise safety, like active pressure ulcer,

XSL•FO
RenderX

pregnancy, or renal failure; and (3) any cognitive dysfunction or language barriers that would prevent participants from following English instructions.

Recruitment and Enrollment

We reviewed our database and identified 1016 persons who fit our inclusion criteria (disability status and expressed interest to participate in future research). Additionally, we identified 347 people with spinal cord dysfunction through an external database. We sent out invitation emails to all potential participants across the United States.

We advertised the study information through social media channels and the Lakeshore Foundation. The Lakeshore Foundation has the ability to distribute an electronic newsletter for people with SCI and other disabilities, social media channels, community events, and through the National Center on Health, Physical Activity and Disability (a center funded by the US Centers for Disease Control and Prevention).

Interested individuals can contact the study staff via phone, email, or online application linked with REDCap. A digital form of informed consent is given to eligible participants to review the study details, signed, and submitted. A project coordinator, who is responsible for participant communications and process management, follow-ups with the prospective participant via phone call, verbally reviews the consent form, answers any study-related questions and concerns, and guides the following study procedures.

Randomization Allocations and Other Trial Considerations

Participants are potentially randomized up to twice throughout the 12-week intervention period. A study statistician generated 3 randomization sequences a priori using a computer-generated random schedule (SAS version 9.4; SAS Institute) with a 1:1 allocation ratio and a permuted block approach. The sequences were stored into a randomization module in the REDCap and external program, which allows project staff to unfold the randomization schedule when needed (after completing baseline assessment and after a 3-week or 6-week check-in call). One sequence was used to perform the first randomization of 30 participants into one of the asynchronous M2M exercise groups (group 1 vs group 2), whereas other 2 sequences were used to perform the second randomization of participants who need a transition from asynchronous M2M exercise to M2M Live or IBC based on the adherence rate to the intervention. Response assessment (ie, adherence rate to the program) will be administered at week 3 and week 6, respectively, for the intervention groups 1 and 2. Participants identified as responders who watched the video more than 95% (accounting for 5% error rate) will continue with the first treatment regime. Participants will be considered nonresponders if they adhere to the exercise program less than 95% using video watch minutes. This is based on observation with a few weight loss studies that suggested sessions 3 and 7 as potential time points for intervening with participants to assess needs and difficulties and make necessary changes to maximize the treatment response [39-42].

The outcome assessor will be blinded to group allocation (single-blinded trial design). Due to the nature of the intervention, it is not plausible to blind participants and study staff who enroll participants and monitor the intervention delivery. However, study investigators and staff who are involved in data analyses and reporting will be blinded to group assignments throughout the study period.

Access to the REDCap database will be given to the study personnel only, including the biostatistician and data entry or management personnel. Data that are analyzed will be exported in a deidentified format. The identities of participants will not be revealed in the presentation or publication of any result from this project.

Home-Based Intervention

Overview

The interventions will be delivered through Canvas, which is a secured, commercialized learning management system. First, all participants will receive weekly notifications when a new module is available on Canvas, including exercise videos and educational studies. The weekly notifications can be delivered through the Canvas system and email. Third, participants will be able to leave comments and questions on exercise videos, educational studies, and post workout comment section. Fourth, to ensure any questions or technical issues can be addressed in a timely manner, participants will be able to reach the study team via multiple communication channels, including a study phone number, email, or messaging via the Canvas system.

Prerecorded, Asynchronous M2M Videos

Both groups of participants receive the same exercise prescriptions at the first phase of the intervention. The M2M program provides a sequence of exercise routine, which is accompanied by music to improve range of motion, muscular strength and endurance, cardiovascular capacity, and balance or proprioception. The weekly exercise video is set to progressively increase the exercise minutes to enable the participants to reach and exceed the recently published SCI exercise guideline [38]. Both groups of participants will begin with 30 minutes of exercise (twice weekly or 15 minutes per session) and increase the minutes incrementally until they reach the SCI guideline of 90 minutes at week 6 (3 times weekly or 30 minutes per session) and 150 minutes at week 9 (3 times weekly or 50 minutes per session). The detailed exercise prescription is presented in Table 1.

[a]ROM: range of motion.

[b]N/A: not available.

[c]FSB: functional strength and balance.

[d]Participants will be instructed to repeat the prerecorded videos 2 times per week for the first 5 weeks (week 1-5) and then increase the repetition to 3 times per week for the second 7 weeks (weeks 6-12).

At week 3 and week 6, adherence to the exercise program will be administered using Canvas video analytics. Participants who did not adhere to more than 95% of prescribed video watch minutes will be considered as nonresponders. These individuals will be communicated with by research staff at a prescheduled check-in date and guided to the changes of the program at the second phase intervention period:

IBC Group

Participants who are allocated into the IBC group will receive the remaining asynchronous M2M exercise prescriptions and augmented with weekly behavioral coaching. The first session was 50 minutes, and the remaining sessions were approximately 15 minutes. The coaching is designed to improve self-regulatory skills based on prior research and help them stick to the exercise prescription. An example of tailoring the exercise prescribed involves setting a goal of completing the exercise routine 1 time for the upcoming week instead of 3 times. The coach will be trained in motivational interviewing to help the participants modify their exercise habits. Telehealth coaching alone has been shown to increase self-reported physical activity in adults with SCI.

Synchronous, Instructor-Led M2M Program

Participants who are allocated into M2M Live will switch to one-on-one, synchronous tele-exercise training with an M2M instructor. M2M Live provides accountability and immediate, tailored feedback along with custom movements and music. Videoconference-delivered exercise has been shown as feasible among adults with SCI. During the first session of M2M Live, the participant will meet 1 time per week with the M2M instructor and perform an exercise session. The session will be video recorded, so participants can go back and complete the remaining sessions of the week.

Educational Newsletter

All participants will receive an educational newsletter per week, discussing health behavior change strategies such as goal-setting, planning, and coping with barriers. The purpose is to educate participants on self-regulation strategies and health-promoting behaviors.

Remote Study Procedures

All study procedures, including screening, consent, data collection, and intervention, are conducted remotely at home. Survey data are collected through REDCap. Participants who complete baseline assessments will receive all equipment via

XSL•FO
RenderX

mail and will be randomly allocated to 1 of the 2 M2M interventions. After randomization, each participant will receive an invitation email with a link to the Canvas platform, instructed to create a password, and schedule a check-in date at week 3 or 6 based on the group assignment. Participants will be instructed to perform the exercise program at least 3 times per week. Data collection equipment includes: (1) Chromebook (Lenovo Chromebook or Acer Chromebook 15); (2) Fitbit (Inspire 2, Fitbit); (3) Digital peak flow meter (Peak Flow Meter SMPF-1 and SONMOL); (4) blood pressure monitor (Omron 3 Series Upper Arm, Omron); (5) Two 454-gram wrist weights (Neoprene, thumb hole weights, Biicoon).

Outcomes

Aim 1: Feasibility Metrics

All feasibility outcomes will be collected throughout the 12-week study period. This study will gather metrics of feasibility, including recruitment or enrollment (eg, frequency of contact with potential participants and recruitment sources, with questions such as, Where did you hear about our study? and the percentage of individuals who follow through the enrollment procedure); adherence and retention rates (eg, video watch minutes, attendance of M2M Live or IBC coaching sessions); resources and management issues (eg, preparation and completion time in minutes for functional outcome assessment; time in minutes for survey assessment); timing to identify nonresponders; and AE. The study team will monitor AEs throughout the study period and report them followed by the Behavior Change Consortium of the National Institutes of Health. The four types of AEs are (1) falls, (2) cardiovascular-related episodes, (3) musculoskeletal-related events, and (4) health care use. The severity and causality of each AE will be assessed and will be reported to IRB and relevant regulatory parties when necessary.

Aim 2: Acceptability

Acceptability will be assessed qualitatively via thematic analysis of semistructured exit interviews conducted at 3 months from baseline with participants who complete the pilot study.

Aim 3: Scientific Outcomes

Table 2 shows the physical and psychosocial outcomes, the schedule of data collection, and instruments used.

[a]NIH: National Institutes of Health.

[b]Patient-Reported Outcomes Measurement Information Systems.

Adherence to the Exercise Program

Video statistics (as a percentage) will be recorded through a secured, commercialized learning management system.

Physical Activity

Physical activity will be administered using both objective and self-reported measures. Objective physical activity will be measured using Fitbit throughout the 12-week intervention period, while self-reported physical activity will be measured using the weekly Leisure Time Physical Activity Questionnaire for People With SCI.

Postworkout Survey

Weekly survey will be administered within the learning management system to capture the perceived intensity of exercise and any verbatim comments to the program.

XSL•FO
RenderX

Physiological Function

All functional teleassessment will be conducted via videoconferencing calls (teleassessments). Data collection toolkits (eg, blood pressure monitors and spirometry) will be mailed to the participants' location upon the completion of randomization. The data collection will take approximately half an hour and led by an exercise physiology specialist.

Psychosocial Health

Psychosocial health outcomes will include pain, sleep, fatigue, perceived exercise enjoyment, quality of life, and SCT constructs. These outcomes will be collected via REDCap. All self-report data will be collected directly through electronic questionnaire packets delivered via REDCap at baseline and post intervention assessments. All question items of the questionnaire packets are made as required to answer to prevent any missing data. Each questionnaire packet is also set to be delivered to participants' email 3 times, within a span of 3 days if it is not completed. Research staff will be notified via REDCap when the third packet was sent out to participants. A follow-up phone call will be made to ensure participants receive the packet and remind them to complete it within the next 3 days. Packets that are incomplete within the 3 days after the phone call will be closed and recorded as incomplete, missing data.

Analysis

Overview

All data will be exported and analyzed using SPSS (version 22.0; IBM). Data will be initially examined for variations, outliers, errors, and patterns of missing values. Missing data will be inputted using multiple imputation techniques where necessary based on the assumption that the missingness mechanism is at random. All statistical analyses will be conducted in an intent-to-treat manner at the individual level.

Aim 1

The primary outcomes of this pilot study will include enrollment rate, retention rate, and completion rate of surveys and physiological measures. Process, resource, and management feasibility will initially be examined via percentage, frequency analysis, and descriptive statistics.

Aim 2

A qualitative study of participants' experiences, perceptions, and suggestions regarding the SMART-HEALTH program will be completed at week 12. This study will refine the study components and implementation processes for a future trial. In brief, participants who complete the SMART-HEALTH program will take part in single, one-on-one semistructured interviews with questions focusing on what worked and did not work. Interviews will be audio-recorded, transcribed, and analyzed using thematic analysis using a qualitative descriptive design [43].

Aim 3

The study will estimate recruitment and retention rates, as well as estimate outcomes and variability of efficacy outcomes for a larger clinical trial (aim 3), which will measure rates of physical activity, psychosocial variables (eg, depression), and physiological variables (eg, lung function). Additional fidelity measures will include adherence to exercise intervention (minutes of sessions viewed), number of coaching sessions completed, and intervention safety (number of AEs).

Power

We will aim to enroll at least 40 people with SCI, considering 25% of the attrition rate based on the preliminary data obtained in the exercise intervention study with the M2M program [44]. The sample size of 30 participants aligns with the statistical recommendations for pilot trials to determine precise estimates, and the expectation that at least 5 participants will move each rerandomization group aligns with the statistical recommendations for the pilot SMART trial to determine precise estimates [45,46].

Results

This study was approved by the university IRB on March 10, 2021, and initiated on May 1, 2021. Recruitment started on June 22, 2022, and the first participant was enrolled on June 15, 2022. The trial is expected to be completed in September 2023.

Discussion

Principal Findings

This paper has presented the background and design for a SMART-HEALTH study investigating the feasibility of a home-based M2M exercise program, using an adaptive design for adults with SCI. Exercise is a critical health-enhancing behavior; yet, substantial evidence supports various challenges of engaging in the recommended physical activity levels for many people with SCI. Tele-exercise programs may be suitable to overcome logistic barriers to exercise participation (eg, lack of transportation, travel time, and accessible facilities) and potentially more cost-efficient and convenient than programs offered in the community [16]. In addition, the application of the adaptive design to exercise intervention allows investigators to provide more tailored and targeted program delivery for people with SCI based on their needs while maintaining systematic approaches and scientific rigor. The ultimate goal of the SMART-HEALTH study is to find effective strategies to help guide and shape the exercise behavior of people with SCI toward higher levels of adoption and sustainable exercise participation. The SMART-HEALTH study will test multiple sets of adaptive intervention designs and their delivery strategies to optimize future intervention.

Strength and Limitations

The trial uses an innovative study design to address adherence to exercise interventions among people with SCI. It addresses a growing need among physicians treating patients with mobility disabilities to have easily accessible eHealth home-based exercise videos that can be tailored to the functional level of their patients. This is a pilot trial to assess the feasibility of using a SMART design and is not powered for effectiveness.

XSL•FO
RenderX

Conclusions

The trial serves to inform the development of adaptive interventions, including whether, how, or when to alter treatment intensity, type, or delivery. In addition, this can determine the actual efficacy of home-based exercise based on the SCI-specific physical activity programs for improving adherence to the program and physical activity.

Acknowledgments

This study was supported by the Craig H. Neilsen Foundation (645335). The contents of this study do not necessarily represent the policy of these groups or the endorsement of the US federal government.

Data Availability

The data generated as part of this study will be made available through a data repository. Deidentified data sets will be shared upon reasonable request.

Authors' Contributions

JW contributed to the conception and design of the study protocol, exercise intervention, drafted and manuscript writing, and supervision of the entire process of the study. JR, HJY, and BL contributed to the conception and design of the study protocol, exercise programs, and editing of the manuscript. DP contributed to this study as the study physician and reviewed and signed the medical clearance for participating in an exercise program. TM supervised the statistical aspects of the trial and contributed to editing the manuscript. YK and JG contributed to the recruitment strategy; design, delivery, and evaluation of the trial; and drafting of the manuscript. All the authors approved and critically revised the manuscript.

Conflicts of Interest

TM served as a consultant to Novo Nordisk through a consulting arrangement to serve on Obesity Management in Primary Care Advisory Board. He is serving as a consultant providing design and consulting support to Heart Rhythm Clinical Research Solutions. TM also served as a consultant to New Balance Foundation Obesity Prevention Center. All other authors declare that they have no conflicts of interest.

Abstract

Background: Reducing avoidable nursing home (NH)–to-hospital transfers of residents with Alzheimer disease or a related dementia (ADRD) has become a national priority due to the physical and emotional toll it places on residents and the high costs to Medicare and Medicaid. Technologies supporting the use of clinical text messages (TMs) could improve communication among health care team members and have considerable impact on reducing avoidable NH-to-hospital transfers. Although text messaging is a widely accepted mechanism of communication, clinical models of care using TMs are sparsely reported in the literature, especially in NHs. Protocols for assessing technologies that integrate TMs into care delivery models would be beneficial for end users of these systems. Without evidence to support clinical models of care using TMs, users are left to design their own methods and protocols for their use, which can create wide variability and potentially increase disparities in resident outcomes.

Objective: Our aim is to describe the protocol of a study designed to understand how members of the multidisciplinary team communicate using TMs and how salient and timely communication can be used to avert poor outcomes for NH residents with ADRD, including hospitalization.

Methods: This project is a secondary analysis of data collected from a Centers for Medicare & Medicaid Services (CMS)–funded demonstration project designed to reduce avoidable hospitalizations for long-stay NH residents. We will use two data sources: (1) TMs exchanged among the multidisciplinary team across the 7-year CMS study period (August 2013-September 2020) and (2) an adapted acute care transfer tool completed by advanced practice registered nurses to document retrospective details about NH-to-hospital transfers. The study is guided by an age-friendly model of care called the 4Ms (What Matters, Medications, Mentation, and Mobility) framework. We will use natural language processing, statistical methods, and social network analysis to generate a new ontology and to compare communication patterns found in TMs occurring around the time NH-to-hospital transfer decisions were made about residents with and without ADRD.

Results: After accounting for inclusion and exclusion criteria, we will analyze over 30,000 TMs pertaining to over 3600 NH-to-hospital transfers. Development of the 4M ontology is in progress, and the 3-year project is expected to run until mid-2025.

Conclusions: To our knowledge, this project will be the first to explore the content of TMs exchanged among a multidisciplinary team of care providers as they make decisions about NH-to-hospital resident transfers. Understanding how the presence of evidence-based elements of high-quality care relate to avoidable hospitalizations among NH residents with ADRD will generate knowledge regarding the future scalability of behavioral interventions. Without this knowledge, NHs will continue to rely on ineffective and outdated communication methods that fail to account for evidence-based elements of age-friendly care.

Introduction

Overview

There are over 15,000 nursing homes (NHs) in the United States, where care is delivered to over 1.3 million residents [1]. Approximately 48% of NH residents have a diagnosis of Alzheimer disease or a related dementia (ADRD) [2]. NH residents with ADRD are at high risk for hospital transfer due to high incidence of comorbidities, polypharmacy, and progressive loss of language, resulting in difficulty communicating preferences [3-5]. Reducing avoidable NH-to-hospital transfers of residents with ADRD has become a national priority due to the physical and emotional toll it places on residents and the high costs to Medicare and Medicaid [6-8]. NH-to-hospital transfers result in expenditures of more than US $2.6 billion annually [9] and in as many as 60% of cases, they are avoidable, meaning the resident could have been safely managed in the NH [10,11]. Early illness recognition and treatment could prevent the need for hospital transfer altogether, ultimately reducing morbidity in residents with ADRD while controlling costs [7,9].

Avoidable NH-to-hospital transfers refer to transfers that follow acute flare-ups of clinical conditions that could have been avoided if appropriate preventative care had been provided in the NH [10]. Recent studies have identified clinical factors such as falls, fever, urinary symptoms, and incontinence that contribute to avoidable transfers [11]. Dementia was the only high-risk clinical condition associated with avoidable NH-to-hospital transfers [11]. Other factors contributing to the decision to transfer, for those deemed avoidable, included a condition that could have been safely managed in the NH, better communication, early detection of new signs or symptoms, and earlier discussion of resident or family preferences [11]. Others have reported communication problems as barriers to timely care for NH residents [12,13]. Specifically, barriers include failure of the communication medium, evening or weekend illness onset with concomitant difficulty contacting an on-call physician, clinical decision-makers who interact through intermediaries, and communication of inappropriate or inaccurate information [13]. Improving communication among health care team members could have a considerable impact on reducing avoidable NH-to-hospital transfers.

NH-to-hospital transfer decision-making is complex and relies on the timely transmission of information among the multidisciplinary team. Unfortunately, many NHs rely on antiquated methods of communication (eg, phone and fax) rather than leveraging modern, convenient, and low-cost options, like exchanging text messages (TMs), which could improve health information sharing, especially in resource-limited settings [12,14-16]. In a pilot analysis using 6 months of TMs exchanged among a multidisciplinary team, the most common messages sent (3244/8946) and received (2319/8946) were about patient updates (updates on symptoms, vital signs, and lab and test results) [17]. However, greater understanding is needed regarding how communication differs between residents with and without ADRD and how TMs can be used among the NH multidisciplinary team to decrease avoidable transfers.

We propose to examine the content of TMs using a framework from Age-Friendly Health Systems that includes 4 evidence-based elements of high-quality care called the 4Ms (What Matters, Medication, Mentation, and Mobility) [18]. Age-Friendly Health Systems is an initiative builds upon a number of fundamental characteristics common to existing geriatric care models, including reliable use of evidence-based care, staff who are specifically trained and proficient in the care of older adults, high-performing care teams focused on measurable outcomes, a systematic approach for coordinating care with other organizations, and engaging patients and their families in a clear process for eliciting goals and priorities and using those goals to individualize care [19]. The 4M framework addresses the core issues that should drive all decision-making in the care of older adults and is a way of systematically rethinking care in ways that improve patient health and satisfaction. A critical need exists to examine how convenient, low-cost communication options like TMs can reduce avoidable NH-to-hospital transfers of residents with ADRD.

Aims and Research Questions

The objective of this study is to understand how members of the multidisciplinary team communicate and how TMs can be used to avert poor outcomes for NH residents with ADRD, including hospitalization. Our scientific premise is that if multidisciplinary communications are timely and centered around the evidence-based elements of high-quality care for older adults (4Ms), more appropriate decisions will be made, in this case regarding hospital transfer. Thus, the project will consist of complementary steps aimed at (1) identifying documentation of the 4Ms in health information shared by the multidisciplinary team through electronic TMs 2 weeks before NH-to-hospital transfer of residents with ADRD, (2) exploring the association between the 4Ms found in TMs and avoidable NH-to-hospital transfers, and (3) comparing communication patterns of multidisciplinary teams making transfer decisions about residents with and without ADRD.

Methods

Overview

Using a retrospective design, we will identify documentation of the 4Ms in health information shared by multidisciplinary teams through electronic TMs and compare communication patterns that occur when making transfer decisions about residents with and without ADRD. This project will use data collected from a Centers for Medicare & Medicaid (CMS)–funded demonstration project designed to reduce avoidable hospitalizations for long-stay NH residents [20,21]. The goals of the project for long-stay NH residents were to

XSL•FO
RenderX

reduce the frequency of avoidable hospital admissions and readmissions, improve resident health outcomes, improve the process of transitioning between inpatient hospitals and NHs, and reduce overall health care spending. The project included a multifaceted intervention implemented within 16 NHs in the midwestern United States. The intervention included an advanced practice registered nurse (APRN) embedded full-time within each NH, use of the Interventions to Reduce Acute Care Transfers (INTERACT) tool [22], and an expert support team comprising nurses, social workers, technology experts, and medical directors. Further, the project included enhanced electronic communication using health information exchange, specifically the use of a collaborative text messaging system.

Ethics Approval

All procedures were approved by the University of Missouri Institutional Review Board (2092039).

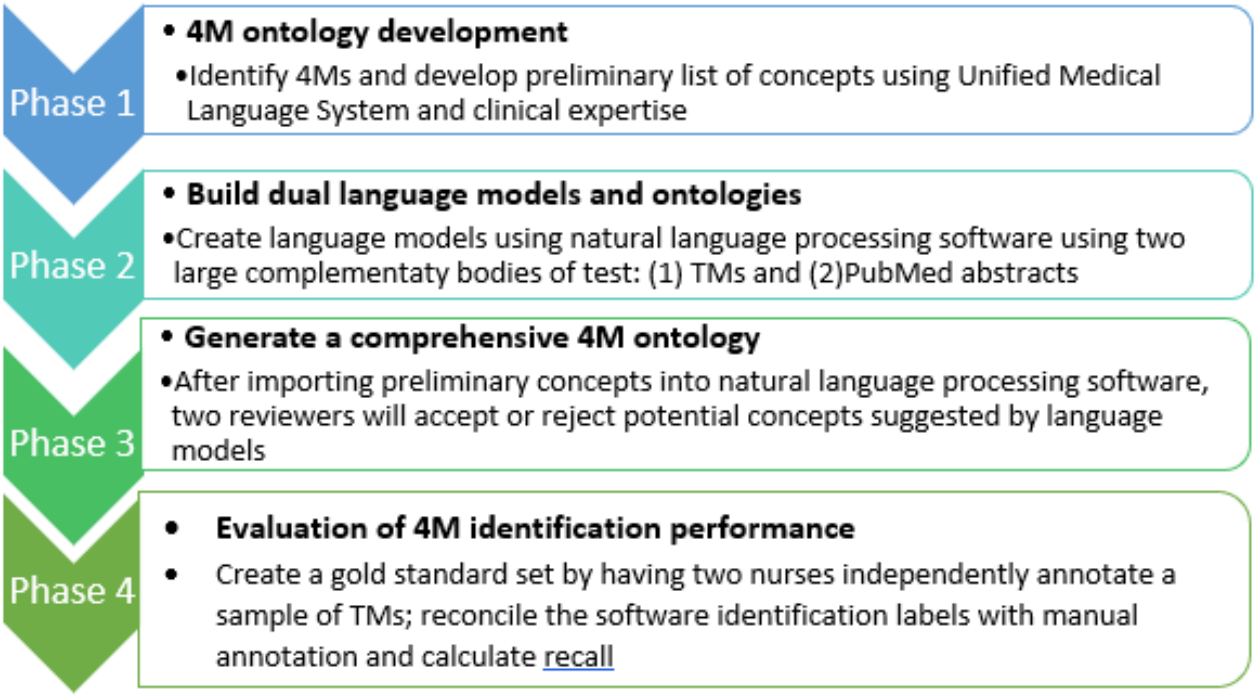
Data Sources

We will use two data sources for this project: (1) TMs and related attributes (eg, sender, recipient, date, and timestamp) and (2) a survey completed by APRNs about NH resident transfers. The TMs were exchanged through a Health Insurance Portability and Accountability Act (HIPAA)–compliant communication and clinical collaboration tool primarily designed to be used among providers, pharmacies, and prescribers. The messaging platform includes the capability to communicate with outside vendors, patients, and anyone seeking to communicate protected health information in a secure environment that meets the requirements of the National Institute of Standards and Technology as well as the Health Information Technology for Economic and Clinical Health Act [23]. Users can access the messaging platform using a browser or mobile device (app). The platform includes workflow features specifically designed for the long-term care and postacute setting, such as read receipts, average response time tracking, adding and removing users from a message, and multiuser accounts with shared names for easy identification. The data set includes sender, recipient, date, and time stamp for each message. Crosswalks have been developed linking individual users to their roles (eg, bedside nurse, unit manager, director of nursing, APRN, and medical doctor [MD]).

The second data source is a Qualtrics survey completed by APRNs that included the INTERACT tool every time a resident transfer occurred during the study period (August 2013-September 2020). Broad categories of the survey included resident characteristics, risk factors for hospitalization, acute change in condition, nonclinical factors contributing to the transfer, and actions taken to evaluate and manage the change in condition before transfer. Individual items within each of the broad categories described common clinical and nonclinical factors that helped clinical staff understand the reasons for the transfer and process improvement considerations to avoid future transfers. APRNs completed the tool for each transfer using a combination of chart review and nurse interviews. These procedures included (1) monthly review of all INTERACT surveys by a team composed of the APRN, project coordinator, and APRN supervisor; (2) identification of resident and NH factors contributing to the transfer; and (3) agreement by the team on the question “Was the transfer potentially preventable (avoidable)?” using the “five whys” quality improvement technique [24]. This technique is an iterative interrogative approach to exploring cause and effect and was used by the team to assure root causes of transfers were considered when establishing agreement on which transfers were deemed avoidable versus unavoidable.

Sample

We will extract TMs and merge them with resident transfer data for NHs that participated in the CMS demonstration project. Between August 2013 and September 2020, there were 2551 resident transfers, of which 528 had a diagnosis of ADRD. We will extract TMs for 2 weeks before the resident transfer date. This time period was selected because there is evidence that technology can facilitate earlier detection of declining conditions (1-2 weeks earlier) when used to assess older adults [25].



4M Ontology Development (Aim 1)

Overview

We will use a 4-phased approach (see Figure 1) using standardized vocabularies, clinical expertise, and natural language processing (NLP) to generate a 4M ontology and quantify the 4M content in TMs sent or received 2 weeks before NH resident transfer to the hospital. To enable the extraction of 4M knowledge from TMs, we first need a taxonomy (a set of terms) that formalizes the hierarchical relationships among concepts and specifies the terms to be used to refer to each. From the taxonomy, we can begin to develop an ontology that identifies and distinguishes concepts and their relationships. In information science, ontology is a data model that represents a set of concepts within a domain and the relationships between those concepts [26]. Ontology formalizes the relationships among concepts, which allows computers and humans to interpret the semantic relationships among concepts and infer implicit knowledge [27].

XSL•FO
RenderX

Figure 1. Four phases to generate the 4M ontology. 4M: what matters, medication, mentation, and mobility; TM: text message.

Phase 1: 4M Taxonomy Development

While many clinical (eg, Systematized Nomenclature of Medicine Clinical Terms [SNOMED]) and nursing (eg, International Classification for Nursing Practice [ICNP]) standardized languages exist, they might not adequately describe the TMs. The first step in creating our 4M ontology is to use Metamap, the NLP tool provided by the Unified Medical Language System, to extract concepts from our TMs that have relevant semantic types such as “mental process” (menp), “sign or symptom” (sosy), or “clinical drug” (clnd) [28]. The Unified Medical Language System is a compendium of many health terminologies, including SNOMED, INCP, North American Nursing Diagnosis Association, and others, that only extracts concepts with relevant semantic types [29]. Extracted concepts will be reviewed by nurse-clinician scientists with extensive research expertise in NH care and arranged in a taxonomy. The resulting taxonomy will be enriched by the same experts with concepts that might not appear in our TMs. The nurse-clinician scientists will review these lists and make recommendations for changes (eg, addition and removal of concepts and addition and removal of synonyms). The NLP pipeline will be implemented in the Python Natural Language Toolkit and will use the newly developed taxonomy. The NLP pipeline is the set of ordered stages from a labeled data set to create a classifier that can be applied to new samples (ie, supervised machine learning classification). The above procedure will be performed several times, followed by a taxonomy refinement, until at least 90% of the 4M information (ie, 90% recall) is extracted from the entire sample.

Phase 2: Building Dual Language Models

We will use two large bodies of text to generate two possibly complementary language models with the NLP software: (1) TMs and (2) PubMed abstracts. These 2 sources were selected because they will allow us to extract a complementary and diverse range of concepts. TMs include clinical jargon and abbreviations, whereas PubMed abstracts have more standardized concepts used in the scientific literature. For the TM source, we will obtain all TMs pertaining to residents with ADRD who had a hospital transfer across the entire CMS demonstration project period (August 2013-September 2020). For the PubMed source, we will extract all available PubMed abstracts containing relevant Medical Subject Headings (MeSH) descriptors. Text from each source will be converted into a single text (.txt) file and uploaded into Metamap. We will use Metamap to perform text preprocessing, convert frequently co-occurring words into triadic expressions (eg, “nurse communicates to physician”), and build language models as described in phase 1.

Phase 3: Generating a Preliminary 4M Ontology

We will harmonize the TMs and PubMed versions of the 4M ontology. Two nurse-clinician scientists will independently review and accept or reject suggested concepts for each of the 4Ms. The 2 reviewers will compare lists of words and expressions and discuss discrepancies. If the 2 reviewers cannot come to an agreement on whether a word or expression should be included as a 4M concept synonym, an adjudicator will make the final decision. The output from this step will be a preliminary ontology for each of the 4Ms.

Phase 4: Evaluation of NLP 4M Identification Performance Using a Gold Standard Set

We will collect a random sample of TMs, using stratified sampling, from 10% of the resident transfers during the study period. Two nurse-clinician scientists will manually review each TM for the presence or absence of each of the 4Ms.

XSL•FO
RenderX

Relative observed agreement (percent agreement between 2 raters) and interrater reliability (Cohen) will be calculated for each of the 4Ms. The 2 nurses plus a third nurse adjudicator will discuss nonagreement until consensus is achieved. Next, we will use our Natural Language Toolkit NLP software to identify 4Ms in the same gold standard TM set. We will then compare the NLP identification labels to the manual annotation and calculate recall (the NLP software's ability to identify all notes with a positive occurrence of a particular symptom), precision (proportion of notes with a particular symptom endorsed by NLP), and *F*-measure (a measure of test accuracy that considers both precision and recall). *F*-measures range from 0 (no precision and recall) to 1 (perfect precision and recall). Last, we will review all instances of disagreement between the NLP software identification labels and gold standard annotations. After we validate our 4M extraction pipeline, we will label each TM in our data set with a 4-dimensional vector that would represent the amount of each of the 4Ms that it contains (ie, matter, medication, mentation, mobility). For example, the TM "Resident was depressed after falling and breaking hip" will be labeled as (0,0,1,1). The 4M content will be further used in the analysis for aim 2.

Exploring the Association Between the 4Ms Found in TMs and Avoidable NH-to-Hospital Transfers (Aim 2)

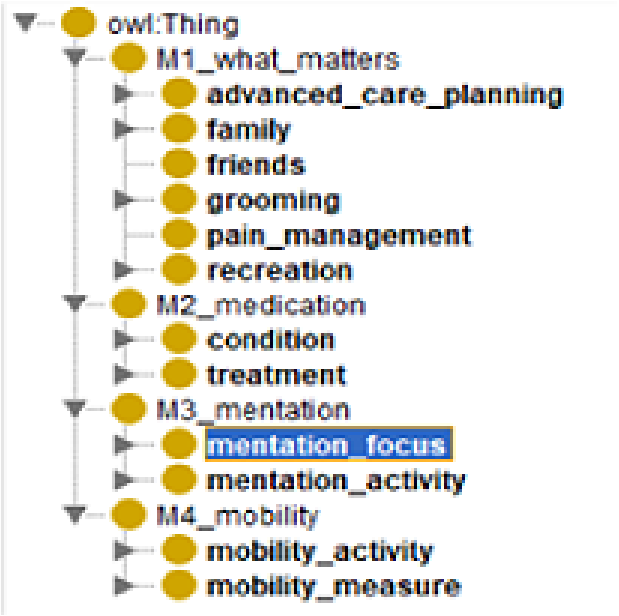
Using our rich data set, we will compare the representation of the 4Ms in TMs about avoidable and unavoidable transfers while controlling for resident characteristics. We will build a generalized linear model of the Poisson process to compare the representation of the 4Ms in TMs about transfers that were avoidable and unavoidable while controlling for resident characteristics including sex, race or ethnicity, severity of ADRD, and advanced directive status. Our hypothesis is that TMs about avoidable transfers will have more evidence (higher frequency of terms) of the 4Ms compared to TMs about unavoidable transfers.

Comparing Communication Patterns of Multidisciplinary Teams Making Transfer Decisions About Residents With and Without ADRD (Aim 3)

Using the same 2 data sources, we will use social network analysis (SNA) to discern communication and organizational patterns found in TMs occurring in the 2 weeks before NH-to-hospital transfers of residents with and without ADRD. This analysis will allow us to visualize networks and calculate social network measures including density, clustering coefficient, hierarchy, and centralization. Our hypothesis is that TM communication about residents with ADRD will have more decision-making interactions (network density), higher rates of information exchange (clustering coefficient), and more individuals communicating with each other (centralization) compared to TM communication about residents without ADRD. Our premise for this hypothesis is that the gradual loss of language that occurs with ADRD will impact the individual's ability to communicate with the care team in the earliest stages, regardless of dementia severity [5]. This progressive decline sometimes leaves the person living with ADRD unable to make autonomous decisions. Understanding communication patterns both visually and quantitatively when the multidisciplinary team is making decisions about residents with and without ADRD could help inform decision-making.

Results

Data Extraction and Preparation



The initial extraction of TMs resulted in over 77,000 messages that were exchanged by NHs that participated in the CMS demonstration project. We used a stepwise approach to preprocess the TMs. First, we removed TMs where no resident was discussed. For example, there were TMs of a personal nature (eg, "how are you" and "what's for lunch today"). After removing messages where no resident was discussed, we identified messages about NH residents who had a NH-to-hospital transfer during the study period. NH staff were able to use TMs to communicate about all residents at their facility; therefore, we needed to remove any resident who did not have a hospital transfer during the study period. We excluded over 43,000 messages that were about NH residents that were not in our resident transfer data set, resulting in 30,067 TMs available for analysis. Our next step is to begin identifying the roles of individuals (eg, MD, APRN, bedside nurse, and unit manager) exchanging TMs in preparation for SNA.

Building the 4M Ontology

The methodology for building the 4M ontology uses 2 strategies. One strategy is expert-based and top-down, in which the clinical expert outlines the most important concepts for each of the 4Ms. For example, using the concept "what matters," some concepts we have identified are advanced care planning, family, friends, grooming, pain management, and recreation (see Figure 2). The second strategy is data-driven and bottom-up and consists of extracting meaningful terms from the TMs and inserting them at the right location in the top-level ontology framework created by the expert. The data-driven strategy ensures that we can identify the 4M content of each TM. Expected results to be published in fall 2025.

Discussion

Study Implications

To our knowledge, this project will be the first to explore the content of TMs exchanged among a multidisciplinary team of NH care providers as they make decisions about NH-to-hospital resident transfers. Our goal is to apply existing methodologies (SNA and NLP) in a new way, that is, to analyze TMs in NH settings. SNA uses visualization techniques to illustrate patterns of relationships formed among clinical partners, which provides novel quantitative measures of relationship strength and hierarchical structures. NLP is crucial for advancing health care research because it is needed to transform relevant information locked in text into structured data, a prerequisite to quantitative analysis of large amounts of text. The results of the proposed study have the potential to shift both research and clinical paradigms.

This study will produce knowledge of the mechanisms and principles necessary for the successful development and implementation of behavioral interventions using TMs to enhance multidisciplinary team communication in NHs. Knowledge of these principles will make it easier to predict who might respond well to a future intervention and who might not, so that the intervention might be better personalized and given only to those who are likely to benefit from it [30]. Findings from this study, specifically the 4M structured language ontology, could also inform TM interface design, creating the opportunity for standardized, seamless portability of information centered around what matters to older adults. The idea is to address, as much as possible, issues of real-world fidelity and the ability to implement before the intervention is studied at later stages to maximize the chances of success. This approach aligns with the National Institute for Aging Stage Model for Behavioral Intervention Development, with the proposed project falling between stages 0 and 1A [30]. Demonstrating how the 4Ms are represented in TMs must be done before intervention development (stage 0). Understanding how the presence of the 4Ms in TMs relates to avoidable hospitalizations among NH residents with ADRD will inform the evidence base regarding future scalability (stage 1A). Without this knowledge, NHs will continue to rely on ineffective and outdated communication methods that fail to account for evidence-based elements of age-friendly care.

Limitations

This study will generate knowledge that will have far-reaching implications for NH residents with ADRD. Nonetheless, there are potential limitations to generalizability to consider. Our data set is limited to NHs that participated in the CMS demonstration project. The NHs that participated in the project each had an APRN working as an essential staff member in the facility. Not all NHs have an APRN presence in the facility, so generalizability beyond NHs with this support in place could be limited. To address this limitation, we will consider the wide variability of the use of TMs among APRNs. For example, in our pilot analysis using 6 months of TM data, we found the total number of TM sent by APRNs ranged from 0 to 607 [17]. In the CMS demonstration project, data were captured only for residents who had a NH-to-hospital transfer, so comparing residents who transferred to those who were not transferred is not possible from this data set. To address this limitation, we will compare transfers according to whether they were considered avoidable or unavoidable.

In some cases, NH-to-hospital transfer is appropriate and necessary. Our focus on reducing avoidable NH-to-hospital transfers accounts for this limitation. Although our data set includes novel components, including TMs sent and received between a multidisciplinary care team, resident characteristics, and transfer data, it does not include direct communication with family members of NH residents. To address this limitation, we will account for indirect family communication. For example, family preferences were frequently mentioned in TMs shared among the care team and can be conceptualized with “what matters.” Finally, while the focus of the proposed study is

XSL•FO
RenderX

improving communication using TMs, we recognize other factors such as staffing, workload, and skill mix of the NH staff could impact the outcome, that is, avoidable NH-to-hospital transfers. To address this limitation, we will use SNA, which accounts for skill mix by identifying roles (eg, MD, registered nurse, licensed practical nurse, and certified nursing assistant), interactions between social positions and groups, and relationships among groups.

Conclusions

Identifying evidence-based elements of communication in TMs exchanged among NH health care team members can potentially decrease avoidable hospitalizations and ultimately morbidity and mortality in NH residents with ADRD. The development of a structured language ontology using an evidence-based framework (4M) to improve communication among NH team members is a direct and effective implementation strategy designed to address issues of real-world fidelity before the development of interventions to promote timely and seamless portability of information across the complete spectrum of care, optimizing the health of individuals and populations.

Abstract

Background: Globally, COVID-19 is in transition from the acute pandemic phase into a postacute phase, and special attention should be paid at this time to COVID-19 control strategies. Understanding public knowledge and attitudes plays a pivotal role in controlling COVID-19's spread and provides information about the public's adherence to preventive and control measures.

Objective: This study protocol describes the planning and management of a survey to investigate the persistent or changing trends in knowledge and attitudes regarding COVID-19, vaccination, and nonpharmaceutical preventive measures among COVID-19 cases' household contacts aged 18 years and older, after the acute phase of the pandemic in Catalonia and Navarre in Spain. The secondary objectives include investigating the rate of secondary transmission in households, taking into account the demographic characteristics, clinical manifestations, and preventive measures toward COVID-19.

Methods: A telephone questionnaire was designed to assess the changing trends in knowledge, preventive measures, and attitudes toward COVID-19 in 3 rounds (after identification as a household contact, 3 months later, and 6 months later). The questionnaire was developed following an extensive literature review and through discussions with a panel of experts who designed and assessed the validity of the questionnaire in terms of relevance, consistency, completeness, and clarity. The questionnaire consists of the following 7 sections: social and demographic characteristics (ie, gender, age, educational level, and workplace), comorbidities and risk factors (according to the recommendations from the COVID-19 vaccination strategy), epidemiological data (ie, exposure time, relationship with index cases, and frequency of use of nonpharmaceutical preventive measures), COVID-19 vaccination status (ie, the number and date of doses received), knowledge and attitudes toward COVID-19 (assessed using a 5-point Likert scale—totally agree, agree, neither agree nor disagree, disagree, and totally disagree), and sources of information (including traditional mass media, social media, and official sources).

Results: A pilot study was performed in May 2022 to evaluate the questionnaire with 22 household contacts. Preliminary findings indicated that the questionnaire was feasible and acceptable in the general population. The average response time was 15 minutes, with greater variations in responses by older participants. After the pilot study, recruitment of participants began and is expected to be completed at the end of the year 2023, after which the final results will be available in 2024.

Conclusions: Despite the low transmission levels of SARS-CoV-2 and the relaxation of containment measures, the implementation of the survey during the postacute phase will provide valuable insight to assist public health decision-making and control the

XSL•FO
RenderX

transmission of SARS-CoV-2 and other respiratory viruses, thereby attenuating the negative effects of COVID-19 at individual and population level.

Introduction

Overview

The COVID-19 pandemic has demonstrated that infectious diseases are a continuous challenge for public health. Prevention and control measures to diminish the burden of SARS-CoV-2 infection in the population have changed over time, from exclusively implementing nonpharmaceutical interventions to extensive vaccination programs [1-3].

According to the last report of the European Centre for Disease Prevention and Control (ECDC) [4], many European countries are currently de-escalating their response measures due to the transitional process of the acute pandemic phase into the postacute phase. However, the ECDC encourages governments and national authorities to monitor pandemic trends and key indicators, focused on preventing and managing not only SARS-CoV-2 variants but also the long-term health consequences due to COVID-19 [4]. Although many studies on knowledge and attitudes related to COVID-19 have been published [5,6], there are still several knowledge and behavioral gaps, which can serve as a guide to address future emergencies relating to SARS-CoV-2 variants and other pandemics, considering that knowledge, attitude, and behavior can change over time [6].

It is generally recognized that populations' levels of knowledge and attitudes regarding COVID-19 and its preventive measures are important factors for controlling transmission during the pandemic [4]. In the acute phase of the COVID-19 pandemic, some studies evaluating knowledge and attitudes have been conducted worldwide, both in the general population and in specific groups [7-10]. However, many gaps in the knowledge and practices concerning COVID-19 need to be filled. For example, in a multinational sample, including 22 countries, authors showed that almost one-third of participants did not know that infected individuals can be asymptomatic, increasing their risk of exposure to COVID-19 [5]. In addition, a higher correlation was found between attitudes and practices compared to knowledge and practices, indicating that knowledge itself is not enough and that effective interventions to improve practices should aim to encourage both adequate knowledge and positive attitudes [5]. Other studies demonstrate that the probability of transmission is higher for people who meet the criteria of close contacts, due to their exposure to COVID-19 cases with laboratory-confirmed infection. Close contacts include household contacts, among whom exposure is usually more intense and repeated; therefore, the risk of transmission may be high, even in the absence of other factors that enhance transmission [11,12].

At this time, the population has access to accurate real-time information on the evolution of the pandemic and the recommendations to follow, which could be reliably disseminated by health authorities and official institutions through various secure communication channels [1-3]. Nevertheless, the population is also exposed to other media sources that spread unreliable and contradictory information about the evolution of the pandemic, causing confusion regarding the measures to be followed. In addition, it must be noted that the absence of knowledge and inappropriate beliefs about the importance and best methods of prevention may increase the risk of infection [13]. In this context, data about gaps in knowledge and behavioral information is crucial to the prevention and management of future resurgences of SARS-CoV-2 variants.

Objectives

The main objective of this study is to investigate the persistent or changing trends in knowledge and attitudes about COVID-19, vaccination, and nonpharmaceutical preventive measures in household contacts of COVID-19 cases after the acute phase of the pandemic in Spain.

The secondary objectives of the study are as follows:

- To compare the characteristics of index cases and primary cases of COVID-19
- To investigate the rate of secondary transmission, taking into account factors such as age, sex, clinical manifestations, and preventive measures related to the first case in the household
- To determine the rate of secondary transmission in households with primary cases of COVID-19 caused by new variants of SARS-CoV-2 and the existence of vaccination failures

Methods

Study Design

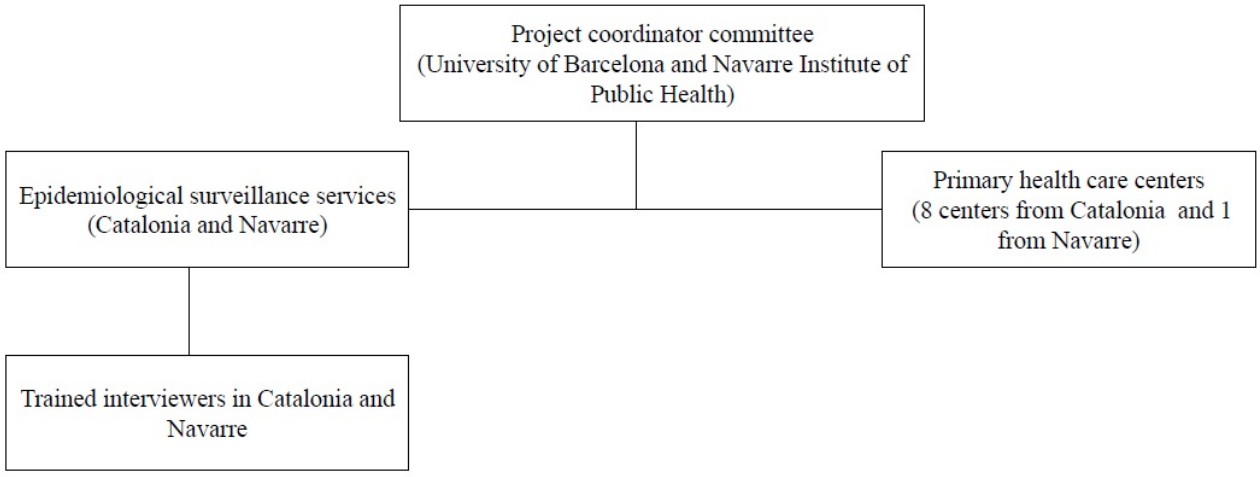
This study is a prospective epidemiological study using a telephone survey addressed to household contacts of confirmed COVID-19 cases in 2 regions of Spain: Navarre and Catalonia. The telephone survey is being conducted in 3 rounds: the first round is directly after the identification of an eligible contact; the second round will be 3 months later, and the third round will be 6 months after the initial contact. These interviews are currently in progress, with most participants having completed the second interview as of the date of this paper's submission.

XSL•FO
RenderX

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Ethics Committee of the University of Barcelona (protocol code IRB00003099) on March 2, 2023. Oral consent is requested from participants by the Institutional Ethics Committee of the University of Barcelona, and an informative document about the study is sent by email to whoever requests it.

Participants



The recruitment of household contacts is currently being conducted in 9 primary health care centers (1 from Navarre and 8 from Catalonia) associated with COVID-19 cases. The inclusion criteria are as follows: patients who are positive for COVID-19 (cases) and household contacts aged ≥18 years at the time of selection, who agree to participate in the study and provide oral consent. Those aged <18 years and those with the presence of severe and uncorrectable cognitive, visual, or hearing impairments that hinder the participants' ability to complete interviews are excluded from the study.

Organization and Coordination Activities

The study was managed by Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública through the University of Barcelona and the Institute of Public Health of Navarre, in coordination with the epidemiological surveillance services of both regions. The main function of the project coordination committee is to supervise and monitor the adequate application of the methodology and working plan to achieve the project objectives. The selection of COVID-19 cases is being carried out by primary health care professionals who also report the COVID-19 cases to the epidemiological surveillance services. COVID-19 cases are being selected if they have had at least 1 eligible household contact who could be identified. All household contacts of COVID-19 cases reported to the epidemiological surveillance services in both regions are selected to participate in this study. All participants are informed of the objectives of the study and invited to participate. Individuals included in the study have provided prior oral consent to be contacted and are informed that all information will be treated anonymously in the subsequent statistical analyses.

Qualified interviewers are conducting the surveys by telephone in both regions (Figure 1). Complete information on the coordination of activities is accessible to all researchers involved in the study through a manual of procedures developed by the coordinating committee.

Figure 1. The organizational structure of the project team.

During the initial stages of screening, household contacts of COVID-19 cases will be identified through the epidemiological surveillance services or primary health care centers from Catalonia and Navarre. Trained study personnel will perform a formal screening evaluation to confirm eligibility for the study, which will take place after the patient has provided oral informed consent.

Data Collection

Literature Review and Design of the Questionnaire

The first step of the questionnaire design, an exhaustive literature review, was carried out by the coordination committee [14]. After this literature review, the questionnaire was structured, taking into account the recommendations against COVID-19 provided by the World Health Organization, ECDC, and the Spanish Ministry of Health [1-3,15]. The research team, composed of professionals with experience in epidemiological and public health research, held a series of preliminary meetings to develop all sections of the survey, including the selection of questions and the number of items included. Discussion of the survey focused on the relevance, consistency, completeness, and clarity between linked questions, the length of the survey, and the overlap of questions between sections of the survey. All the sections of the questionnaire, especially the items related to knowledge and attitudes, were adapted from instruments used in other publications related to the study topic, specifically the questionnaires used by Xu et al [16] and Geldsetzer [17]. The questions were adapted to the specific circumstances of the Spanish population, ensuring conceptual and semantic equivalence. Following an iterative process that resulted in several major revisions of the first draft.

The survey was developed in Spanish, and it consisted of 7 sections: social and demographic information, comorbidities and risk factors, epidemiological information, COVID-19

XSL•FO
RenderX

vaccination status, knowledge concerning COVID-19 and its preventive measures, attitudes toward COVID-19 and its preventive measures, and participants' sources of information about COVID-19.

The questionnaire also includes demographic information, variables related to comorbidities, and COVID-19 vaccination status, which could be validated through electronic health record linkage with the regional vaccination registers and databases of epidemiological surveillance.

Questionnaire Structure

Social and Demographic Characteristics

Demographic variables include participants' gender; age; educational level (according to the International Standard Classification of Education by the United Nations Educational, Scientific and Cultural Organization); workplace (remote work, on-site work, or both); and the severity of the index case, including whether or not their treatment involved hospitalization.

Comorbidities and Risk Factors

Information about the prior presence of major chronic conditions is being collected according to the recommendations from the COVID-19 vaccination strategy, including chronic obstructive pulmonary disease, coronary heart disease, stroke, diabetes mellitus, immunodeficiency (eg, HIV/AIDS and immunosuppression), chronic kidney disease, chronic liver disease, neurological and psychiatric disease, and cancer [18]. Information about risk factors, including tobacco use (smoker, former smoker, or nonsmoker), obesity (BMI>30, BMI>40), and hypertension, is also obtained from the household contacts. These data are collected in dichotomous variables according to the presence or absence of each one of them.

Epidemiological Information

The epidemiological section registers data related to whether the participants have had close contact with the index case (first positive case in the household); the exposure time; the relationship with the index case (ie, partner, father, or mother); whether they have shared a vehicle or bedroom with the index case; and whether the contact has symptoms, and if so, which ones. Other data collected include the frequency of use of nonpharmaceutical preventive measures at home (eg, ventilation, use of mask, distance, and frequency of hand washing); the results of, and the type of COVID-19 test (eg, polymerase chain reaction test or rapid antigen test) they may have had after the positive test results of the index case; and any previous COVID-19 infection, including details about severity, possible hospitalization, and any other relevant details.

COVID-19 Vaccination Status

This section provides data concerning COVID-19 vaccination history, including the date of administration and brand of each dose. The data provided by the participants in this section can be validated by the vaccination records. To evaluate vaccination hesitancy, if the participant has not received any vaccine, they are asked for possible reasons for their lack of willingness to receive it.

Knowledge Concerning COVID-19 Disease and Its Preventive Measures

In this section, the patients' knowledge of COVID-19 is evaluated, considering that adequate knowledge about COVID-19 infection, severity, and preventive measures are important factors associated with the decision of vaccine uptake, and therefore, the spread of infection [19]. This section consists of 6 questions, and participants are asked about COVID-19 modes of transmission and preventive measures during a situation of COVID-19 circulation (Table 1). The knowledge about COVID-19 disease and preventive actions, such as vaccination and nonpharmaceutical measures, are assessed using a 5-point Likert scale (totally agree, agree, neither agree nor disagree, disagree, and totally disagree) [10].

Table 1. Items concerning knowledge of COVID-19 disease and its preventive measures.

	Totally disagree	Disagree	Neither agree nor disagree	Agree	Totally agree
All people who become ill with COVID-19 develop severe cases.	__[a]	—	—	—	—
Asymptomatic persons diagnosed with COVID-19 can transmit the infection.	—	—	—		—
Persons diagnosed with COVID-19 can transmit infection despite vaccination.	—	—	—	—	—
The COVID-19 virus is spread by respiratory droplets from infected individuals when coughing, sneezing, talking, laughing, and singing.	—	—	—	—	—
Handwashing is important to reduce the risk of contracting COVID-19.	—	—	—	—	—
To prevent transmission of COVID-19, measures such as wearing face masks and avoiding crowds in enclosed spaces should be maintained.	—	—	—	—	—

XSL•FO
RenderX

Attitudes Toward COVID-19 Disease and Its Preventive Measures

This section consists of 6 questions, evaluating attitudes toward COVID-19 vaccination; stigma against symptomatic individuals; and the effects of COVID-19 on daily life, considering the current situation (Table 2). For this section, participants are being asked to state their level of agreement with specific attitudes and preventive actions related to COVID-19 again, expressed on a 5-point Likert scale [7].

Table 2. Items related to attitudes toward COVID-19 disease and its preventive measures.

	Totally disagree	Disagree	Neither agree nor disagree	Agree	Totally agree
I consider myself susceptible to developing a severe disease if I become ill with COVID-19.	__[a]	—	—	—	—
I consider that my inner circle has complied with the preventive measures to avoid becoming ill with COVID-19.	—	—	—	—	—
I consider that my inner circle has complied with the vaccination recommendations given by the health authorities.	—	—	—	—	—
I consider that it is better to develop immunity by getting sick with COVID-19 than by getting vaccinated.	—	—	—	—	—
It is convenient for the general population to wear a facemask correctly (covering the nose and mouth) to prevent COVID-19 in crowded, closed environments.	—	—	—	—	—
I consider that COVID-19 had a negative influence on my daily life.	—	—	—	—	—

[a]To be filled.

COVID-19 Information Sources

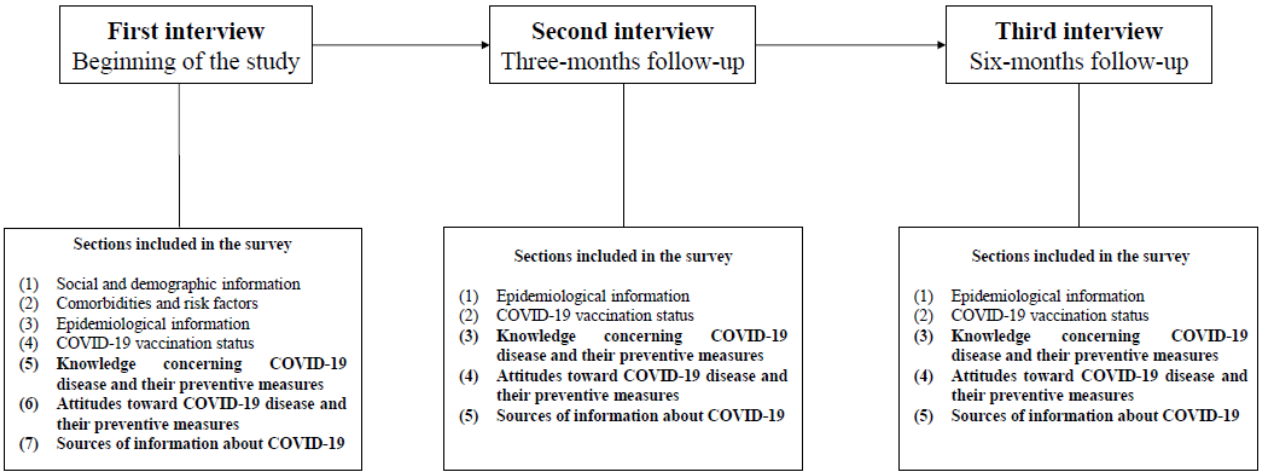
Additionally, the survey includes a section regarding the most common source of information on COVID-19 disease and the preventive measures consulted by the participants. The survey contains a list of possible information sources as the primary source used by the participant and has the following options: nonofficial sources, such as traditional mass media (eg, television and written or web-based press); social media (eg, Instagram, Facebook, and Twitter); and official sources, such as medical professionals and government or other official sources (eg, World Health Organization, ECDC, or Spanish Ministry of Health).

Results

Pilot Test

The content validity of the questionnaire was evaluated in a pilot study performed in Navarre, consisting of a sample of 22 household contacts during the period between April and June 2022. In the pilot test, participants were presented with a set of items and questions by a trained staff interviewer. The interviews were performed by telephone, and all observations were collected during this phase. No changes to the initial questionnaire's items related to the knowledge and attitudes toward COVID-19 disease, its preventive measures, or information sources were needed. The pilot test confirmed that the questionnaire had established content and was well understood and concise.

The final questionnaire consisted of 23 questions distributed in 7 sections (described in the previous section). The average response time was 15 minutes, with older participants exhibiting a more noticeable variation in their responses.



Evaluation of the Trends in Knowledge and Attitudes Over Time

To evaluate the persistence or changing trends in knowledge and attitudes about COVID-19, vaccination, and nonpharmaceutical preventive measures, the telephone survey of household contacts is being conducted in 3 rounds, at different epidemiological moments. The first round is done just after their identification as a household contact, and the second and third rounds are done 3 and 6 months later, respectively.

In the first round, all the information from the questionnaire is collected, thus obtaining reference information at the time of contact with the index case. In the 3-month and 6-month follow-up rounds, we will inquire whether they have had any change in their COVID-19 vaccination status or whether they have become infected by the SARS-CoV-2 since the last call; we will also inquire about various items related to knowledge and attitudes about COVID-19 and its preventive measures as well as the information sources upon which they rely (Figure 2). The background information is not collected again, as it is not subject to change over time. After the pilot study, participant recruitment began and is expected to be completed by the end of 2023. The final results will be available in 2024.

XSL•FO
RenderX

Figure 2. Study design and follow-up timetable of the study.

Discussion

Principal Findings

This study will provide valuable insights into the knowledge and attitudes of household contacts of confirmed COVID-19 cases, after the acute phase of the pandemic, toward the disease and its preventive measures, including vaccination and nonpharmaceutical preventive measures, and will allow for evaluating the trends in these data over time.

At this moment, this study is still in the recruitment process. It must be mentioned that this study is being carried out within the framework of the postacute phase of COVID-19, where infections continued to decrease. Therefore, including a preliminary analysis of this questionnaire, considering the recruited population at this moment, could provide biased results. However, despite the abundance of information available about infection and preventive measures for COVID-19, studies have shown that there are still some gaps related to the use and maintenance of preventive measures during this transitional phase of the pandemic, especially in households, where the probability of SARS-CoV-2 transmission is higher [11,12]. Preventive measures, such as vaccination and nonpharmaceutical measures, are of special relevance for controlling this infection. More than 50% of transmission chains are generated in households, and the use of nonpharmaceutical preventive measures before the occurrence of cases is probably limited [20].

Some studies reported that nonpharmaceutical public health measures, such as physical distancing and wearing masks, had a strong impact on person-to-person COVID-19 transmission at the individual level [21,22]. Funke et al [22] evaluated the containment of nonpharmaceutical measures during the first 3 pandemic waves in countries from North and South America, Europe, and Asia-Pacific. Results showed a dual cause-effect channel where nonpharmaceutical interventions had a direct impact on several health outcomes and an indirect effect on voluntary changes in social distancing. Some authors have identified that accurate knowledge is essential in managing epidemic situations caused by infectious agents and that nonadherence to nonpharmaceutical preventive measures is likely to be the consequence of a knowledge gap [23-25].

Detecting the weak points in the population's attitudes and knowledge regarding the studied preventive measures, as well as monitoring the persistent or changing nature of adherence to them over time, is important for planning strategies to improve prevention and health promotion. It also serves as a benchmark for future epidemics of respiratory viruses that affect the population every winter. This issue is particularly relevant in the current scenario in which vaccines do not totally reduce the risk of transmission [26].

The current situation of the COVID-19 pandemic, following the acute phase during the emergence of the Omicron wave, indicates a notable decrease in the number of new cases, which many might interpret as a sign of the end of the pandemic. Corresponding with this, we have seen a change in the surveillance and control strategy against COVID-19 implemented by the Spanish government and health authorities. This shift is accompanied by reductions in the compulsory and recommended use of nonpharmaceutical interventions, such as the compulsory use of face masks [27]. This will naturally result in the lower use of these measures in the population and possibly a shift in their beliefs regarding these measures and COVID-19 itself.

A key factor is to understand how containment measure strategies impact pandemic stages to minimize the risk of further waves of SARS-CoV-2. Cascini et al [28] compared the impact of COVID-19 containment measures in 5 European countries on the epidemic curves. Authors indicated 3 main factors that affected COVID-19 transmission. First, the time when preventive measures were adopted—as long as these measures were implemented early, they showed better results; second, the duration of containment measures; and finally, the number of COVID-19 cases before relaxing containment measures. It is important to emphasize that the effectiveness of preventive measures depends on their adherence.

The attitude of acceptance of the recommended measures is essential to control the transmission of SARS-CoV-2 and reduce its incidence, especially in situations in which these measures

XSL•FO
RenderX

are extended over time with different intensities, and as a consequence, the population is liable to reduce their compliance [29,30]. Knowledge and attitudes are important cognitive keys in public health regarding prevention and health promotion. Other factors that influence noncompliance may include a range of beliefs about the causes of the disease, knowledge of the identification of symptoms, available methods of treatment, consequences, and possible long-term complications [25]. Some studies related to knowledge and attitude regarding COVID-19 have been conducted, but most of them were performed on the general population [31-34], in which the risk of transmission is lower than in a closed environment, such as a household. Evidence from these studies on knowledge and attitudes during epidemics allows us to recognize and identify key attitudes and practices to prevent the spread of the disease. Consequently, several policies and political interventions have been established and reinforced to optimize the management of the COVID-19 pandemic by health authorities.

We believe that it is important to monitor such changes over time and assess any knowledge gaps to understand both the current situation and how such knowledge and beliefs evolve over time. The low current incidence of COVID-19 cases reflects a complex matrix of influences rather than being a reliable sign of the end of the pandemic. A combination of high vaccination coverage, an increase in immunity in the population generated by natural infections, and the cumulative effects of compulsory and recommended preventative measures [35-37], along with other factors, create the situation we currently experience. In the case that a new outbreak may occur, information about the ongoing beliefs, preventative practices, and knowledge gaps in the population will be invaluable in designing new strategies to combat the disease.

A strength of this study is that the coordination committee is composed of professionals with expertise in communicable diseases and vaccination research. They have been involved in the surveillance and monitoring of the infection in Catalonia and Navarre since the beginning of the COVID-19 pandemic, which facilitates the implementation of the study in both regions and allows adequate management of fieldwork, with a unified work protocol. Another strength of the study is that it is being carried out in 2 regions of Spain (Catalonia and Navarre) that present different situations of SARS-CoV-2 household transmission, increasing the representation of the Spanish population. Additionally, conducting a longitudinal study assessing changing beliefs and knowledge in the community during the postacute phase of the pandemic provides, in our view, an essential dimension to understanding the social landscape in which the measures are being applied. The combination of these 3 factors makes the results of this study uniquely valuable in disease prevention.

This study has some limitations. First, it is being carried out at a time when the epidemiological situation presents a low incidence of COVID-19 cases, which could alter the sample size of the contacts to follow. Therefore, we have planned to contact every single reported case during the study period and carry out an exhaustive census of household contacts to maximize participation. Second, it is a survey-based study, and the information will be self-reported, so information biases could possibly be introduced in the outcome variables and information about vaccination status. However, demographic characteristics, comorbidities, and COVID-19 vaccination status can be verified with electronic health records and vaccination registers. Third, the relaxation of the containment measures might have an impact on the attitudes toward COVID-19 over time, but our study could provide relevant information on attitudes toward preventive measures during this postacute phase of the pandemic [4].

Conclusions

The development of a questionnaire to assess knowledge and attitudes about COVID-19, vaccination, and nonpharmaceutical preventive measures over time after the acute phase of the pandemic will provide valuable insights regarding the control of infection in the population, in a low transmission scenario. This questionnaire will provide information about knowledge and attitudes over time and will be important for public health decision-making during the relaxation of containment measures in the event of an increase in COVID-19 cases or a new health emergency due to respiratory viruses.

Acknowledgments

We thank the professionals in primary health care centers in Catalonia and Navarre for the notification of COVID-19 cases and their household contacts to perform this study.

We would like to thank the members of the Working Group of project ESP22PI01 who contributed to the implementation and execution of the project in the fieldwork: Diana Toledo, Núria Soldevila, Núria Torner, Mireia Jané, Ana Martínez, Pilar Ciruela, and Angela Domínguez from Universitat de Barcelona—Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Barcelona, Spain; Pere Godoy from the Institut de Recerca Biomèdica de Lleida—CIBERESP, Catalonia, Spain; Cristina Rius, Glòria Pérez, Patricia García de Olalla, and David Palma from Agència de Salut Pública de Barcelona—CIBERESP, Barcelona, Spain; Nerea Iriarte, Cristina Burgui, Itziar Casado, Manuel García Cenoz, Jesús Castilla, and Iván Martínez-Baz from Instituto de Salud Pública de Navarra (IdiSNA)—CIBERESP, Barcelona, Spain.

This study was supported by resources provided by the call for the 2022 intramural projects of CIBERESP (project code ESP22PI01) and by Instituto de Salud Carlos III (ISCIII), cofunded by the European Regional Development Fund “Investing in your future” (project codes PI21/01883 and CP22/00016). IMB acknowledges a grant from the 2022 Miguel Servet tenure track program (CP22/00016) awarded by the ISCIII (Miguel Servet Program 2022 is cofunded by the European Union Fund—Fondo Social Europeo Plus).

Abstract

Background: Leptospirosis is considered a neglected zoonotic disease in temperate regions but an endemic disease in countries with tropical climates such as South America, Southern Asia, and Southeast Asia. There has been an increase in leptospirosis incidence in Malaysia from 1.45 to 25.94 cases per 100,000 population between 2005 and 2014. With increasing incidence in Selangor, Malaysia, and frequent climate change dynamics, a study on the disease hotspot areas and their association with the hydroclimatic factors would further enhance disease surveillance and public health interventions.

Objective: This study aims to examine the association between the spatio-temporal distribution of leptospirosis hotspot areas from 2011 to 2019 with the hydroclimatic factors in Selangor using the geographical information system and remote sensing techniques to develop a leptospirosis hotspot predictive model.

Methods: This will be an ecological cross-sectional study with geographical information system and remote sensing mapping and analysis concerning leptospirosis using secondary data. Leptospirosis cases in Selangor from January 2011 to December 2019 shall be obtained from the Selangor State Health Department. Laboratory-confirmed cases with data on the possible source of infection would be identified and georeferenced according to their longitude and latitudes. Topographic data consisting of subdistrict boundaries and the distribution of rivers in Selangor will be obtained from the Department of Survey and Mapping. The ArcGIS Pro software will be used to evaluate the clustering of the cases and mapped using the Getis-Ord Gi* tool. The satellite images for rainfall and land surface temperature will be acquired from the Giovanni National Aeronautics and Space Administration EarthData website and processed to obtain the average monthly values in millimeters and degrees Celsius. Meanwhile, the average monthly river hydrometric levels will be obtained from the Department of Drainage and Irrigation. Data are then inputted as thematic layers and in the ArcGIS software for further analysis. The artificial neural network analysis in artificial intelligence Phyton software will then be used to obtain the leptospirosis hotspot predictive model.

Results: This research was funded as of November 2022. Data collection, processing, and analysis commenced in December 2022, and the results of the study are expected to be published by the end of 2024. The leptospirosis distribution and clusters may be significantly associated with the hydroclimatic factors of rainfall, land surface temperature, and the river hydrometric level.

Conclusions: This study will explore the associations of leptospirosis hotspot areas with the hydroclimatic factors in Selangor and subsequently the development of a leptospirosis predictive model. The constructed predictive model could potentially be used to design and enhance public health initiatives for disease prevention.

Introduction

Background

Leptospirosis is a neglected zoonotic disease caused by the bacteria agent from the genus *Leptospira* [1,2]. The disease primarily affects vulnerable populations in the urban slums, especially in developing countries, rural farmers, and those involved with water recreational activities [3,4]. Outbreaks are also reported during heavy rainfall and flood seasons and in areas with higher humidity and temperature climates [5].

Although animals are the primary reservoir of *Leptospira*, a human could acquire the infection through the percutaneous contact of contaminated water or soil with the urine of infected animals [1,6]. The clinical presentation could range from afebrile flu-like symptoms to severe manifestations such as pneumonia, acute kidney injury, pulmonary hemorrhages, and even death. Although most infection causes are mild symptoms and can resolve without requiring treatment or be settled with antibiotics, the spread of infection is best controlled by applying preventive measures to minimize potential outbreaks and mortality [6]. Furthermore, better surveillance and disease control could be achieved by integrating hydroclimatic factors of the disease with spatio-temporal hotspot area analysis [7].

Based on morbidity and mortality from hospital-based surveillance studies, the global burden of leptospirosis was estimated to be 1.03 million cases, with 58,900 deaths per year [3,8]. From these data, the disease burden in terms of disability-adjusted life years was 2.90 million per annum, translating to 2.80 million years of life lost and 103,200 years lived with a disability [3]. The Leptospirosis Epidemiology Reference Group of the World Health Organization was established in 2009 to estimate the global burden of leptospirosis. According to the Leptospirosis Epidemiology Reference Group report in 2011 summarizing studies on leptospirosis complications and case fatality in a systematic review, there were 36% (range 0%-88%) of patients reported having an acute renal injury, while 17% reported acquiring acute lung injury (range 0%-62%). Among them, 12% and 25% had died from disease complications, respectively [8]. Pulmonary hemorrhage syndrome is another severe manifestation of leptospirosis that could be life threatening [8].

Leptospirosis is endemic in humid and tropical regions in South Asia, Southeast Asia, and Southern America. Developed countries in temperate zones, such as in the United States and Europe, report fewer cases due to unfavorable environmental conditions for the bacteria's animal reservoirs, thus considering the disease neglected [9]. However, outbreaks in the aforementioned regions have been reported as having been linked to travel-related reasons to endemic countries or to water activities [1,6].

The disease occurs more in suitable environments with poor sanitation and hygiene conditions, favoring the survival and proliferation of the rodent population, the leading animal reservoir in the South East Asia (SEA) region. [9]. The SEA countries are in the tropical belt, which experiences warm to hot climates with high rainfalls during wet seasons. This phenomenon promotes soil moisture, favoring *Leptospira* growth, subsequent contact, and transmission to humans [10]. An epidemiological study on the agent for human leptospirosis prevalent in the SEA countries identified the main *Leptospira* species pathogenic to humans; *L. interrogans* and *L. borgpeterseni* [11].

A meta-analysis studying the risk factors for leptospirosis following flooding discovered that the presence of rodents squirming near human settlements following the catastrophe and adult males having abrasion wounds or walking barefoot were significantly associated with the infection [12]. For instance, a massive flood following heavy rainfall hit Kerala, India, which took around 500 lives, and approximately 70 were reportedly killed by leptospirosis or dengue fever [13]. Indonesia, a country in the SEA region in the tropical rain belt, has seen 122 deaths from 920 leptospirosis cases reported in 2019 [14,15]. The country often experiences floods that commonly act as a catalyst for stagnant water, and poor sewer and sanitation systems are risk factors for leptospirosis infection [15].

Malaysia has the climate of a dynamically alternating, moderately hot and humid environment throughout the year, with bouts of heavy rains that could cause floods in prone regions. These characteristics are known to influence regional leptospirosis occurrence in Argentina, where the monthly precipitation, monthly river hydrometric level, and Oceanic Nino Index were the hydroclimatic indicators of the disease [16]. On the other hand, a study in Africa demonstrated that rainfall influences the population of rodents, which act as vectors for leptospirosis [17].

Leptospirosis is endemic in Malaysia, affecting mainly 5 states from 2005 to 2014, namely Kelantan, Selangor, Sarawak, Sabah, and Perak. The incidence in these states was constantly increasing and caused a peak of cases in 2014 [18]. Significant leptospirosis outbreaks have occurred on several occasions, such as during an Eco-Challenge in Sabah in 2000 and following a major flood event that mainly hit the northeastern states of Malaysia in 2014 [19,20]. Out of the 304 athletes who participated in the adventure sport in Borneo, 80 had met the clinical case definition of leptospirosis, with 26 of them testing positive for leptospirosis immunoglobulin M by enzyme-linked immunosorbent assay [19]. Meanwhile, Kelantan, one of the states hit by a major flood in 2014, saw more than 1000 leptospirosis cases identified during and after the flood incident [20].

Selangor is one of the states facing a high incidence of leptospirosis. The state recorded the highest cases in 2013, with the highest incidence rate of 24.68 per 100,000 population [21]. Even though there has been a steady rise in reported leptospirosis cases, the actual incidence might be underestimated as the clinical symptoms resemble other endemic acute febrile

XSL•FO
RenderX

illnesses such as dengue fever and malaria [22]. The impacts of climate change with increased flood intensities and frequent weather fluctuations increase vector population and enhance pathogenic *Leptospira* growth [23].

The geographic information system is a tool to analyze disease patterns through techniques such as spatial and temporal analysis [24,25]. A spatio-temporal study combines geographic data as well as trends of disease patterns over a specified period, subsequently generating a predictive model for disease management [25,26]. Walter Langbein, a Scientific Hydrologist, defines hydroclimatology as the "study of the influence of climate upon the waters of the land" [27]. The study of hydroclimatic factors concerned with leptospirosis infection would include factors of temperature, precipitation events, watercourses such as rivers and streams, and floods [16,28].

Objectives

This research aims to explore the spatio-temporal distribution of leptospirosis hotspot areas and their association with the hydroclimatic factors to develop a predictive hotspot area using geographic information system and remote sensing methods. Therefore, this study conducted in Selangor would be able to (1) describe the characteristics of leptospirosis cases in Selangor from 2011 to 2019; (2) map the spatio-temporal distribution of the leptospirosis cases; (3) develop leptospirosis hotspot maps; (4) explore the hydroclimatic characteristics (monthly rainfall, monthly river hydrometric level, and monthly land surface temperature) for Selangor; (5) examine the association between hydroclimatic factors and leptospirosis hotspot areas; and (6) develop a leptospirosis hotspot predictive model based on the hydroclimatic factors.

This potentially life-threatening condition will be challenging to address if potential outbreaks are not predicted with hotspot areas not being outlined. Furthermore, this research may act as a pilot study in the country for the spatio-temporal analysis of leptospirosis with its association with hydroclimatic factors. The predictive model produced in this study can be replicated for future applications and studies.

Methods

Regional Setting

Study Location

The state of Selangor is located in the central part of the west coast of Peninsular Malaysia, bordered to the North, East, and South by Perak, Pahang, and Negeri Sembilan. Selangor lies to the west of the Titiwangsa range between the latitudes of 2°39'18.0" and 3°50'54.4" north to the equator and longitudes of 101°44'49.0" and 100°52'07.7" east. The state covers an area of approximately 8100 km^2. There are 55 subdistricts, also known as mukim, in 9 districts within Selangor (ie, Sabak Bernam, Hulu Selangor, Kuala Selangor, Gombak, Klang, Petaling, Hulu Langat, Kuala Langat, and Sepang). Generally, the irrigation in Selangor comes from 4 main river basins, namely Sungai Selangor and Sungai Bernam to the north, and Sungai Langat and Sungai Klang to the south. Historically, these major rivers were seen as the major drivers of early community settlements around these areas.

Study Design

This will be a retrospective, hydroclimatic study concerning leptospirosis, whereby secondary data of leptospirosis cases and hydroclimatic factors (rainfall, land surface temperature [LST], and river hydrometric data) will be obtained over a period of 10 years, from January 2011 to December 2019.

Study Population

The study population of this study will be leptospirosis cases in the Selangor state from January 2011 to December 2019.

Sampling Method

The sample population includes all mukim polygons in Selangor. The sampling frame will be the lists of mukim areas in Selangor, with each polygon representing a sampling unit. The sampling size of the study will be 54 mukim polygons in Selangor using a universal sampling method of notified leptospirosis cases.

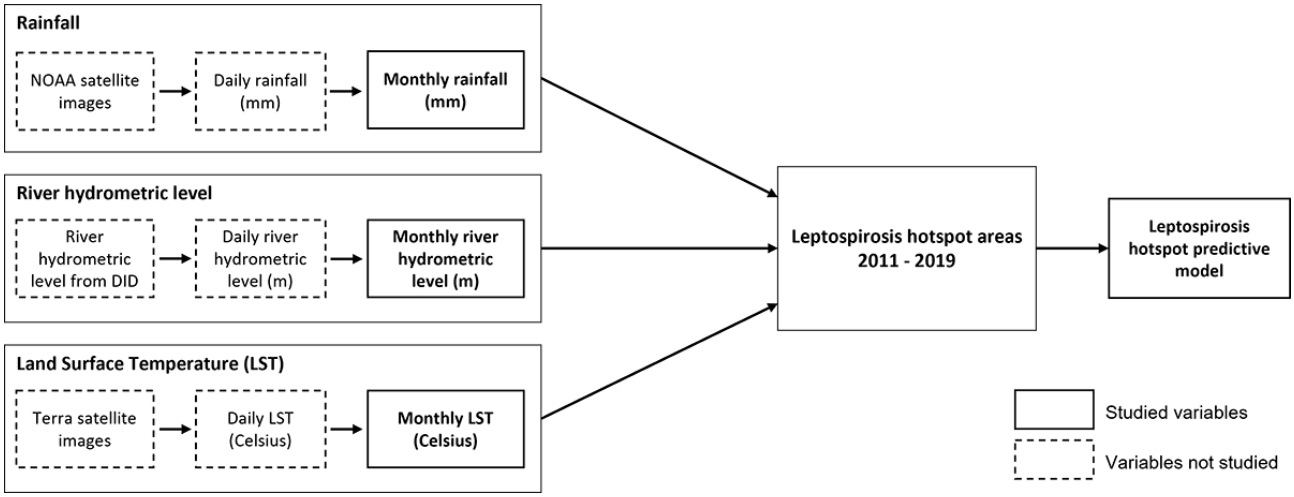
Data Collection

Data on leptospirosis cases from 2011 to 2019 will be obtained from the Zoonosis Unit, Selangor State Health Department. A period of 9 years was taken to compare the results from other similar studies in Argentina and Malaysia [16,29]. The data obtained will be analyzed for the sociodemographic information of the cases and locations of possible sources of infection with their longitude and latitude coordinates. Permission for data collection from relevant agencies has been obtained from the Medical Research and Ethics Committee, the Ministry of Health, and the Ethics Committee for Research Involving Human Subjects before the commencement of the study.

The topographical data for the Selangor state will be obtained from the Department of Survey and Mapping (JUPEM). The data will be in the shapefile format. Satellite images from the Integrated Multi-satellite Retrievals for Global Precipitation Management will be used to derive rainfall data for the Selangor state from January 1, 2011, to December 31, 2019. Images will be obtained from the Giovanni NASA EarthData website [30]. The LST is measured using the MOD11A2 satellite through the onboard Moderate Resolution Imaging Spectroradiometer sensor. It captures 1 km/pixel images at an emissivity of 8 days. Data will be downloaded in a Network Common Data Form format [30]. Meanwhile, the river hydrometric level of rivers in Selangor will be obtained from the Department of Drainage and Irrigation (DID) over a period from January 1, 2011, to December 31, 2019.

Operational Definition of Variables

Dependent Variable



Leptospirosis hotspot area is defined as zones that are hydroclimatically hotspots for leptospirosis transmission in Selangor. The zones will be divided into buffer zones according to color coding based on susceptibility, which are as follows: (1) green zone, not susceptible; (2) yellow zone, less susceptible; (3) orange zone, susceptible; and (4) red zone, highly susceptible.

XSL•FO
RenderX

Independent Variables

The independent variables for the study are as follows: (1) the rainfall images in millimeters captured by the satellite will be analyzed to obtain the average monthly rainfall; (2) the LST is the earth's surface temperature captured by the satellite in degrees Celsius; and (3) the river hydrometric level is the water level threshold classified for risk of flooding according to the DID, into normal, alert, warning and danger. The alert level is when the level increases significantly above average. In the warning stage, the level increases to near flooding, and preparation for evacuation is commenced. When the level reaches the danger level, a significant flooding event would likely occur, and the evacuation of people is initiated. Figure 1 shows the conceptual framework of this study. The framework outlines the geospatial processes of satellite photography images and river hydrometric level and their association with leptospirosis hotspot areas in Selangor from 2011 to 2019.

Figure 1. Conceptual framework. DID: Department of Drainage and Irrigation; LST: land surface temperature; NOAA: National Oceanic and Atmospheric Administration.

Data Processing

Processing Leptospirosis Data

The data cases will be cleaned and mapped according to the spatio-temporal variability to identify areas and periods with the highest incidence. The longitudes and latitudes of the possible source of infection of cases will be determined and reconfirmed with JUPEM. Subsequently, the coordinate table in Excel (Microsoft Corporation) will be added in the CSV format and imported to the ArcGIS Pro software (Esri) to determine the spatial distribution of leptospirosis cases. After analysis with the independent variables, leptospirosis hotspot areas will be generated and clipped with mukim polygon areas in Selangor.

Processing Topographical Data

The shapefile obtained from JUPEM will be projected in ArcGIS Pro software and extracted to thematic layers. The river hydrometric level data will be averaged into monthly data, tabled in Excel, and then saved in the CSV file format. Zonal statistics will be used for the analysis of each polygon.

Processing Satellite Data

Images obtained will be processed to obtain average monthly data for rainfall and LST for each mukim using the clipping tool in the ArcGIS Pro software to extract temperature and rainfall data for each polygon.

Data Analysis

The descriptive statistics of leptospirosis cases for each month from 2011 to 2019 will be analyzed using SPSS, version 27.0 (IBM Corp). The data will be presented using the frequency, percentage table, and appropriate bar charts or graphs for the variables studied.

The spatio-temporal analysis of patterns and distribution of leptospirosis hotspot areas in Selangor will be analyzed using the Moran I and Getis-Ord Gi* spatial statistical tools in ArcGIS Pro. Meanwhile, the relationship between leptospirosis hotspot areas and the hydroclimatic hotspot areas will be analyzed using Pearson correlation. Next, a generalized linear mixed model will be used to examine the correlation between the studied variables. The best-fitted model will be determined through the multivariate analysis by equations that give the lowest value of the Akaike information criterion result.

A predictive model for leptospirosis hotspot areas will be developed using the Phyton intelligent software to run the artificial neuron network analysis. The Phyton software will be able to examine the best-fit model for the association between leptospirosis hotspot areas with its hydroclimatic indicators.

Ethical Consideration

The study protocol obtained ethical approval with expedited review by the Medical Research and Ethics Committee, Ministry of Health Malaysia, on August 25, 2022 (NMRR ID-22-01548-C0Z). Data collection began in October 2022 and is expected to complete in March 2023.

Results

The results of this study are expected to be published by the end of 2024. The leptospirosis distribution and clusters are expected to be significantly associated with rainfall, land surface temperature, and the river hydrometric level. Both models,

XSL•FO
RenderX

constructed through the use of statistical analysis and Python intelligent software, possess the potential to offer a comprehensive and multidimensional assessment of leptospirosis distribution and clustering. This integrated approach may enhance the comprehension of disease dynamics and facilitate the development of more effective strategies for prevention and control.

Discussion

Principal Findings

Globally, leptospirosis occurs in humid and tropical regions favoring the dwelling of mammals, including rodents, the main reservoirs of *Leptospira* causing the disease [6]. The threat of leptospirosis as an emerging neglected zoonotic disease is due to world climate changes and globalization. Flooding, rising temperatures, and the concurrent increase in rodent density greatly influence its distribution [5]. Domestic animals may harbor the organisms, but rodents are the main reservoirs of leptospires that incidentally transmit infections to humans through contact with contaminated water soiled with the reservoirs' urine [31].

Most infections with the pathogenic *Leptospira* cause subclinical manifestations or remain asymptomatic [1]. Symptomatic patients can have clinical manifestations, from mild fever, chills, headache, and muscle tenderness to severe forms characterized by dysfunction of multiple organs, including the liver, lungs, kidneys, and brain [1,32]. Commonly noticed manifestations are muscle pain involving the lower back and calves as well as conjunctival suffusion [32]. Severe forms of the disease are found in 10% of affected individuals who develop life-threatening pulmonary hemorrhages, Weil syndrome, and acute kidney injury [1].

The influence of climate change, such as the variations in rainfall, land temperature, and frequent floods, increases leptospirosis cases [5]. Studies in South America and East Asia ascertained the association of these factors to the disease, where heavy rainfall and flood events during the El Nino phenomenon and rainfall events that cause an increase in soil moisture impact regional leptospirosis [16,33]. A local study using weather data and artificial neuron network modeling to link leptospirosis occurrence in Seremban discovered their significant correlation with temperature and rainfall at a lag between 12 and 20 weeks [29].

Targeting hotspot areas for disease control is one of the widely used strategies. A hotspot can be described as an area that shows evidence of increased disease incidence, a higher risk of transmission, or a greater chance of disease emergence [34]. Many environmental factors influence leptospirosis incidence. They include factors involving occupation, natural disasters, and recreational or avocational exposure [9]. This study will focus on the major hydroclimatic factors for leptospirosis, including rainfall, river hydrometric level, and land surface temperature, due to global climate change dynamics and concurrent increase in disease incidence [16,18,28].

Strengths

This research will act as a pilot study for the whole country for a spatio-temporal analysis of leptospirosis with its association with the hydroclimatic factors. The predictive model developed could be used to replicate and improve similar studies in the future by investigating other hydroclimatic factors, such as water storage in the ground and in vegetation.

Limitations

The limitation of the study is that it only evaluates 3 main hydroclimatic factors in Malaysia that might only be applicable to regions or countries with the same climate. There may be additional hydrological factors that contribute to leptospirosis hotspot areas. Furthermore, this study did not analyze other significant environmental or nonenvironmental factors that might contribute to leptospirosis hotspot areas.

Conclusion

In conclusion, this study may illuminate whether leptospirosis infections occur in clusters and the role of hydroclimatic factors in contributing to the emergence of leptospirosis hotspot areas in Selangor. Moreover, public health managers can use the findings from the hotspot map and statistical models, along with the Python intelligent software analysis, to identify areas of high disease prevalence and implement targeted interventions to prevent and control the spread of leptospirosis more effectively.

Acknowledgments

The authors would like to thank the Director General of the Ministry of Health, Malaysia, the Medical Research Committee on the Ministry of Health, and the Ethic Committee for Research Involving Human Subjects, Universiti Putra Malaysia, for their support in granting ethical approval for this research. This study receives funding from the Putra Focus Grant (grant 6302013-14001).

Data Availability

Data availability can be accessed on the NASA EarthData website for satellite images and the DID for hydrological data on river hydrometric levels. Data were also made available from respective agencies with requests and approval letters.

Conflicts of Interest

None declared.

Abstract

Background: Human papillomavirus (HPV) infection, a common sexually transmitted disease, is associated with cancers of the cervix, vulva, vagina, penis, anus, and head and neck. Oropharyngeal squamous cell carcinoma (OPSCC; throat cancer) is a type of cancer involving the head and neck area that is rapidly increasing across the globe. There are higher rates of OPSCC among Indigenous populations relative to non–Indigenous Australian populations, although the HPV-attributable fraction remains unknown. For the first time at a global level, we plan to extend an Indigenous Australian adult cohort to monitor, screen, and ultimately prevent HPV-associated OPSCC and to undertake extensive cost-effectiveness modelling around HPV vaccination.

Objective: This study aims to (1) extend follow-up to a minimum of 7 years post recruitment to describe the prevalence, incidence, clearance, and persistence of oral HPV infection; and (2) conduct clinical examinations of the head and neck, oral cavity, and oropharynx and collect saliva samples for early-stage OPSCC testing.

Methods: We will continue to implement a longitudinal design for the next study phase, where we will ascertain the prevalence, incidence, clearance, and persistence of oral HPV infection at 48, 60, and 72 months; undertake clinical examinations/saliva assessments to detect early-stage OPSCC; and refer for treatment. The primary outcome measures are changes in oral HPV infection status, biomarker measures of early HPV-related cancer, and clinical evidence of early-stage OPSCC.

XSL•FO
RenderX

Results: Participant 48-month follow-up will commence in January 2023. The first results are expected to be submitted for publication 1 year after 48-month follow-up begins.

Conclusions: Our findings have potential to change the way in which OPSCC among Australian Indigenous adults is managed, with desired impacts including cost-savings on expensive cancer treatments; improved nutritional, social, and emotional outcomes; and improved quality of life for both Indigenous adults and the Indigenous community more broadly. Continuing a large, representative Indigenous adult cohort to track oral HPV infection and monitor early OPSCC is essential to yield critical information to include in the management armamentarium of health and well-being recommendations for Australia's First Nations.

KEYWORDS

Aboriginal South Australian; human papillomavirus; oral HPV infection; oral pharyngeal squamous cell carcinoma; OPSCC

Introduction

Human Papillomaviruses

Human papillomaviruses (HPVs) are a heterogeneous group of circular, double-stranded DNA viruses that grow in stratified epithelium (skin and mucosa). Prior to the implementation of vaccination, HPV was the most common sexually transmitted infection in Australia, with an estimated 4 out of 5 Australians having an HPV infection at some point in their lives [1]. HPV is a precursor to a range of cancers, including cervical cancer, other anogenital cancers, and oropharyngeal cancer. It is usually transmitted within 2-5 years of sexual activity debut [2]. The prevalence of HPV infection at a population level in Australia is unknown as there is no national level or representative survey data, and almost all surveys have focused on females only. There is reasonable HPV DNA data on prevaccination cervical HPV infection in females in both general and Indigenous populations. For example, prior to HPV vaccination, a survey of females aged 15-40 years attending routine Papanicolaou screening at 16 Indigenous health services, 8 family-planning services, and 10 community clinics sites across Australia estimated the age-standardized prevalence of any high-risk (oncogenic) HPV type as 31.3% and 30% among 655 Indigenous and 1494 non–Indigenous females, respectively [3]. The prevalence of HPV 16/18 in this group was 12.2% among Indigenous and 12.8% among non–Indigenous females, respectively.

HPV and Oropharyngeal Squamous Cell Carcinoma

Oropharyngeal cancers include cancer of the middle part of the throat: the tonsils, soft palate, and the base of the tongue [4]. HPV-associated oropharyngeal squamous cell carcinoma (OPSCC) has one of the most rapidly increasing incidences in high-income countries [5], with survival rates of HPV-attributable OPSCC being much higher than non–HPV-attributable OPSCC [6]. The increased incidence, which is particularly notable among males and younger cohorts, may be attributable to increased carriage of high-risk HPV types (especially HPV 16 or 18) via increased oral exposure to infected anogenital sites with changing sexual behaviors, as opposed to the more traditional risk factors such as smoking and alcohol [7,8]. Although estimates vary by setting, the proportion of OPSCC attributable to HPV (mainly HPV 16) has been cited in high-income countries as between 65% and 83% [9-11]. OPSCC has now surpassed cervical cancer as the most common HPV-driven cancer [12,13].

Burden of OPSCC in Australia

In 2008, age-standardized rates of lip, oral cavity, and oropharyngeal cancer in Australia were 11.0 per 100,000 for males and 4.1 per 100,000 for females [14]. Overall rates of overall lip, oral cavity, and oropharyngeal cancer declined between 1982 and 2008, but when considered in isolation, OPSCC rates increased during this time (1.2% per annum for males and 0.8% per annum for females), possibly due to an increased incidence of oral HPV infection [14]. Hocking and colleagues [15] similarly found a significant increase in OPSCC in Australia between 1982 and 2005, with an annual percentage increase of 1.4% for males and 1.0% for females. Hong and colleagues [16] reported that the proportion of OPSCCs that were positive for HPV DNA and p16 increased in males from 19% in 1987-1990 to 47% in 2001-2005 and 60% in 2005-2006. In 2 Brisbane-based studies, the HPV prevalence in patients with OPSCC diagnosed from 2004-10 was 49% and increased to 72% in patients diagnosed from 2013-15 [17,18].

There is little documented evidence of the incidence of OPSCC among Australian Indigenous persons. Indigenous persons living in Queensland were more likely than the total Queensland population to be diagnosed with head and neck cancers between 1997 and 2012, specifically in the base of the tongue/tonsil/oropharynx; the standardized incidence ratio was 2.16 (n=81) [18]. The incidence of oral cavity and oropharyngeal cancer among Aboriginal South Australians between 1977 and 2001 was 29.7 annual cases per 100,000 compared with 8.5 per 100,000 in the non-Aboriginal population [19]. It was the fourth most common cancer type in Aboriginal women, after lung cancer, gynecology-related cancer, and breast cancer. Between 1991 and 2005 in the Northern Territory, oral cavity and oropharyngeal cancer incidence for Indigenous Australians was 2.5 times that of the general Australian population, with the mortality rate being 4.8 times higher in Indigenous men and 4.0 times higher in Indigenous women [20]. In 2015, the rate ratio of disability-adjusted life years due to oral cavity and oropharyngeal cancer among Indigenous Australians was 3.8 times that reported for the total Australian population [21].

XSL•FO
RenderX

Early Detection of OPSCC

HPV 16-E6 antibodies are detectable in peripheral blood before diagnosis in the majority of HPV 16–driven OPSCCs. Using data from 743 incident OPSCC cases and 5814 controls from 9 population groups across Australia, North America, and Europe, Kreimer and colleagues [13] reported that HPV 16-E6 seropositivity increased with lead time: 0%, 13.5%, 23.7%, and 38.9% with lead times of >30 years (n=24 cases), 20-30 years (n=148), 10-20 years (n=228), and <10 years (n=301), respectively (*P*<.001). Of the 47 HPV 16-E6 seropositive cases with serially collected samples, 17 cases seroconverted during follow-up, ranging from 6 to 28 years before diagnosis. For the remaining 30 cases, robust seropositivity was observed up to 25 years before diagnosis. The authors concluded that the immune response to HPV 16–driven tumorigenesis is detectable several decades before OPSCC diagnosis.

Accuracy of Saliva Samples for the Detection of Early-Stage OPSCC

Saliva covers the oropharyngeal mucosa and can be collected noninvasively, making it an ideal bodily fluid for early biomarker detection of HPV-induced OPSCC. Recent studies have examined HPV mitochondrial RNA (mRNA) in oral (oropharyngeal swab or saliva) samples from patients with head and/or neck squamous cell carcinoma. The high rates for HPV E6 oncoproteins and E6/E7 mRNA suggest that most patients were experiencing transcriptionally active HPV-related OPSCC [22,23]. The clinically validated Hologic Aptima assay gives a result for the presence of HPV E6/E7 mRNA for 14 HPV types (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, and 68). There is also an option to examine whether the specific HPV type is HPV 16 or HPV 18/45. As with the findings from Kreimer and colleagues [13], the persistence of HPV 16 is a precursor for OPSCC.

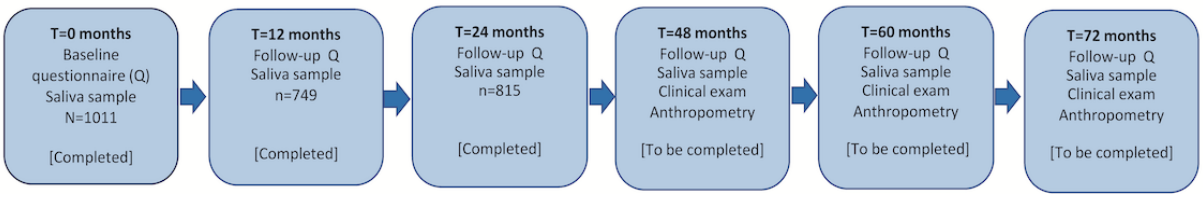
The Indigenous Australian HPV Cohort Study

The first phase of this prospective longitudinal cohort study was developed in partnership with Aboriginal communities in South Australia and funded by the National Health and Medical Research Council in 2016. The study is governed by an Aboriginal Reference Group, with data collected by trained Aboriginal research officers [24]. To be eligible at baseline, participants needed to identify as being Aboriginal and/or Torres Strait Islander, aged 18+ years, and residing in South Australia. Participants were recruited from February 2018 to January 2019 across 8 South Australia sites, primarily through Aboriginal Community Controlled Health Organisations (ACCHOs) whose chief executive officers are key stakeholders. The 1011 participants recruited at baseline represented 5% (1011/20,220) of Aboriginal South Australian adults eligible during the recruitment period, 8.2% (633/7720) of those eligible in nonmetropolitan locations, and 3% (376/12,533) of those in metropolitan locations. Participants were followed-up at 12 months (March 2019 to March 2020), with data from 749 (74.1%) out of 1011 participants obtained (suspended early due to COVID-19 restrictions). Follow-up at 24 months ceased in December 2021, with data from 815 participants obtained. Across baseline and 12- and 24-month follow-ups, saliva samples to test for oral HPV infection were collected in commercially available kits, and the DNA was tested for HPV detection.

Study Aims

In continued partnership with Aboriginal South Australian stakeholders and study participants, the aims of the second phase of the Indigenous Australian HPV cohort study are as follows:

Aim 1: To extend follow-up to a minimum of 7 years post recruitment to describe the prevalence, incidence, clearance, and persistence of oral HPV infection, including high-risk types, across 48-, 60-, and 72-month follow-ups and to correlate with lifestyle and sociodemographic characteristics



Aim 2: To conduct a thorough clinical examination of the head and neck, oral cavity, and oropharynx and to collect anthropometrics and saliva samples for OPSCC testing

Methods

Study Design

We will continue to implement a longitudinal design for the next study phase. A study schema is included in Figure 1.

Figure 1. Timing of data and sample collection. T: time point.

Inclusion Criteria and Retention

All participants initially recruited will be eligible for the 48-, 60-, and 72-month follow-ups. Retention strategies will involve those successfully used thus far: (1) continuing to employ Aboriginal staff who have built up personal relationships with participants and who are committed to following up participants despite challenges in doing so; (2) ensuring participants are contacted regularly to ensure the accuracy of contact details; (3) ascertaining contact details of 3 new key personnel who may know the whereabouts of participants should the study team be unable to contact them; (4) sending birthday and Christmas cards to participants; and (5) facilitating one-on-one relationships between study staff and participants, with study staff ideally seeing each of their participants for each research phase. We perceive no difficulties in continuing with the high retention of participants given our past success.

XSL•FO
RenderX

Ethical Approval

Ethics approval has been received by the Aboriginal Health Council of South Australia's Human Research Ethics Committee (04-22-1001) and the University of Adelaide's Human Research Ethics Committee. Prior to being recruited, all participants will be required to sign an informed consent form, which includes consent for the authors to publish the findings in the peer-reviewed scientific literature.

Data Collection

After completing informed consent with the assistance of the Aboriginal research staff, participants will be again asked to provide saliva samples using a commercially available kit from which microbial DNA and mRNA for genotyping will be extracted. This will involve the participant (1) not eating or drinking for 30 minutes prior to collection; (2) removing the funnel lid on the container; (3) spitting until 2 mL of saliva reaches the fill line on the container (this will take 2 minutes); (4) closing the lid and unscrewing the lid from the funnel; and (5) placing the small cap on the tube and shaking the tube for 5 seconds. The saliva samples will be sent to Victorian Cytology Services Ltd for analysis.

A thorough clinical examination of the external head and neck, intraoral cavity, and oropharynx will be undertaken by trained and calibrated dental professionals. Soft and hard tissue characteristics, caries experience, periodontal disease, and gingivitis will be assessed through standardized oral epidemiological examinations used in national oral health surveys. Weight will be measured in duplicate to the nearest 0.1 kg using Seca model 803 scales and averaged. Height will be measured in duplicate to the nearest 1 mm using a Seca model 213 portable stadiometer, using a standard anthropometric procedure. Any pathology detected via the clinical examination or saliva results will be immediately fed back to participants, with referrals to specialist or local primary care services promptly arranged.

Data collection will be at participants' homes, ACCHOs, or wherever participants feel the most comfortable.

Data Analysis

In brief, the analysis plan for each aim is as follows:

Aim 1: Oral HPV Infection Prevalence, Incidence, Clearance, and Persistence at 48, 60, and 72 Months

Saliva samples will be stabilized at the point of collection using PreservCyt media. Samples will be run on the real-time polymerase chain reaction–based Seegene HPV 28 assay using the Starlet extraction platform and the BioRad CFX96 amplification/detection instrument. The Seegene HPV 28 assay is the benchmark for HPV surveillance [25] due to its high level of automation, which reduces variation in the sensitivity/specificity between specimens processed at different time points. The Seegene HPV 28 assay gives individual HPV type outputs from 28 HPV types (19 high-risk HPV types: 16, 18, 26, 31, 33, 35, 39, 45, 51, 52, 53, 56, 58, 59, 66, 68, 69, 73, and 82; and 9 low-risk HPV types: 6, 11, 40, 42, 43, 44, 54, 61, and 70), including the 14 HPV types defined by the International Agency for Research on Cancer (IARC) as oncogenic, the additional 2 nononcogenic types covered by HPV vaccination (HPV 6 and HPV 11), and β-globin (for DNA integrity check). HPV 13 and HPV 32 are not included in the Seegene HPV assay but the DNA extraction from this assay is able to be run on a separate polymerase chain reaction based on the protocol by Bolis and colleagues [26]. The prevalence, incidence, clearance, and persistence of oral HPV types across all time points from recruitment at an individual level and collectively will be calculated using simple descriptive analysis.

Aim 2: Oral Clinical Examinations/Saliva Samples for OPSCC Testing

The prevalence, extent, and severity of dental diseases, including early clinical signs of OPSCC, will be calculated using standard World Health Organization (WHO) oral health benchmarks [27]. The recently completed 2017-18 National Survey of Adult Oral Health data set [28] will enable comparison with both general and Indigenous population-level estimates. General analysis will comprise chi-square and Student *t* test (2-tailed) within the study sample and nonoverlapping 95% CIs when comparing population estimates. Antibodies against HPV 16-E6 will be measured using saliva samples (Aptima HPV assay) [22]. Assay results will be interpreted based on the signal-to-cutoff ratio, with values ≥ 0.5 considered positive.

Results

Of the 1011 participants recruited, 910 (90%) provided β-globin positive saliva samples (β-globin is a DNA integrity check). Of these 910, 35.1% (n=319) were positive for any HPV infection [29]. This was 15 times the prevalence reported in a study of young non–Indigenouss Australians [30] and 5 times the prevalence reported in a systematic review involving the United States, Brazil, Mexico, and Finland [31]. Antonsson and colleagues [32] described a longitudinal study (0, 6, 12, and 24 months) of 704 people from Brisbane (18-70 years old). They reported an oral HPV infection prevalence of 10.7% (high-risk HPV prevalence of 6.4%) at baseline in 636 people who were β-globin positive. In our study, the most prevalent HPV types at baseline were those associated with Heck disease (multifocal epithelial hyperplasia; 207/910, 23% of the HPV types found)—a relatively benign and rare condition caused by oral HPV 13 or 32 infection that is more prevalent among Indigenous populations [33-35]. Clinically, Heck disease presents as soft, distinct, mostly multiple, and smooth papules or nodules having the same color as the surrounding mucosal epithelium (a "cobblestone" appearance), predominantly affecting the lower and upper labial mucosa and tongue. The condition usually regresses naturally but can be treated by surgical excision or cryotherapy when lesions are aesthetically unpleasing [36]. The next most prevalent HPV types were those associated with OPSCC (HPV 16 or 18; 30/910, 3.3% of the types found) [29,32].

In our Indigenous Australian HPV Cohort study, of the 749 participants retained at 12-month follow-up, 645 (86.1%) provided β-globin positive saliva samples. Of these, 43% (277/645) were positive for any HPV infection. The most prevalent HPV types at 12-months were again those associated with Heck disease (213/645, 33% of the HPV types found),

XSL•FO
RenderX

followed by HPV types associated with OPSCC (HPV 16 or 18; 16/645, 2.5%). A total of 588 participants had samples at baseline and 12-month follow-up that were β-globin positive. The prevalence of any oral HPV infection increased from 34% (200/588) to 44% (259/588). This increase was largely due to increases in HPV types 13 or 32 (Heck disease): from 20% (118/588) at baseline to 34% (200/588) at 12 months. The prevalence of HPV 16 or 18 decreased from 3.9% (23/588) at baseline to 2.7% (16/588) at 12 months. The prevalence of high-risk HPV types according to the IARC definition [37] decreased from 8.5% (50/588) at baseline to 7.1% (42/588) at 12 months [38]. A total of 473 participants had samples at baseline and 12- and 24-month follow-up that were β-globin positive. The prevalence of any oral HPV infection was 24.7% (117/473), the prevalence of HPV type 13 or 32 was 15.6% (74/473), and the prevalence of HPV type 16 or 18 was 1.7% (8/473).

Participant follow-up for this study will commence in January 2023. We anticipate the first results to be submitted for publication 1 year following initial recruitment.

Discussion

Expected Findings

Our findings have potential to change the way in which OPSCC among Australian Indigenous adults is managed, with desired impacts including cost-savings on expensive cancer treatments; improved nutritional, social, and emotional outcomes; and improved quality of life for both Indigenous adults and the Indigenous community more broadly.

Approaches to Aboriginal Community Engagement

The strong Aboriginal partnership, engagement, and buy-in of the first study phase were reported against the Consolidated Criteria for Strengthening Reporting of Health Research involving Indigenous Peoples (CONSIDER) statement [39,40]. The success of our community engagement processes was summarized as (1) engaging with ACCHOs as equal partners very early in the research process; (2) having an Aboriginal Reference Group; (3) having ACCHOs actively promote the study; (4) having a flexible agenda that is responsive to broader environment demands; and (5) including Aboriginal capacity building. Specific lessons learned include the need for active and wide Aboriginal community consultation that is initiated early in the research process, strong and sustained Aboriginal capacity building, and an active Aboriginal Reference Group—all of which we will continue to incorporate in the proposed second phase. There are additional benefits in having Aboriginal staff as representatives in each of the field sites. These representatives have been able to build their reputation in a new area of Aboriginal health, with oral HPV infection not being noticeably recognized previously. Australian Indigenous communities now have a contact, with study continuation facilitating improved HPV knowledge for both the ACCHO workforce and broader community. The next phase of this study will continue to implement and strengthen these community engagement strategies.

Why Is Continuation of This Cohort Important?

By December 2021, study participants had been followed for a median of 3.5 (range 3.0-3.9) years from baseline, allowing the analysis of short-term outcomes including oral HPV infection prevalence, quality of life, health state valuations of OPSCC, and incidence/clearance in the 12-24 months after baseline. There is not, however, sufficient follow-up to assess whether oral HPV infections, especially persistent high-risk HPV infections, lead to early-stage OPSCC and what the attributable risk from HPV will be. Continuing the largest Indigenous HPV cohort in the world to track oral HPV infection and to monitor the early stages of OPSCC is essential to yield critical information to include in the management armamentarium of health and well-being recommendations for Australia's First Nations. It is especially relevant in light of the imminent rollout of self-sampling HPV testing initiatives in Australia.

Strengths and Limitations

There are 2 main strengths of the Indigenous Australian HPV Cohort study. The first of these has been the engagement of South Australia's Aboriginal communities. This has contributed to the excellent recruitment and follow-up rate (approximately 749/1011, 74% to 815/1011, 80.6%), which needs to be taken into context. For example, this study has been undertaken over vast distances (travelling 700 km west, 400 km east, and 800 km north of the city of Adelaide), involving highly disadvantaged participants who have, in the past, not always enjoyed positive research interactions. The fact that over 1000 participants were recruited in less than 12 months demonstrates the widespread community support. The second strength is the multidisciplinary skill set of the team that is Aboriginal led. The main limitation is the lack of clinical examinations, anthropometrics, and samples to detect HPV 16-E6 antibodies that would yield important biomarker estimates, with funding not provided for this in the first 3 waves of the study.

In conclusion, by continuing the follow-up of the Indigenous Australian HPV Cohort, we will generate novel information regarding oral HPV exposure and OPSCC, including a range of cost-effectiveness modelling to ascertain cost-savings of extending HPV vaccination initiatives beyond what is currently available. This information has potential to vastly increase the relatively unknown causes of such dramatic HPV-related OPSCC incidence rates. Over the past 7 years, we have established excellent community buy-in with Aboriginal groups across South Australia. Everything is in place to continue the follow-up of this essential cohort, with findings likely to be game-changing in terms of influencing Indigenous HPV vaccination policy, oral HPV infections, OPSCC, health policy, and clinical guidelines throughout Australia and, indeed, the world.

Acknowledgments

Funding for this study is from a National Health and Medical Research Council (NHMRC) project grant (APP1120215). GG is supported by an NHMRC investigator grant (APP1176651). LJ is supported by an NHMRC research fellowship (APP1102587).

Data Availability

The data sets generated and/or analyzed during the current study are not publicly available due to privacy issues of the participants. Data are available from the corresponding author on reasonable request.

Authors' Contributions

All authors are named investigators on the project; they all contributed to the intellectual input of the study design and in writing this protocol.

Conflicts of Interest

KC is co—principal investigator (PI) of an investigator-initiated trial of cervical screening, “Compass”, run by the Australian Centre for Prevention of Cervical Cancer (ACPCC), which is a government-funded not-for-profit charity. Compass receives infrastructure support from the Australian government and the ACPCC has received equipment and a funding contribution from Roche Molecular Diagnostics, USA.
KC is also co-PI on a major implementation program Elimination of Cervical Cancer in the Western Pacific which has received support from the Minderoo Foundation and the Frazer Family Foundation and equipment donations from Cepheid Inc.

Abstract

Background: Fungal-bacterial cocolonization and coinfections pose an emerging challenge among patients suspected of having pulmonary tuberculosis (PTB); however, the underlying pathogenic mechanisms and microbiome interactions are poorly understood. Understanding how environmental microbes, such as fungi and bacteria, coevolve and develop traits to evade host immune responses and resist treatment is critical to controlling opportunistic pulmonary fungal coinfections. In this project, we propose to study the coexistence of fungal and bacterial microbial communities during chronic pulmonary diseases, with a keen interest in underpinning fungal etiological evolution and the predominating interactions that may exist between fungi and bacteria.

Objective: This is a protocol for a study aimed at investigating the metabolic and molecular ecological evolution of opportunistic pulmonary fungal coinfections through determining and characterizing the burden, etiological profiles, microbial communities, and interactions established between fungi and bacteria as implicated among patients with presumptive PTB.

Methods: This will be a laboratory-based cross-sectional study, with a sample size of 406 participants. From each participant, 2 sputa samples (one on-spot and one early morning) will be collected. These samples will then be analyzed for both fungal and bacterial etiology using conventional metabolic and molecular (intergenic transcribed spacer and 16S ribosomal DNA–based polymerase chain reaction) approaches. We will also attempt to design a genome-scale metabolic model for pulmonary microbial communities to analyze the composition of the entire microbiome (ie, fungi and bacteria) and investigate host-microbial interactions

XSL•FO
RenderX

under different patient conditions. This analysis will be based on the interplays of genes (identified by metagenomics) and inferred from amplicon data and metabolites (identified by metabolomics) by analyzing the full data set and using specific computational tools. We will also collect baseline data, including demographic and clinical history, using a patient-reported questionnaire. Altogether, this approach will contribute to a diagnostic-based observational study. The primary outcome will be the overall fungal and bacterial diagnostic profile of the study participants. Other diagnostic factors associated with the etiological profile, such as incidence and prevalence, will also be analyzed using univariate and multivariate schemes. Odds ratios with 95% CIs will be presented with a statistical significance set at $P<.05$.

Results: The study has been approved by the Mbarara University Research Ethic Committee (MUREC1/7-07/09/20) and the Uganda National Council of Science and Technology (HS1233ES). Following careful scrutiny, the protocol was designed to enable patient enrollment, which began in March 2022 at Mbarara University Teaching Hospital. Data collection is ongoing and is expected to be completed by August 2023, and manuscripts will be submitted for publication thereafter.

Conclusions: Through this protocol, we will explore the metabolic and molecular ecological evolution of opportunistic pulmonary fungal coinfections among patients with presumptive PTB. Establishing key fungal-bacterial cross-kingdom synergistic relationships is crucial for instituting fungal bacterial coinfecting etiology.

Introduction

Overview

Fungi are ecologically regarded as environmental saprophytes that feed on decaying organic matter. However, over the past 30 years, fungi have transitioned into key etiological agents for difficult-to-manage infections, killing at least 1 million people each year. Yet they remain among the most neglected diseases worldwide [1,2]. The most serious invasive fungal infections often occur in the immunocompromised patients, such as those with HIV, cancer, and organ transplant, all of which have increased dramatically in the last 20 years [2]. Clinical manifestations of fungal infections have ranged from superficial to disseminated diseases with rates of invasive opportunistic fungal infections having upsurged during recent decades. Opportunistic pulmonary fungal coinfections are also emerging due to recent changing trends in predisposing factors and etiology. In Africa, pulmonary fungal coinfections are reported in about 15%-35% of cases, mainly within the cohort of individuals coinfected with HIV and tuberculosis (TB) [3,4]. This is posing enormous challenges to health care professionals, especially in resource-limited settings, where the diagnosis is not precise.

The chronic pulmonary disease has been linked with fungal etiology in the past but is often ignored. However, there is an emerging and interesting twist to fungal etiology, where cross-kingdom interactions appear to impact fungal virulence but are not fully explored. For instance, there are reports that bacteria can influence eukaryotic biology through various roles, such as parasites, commensals, or beneficial symbionts, in addition to acting as sources of new genetic sequences through subtle mechanisms like horizontal gene transfer [4-7]. In this context, the coexistence of fungi with other microbes, such as bacteria, in the same infection niche may unveil highly coordinated metabolic or molecular interaction profiles. This has been shown in chronic wound infections, where fungal-bacterial coexistence disrupts the highly controlled sequence of wound healing [3,8]. In fact, chronic wound microbiome and mycobiome studies reveal that fungal coinfections contribute to impaired wound healing [8]. A study by Mucunguzi and colleagues [9] reported a 22.2% prevalence of pulmonary fungal infections among people living with HIV in Southwestern Uganda. Therefore, it is possible that fungi also affect the outcome of chronic pulmonary diseases but are missed due to the lack of specific clinical or diagnostic signatures, leading to high rates of morbidity and mortality [3,10,11].

In the immunocompromised cohort, pulmonary infections can be exacerbated by a range of pulmonary opportunistic fungal coinfections. Unfortunately, infected individuals often present with symptoms similar to those of the most prevalent diseases, such as pulmonary tuberculosis (PTB) or bacterial pneumonia [3]. This propagates their rapid spread and augments poor prognosis. Hitherto, fungi co-isolated with bacteria have been considered irrelevant and often regarded as environmental contaminants [12]. This is further worsened by limited exposure of clinicians and laboratory fraternity to fungal infection biology. Nevertheless, patients could benefit from the definitive diagnosis of these infections and an exploration of the underlying mechanisms that drive saprophytic fungi to cause diseases in this patient population.

The changing trend of fungal etiology calls for the employment of advanced technology in profiling etiological agents. The synergistic ability of fungi to interact with other microbes, such as bacteria, in health and disease proves complex and can unveil new etiological agents and highlight novel virulence traits and antimicrobial targets. In this project, we propose to study the coexistence of fungal and bacterial microbial communities

XSL•FO
RenderX

during chronic pulmonary disease, with a keen interest in underpinning fungal etiological evolution and the predominating interaction relationships that may exist between fungi and bacteria. There is already evidence that such interactions may culminate into properties distinct from those of their individual consortia [4,7,13-17]. Three hypotheses define this study, specifically that the following: (1) the burden of opportunistic pulmonary fungal coinfections is higher than what culture-dependent data suggest; (2) culture-independent data complement culture-dependent data in supporting therapeutic decisions; and (3) fungal-bacterial coexistence influences fungal and bacterial virulence. Thus, through these questions, we hope to reveal elusive interplays between the 2 microbial communities during disease development to explain differences in patient outcomes.

Significance of the Study

Through this study, we can improve diagnosis and enhance clinical relevance as well as our epidemiological understanding of cross-kingdom etiological interactions. Pilot explorations of polymicrobial interactions, including bacterial-fungal interactions, can mediate a shift in substrate consumption, enzyme production, sexuality, thermostolerance, antimicrobial resistance, metabolism, and virulence [4,7,17-26]. For instance, some Mucorales fungi harbor bacterial endosymbionts that significantly modulate their metabolic profiles and virulence attributes in plants [16,17,27,28]; a similar interaction strategy is suggested in animal hosts [29,30].

During blight light disease of rice seedlings, a saprophytic fungus, *Rhizopus microsporus*, benefits from a toxicogenic alliance formed between this fungus and its endosymbiont bacteria, *Burkholderia rhizoxinica* or *Burkholderia endofungorum*; this alliance enables them to produce a potent anti–beta-tubulin toxin rhizoxin, which is a hepatotoxic cyclopeptide [17,27,31]. In addition, a range of phytotoxins with the potential to mediate virulence, which is thought to be produced by fungi, is a consequence of such interaction [16].

Although the impact of such relationships on clinical outcomes remains unclear, we recently demonstrated that another bacterial endosymbiont, *Ralstonia pickettii*, enabled *Rhizopus microsporus* to modulate innate immune responses in an animal model via a novel secreted factor [29,30]. Removing the endosymbiont using antibiotics rendered *Rhizopus microsporus* completely avirulent. These bioactive compounds are, therefore, important for fungal virulence as well as having potentially exploitable activities as demonstrated by the long history of fungal natural products in medicine, agriculture, and research [32].

Study Aims

This study aims to determine and characterize the burden, etiological profiles, microbial communities, and interaction relationships established between fungi and bacteria implicated in pulmonary fungal coinfections.

Methods

Study Design

This study will be a laboratory-based observational cross-sectional study.

Study Setting and Population

The study is being conducted at Mbarara Regional Referral and Teaching Hospital (MRRH) in Southwestern Uganda among patients suspected of having PTB.

Selection Criteria

The target population under study consists of patients suspected of TB at MRRH. Participants will be included if they are 18 years and older, provide consent, and have at least one of the following qualities: presenting with PTB-like symptoms, having no prior history of TB, testing positive or negative on smear test and GeneXpert test, exhibiting lipoarabinomannan antigen positivity along with persistent respiratory symptoms, and being on anti-TB treatment and severely ill yet able to produce sputum. Conversely, HIV-positive or HIV-negative patients who have TB-like symptoms but are on anti-TB treatment with a favorable prognosis will also be included. Patients who are on anti-TB treatment and severely ill but unable to produce sputum, critically ill patients, and pregnant women will be excluded from the study. Patients who are critically ill are excluded because their condition may cause delays in sample collection and obtaining consent, which would impact the recruitment process. Additionally, pregnant women suspected of TB are excluded since they are managed differently according to TB guidelines.

Statistical Analysis Plans and Power Calculations (Sample Size)

Based on the preliminary study, the prevalence of fungal coinfections among patients suspected of TB has been previously determined to be 40% using Kish-Leslie formula ($n=Z^2$ P (1-P)/ d^2) for determining the sample size in a cross-sectional study. In this formula, n is the sample size, Z (1.96) is the statistic for the level of confidence, P (0.4) is the estimated prevalence, and d (0.05) is the margin of error for the confidence interval. Using the Open Epi calculator, considering a population of 195,013 for Greater Mbarara, the sample size was determined to be 369 patients. Since we anticipate a 10% dropout rate, we will recruit 406 patients. From these patients, only 2 sputum samples will be collected—an on-spot sample on the day of recruitment and an early morning sample the following day, making a total of 812 samples to be collected. Obtained data will be analyzed using appropriate software, such as GraphPad (GraphPad Software Inc), Stata (StataCorp), or Epi Info (Centers of Disease Control and Prevention), among many others.

Recruitment Strategy and Retention

Patients will be recruited by convenient sampling as they report for medical services at the HIV/TB clinic of MRRH. The recruitment of the participants will follow the existing diagnosis and point-of-care procedures at both study sites. The clinic receives an average of 10 new cases per day. Considering both

XSL•FO
RenderX

our inclusion and exclusion criteria, we hope to recruit an average of 4 patients per day, resulting in an average total of 88 patients per month. This recruitment plan is achievable based on the rate of patients' inflow at the clinic. Additionally, sputum sample collection is not an invasive method that would scare away patients, so we do not anticipate any major challenges with patient retention. However, we will factor in a possible 10% dropout rate among patients, and thus, the final sample size will be increased by 37 more patients, resulting in a total of 406 patients, as previously mentioned.

Recruitment Site Selection

We have selected Uganda for this study because the country ranks high among the severely affected nations with HIV and TB pandemics. This is particularly true in western Uganda, where Mbarara (the proposed study site) is located. This subpopulation is also ranked among those most at risk of opportunistic fungal coinfections, yet it has been grossly ignored. Opportunistic pulmonary fungal coinfections are not uncommon among the immunosuppressed cohort, such as patients with HIV. We have selected patients suspected of having TB because most of the opportunistic pulmonary fungal infections present like TB, and therefore, are often missed during routine diagnosis. We have selected Mbarara Hospital as the study site because it is a regional referral hospital for the western region of Mbarara and a treatment center for patients with HIV or TB. Thus, we will have easy access to our study cases due to the high incidence of HIV or TB in this community. However, several population-based studies have been conducted in the past, focusing on HIV and TB, but are not associated with fungal coinfections [33,34]. Additionally, Mbarara University of Science and Technology has the infrastructure to handle most of the study demands. For instance, the Department of Microbiology in the Faculty of Medicine hosts a microbiology laboratory with medical mycology and TB units that have the capacity to respectively perform routine fungal or TB-based sputum analytical protocols, such as TB and GeneXpert testing, potassium hydroxide, and lactophenol cotton blue staining, as well as fungal and bacterial cultures. Additionally, the department has the capacity to do molecular-based procedures, including DNA isolation, polymerase chain reaction (PCR) amplification, and sequencing. The Department of Microbiology has also established collaborations with both national and international institutions, such as the Infectious Diseases Institute of Makerere University, Gulu University, Soroti University, and Muni University in Uganda; Massachusetts General Hospital and University of Minnesota in the United States; University of Birmingham, Sheffield University, and University of Exeter in the United Kingdom; and University of Aberdeen in Scotland.

Approach and Methodology

Aim 1: Determining the Burden and Etiological Profiles of Fungal Coinfections Among Patients Suspected of TB

Patients' sputum samples will be collected and cultured on both fungal and bacterial media for either organism's isolation. The isolates will be identified and profiled accordingly using conventional phenotypic and genomic-based assays. Total DNA will be extracted from the same sputum samples using a bead-beating phenol-chloroform approach. PCR primers targeting region 2 intergenic transcribed spacer (ITS2) will be used to amplify the fungal DNA present in the sputum samples; the amplified DNA will then be sequenced by Illumina MiSeq technology. This approach has been demonstrated to sensitively identify and determine the relative abundance of all fungi present in similar respiratory samples [35]. In this study, we will use this approach to identify the most abundant fungi present and detect any potential coinfections, which maybe challenging to identify using traditional culture methods. Fungal data will be analyzed using Mothur and the R statistical package Phyloseq (R Core Team) and will be speciated with reference to the UNITE2 database. Fungal quantitative PCR will be applied to determine the total burden of fungi present in each sample. Shotgun metagenomics will also be applied to a subset of samples. This metagenomics approach will reveal genomic detail of the fungi present, which will potentially include antimicrobial resistance genes and virulence genes and provide further typing information that reveals common clones or transmission among patients. Using long-read technology, the Oxford Nano pore GridION has the advantage of being a rapid sequencing technology that has shown promise as a rapid point-of-care test for the identification of microorganisms in clinical samples. As such, the use of this technology in this study may also reduce the time until diagnosis for fungal infections.

Aim 2: Establishing and Characterizing Microbial Communities Associated With Patients Suspected of Having TB

16S ribosomal RNA (rRNA) gene sequencing will be used to target the bacterial communities present in the same samples, using the same DNA extract, to identify bacterial coinfections. The results obtained will be used to describe the bacterial communities present in the sputum samples and then will be integrated with ITS2 fungal data [13,36-38]. To determine the association with the host phenotypes, the clinical metadata, including but not limited to age, gender, BMI, race or tribe, behaviors, and immune status, will be used to determine the association between fungal and bacterial communities with host phenotypes. For correlations between taxa, a combination of 16S rRNA gene and ITS2 sequencing data from the same samples will be used. Co-abundance patterns of bacteria and fungi will reveal potential interactions between and within fungal-bacterial communities, which can be further explored using DNA-independent methods in Aim 3. Both fungal-fungal, bacterial-bacterial and fungal-bacterial relationships will be interrogated using appropriate software packages, such as SparCC [38,39].

Aim 3: Characterizing Potential Interaction Relationships Established Between Fungal and Bacterial Communities

We will use a metabolomics approach in which sputum samples will be homogenized with methanol for metabolite extraction and derivatization. The extract and derivatives will then be analyzed for chemical composition using quantitative gas chromatography-mass spectrometry technique based on

XSL•FO
RenderX

metabolite profiling [40]. Gas chromatography-mass spectrometry–based metabolite raw data will be processed using the XCMS toolbox; this processing will involve peak detection, alignment, and multivariate statistical analysis using the XCMS outputs.

We will also attempt to design a genome-scale metabolic model for pulmonary microbial communities to infer the entire microbiome (bacteria and fungi) and host-microbial interactions under different patient conditions. This will be based on the interplays of genes (identified by metagenomics and inferred from amplicon data) and metabolites (identified by metabolomics) by analyzing the full data set and using specific computational tools, including but not limited to Meta-genomic Operationalized Assembly and Annotation Tool 2 for functional categorization and Human Microbiome Project Unified Metabolic Analysis Network 2 for profiling abundance of microbes and activity of their metabolic pathways. A genome-scale model will be developed to explore complex relationships between microbial components, such as genes, using assembly of gut organisms through reconstruction and analysis, a reconstruction-based tool used for microbial-host metabolism, and interactions' analysis [41,42]. In this manner, a genome-scale metabolic model will help us to postulate and test the underlined hypotheses that could link the burden, genotype, and phenotype of pulmonary microbial communities. Through these analyses, we also hope to infer ecological relationships, including but not limited to mutualism, commensalism, competition, antagonism, and symbiosis.

Expected Deliverables

The following will be expected deliverables to be achieved during the project:

- Total fungal burden in 406 patients and its changes over time (using quantitative PCR)
- Fungal microbiome analysis: relative abundance of sputum fungi and their identity (using ITS2 sequencing)
- Bacterial microbiome analysis: relative abundance of sputum bacteria and their identity (using 16S rRNA gene sequencing)
- Whole community metagenomics: detailed genomic identification and characterization of abundant members of the sputum microbiome, including gene-level detail
- Metabolomics profiling of sputum: analysis of host and microbial metabolites in longitudinal sputum samples
- Integration of culture-dependent and culture-independent data with clinical information to understand disease processes in the patient cohort
- A genome-scale metabolic model of the disease
- Identification of fungal and bacteria in the disease to support subsequent epidemiological, treatment, and basic research investigations
- Training and knowledge transfer in cutting-edge microbiome techniques

Study Safety

Study participants will be patients with infectious diseases and will be subjected to minimal risks during sample collection. However, the study will involve the collection, handling, and processing of contagious infectious human biological materials, such as sputum. Additionally, some of the proposed laboratory procedures will involve the use of hazardous reagents, which raise health and safety issues for both study staff and the general environment. However, to mitigate the anticipated risks, we will perform risk assessment procedures to identify the associated risks. Following risk assessment, we will develop standard operating procedures and comply with Control of Substances Hazardous to Health Regulations. These procedures will highlight health and safety measures conforming to the relevant local, national, or international guidelines. To this end, necessary precautions will be taken to ensure that these legislations are followed by both participants and staff involved in the metabolic and molecular ecological evolution of opportunistic pulmonary fungal coinfections (MeMoF) project.

Study Registration

After a careful audit of the protocol and design, the study was registered in the International Standard Randomized Controlled Trial Number registry (ISRCTN33572982).

Ethics Approval

The study has been approved by the Uganda National Council of Science and Technology (HS1233ES) and Mbarara University Research Ethics Committee (MUREC1/7-07/09/20) and will be conducted according to Uganda National and European Union legislation.

Informed Consent

Target patients will be fully informed of the purpose and procedures of this study, their obligations, potential benefits, and risks. To this effect, an informed consent form was prepared and approved by the institutional review board of Mbarara university for use; the form will be signed voluntarily by each of the study participants prior to enrolment.

Results

Study design, ethical review, approval, and research registration have all been completed. Patient enrollment commenced in March 2022. Most of the enrolled patients have completed their 2 visits. Patient enrollment was completed in June 2023, and the study results will be submitted for publication in late 2023.

We will share the study findings with the department of Microbiology, Faculty of Medicine, Mbarara University of Science and Technology; Ministry of Health Uganda; and other partner nongovernment organizations working with TB and related coinfections. We will discuss the scope, impact, and limitations of pulmonary fungal coinfections and bacterial fungal synergism based on our study findings. We hope to achieve technical and policy-level interventions, conduct capacity building, and increase public awareness of microbial ecological evolution. Finally, we will write abstracts and manuscripts for international conferences to an international audience and for peer-reviewed journals, respectively.

XSL•FO
RenderX

Discussion

Expected Findings

We anticipate that the findings of our study will enhance understanding and awareness of invasive pulmonary fungal coinfections among patients suspected of having TB. We hope that the diagnosis of invasive pulmonary fungal infections will improve, thereby advancing patient prognosis. In this study, we highlight an important aspect of cross-kingdom synergism during infection. In particular, we will highlight that fungal-bacterial coinfection is common among the susceptible cohorts of patients, particularly patients suspected of having TB. Our study aims to establish and characterize a network of microbial communities associated with chronic pulmonary diseases, in addition to TB. In doing so, we also hope to characterize potential interaction relationships established between fungal and bacterial coinfected communities.

Previous Findings

PTB is the most common opportunistic pulmonary disease, especially among the cohort infected with HIV/AIDS [3,33]. However, the prevalence of TB has been masked by other possible and somewhat endemic infections that can be as common [43-45]. Accordingly, invasive pulmonary fungal coinfections have been highlighted. Several studies show that endemic pulmonary mycoses are not uncommon; however, clinically, many of them manifest with similar signs to TB [45]. This seems to have promoted the misdiagnosis of many pulmonary fungal infections. In other instances of fungal infections, such as aspergillosis, the treatment of PTB is further complicated with residual activation. Thus, in many parts of the world, pulmonary fungal infections continue to be missed or misdiagnosed.

The spectrum of fungal etiology has evolved over the years, expanding from the commonly isolated Candida species to encompass clinically rare but commonly environmental opportunists, such as *Cladosporium* spp, *Acremonium* spp, *Alternaria* spp, *Aspergillus* spp, and *Fusarium* spp, among others. This evolutionary event seems to be directly proportional to a recent dramatic increase in predisposing conditions, such as solid organ transplantation, prolonged chemotherapy, and hematological malignancies, which have more than doubled over the last 20 years.

Although the etiology of chronic pulmonary infections is often attributed to *Mycobacterium tuberculosis*, several data reveal that numerous unappreciated fungal opportunists and other non-TB bacterial pathogens can also coinfect or serve as the primary cause of the chronic pulmonary disease [43,45]. Our preliminary hospital data show that up to 92% of patients suspected of having PTB develop pulmonary fungal colonization. Previously, Njovu et al [35] determined a 70.7% prevalence for pulmonary fungal coexistence among patients suspected of having TB. However, the causal profile of disease by most of these cocolonizers has not been explored yet. The challenge is that current diagnostic approaches are not designed to routinely assess polymicrobial infections, and therefore, may fail to detect the presence of fungal-bacterial coinfections.

In this protocol, we hypothesized that cocolonization of a host by multiple microbial communities is influenced by the environmental frequency and antimicrobial resistance profiles of both commensal bacterial and fungal opportunists; furthermore, understanding the nature, diversity, and environmental origin of these communities will provide important insight into their pathological potential. Sadly, not much attention has been given to the possibility of cross-kingdom etiology linking TB and pulmonary mycoses. Polymicrobial infection of the pulmonary system is not uncommon. Importantly, how the different etiological entities influence each other is mostly unknown. However, stemming from the wider environment, we know that bacteria and fungi interact on several levels and can have various effects within each consortium [4,7,17-26]. Yet the impact of these effects is barely known.

Taken together, our data so far suggest that fungal-bacterial coexistence may influence their virulence attributes and antimicrobial resistance patterns, with relevance to patient outcomes. Therefore, in this project, we will investigate how these cross-kingdom synergistic interactions in the wider environment shape the evolutionary trajectories of fungi and bacteria, priming them for antimicrobial resistance and virulence in mammals. Importantly, the diversity of pulmonary infective fungi and bacteria and their complex population structures pose challenges to the analysis and interpretation of conventional data.

Strengths and Limitations

The main strength of our study is that it is the first research project to integrate fungal-bacterial interactions at the interface of metabolic and molecular ecological evolution of fungal-bacterial etiology that is conducted using direct patient samples. Thus, the methodological setup has been designed to enhance awareness of fungal etiology and fungal-bacterial interactions among patients suspected of having TB. Through this study, we hope to improve the diagnosis and management of pulmonary coinfections. The downside of the study is purely technical; we anticipate a limitation in our methodological approach to study key co-interaction effects of the etiological agents at the metabolic level. This limitation might be associated with our lack of capacity to perform metabolomics experiments.

Conclusions

We present the protocol of a laboratory-based cross-sectional study involving patients with TB-like symptoms. Through this study, we will explore the metabolic and molecular ecological evolution of invasive opportunistic pulmonary fungal coinfections. This will be achieved by determining the fungal burden, characterizing the associated microbial communities and exploring the potential interaction relationships established between fungal and bacterial etiologies. Through this study, we aim to create diagnostic profile schemes that can be used to infer patient prognostic outcomes in at-risk individuals. Establishing key fungal-bacterial cross-kingdom synergistic relationships is crucial for instituting fungal-bacterial coinfecting etiology.

Acknowledgments

This study is funded by the European Developing Countries Clinical Trials Partnership (EDCTP) in collaboration with the European Union (grant TMA 2019CDF-2789). The authors also acknowledge the study collaborators from the Birmingham, Exeter, and Sheffield universities in United Kingdom; Infectious Diseases Institute in Makerere university as well as Gulu, Kabale, Soroti, Muni and Busitema universities in Uganda.

Data Availability

All the data sets generated during this study will be available from the corresponding author as governed by the data-sharing act of Mbarara University of Science and Technology. All generated data sets will be deposited in publically available repositories or published as study manuscripts.

Authors' Contributions

HI, ERB, MJC, RM, and JKM developed the study concept. HI, ERB, EN, MJC, and LA developed the study design. HI, ERB, IKN, BM, KK, JKM, JSI, PPN, JSK, FB, RK, AB, and BM provided input into the biological sample collection. HI drafted the paper, and all authors read and commented on the paper and agreed on the final version.

Conflicts of Interest

None declared.

Abstract

Background: Children's mental health is a public health priority, with 1 in 5 European children younger than 12 years having a behavioral, developmental, or psychological disorder. Mental health literacy (MHL) is a modifiable determinant of mental health, promoting psychological well-being and reducing mental health problems. Despite its significance, no interventions or scales currently exist for increasing and measuring MHL in this population.

Objective: This study has dual objectives: (1) cocreating and evaluating an intervention on children's MHL, and (2) developing and validating a scale that measures children's MHL.

Methods: Our study focuses on children aged 9-11 years attending primary school classes in various settings, including urban and rural areas, and priority education zones within a French department. Using a participatory research approach, we will conduct workshops involving children, parents, teachers, and 1 artist to cocreate an intervention comprising multiple tools (eg, a pedagogical kit and videos). This intervention will undergo initial evaluation in 4 classes through observations, interviews, and satisfaction

XSL•FO
RenderX

questionnaires to assess its viability. Concurrently, the artist will collaborate with children to create the initial version of the CHILD-MHL scale, which will then be administered to 300 children. Psychometric analyses will validate the scale. Subsequently, we will conduct a cluster randomized controlled trial involving a minimum of 20 classes, using the CHILD-MHL scale scores as the primary end point to evaluate the intervention's efficacy. Additional interviews will complement this mixed methods evaluation. Both the intervention and the scale are grounded in the Child-Focused MHL model.

Results: The first tool of the intervention is the pedagogical kit Le Jardin du Dedans, supported by the public organization Psycom Santé Mentale Info and endorsed by UNICEF (United Nations Children's Fund) France. The second tool is a handbook by the Pan American Health Organization and the World Health Organization, which is addressed to teachers to sensitize them to children's mental health problems. The third is a 5-page supplementary leaflet produced by the nongovernmental organization The Ink Link, which teaches children the notion of MHL. Finally, we produced 56 items of the MHL Scale and listed existing education policies for children's mental health.

Conclusions: After its robust evaluation, the intervention could be extended to several schools in France. The scale will be the first in the world to measure children's MHL. It will be used not only to evaluate interventions but also to provide data for decision makers to include MHL in all educational policies. Both the intervention and the scale could be translated into other languages.

Introduction

Children's Mental Health

Children's mental health is a public health priority [1]. Promoting their mental health means strengthening their capacity to learn and build meaningful relationships. Good mental health during childhood strongly contributes to positive outcomes in adulthood [2]. It is during this period of life that we learn to reinforce protective factors, as well as internal and external resources. A good home environment, convenient conditions at school, a healthy lifestyle, child protection policies, and adequate mental health services promote children's mental health [3]. Without mental health, there can be no physical health [4]. Nevertheless, children's mental health has been largely ignored, including by public policies [5].

Only recently, in the aftermath of the COVID-19 pandemic, children's mental health has been put under the spotlight. Repeated lockdowns, movement restrictions, and school closures have had an undeniable negative impact on children's mental health status. Statistics report that levels of anxiety and depression in preadolescents increased by 57.4% and 39.3%, respectively [6]. However, the pandemic has been the tip of the iceberg when it comes to poor mental health outcomes in children who represent an undoubtedly vulnerable population.

Previous studies report alarming statistics: in Europe, 1 child out of 5 is affected by a mental health problem before the age of 12 years [7]. While the prevalence of mental disorders is unstable across national and international studies, all statistics confirm that children are especially suffering from, in order of frequency, anxiety, attention-deficit/hyperactivity disorder, depression, learning disability, and autism [8]. Their onset can be detected between ages 3 and 11 years [9]. These problems have irreversible consequences on adulthood if they are not treated early, even leading to premature death [10]. In fact, 50% of adult mental illnesses have their origins in childhood [11].

Paradoxically, previous studies report that mental health problems in children are often underdiagnosed and untreated. Their signs and symptoms can be difficult to detect, thus delaying appropriate access to care.

When talking about children's mental health, it is important not to reduce it to problems or illness, but to help children adopt and maintain healthy lifestyles and provide supportive living conditions and environments. Accordingly, to increase children's psychological well-being, mental health promotion strategies have been encouraged worldwide [12,13]. The objective was to improve resilience and develop psychosocial skills so that children could learn to overcome adversity and enhance positive mental health through the encouragement and increase of protective factors and healthy behaviors.

The Population Under Study

Among different childhood stages, mid-late childhood or preadolescence (9-11 years old) deserves attention as it is a vulnerable transition period during which children have many developmental tasks to accomplish and difficulty in achieving them [14]. The age between 9 and 11 years corresponds to the last 2 years of primary school across the world according to the UNICEF (United Nations Children's Fund) definition [15]. Children at this age are cognitively, emotionally, behaviorally, and socially developing: they build their self-esteem, their mood changes, and they acquire skills in communicating personal experiences and feelings [16]. They have a level of cognitive maturity that enables mental health representations and stigma to develop [17], and they are particularly prone to receive accurate mental health information [18]. At this age, children are a perfect target population for early interventions to modify the trajectory of many mental health issues, prevent progression to more chronic conditions, and promote resilience. Learning proactive coping skills can guide them in the transition into adolescence and middle school, laying the foundation for lifelong positive mental health. Although the incidence of mental illness is high in this age span [19], only a few programs on

mental health have been implemented in primary schools [20]. Nonetheless, on an international level, several reports from the World Health Organization (WHO), the Centers for Disease Control and Prevention, and the National Institutes of Health, among others, have advocated for the development and implementation of multisectoral, evidence-informed, and human rights–based interventions for the promotion of mental health and prevention of mental health problems worldwide [21].

Mental Health Literacy: Definition, Scales, and Interventions

Overview

In the field of mental health promotion and prevention, mental health literacy (MHL) is a growing multidisciplinary (psychology, communication sciences, education sciences) theory [22]. It was first conceptualized by Jorm [23] as "knowledge relating to the recognition of a mental health disorder, help-seeking, accessing mental health information, causes and risk factors, professional help and treatments available, self-help strategies, and general attitudes about mental illness." Kutcher et al [24] have later added to this definition the notion of promoting well-being and developing coping skills. According to MHL, knowledge, information, and understanding are the simplest, quickest, and best ways to overcome mental health problems and enhance positive mental health. Mental health literate people can detect personal and others' signs of psychological disorders, thus prompting timely help-seeking and access to care. MHL contributes to destigmatizing mental health problems and sensitizing them without any preconceived opinions. Thus, the higher the MHL level, the lower the prevalence of mental health problems [25]. In this sense, MHL is considered a modifiable determinant of mental health [23] because its improvement can contribute to the individual's empowerment and intervene in mental health behavior change [26].

MHL is defined as "multiconstruct" and "evolving," meaning that it continuously adjusts depending on the population under study and the context [22]. In this line, in 2020, an Australian team developed an MHL conceptual framework adapted to children below 12 years of age: the Child-Focused MHL model [27]. According to this model, children's MHL includes 6 dimensions: (1) understanding of mental health and recognition of its fluctuations; (2) help-seeking actions; (3) supports available; (4) influences on mental health; (5) coping and resilience; and (6) stigma.

According to this model, children with good MHL can identify early the signs of distress [28], avoiding late recognition of a mental health problem. MHL encourages help-seeking or the ability to help others promptly. Children can identify the roles of teachers, school nurses and psychologists, pediatricians, and psychiatrists in helping them in case of need. On the one hand, the child learns about risk factors such as difficulties at school, with friends, with the family, or with bullying [29]. On the other, they recognize protective factors such as individual, family, and social resources (optimism and parental support) [30]. Children learn to remain calm, to face their difficulties, and to sympathize with others. Finally, MHL also reduces stigma: mental health problems are common and a child does not have to be ashamed or shame another child.

In its report "The State of the World's Children 2021 – On My Mind" [31], UNICEF invites all of us to raise MHL to challenge stigma, break the silence about mental health, and ensure the voices of children in distress are heard. According to the Organization for Economic Co-operation and Development (OECD), "good prevention and promotion policies should ensure MHL across populations" [32]. There is thus an urgent need to promote MHL in children before the age of 12 years.

MHL Scales

Validated scales are essential for providing precise and reliable data concerning the evaluation of interventions. They have 3 objectives: (1) providing baseline information to monitor health behaviors; (2) providing information for planning and developing an intervention; and (3) raising awareness and improving the agenda for health promotion [33].

Only a few scales are measuring MHL. The very first MHL instrument comprised brief vignettes about people with depression, schizophrenia, attention-deficit/hyperactivity disorder, and anxiety disorder [34]. Individuals were asked to identify the disorder and answer questions about symptoms and treatment. Other measurement tools were quizzes with true/false answers [35]. The Mental Health Literacy Scale (MHLS) [36] is currently the most known tool to measure MHL in the general adult population and includes several close-ended questions and Likert scales.

Concerning young people, there exist only a few scales for adolescents/high school students [37], ranging from telephone interviews [38] to open-ended responses or vignettes [39]. They mostly cover only 1 of the 6 dimensions of MHL [40,41]. There is also no scale for children younger than 12 years, apart from a scale on stigmatization [42] and another scale addressed only to children having a parent with mental illness [43]. Thus, a scale covering all 6 MHL dimensions addressed to primary school children (ages 9-11 years) does not exist so far. Only an attempt has been made by Bale et al [27], but the work has not been finished.

MHL Interventions for Young People

To date, most MHL programs have targeted adolescents (12-18 years old), while little attention has been paid to improving MHL among primary school children younger than 12 years. A systematic review synthesized data from 27 articles on MHL interventions in teenagers and young adults [44]. Formats were classroom lectures or presentations, video-watching group discussions, posters, role-playing, drama, internet searching, serious games [45], educational lectures [46], art courses [47], mental health first aid training [48], etc. Concerning the evaluation of their effectiveness, the quality of the evidence was low due to the lack of validated measures and the absence of a robust study design and methodologies (eg, randomized controlled trial [RCT] or mixed methods). Furthermore, there was no collection of data on their acceptability and children's satisfaction. Identified interventions were only 1 of the dimensions of MHL among either knowledge acquisition or stigmatizing attitudes toward mental illness or help-seeking

XSL•FO
RenderX

behaviors. Another systematic review [49] collected information on 20 middle school–based MHL interventions including storytelling and discussions/lectures in class. Once again, evidence of their effectiveness was moderate. Globally, there does not exist any school-based MHL intervention addressed to children aged 9-11 years whose effectiveness has been demonstrated under rigorous scientific conditions.

Building an Effective Intervention

Several studies [50-52] have shown that school-based interventions have positive effects on children's well-being. These interventions are inclusive because they are addressed to all pupils without distinction (socioeconomic background or presence of a mental health problem) considering that the large majority of children spend a large amount of their time at school [45,49]. Thus, interventions conducted in this setting can palliate the social gradient enabling children to appraise the concept of mental health and seek help without disparities through an educational approach [53]. In general, the whole-school approach [54] has proved to be effective, as reported by the WHO [55,56]: teachers, school psychologists and nurses, school principals, parents, and children themselves are all involved in promoting organizational MHL [57]. The role of teachers is pivotal. They are the key actors in any school-based intervention. Their implication is essential to the implementation of these interventions.

The effectiveness of interventions is enhanced also by cocreation following the principles of participatory research. The WHO states that collaboration must be initiated from the beginning of the development of interventions as this can contribute to a wider acceptability from the target population and feasibility of the intervention under real-world conditions [58]. To ensure that the intervention is appropriate for the target audience, end users are included in the intervention design and development process. Any other actor in the life of the child is also called upon: for example, teachers, parents, or school psychologists [59].

Theory-based interventions target change in modifiable mechanisms to maximize their effect [60]. Theory-driven approaches can increase our understanding of how a health-related action contributes to an outcome and provide guidelines for producing a successful intervention [61]. The Child-Focused MHL model by Bale et al [27] will be used as the theoretical construct of this project. It explains how knowledge and information build the representations and behaviors of children as far as mental health is concerned. It refers to the mechanisms of actions and beliefs of children for their well-being and those of their entourage. MHL is based on both individual and population-based determinants (eg, socioeconomic status, place of residence, history of a mental health problem) within a specific context explaining the accomplishment of an MHL intervention.

Finally, using several tools (images, videos, or audio) and teaching techniques (transmissive, interactive, experimental, or playful) helps reinforce the transmission of a message, following a communication mix approach [62].

Objectives, Hypotheses, and Scope

The principal objective of the CHILD-MHL project is 2-fold. It aims to (1) implement an intervention and evaluate its effectiveness concerning children's MHL and (2) develop and validate a scale measuring children's MHL.

The CHILD-MHL intervention and the CHILD-MHL scale are the core outputs of the project. They are built in parallel, and they are strongly associated with one another. The effectiveness of the intervention cannot be tested without a scale whose responsiveness can be proved only by an intervention.

The specific objectives are to (1) enhance the effectiveness of the CHILD-MHL intervention using different features—cocreation and design thinking, whole-school approach, theory-based approach, and multitools; (2) outline the CHILD-MHL scale—defining and testing items, administering the scales to a large sample of children, and conducting psychometric analyses for the final validation; and (3) evaluate the effectiveness of the CHILD-MHL intervention using different techniques and methods—performing a viability evaluation, performing a cluster RCT (cRCT), and using mixed methods.

The first hypothesis is that a cocreated, whole-school, theory-based, and multitool intervention makes the intervention itself effective. The second hypothesis is that, to be robust, a scale should be developed through different steps, from an inventory of items (the largest number as possible), their test among the target audience, and the administration in a large sample. The third hypothesis is that strong evidence of the effectiveness of an intervention is provided by the combination of several types of study and the collection of as much data as possible (quantitative and qualitative).

Methods

Setting and Participants

This study will be conducted in the department of 1 of the French academies. These are state services that relay, at the local level, the decisions taken by the central administration, the Ministry of National Education and Youth. Each academy is placed under the authority of a rector, appointed by the President of the Republic. For this study, the academy will be selected voluntarily. Each department includes public and private primary schools, in urban, peri-urban, and rural areas. Within each area exist priority education zones (REP) and high-priority education zones (REP+). These schools are considered in need of reinforced pedagogical policies and activities as they face more socioeconomic challenges.

Academies will give access to schools voluntarily (approval by school principals), but we will monitor the inclusion of schools from different geographical and socioeconomic areas and private versus public. We also aim to include localized units for inclusive education. The quota sampling method will be used to ensure the representability of all aforementioned types of schools. All children from recruited classes will participate in the study without any exclusion criteria. Only children whose legal guardians have not given their consent will be excluded. We are targeting children aged 9-11 years.

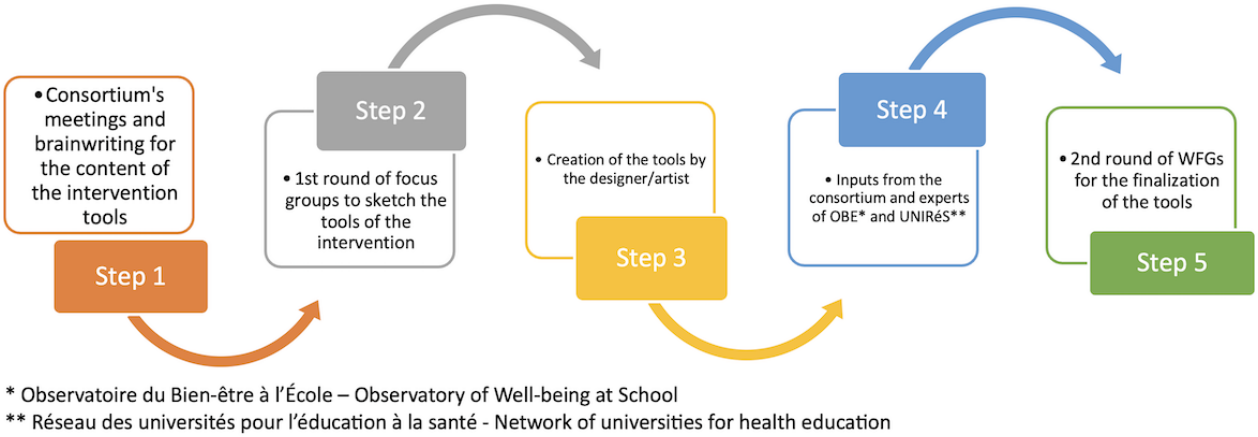
Creation: Developing the Intervention and Setting Up the Scale

Cocreation of the Intervention

The intervention will be cocreated by different stakeholders: (1) the consortium of the project covering different disciplines (developmental psychology, clinical psychology, educational sciences, child psychiatry, health communication, statistics, public health, and human and social sciences); children; parents; teachers; and 1 designer/artist. Previous reviews on the mechanisms facilitating the effectiveness of school-based interventions will be considered for the development of the intervention [63].



Ahead of the cocreation phase, a survey will be conducted to assess the relevance of an MHL intervention for teachers. An online form will be sent out to teachers from the selected academy. Teachers will then be asked to state whether this intervention is a priority for them and if they can include it in their work plan, among other questions. Some questions will also explore the characteristics that an MHL intervention should have to be easily implemented with positive outcomes.

The cocreation process will be developed in 5 steps as shown in Figure 1 and Textbox 1.

All working focus groups will last no more than 2 hours to help children focus and pay attention to the tasks.

The entire cocreation process uses the design thinking methodology, involving multiple iterations with all stakeholders until the final production of the tools.

Figure 1. The 5 steps of the co-creation of the CHILD-MHL intervention. MHL: mental health literacy; WFG: working focus group.

Textbox 1. Steps involved in the cocreation process.

Step 1

The consortium will define the contents of the intervention following the Child-Focused Mental Health Literacy model and covering its 6 dimensions. The consortium will meet online every 2 weeks for 2 months. Using the brainwriting technique (brainstorming through writing and commenting on a shared document), the consortium will produce a report with the key concepts to be transmitted to the target audience.

Step 2

During the initial 3 months, a first round of working focus groups (WFGs) will be conducted in 4 classes (priority education zones [REP] or high-priority education zones [REP+], NO-REP, urban, and rural) with a purposive sample of 2 children, 2 parents, 2 teachers, the principal investigator, and 1 designer/artist for each WFG. We plan to have a first round of 4 WFGs, with each corresponding to an end user of the intervention: children, teachers, parents, and school environment (represented by teachers or a school principal). The objective of this step is to transform the contents produced by the consortium into tools adapted to the target audiences. Participants for the WFGs will be recruited voluntarily, and they will draft the first version of the tools, sketching prototypes.

Step 3

The designer/artist that participated in the WFGs will collaborate with a colleague to produce mock-ups of the intervention tools based on fieldwork.

Step 4

The mock-ups of the tools will be shared with the consortium and other health promotion/education experts and researchers for their feedback.

Step 5

After integrating the inputs from the consortium, the tools will be finalized in the second round of the WFGs (3 months), which will take place over 3 months as outlined in step 2.

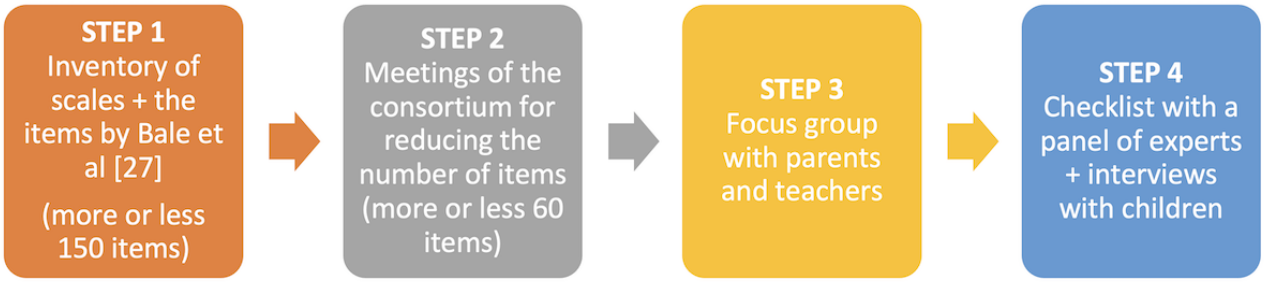
Preparation of the CHILD-MHL Scale

A total of 95 items have already been identified by the founders of the Child-Focused MHL model [27] through a rigorous Delphi study with more than 30 experts. The principal investigator and the research assistant will add items from other MHL scales for adolescents and adults [37,42,64] (inventory

XSL•FO
RenderX

of MHL scales) to have a comprehensive list of items necessary to use a reflective model in the definition of the MHL construct. All items will be translated into French and categorized according to the 6 dimensions of the Child-Focused MHL model. We expect a maximum of 150 items.

The consortium will convene online, exchange emails, and use shared documents to streamline the number of items to 60 (ie, 10 per dimension), which corresponds to the first draft of the scale. This number is planned with the objective of limiting the final scale to a maximum of 24-30 items for ease of administration, especially for children who may encounter difficulties due to factors such as limited attention span or the complexity of the tasks. Literature suggests that a preliminary scale must contain 2-3 times the number of items of the final scale and that there must be at least three or four items per dimension [65].



The items will be discussed with a group of 5 parents and 5 teachers to adapt them to children (language and contents). A group of 5 children, who will be recruited from a recreation center (*centre de loisirs*) in a randomly selected area, will then codraw with 1 designer/artist, as a craft activity, the items to obtain a more understandable digital visual scale during a 2-hour workshop. Finally, this scale will be administered to 25 or 30 children from a class randomly selected by a French academy. Each child will be interviewed to assess whether the items are understandable and clear.

In parallel, the same scale will be sent to around 30 experts (eg, psychologists, teachers, health promotion professionals, researchers, and statisticians) who will have to rate each item and complete a checklist measuring the practicality, acceptability, clarity, and appropriateness of the scale.

Qualitative data from children and quantitative data from the checklist will be discussed by the consortium to adapt the items and finalize the scale items. This phase corresponds to the content validity of a scale. This refers to "the degree to which the content of a measurement instrument is an adequate reflection of the construct to be measured" [66], which, in this case, refers to the Child-Focused MHL model.

Figure 2 illustrates the 4 steps for defining the items of the scale.

Figure 2. The steps of the content validity of the CHILD-MHL scale. MHL: mental health literacy.

Refinement: Viability Evaluation of the Intervention and Scale Validation

The Viability Evaluation of the Intervention

Conducting a viability evaluation refers to collecting stakeholders' views and experiences regarding whether the intervention is acceptable, practical, affordable, suitable, integrable, helpful, and sustainable in real-life conditions. For this purpose, a pilot test will be conducted in 4 randomly selected classes, representing various settings (1 REP, 1 rural, 1 urban, and 1 private), within the participating department, involving about 130 children. This number is defined by convenience in an attempt to consider social and territorial disparities.

The principal investigator and the research assistant will monitor how the intervention is carried out and identify the barriers and levers for its implementation. About 15 people among teachers, school psychologists, nurses, school directors, parents, and pupils (purposive sample) will be interviewed for feedback. In particular, the directors of the school will be interviewed to comment on the intervention, its advantages and disadvantages, and whether they think that it can be routinely conducted in their schools. Satisfaction questionnaires will be administered to all participants in the viability study. Data from observations, semistructured interviews, and questionnaires will be analyzed through the mixed methods design.

The intervention (contents, form, and language elements) will also be adapted considering the socioeconomic inequalities. For instance, some tools could be canceled or repeated. Teachers from REP areas will receive extra incentives (salary or learning credits) subject to authorization by the academy.

The viability evaluation conditions will mirror the real implementation of the intervention in the cRCT, with the objective of identifying and addressing potential difficulties and inaccuracies on a tool-by-tool basis.

At this stage, we will define and test the process of recruitment: how to inform schools and teachers (eg, through the academy with flyers, mailing, and videos) and how to obtain the consent of parents (eg, an explanation of the intervention through a detailed booklet, access to all tools for checking their contents). Parents will be informed through school mobile apps, contact book (carnet de liaison), and school meetings. All information will help assess the intervention's replicability. The viability evaluation will study whether and how teachers can conduct the program autonomously.

This pilot phase is also useful for the implementation of the cRCT because we will record all difficulties encountered while

XSL•FO
RenderX

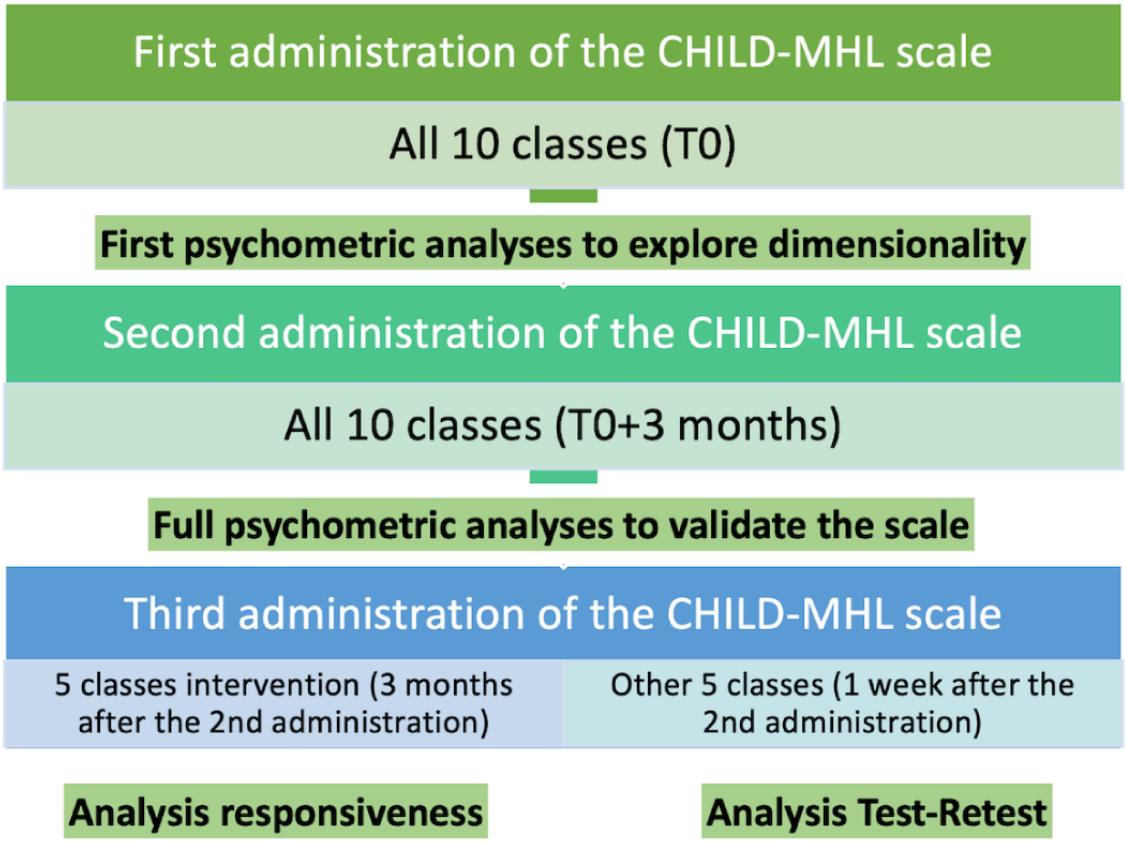
conducting the intervention (eg, access to schools and teachers' availability).

Analysis of Current Policies for Promoting Mental Health in Schools

To verify whether the effectiveness of the intervention is driven by a favorable political environment, we will identify and analyze policies and road maps promoting school-based mental health programs at the micro (department) and macro (France) levels. This mapping will involve approximately 5 semistructured interviews with rectors from various regions and departments, and ideally, some members of the Ministry of National Education and Youth's cabinet. All collected materials will be synthesized in a narrative review and used to write a policy brief aimed at explaining the need for including MHL interventions in schools in addition to existing mental health–related programs. If the CHILD-MHL intervention effectively increases children's MHL, we will investigate if this success is emphasized by the local political environment. This might reinforce the need for decision makers to include MHL in all educational policies.

Validation of the CHILD-MHL Scale

We will use a specific procedure called COSMIN (Consensus-Based Standards for the Selection of Health Measurement Instruments) [67] for scale validation. The questionnaire including the scale and other variables of interest will be initially administered to children from 10 classes from different schools (ie, around 250 children). Half of these classes are those of the viability evaluation. The sample size of 250 respondents is acceptable, considering feasibility and following the rule of thumb of 10 respondents per item [68]. Besides, feasibility must be considered for data collection. Data will be recorded on a tablet for each child consecutively, with supervision provided by the principal investigator and the research assistant. The research assistant will be the only person in possession of a document containing the child's name and the corresponding code, allowing for matching the questionnaire administrations. The data from the initial administration will be analyzed to assess the scale's dimensionality and whether the 60 items adequately cover the 6 dimensions of the Child-Focused MHL model. Exploratory and confirmatory factor analyses will be performed. At this stage, it will be possible for the consortium to add or remove items to cover the 6 dimensions.



After 3 months, the questionnaire with the scale, which might have been modified, will be readministered for the second time to all 250 children from the 10 classes during the week preceding the start of the viability evaluation intervention. This second data collection is essential if the scale has been modified and is highly recommended to refine the scale dimensions. Using this large data set, analyses will be performed to reduce the number of items by employing the Classical Test Theory and the Item Response Theory [69]. Exploratory and confirmatory factor analyses will be performed again to assess the dimensionality and structural validity of the scale. For the convergent and discriminant validity of the scale, the questionnaire will include other variables, including, sex, age, or emotional status measured by the KIDSCREEN-10 [70]. We will check for variations in the scores of scale dimensions among different groups.

Children from the 5 classes of the viability evaluation intervention will complete the questionnaire for the third time after a 3-month interval (ie, the maximum time of the intervention). Data collected from these classes will be used to assess the sensitivity to change or responsiveness of the scale. If the score changes after the intervention, it indicates that the scale can measure the effect of the intervention on children's MHL. In this case, the items are expected to be "actionable," meaning that interventions can influence them and lead to changes in the results.

Finally, children not receiving the intervention will answer the questionnaire for the third time after a month. Data will be used to assess the test-retest reliability, determining whether answers remain consistent between administrations and if the items are stable over time. Figure 3 illustrates the phases of the data collection and data analyses for scale validation.

XSL•FO
RenderX

Figure 3. The flow of data collection and analysis for the CHILD-MHL scale. MHL: mental health literacy.

Assessment: cRCT and Semistructured Interviews

Implementing the cRCT

We will conduct the cRCT in a minimum of 16 new classes, representing all typologies under the study, from different schools: 4 REP, 4 rural, 4 urban, and 4 private ones (quota sampling). Feasibility will be a major criterion for participant inclusion. Therefore, a minimum of 400 children will be involved in this small-scale cRCT, which is a substantial sample size, as the literature suggests a minimum of 300 participants is sufficient for a cRCT in children [71]. Furthermore, a limited number of participants will allow us to explore in depth the mechanisms influencing the effectiveness of the intervention by analyzing results for each class.

Classes will be randomly assigned to either the intervention group or the control group (on a waiting list without engaging in any activities). Randomization will involve creating matched pairs based on class types, such as pairing 1 urban school class with the intervention and 1 urban school class without the intervention. The CHILD-MHL scale will be administered 1 week before and 2 weeks after the intervention in all classes. We will collect covariates related to children and their environment, including sex, age, school characteristics (geographical and socioeconomic area, population density), parental background (at least one parent not being French, divorced/separated parents), family size (number of siblings), and self-perceived health and emotional status measured by the KIDSCREEN-10 [70]. If possible, with parental consent, teachers will be asked to report whether there is at least one child with a diagnosed mental health problem in the class and provide information on the parents' socioeconomic situation. Macro-level data will be also included in the analyses (eg, precariousness indexes). The data from the second administration may offer insights into the intervention's potential impact on children's well-being and help-seeking actions. Furthermore, participants who received the intervention will respond to closed-ended questions regarding their intention to help someone with a problem, seek help, and their ability to apply strategies for feeling better and recognizing signs of personal distress. The statistical analysis plan will encompass mixed linear models, multilevel models, descriptive statistics, and random effects, with an intention-to-treat primary analysis.

Conducting Semistructured Interviews and Analyzing Data Through Mixed Methods

This phase marks the conclusion of the project, during which we will gather and collate all data to demonstrate the effectiveness of the intervention in improving children's MHL. We will conduct semistructured interviews with a deliberate selection of 30 pupils and 10 parents from various schools participating in the cRCT. All teachers of involved classes will be also interviewed. These stakeholders will comment on the effects of the intervention on children's attitude toward mental health: self-perceived benefits of the intervention, what children have learned, and how they will reuse their new knowledge and competencies (from help-seeking to detection of a mental health problem). Interview texts will be coded and treated per theme.

XSL•FO
RenderX

Quantitative and qualitative data, collected separately, will be combined and analyzed using a convergent design [72]. When combining the data, we will also consider contextual factors, location, the study population, and other relevant elements that might influence the results. The mixed methods analysis will provide a comprehensive understanding of the intervention.

Ethics and Regulatory Affairs

Given that children constitute a vulnerable population with limited autonomy, we will implement stringent measures to safeguard their well-being. The CHILD-MHL scale itself should not raise any privacy concerns as it does not collect private or sensitive information. However, variables such as emotional status or self-perceived mental health may introduce potential delays in the procedures. Their inclusion in the questionnaire will be thoroughly justified, but if collecting these data proves challenging, we will rely exclusively on macro-level data (eg, school geographical area, class size) for analysis.

Quantitative data will be collected through a secure tablet-based self-administration software, while qualitative data will be gathered via recorded interviews and subsequently transcribed. We will conduct a Privacy Impact Assessment (PIA) and risk analysis. Additionally, a data management plan will be established to outline data handling procedures throughout and after the project, covering collection, storage, analysis, preservation, and sharing. All collected data will be anonymized.

Ethics Approval

Ethical approval for the study is going to be obtained from the People Protection Committee (Comité de Protection des Personnes), which is the French Ethical Review Authority. We will strictly adhere to the requirements of the Helsinki Declaration for research involving humans. As a systematic examination of ethical considerations is also needed in the survey study, additional ethical approval will be sought from external researchers. We will make sure that project staff are trained and supervised on ethical issues, with specific attention paid to collecting data from children. In case participants (children, parents, or teachers) have questions, the contact information of the responsible researchers will be provided. In the information letter, study participants will be informed about confidentiality and their right to withdraw from the study at any time. The letter will be adapted for young people. All data will be collected and stored in compliance with the requirements of the Ethical Review Authority and the GDPR (General Regulations for the Protection of Personal Data), as well as the French National Commission on Informatics and Liberty (Commission nationale de l'informatique et des libertés).

Results

After obtaining the ethical approval, data collection and analyses will be conducted from March 2024. The first paper is expected to be submitted at the beginning of 2025. Finally, the results from all parts of the study will be synthesized in 2026.

We started working on the project in 2022 to predefine some contents and tools. The first tool of the intervention is the pedagogical kit Le Jardin du Dedans, supported by the public organization Psycom Santé Mentale Info and endorsed by UNICEF France. The kit is composed of 12 storyboards introducing MHL to children through an animated story. Each storyboard corresponds to a drawing with specific text. Two manuals are given to educators (eg, teachers, parents) to animate the story and discuss its content with children through tips and key messages. The animation includes 3 sessions conducted in 2 weeks covering the 12 storyboards. Le Jardin du Dedans is based on a metaphor stating that mental health is like an inner garden that we need to take care of across all seasons, from joyful summer to dark winter.

The second tool is a handbook that is addressed to teachers to sensitize them to children's mental health problems. In 35 pages, teachers are taught the meaning of mental health, the importance of well-being in school, child development and related influences, and main emotional and behavioral disorders (from anxiety disorder to autism spectrum disorder). After reading it, teachers are expected to feel empowered and more confident in dealing with children with mental health problems. The handbook is produced by the Pan American Health Organization and the WHO.

In a 5-page leaflet produced by the nongovernmental organization The Ink Link, children become acquainted with the notion of MHL by discovering its 6 dimensions. Each dimension is illustrated by some examples (eg, the description of mental health professionals and risk and protective factors).

We have also compiled the initial list of items (n=56) for the scale. These 56 items were listed by 2 public health researchers, and revised by 11 experts in the field of child health, including child psychiatrists and developmental psychologists. These items will then undergo further review by a panel of at least 30 experts, including psychologists, educators, and public health researchers. Following this selection process, 1 artist will collaborate with children to illustrate the items. Subsequently, the scale will be administered to several hundred children to collect data for psychometric analyses.

Finally, we compiled a report listing the existing education policies for children's mental health in France.

Discussion

Anticipated Findings

We have started cocreating the intervention to increase children's MHL. The current partial intervention is composed of 3 tools: a pedagogical kit, a handbook, and a leaflet. In the cocreation process, experts provided the contents of each tool, and artists shaped/transformed them into visually appealing illustrations. These tools were tested with small groups of children and teachers to gather feedback; particularly, the pedagogical kit was animated in several classrooms, the handbook was proofread by teachers, and the leaflet underwent refinement in a classroom setting. The involvement of renewed institutions, namely, UNICEF France, the Pan American Health Organization/WHO, and the nongovernmental organization The Ink Link, ensures a solid foundation for this global intervention [73].

XSL•FO
RenderX

The inclusion of children, teachers, and parents from the outset of the cocreation process proved challenging due to their availability and time constraints, which often conflicted with project funders' requirements and local service expectations, such as school complexes. These challenges align with findings in the literature [74,75], with logistics and timeline management being the most commonly cited difficulties. However, our study is among the few to employ cocreation with children on a sensitive topic such as mental health, allowing them to play an active role in designing and producing a health-related intervention [76]. Moving forward, our goal is to involve all stakeholders in the cocreation process from the project's inception.

Few multitool interventions, especially those involving the target audience and the child's environment, including teachers and parents currently exist [55,77]. Accordingly, we have adhered to a whole-school approach to enhance the tool's effectiveness. Additionally, it is worth noting that the theory of MHL remains unaddressed in existing interventions.

Usually, only 1 type of support is used (eg, videos or courses). The novelty and uniqueness of our intervention lie in the integration of several tools, potentially enhancing its acceptability and effectiveness [78].

Once all the tools are produced, they will be pieced together and evaluated. Data from viability assessment, cRCT, and interviews will be combined through a mixed methods approach to produce the most accurate evidence [79]. Initial testing of the first tools has shown promising results, particularly with positive feedback from children regarding the pedagogical kit. Furthermore, we have initiated contact with schools to collect data, and the project is gaining recognition within the French academies.

Simultaneously, we have begun developing the scale. Following a rigorous approach, we plan to create an initial version of the scale that aligns with the dimensions of the Child-Focused MHL model. According to the guidelines for scale development [80], the first essential step involves defining a substantial number of items that capture the concept being measured. To ensure content validity (ie, the adequacy with which a measure assesses the domain of interest [81]), we have engaged one of the founders of the Child-Focused MHL model in the item inventory process.

In the end, conducting an inventory of policies in the French academies related to educational programs for children's mental health is crucial to gauge the acceptability of our intervention. We will assess whether the intervention is more effective in schools with existing mental health programs and a general sensitivity to this topic [82]. Thus, we have initiated a viability evaluation to provide initial evidence on the factors, such as policies, influencing the adoption of the intervention in real-life conditions.

Limitations

The project is complex, with dual objectives requiring extra effort. Significant human resources are required, particularly for the intervention, which involves recruiting a large number of children. These challenges must be carefully addressed during project planning. However, ambitious studies become feasible with the support of multiple funders (3 are involved in this project, contributing a total of over US $300) and collaboration among researchers from diverse disciplines.

Concerning the cocreation process, the number of participants is small, which might hinder generalizability. However, we hypothesize that the characteristics of the stakeholders involved in our study are representative of children, teachers, and parents in the selected department in France. Therefore, adapting the approach for use in other departments and translating it for other countries will be necessary.

In terms of evaluation, the design we will implement is arduous. While producing robust results, it will be difficult to put into practice. It will require strong logistic capacities and numerous staff members for the cRCT. The multiple semistructured interviews will be time-consuming. Similarly, the statistical analysis of both the evaluation and the scale will require the expertise of 1 or more statisticians for several months.

Conclusions

Currently, only a few interventions are designed to enhance children's MHL. Therefore, this project will offer unique insights and practical applications in the field. While the intervention has the potential to reach children in French-speaking countries, its effectiveness must first be demonstrated through rigorous experimental and real-world testing. The project's findings will inform decisions regarding the extent of implementation efforts. Additionally, this project will pioneer the creation of the world's first children's MHLS. Once validated in French, it will be translated into other languages, with English and Spanish taking priority, enabling the measurement of children's MHL at an international level.

Acknowledgments

The project is supported by the French Institut pour la Recherche en Santé Publique (IReSP), Santé publique France, and the AUF CO//ectif (DREO-7450). The authors acknowledge and thank Alexandra Philiatreau for helping with the development of the scale. We are also indebted to Zeinab El Hajj for working on the identification of the policies. We wish to thank all those who advised on the project.

Data Availability

The pedagogical kit Le Jardin du Dedans by Psycom Santé Mentale Info, with the support of UNICEF France, is freely available online [83]. The handbook by the Pan American Health Organization and the World Health Organization is also freely available

XSL•FO
RenderX

online [84]. The scale items and the list of policies are available upon request. The other tools of the intervention are under construction and will be freely available in the months to come.

Authors' Contributions

FF-O wrote the protocol and the first version of the manuscript, as well as defined the methodologies. CL, CG, AM, R Shankland, R Salamon, EP, LG, and MO wrote the protocol and edited the manuscript. CG and EG edited the manuscript. JLG-C wrote the protocol, performed the methodologies listed, and edited the manuscript. IM conceptualized the project, performed the methodologies listed, reviewed and edited the manuscript, and supervised the work.

Abstract

Background: Increasing harms related to prescription opioids over the past decade have led to the introduction of a range of key national and state policy initiatives across Australia. These include introducing a mandatory real-time prescription drug–monitoring program in the state of Victoria from April 2020 and a series of changes to subsidies for opioids on the Pharmaceutical Benefit Scheme from June 2020. Together, these changes aim to influence opioid supply and reduce harms related to prescription opioids, yet few studies have specifically explored how these policies have influenced opioid prescribing and related harms in Australia.

Objective: The aim of this study is to examine the impact of a range of opioid-related policies on hospital admissions and emergency department (ED) presentations in Victoria, Australia. In particular, the study aims to understand the effect of various opioid policies and opioid-prescribing changes on (1) the number and rates of ED presentations and hospital admissions attributed to substance use (ie, opioid and nonopioid related) or mental ill-health (eg, suicide, self-harm, anxiety, and depression), (2) the association between differing opioid dose trajectories and the likelihood of ED presentations and hospital admissions related to substance use and mental ill-health, and (3) whether changes in an individual's opioid prescribing change the risk related to ED presentations and hospital admissions related to substance use and mental ill-health.

Methods: We will conduct a population-level linked data study. General practice health records obtained from the Population Level Analysis and Reporting platform are linked with person-level data from 3 large hospital networks in Victoria, Australia. Interrupted time series analysis will be used to examine the impact of opioid policies on a range of harms, including the rates of presentations related to substance use (opioid and nonopioid) and mental ill-health among the primary care cohort. Group-based trajectory modeling and a case-crossover design will be used to further explore the impact of changes in opioid dosage and other covariates on opioid and nonopioid poisonings and mental ill-health–related presentations at the patient level.

Results: Given that this paper serves as a protocol, there are currently no results available. The deidentified primary health data were sourced from electronic medical records of approximately 4,717,000 patients from 542 consenting general practices over a 6-year period (2017-2022). The submission of results for publication is planned for early 2024.

Conclusions: This study will add to the limited evidence base to help understand the impact of opioid policies in Australia, including whether intended or unintended outcomes are occurring as a result.

KEYWORDS

data linkage; drug policy; general practice; opioid; primary care

Introduction

Over the past decade, Australia has witnessed an almost 2-fold increase in opioid-related deaths [1], which led to the introduction of a range of national and state policy changes [2-4]. On April 1, 2020, a mandatory real-time prescription drug–monitoring program (PDMP) was introduced in the state of Victoria [5], which was followed by other Australian jurisdictions also implementing voluntary and mandatory PDMPs [6]. In June 2020, a series of changes to subsidies for opioids on the pharmaceutical benefits scheme were also implemented, including reduced pack sizes, limits on long-term use of opioids for chronic pain, and more restricted indications for opioids [7]. Together, these changes aim to influence opioid supply and reduce harms related to prescription opioids, yet few studies have specifically explored the outcomes of these policy changes in Australia.

In the United States, supply-side policies, including the implementation of PDMPs, were identified as a key precipitating factor for the current opioid crisis, including driving harms related to illicit drug use [8]. In Australia, most opioids are prescribed in primary care settings, and most opioid mortality is still attributed to prescription opioid use [9-11]. Yet, we have little understanding of how similar supply-side interventions are influencing opioid prescribing in primary care and whether changes in prescribing lead to their intended outcome of reducing harms. This is particularly important to study among subgroups of people who are prescribed opioids, such as patients receiving high doses or high-risk medication combinations, who are often the intended target of these policy changes.

Opioid deprescribing has been identified as a key clinical strategy for reducing opioid-related adverse effects and improving quality of life [12-14]. However, policies that have aimed to reduce opioid prescribing have had mixed outcomes elsewhere, including a range of unintended adverse consequences [15,16]. For example, in the United States, hydrocodone rescheduling led to an increase in total opioid prescribing [17], while PDMP implementation led to an increase in heroin-related mortality [15]. Other adverse unintended consequences that have been reported in patients prescribed opioids following opioid restrictions include increases in withdrawal symptoms (eg, uncontrolled pain and psychological distress), uncontrolled pain, psychological distress, illicit opioid use, and suicide attempts [18-20].

Emergency department (ED) presentations and hospital admissions are considered crucial indicators when evaluating outcomes of policies targeting opioid prescribing due to their ability to capture acute incidents (eg, overdose poisonings or opioid-related injuries or accidents), assess the severity of complications, and provide valuable population-level insights [21,22]. Hospitalizations and ED presentations were common outcomes examined in US studies of PDMP implementation [23-25]. Yet, to date, few studies outside the United States have examined similar outcomes following the introduction of opioid-related policies. Given the adverse outcomes reported following the introduction of opioid-prescribing interventions elsewhere, this study seeks to examine the impact of introducing a range of opioid-related policies on hospital admissions and ED presentations in Victoria, Australia. In particular, the study aims to understand the effect of various opioid policy and opioid-prescribing changes on the following:

- The number and rates of ED presentations and hospital admissions attributed to substance use (ie, opioid and nonopioid related) or mental ill-health (eg, suicide, self-harm, anxiety, and depression).
- The association between differing opioid dose trajectories and the likelihood of ED presentations and hospital admissions related to substance use and mental ill-health.
- Whether changes in an individual's opioid prescribing change the risk related to ED presentations and hospital admissions related to substance use and mental ill-health, after considering other confounding factors, using a case-control design.

Methods

Study Design and Setting

This is a retrospective data linkage study using data from Victoria, Australia. Patient-level data from primary health networks (PHNs), extracted from the Population Level Analysis and Reporting (POLAR) platform provided by Outcome Health, and admission and ED data sets from 3 metropolitan hospital networks will be linked. These data were chosen because they provide patient-level demographic, diagnosis, medication, and hospital attendance information, and they can be accessed in a timely manner to address the research questions.

The state of Victoria is the second-most populous state in Australia, with 26% of the nation's population residing there. The current POLAR database covers approximately 30% of general practices across southeastern Victoria [26]. A total of 3 hospital networks in Victoria (Monash Health, Eastern Health, and Peninsula Health) that align with the Eastern and Southeast PHN catchments were chosen to examine opioid harms due to the high number of POLAR-participating practices in these 3 health regions. These hospital networks are located in the greater Melbourne metropolitan area and have catchments of nearly 2.6 million people, covering 40% of Victoria's population, with their EDs managing around 500,000 presentations per year. The areas represented by these data are geographically, demographically, and socioeconomically diverse [27].

XSL•FO
RenderX

Population

The study population will include people 18 years or older who had at least 1 attendance at general practice sites participating in POLAR data provision during the study period (2017-2022).

Medications of Interest

We will include all opioids prescribed for pain (ie, codeine, dextropropoxyphene, fentanyl, hydromorphone, morphine, oxycodone, pethidine, tapentadol, tramadol, buprenorphine [transdermal products only], and methadone [tablet formulations only]). Formulations that are only used as cough suppressants (eg, dihydrocodeine) or for opioid replacement therapy (eg, high-dose sublingual buprenorphine-naloxone and methadone liquid) will be excluded (Table S1 in Multimedia Appendix 1). The use of nonopioid medicines (eg, gabapentinoids and benzodiazepines) will be considered as covariates.

Outcomes of Interest

The main outcomes of interest are ED presentations and hospital admissions attributed to substance use (both opioid and nonopioid) or mental ill-health (eg, suicide, self-harm, anxiety, and depression). We focus on these outcomes as opioid- and nonopioid-related substance use, mental health crises, and suicide have all been demonstrated to be key outcomes related to changes in opioid prescribing [18-20].

Primary and secondary diagnoses related to ED presentations and hospital attendance are coded according to the International Statistical Classification of Diseases and Related Health Problems, Tenth Revision, Australian Modification (ICD-10-AM). Opioid-related presentations will be identified where the primary or additional diagnoses include (1) F11.0-F11.9 (opioid-related disorders) and (2) T40.0-T40.4, T40.6 (poisoning by, adverse effects of, and underdosing of narcotics and psychodysleptics).

Non–opioid-related substance use will include substances such as alcohol, heroin, and cannabis. The ICD-10-AM codes F10, F12-F19 will be used to identify cases of unintentional poisoning. Cases of suicide attempts and self-harm that satisfy the following criteria will be included: (1) a principal diagnosis in the ICD-10-AM range S00-T75, T79 (injury, poisoning, and certain other consequences of external causes); (2) the first reported external cause code in the record in the ICD-10-AM range X60-X84, Y87.0 (external causes of morbidity); and (3) suicide-related behaviors (R45.81 [suicidal ideation]). A full list of ICD-10-AM diagnosis codes used to define mental ill-health–related hospital separations by the Australian Institute of Health and Welfare is provided in Table S2 in Multimedia Appendix 1.

Data Source, Data Variables, and Data Linkage

Population-Level Analysis and Reporting Data

Primary health data are collected from constituent general practice clinics in 3 participating Victorian PHN regions (Eastern Melbourne PHN, Gippsland PHN, and Southeastern Melbourne PHN) by the POLAR system. POLAR is a cloud-based clinical intelligence platform that extracts, processes, and organizes deidentified information from clinical information systems within participating practices. The subset of the deidentified primary health data was sourced from electronic medical records of approximately 4,717,000 patients from 542 consenting general practices over a 6-year period (2017-2022). A total of 4 sub–data sets from POLAR will be used for this study:

- Patient data set: It contains data relating to patients' demographic details such as age, gender, postcode, concession, and marital status.
- Prescription data set: It contains data on medications prescribed by the general practitioner (GP), including the date each prescription was written, generic ingredient name and brand prescribed, medication dose, strength and frequency, and Anatomical Therapeutic Chemical Classification.
- Diagnosis data set: It contains data on patients' diagnoses as extracted from the clinical information system, including diagnosis recorded dates and documented diagnoses that have been coded and validated by Outcome Health using SNOMED CT (Systematized Nomenclature of Medicine Clinical Terms).
- Activity data set: Details of patient activity at the primary care practices are coded in POLAR, including the type of consultation provided (eg, face-to-face, telehealth, and telephone) and the date the activity occurred.

Hospital Data

Monash Health, Eastern Health, and Peninsula Health will provide data on (1) hospital admissions and (2) ED presentations. Hospital admission data contain hospital admission records of admitted patients between 2017 and 2022, including dates of admission, separation date and mode (the process by which an episode of care for an admitted patient ceases), and diagnostic and procedure ICD-10-AM codes. ED data are provided separately with a single record for each presentation episode, including dates of presentation and departure, referral source, arrival mode, visit type, triage, and diagnosis.

Data Linkage

POLAR and hospital data will be linked at the patient level. A privacy-preserving method using a set of 3 statistical linkage keys (SHA-256 HASH keys) using personal identifying information contained in each of the data sets is used for data linkage. These linkage keys enable the identification of the same patients at different practices (removing patient duplication) without the need to export personal identifying data. The keys are developed through "ORCA," specialist linkage software developed and used by Outcome Health that can generate the same linkage keys in each of the hospital systems and the POLAR database.

The linkage keys are generated within the practice and hospital data environments based on available identifiable data fragments (eg, name, gender, date of birth, and Medicare number), and the ORCA tool ensures that identifiable information does not leave the clinical practice environment. Each linkage key is hashed and irreversible; that is, it cannot be used by the researcher to reidentify individuals or their data.

XSL•FO
RenderX

This linkage process follows a method described in detail elsewhere [28]. When the linkage is complete, the linkage keys allow the matching of records across both the hospital and POLAR data. The use of multiple keys and probabilistic matching maximizes linkage accuracy.

Deidentified data with linkage keys will be released by each of the organizations into Monash University's Secure eResearch Platform, a secure environment that provides a high-powered computing environment that ensures secure storage of linked data with remote access and a clear audit trail of access.

Covariates

Analyses will adjust for key covariates associated with opioid-related outcomes such as age, sex, physical and mental health comorbidity, and substance use (including alcohol and nicotine use; Textbox 1) [29-34].

Textbox 1. Covariates from the Population Level Analysis and Reporting database.

- **Sociodemographic**

Age, sex, Socioeconomic Indexes for Areas status for residence, and concessional status

- **Prescription medicine use**

All prescription medicine use and analysis of medication classes of interest including benzodiazepines, gabapentinoids, antidepressants, and antipsychotics

- **Physical health comorbidity**

Documented diagnoses

- **Mental health**

Treatment for mental disorders with medicines, mental health care plans, and documented diagnoses

- **Pain**

Relevant documented diagnoses

Mental Health

Individuals will be classified as having a mental health condition if there is evidence of a recorded diagnosis based on the lists of SNOMED (Systematized Nomenclature of Medicine) codes (Table S3 in Multimedia Appendix 1), a prescription for medication used in the treatment of mental health issues, or enrollment in mental health care plans. This integrated approach overcomes a common limitation where some individuals may receive treatment with medication for a mental health condition or a formal diagnosis but not both [35,36]. Mental health conditions will be further categorized into major groups, including anxiety, depressive disorder, psychotic disorder, and suicidal and distressed behaviors.

Pain

We will use established lists of SNOMED codes and relevant keywords from previous research (Table S4 in Multimedia Appendix 1) to identify patients diagnosed with pain conditions that are likely to be treated with opioid analgesics [37,38]. However, conditions that are not primarily treated with opioids despite having potentially painful symptoms (eg, epilepsy and seizures) will not be included in our analysis.

Comorbidity

A modified Cambridge Multimorbidity Score (CMS) will be used to categorize comorbidities using SNOMED codes in the POLAR data [39]. There have been a number of approaches to measuring comorbidity, with the modified CMS recently validated for use in primary care, offering an advantage over the Cambridge Comorbidity Index, which, while widely used, was developed, and valued for use in secondary hospital settings.

Other Prescribed Medicine Use

Other medications of interest that may be prescribed for pain management, including nonsteroidal anti-inflammatory drugs, benzodiazepines, gabapentinoids, and tricyclic antidepressants, will also be extracted.

Data Preparation and Quality Assessment

Before the analysis, data will be prepared, and a quality assessment undertaken. Preparation involves (1) archiving a copy of primary data on the secure environment in original format and creating a copy for use in further analysis; (2) converting data from the received format (often .csv or .xls format) to formats used in statistical packages such as STATA (StataCorp), R (R Foundation for Statistical Computing), and SPSS (IBM Corp); (3) checking naming conventions for indicators and fields to ensure that these are consistent with data dictionaries; and (4) developing a study data dictionary and creating metadata.

Data validity and quality assurance will be conducted on the linked database. This will involve examining the missingness of individual data fields, inconsistency between data sets, inaccurate and unreasonable data values (eg, prescription quantity >200), identification and removal of duplicate records, and merging multiple episodes that occur within a single presentation (eg, where a patient may move between wards within a hospital).

Data Exploration and Description

Data exploration and visualization will be undertaken to enable the research team to examine the properties of the data sets, such as dispersion or distribution of values, correlation between

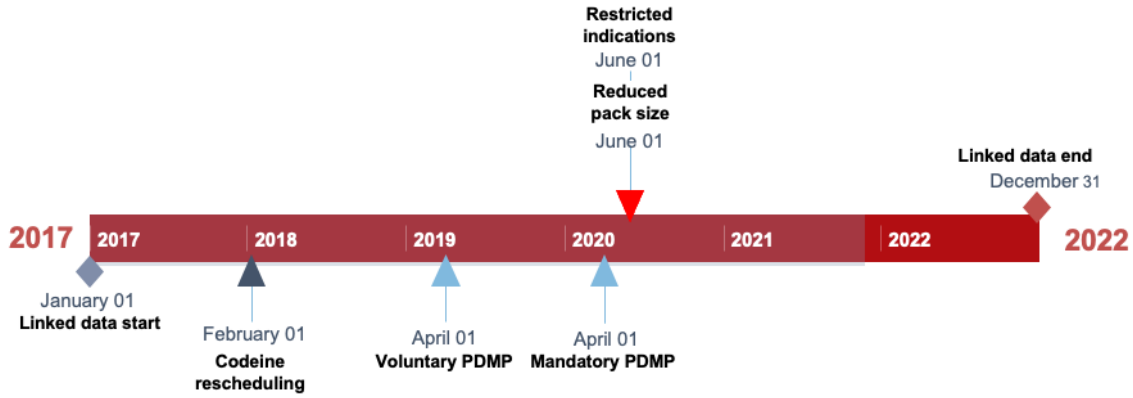
XSL•FO
RenderX

variables, and time trends. Descriptive statistics (counts, means, medians, etc) will be calculated based on demographic data, diagnosed conditions, and medication use. Preliminary methods for defining key variables will be developed. Next, we will check the internal consistency of the linked data. This will help quantify the success of data linkage across POLAR, hospital, and ED data. We will define and examine the consistency of a range of indicators, such as patients' age and gender.

Analysis Plan

Aim 1

The first aim was to examine the effect of opioid policies on the number and rates of ED presentations and hospital admissions attributed to substance use (ie, opioid and nonopioid related) and mental ill-health (eg, suicide, self-harm, anxiety, and depression).



Hypotheses

The 3 hypotheses were:

- Hypothesis 1: Reduced prescription opioid harm will follow each policy change.
- Hypothesis 2: Unintended outcomes in the form of non–opioid-related presentations and mental ill-health–related presentations will occur following policy changes restricting opioid access.
- Hypothesis 3: There will be disparities in policy impacts in different populations, with greater reductions in those prescribed opioids and no impact on harm among subpopulations who are not targets of the policy changes (eg, those with cancer pain).

The key policies of interest in this study will be national and state policies that aim to restrict opioid supply (Figure 1).

Figure 1. Key exposure of interest. Australian national and state policies relating to opioids. PDMP: prescription drug–monitoring program.

State-Level Policy

Victoria's PDMP "SafeScript" was implemented in April 2019, before use became mandatory for all community prescribers and pharmacists on April 1, 2020. It indicates potential risk to prescribers and dispensers at the time of medication supply by issuing amber and red-flag alerts, for example, with higher opioid doses (above 50 mg oral morphine equivalent) and high-risk drug combinations such as fentanyl and benzodiazepines [6].

National-Level Policy

On February 1, 2018, all codeine preparations became available only on prescription after lower-dose (up to 15 mg) codeine products were removed from "pharmacist only" (Schedule 3) sale. On June 1, 2020, changes were made to the listings of many opioids and multiple formulations listed on the Pharmaceutical Benefits Scheme (PBS) General Schedule. Changes included new listings for smaller pack sizes, increased restrictions on indications, and additional requirements for a second opinion to continue long-term opioid prescribing.

We will use an interrupted time series study design to understand the effects of these policy interventions. This method is widely used in public health research studies, particularly where randomization is neither feasible nor ethical [40]. Interrupted time series goes beyond a simple prepost design by considering the comparison of slopes generated across multiple time points and taking into account the underlying secular trends and random fluctuations. It allows researchers to examine the changes in the outcome variable and determine whether they are attributed to the intervention or other factors.

The primary outcomes of interest for this analysis are changes in ED and hospital admissions related to substance use (opioid and nonopioid) and mental ill-health. A total of 2 types of denominators will be used to estimate monthly rates: total patients' exposure to opioid prescription in the POLAR primary cohort before and after the policy changes and total patients who had GP consultations in the whole POLAR primary care cohort in the same month.

To evaluate the impact of codeine rescheduling on the same outcomes, the observation period will be 12 months before and 12 months after the policy change, with data points defined by calendar month. The same observation period will be applied to evaluate the impact of the mandated implementation of PDMP, and reduced pack size policies using data from 24 months before and after the intervention change. As these 2 policies were implemented within a 2-month period, we will consider a policy intervention window between April 1, 2020, and June 1, 2020, with outcome data during the intervention implementation period excluded.

Outcomes will be measured by comparing level changes and trends over time during the study period using segmented regression modeling. This method involves partitioning outcome

XSL•FO
RenderX

data into time intervals consistent with the times at which intervention interruptions occur and fitting a separate regression line segment to each time interval. Sensitivity analyses using different lags will be conducted to account for autocorrelation and determine the robustness of the primary results. If statistically significant, harmonic terms will be added to the models to account for seasonality. Additional segmented regression models will be used to examine the outcome among certain subpopulations such as patients with cancer diagnoses, those prescribed opioids, and those not prescribed opioids.

Aim 2

The second aim was to examine the association between differing opioid dose trajectories and the likelihood of ED presentations and hospital admissions related to substance use (opioid and nonopioid related) and mental ill-health (eg, suicide, self-harm, anxiety, and depression).

Hypothesis

Compared with patients with gradual dose discontinuation or a stable opioid dose, those with a rapid dose reduction or a gradual dose increase will have a higher risk for substance use and mental ill-health–related presentations.

This analysis will compare the trajectories of prescription opioid doses and the risk of ED presentations due to opioid-related and other adverse events. This analysis will be limited to patients receiving long-term opioid therapy, defined as those who were prescribed opioids regularly and continuously for 90 days or more [41,42]. Patients with a cancer diagnosis record in the POLAR data will be excluded from this analysis. The exposure of interest in this study is a distinct trajectory of opioid prescriptions among long-term opioid users. We will identify these trajectories by calculating the average daily oral morphine equivalent during the 6 months after the first eligible opioid prescription, when the persistence was identified (ie, 90 days of persistent opioid use and an additional 90 days). The index date is the first day following this 180-day period of long-term opioid therapy. Then, we will identify distinct opioid prescription patterns based on doses over time using group-based trajectory models. This model is a statistical method used to identify subgroups of individuals with similar patterns. The primary outcome is defined as the time to the first ED presentation, captured in the hospital data in the 6 months following the 6-month opioid prescription trajectory measurement period. The Cox proportional hazards models will be used to compare time-to-event, adjusting for covariates. These covariates included demographics (eg, age, gender, and socioeconomic status), characteristics of opioids prescribed, chronic pain diagnoses recorded (eg, musculoskeletal, neuropathic, migraine, and headache), polypharmacy (defined as having 5 or more different medications daily [43]), comorbidities (as measured by the modified CMS [39]), and ED presentations during the trajectory measurement period.

Aim 3

The third aim was to determine whether an individual's opioid-prescribing changes lead to ED presentations related to substance use (opioid and nonopioid related) and mental ill-health (eg, suicide, self-harm, anxiety, and depression), after considering other key covariates using a case-crossover design.

Hypothesis

Opioid dose tapering or abrupt discontinuation during the case period will be associated with an increased risk of opioid- and nonopioid-related harms and mental ill-health–related presentations.

This analysis will evaluate whether changes in opioid prescribing increase the risk of related outcomes through the application of a case-crossover design. The case-crossover design is an epidemiological design used for studying potential causes of sudden events and has previously been used for investigating the association between substance use and suicidal behavior [44]. It uses each case as its own control, thereby eliminating the time-invariant characteristics among individuals (eg, age, sex, and chronic substance use). In this study, adverse outcomes will be ED presentations across the 3 hospital data sets. The index date will be defined as the date of arrival. Each enrolled case for the case-crossover analysis will be restricted to patients who received opioids at least once during the hazard or control periods. The hazard period will be 60 days before the index date, and a single hazard period will be matched with 5 sets of 60-day control periods before and after without an ED attendance.

Comorbid mental health conditions will be the main confounding factors and will be assessed during the 12 months before the index date. Individuals will be identified as having a mental health condition using the aforementioned definition. It is common for individuals who die by suicide or attempt suicide to also have additional comorbidities related to mental health disorders. Therefore, referring to previous patient diagnoses, CMS will also be determined for the 12 months before the index date. Concurrent use of benzodiazepines and antidepressants, tricyclic antidepressants, and pregabalin will also be included as a confounding factor. Discordant pairs of these confounders between the hazard and control periods will be adjusted in the outcome models.

Odds ratios and 95% CIs will be determined by conditional logistic regression. We will evaluate the risk of substance use–related attendance for opioid dosage tapering and abrupt discontinuation, adjusting for confounding factors, and perform sensitivity analyses by varying the time window of the exposure period from 60 to 30 days to evaluate the robustness of the results. Additional sensitivity analyses will be performed by varying the number of controls from 5 sets of control periods (main analyses) to 2 or 3 sets of control periods to confirm whether the exposure trend affects the estimated odds ratio.

Management of Missing Data

To ensure comprehensive and accurate demographic information, a cross-check will be conducted to address missing data in both hospital records and the POLAR data set. When key demographic information is absent in hospital data, the gaps will be filled by leveraging the variable field from the POLAR data. Similarly, in instances where the POLAR data lack essential demographic details, an imputation process will be used based on the available hospital data. In cases where a

XSL•FO
RenderX

discrepancy in demographic information is identified between the hospital data and the POLAR data set, priority is given to the values recorded in the hospital records. The demographic details present in the hospital data are considered more reliable and representative of the specific patient population being studied. In addition, where key prescription-related information in the POLAR data is missing (eg, quantity prescribed or dose), these will be imputed based on standard pack sizes and the most common formulations used. Missing data for all variables will be checked and quantified. Multiple imputation methods will be considered where there are more than 5% missing data within variables.

Ethics Approval

The process of collection, transfer, and storage of general practice data on the POLAR platform was granted ethics approval in August 2017 (NREEC RACGP Protocol ID: 17-008). Consent for the use of deidentified patient data for research extracted and processed on the POLAR platform occurs as follows: practices that contribute data to the POLAR system enter into an agreement with their local PHN. The agreement articulates the responsibility of practices to inform their patients that data are being collected and of their potential use for research. As an additional layer of assurance, practices contributing data to the POLAR platform adhere to the RACGP Accreditation Standards, which stipulate requirements for responsible management of health data. Patients are informed at the point of collection and are presented with the opportunity to opt out. POLAR data are deidentified at the point of collection, according to Outcome Health's Data Deidentification Decision-Making Guide, developed with guidance from the Office of the Australian Information Commissioner. Hospital data are proposed to be used without the consent of individuals. A multisite ethics application was approved by Monash Health as the lead Human Research Ethics Committee (ID 76744), with site-specific applications approved by Monash Health (RES-22-0000-026A), Peninsula Health (SSA/76744/PH-2022), and Eastern Health (S22-032-76744). A waiver of consent was granted by the respective Human Research Ethics Committees for linkages between the POLAR data and hospital data. Privacy-preserving encrypted linkage software was used to link the data, and deidentified content data were submitted into a secure e-research environment by each of the data custodians for analysis by the research team. Ethics approval has been obtained from the Monash University Human Research Ethics Committee (ID 76744), Monash Health (RES-22-0000-026A), Peninsula Health (SSA/76744/PH-2022), and Eastern Health (S22-032-76744).

Results

Data linkage commenced in January 2023 and was completed in August 2023. Data analysis has not yet commenced. Submission of results for publication is planned for early 2024.

Discussion

Overview

Policies restricting access to medications such as opioids are commonly implemented, with limited evidence of their effect on reducing opioid-related or other harms. This study will add to the limited evidence base to help understand the impact of these policies in Australia, including whether intended or unintended outcomes are occurring as a result. By closely monitoring and analyzing ED presentations and hospital admissions as markers, policy makers can assess the impact of interventions, identify areas for improvement, and drive evidence-based policy changes that effectively address the complex challenges associated with opioid use and promote healthier communities.

Strengths

This study will link primary care and hospital data to investigate opioid exposure and adverse outcomes. POLAR data contain rich patient-level data, including diagnoses and comorbidities, that are often missing from existing administrative data such as Medicare Benefits Schedule and PBS data in Australia. The linked data set will also capture both publicly subsidized and nonsubsidized prescriptions, making it distinct from the more commonly used PBS (government subsidy) database. Moreover, the linkage key is consistent throughout POLAR participating practices, which will allow for a more comprehensive capture of covariates, particularly coprescribing and hospital readmission.

Limitations

There are several limitations to note. First, the use of prescribing data does not enable confirmation that prescribed medicines were dispensed or taken by the patient. Second, as both primary care and hospital data are drawn from 3 specific geographical areas, there is potential for selection bias. This concern is lessened by the inclusion of 3 PHNs whose average opioid-prescribing patterns are consistent with national opioid-prescribing patterns [45]. Further, there is established geographic and sociodemographic diversity across these health areas that limits concerns about generalizability [46]. Third, patients who visited non-POLAR GP practices and were admitted to hospitals other than the selected ones are not captured in this study; however, it is noted that the 3 large hospital networks serve the majority of the population in each of the catchment areas. Fourth, a list of ICD-10 codes will be used to identify study outcomes. However, there are limits to the completeness of the coding. For instance, suicide in EDs is commonly recorded using a single diagnostic code [47], and opioid-poisoning presentations can be coded under the more generic code T50: "Poisoning by diuretics and other and unspecified drugs, medicaments and biological substances" [48]. Therefore, our opioid-related poisoning and suicide and self-harm estimates are likely to be an underestimate of the true prevalence. In addition, deaths that occur before reaching the hospital and harm that occur outside the hospital setting (eg, ambulance attendances) would not be captured unless the patient was later transferred to a hospital.

Acknowledgments

The data supplied for this study were sourced from contributing general practices by Outcome Health (through the Population Level Analysis and Reporting platform) on behalf of Eastern Melbourne primary health network (PHN), Gippsland PHN, and Southeastern Melbourne PHN. The authors extend their gratitude to Eastern Health, Monash Health, and Peninsula Health for providing the emergency department presentation and hospital admission data. This work was supported by the Australian National Health and Medical Research Council (NHMRC, GNT2002193). LP is the recipient of an NHMRC Investigator Grant (#2016909). JSB is the recipient of an NHMRC Dementia Leadership Fellowship. RB is funded by an NHMRC Investigator Fellowship (#1194483). DIL is the recipient of an NHMRC Investigator Grant (#1196892).

Data Availability

Data sharing is not applicable to this protocol paper as no data sets were generated or analyzed during its writing. Those wishing to access the data should approach Outcome Health (the data custodians of Population Level Analysis and Reporting platform), Monash Health, Eastern Health, and Peninsula Health. Access fees for data and analyses may apply.

Authors' Contributions

SN conceptualized and received funding for the study with chief and associate investigators (NEA, RB, JSB, CP, and SL). TX, LP, and SN constructed the data linkage and key covariates for the study. The original draft was produced by TX, LP, and SN. All authors were involved in manuscript revision and jointly took responsibility for all aspects of the work.

Conflicts of Interest

LP, NEA, RB, CP and TX have no conflicts. JSB has received grant funding or consulting funds from the National Health and Medical Research Council, Medical Research Future Fund, Victorian Government Department of Health and Human Services, Dementia Australia Research Foundation, Yulgilbar Foundation, Aged Care Quality and Safety Commission, Dementia Centre for Research Collaboration, Pharmaceutical Society of Australia, Society of Hospital Pharmacists of Australia, GlaxoSmithKline Supported Studies Programme, Amgen, and several aged care provider organisations unrelated to this work. All funds were paid to his employing institution. SN has received untied educational grants to study pharmaceutical opioid-related harm from Seqirus and is a named investigator on an implementation trial of buprenorphine depot funded by Indivior (no funding received by SN personally or through her institution). DL is supported by a NHMRC Leadership Fellowship (1196892) and has received untied educational grants from Camurus and Seqirus Pty Ltd, unrelated to this work.

Abstract

Background: Given the significant investment of governments and families into the provision of child dental care services in Australia, continued population oral health surveillance through national oral health surveys is imperative.

Objective: The aims of this study are to conduct a second National Child Oral Health Survey (NCOHS-2) to (1) describe the prevalence, extent, and impact of oral diseases in contemporary Australian children; (2) evaluate changes in the prevalence and extent of oral diseases in the Australian child population and socioeconomic subgroups since the first National Child Oral Health Study (NCOHS-1) in 2012-2013; and (3) use economic modeling to evaluate the burden of child oral disease from the NCOHS-1 and NCOHS-2 and to estimate the cost-effectiveness of targeted programs for high-risk child groups.

Methods: The NCOHS-2 will closely mimic the NCOHS-1 in being a cross-sectional survey of a representative sample of Australian children aged 5-14 years. The survey will comprise oral epidemiological examinations and questionnaires to elucidate associations between dental disease in a range of outcomes, including social and emotional well-being. The information will be analyzed within the context of dental service organization and delivery at national and jurisdictional levels. Information from the NCOHS-1 and NCOHS-2 will be used to simulate oral disease and its economic burden using both health system and household costs of childhood oral health disease.

Results: Participant recruitment for the NCOHS-2 will commence in February 2024. The first results are expected to be submitted for publication 6 months after NCOHS-2 data collection has been completed. Thematic workshops with key partners and stakeholders will also occur at this time.

Conclusions: Regular surveillance of child oral health at an Australian level facilitates timely policy and planning of each state and territory's dental public health sector. This is imperative to enable the most equitable distribution of scarce public monies, especially for socially disadvantaged children who bear the greatest dental disease burden. The last NCOHS was conducted in 2012-2014, meaning that these data need to be updated to better inform effective dental health policy and planning. The NCOHS-2 will enable more up-to-date estimates of dental disease prevalence and severity among Australian children, with cost-effective analysis being useful to determine the economic burden of poor child dental health on social and emotional well-being and other health indicators.

Australian children; cost-effective analysis; dental caries; social and emotional well-being

Introduction

Overview

Dental caries is the most common childhood condition in Australia, resulting in costly treatment (up to Aus $ 1 billion [US$ 651,190,049] dollars annually), poor school performance, inadequate nutrition, problems with sleeping, and adverse mental health (social and emotional well-being) [1]. In addition to treatment costs, there are productivity losses due to caregiver absenteeism from work [2]. The burden of child oral diseases is overrepresented among socially vulnerable groups. For example, in the first National Child Oral Health Study (NCOHS-1) from 2012-2014, a total of 23% of children aged 5-10 years had dental caries in the primary dentition compared to 36% of Indigenous children, and 41% of non-Indigenous children aged 6-14 years had dental caries in the permanent dentition compared to 61% of Indigenous children [3]. From 2016-2017, approximately 70,200 hospitalizations for dental conditions could have been prevented; these hospitalizations were highest among socially vulnerable children [4].

As described in Australia's National Oral Health Plan 2015-2024 [5], there is a lack of routinely collected population-based dental data in Australia. This affects the capacity to effectively evaluate the impact of local and national policies, programs, and service models, which, in turn, makes it difficult to translate research and evaluation findings into policy and improved models of care. The NCOHS-1 has been influential in the development of public policy in Australia. It has provided valuable information on the oral health outcomes of children from different socioeconomic backgrounds and identified a number of underlying causes of oral health inequities, thus providing a sound evidence base for selecting interventions to reduce these inequalities.

Impact of Child Dental Disease on Social and Emotional Well-Being and Economic Productivity

Evidence shows that chronic illness is a major contributor to school absenteeism in childhood, thus impacting child school performance and social or emotional well-being [6]. Guarnizo-Herreno and Wehby [7] assessed associations between poor dental health and school performance or psychosocial well-being in a nationally representative sample of over 40,000 children in the United States. They reported that children with dental caries were more likely to have problems at school (odds ratio [OR] 1.52, 95% CI 1.37-1.72), more likely to miss school (OR 1.42, 95% CI 1.23-1.64), and less likely to do all required homework (OR 0.76, 95% CI 0.68-0.85). Dental problems among schoolchildren were associated with shyness, unhappiness, feelings of worthlessness, and a reduced ability to make friends. This may have far-reaching consequences in adulthood, affecting both economic productivity and meaningful engagement in civic activities. To the best of our knowledge, there has been no analysis of the association between poor dental health and Australian children's social and emotional well-being; this is an important strategic priority with the Australian Government launching the world's first National Children's Mental Health and Wellbeing Strategy in October 2021 [8]. Poor oral health in childhood also has an immediate impact on caregiver workplace productivity, with some dental procedures for children requiring care under a hospital-based general anesthetic. These services are only available in major metropolitan locations and typically have long waitlists [9]. This means caregivers need to take substantial leave from employment, with out-of-pocket costs including transport, accommodation, and childcare arrangements [10].

Provision of Dental Care for Australian Children

The provision of dental services for children varies by jurisdiction in Australia, although the federally operated (through Medicare) Child Dental Benefits Schedule (CDBS) is available for families already receiving other benefits, such as the Family Tax Benefit [11]. This scheme provides each eligible child up to Aus $1052 (US $ 668.96) over 2 calendar years for covering checkups, routine cleaning, simple restorations, extractions, and root canals. It does not cover orthodontic treatment, hospital-based dental care, or cosmetic dental procedures. Children who are eligible for the CDBS can receive treatment in any public dental clinic, with the claim being bulk billed with no out-of-pocket costs. Waitlists in public dental services, up to 2 years in some jurisdictions, are common. Some, but not all, private dentists also accept CDBS payments. Children not eligible for the CDBS need to pay for dental care out-of-pocket, or through dental insurance, in the private sector. In 2019, the Australian Government paid CDBS benefits of US $324,483,573 for 5,450,996 dental services across Australia, averaging US $59.53 in benefits per service. The average benefits paid per service ranged from US $40 for a diagnostic service to US $138 for a restorative service [12]. Data from the 2014-2015 National Health Survey indicated that around 1 in 5 children aged 2-14 years had never visited a dental professional [13]. Estimates from the 2013 National Dental Telephone Interview Survey showed that around 1 in 5 children aged 5-14 years had last visited a school dental service and around 2 in 3 had last visited a private dental practice. The proportion of children aged 5-14 years who had last visited a school dental service more than halved over the 1994-2013 period, from 54% to 21% [14].

Dental-Related Child Hospitalizations

Reducing rates of hospital-based child dental service provision is a key performance indicator of the 2015-2024 National Oral Health Plan [5]. The rate of preventable hospitalizations for dental conditions is influenced by the adequacy of preventive and primary dental care services, the prevalence of severe dental disease in the community, and the availability and accessibility of appropriate community and hospital-based dental services [5]. From 2017-2018, the rate of preventable hospitalizations due to dental conditions was highest among those aged 5-9 years (9.5 per 1000 population). Some children receive dental care under general anesthesia, usually due to the severity of the disease or other medical, physical, or behavioral complications.

XSL•FO
RenderX

Dental care under general anesthesia is resource intensive and not without risk.

Calculating the Economic Impact of Child Dental Disease

In Australia, it has been estimated that over 10,000 days of work and 2.5 million school hours are lost each year because of dental-related illnesses [15]. Identifying the economic burden of child dental disease is useful to understand the maximum number of resources that could be saved or gained if that disease were partially or fully eradicated. While there has been some attempt to quantify the indirect costs to government and society of child dental disease on the health system, there is a lack of consistent quantitative analysis and information. Robust data and economic analysis are urgently required to quantify these costs and the indirect financial pressures that child dental disease places on government and society. While treatment is a direct and costly consequence of child oral disease, reductions in morbidity may also imply other economic benefits. For example, indirect costs include productivity losses due to absenteeism from school and work, yet relatively little evidence exists in this regard.

Child Oral Health Surveys in Australia

The 2012-2014 NCOHS-1 was a cross-sectional study of the child population aged 5-14 years in Australia [3]. A total of 24,664 children from 841 participating schools were involved. Children were selected using a complex, multistage, and stratified sampling design, with a sophisticated weighting procedure implemented to adjust for variations in probabilities of selection and response rates. Information was collected through a parental questionnaire and a detailed dental examination by trained dental professionals. The findings suggested substantial social patterning of oral health status, dental service use, and dental and general health behaviors among Australian children. It was clear that addressing factors at the child, family, school, and community levels was necessary for reducing social inequalities in child oral health.

The proposed research will build upon the already established population-based epidemiological platform of the NCOHS-1, with the conduct of a second National Child Oral Health Survey (NCOHS-2), enabling a follow-up snapshot of a large and representative national child cohort. The specific study aims to (1) describe the prevalence and extent of oral diseases and their associations with social and emotional well-being and other outcomes in contemporary Australian children, (2) evaluate changes in the prevalence and extent of oral diseases in the Australian child population and socioeconomic subgroups since the NCOHS-1, and (3) use economic modeling to evaluate the burden of child oral disease from the NCOHS-1 and NCOHS-2 and to estimate the efficacy and cost-effectiveness of targeted programs for high-risk child groups.

Methods

The NCOHS-2 will be the second representative child oral health survey conducted in Australia in partnership with the dental public health sector of each of Australia's states and territories and the Federal Department of Health.

Study Design

The study design will closely mimic the NCOHS-1 in being a cross-sectional survey of a representative sample of Australian children aged 5-14 years. The survey will comprise oral epidemiological examinations and questionnaires to elucidate the impacts of dental disease on social and emotional well-being and other outcomes. The information will be analyzed within the context of dental service organization and delivery at national and jurisdictional levels. A key goal is to evaluate changes in the prevalence and extent of oral diseases in the Australian child population and socioeconomic subgroups since the NCOHS-1, using age-period-cohort analysis (NCOHS-1 and NCOHS-2, with both cohorts aged 5-14 years).

Sampling and Recruitment

As with the NCOHS-1, in the NCOHS-2, a multistage, stratified, and clustered random sampling design will be implemented to ensure sufficient geographic representation from both urban and rural settings in all states and territories while optimizing the efficiency of fieldwork for dental examiners. The sampling frame will include public and private schools in all states and territories. As with the NCOHS-1, NCOHS-2 participants will be selected in each state or territory using a 2-stage stratified clustered sampling design with a combined allocation of children per state proportional to population size.

Data Collection

Oral Epidemiological Examination

All selected children will be invited to undergo a standardized oral epidemiological examination at school-based units organized by state- or territory-appointed dental professionals. Small teams of examiners and data recorders (3-10 examining teams per state or territory) will be trained in the clinical assessment of key oral epidemiological outcomes. All NCOHS-2 examiners will be calibrated and tested in the field against a gold standard examiner to estimate interexaminer reliability and to ensure rigor and consistency of measurement. To facilitate comparisons across time, the oral outcome measures in the NCOHS-2 will be the same as those assessed in the NCOHS-1 using accepted indices and benchmark measures for large oral epidemiological surveys. The outcomes will include the number of teeth, experience of dental caries, dental fluorosis, molar incisor hypomineralization, dental plaque, and dental trauma.

Self-Report Questionnaire

The caregiver-reported questionnaire in the NCOHS-2 will comprise items on sociodemographics, self-rated oral health, self-rated general health, items used for cost-effective analysis (Dental Caries Utility Index) [16], oral health-related quality of life (Child Perceptions Questionnaire 11-14) [17] and Caries Impacts and Experiences Questionnaire for Children quality of life [18]), dental service use, dental behaviors, psychosocial factors, and social and emotional well-being. Social and emotional well-being will be assessed using the Stirling Children's Wellbeing Scale, a 15-item instrument developed by the Stirling Educational Psychology Service to measure emotional and psychological well-being among children aged 8-15 years [19]. The Stirling Children's Wellbeing Scale has

XSL•FO
RenderX

been validated and displayed good psychometric properties across multiple countries, including Scotland [19], Japan [20], and Bangladesh [21], among others [22].

Sample Size

The minimum required sample size was determined using standard methods to address the specific aims of the NCOHS-2 [23]. The main outcomes evaluated were the "decayed, missing, and filled teeth" (DMFT) index, the "decayed, missing, and filled surfaces" index, the percentage of children with untreated decay, and the percentage of children with overall caries experience. These outcomes were evaluated for primary dentition, among the age groups of 5-6, 7-8, and 9-10 years, and permanent dentition, among the age groups of 6-8, 9-11, and 12-14 years. The sample size was calculated to detect a 40% difference in the mean of the outcome or a 40% difference in the prevalence of the outcome with a power of 80% and a significance level of 5%. Sample size requirements were calculated for a simple random sample and then adjusted by the design effect to account for the NCOHS-2–stratified, 2-stage sampling design [24]. The design effect values were estimated based on existing NCOHS 2012-2014 data, which included information on children's oral health status (for all abovementioned outcomes) [3] and were used as a proxy in the calculation formula to estimate sample sizes for the NCOHS-2 [25]. The estimated sample size analysis was conducted with R software [26] and the R packages *survey* [27] and *pwr* [28]. The minimally required overall sample size of the NCOHS-2 was based on the outcome that required the largest sample—the percentage of children with untreated decay in the permanent dentition (n=16,678)—meaning that the NCOHS-2 would be adequately powered to detect all other outcomes. Because the percentage of children with untreated decay in the permanent dentition was not evaluated for children aged 5 years, an additional sample size (n=885)—estimated based on the sample required to evaluate the percentage of children with untreated decay in the primary dentition at age 5 years—was added to constitute the NCOHS-2 minimally required overall sample size (n=17,563). The sample allocation per state was conducted using combined allocation, consisting of an unweighted sum of equal allocation and proportional allocation [29]. The state and territory sample sizes were then further upwardly increased to meet jurisdiction objectives (N=18,700; Northern Territory, n=1400; Australian Capital Territory, n=1400; Tasmania, n=1400; South Australia, n=1850; Western Australia, n=2150; Queensland, n=3000; Victoria, n=3500; Norfolk Island, n=4000).

Economic Modeling

Information from the NCOHS-1 and NCOHS-2 will be used to simulate oral disease and its economic burden using both health system and household costs of childhood oral health disease. The cost of illness approach will be used to estimate the economic burden of dental disease. Direct and indirect costs will be estimated using available and collected information. Direct health system costs will include dental, pharmaceutical, emergency department, hospitalization, specialist appointments, diagnostic testing or pathology, and other health care services related to the provision of dental treatment. Indirect patient costs (out-of-pocket) will include Medicare Benefits Schedule and Pharmaceutical Benefits Scheme item copayments and other out-of-pocket costs, income loss for parents and children after attaining adulthood, and travel costs. Indirect societal financial costs will include other direct health system costs, patient financial costs, business financial costs, and government costs.

Statistical Analysis

We will specifically test for each aim.

- Aim 1: to evaluate the prevalence and extent of oral diseases and their association with social and emotional well-being and other outcomes in contemporary Australian children
- Aim 2: to evaluate changes in Australian child dental disease

The design of 2 cross-sectional, nationally representative surveys will enable comparisons between 2 time points from the NCOHS-1 and NCOHS-2 to be conducted. The main outcomes will be the prevalence and extent of decayed, missing, and filled teeth in the primary and permanent dentition (percentage of DMFT>0 and mean DMFT). Analysis will be performed progressively from descriptive to explanatory multivariable analysis, multilevel regression models, and causal inference models, accounting for systematic differences between the 2 periods, including family and area socioeconomic status, model of dental service provision, exposure to fluoride, dental behaviors, and diet. SAS (SAS Institute) or SUDAAN (RTI International), STATA (StataCorp), and R software will be used to generate sample estimates and standard errors and adjust for the complex sampling design of each survey.

- Aim 3: to evaluate the child oral disease burden from the NCOHS-1 and NCOHS-2 and estimate the efficacy and cost-effectiveness of targeted programs for high-risk child groups

Economic modeling using the R and TreeAge software (TreeAge Software, LLC) will be used to assess variations in cost-effectiveness according to accessibility and cost of child dental care. Different cutoffs and thresholds will be used to determine the most cost-effective models for targeted child oral health programs, preventive dental services, and insurance plans for optimal economic productivity. The analysis will involve the estimating costs incurred by the child population and population subgroups. Other costs will be estimated from a societal perspective, including productivity effects (based on expected time off work associated with child dental conditions and treatment) and dental service costs incurred by insurance companies and taxpayers. In collaboration with the Australian Institute of Health and Welfare's Australian Burden of Disease Unit, NCOHS-1 and NCOHS-2 estimates will be used to project the burden of child oral diseases in the 2020 decade and beyond. Markov models will use both health system and societal perspectives according to the cost being considered. The economic analysis will use cost-effectiveness (natural units as outcome measures) and cost utility analysis (quality-adjusted life years as outcome measures) depending on the outcome measure. Deterministic and probabilistic sensitivity analyses will be performed for all model base-case analyses.

Ethical Considerations

Ethics approval has been obtained from the University of Adelaide Human Research Ethics Committee (37659 H-2023). Before being recruited, all participants will be required to sign an informed consent form, which includes consent for the authors to publish the findings in peer-reviewed scientific literature. Data will be de-identified and there will be no compensation provided. All authors are named investigators on the project; they all contributed to the intellectual input of the study design and in writing this protocol.

Results

Participant recruitment for the NCOHS-2 will commence in February 2024. The first results are expected to be submitted for publication 6 months after NCOHS-2 data collection has been completed. Thematic workshops with key partners and stakeholders will also occur at this time.

Discussion

Overview

Regular surveillance of child oral health at an Australian level facilitates timely policy and planning in each state's and territory's dental public health sector. This is imperative to enable the most equitable distribution of scarce public monies, especially for socially disadvantaged children who bear the greatest dental disease burden. The last NCOHS was conducted in 2012-2014, with these data being effectively outdated in terms of contemporary and effective dental health policy and planning [30]. The NCOHS-2 will enable more up-to-date estimates of dental disease prevalence and severity among Australian children, with cost-effective analysis being useful to determine the economic burden over a lifetime of poor child dental health on social and emotional well-being and other health indicators.

As described in the National Oral Health Plan 2015-2024, there is a lack of comprehensive, routinely collected population-based dental data in Australia. This affects the capacity to effectively evaluate the impact of local and national policies, programs, and service models, which, in turn, makes it difficult to translate research and evaluation findings into policy and improved models of care. Both the National Oral Health Plan 2015-2024 and the previous National Oral Health Plan 2004-2013 call for regular national data collections of oral health to ensure quality planning, monitoring, and evaluation at both population and service levels. The previous NCOHS has been influential in the development of public policy in Australia. It has provided valuable information on the oral health outcomes of children from different socioeconomic backgrounds and allowed the diagnosis of a number of underlying causes of inequalities in oral health, thus providing a sound evidence base for selecting interventions to reduce these inequalities. It is expected that the results derived from this project will be important in informing public policy at both the state and national level over the next decade.

Optimal prevention and treatment of child dental disease, which in turn will improve child social and emotional well-being and economic productivity in the long term, requires appropriate health care systems, organizational governance, infrastructure, and resources that are evidence-based.

Outcomes and Significance

The National Children's Mental Health and Wellbeing Strategy, launched by the Australian Government in 2021, identifies the importance of improving Australian child health and well-being [8]. Evidence shows that dental problems among schoolchildren are associated with shyness, unhappiness, feelings of worthlessness, and a reduced ability to make friends. Linking the impact of poor dental health on Australian child school and social and emotional well-being using a large, nationally representative data set will lead to crucial insights regarding this prevalent and preventable childhood condition. Using cutting-edge cost-effectiveness modeling will be a significant contribution to dental service policy and planning to estimate the projected burden of child oral disease from 2012 and beyond, the impact on economic productivity over the life course, and the efficacy and cost-effectiveness of targeted programs for high-risk child groups. With strong partnerships with key state and territory and Commonwealth stakeholders, the findings of the NCOHS-2 will enable complex questions to be answered that will guide policy on improving child oral health that is relevant for all Australian children.

Acknowledgments

Funding is obtained from a National Health and Medical Research Council (NHMRC) partnership grant (APP2016736), the Department of Health, and in-kind support from each partnering state and territory dental public health sector. LJ is supported by an NHMRC research fellowship (APP1102587).

Data Availability

The data sets generated during this study are not publicly available due to privacy issues of the participants but are available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Scaling effective primary care innovations to benefit more people is of interest to decision makers. However, we know little about how promising innovations are being scaled "spontaneously," that is, without deliberate guidance.

Objective: We aim to observe, document, and analyze how, in real-life conditions, 1 primary care innovation spontaneously scales up across Quebec, Canada.

Methods: We will conduct a participative study using a descriptive single-case study. It will be guided by the McLean and Gargani principles for scaling and reported according to the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines. Informed by an integrated knowledge translation approach, our steering committee will include patient users throughout the project. Inspired by the Quebec College of Family Physician's "Dragons' Den" primary care program, we will identify a promising primary care innovation that is being or will be scaled spontaneously. We will interview the innovation team about their scaling experiences every month for 1 year. We will conduct interviews and focus groups with decision makers, health care providers, and end users in the innovation team and the target site about their experience of both scaling and receiving the scaled innovation and document meetings as nonparticipant observers. Interview transcripts and documentary data will be analyzed to (1) compare the spontaneous scaling plan and implementation with the McLean and Gargani principles for scaling and (2) determine how it was consistent with or diverged from the 4 McLean and Gargani guiding principles: justification, optimal scale, coordination, and dynamic evaluation.

Results: This study was funded in March 2020 by the Canadian Institutes of Health Research. Recruitment began in November 2023 and data collection began in December 2023. Results are expected to be published in the first quarter of 2024.

XSL•FO
RenderX

Conclusions: Our study will advance the science of scaling by providing practical evidence–based material about scaling health and social care innovations in real-world settings using the 4 guiding principles of McLean and Gargani.

KEYWORDS

scaling; spread; primary care; spontaneous; knowledge translation; implementation science; scaling science

Introduction

The subject of scaling has long been present in various knowledge areas such as renewable energy sources [1], sustainability [2], and education [3]. Scaling is now rapidly gaining the attention of decision makers in health and social care, particularly in high-income countries [4]. In the literature and practice record, there are numerous means proposed for scaling innovations [5]. Many of these propose modifiers, such as scaling up or out and vertical or horizontal scaling, are used in an attempt to describe the different ways in which innovations are scaled or spread. ExpandNet, a World Health Organization–affiliated group, has produced several widely used practical guides on the topic and defines scaling up as an action that aims to increase the impacts of successfully tested innovations to benefit more people [6]. Thus, it is no surprise that alongside this World Health Organization practice–oriented initiative, scaling science is emerging as a distinct complement to applied or implementation science [7-9]. The term "scaling science" has a double meaning: the first referring to approaches to bringing innovations to optimal scale for the public good and the second referring to the critical and systematic (ie, scientific) study of these approaches to scaling [7,8].

Unfortunately, Canada is a country notorious for promising pilot projects that do not get scaled [10]. Explanations for this include the fact that Canada is comprised of multiple distinct health and social care systems [11]. In addition, the most effective scaling seems to occur in low- and middle-income countries, which may reduce the opportunities for decision makers from high-income countries to improve their knowledge and competencies in scaling [5]. Another potential explanation lies in the complexity of scaling health and social innovations [12,13] and the methodological traditions that prioritize testing with randomized controlled trials before scaling up [14,15]. This contributes to lengthening the scaling process, while decision makers are often focused on short-term impact. Finally, there is increasing pressure on high-income countries to reduce waste and implement effective innovations already scaled in low- and middle-income countries [16]. Now that high-income countries face a rapidly changing society with increasing resource constraints, effective scaling of beneficial innovations has become a high priority [17].

Most scaling occurs in the absence of scaling guidelines [5]. While there are attempts to establish rigorous and standardized guidelines, there is also a pressing need for studies that look at how scaling currently occurs on the ground when a promising or effective health care innovation is naturally or "spontaneously" expanded to reach a broader population. We adopted ExpandNet's definition of spontaneous scaling as "diffusion of the innovation without deliberate guidance" [18]. The likelihood of spontaneous scaling is highest when the innovation effectively meets a clearly recognized need in a population or when a significant and urgent harmful event brings attention to the need to scale, for example, the COVID-19 pandemic [18]. Although the effectiveness of the innovation to be scaled should be demonstrated by its positive impacts on the public good, that is, it improves the well-being of individuals and populations through an increase in the quality of care [5,8], many experts and decision makers recognize that this is not always possible when facing a public health emergency [15,19]. Observation and analysis of spontaneous scaling are necessary to capture this process of adjusting plans and practice in real-life situations and will inform the knowledge base of scaling. Therefore, we aimed to observe, document, and analyze the spontaneous scaling (ie, that reflects the needs of a population but does not follow guidelines) of a promising primary care innovation within a specific health care context, compare it with the guiding principles of scaling described by McLean and Gargani [7-9], and make recommendations.

Methods

Overview of Study Design and Context

This study is a descriptive case study [20-22] adhering to the Rosenberg and Yate [23] recommendations for case study designs, which aim to comprehensively explore a particular case, including exploration of the phenomenon of interest and its contextual factors. Specifically, we define the case as the spontaneous process of scaling a promising primary care innovation within a specific health care context. The health care context is 2 large regional primary care organizations (an Integrated Health and Social Services Center [*Centre Intégré de Santé et de Services Sociaux*; CISSS] and an Integrated University Health and Social Services Center [*Centre Intégré Universitaire de Santé et de Services Sociaux*; CIUSSS]) within the Quebec health and social care services system. These 2 organizations are the administrative entities responsible for the delivery of health and social care services within their designated regions and for coordinating and integrating various facilities, such as hospitals, long-term care centers, rehabilitation centers, and community health centers.

Case Study Approach

To gain insights into the real-life spontaneous scaling process of a promising innovation, we will delve into a specific case and draw broader conclusions about the phenomenon at conclusions. This research will also take an interpretative epistemological approach [24] to understand the context of the case from different perspectives. By using these approaches,

XSL•FO
RenderX

we will shed light on the various factors and challenges associated with the scaling of spontaneous primary care innovations in real-world settings. We will report our findings using the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [25].

Scaling Framework

The documentation and analysis of the scaling process for this case study will be guided by a framework inspired by guiding principles proposed by McLean and Gargani [7-9]. This framework is based on a retrospective review of over 200 research and innovation projects funded by Canada's International Development Research Centre. The choice to use the McLean and Gargani principles was influenced by three factors: (1) they allow for adaptability and flexibility throughout all phases of the scaling process, which is coherent with a spontaneous approach and with the real-life context of this study (ie, unexpected changes can be accommodated and plans adapted); (2) the guidelines apply an equity lens and emphasize the importance of ethics in assessing scaling impacts; and (3) the principles support our aim of focusing on the impacts of scaling on the public good, a focus that promotes placing the main emphasis on the end users in all scaling initiatives.

The 4 guiding principles for scaling impact described by McLean and Gargani [8,9] are justification, optimal scale, coordination, and dynamic evaluation. "Justification" addresses both ethical and technical issues. Before asking how to scale, one must ask why or whether to scale and about its technical feasibility. For example, does this web-based course for social workers have the necessary infrastructure to reach more professionals (technical justification)? What kind of impact on the public good will the course provide (ethical justification)? "Optimal scale" challenges the logic of "the more the merrier" and involves making informed decisions about choosing a scale that creates an optimal mix of magnitude, variety, sustainability, and equity [7]. This requires careful consideration of the potential benefits and risks and requires judgment in balancing desirable and undesirable impacts. For instance, if the course is scaled up to 1000 social workers but is only available temporarily, and only to those working in private settings, scale-up meets the magnitude goals but not the sustainability or equity goals. "Coordination" addresses relational issues; demands flexible articulation among the complex systems; and connects the diverse actors in the scaling process, such as the initiators, the enablers, the competitors, and the people affected by scaling. For example, coordination among those involved in identifying the need for the social workers' course, those who developed the course, those who adapted and scaled it to further contexts, those who are evaluating it, those who are receiving the scaled-up version, and those who are receiving services from the newly trained social workers. For example, coordination in the case of the social workers' course would involve coordination among those who identified the need for the course, the course developers, those responsible for adapting and scaling it to diverse contexts, the evaluators assessing its effectiveness, and recipients of the scaled version. Coordination involves complexity, and this involves flexibility that requires an iterative process [8]. "Dynamic evaluation" addresses assessments in all phases of scaling: before, during, and after. Dynamic evaluation is not a linear before-after comparative assessment, but a constant application of evaluative thinking to check and adapt when necessary since scaling is a process that can change depending on the context of the site and innovation.

Coproduction Approach and Project Governance

Following the integrated knowledge translation approach [26,27], this study embraces the active engagement of knowledge users as equal partners working alongside researchers in all research steps. Through coproduction [28,29], we aim to generate knowledge that is valuable and meaningful to all stakeholders involved in the research process.

To ensure effective project governance, the research team will establish a steering committee consisting of key stakeholders who will provide expert advice, recommendations, and feedback on questions as they arise. This committee will oversee and coordinate each stage of the study and focus on topics that directly impact the project. The committee members will include the project leader; study coordinator; coinvestigators (1 or 2); knowledge users (1 or 2); and end users, who may include citizen or patient partners (1 or 2). This diversity of stakeholders ensures inclusive representation throughout the project's duration.

Participants

Criteria for Choice of Innovation, Innovation Team, and Target Site

We will choose an innovation from a previous edition of the *Innovation Symposium*, a program organized by the Quebec College of Family Physicians inspired by the TV program "The Dragon's Den" [30]. This event allows innovators, most of whom are from a clinical context and not from a research background, to pitch their promising innovations to clinical leaders and influential stakeholders (the Dragons) in Canada's primary care ecosystem. If the Dragons consider the innovation promising, they will contribute toward accelerating its growth and scaling it. Based on our research team's firsthand experience as attendees at previous symposiums (2017, 2019, and 2022), we will identify a spontaneous primary care innovation with considerable potential for scaling.

We will determine if the team is willing to participate in the project and, through a three-part questionnaire, whether (1) the innovation, (2) the innovation team, and (3) the context in which the innovation is embedded meet the following inclusion criteria based on our previous work [31-33] (Figure 1).

1. Inclusion criteria for the innovation: there is a spontaneous demand for scaling, the innovation aims to meet a demand for relevant primary care and services in the province of Quebec, the innovation has an epidemiological justification, the innovation is part of a health organization in Quebec, and the innovation has already been piloted and shown to be effective.
2. Inclusion criteria for the innovation team: it has a committee or governance for the development and scaling of the innovation, it is part of a health organization in Quebec, it accepts that the research team participate as an observer in its strategic meetings, it agrees to nominate a person to be

XSL•FO
RenderX

the coordinator responsible for the monthly and weekly follow-up with the members of the research team, the innovation team coordinator accepts the responsibility for connecting the research team with managers and health professionals in the target scaling setting, and the innovation team will be available during the research period (1 year) for monthly update meetings to respond to weekly ad hoc email requests from the research team on the innovation and the scaling process.

3. Inclusion criteria for the target site: a specific geographical place is targeted to receive the innovation or there are professionals already using the innovation in the place where it is exposed who are not members of the innovation team, the plan for receiving the scaled innovation is embedded in a health organization in Quebec, an organizational structure is available for receiving the scaled innovation, and partners in the target site are in place to support the scaling plan.
4. Inclusion criteria for individual participants: participants must be at least 18 years old; able to provide informed consent; able to actively participate, read, understand, and communicate in English or French; involved; in contact with or affected by the scaling initiative; and a decision maker in a health and social care organization, a health care provider, or a scaling expert working in the province of Quebec.

Figure 1. Process flow for choosing a promising innovation. CQMF: Quebec College of Family Physicians.

Support for Scaling

The steering committee will establish a support network for the innovation team. Supporting organizations will be instructed to offer support and advice for scaling without providing a ready-made scaling plan. We will conduct semistructured interviews and focus groups, with the following four categories of interviewees: (1) decision makers from health and social care organizations (n=1-4), (2) health care providers (n=3-8), (3) members of the innovation team responsible for scaling (n=2), and (4) end users (n=2-4).

Recruitment

The innovation team will be asked to appoint a coordinator who will act as the primary point of contact between the research team and the innovation team. This individual will serve as a facilitator and work closely with decision makers, health care providers, end users, and the research team to ensure effective communication and collaboration. Additionally, the coordinator will be responsible for identifying potential participants and providing their names to the research team for consideration for semistructured interviews and focus groups. Once potential participants have been identified, the research team will send them an email inviting them to participate in the study. The email will outline the main objectives of the research and extend an invitation to participate.

Qualitative Data Collection

Innovation Team

We plan to ask the team about (1) the components of the innovation (including technical requirements and costs) and its impacts on patients and health care professionals, (2) their opinions on how and why it should be scaled, (3) their scaling plan and strategies, and (4) their experiences of creating and implementing the scaling plan. We will also document any challenges encountered and how they were addressed in practice. We will follow developments with weekly emails and monthly follow-up meetings for 1 year.

Target Site

We intend to seek input from a range of decision makers (n=1-4), health care professionals (n=3-8), and end users (n=2-4) at the target site, as identified by the innovation team, regarding their firsthand experience with implementing the scaled innovation. We will conduct 1-hour semistructured interviews and focus groups (n=6-8). Participants in both interviews and focus groups will be asked about the innovation and their experience of scaling the health innovation, their view on the successful adaptation or not of the innovation, suggestions for improvement, potential factors influencing its implementation in their context, and possible complementary actions to be put into practice. One-hour individual structured interviews will be conducted face-to-face or on digital platforms (Teams [Microsoft Corp] or Zoom [Zoom Technologies Inc]) and adapted to accommodate the availability of participants. We will hold focus groups with the health care providers lasting 2 hours (maximum) outside office hours to reduce the impact on the services offered. Interviews will be conducted in English or French. One of the research team members with expertise in scaling and training in health care research innovation will conduct the interviews and focus groups. The interviews and focus groups will be recorded and transcribed, while an assistant moderator will be responsible for taking meeting notes during the interviews and focus group sessions. We will also participate as nonparticipant observers in some key meetings of the innovation team or training sessions given by the innovation team. During the

XSL•FO
RenderX

observation periods, the research team will take observation notes about the meeting and the scaling process.

Interview Guide

The interview guide will be based on the 4 McLean and Gargani guiding principles of scaling and will be adapted to the different roles of the interested parties (1 interview guide for decision makers, health professionals, and the innovation team and another one for end users).

We plan to carry out supplementary descriptive quantitative data collection that includes self-administered questionnaires to collect sociodemographic information from each participant (eg, age, sex, gender, civil status, and employment status) involved in the semistructured interviews in addition to a descriptive data collection of organizational characteristics of the target scaling site. The second source of quantitative data will be the various documents describing the scaling process (eg, archival records, reports on the innovation development, minutes of meetings, email exchanges, data from the monitoring of scaling, training manuals and materials, and postintervention feedback) to complement and support our qualitative analysis [34]. We will proceed to content analysis and direct analysis based on the 4 McLean and Gargani guiding principles, providing a comprehensive account of the execution of the scaling plan for detailed analysis.

Data Analysis

Theoretical Model

Using a framework approach [35], we will develop an a priori template of codes based on the McLean and Gargani guiding principles. We will use the data collected, both qualitative (interview transcripts and documentation) and quantitative (questionnaires and documentation), to (1) compare the innovation team's scaling plan with how scaling was implemented in practice at the target site and (2) determine the concordances or discordances between the 4 principles and participants' observations regarding their experience of developing the innovation, planning scaling, implementing scaling, and receiving the scaled innovation at the target site.

We will conduct a directed analysis by reading the full transcripts of the focus groups and the semistructured interviews as well as the third-party observations to obtain a sense of the overall data and compare coders' findings to reach agreement about the key themes identified based on the McLean and Gargani guiding principles. Using intracode methods, the research team will compare findings to reach a consensus on the key themes. Participants will be sent summaries of the results of the interviews and focus groups that they participated in and asked to verify their accuracy. A descriptive analysis of organizational (sites, decision makers, and health care providers) and sociodemographic (decision makers and health care providers) characteristics will also be conducted.

Validation

To ensure the internal validity of the analysis, the principal investigators will perform triangulation of data, cross-referencing data from multiple sources. To ensure external validity, a detailed description of the context in which scaling takes place will be provided, that is, the target clinic and its professional health care provider team. To further ensure the accuracy and credibility of the final report, it will be circulated among the collaborators and the committee to validate its content.

Knowledge Mobilization

Our knowledge mobilization plan is to involve knowledge users (eg, investigators, health care providers, and decision makers) and end users (eg, patient partners) in the steering committee. They will meet every 3 months via teleconference to discuss research progress and provide guidance on research directions. Our team already has extensive experience in the involvement of end users in the design, development, and implementation of health care solutions. Our approach considers the opinions of all end users as equally important. We will send out a newsletter every 4 months for all stakeholders.

We will produce and deliver an adapted and improved scaling plan, based on our results as seen through the lens of the McLean and Gargani guiding principles, to the innovation team. An executive report will be made available free of charge on the research team's website. We will prepare summaries of our research results tailored to specific knowledge user groups such as clinicians' organizations (family physicians, nurses, psychologists, and social workers) and researchers (peer-review publications).

Finally, we will disseminate study results in the form of (1) recommendations for preparing and monitoring scaling in primary care with an ethical lens, (2) presentations at scientific and professional conferences, (3) publications in peer-reviewed journals, and (4) through relevant networks such as the Research on Patient-Oriented Scaling-up network, the Strategy for Patient-Oriented Research (SPOR) Evidence Alliance, the Quebec College of Family Physicians and Réseau-1 Québec.

Ethical Considerations

Ethical approval was obtained from the CIUSSS de la Capitale-Nationale ethics board (MP-13-2023-2770). All stages of this research project will be carried out in accordance with Canadian procedures for informed consent (Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans) [36].

Results

This study was funded in March 2020 by the Canadian Institutes of Health Research. The steering committee has been formed and is giving expert advice and recommendations. The innovation has been identified, and the innovation team has agreed to contribute to this study by informing potential participants for interviews. Participants recruitment started in November 2023, and data collection began in December 2023. The interview guide has been developed through collaboration with 1 of the authors of the McLean and Gargani guiding principles, and a second interview guide has been adapted for conducting interviews with end users. Results are expected to be published in the first quarter of 2024.

XSL•FO
RenderX

Discussion

This study aims to use a single descriptive case study to observe, document, and analyze how, in real-life conditions, a promising health care innovation is being or will be spontaneously scaled in a health and social care organization across the province of Quebec. During the process of scaling, many external factors that may not be accounted for in most guidelines, such as the type of innovation being scaled, may influence the outcome. By taking a holistic approach that considers multiple interested parties (eg, patient or citizen partners, decision makers, professionals, researchers, and community members), we will gain a broad perspective on the spontaneous scaling process, enabling us to better understand real-life situations and the challenges that arise during scaling. One of the expected results is a better understanding of the role of flexibility and adaptability in scaling. Few studies have documented the actual process of spontaneous scaling and its practical implications.

By using the McLean and Gargani guiding principles, we also expect our results will give us insight into the ethical aspects of scaling that are overshadowed by the technical aspects and often given insufficient attention, despite their importance. The choice to use this framework was influenced by a need to better define and distinguish ethical considerations in scaling guidelines [5]. While "justification" may seem to be the most critical ethical principle of scaling among the 4, the other 3 also integrate ethical considerations. For instance, "coordination" is sometimes described by McLean and Gargani [9] as *inclusive coordination* because it involves engaging with stakeholders who are usually excluded in impact studies (eg, patients) to ensure the success of the innovation. By using these principles, we can single out the equity-related processes of an innovation and explore its ethical aspects in greater detail.

This study will provide valuable insights into the strategies, challenges, and outcomes of scaling innovations in real-life practical settings. It will provide evidence-based material to support scaling projects to integrate ethical considerations and to incorporate the flexibility to accommodate real-life demands.

Acknowledgments

We acknowledge the Quebec College of Family Physicians and all stakeholders, including the facilitators, for contributing to this study. We thank Louisa Blair for her editing. We thank the Canadian Institutes of Health Research for funding this research (grant 431716). FL holds a Tier 1 Canada Research Chair on Shared Decision Making and Knowledge Mobilization.

Abstract

Background: Pregnant women are considered a “high-risk” group with limited access to health facilities in urban slums in India. Barriers to using health services appropriately may lead to maternal and child mortality, morbidity, low birth weight, and children with stunted growth. With the increase in the use of artificial intelligence (AI) and machine learning in the health sector, we plan to develop a predictive model that can enable substantial uptake of maternal health services and improvements in adverse pregnancy health care outcomes from early diagnostics to treatment in urban slum settings.

Objective: The objective of our study is to develop and evaluate the AI-guided citizen-centric platform that will support the uptake of maternal health services among pregnant women seeking antenatal care living in urban slum settings.

Methods: We will conduct a cross-sectional study using a mixed methods approach to enroll 225 pregnant women aged 18-44 years, living in the urban slums of Delhi for more than 6 months, seeking antenatal care, and who have smartphones. Quantitative and qualitative data will be collected using an Open Data Kit Android-based tool. Variables gathered will include sociodemographics, clinical history, pregnancy history, dietary history, COVID-19 history, health care facility data, socioeconomic status, and pregnancy outcomes. All data gathered will be aggregated into a common database. We will use AI to predict the early at-risk pregnancy outcomes (in terms of the type of delivery method, term, and related complications) depending on the needs of the beneficiaries translating into effective service-delivery improvements in enhancing the use of maternal health services among pregnant women seeking antenatal care. The proposed research will help policy makers to prioritize resource planning, resource allocation, and the development of programs and policies to enhance maternal health outcomes. The academic research study has received ethical approval from the University Research Ethics Committee of Dehradun Institute of Technology (DIT) University, Dehradun, India.

Results: The study was approved by the University Research Ethics Committee of DIT University, Dehradun, on July 4, 2021. Enrollment of the eligible participants will begin by April 2022 followed by the development of the predictive model by October 2022 till January 2023. The proposed AI-guided citizen-centric tool will be designed, developed, implemented, and evaluated using principles of human-centered design that will help to predict early at-risk pregnancy outcomes.

XSL•FO
RenderX

Conclusions: The proposed internet-enabled AI-guided prediction model will help identify the potential risk associated with pregnancies and enhance the uptake of maternal health services among those seeking antenatal care for safer deliveries. We will explore the scalability of the proposed platform up to different geographic locations for adoption for similar and other health conditions.

Introduction

Background

The World Health Organization has defined maternal mortality as the annual number of female deaths from any cause related to or aggravated by the pregnancy or its management (excluding accidental or incidental causes) during pregnancy and childbirth or within 42 days of termination of pregnancy, irrespective of the duration and site of the pregnancy, which is estimated to be 295,000 globally each year [1]. Of the total maternal deaths, 94% occur mostly in low-resource settings, which could have been prevented in most cases. In India, there has been a significant decline in maternal deaths in 2015 by 68.7% (n=130 in 2016) against a global maternal mortality rate of 216 (2015) compared with 556 (1990) women dying during childbirth per hundred thousand live births as per the UN Maternal Mortality Estimation Interagency Group report. It has been targeted to reduce below 70 by 2030 under the Sustainable Development Goal [2,3].

There have been various factors contributing to maternal mortality found between the onset of obstetric complications and its outcome. If prompt, adequate treatment is provided, the outcome will usually be satisfactory; therefore, the outcome is most adversely affected by delayed treatment. A review of delayed decisions to seek care and delay in accessing adequate care can provide the actual picture to address the satisfactory utilization of maternal health care services in the context of low- and middle-income countries (LMICs) [4].

There are various national maternal health programs initiated by the Government of India under National Health Mission. Some of them are as follows: (1) Janani Shishu Suraksha Yojana, which is a new approach to health care that emphasizes entitlements and elimination of out-of-pocket expenses for both pregnant women (free delivery including cesarean section in public health facilities) and sick infants [5]; (2) Janani Suraksha Yojna, which provides safe motherhood intervention for reducing maternal and neonatal mortality by promoting institutional deliveries among poor pregnant women by providing conditional cash assistance to below poverty line/schedule caste/schedule tribe women for giving birth in a public health care institution or accredited private hospitals [6]. The Anganwadi center is one of the types of rural childcare service providers in India under the scheme of Integrated Child Development Services, which is one of the flagship programs of the Government of India launched in 1975. It is unique and one of the world's largest programs for early childhood care and development. With a history of high maternal and infant mortality and morbidity in LMICs like India, the scheme provides preschool nonformal education, on one hand, and breaks the vicious cycle of malnutrition, morbidity, reduced learning capacity, and mortality, on the other, to the beneficiaries including children in the age group of 0-6 years, pregnant women, and lactating mothers [7].

The application of citizen-centric design in this study will primarily keep pregnant women as the beneficiary by understanding user characteristics, needs, and preferences that are critical for developing a human-centered artificial intelligence (AI)–guided predictive model. Analysis of demographic parameters such as gestational age, medical history, immunization, education, and socioeconomic status as well as prior exposure knowledge, practice, and attitude toward the use of antenatal care (ANC) services plays a key role in ensuring optimal use of maternal health services in slums [8].

In urban slums, pregnant women are a "high-risk" group with limited access to health facilities. Barriers to utilization of health services are well documented in a few studies where the urban poor cannot be treated as homogeneous entities because of strong evidence on important sociodemographic variations within the urban poor population with their use of services and the barriers faced in service usage [2,9,10]. On the assessment of social-economic barriers, women reported the poor attitude of health workers. Other barriers reported were men's stigma-related refusal to accompany their spouses for HIV screening and some bylaws that restrict women who had pregnancy outside marriage to seek an authorization letter from local traditional leaders for ANC services at the health facility [11].

Rationale of the Study

Most of the urban slums comprise immigrant families bearing their area-specific social customs, rituals, and taboos. Depending on these factors, the slums may differ from one another in their health indicators, which acts as a barrier to timely and appropriate utilization of maternal health care services under the national programs [12,13].

The identified barriers in the utilization of maternal health care services at a local level may differ significantly between slums that need to be recognized, identified, and addressed in the district-level planning for health [14]. Poor families are unable to seek maternal services because of various cultural and demographic factors. The public health care delivery system plays a vital role in the national programs that have been

XSL•FO
RenderX

reported to be inefficient; even the minimum facilities are not often made available to the target groups [13,15].

Research shows that AI, automation, and data science can support overburdened health systems and health workers when responsibly deployed. AI-enabled platforms can be used to communicate timely information to the public, support self-care, and communicate initial recommended preventive options and even psychosocial care [16-20]. Hence, we plan to develop an AI-guided citizen-centric predictive model that will help to identify the gaps in using maternal services during ANC and enhance the uptake in utilizing maternal health services during the antenatal period and related pregnancy outcomes.

Research Hypothesis

The research hypotheses are as follows:

- Is there an association between sociodemographic factors, health behaviors, health care access, clinical factors, and use of maternal health care services such as ANC services?
- Is the design and development of an internet-enabled AI-guided predictive model using a human-centered approach a good fit for enhancing the uptake of maternal health services among pregnant women living in urban slum settings?
- Can the proposed AI-guided predictive model be useful to enhance maternal health services to improve pregnancy-related health outcomes?

Aims and Objectives

Aims

The study has three aims:

1. Identify the factors that affect the uptake of maternal health services such as ANC among pregnant women living in urban slum settings of South Delhi
2. Use community data to design and develop a comprehensive AI-guided citizen-centric tool for improved utilization of maternal health services among pregnant women
3. Evaluate the usefulness and effectiveness of the proposed AI-guided citizen-centric tool to enhance the uptake of maternal health services for ANC services

Objective

The objective of our study is to develop and evaluate the AI-guided citizen-centric platform that will support the uptake of maternal health services among pregnant women seeking ANC and living in urban slum settings.

Methods

Study Design

A cross-sectional mixed methods study will be conducted to gather both qualitative and quantitative data on an android-based electronic platform.

Study Site

The study will be conducted in the urban slums of South Delhi, and participants will be enrolled from the Anganwadi centers. The Anganwadi workers will assist in mobilizing the eligible participants seeking ANC services to participate in the study.

Inclusion and Exclusion Criteria

The inclusion criteria are as follows:

- Eligible married pregnant women aged between 18 and 44 years regardless of pregnancy order
- Pregnant women residing in urban slum settings for the last 6 months
- Participants who gave written/e-informed consent
- Participants having a smartphone

Participants who are not willing to participate are not included in the study.

Study Population

Eligible pregnant women seeking ANC and aged between 18 and 44 years will be enrolled in the study.

Sample Size

A convenience sampling approach will be employed in selected urban slums across 4 geographic zones of South Delhi where only 10% of the households in each slum site will be selected from each zone. Very few studies reported ANC utilization in urban slums in Delhi. Using a reference of this indicator for urban Delhi considering an expected proportion of 30% of participants completing at least 3 ANC visits, with 95% confidence levels, 6% of absolute precision, and a nonresponse rate of 10%, the estimated sample size of the study will be 225.

Study Tools

Data collection will be done at the Anganwadi centers using prevalidated instruments adapted from the National Family Household Survey (NFHS). The data will be collected using the electronic data collection tool (Multimedia Appendix 1) focusing on certain predictors that will help in predicting the pregnancy outcomes by measuring the risk associated with the type of delivery method, the term (preterm/full term), and related complications during the delivery. The proposed predictors (Textbox 1) will help in analyzing and comparing the pregnancy outcomes using machine learning from the primary data set.

XSL•FO
RenderX

Textbox 1. Pregnancy predictors to be evaluated in model development: definition.

Age

- Age of the women at the time of data collection during pregnancy

Duration of pregnancy

- The current duration of pregnancy from the last menstrual period until the date of data collection

Education

- The literacy level of the participant to understand the importance of antenatal care

Birth order

- The order a child is born in their family

Abortion history

- History of medical termination of pregnancy

History of diabetes

- A family history that can make women with a family history of diabetes more at risk for developing the disease

Hypertension

- Family history of high blood pressure inducing the pregnancy

Thyroid

- Family history of hypo- or hyperthyroidism inducing the pregnancy

Number of visits

- Frequency of seeking antenatal care services through Anganwadi centers

Immunization

- Immunization against tetanus toxoid during pregnancy

Supplements

- Iron folic acid supplements are prescribed during pregnancy

Ultrasonography

- Ultrasonography for fetus growth, development, and monitoring of pregnancy

Related complications

- Pregnancy-related complications during the prepartum, antepartum, and postpartum period

COVID-19 history and its related complications

- History of COVID-19 during pregnancy and its related complications

Immunization

- Vaccinations against COVID-19 infection

Height

- Height of women during pregnancy at the time of data collection

Weight

- Weight of women during pregnancy at the time of data collection about the duration of pregnancy

Blood pressure

- Monitoring blood pressure of women during pregnancy

XSL•FO
RenderX

Pregnancy BMI

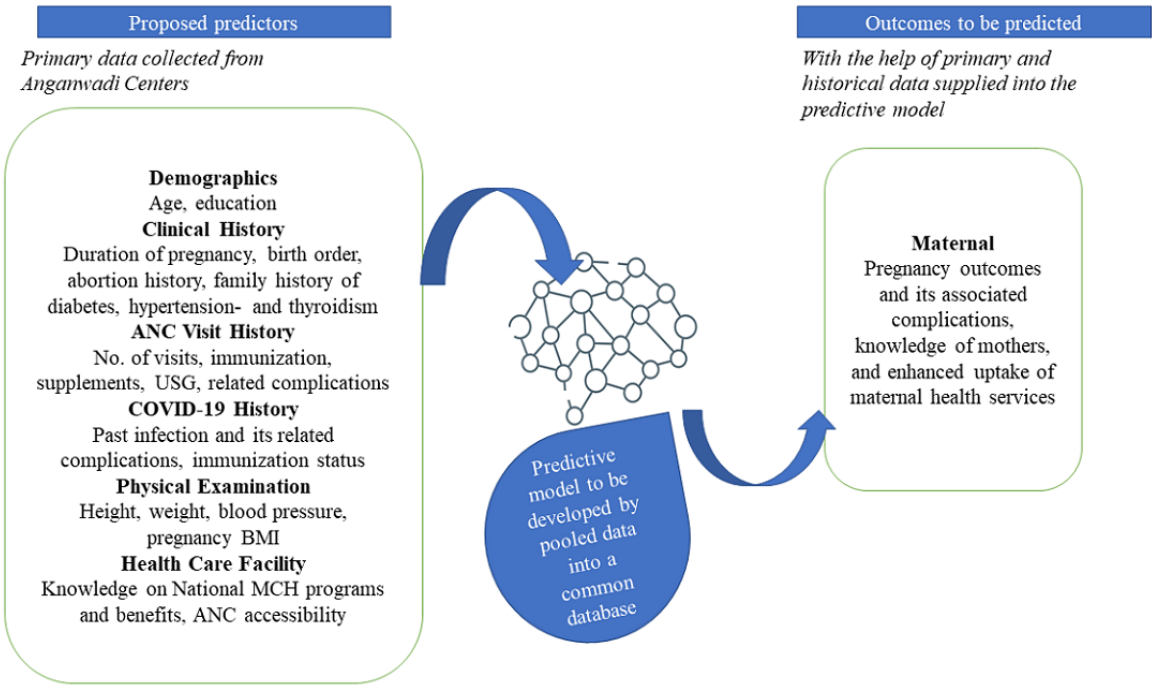
- Body mass divided by the square of the body height

Knowledge of national maternal and child health programs and benefits

- Knowledge about various maternal and child health schemes under the Government of India

Antenatal care accessibility

- Women seeking antenatal care from health care providers and distance from their residence



Predictive Model Design

We will develop a machine learning predictive model for early at-risk pregnancy outcomes using citizen-centric design to enhance the uptake of maternal health services among the beneficiaries seeking ANC. This includes some common parameters based on which the model will be developed (Figure 1).

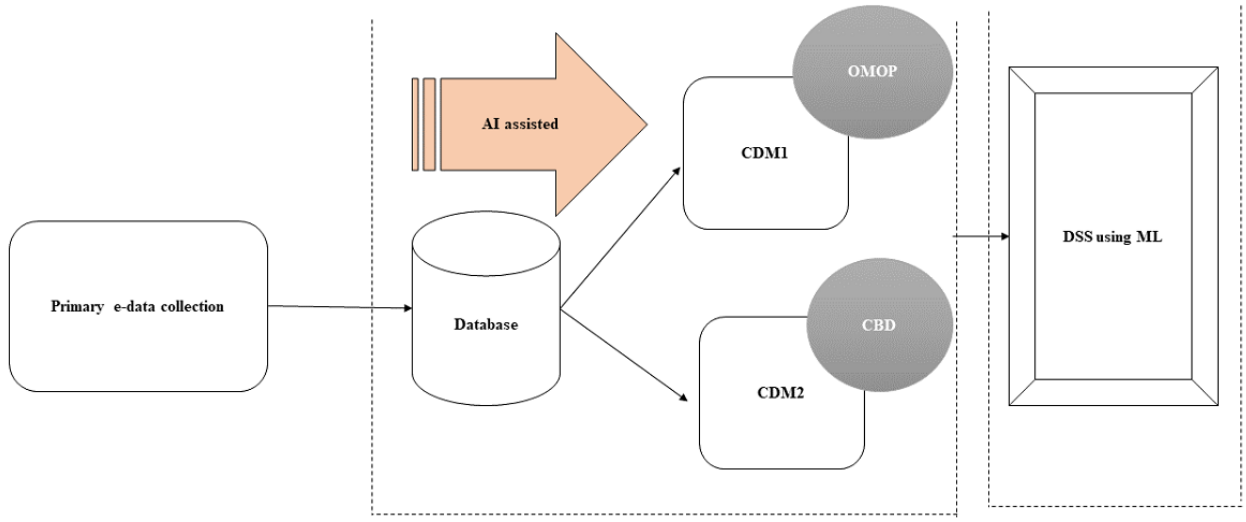
The data pool will be structured following well-established common data models (CDM), which will facilitate harmonizing the data set providing access to relevant data concurrently for ease of consistent and accurate analysis. The CDM, identified at this stage, will include the Observational Medical Outcomes Partnership (OMOP) for clinical data extracted from sources and the customized Community-Based Demographic model for data extracted from communities (Figure 2). The OMOP CDM will allow the organization to standardize medical terms used across the data set for analysis. This platform will focus on algorithm development using evidence-based guidelines [21], existing gaps, and available literature [22,23] to create "IF," "AND," and "OR" logics to create a guide for logical thinking and future research, and will help to understand how these data will be processed at the backend, which would help policy makers and other public health researchers in decision-making.

The participants will be followed every 3 months from the date of enrollment until their pregnancy outcomes through telephonic calls. The data collected from the first 100 participants will help to develop the AI-guided tool, and the same will be evaluated for its potential competitiveness in the next 125 participants' data (Figure 3).

Figure 1. Predictors for comparison in a predictive model of pregnancy outcomes. ANC: antenatal care; MCH: maternal and child health; USG: ultrasonography.

XSL•FO
RenderX

Figure 2. Conceptual framework of data flow to develop the decision support system. AI: artificial intelligence; CBD: community-based demographic model; CDM: common data model; DSS: decision support system; ML: machine learning.



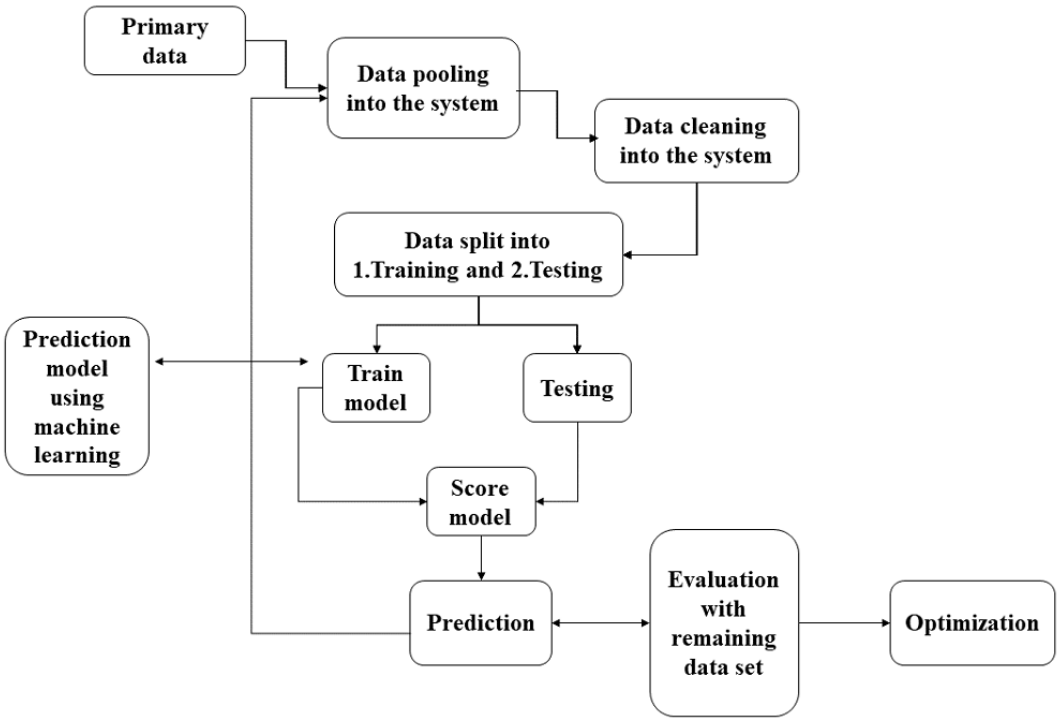


Figure 3. Analytic framework for prediction model of pregnancy outcomes.

Data Management and Availability

The data will be collected in bilingual languages (English and Hindi) electronically. Source data verification and quality control will be managed by the team of researchers. The anonymized data set for the entire study will be stored in Amazon Web Server (cloud server) and will be used in the model.

Statistical Analysis

Data will be analyzed using a multivariate regression model that may account for the clustered nature of the pooled data. Uptake in the utilization of maternal health services especially during the antenatal period and pregnancy outcomes (dependent variables: number of ANC visits, tetanus toxoid injections, iron folic acid tablets) will be tested against all independent variables: maternal morbidity, pregnancy outcome, complications of previous pregnancy, literacy, and availability of health care facility using the SPSS statistical tool. Predictive analysis will be compared for accurate future outcomes through the supplied data sets using machine learning to further optimize the model.

Expected Outcome Measures

The anticipated outcome from this study will be more focused on the epidemiology of maternal health in terms of a better quality of life through the uptake and proper utilization of maternal health services in terms of ANC service utilization efficiently through behavior change communication, advocacy, and health monitoring defining the aspects other than the clinical side in urban slums. Different parameters based on which the efficacy of this proposed platform will be assessed are as follows:

XSL•FO
RenderX

1. Monitoring the trend of the utilization of maternal health services by pregnant women seeking ANC through local service providers (Anganwadi centers) in urban slums
2. Risk identification during the antenatal period
3. Mapping of health care facilities (Anganwadi centers)
4. Evaluating the competencies of the proposed platform in predicting early at-risk pregnancy outcomes.

Quality Assurance

Three levels of data security will be implemented, namely participant level, data transmission level, and server level, ensuring no harm to study participants (neither physical nor mental) while collecting primary data. For secondary data access from individuals or institutions, prior permissions from respective data owners unless the aforesaid data are in the public domain are obtained (if applicable).

Ethics Approval

The academic research study has received ethical approval from the University Research Ethics Committee (UREC) of the Dehradun Institute of Technology (DIT) University, Dehradun, India, bearing the approval letter number Protocol DITU/UREC/2021/07/4 dated July 4, 2021. The results will be disseminated at various presentations, seminars, and conferences; as a part of a PhD thesis in Population Health Informatics at DIT University, Dehradun; and in a manuscript that will be submitted to peer-reviewed journals only. The evaluation of the proposed outcome areas will be completed by January 2023.

Results

The study was approved by the University Research Ethics Committee of DIT University, Dehradun, on July 4, 2021. Enrollment of the eligible participants will begin by April 2022 followed by the development of the predictive model by October 2022 until January 2023. The proposed AI-guided citizen-centric tool will be designed, developed, implemented, and evaluated using principles of human-centered design that will help to predict early at-risk pregnancy outcomes. The results of the study will identify the factors that affect the proper use of maternal health services during the antenatal period. The study results will also intend to make an important contribution by evaluating the usefulness and effectiveness of the proposed predictive model, further evaluating the model for accuracy.

Discussion

Principal Findings

In India, slums have been identified in 2613 towns including 20 census towns (19 from the National Capital Territory of Delhi and 1 from Uttar Pradesh) irrespective of their population size in the Census 2011 report, wherein the slum population was enumerated as 22.4% of the total slum population in cities/towns and 17.4% of the total urban population of all the states and union territories [24-27]. The significant community representation from the urban slum population and experience of maintaining population cohorts in the selected study sites are being leveraged to fill knowledge gaps related to the actual burden of maternal morbidity and mortality.

Operational challenges unique to the COVID-19 pandemic, in the form of barriers due to administrative lockdown, restrictions in field mobility in containment zones, and outbreaks at the study site, are anticipated in the study. Hesitance on the part of potential participants toward commonplace data collection at Anganwadi centers and a guarded attitude toward disclosing any health issues due to COVID-19–associated stigma are expected in some communities. We expect that functional linkages with the local health system will be established at each Anganwadi from where the potential participants can be enrolled and benefit from this research study. The study tools adopted from the NFHS will assist in collecting reliable data that are a part of the Indian census enumeration program. The NFHS is a large-scale, multiround survey conducted every 10th year in a representative sample of households throughout India to provide state and national information on fertility, infant and child mortality, the adoption rate of family planning, maternal and child health, reproductive health, nutrition, anemia, and utilization and quality of health and family planning services [28]. Thus, the data collected electronically will thereby help in transforming the raw data into meaningful interpretations and representations for other researchers.

The recruitment sites represent the residents living in the periurban area, generally defined as slum dwellers/*Jhuggi Basti*.

This study will establish the clinical need for a robust prediction model for adverse event–related pregnancy outcomes during the antenatal period to support therapeutic decision-making and continuum of care. Engagement with stakeholders in the model design stage will improve the clinical acceptability of the model and will also support future implementation efforts in the field through the references to a systematic review.

There are a few limitations of this study, such as difficulty in enrollment due to the COVID-19 pandemic, the potential loss to follow-up given the current increase in COVID-19 cases and its complications, participants of the first trimester to be followed until the third trimester down the line to strengthen the system, and results cannot be generalized as the study is limited to one geographic setting with a small sample size.

In this study, no possible risk is anticipated as of now other than the exposure of participants to an infected individual who could be a point of transmission for COVID-19 (considering mega vaccination drives in India) and the emergence of a new variant (Omicron) in the community.

The design of the study will enable us to understand the dynamics of the community, household, and individual due to the inclusion of basic demographic parameters and the socioeconomic status of the family, which will help to analyze the root cause of the underuse of maternal health services and leading complications related to pregnancy outcomes. Subsequent follow-up with the participants will help to evaluate and optimize the model.

XSL•FO
RenderX

Conclusions

The proposed internet-enabled AI-guided predictive model will help to identify the potential risk associated with pregnancies and enhance the uptake of maternal health services among those seeking ANC for safer deliveries. This study will help to get an insight into various sociodemographic factors other than clinical aspects for underutilization of maternal health services in the community, which will motivate pregnant women to use the government-facilitated national maternal health care program more efficiently, thereby reducing maternal mortality and morbidity during pregnancy. We will explore the scalability of the proposed platform to different geographic locations for use with similar and other health conditions.

Data Availability

For data security, we will implement and maintain appropriate technical and organizational measures following applicable data protection laws to ensure a level of security appropriate to the risks. Information will be collected in an electronic format and will be stored in a secure database. The data will be accessible only to authorized research staff during the study. All the records will be identified with a code and the results/findings may be presented at meetings or in publications; the participant's identity will not be revealed at any point in time. All possible measures will be taken before the data are made publicly accessible by removing all information that could identify any participant.

Conflicts of Interest

None declared.

Abstract

Background: Early action by bystanders is particularly important for the survival of individuals in need of emergency care, especially those experiencing a cardiac arrest or an airway obstruction. However, only a few bystanders are willing to perform cardiopulmonary resuscitation. The use of a live video during emergency calls appears to have a positive effect on the number of cardiopulmonary resuscitations performed by bystanders.

Objective: The objective of this study is to propose and evaluate the relevance of a living lab methodology involving video calls in simulated life-threatening emergency situations.

Methods: The first study aimed at analyzing the process of dealing with out-of-hospital cardiac arrest at a dispatch center and identifying the needs of the dispatchers. The second study is a pretest of a living lab. The third study focuses on a living lab in which 16 situations of cardiac arrest and airway obstruction are simulated. The simulation includes both a live video and transmission of a video demonstration of emergency procedures. The measures focus on 3 areas: the impact of video tools, development of collaboration within the community, and evaluation of the method.

Results: The results of the first study show that dispatchers have an interest in visualizing the scene with live video and in broadcasting a live demonstration video when possible. The initial results also show that collaboration within the community is enhanced by the shared simulation and debriefing experiences, clarifying regulation procedures, and improving communication. Finally, an iterative development based on the lessons learned, expectations, and constraints of each previous study promotes the existence of a living lab that aims to determine the place of live video tools in the sequence of care performed by dispatchers.

Conclusions: Living labs offer the opportunity to grasp previously undetected insights and refine the use of the applications while potentially developing a sense of community among the stakeholders.

Introduction

Background

The care provided in life-threatening emergencies is constantly evolving, partly because of the technological advances that are leading to changes in health care and further improvements in the way dispatchers respond to and handle emergency calls. Current health recommendations emphasize that all available resources, both human and technological, should be used to achieve better outcomes in terms of patient care [1]. For instance, in France, a new law has been in place since July 2020 establishing the status of citizen rescuers, whereby citizens can and should attempt to rescue an individual in a critical situation and will not be held responsible for any consequences related to this attempt. This legislation has the broad goal of improving survival after an out-of-hospital cardiac arrest (OHCA). In addition, since 2015, European and International recommendations for the treatment of OHCAs have included the use of digital applications dedicated to train citizens to promote rapid response to individuals experiencing an OHCA [2-4]. This concern stems from the fact that individuals experiencing an OHCA have a very low probability of survival (around 10%) despite the numerous measures taken, such as training citizens in first aid, prevention, and massive deployment of automatic electric defibrillators [5-7]. Furthermore, OHCA is not the only emergency situation where rapid intervention, by a bystander, for example, can be crucial. In the case of a sudden airway obstruction (choking), particularly prevalent among children and older adults, who are a high-risk population [8,9], it is the speed of the action that is pivotal. In choking situations, it is recommended that back blows (Mofenson maneuver), abdominal thrusts (Heimlich maneuver), or chest thrusts be performed. These have been shown to be effective in relieving foreign body airway obstruction (FBAO) [10]. In both situations, the direct intervention of a bystander results in better survival rates. As for OHCA, 13.6% of the patients discharged alive were the ones who received bystander cardiopulmonary resuscitation (CPR), compared with 7.3% of the patients who did not receive early CPR [11]. When defibrillation is performed by a bystander using an automated electrical defibrillator, the rate of increase in survival is similar to that seen among patients who received bystander CPR: 47% of patients survived to hospital discharge, compared with 28% of the patients initially defibrillated by a first responder who arrived later [12]. As for sudden airway obstructions, direct witness action resulted in a 68% survival rate, compared with 44.7% survival rate among the patients who received intervention at a later stage [13]. However, bystanders rarely intervene when they witness an emergency. With respect to cardiac arrest, the rate varies from 1% to 18% for defibrillation and from 10% to 40% for CPR [14,15]. Similarly, although bystanders performing the Heimlich maneuver have been shown to be essential in improving the outcome of individuals who are unconscious or unresponsive because of choking, only 25% of these individuals receive this assistance [16].

Components Affecting the Willingness of Bystanders to Act

Several elements can affect a bystander's willingness to intervene. A study showed that in terms of performing CPR, the fear of hurting the patient is the first barrier (reported by 63.1% of the respondents for older adults and 50.9% for children), followed by a perceived lack of appropriate skills (13.4% for older adults and 23.4% for children) and fear of parental blame (5.2%) in cases involving child CPR [17]. Numerous other studies have indeed shown that bystanders were afraid of causing injury to individuals in need of emergency care [18-20]. Therefore, to reduce these barriers, it is necessary to better inform citizens about the consequences of individuals not receiving adequate assistance in emergency situations and to train the population more widely in first aid. In addition, health professionals have limited trust in bystanders, specifically those who are in initial contact with dispatchers. For example, several studies have shown that dispatchers perceive bystanders as a nuisance because of their inexperience, limited training in first aid, and insufficient knowledge [21-24]. This mistrust is compounded by the fact that interactions between both populations are very rare, which can lead to tension and misunderstanding during their communication [22,25]. Moreover, neither of them is accustomed to collaboration [26], and during a call involving an emergency-related interaction, there is no time to build the necessary trust for effective collaboration [27]. To improve the relationship between the dispatcher and the bystander who can perform first aid procedures, two pathways can be considered: (1) establish a common frame of reference between bystanders and health professionals that allows for more efficient collaboration based on already established trust and (2) providing new tools (eg, live video) to overcome the lack of knowledge and training in bystanders and allow them to overcome their fear of performing emergency procedures while providing a sense of confidence to the dispatcher.

Use of Live Video to Enhance Communication Between the Bystander and the Dispatcher

The use of live videos is an emerging trend in handling emergency calls. Live videos can be used to assess the condition of the patient or the context and thus provide feedback to the dispatcher, allowing them to have better visibility of the situation. Indeed, there seems to be a discrepancy between the reality of the situation in the field and what the dispatcher perceives when receiving only audio information [28,29]. Live video feedback has also proven to be an asset in guiding CPR [30]. In England and Denmark, video feedback is currently used at certain dispatch centers using the app GoodSAM [30,31]. The dispatcher also has the option of sending a live video demonstration of the rescue actions that can be performed by the bystander. Studies have shown that viewing a live video demonstration of CPR increases the rate of bystander CPR [31] and improves the quality of chest compressions (rate, frequency, depth of compressions; reduction in interruptions; and the accuracy of one's hand placement) [32-36]. Therefore, it is needless to prove the beneficial effect of bystander CPR on medical care. However, this study aims to understand the subjective effect of using such applications in a high-fidelity

XSL•FO
RenderX

simulation context [37,38]. The high-fidelity context refers to the inclusion of all the real actors in the survival chain.

The Living Lab as a Space to Create a Shared Referential

The living lab is a method developed in the 1990s at the Massachusetts Institute of Technology, which aims to provide a meeting place for all the stakeholders involved in a situation to test a technological innovation [37,39]. This method allows a test in a situation close to reality and makes it possible to identify and confront the real constraints even before reaching a more advanced development process. It also provides opportunities for different populations, varying in their level of familiarity, to interact and collaborate. Living laboratories are sometimes used in the medical industry and show positive effects on the development of trust between participants owing to a better understanding of the reality of others [38]. Moreover, living laboratories offer the opportunity to use a diverse set of complementary methodologies. For life-threatening emergencies, simulation seems to be the most appropriate setting. It is important to point out that to preserve the safety of individuals in need of emergency care and the potentially traumatic effects on the participants, it is not possible to conduct this experimentation in a real context [40]. The use of simulations with scenarios in a semireal context seems adequate and can genuinely benefit the participants in moments of emergency or crisis [40,41]. Experiencing the simulations together contributes to the creation of a discourse and a common frame of reference allowing for a more efficient cooperation later [40,42]. We also hypothesize that learning first aid in this type of setting will allow for a longer retention of skills than learning through more typical training, in which case the learning tends to dissipate after6 months [43]. Simulation helps induce strong emotions, and such induction and feeling of strong emotions are a prerequisite for experiential learning [44] and are demonstrated to be an effective method to retain the acquired knowledge.

Research Aim

The objective is to propose and evaluate the relevance of a living lab methodology in simulated life-threatening emergency call situations where live video tools are introduced into the call sequence with the aim of developing skills, trust, and collaboration among all emergency chain stakeholders (bystanders, first responders, dispatchers, and paramedics).

Methods

Research Questions and Settings

The 2 objects of this study are apps that allow video feedback (Urgentime) and video demonstration of rescue actions (SARA) during vital emergencies for cardiac arrest and FBAO. The emphasis lies on 1 main research question (QR; QR1) and 2 secondary QRs (QR2 and QR3):

- QR1 focuses on the practitioner: does the inclusion of videos have an influence on the early treatment of a patient by a bystander in the context of an emergency call?
- QR2 focuses on the community: does the shared workshop have an influence on the building of a common frame of reference among stakeholders?
- QR3 focuses on the method: does the living lab methodology adapt to the needs and constraints of the stakeholders during the process?

The emergency medical communication center (EMCC) of the Geneva region (emergency number 144) in Switzerland is part of the University Hospitals of Geneva (HUG). In 2021, this center responded to 115,000 emergency calls from the entire region of Geneva (500,000 inhabitants and 120,000 cross-border commuters). Paramedics (50% of the team) or certified nurses (the other 50%) take calls, assess situations and patients, dispatch ambulances and other rescue teams, and assist callers in performing rescue procedures. Geneva's emergency medical system is a 2-tier (or 3-tier) system, with the paramedic ambulance as the first tier and an emergency physician as the second tier. The third level consists of a senior specialist physician. In addition to these professional teams, the center can dispatch volunteer first responders for OHCAs or choking situations. A "Save a Life" first responder community was created in 2019, which currently consists of 1500 people, who are notified by an alarm app (Momentum [DOS Group]). Sending instant notification to these first responders is extremely simple (with the push of a button) in the computerized aid dispatch system used by the dispatchers. These first responders usually arrive between 2 and 4 minutes before a paramedic ambulance.

Materials

Overview

The videos used during the experimentation come from SARA, an app developed by The Paris Fire Brigade in 2017. It consists of a smartphone or web application and a back office for the dispatch center. Dispatchers can transmit 1 of the 8 videos demonstrating life-saving techniques CPR and Heimlich maneuver, etc to the bystander. The first aid applications allow acting on the situation only when the volunteer arrives at the site, whereas SARA videos launch an initial relay of information with the calling witness. As the living lab is a living project that evolves based on the needs of the end users (in this case, citizens and dispatchers), choosing a flexible and diversified application was important and appealing to us.

InstantView is a web application that allows the dispatcher to see the patient and the environment through the caller's smartphone camera. The dispatcher sends a URL via SMS text message, and when the caller selects this link, the smartphone camera is activated. If the bystander has called the EMCC with the same phone as the one the link was sent to, there is no interruption in the audio communication. The video stream is simply added via data exchange (Wi-Fi, 4G, or 5G). Once the connection is established, the InstantView platform can also allow for documents or demonstration videos to be broadcasted on the smartphone that is connected directly to the EMCC's dispatcher. In light of this innovative context, this is a mixed methods study, which is divided into 3 parts, the first being a comprehension study, followed by 2 experiments (a pretest and living lab). The sequence of the steps is outlined in Figure 1.

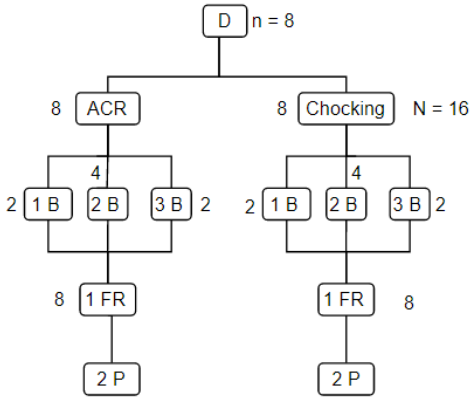
Population

In the first study, there were 5 participants: 2 (40%) dispatchers, 1 (20%) dispatch coordinator, 1 (20%) assistant dispatcher, and 1 (20%) physician. Our objective was to obtain an overall view of the stakeholders at the center. We solicited the individuals currently working in the dispatch center and interviewed them on a volunteer basis. For the second study, we recruited 23 participants: 6 (26%) citizens, 2 (9%) dispatchers, 5 (22%) first responders, and 10 (43%) paramedics, distributed as shown in Figure 2.



The citizens were solicited via the Geneva Association of Partner Patients, which is a network of former hospital patients who have registered as volunteers to participate in studies conducted at the HUG. There were no exclusion criteria in this study. The regulators were the volunteer regulators working on that day. As this study was planned within the context of the National Heart Day, jointly organized by the HUG, the ambulance service, and the Save a Life Association, we previously solicited first responders and ambulance attendants to participate in the simulations if they were interested. Concerning the third study, the distribution of participants was planned as shown in Figure 3. We were able to reach 34 citizens via the ads in social networks of the Geneva hospitals. Citizens who wanted to participate in a simulation were invited to register via the web. Those who received first aid training in the past 5 years and those were a health care professional were excluded from the study. We set a minimum threshold of 30 participants in congruence with studies on qualitative methods demonstrating saturation (the absence of contribution of new elements) beyond this number [45,46]. Of the 22 participants we recruited on a voluntary basis, 8 (36%) were dispatchers (each dispatcher carried out 2 simulations), 8 (36%) were first responders, and 6 (27%) were ambulance attendants.

Figure 3. Participant distribution in study 3. ACR: cardiac arrest; B: citizens; D: dispatchers; FR: first responders; P: paramedics.

Methodological Approaches and Data Collection

For the exploratory study, we constructed a semistructured interview guide that allowed us to collect the following information:

1. Description of the current procedure of a cardiac arrest call (eg, "Can you describe how a call is taken?")
2. Perceived benefits of and barriers to using an app to send emergency actions (eg, "In what situation do you think it would be beneficial to use SARA?")
3. Dispatcher needs (eg, "Would there be any other apps that you perceive as useful? Why?")

We conducted 5 interviews (with a mean duration of 24.14, SD 6.05 minutes).

During the pretest, 1 scenario was tested: "You find a 60-year-old unconscious man in Chaumettes Park. You call 144 and follow the instructions the dispatcher gives you." The dispatcher assesses the patient via audio communication. The patient turns out to be in cardiac arrest and the dispatcher sends the relevant demonstration video via SARA. The dispatcher then asks the participants to perform CPR on the mannequin until the paramedics arrive (8 minutes in the Geneva region). Save-a-Life first responders join the participant around the 6-minute mark.

The living lab tests 2 scenarios:

1. "You find a 60-year-old unconscious man. You call 144 and follow the instructions the dispatcher gives you." A live video feed allows for the assessment of the patient (Urgentime). Once the dispatcher diagnoses the patient as having a cardiac arrest, he sends the SARA recorded video demonstration of CPR. Participants start to perform CPR on the mannequin until the arrival of the ambulance (8 minutes in the Geneva region). Save-a-Life first responders join the participant around the 6-minute mark. Overall, 8 situations are performed with 1 participant and 8 with 2 participants.
2. "You encounter a panicked person with an infant who appears to be choking. You call 144 and follow the instructions the dispatcher gives you." A live video feed allows for the assessment of the patient (Urgentime). The dispatcher determines that the infant is experiencing sudden airway obstruction. The dispatcher sends the recorded video demonstration of the Mofenson maneuver. The participants are invited to perform the maneuver until the child cries (responsive mannequin) or until the situation deteriorates into cardiac arrest (2 out of 8 situations). Overall, 8 situations are performed with 1 participant and 8 with 2 participants.

All simulations were filmed and recorded in an audio format.

Collective elicitation interviews were conducted after each simulation with the respective participants (for approximately 24 minutes). Elicitation interviews [47] are an interview technique aiming for the interviewee to focus on their experiences and feelings during a particular event. The interviewer aims on deepening the lived experience and sensations while avoiding questions that lead to a rationalization of discourse [47,48]. This technique can be used with a single person or a group [43].

We built an interview guide that allowed us to collect the following details:

1. Feelings related to the use of the applications: benefits, constraints, and perceived helping elements (eg, the citizen was asked, "When you received the SARA video, how did you feel?")
2. Subjective contributions of the method: perceived contributions in terms of learning, understanding of the course of an action, and feeling of community (eg, the dispatcher was asked, "Did the simulation make you aware of elements that you had not perceived until then?")

Throughout the construction process of the living lab, an artist follows the preparatory meetings between researchers and stakeholders and collects information on how the living lab evolves based on the results of the preliminary experiment. They contribute to the added value by proposing to photograph a particularly crucial scenes coconstructed with the participants during the living lab.

Data Analysis

First, we transcribed all the audio recordings (interviews and debriefings), which allowed us to obtain a corpus for our studies 1, 2, and 3. In the filmed sequences (studies 2 and 3), we also recorded the times from the moment the dispatcher picked up the phone, including the recognition of the cardiac arrest, implementation of the emergency procedures, transmission of

XSL•FO
RenderX

the video, and reception of the video. We then compared our data with those from the literature. We also noted the number of times the applications were not successful. We then categorized the different simulations into action sequences (discovery of the individual in need of emergency care, call for help, 144 call, evaluation of the individual's condition, implementation of gestures, arrival of the first responder, implementation of the defibrillator, and arrival of the paramedics) to compare the situations among them in terms of actions carried out (observations) and feelings (debriefings). Second, we performed a thematic analysis using ATLAS.ti (version 8.1; ATLAS.ti Scientific Software Development GmbH) on our corpus. Thematic analysis is a method that "consists of systematically identifying, grouping and, subsidiarily, examining the discourse of the themes addressed in a corpus" [49] by categorizing the verbatim accounts according to the themes of the QRs. Thus, for study 1, we had 3 main themes (OHCA procedure, interest in and obstacles to using SARA, and the need for regulators), which we were able to divide into subthemes (eg, for the OHCA procedure: an evaluation procedure, a procedure for implementing the gestures, and difficulties mentioned). Likewise, for study 2, we had 3 themes: the impact of SARA on care (with the subthemes difficulties, obstacles, and benefits mentioned), the benefits for the community (with the subthemes learning, awareness, and confidence), and the subjective evaluation of the method (with subthemes obstacles mentioned, bias, and elements to be modified). Finally, for study 3 as well, we had 3 themes: impacts of the applications (with subthemes SARA, InstantView, feelings related to use, and evoked benefits), evoked benefits of the method (confrontation with reality, training, feeling of federation, and discovery of the chain of survival), and subjective evaluation of the method (with the same subthemes as those of the study 2 counterpart). This categorization into subthemes allowed us to link the sequences of actions and the related feelings to understand which elements allowed for a positive feeling and which ones were more of an obstacle. Finally, for studies 2 and 3, we used the times we recorded to evaluate the reliability of the applications and their temporal impact. For quantitative analysis, we used Microsoft Excel (version 2016; Microsoft Corp).

Ethical Considerations

We provided a document to all the participants explaining that we were collecting data (photographic, audio, and video) as part of the research and that these data would be used only to analyze the process and as support for scientific presentations. At the beginning of the session, all the participants were asked to read and then sign the consent forms or indicate their opposition before the experiment. The analysis and presentation of the data and their results are anonymized (participants are identified using a coding system). The compensation offered was 1 hour of free training in first aid and emergency procedures by certified professionals. Each participant signed a General Data Protection Regulation consent form, providing permission for audio and video recording and the use of the recordings for research purposes.

Results

In this section, we present the results of the first 2 phases and elaborate on the results expected from the living lab.

Understanding Study

According to the physician who participated in our study, approximately 2 cardiac arrests occur each day in Geneva, 33% of which are in public areas (streets, public transport, etc). With cardiac arrest being first priority, the dispatcher has 90 seconds to send resources from the moment the telephone call starts. An automated cardiac arrest procedure appears when the dispatcher completes gathering the information related to the patient's condition, which is done according to a specific process. Currently, dispatchers can assess the patient via a video feed (Urgentime) or an audio phone call. First, they must obtain the patient's location and then assess their state of consciousness and breathing. If the patient is unconscious and if there is a breathing anomaly (or not), the dispatcher sends an ambulance as first priority, then sends a first responder via the Save-a-Life button, and helps the bystander perform CPR.

It appeared throughout the interviews that asking the bystander to perform CPR is a difficult task for the dispatchers. They described witnesses who were not always willing to come close to the patient during the assessment phase, "even to put their hand on the stomach [to check for breathing]." They specified that the bystander often does not perform CPR because they do not want to take responsibility for the action, and they are frightened.

When asked about the use of SARA videos, the dispatchers expressed that they would need the videos to be integrated directly into the computer-aided dispatch system to avoid going to a separate computer for the video. They also raised concerns about the target population of the application; individuals having a cardiac arrest and older adults are more likely to be at home. Nevertheless, they believed that the CPR video offered a benefit and could be an asset in motivating some hesitant witnesses. Dispatchers also expressed a need to be able to receive video feedback to "keep the connection with the caller." They could gain more insight into the bystander's actions: "you can see the CPR being performed and guide it further" and identify potential mistakes in the execution of CPR. "We think people understand and at the end of the day, what is done in reality may not look so good."

Preliminary Study

The dispatchers recognized the cardiac arrests in 1 minute and 9 seconds, 1 minute and 32 seconds, 1 minute and 21 seconds, 2 minute and 51 seconds, and 1 minute and 56 seconds after picking up the call. The video was described as "useful," "a good input," and "stimulating" by 83% (5/6) of the participants. Overall, they identified 2 advantages of using a video during CPR: a better posture and more accurate performance of CPR. The participants also valued having a sound that signaled each compression to perform. Thus, it was easier for them to follow the right chest compression rhythm compared with if they were alone. It aided the participants to synchronize with the video and follow the "right rhythm."

XSL•FO
RenderX

Early feedback shows that the video had a reassuring effect on the participants emotionally affected by the situation: “emotionally it is quite strong, we imagine the person lying down.” As the dispatchers hinted during the exploratory study, the video does help initiate a massage in cases of hesitation by the witness. It also seems to reassure the bystander regarding the gestures they perform: “I was glad that I could have a link, to be able to see it, it made me feel secure.” Finally, the video provides comfort through words of support: “I felt more like I was getting good support, even encouragement to keep doing well.” The dispatchers also found that sending the video was reassuring: “the fact that they are watching, they are going to correct themselves and for us it is reassuring.” They also sensed more “serene” and “reassured” witnesses on the phone. However, in the subsequent interview with the dispatchers, they actually described being “falsely reassured” because they were ultimately unsure whether CPR was being performed or not, and the fact that they were sending the video prevented them from providing voice guidance over the phone. The simulations also allowed all the stakeholders within the survival chain to interact and collaborate. In contrast to what appears in the literature, professionals (first responders, paramedics, and dispatchers) did not consider the witness to be an obstacle but rather an additional resource to accomplish an essential act. A first respondent told us, “I have other skills; I will let the bystander do the massage.” The bystander can also maintain the link established with the emergency services “By the time the ambulance arrives, you start to get tired and being able to have someone who has a contact with the professionals, even psychologically, helps.” The bystander is, therefore, an additional resource that enables a more optimal distribution of the tasks carried out (a relay for compressions, placing the defibrillator patches, etc). However, both the first responder and the dispatcher must have confidence in the bystander to delegate. The first respondent obtains this trust based on whether the witness appears to be active, calm, and focused. As for the dispatchers, confidence is based on the witness’s ability to understand and respond. The simulation also led some participants to gain a better understanding of the regulation process. This could help prevent frustration in the future. For example, 5% (2/10) of the participants did not understand why they should not act immediately. The joint debriefing gave the dispatchers the opportunity to explain this process.

One of the first obstacles to consider are technical difficulties, as they increase the response time. When fully functional, as in simulation 1, the app enabled cardiac massage to begin within 3 minutes and 15 seconds. However, dispatchers stated that they were unsure whether they saved any time compared with audio guidance. In addition, as the application is still at the prototype stage, its stability is uncertain, and the transmission of video is not always optimal in terms of time or quality. We also chose to give all the participants the same “standardized” cell phone to avoid any differences in participants’ personal phones. However, this led to 2 problems: the difficulty in handling a new phone in an emergency and a very low output sound. Dealing with a phone that was not their own was described as an additional challenge, and even stressful, as the participants were not always able to identify where the speaker was located and where to go to get the SMS text message to open the video or web application on the phone loaned for the test. In a real emergency situation, it can be more complex to perform these simple gestures on one’s own phone; we can assume that the fact that they were given a new phone accentuated these confusing effects. Sound-related problems further negatively affected the handling of the patient. The participants also reported experiencing trouble hearing the instructions given by the dispatcher. As a result, the dispatcher sometimes had to repeat the instructions several times, and in some cases, the participants were unable to understand the action to be performed (especially in the evaluation phase). These elements led to a deterioration of the relationship between the dispatcher and the participant, as they prevented a proper establishment of communication. This can result in a feeling of isolation on both sides.

Results Expected From the Living Lab

The expected results for the practitioner are oriented toward a better handling of the patient by the bystander, both in terms of time and performance of the emergency procedures. For this purpose, a comparison will be made between OHCA and FBAO control situations (audio tapes of real situations) and simulations to understand whether the video saves time during the assessment of the patient’s condition (Urgentime) and the execution of first aid actions (SARA). A comparison of 1-witness situations with 2-witness situations will also be carried out to determine the most appropriate context for using videos. Therefore, we expect the situation to be easier to manage when there are 2 witnesses (one holding the phone and the other performing first aid). In addition, we will evaluate whether the use of live video and demonstration video can reassure the witness and possibly convince them if they are hesitant to perform emergency actions. Finally, we will evaluate whether the use of 2 functionalities (live video and demonstration video) leads to cognitive overload for the dispatcher.

As in the preliminary study, we expect that the shared experiences (simulations, debriefing, and artistic staging) would allow both populations to exchange and learn to collaborate. We expect effects in terms of knowledge transfer, mainly a better understanding of emergency procedures among the participants, and that enhancing communication (with videos) lead to better and faster trust building among the stakeholders. Analyzing the debriefings and the construction of the restaging process provide insights into the key elements for the participants as well as clues for future living lab–focused activities.

As in the previous study, the stakeholders will review and analyze the challenges encountered to facilitate the replication of the living lab tool kit in other emergency dispatch centers. In addition, they will assess the direct benefits (expected) and the secondary benefits (reported by the participants, but not anticipated).

Discussion

Overview

We collected results in 3 areas: practitioner, community development and method insights. The first area provided us

XSL•FO
RenderX

subjective elements for understanding the effects of the inclusion of a video on the early treatment of a patient by a bystander. We were interested in understanding the effects on the experience of the different stakeholders, in particular, on the dispatchers. The second area focused on gathering evidence on whether the simulation developed a sense of community and collaboration among the participants. Finally, the third highlighted the contributions of the living lab methodology in terms of learning and confrontation with reality.

Principal Findings

Regarding the use of applications, the main results involve the identification of the dispatcher's feelings when using an application to help with emergency procedures. Indeed, they expressed that they felt substituted by the application because it took precedence over them, allowing them to neither follow the patient's treatment nor realize that there was a need to restart the guidance on the cardiac massage when there was a technical failure. From a community perspective, we found that all the stakeholders were willing to work together and that there was no reluctance on the part of dispatchers, paramedics, or first responders to work together. Citizens are seen as members of the chain of survival. Regarding the methodological aspect, we found that the approach is flexible and allows for the adaptation of scenarios according to new inputs from the previous steps. Consequently, we were able to integrate the needs of the regulators (feedback) and address the identified constraints. At this stage, the main results concern the fact that the simulation allows us to apprehend difficulties beyond those addressed; it allows us to identify the constraints of internal procedures or the effect of having 3 different tools simultaneously. This advantage is a result of the inclusion of all the stakeholders to ensure that the simulation resembles the reality as closely as possible. It could not have been detected in simulations with a single citizen and a dummy.

Comparison With Prior Work

The dispatchers expressed a strong interest in using a video feedback app to gain visibility of the situation and of CPR guidance, which is consistent with the literature reviewed [28,29]. Since the time this study was carried out, the central office has implemented the Urgentime app, which allows this video feedback. InstantView achieved results similar to those described for the GoodSAM app in the literature [30,31]. The app reaches a reliability of 80%, and allows the dispatcher to recover the view and facilitates the evaluation and guidance. In this setting, we coupled SARA (video demonstration) and InstantView (visual feedback), which has never been done before to our knowledge. The dispatchers showed an interest in testing an application that would allow them to send demonstrations of emergency procedures, as they admitted finding it difficult to convince a bystander to perform CPR just by guiding them via audio calls. Indeed, in the preliminary study, one reluctant bystander performed CPR because he felt "reassured" by the video. Research indicates that a demonstration video can improve CPR quality in terms of the rhythm, number, and depth of the compressions; reduction of interruptions; and accuracy of one's hand placement [32-36]. The depth and number of compressions could not be assessed in the preliminary study. However, when the participants followed the video, a more adequate and sustained rhythm was observed (owing to the rhythmic sound they heard), and their posture was more adequate (by mimicking the expert they saw). To conclude this section, we would like to highlight that a high level of investment is made by the EMCC in the deployment of all possible technological (Save a Life, SARA, and Urgentime) and human resources to improve the handling of cardiac arrests in line with recent European and international recommendations [2-4]. Researchers point out 3 main reasons behind the limited reliance on bystanders in emergency situations: citizens' fear of taking any action [18-20], professionals' mistrust toward them [21-24], and the absence of any prior collaboration [22,25]. Although the dispatchers confirmed this fear of action on the part of citizens during the exploratory study, the results of the preliminary study did not show this element. Some participants expressed that they were intimidated by the situation but felt reassured by the dispatcher's assistance. The dispatchers and first responders never reported any reluctance to rely on a bystander, in contrast to the literature. Furthermore, health professionals have developed skills to quickly assess whether the witness present can be a trustworthy relay. For first responders, it is a matter of seeing an active, calm, and focused person on the task. For the dispatcher, this consists of evaluating how the individual understands and responds to their questions while assessing the patient's condition. Within this short period to recognize cardiac arrest and start CPR, which, in Geneva, is limited to 90 seconds, the dispatcher already knows whether they are communicating with a reliable bystander. Throughout the preparation of the living labs, it became apparent that adapting to the needs of the different stakeholders was crucial to come as close to reality as possible and to try to secure a better commitment from the participants [40,41]. Initially, the end users selected for living labs were only dispatchers and citizens. However, during the exploratory study, we became aware that the Geneva EMCC was working closely with the first responder application Save a Life. Consequently, first responders were integrated into the simulations to remain as close as possible to a real-life cardiac arrest in the Geneva region, where first responders would be alerted. This highlights how the living lab is built upon a preexisting territory and is constantly evolving according to the feedback provided by, difficulties encountered by, and needs and expectations of the stakeholders. Regarding experiential learning [44], we found that the simulations provoked strong emotions in the participants, which is a prerequisite for this learning to occur. We also found that the debriefings were a space to exchange new knowledge with the bystanders, potentially facilitating future collaboration [40,42]. To evaluate the retention rate of knowledge, we will conduct a debriefing with the participants in 6 months.

Strengths

The main strength of these studies is the adoption of a perspective that allows the comprehension of emotions and subjective evaluation of the impact of the applications and of the methods used among the various stakeholders. This perspective makes it possible to document aspects that were not previously addressed. In particular, it allowed us to discover

XSL•FO
RenderX

that the use of applications provoked uncertainty in the dispatcher, an aspect that had not been detected in the simulations in the other studies mentioned in the literature. The integration of all the actors of the survival chain can potentially have a concrete effect on the real care provided in Geneva, as it enables the community to gain a better understanding of each other and to collaborate more efficiently. The aims of our studies are to not only evaluate an application in technical terms but also use the experiments as a pathway to work on the development of collaboration.

Limitations

The main limitation of this study is that the pretest was conducted in the context of National Heart Day, so the citizen volunteers were all sensitive to the issue, and none of them refused to perform cardiac massage. Moreover, the fact that it was only the dispatchers who wanted to participate biased the results because we could not know the possible resistance to using this application. Finally, to achieve broader community development, ongoing sessions of a regular living lab is required with various communities; however, this process is costly in terms of time and investment from all the stakeholders, making it difficult to implemented to be on a large scale.

Abstract

Background: Social and behavioral determinants of health are increasingly recognized as central to effective person-centered intervention in clinical practice, disease management, and public health. Accordingly, social prescribing (SP) has received increased attention in recent times. The rampant global prevalence of obesity indicates that the customary, reductionistic, and disease-oriented biomedical approach to health service delivery is inadequate/ineffective at arresting the spread and mitigating the damaging consequences of the condition. There is an urgent need to shift the focus from reactive downstream disease-based treatments to more proactive, upstream, preventive action. In essence, this requires more effort to affect the paradigm shift from the traditional “biomedical approach of care” to a “biopsychosocial model” required to arrest the increasing prevalence of obesity. To this end, an SP approach, anchored in systems thinking, could be an effective means of moderating prevalence and consequences of obesity at a community level.

Objective: The proposed SP intervention has the following three key objectives: (1) build a sustainable program for Circular Head based on SP, peer education, and health screening to minimize the incidence of obesity and related lifestyle diseases; (2) increase service and workforce connectivity and collaboration and initiate the introduction of new services and activities for obesity prevention and community health promotion; and (3) enhance health and well-being and minimize preventable adverse health outcomes of obesity and related lifestyle diseases through enhancement of food literacy and better nutrition, enhancement of physical literacy and habitual personal activity levels, and improvement of mental health, community connectedness, and reduction of social isolation.

Methods: This paper describes a prospective SP strategy aimed at obesity prevention in Circular Head, a local government area in Northwest (NW) Tasmania. SP is a prominent strategy used in the Critical Age Periods Impacting the Trajectory of Obesogenic Lifestyles Project, which is an initiative based in NW Tasmania focused on assessing obesity prevention capacity. A social prescription model that facilitates the linkage of primary health screening with essential health care, education, and community resources through a dedicated “navigator” will be implemented. Four interlinked work packages will be implemented as part of the initial plan with each either building on existing resources or developing new initiatives.

Results: A multimethod approach to triangulate insights from quantitative and qualitative research that enables the assessment of impact on individuals, community groups, and the health care system will be implemented within the initial pilot phase of the project.

XSL•FO
RenderX

Conclusions: Literature is replete with rhetoric advocating complex system approaches to curtail obesity. However, real-life examples of whole-of-systems interventions operationalized in ways that generate relevant evidence or effective policies are rare. The diverse approach for primary prevention of obesity-related lifestyle diseases and strategies for improvement of health and well-being described in this instance will contribute toward closing this evidence gap.

Introduction

Despite the absence of a widely accepted definition, social prescribing (SP) generally refers to the enablement of health care professionals to refer a patient or client to a social prescriber (eg, link worker, community connector, community navigator, health coach, health trainer, and so on). The social prescriber is responsible for the co-design of interventions to improve the individual's health and well-being [1]. Once seldom acknowledged, or at best, paid "lip service," social and behavioral determinants of health are now becoming increasingly more recognized as centrally critical to the provision of effective person-centered intervention in clinical practice and disease management [2]. Accordingly, a spate of SP-based interventions have been reported in recent times, including those from the United Kingdom and Americas [3], Scandinavia [4], and Australia [5,6]. Despite a paucity of definitive evidence regarding SP, benefits cited include improvements in health behaviors, mental health, and reductions in the use of tertiary care facilities for lifestyle diseases [1,7-10].

Obesity, one of the more prominent contemporary lifestyle-related diseases, has reached pandemic proportions globally and shows no signs of abating [11,12]. Consistent with global trends, the prevalence of obesity in Australia has increased in the past few decades, with 63.4% of adults and 27.6% of children with overweight and obesity in 2014-2015 [13]. If left unchecked, adult obesity and rates of severe obesity in Australia are predicted to reach 35% and 13%, respectively, by 2025 [14]. A further complication is that people living in geographically remote parts of Australia have a disproportionately higher prevalence of obesity. For instance, adults from regional (1.53 times higher) and rural areas (1.32 times higher) were more likely to have obesity than their counterparts from major city or urban areas [15]. Obesity also disproportionately affects low socioeconomic communities with a greater disease burden [16]. Tasmania, as a regional state with low socioeconomic status, has some of the highest rates of adult and childhood obesity and requires urgent intervention.

The rampant global prevalence of obesity is also an indication that the prevailing, disease-oriented biomedical approach to health service delivery is inadequate/ineffective at arresting the spread and mitigating the damaging consequences of the condition [17]. There is an urgent need to shift the focus from reactive disease-based treatments to incorporate some consideration of how individuals and communities are influenced by a growing global, regional, and local interdependence and an increasingly complex array of interlinking factors. Accordingly, more proactive, upstream, preventive efforts, and action to improve health and reduce obesogenic factors are required to arrest the increasing prevalence of obesity [18]. In essence, this requires a paradigm shift from the traditional "biomedical approach of care," wherein the cause of illness is primarily thought to reside in the body, to a "biopsychosocial model," which provides a basis for understanding the broader determinants of disease to arrive at treatment and service response plans [19].

Recent evidence from whole-of-community approaches anchored in systems science principles holds some promise in denting the harmful impact of obesity [20-22]. Dynamic systems theory posits that biological, social, and contextual factors interact in dynamic ways to influence health and participation across the lifespan [18]. Bronfenbrenner person-centered ecological framework allows the varied interactive interpersonal dynamics that influence development (and therefore health and obesity) to be examined [23]. At the center of the system, the individual brings their own unique characteristics, such as their age, genetics, life experiences, temperament, and coping strategies, and other familial, social, economic, and political layers of influence that sit around them [23]. Fundamentally, effective whole-of-system approaches are not limited by predefined agendas; instead, they are reliant on localized community input for context-specific, holistic, preventive work that acknowledges the synergistic interaction of a myriad of biological, social, economic, and environmental factors [24]. This approach has a commonality with effective SP interventions [25]. Following this logic, a community-driven SP approach could be just as effective in obesity prevention as any other initiative anchored in systems thinking. Herein, we discuss an SP protocol aimed at obesity prevention in Circular Head, a local government area (LGA) in Northwest (NW) Tasmania.

Methods

Ethical Considerations

Ethics approval was obtained for all procedures from the Human Research Ethics Committee (Tasmania) Network (H001864) and will be implemented in accordance with relevant guidelines and regulations stipulated in the Declaration of Helsinki. Both written and verbal consent (where practicable) will be obtained from all participants. This work was funded by a National Health and Medical Research Council (NHMRC) grant as part of the Critical Age Periods Impacting the Trajectory of Obesogenic

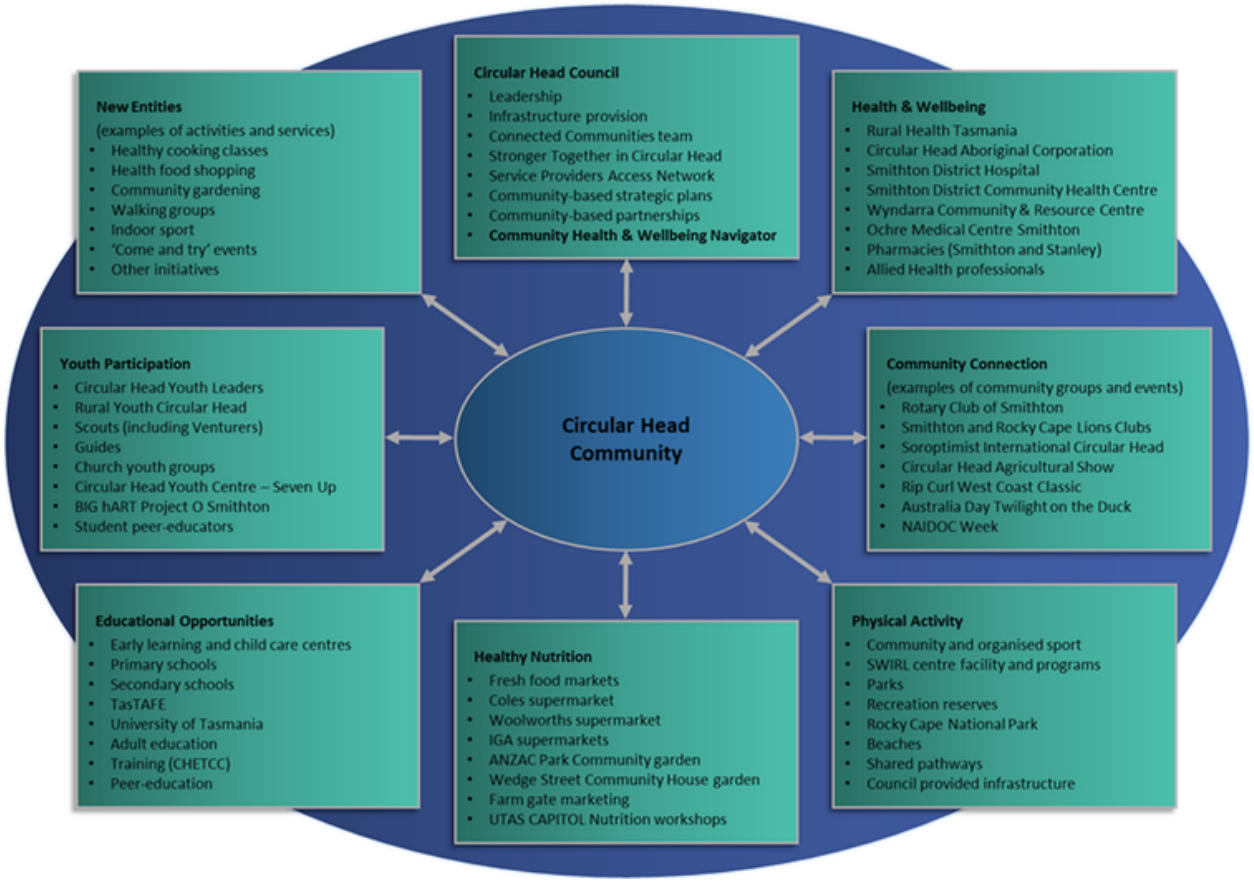
Lifestyles (CAPITOL) Project. The study funder had no role in study design, collection, analysis, or interpretation of the data, in writing the report, or in the decision to submit the article for publication. The contents of this article are the responsibility of the authors and do not reflect the views of the NHMRC.

Setting: CAPITOL Project NW Tasmania

The CAPITOL Project is a community-based "systems thinking" initiative based in the NW with an intentional focus on assessing obesity prevention capacity (OPC), engaging the community in developing OPC, and evaluating OPC development efforts. The central tenet of this work acknowledges the sustained multidisciplinary collaborations required to manage lifestyle risk factors, including nutrition, physical inactivity, smoking, and mental health, which can either be a cause or a consequence of excess adiposity. While NW Tasmania represents an expansive land mass, for reasons of practicality, the CAPITOL project operations are limited to 3 sentinel sites (Burnie, Circular Head, and Devonport). Sentinel sites are communities from which in-depth data can be collected, which has a high degree of transferability [26].

The current health profile of NW Tasmania, combined with its predominantly rural, geographically dispersed and socioeconomically disadvantaged population, is a hotbed for the proliferation of lifestyle-related disease. By virtue, the region also has a high demand/need for health promotion [27,28]. Nonetheless, the existing preventive health system in the region is underdeveloped and underresourced, which compounds existing health issues and stymies the progress of well-intentioned preventive efforts [29]. In addition to the lack of resourcing, the predominant narrative in the region has traditionally been a deficit-based view of health. To help circumvent these challenges, the holistic systems design of the CAPITOL Project is focused on asset-based community development alongside a primary prevention focus (ie, keeping healthy people healthy) with heightened attention on critical life stages (ie, mothers, infants, children, adolescents, and so on).



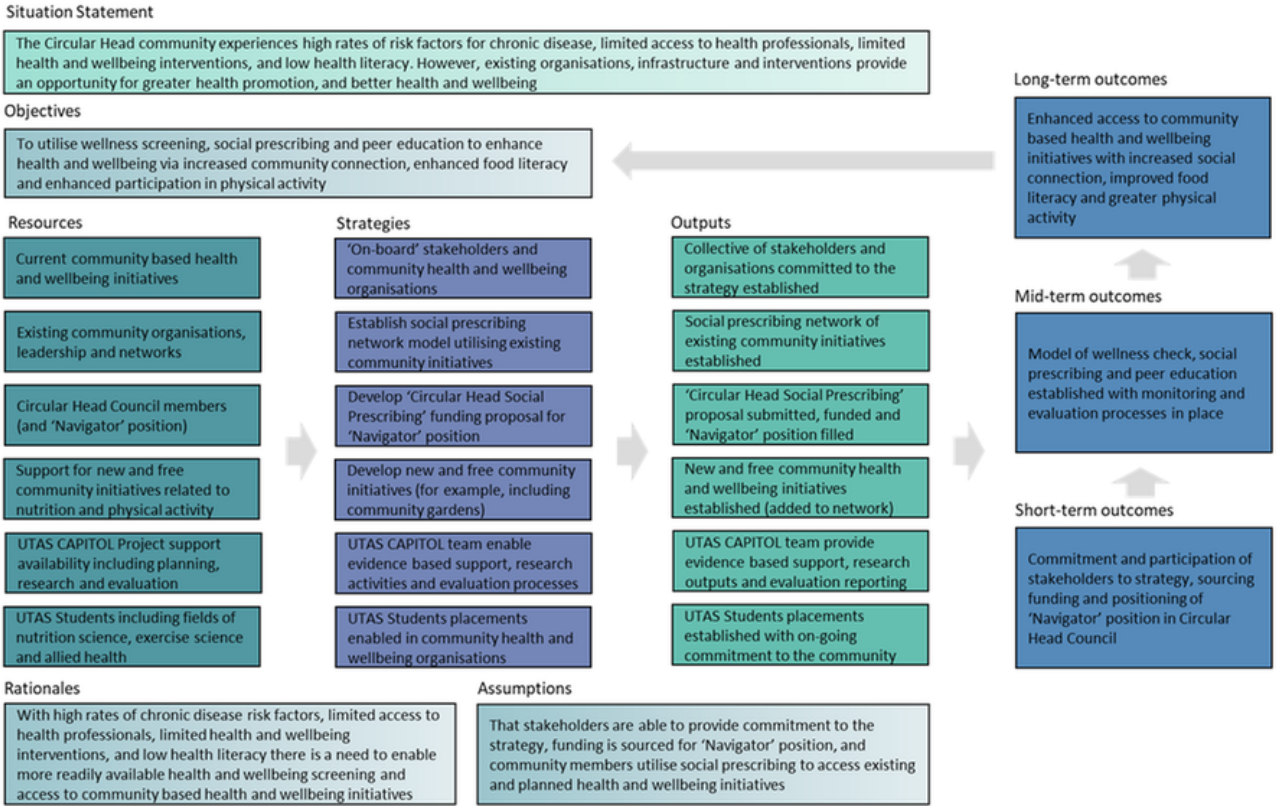
Context: Circular Head

Consistent with other socioeconomically disadvantaged and remote areas, the Circular Head community displays an elevated prevalence of "risk factors" that contribute to adverse health and well-being outcomes. For instance, over 95% and 54% of the population does not meet the vegetable and fruit intake guidelines, respectively [30]. Further, one-fourth of the adult population do not take part in sufficient levels of moderate and vigorous physical activity (PA). Unfortunately, many of these risks are associated with the social determinants of health, including educational attainment, employment status, and housing conditions [31,32]. Low levels of health literacy, particularly in relation to food and PA, help to exacerbate the suboptimal health profile of the LGA (CAPITOL, unpublished data).

Poor access to health professionals, including in allied health, medicine, nursing, and midwifery, is also endemic in the area [33]. Recent situational analyses revealed significant shortages of general practitioners, specialists, dietitians, exercise physiologists, and physiotherapists in Circular Head. Many health professionals are itinerant with the community, frequently enduring long wait periods for health care, extensive travel to access health care, and poor availability and access to preventative health care options (CAPITOL, unpublished data). Despite the availability of a range of community and health services (Figure 1), there is also a perceived lack of preventive services and health promotion interventions in the region. While explanations for the shortcomings cited are manifold, primary reasons include poorer community engagement, a declining volunteer base, and adverse climatic conditions (CAPITOL, unpublished data).

XSL•FO
RenderX

Figure 1. Assets and strengths of Circular Head.



Objectives

Despite the challenges, the Circular Head region has many significant assets that, if utilized optimally, may enable and help sustain community-driven change (Figure 1). To maximize success, there is an urgent need to link existing strategies, networks, committees, infrastructure, community-based interventions, organizations, and partnerships (Figure 2). The harnessing of existing capacity requires buy-in and leadership from local government and service organizations in the community.

The proposed SP intervention has the following three key objectives: (1) to build a sustainable program for Circular Head based on SP, peer education, and health screening to minimize the incidence of obesity and related lifestyle diseases; (2) to increase service and workforce connectivity and collaboration and initiate the introduction of new services and activities for obesity prevention and community health promotion; and (3) to enhance health and well-being and minimize preventable adverse health outcomes of obesity and related lifestyle diseases in the Circular Head LGA through enhancement of food literacy and enabling better nutrition, enhancement of physical literacy and increasing habitual personal activity levels, and improvement of mental health through increased community connectedness and reduction of social isolation.

XSL•FO
RenderX

Figure 2. Circular Head social prescription logic model.

Strategy Mix

Theoretical Background

Historically, overcoming obesity has proven to be extremely challenging given the multifarious etiology of the condition, including individual and societal influences [34]. Prevention of contemporary lifestyle diseases, including obesity, requires multilevel, strategic, cross-sectoral, and systems-thinking solutions implemented in a practice environment supported by realist and capacity building approaches [35-41]. As such, all health promotion and the SP that derives from this research will be guided by realist principles, situated, and informed by evidence, and local context. The identification of context-mechanism-outcome configurations applicable to a variety of scenarios will be utilized to gather intel and explore causal mechanisms of the current lifestyle-related disease predicament in Circular Head.

Project Governance

The University of Tasmania (UTAS) will be the facilitating partner and legal entity responsible for this place-based project. The Circular Head Council will act as the intermediary organization along with key stakeholders to ensure place-based representation and insights. All procedures are informed by the specifications of the Human Research Ethics Committee (Tasmania) Network and will conform to the guidelines of the NHMRC's National Statement on Ethical Conduct in Human Research 2007 (updated 2018). To this end, both written and informed consent will be obtained from the participants where practicable. A project steering group (ie, Circular Head Health and Well-being Coalition) will be formed with the imprimatur of key place-based partners and composed of members from the wider stakeholder group. Key stakeholders will be identified in a process of individual stakeholder consultation and stakeholder identification (through purposive sampling using publicly accessible contact information and professional networks) in line with the methodology of the formative stage of the CAPITOL Project. Specifically, key stakeholders will be individuals living in the sentinel site with attributes including high levels of interest, influence, expertise, or community connection as evidenced by occupational position/role, social standing in the community, or as nominated by other stakeholders consulted in previous community consultations. Each step of the governance process will be structured to ensure that the voice of key stakeholders informs or guides the research and the interpretation of findings across each work package. The Circular Head Council will be responsible for oversight of the co-design, development, and implementation of the project, with accountability for outcomes and impacts intended to be shared by all parties involved.

Project Implementation

Overview

Overall, a social prescription model that facilitates the linkage of primary health screening with essential health care resources through a dedicated navigator will be implemented. Four (interlinked) main work packages will be implemented as part of the initial plan with each focus either building on existing resources or developing new initiatives (Figure 3). The opportunity to partake in this SP initiative will be open to all residents of the Circular Head LGA with recruitment exclusively based on convenience and snowballing. While the realist approach and the fluidity of study confines (as is typical for most SP interventions) renders precise a priori sample size

XSL•FO
RenderX

calculations nonviable, where practicable, we intend to recruit as many participants as needed to achieve meaningful outcomes. For instance, the upper limit of the sample size for focus groups will be based on the attainment of "theoretical saturation."

Figure 3. Social prescription model.

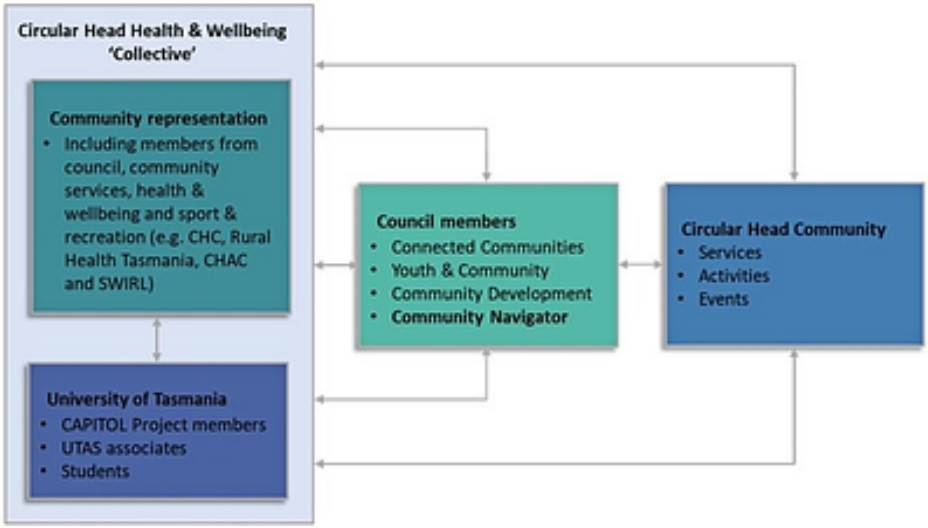
Health and Well-being "Checkup"

The primary aim of health and well-being "checkup" screening is to assist in the accurate identification and assessment of causative risk factors for poor health outcomes. This would involve regular community-level lifestyle screening at local events, workplaces, and sporting groups by qualified as well as trainee (eg, nutrition science, exercise science, nursing, and medical students) health care professionals. It is anticipated that these additional checkups will complement the extant visitations to health care professionals (eg, general practitioners, specialists, and allied health professionals), although they are not intended to replace any existing service. Overall, the checkups will initiate the SP referral process that will primarily be managed by a dedicated navigator.

Health and Well-being "Navigation"

Linking assessment and referral to community resources will be realized via a navigator or "link worker." As evidenced in literature to date, SP protocols in the past have utilized a wide array of (mostly) health workers for the navigation role [6]. Responsibilities of the link worker can be manifold and may include coproducing health goals and action plans, enabling of resident-health service and activity interaction, and providing feedback at multiple stakeholder levels. Existing evidence indicates that such roles have been particularly efficacious in disadvantaged communities where more intensive support is inherently required due to accentuated complexity of health challenges [42]. In this study, the navigator would be employed by the Circular Head LGA and act as the conduit between residents, health care services, and preventive activities.

Community "Education"



Peer education is the process of learning and sharing information with peers in the community and is a key strategic component to amplify health and well-being messaging. In this proposed work model, community educators are tasked with providing community outreach and incentivizing people to seek appropriate health information outside of traditional educational confines. Upskilling community volunteers and leaders would provide a source of community-based support and education for other components of the strategy. Specifically, a smorgasbord of group-based education sessions cofacilitated by project staff, generation of culturally and contextually appropriate education material, and the provision of appropriate technologies to provide information on nutrition and PA will be of central focus within this package. Working examples will be drawn from existing programs such as the Family Food Patch program which uses peer education to help improve health and well-being of Tasmanian children and families through promotion of healthy eating and PA.

New Health and Well-being Activities

This strategy entails the development of new nutrition, PA, and social connection activities to complement existing services and initiatives. A key component of this work model will include the establishment of the Circular Head Health and Well-being Coalition (Figure 4), which will provide guidance and direction for all co-designed health promotion activities within the SP framework. The basis of the coalition is entrenched in the legacy partnerships between the CAPITOL Project and the Circular Head Council and will be emboldened by further collaboration with community and service organizations, including Rural Health Tasmania, Circular Head Aboriginal Corporation, and the Smithton Well-being Indoor Recreation and Leisure center. While it is premature to confirm precise details about the potential activities in this SP initiative, extant literature highlights examples of multifarious "prescribing schemes" including arts, books, education, and exercise [43].

XSL•FO
RenderX

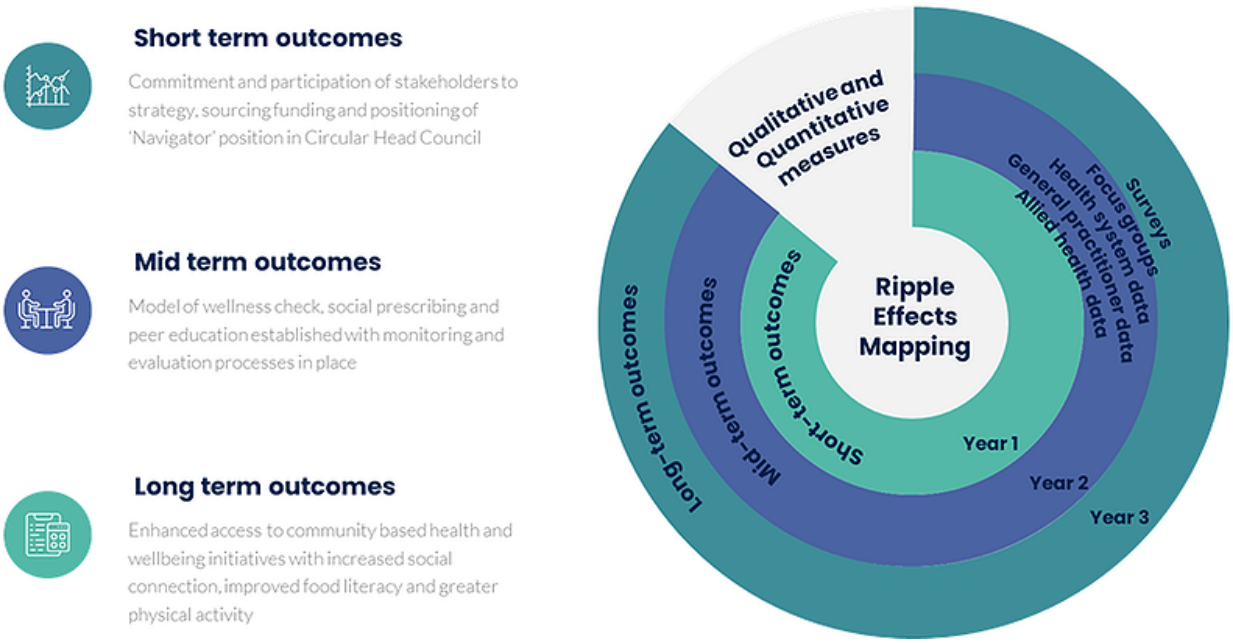


Figure 4. Organizational structure of the Health and Well-being Coalition.

Results

It is imperative that SP models undergo rigorous evaluation using systems science approaches and mixed methods research to ensure understanding of what worked, why it worked, and in what contexts. A multimethod approach to triangulate insights from quantitative and qualitative research that enables the assessment of impact on individuals, community groups, and the health care system will be implemented within the initial 3-year pilot phase of the project. For instance, a range of health and well-being and health care usage outcomes will be measured (Figure 5) to evaluate the efficacy of the SP program. Evaluation will include a review of implementation efforts, project impacts, plans for sustainability, and feedback from participants, educators, administrators, and stakeholders.

Figure 5. Summary of outcome and evaluation strategies. Notwithstanding the complexities of simultaneous measurement of numerous interlinked components of the systemwide SP initiative, a robust set of evaluative frameworks will be applied to all levels (development, formative and summative) and activities.

Given traditional evaluation tools are often ill-suited for co-design work in community settings, we intend to use a ripple effects mapping approach, a participatory technique to engage stakeholders in visually mapping project efforts and results to collect impact data [44]. Specifically, focus group techniques to work with participants to process and reflect on their lived experiences and collectively and visually map project efforts and results. We envisage that the use of mapping will trigger verbal responses, increase the frequency and depth of responses, and aid participants in recalling, organizing, and reflecting on experiences. It is intended that a series of modified nominal group technique (mNGT) consensus method group processes will be executed annually to evaluate progress. The core steps (silent generation, round robin, clarification, and voting [ranking and rating]) [45] of the mNGT approach will facilitate collaborative decision-making and, importantly, enhance equitable participation of stakeholders. Where possible, the progress of key components will also be compared against the

XSL•FO
RenderX

5 pillars (a common agenda, shared measurement systems, mutually reinforcing activities, continuous communication, and backbone support organizations) of the "collective impact" framework [46].

Exact details of the outcome measures will be decided in consultation with the community, as their suitability will be based on nature of referrals, prescribed activities, participant needs, and resourcing. Nevertheless, in line with the popular approaches in contemporary SP initiatives, it is envisaged that a mix of subjective well-being, quality of life, behavior change, physiological changes, frequency of health service access, medication usage, and development of social networks will be measured either quantitatively or qualitatively [43,47]. In addition, where practicable, the social return on investment will also be measured using contextually appropriate inputs [48,49].

Discussion

This proposal describes a diverse approach for primary prevention of obesity-related lifestyle diseases and strategy for improvement of future health and well-being in a remote and socioeconomically disadvantaged population. The SP approach anchored in systems thinking described above could be an effective means of moderating prevalence and consequences of obesity at a community level. Key focal points of this intervention include peer education, health screening, service accessibility, workforce connectivity, food literacy, better nutrition, physical literacy, habitual PA, mental health, social isolation, and community connectedness. The Circular Head Health and Well-being Coalition will be established to address health and well-being inequities affecting people in the region. This collective will be responsible for providing direction for the implementation of the whole-of-community Circular Head Health and Well-being Strategy, broadly based on principles of SP.

As per the global accord in contemporary times, Australia also has a health care system that has a treatment-oriented and reactive bias. For instance, the extant 31 Primary Health Networks of Australia that prioritize mental health, First Nation people's health, population health, health workforce, digital health, aged care, and alcohol/drugs are fundamentally designed for "commissioning of health services" for consumers with diagnosed conditions. Further, Australia is one of the lowest spenders on preventive health (~2 billion per annum; ~1.5% of the total health budget; ~US $89 per person every year) among the Organisation for Economic Co-operation and Development nations such as Canada, the United States, and New Zealand. This is despite public health research consistently indicating that most preventive health interventions are cost-effective (mainly through cost reductions in treating complex conditions), improve quality of life and longevity, and minimize the burden on the health care system as a whole [50]. Therefore, considering the urgency of obesity prevention and health intervention in Circular Head, the SP approach we describe is both timely and necessary.

The effectiveness of an SP initiative may also rely on the collective buy-in from the wider stakeholder group, including, most importantly, the community members. As such, consistent and frequent education regarding the nature and benefits of the program from inception to conclusion will be vital. Further, expansive networking and development of governance structures that entail strong leadership from all stakeholder groups is also of utmost importance. The whole-of-systems approach proposed in this research with SP as the central tenet is expected to address all of the above and improve community cohesion, social engagement, reciprocity in peer support, and community confidence in accessing pertinent resources for improving health and well-being outcomes. Community ownership of public health initiatives has shown significant promise in other settings [51-54], with a satisfactory compromise between community lived experience and contemporary scientific evidence being the key driver of success.

Translation of lifestyle disease–related research findings into sustainable practice is a public health priority. However, existing research indicates that this transition is largely ineffective due to limitations such as insufficient scaling-up for systemwide integration and lack of emphasis on the nonlinear and complex overlapping of various (development, implementation, sustainment, etc) program stages [55-57]. Much of the existing evidence base being underpinned by linear models of cause and effect is also exacerbating this issue. The whole-of-systems approach of the CAPITOL Project, along with 3 years of preliminary work [58-60] and early and frequent engagement of stakeholders in all aspects of project planning, is expected to elicit maximal translatory potential of the current SP initiative. Further, community-wide, representative consultation and equity in decision-making and agenda setting is also considered best practice in this line of intervention [53].

This proposed SP approach can have several limitations. Despite the potential benefits, a robust and generalizable protocol for satisfactory data collection and evaluation of any SP protocol will be challenging. For instance, given the inherent heterogeneity of designs in SP initiatives [61], it is not feasible to gain a wider consensus on the most appropriate outcome measures [62]. Further, nonlinearity of SP initiatives and the inevitability of multiple, fleeting, and intersecting components can also exacerbate this complexity [63]. Consequently, we posit that a realist approach, which acknowledges a set of context-specific outcomes (both biomedical and social determinants) of importance, will yield the most effective SP system in any given setting. As the outcomes will be reliant on local contextual factors, the generalizability of the findings will also be limited and might not be particularly applicable outside of the area under study. Further, any number of commonly reported practical challenges to generating evidence around SP, such as forging collaborative relationships while maintaining researcher independence, lack of a control group for outcome comparison, accuracy of health and social care service usage data, sustained resourcing, and consent and privacy matters, can also be relevant in this instance [64].

The need for complex processes and outcomes that drive change within a whole system and the necessity of doing away with linear approaches to mitigating complex public health issues has been echoed consistently in recent times [65]. Nevertheless, the practicalities of real-life implementation of whole-of systems approaches are ill-defined. This proposal describes a practicable

XSL•FO
RenderX

set of approaches for stakeholder engagement and community participation in uplifting health and well-being standards in a locality with poor socioeconomic and health outcomes.

The Tasmanian Charter of Health Rights and Responsibilities states the following:

> *When viewed as a partnership, the relationship between the health service consumer and the health service provider is more likely to benefit the health outcomes of the service consumer. While the health service provider has a responsibility to meet certain rights of the health service consumer, the consumer in turn, should also assume some responsibility for their own health care.*

The proposed SP initiative will provide a viable opportunity to the residents in Circular Head to have a real-life, at scale attempt to co-design a sustainable solution to their health and well-being challenges while inculcating democratic partnerships between all project members as collaborators through every stage of the project. Further, the proposed program will help to increase access to peer and other support workers able to assist community members to navigate the system and receive adequate, timely, and situational support—a need frequently highlighted in the region [66].

Acknowledgments

The authors would like to thank members of the Circular Head community for their ongoing engagement in this work.

Abstract

Background: According to the World Health Organization, approximately 15% of the global population is affected by mental health or substance use disorders. These conditions contribute significantly to the global disease burden, which has worsened because of the direct and indirect effects of COVID-19. In Mexico, a quarter of the population between the ages of 18 and 65 years who reside in urban areas present a mental health condition. The presence of a mental or substance abuse disorder is behind a significant percentage of suicidal behaviors in Mexico, where only 1 in 5 of those who have these disorders receive any treatment.

Objective: This study aims to develop, deploy, and evaluate a computational platform to support the early detection and intervention of mental and substance use disorders in secondary and high schools as well as primary care units. The platform also aims to facilitate monitoring, treatment, and epidemiological surveillance ultimately helping specialized health units at the secondary level of care.

Methods: The development and evaluation of the proposed computational platform will run during 3 stages. In stage 1, the identification of the functional and user requirements and the implementation of the modules to support the screening, follow-up, treatment, and epidemiological surveillance will be performed. In stage 2, the initial deployment of the screening module will be carried out in a set of secondary and high schools, as well as the deployment of the modules to support the follow-up, treatment, and epidemiological surveillance processes in primary and secondary care health units. In parallel, during stage 2, patient applications to support early interventions and continuous monitoring will also be developed. Finally, during stage 3, the deployment of the complete platform will be performed jointly with a quantitative and qualitative evaluation.

Results: The screening process has started, and 6 schools have been currently enrolled. As of February 2023, a total of 1501 students have undergone screening, and the referral of those students presenting a risk in mental health or substance use to primary care units has also started. The development, deployment, and evaluation of all the modules of the proposed platform are expected to be completed by late 2024.

Conclusions: The expected results of this study are to impact a better integration between the different levels of health care, from early detection to follow-up and epidemiological surveillance of mental and substance use disorders contributing to reducing the gap in the attention to these problems in the community.

Introduction

Background

According to the World Health Organization (WHO), health is not merely the absence of a disease, but it is a state of complete physical, mental, and social well-being [1]. Nevertheless, it is estimated that the number of individuals who have a mental disorder worldwide is approximately 792 million, representing 10.7% of the world population. This percentage is increased to 15% when individuals presenting conditions associated with substance abuse are considered [2]. The consequences of mental and substance use disorders are highly negative; in 2010, these disorders constituted 10.4% of the global burden of disease and were the leading cause of years lived with disability among all disease groups [3]. Moreover, these problems have been exacerbated because of the direct and indirect effects of COVID-19 as already evidenced in recent studies [4-8]. Mental and substance use disorders also produce high mortality rates. For example, major depression (the most prevalent mental disorder in the world population) is the main cause of the 800,000 suicides committed every year [9]. Other studies estimate 585,000 deaths only in 2017 associated with the addiction of different substances such as hepatitis C, liver cancer, or cirrhosis [10].

Mental health and substance use problems are also present in Mexico. According to the results obtained from the WHO World Mental Health Survey Initiative, one-fourth of Mexican respondents aged 18 to 65 years and residents in urban areas present with a mental health condition [11]. The most frequent mental disorder was anxiety, followed by other affective disorders such as depression and substance abuse. These results vary according to the sex of the individuals; men reported a more significant number of substance abuse disorders (particularly alcohol) than women. In contrast, women reported more frequent anxiety and affective disorders than men [12]. Similar to the worldwide statistics, in Mexico, the presence of a mental or substance abuse disorder is strongly associated with suicidal behaviors; about half of people with suicidal ideation (48.8%) and two-thirds (65.2%) of those who have tried it at least once have these types of disorders [13]. These percentages highlight the importance of detecting and treating these types of disorders, especially considering a growing trend in the suicide rate from 3.5 suicides per 100,000 inhabitants in the year 2000 to 5.2 in 2017, reaching a rate of 9.3 among the young population (20-24 years old), which represent the second cause of death in this population group [14].

Despite these statistics, mental health care and addiction prevention have been pending issues for public health for years in many countries, and unfortunately, Mexico is not the exception. Although 1 in 4 Mexicans have had a mental disorder at some point in their life, only 1 in 5 of those who have it receive any treatment [15]. Recent studies have revealed that the treatment gaps for severe mental disorders, severe to moderate mental disorders, and substance use disorders in Mexico and other countries across the Americas are 77.4%, 78.7%, and 83.7%, respectively. This gap in treatment is even greater in children and adolescents, reaching up to 86% in Mexico [16]. Some of the main causes of the lack of care for people with mental and substance use disorders in Mexico are the low percentage of resources invested; not enough psychiatric hospitalization units in general hospitals as well as specific services for children and adolescents; the lack of evaluation and treatment protocols for this type of disorder in primary care; and the low rate of psychiatrists, doctors, and psychologists per 100,000 inhabitants [15].

The Pan American Health Organization has proposed different strategies to reduce the gap in attention to mental health problems and addictions in the region. Some of these strategies include the development of national plans, policies, and laws on mental health; the promotion of mental health and the prevention of psychosocial disorders with an emphasis on children and adolescents; decentralization of outpatient mental health services; the need to develop and expand mental health care in primary care; and the need to strengthen the development of national mental health information systems [17]. For the specific case of Mexico, the gradual increase in health spending for mental health and the restructuring of its distribution mode has also been identified as vitally important. Additional recommended actions are strengthening mental health teaching in medical careers, maintaining continuous training for primary care personnel, and increasing society's participation in establishing solid links with the health sector [15].

Implementing these strategies must have an interinstitutional and multidisciplinary approach allowing for maximum efficiency and does not entirely leave the responsibility to the health sector. In this sense, information and communication technologies are a fundamental tool that would improve the current care model from the phases of detection, early intervention, and continuous monitoring of patients in the community to the creation of information systems for epidemiological surveillance. These computational tools would help in the decision-making and evaluation of the public policies implemented. These digital-based tools would also facilitate a smooth integration between the different levels of health care, offering timely and comprehensive care for people detected with mental health and substance use problems.

One of the main benefits of digital tools for the prevention and treatment of mental and substance use disorders is the increment of access to health care services due to the wide availability of, for example, web-based and mobile apps. Through these apps, adolescents and young adults can be more easily reached and intervened because they are familiar with new technologies or

XSL•FO
RenderX

are more technologically literate and mainly involved in using these digital solutions [18]. Examples of these digital solutions and their reported effectiveness can be found in different reviews for both mental health and substance use disorders (see, eg, [19-22]). Moreover, digital platforms also facilitate the screening of substance use disorders and subsequent referral of patients to specialized services [23], expanding and enhancing their treatment [24], or performing analysis for epidemiological studies and supporting clinical decision-making [25].

Objective

This protocol describes the implementation and evaluation of a computational platform to support the early detection and intervention of mental and substance use disorders at the scholar community level and in primary care units and facilitate monitoring, treatment, and epidemiological surveillance at the second level of care. Three specific objectives lead to the development of the computational platform:

1. Facilitate the early detection of symptoms and risk factors associated with mental and substance abuse disorders through a web-based module for the screening of symptoms and risk factors related to mental and substance abuse disorders in the scholar community.
2. Support the follow-up process and the surveillance of detected cases through the module to collect, process, and visualize the information of individuals screened and under treatment. Integrating the collected information from the screening, the first contact in primary care, and the treatment and follow-up provided at the secondary care level will optimize the whole care process of individuals with mental health and substance use disorders.
3. Support early interventions and the continuous monitoring of patients under treatment. These applications aim to prevent and minimize the appearance of risk behaviors or promote and motivate the change of these behaviors to maintain an adequate state of health.

Consortium

The development and evaluation of this computational platform is a collaborative effort between 4 institutions located in the state of Nayarit, Mexico. The Centre for Scientific Research and Higher Education at Ensenada is a public research center and is the project's coordinating institution. Moreover, it contributes to the technical development of the computational platform integrating artificial intelligence and human-computer interaction techniques in the different modules of the platform. The Health Services of Nayarit is the local government institution responsible for the health services in Nayarit. The clinical specialists of this institution contribute to defining the screening, intervention, and follow-up processes supported by the computational platform. The specialists of this institution are also involved in the deployment and evaluation of the platform involving the patients at different stages of the detection and follow-up processes. The Public Education Department of Nayarit is the institution that coordinates with the educative institutions in Nayarit. The participants from this institution contribute to facilitating access to the selected secondary and high schools for the early detection process. They will also contribute to evaluating the platform's impact on the scholar community. The Autonomous University of Nayarit is the fourth participant institution. The researchers of this institution contribute to the definition of the functional and user's requirements, participate in the detection and follow-up process of students from high schools, and evaluate the platform.

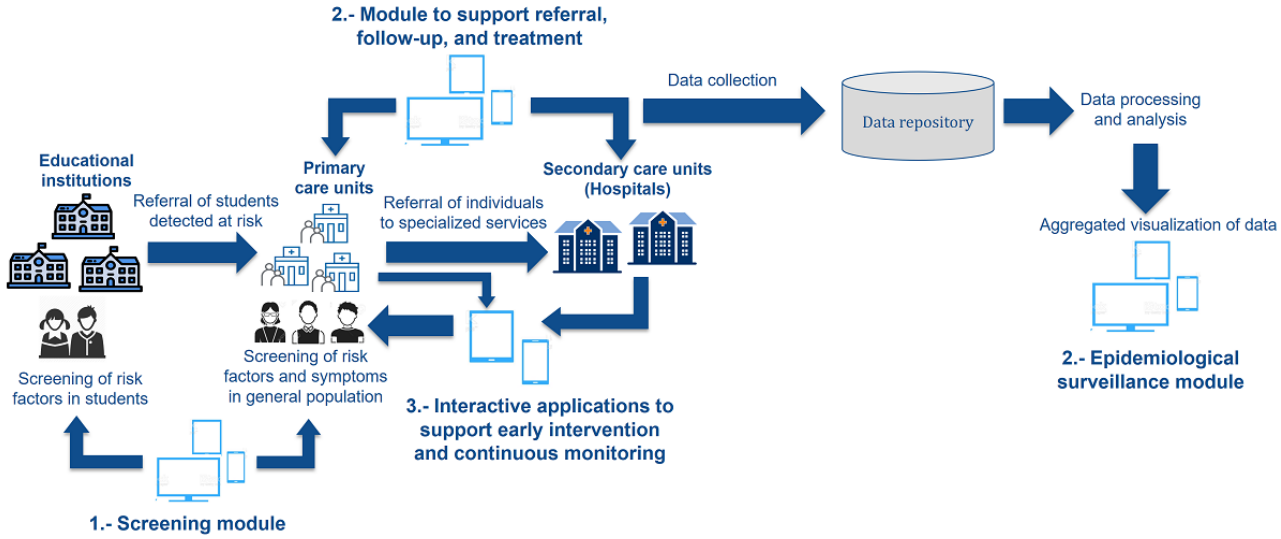
Methods

Modules of the Computational Platform

The achievement of the specific objectives guides the identification of the different functionalities that the computational platform provides to all the users involved: clinicians, teachers, and individuals at risk or detected with mental health and substance use disorders. Three main modules make up the proposed computational platform:

1. The module to support the screening of symptoms and risk factors. This module implements a set of standardized and validated instruments to detect individuals at risk. The screening module can be accessed from the scholar community (secondary and high schools) and primary care units. Based on the screening results and when necessary, this module provides personalized suggestions to refer detected individuals to the different services offered by the health sector. Moreover, the personnel responsible for the prevention and early detection processes (clinical specialists and school staff) will be informed about those individuals at risk to continue with the follow-up process.
2. The module to facilitate the referral, intervention, treatment, and epidemiological surveillance of the detected cases of mental health and substance use disorders. The specialists will use this module at the primary and secondary care to aid in the management and monitoring of individuals under treatment in both care levels. All the collected information from the detected cases is processed to generate graphical and statistical reports at the aggregated level for epidemiological surveillance purposes.
3. The module to support early intervention and continuous monitoring. This component includes the integration of web-based or mobile apps used by patients or individuals at risk. Our research group has experience in developing these types of apps with advanced interaction and artificial intelligence techniques such as embodied conversational agents and serious games (eg, [26,27]). Together with clinical specialists of our research consortium, we are assessing the development of the most appropriate strategy according to the characteristics and conditions of the target population.

The visual representation of the components and deployment of the computational platform to be developed is shown in Figure 1. Each of the computational platform modules is accessible by different users according to the phases of detection, intervention, monitoring, and epidemiological surveillance. The screening module can be accessed from any device, and the implemented questionnaires can be answered directly by the individuals to assess with the guidance of a specialist. This process makes it easier to reach a greater number of people and can be applied anywhere: schools, primary care units, or emergency areas of hospitals. Depending on the



XSL•FO
RenderX

obtained results, individuals' referral to primary or secondary health care services is also supported by the platform.

The collected information during the screening process is sent to the primary care units facilitating an early identification of those individuals detected at risk who would require a complementary medical assessment. All these detected individuals are asked to attend the primary care unit. When the person arrives at the primary care unit, the computer platform will facilitate recording the data and the complementary assessment and, if required, referring to the second level of care to receive specialized treatment. The information collected during this process is stored in a central information repository available to all the specialists involved in the care process. Additionally, the analysis and processing of the collected information in an aggregated and anonymized fashion is performed for epidemiological surveillance purposes.

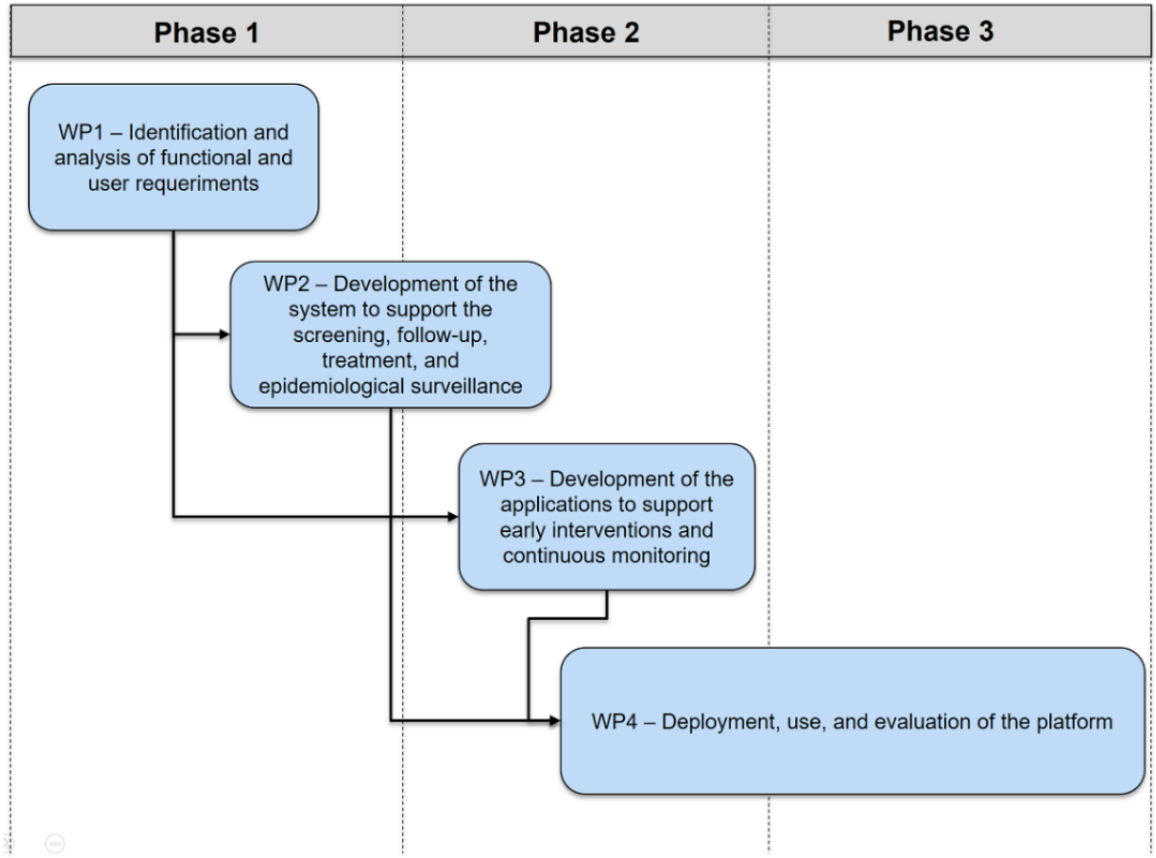
Finally, as part of the computational platform, web- or mobile-based apps are considered to support early intervention or complement psychotherapeutic treatment through continuous monitoring. Examples of these apps are serious games to help in the prevention of alcohol and drug consumption, or an interactive app for the monitoring of, for example, emotional states, behavioral activities, or frequent thoughts would help to assess the evolution of the patient's condition. The information collected from these apps is integrated into the patient's electronic file stored in the data repository for subsequent consultation by the specialist. This information has proven helpful for specialists as it makes it easier to get relevant details about a patient's condition during interconsultation periods.

Figure 1. Functional architecture of the computational platform.

User-Centered Design

One of the main issues when developing computer-based systems within the health sector is the failure to adopt these solutions as part of the activities within clinical practice. Scientific evidence in the area agrees that technological factors do not cause this problem, but it is caused by the systematic lack of consideration of human and sociotechnical factors from the target users, especially during the design and implementation stages of these solutions [28]. The lack of adequate involvement of end users leads to a poor understanding of the functional requirements, suboptimal usability of these systems, and an exacerbated resistance to the change and adoption of these systems. To minimize these risks and maximize the acceptability (and consequently the effective adoption) of the proposed computational platform, we follow a user-centered design methodology, which is widely used in developing software and technological solutions. The most relevant characteristics of this methodology are as follows [29]:

1. Emphasize the identification of the needs and requirements of end users that the technological product must cover.
2. Identify and understand the context in which the technological product will be implemented.
3. Design the technological solution based on these real needs of the users and the identified context and not on preconceived ideas of the developers or established and rigid guidelines.



Thanks to the participation of the different institutions in the consortium, the adoption of the user-centered design methodology will be facilitated by involving all the direct and indirect users of the platform: clinical specialists at the different levels of care, personnel from the educational institutions, and people at risk or under treatment of mental health and substance use disorders. All these users collaborate from the beginning of the project and throughout its final deployment and evaluation.

Workplan

The designed workplan for the development of the computational platform considers the 4 work packages (WPs), as illustrated in Figure 2, distributed into 3 annual stages: WP1 identification of the functional and user requirements; WP2 development of the system to support the screening, follow-up, treatment, and epidemiological surveillance; WP3 development of the apps to support early interventions and continuous monitoring of patients; and WP4 deployment and evaluation of the platform.

XSL•FO
RenderX

Figure 2. Overview of the work packages defined for the development of the computational platform. WP: work package.

The activities defined in WP1 are focused on identifying functional requirements for every module of the computational platform. Examples of these requirements include the selection of all the standardized and validated—in the Mexican population—instruments used in the screening process. Depending on the characteristics of the individuals (eg, the age) to screen, the system will show the adequate set of instruments (eg, the Problem-Oriented Screening Instrument for Teenagers [POSIT] [30]) that the specialist selects to detect the type of mental health or substance use problem. This WP1 also define the data to collect from each screened person, the recommendations provided according to the screening results, and the process to facilitate the follow-up and treatment of the individuals detected at risk in the subsequent attention at primary and secondary health units.

Other activities in this WP1 include the identification of the user and functional requirements for the development of the apps to support early interventions and continuous monitoring. Different focus groups with the target users will be considered to identify the specific objectives of these apps. Examples of these apps are to support (universal or particular) prevention of substance use through a gamified app for teenagers or an app for the remote and continuous monitoring of individuals with a mental health disorder (eg, depression and anxiety) based on cognitive behavioral therapy contents. Moreover, in this WP1, the selection of the scholar community forming the study sample for the screening process is performed. The schools' selection follows a set of agreed criteria (eg, geographical location, the quantity of student population, number of cases previously detected, or students' sociodemographic characteristics). Sensibilization sessions will be carried out with the personnel of the selected schools to inform them about the characteristics and objectives of the project.

WP2 and WP3 contain all the activities for the design and development of the different modules of the computational platform. The design, development, and testing process are iterative and follow the user-centered design methodology. Based on the information identified in WP1, each module is designed for the collection and processing of the data at different stages of the health care process: screening, intervention, treatment, monitoring, and epidemiological surveillance. Focus groups with different types of users have been considered since the first iterative design process. The result of these 2 WPs is the integration of the different modules forming the computational platform ready for its deployment and use in the selected educative institutions and health units.

The last WP4 includes all the activities required for the deployment, use, and evaluation of the computational platform. The deployment is planned to be gradual along the project's final year in the selected schools and health units. Training sessions will be carried out with the personnel of all the institutions where the platform is deployed. All technical issues that could emerge during the platform use are collected for the functional improvement of each module. Moreover, the collected information from the use of the platform will be processed for usability, acceptability, and impact evaluation in the health care process. Activities for the diffusion and dissemination of the project and the obtained results are also included in this WP4.

XSL•FO
RenderX

Recruitment

The study participants from whom information will be collected in the computational platform are of two types:

1. Participants in the scholar community (secondary and high schools) will be screened using a set of validated and standardized questionnaires to detect symptoms and risk factors associated with mental or substance abuse disorders.
2. People attending a health unit because of the presence of a mental or substance abuse problem. These participants can be 12 years and older and of both sexes. Personal data and relevant information related to the follow-up process will be recorded, for example, reference data between the different levels of health units, personal data, and notes of diagnostic evolution that will form their electronic clinical file.

For the screening process in the scholar community, the participants are the students (males and females aged 12-18 years) of the selected schools for the study sample. In coordination with the school personnel in each school, the health professionals select the specific groups for the screening. Explicit informed consent is asked from each student and their parents or legal guardians. Then, the screening instrument (the POSIT questionnaire) is applied to all the students who provide their explicit authorization. The teacher or the health specialist provides the instructions to respond to the questionnaire and is available to answer any questions during the process. The screening session is expected to last around 45 minutes for each group.

For the people who attend primary care units to receive medical attention, the doctor who receives them will inform them that the screening is part of the diagnostic assessment process. If the patient is a minor, an explicit authorization to carry out the screening process must be provided by the minor and by the accompanying adult. The duration of the session will be the time of the medical visit that the specialist decides.

In both groups, depending on the obtained results provided by the computational platform, health personnel identify those individuals who require a follow-up intervention delivered by a specialist and are referred to the corresponding health care unit.

The recruitment of participants who will use the apps to support early intervention and continuous monitoring will be carried out by the specialist responsible for their treatment. In the case of minors, explicit authorization from their parents or guardians will be asked before the provision of the application. In all the cases, the following exclusion criteria are considered:

1. A diagnosis of schizophrenia, psychosis, or borderline personality disorder
2. Not having a digital device to execute the app
3. Any disability that makes the individual unable to use a digital app
4. Requirement to be under personal surveillance due to current symptoms associated with a mental health or substance use disorder.

Data Collection

The collected data from all the participants include personal and sociodemographic data such as age and sex. For participants of secondary and high schools, the answers to each of the POSIT's questions and the final score are also collected. For the individuals recruited in primary care units, the results obtained from different instruments to assess their condition (eg, the Alcohol, Smoking, and Substance Involvement Screening Test questionnaire [31], a suicide risk measure [32], or the Hamilton Anxiety Rating Scale [33]) are also collected. The epidemiological surveillance module uses the final scores and the corresponding interpretation of these instruments to visualize the type of risks or disorders detected in schools and health care units. Moreover, all the information produced during the follow-up process is also collected to support the specialists with the whole treatment of the individuals who require the services of a secondary level of care. The data generated during the use of the web- or mobile-based apps by the participants are also collected, and the information is used for a continuous patient evolution monitoring. These data include, for example, the current mood, frequent—rational or irrational—thoughts, or the planning and development of specific activities.

Storage and Security of the Information

The data collected at schools and health units will be sent via the internet, using a secure data transfer protocol (https) to a central information repository. All data will be textual, and no multimedia files such as photographs and audio or video recordings are included. The data repository is located in the central offices of the Health Services of Nayarit, with the appropriate access and security protocols and the necessary data backup processes. The collected data are accessed through a username and encrypted password through the developed computer platform. The access depends on the user's role; the personnel who analyze the screening results have access to consult the data that allow the person screened to be located and recommend the appropriate follow-up. The specialists responsible for clinical treatment have access to all the information collected in the electronic health record created for each patient. Finally, the users of the epidemiological surveillance module have access to the aggregated and anonymized data to know the incidence and prevalence of the different mental and substance use disorders registered in the computer platform.

Evaluation

According to the WHO, the evaluation of a digital health intervention involves the measures taken and analysis performed to assess two main issues: (1) the interaction of users or a health system with the digital health intervention strategy or (2) the changes attributable to the digital health intervention [34]. The assessment of the interaction between the platform and the target users will be performed through a mixed methods approach [35] with an explanatory design study using validated and standardized questionnaires to get information about the usability, acceptability, and perceived usefulness from the users of the different modules of the platform: health specialists, teachers and personnel of the educational institutions, and individuals at risk or patients. Existent validated instruments

XSL•FO
RenderX

will be applied to a representative set of users after the deployment and use of each module. Qualitative information will be gathered throughout focus groups with a Logical Framework Approach.

For all web-based modules, the System Usability Scale and the Technology Acceptance Module will be provided to the users to rate the platform modules' usability, acceptance, and ease of use. The System Usability Scale consists of a 10-item questionnaire with 5 response options for respondents: from *strongly agree* to *strongly disagree*. This instrument allows evaluating a wide variety of products and services, including web-based health apps [36,37]. The Technology Acceptance Module measures the constructs of perceived usefulness, ease of use, and user acceptance of the technological product in the participant's workflow by explaining the user's "behavioral intention" with the system. This instrument is based on the theory of reasoned action [38], a psychological approach that seeks to explain behavior, and has also been widely applied in eHealth systems [39]. If any of the platform modules is deployed through a mobile device (eg, the apps for early intervention and continuous monitoring of patients in the community), a complementary instrument such as the Mobile App Rating Scale will be used to evaluate these modules. The Mobile App Rating Scale is a simple, objective, and reliable tool for classifying and assessing the quality of mobile health apps [40].

The changes in the health care process attributable to the platform will be assessed through a quantitative study by comparing the population coverage achieved with the computational platform in relation to current and historical data. Moreover, a Logical Framework Approach will be adopted to identify individual, social, and contextual factors affecting the mental and substance use health care process at primary and secondary levels. This approach has previously used to identify relevant factors and characteristics in different health care processes such as emergency care [41], hospital-based health care services [42], or rural health missions [43]. The Logical Framework Approach will be implemented through focus group sessions involving specialists and asking to identify the main problems (barriers) and solutions (facilitators) each participant faces during the different stages of the health care process. These sessions will be carried out before the platform's implementation and then after its deployment and use by the different specialists and patients or individuals at risk. The collected information from these sessions will allow the identification of specific problems that could be minimized or removed due to the different functionalities of the platform. The detected changes will help to assess the impact of the digital intervention along the process: from the early detection in the scholar community to the follow-up and treatment of individuals with mental health and substance use disorders in primary and secondary health units.

The evaluation results will be disseminated among the community and public health policy makers, emphasizing the platform advantages of adopting it as part of a public health program. Moreover, these results will lead to the identification of lessons learned during the deployment and use of the platform providing valuable recommendations to maximize the benefits for the attention of mental health and substance use disorders in other regional and national health systems.

Ethics Approval

The study has obtained research ethics approval from the institutional review board of the Health Services of Nayarit (CEBN/04/2020). Participation will be voluntary, and informed written consent or digital consent will be obtained from participants and from parents of those participants younger than 18 years. The participants will be informed about the confidentiality of their answers to the applied questionnaires. All identifiable information will not be accessible, except for the clinicians who will provide formal care services to the participants. Participants' data will not be identifiable in any publication or report. No monetary compensation will be offered to the participants.

Results

The project has been running since July 2021 and is intended to complete in June 2024. An initial version of the modules to support the screening and follow-up treatment processes has been developed, and the initial deployment and testing of these modules in a school sample of 10 secondary schools and 10 high schools located in the city of Tepic has started during the second semester of 2022. Currently, 6 schools have used the screening module implementing the POSIT questionnaire, and as of February 2023, a total of 1501 students have undergone screening. The referral of those students presenting a risk in mental health or substance use to primary care units has also started. The second stage includes the development of the interactive apps to support early intervention and continuous monitoring and the epidemiological surveillance module. The use and evaluation of the complete platform are the main activities for the final year of the project, and the obtained results will be disseminated between the research community, health specialists, and the general public.

Discussion

Principal Findings

This protocol describes the development and evaluation of a computational platform to support the detection, intervention, treatment, and epidemiological surveillance of mental health and substance use disorders in the community and primary and secondary health units. Three main modules form the computational platform: (1) a module to support the screening of symptoms and risk factors; (2) a module to facilitate the referral, intervention, treatment, and epidemiological surveillance of the detected cases; and (3) interactive apps to support and complement the provision of early intervention and continuous monitoring. Some modules of the platform are currently under development, and their complete deployment and evaluation are expected at the end of 2024.

It is expected that the proposed platform will contribute to a better integration of the involved institutions, professionals, and processes in the attention to mental health and substance use disorders. The early detection of risks in the scholar community will contribute to a timely referral to formal health services,

XSL•FO
RenderX

minimizing the future chronicity of these disorders and the subsequent associated problems, including suicides. The functionalities of the computational platform to support the follow-up and monitoring of patients under formal treatment, as well as the generation of epidemiological information on the incidence and prevalence of these disorders, will help to perform qualitative and quantitative analyses to target better public policies and strategies implemented as responses to this problem, as well as their evaluation.

Limitations

This study has some limitations that require consideration. First, the recruitment of participants aged 13 to 17 years is restricted to those attending secondary and high schools. In Mexico, there are a significant number of individuals within this age range who are not in school and are at high risk of substance use. Second, the platform will only be used by clinicians belonging to the public health services of Nayarit. However, there are various public health systems in Mexico, even within the same city or region, and individuals identified with risk factors or symptoms will be referred to the corresponding institution where they receive their health services. Therefore, individuals referred to health units outside of the public health services of Nayarit will not be followed up or treated with the platform. It is expected that positive results, such as a better integration between the different levels of care, from early detection to follow-up and epidemiological surveillance, will encourage the adoption of the platform by other public health systems.

Conclusions

Digital-based solutions designed to support health care processes have the potential to increase the accessibility of the general population to health services, mainly due to the wide availability of, for example, web-based and mobile apps. This is particularly important for mental health and substance use disorders, where treatment gaps reach percentages above 75% in Mexico. The development, deployment, and evaluation of the computational platform proposed in this study have the potential to contribute to the reduction of this treatment gap by improving the integration and exchange of information between the different specialists and health care units involved in the different processes of attention: from the early detection of these health problems in the community to the analysis and visualization of the identified cases with epidemiological surveillance objectives.

Abstract

Background: Virtual reality (VR) technology has been solidifying its ground since its existence, where engagement and a sense of presence are key. The contemporary field of development has captured the attention of researchers due to its flexibility and compatibility attributes. During the COVID-19 pandemic, several research outputs have shown promising prospects of continuing research in the field of VR design and development—in health sciences including learning and training.

Objective: In this paper, we aim to propose a conceptual development model named V-CarE (Virtual Care Experience) that can facilitate the understanding of pandemics when it comes to a crisis, taking precautionary measures where needed, and getting used to certain actions for preventing pandemic spread through habituation. Moreover, this conceptual model is useful to expand the development strategy to incorporate different types of users and technological aid as per need and requirement.

Methods: For a detailed understanding of the proposed model, we have developed a novel design strategy to bring awareness to the user about the current COVID-19 pandemic. VR research in health sciences has shown that with appropriate management and development, VR technology can efficiently support people with health issues and special needs, which motivated our attempts to explore the possibility of employing our proposed model to treat Persistent Postural-Perceptual Dizziness (PPPD)—a persistent nonvertiginous dizziness that could last for 3 months or more. The purpose of including patients with PPPD is to get them engaged in the learning experience and to make them comfortable with VR. We believe this confidence and habituation would help them get engaged with VR for treatment (dizziness alleviation) while practicing the preventive measures during the pandemic in an interactive environment without actually facing any pandemic directly. Subsequently, for advanced development using the V-CarE model, we have briefly discussed that even contemporary technology like internet of things (IoT) for handling devices, can be incorporated without disrupting the complete 3D-immersive experience.

Results: In our discussion, we have shown that the proposed model represents a significant step toward the accessibility of VR technology by creating a pathway toward awareness of pandemics and, also, an effective care strategy for PPPD people. Moreover, by introducing advanced technology, we will only further enhance the development for wider accessibility of VR technology while keeping the core purpose of the development intact.

Conclusions: V-CarE–based developed VR projects are designed with all the core elements of health sciences, technology, and training making it accessible and engaging for the users and improving their lifestyle by safely experiencing the unknown. We suggest that with further design-based research, the proposed V-CarE model has the potential to be a valuable tool connecting different fields to wider communities.

KEYWORDS

COVID-19; immersion; pandemic; Persistent Postural–Perceptual Dizziness; PPPD; virtual reality

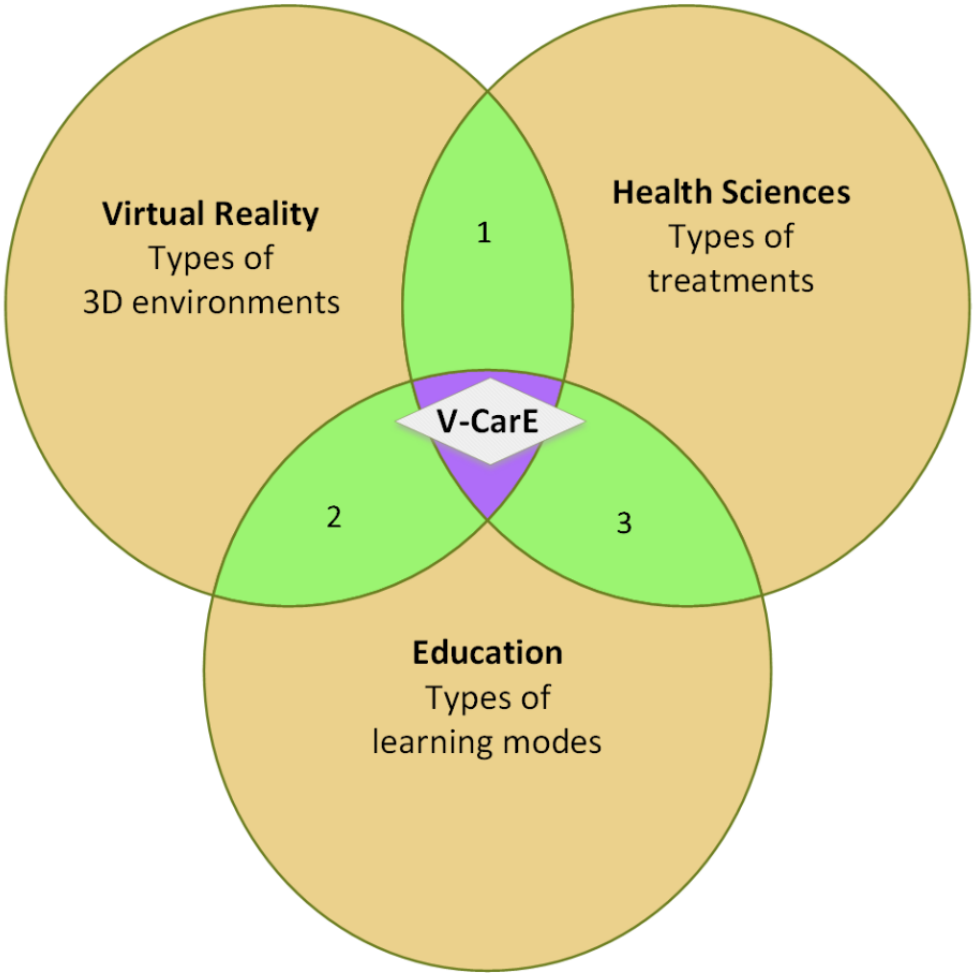
Introduction

Recently, virtual reality (VR) technology has received growing attention in diverse areas and a plethora of research. VR creates an immersive 3D visual experience and sensory environment trying to mimic the real world using simple wearable devices. Interestingly, VR technology has been widely used as a cost-effective tool in advanced fields of education, health, engineering, and medicine. Immersion, presence, and interactivity are key factors in VR [1-5]. We believe that these factors mark the prominent capability of VR, which has drawn great attention in the field of education, learning, and health sciences [6-11]. VR has significantly improved the education and skills of health professionals [10,12], but further research is still required to study the effectiveness of more immersive and interactive forms of VR in different settings. In this study, we have proposed a VR-based model that incorporates education and health science elements to examine and evaluate the effectiveness of a 3D immersive experience in learning and training.

The proposed VR conceptual framework, V-CarE (Virtual Care Experience) model, can be applied by VR developers to create a 3D simulation incorporating educational and health elements (Figure 1). The desired 3D environment would give the users an immersive experience to practice how to react in a serious situation, which would eventually benefit their health through their actions. The proposed model is flexible and can be generalized for different purposes, including engagement and habituation. This would cater for a wider acceptance of the technology, which will contribute to public health and serve the community. It is worth noting that the internet of things (IoT) would be incorporated within our proposed model for providing a 3D and fully immersive simulation. The users would experience real situations developed objectively with required surroundings and settings for different training cases and purposes. IoT is a system that connects different objects or things in one network that has been widely used in numerous applications in a wide range of domains like health care, agriculture, and smart homes [13-15].

Furthermore, the V-CarE model aims to enhance awareness of pandemics during unforeseen circumstances, implement necessary preventive measures, and encourage habitual actions for disease prevention. The COVID-19 respiratory illness outbreak started in China in 2019 [16]. It spread all over the world, resulting in a global pandemic in less than a year [17]. In an attempt to control its spread, preventive measures, and social distancing were suggested based on the situation and conditions of the outbreak [18].

With the rise of the prevalence of COVID-19, VR played an important role in fighting the pandemic by providing a virtual and safe environment for leveraging remote interactions and connecting people. It can be used to change individual behavior while maintaining social distancing through immersive learning and training through 3D simulation. A web-based survey was introduced to study the importance of using VR to help people improve their mental health and physical well-being during the lockdown [19]. Many VR-based apps have been recently introduced in the context of the COVID-19 pandemic to help in cognitive and physical rehabilitation therapies, web-based education, training, and treatments [20-23]. However, there is no strategy for implementing and practicing preventive measures such as social distancing to accommodate performing normal work procedures in the industry, education, health care, and other fields. The proposed V-CarE model is developed to educate people about COVID-19 through VR immersive environment experience, focusing on implementing preventive measures, and social distancing strategies for controlling the disease spread.



To test and validate the extendible capabilities of V-CarE, we have applied our proposed model to people with Persistent Postural–Perceptual Dizziness (PPPD). V-CarE model has been designed with strategies for preventive measures to avoid triggering the symptoms. PPPD has been identified as a vestibular disorder that causes persistent dizziness and unsteadiness for 3 months or more [24]. Other than this study, very limited research has been done on using VR simulation as a cost-efficient tool for understanding and managing patients with PPPD through exposure therapy [25-28]. It is very challenging for patients with PPPD to follow the preventive measures that are crucial nowadays to control the current COVID-19 pandemic. Recently, there has been some significant work conducted on the application of VR and its capabilities to handle situations during the COVID-19 pandemic. Telemedicine services, mental health support, remote work collaborations, and similar engaging activities have been potential areas of research in VR development. Engagement and interactive rehabilitation experiences have been the main focus of the research as COVID-19 largely impacted daily life activities and approaches toward looking at day-to-day activities for the future [29-32]. Despite progress, there has been no discussion on how VR development strategies are made to keep the elements of entertainment, engagement, and interactivity intact for the wider audiences. In this study, we have highlighted the need for a proper visual map and introduced a conceptual model that can involve experts in their fields to connect strongly and develop an effective 3D simulation addressing the needs of the users. Moreover, we have also suggested that V-CarE, being a promising development model, can also facilitate people with PPPD who are already going through the complexity of living that comes with the symptoms [33].

Therefore, this study aims to employ the proposed V-CarE conceptual model for VR developers to provide people with awareness of the pandemic and its preventive measures through 3D immersion. Also, we have highlighted that the similar 3D simulation developed here can facilitate people with PPPD. The

XSL•FO
RenderX

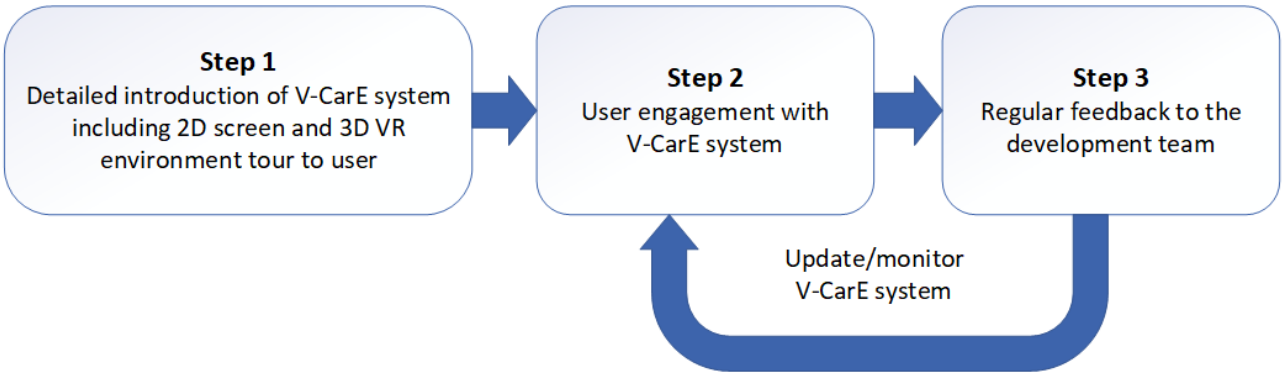
product can further be enhanced with little to no major change, whereas contemporary technology (eg, IoT) can be incorporated into the V-CarE–based design for a wider accessibility. Finally, we have concluded that the V-CarE approach positively impacts daily life at a time when the pandemic crisis and personal dizziness struggles are the major health issues.

Figure 1. V-CarE (Virtual Care Experience) conceptual model.

Methods

The Proposed V-CarE Model

The term V-CarE is inspired by the term "We Care," which stands for Virtual Care Experience, which refers to the concept that VR technology positively impacts people's lives. People would learn and train themselves to remain safe and keep themselves healthy using this technology. V-CarE is designed to be a general and flexible learning and training model that provides an immersive 3D experience for the users to have a healthy lifestyle through improved habits and daily activities. It can also help in understanding and building awareness of different pandemics, as well as practicing its required preventative measures through habituation. In addition, V-CarE represents a conceptual framework that facilitates further refining the investigation process of understanding primary symptoms among patients (users) for researchers and clinicians. In addition, it can assist researchers to handle cross-disciplinary work more objectively.



As the V-CarE concept resides at the core of 3 different major fields, including VR (3D environment), education, and health sciences, it is important to go through each field and reach the core (V-CarE) design as shown in Figure 1. In this way, the design can be easily customized as per the needs of the development. Table 1 describes how the 3 generic areas are set together and blended into 1 core that would have the essence of all the major fields. Based on the required type of VR environment, the order of considering mapping of sets would vary in each row of Table 1, but it would remain in the same column sequences (from left to right). To develop the right product at the end, the V-CarE team are expected to have experts in the 3 fields (education, VR, and health sciences), so that all common elements of the 3 major fields are addressed accurately. Once the V-CarE–based product is ready, to continue keeping the positive impact of the product based on the V-CarE concept, we have proposed a standard protocol as depicted in Figure 2 to make users feel comfortable with the VR experience.

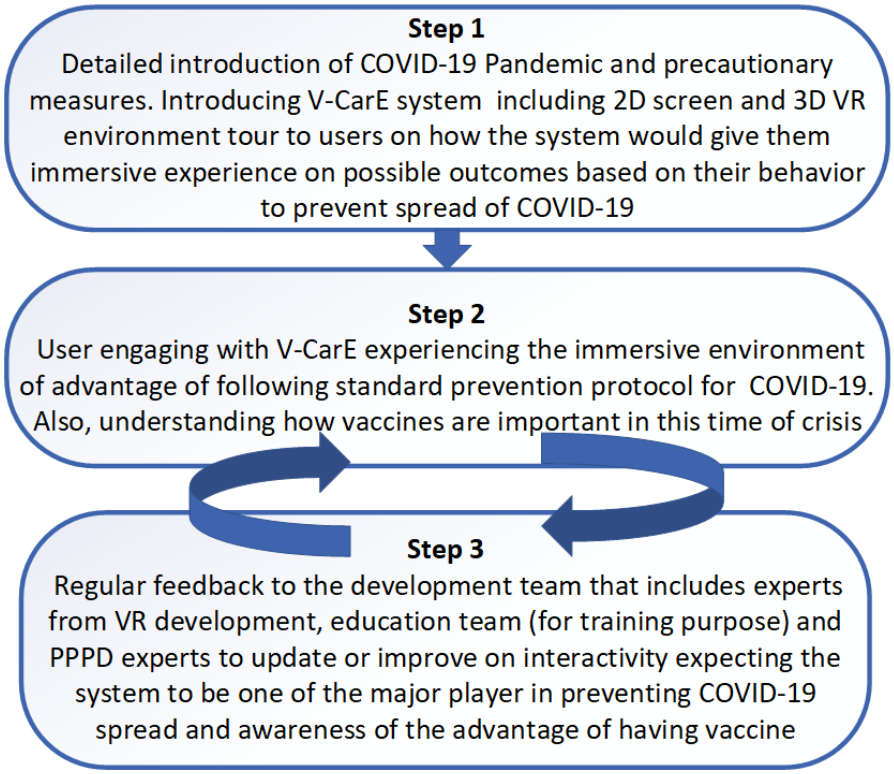
Figure 2. V-CarE (Virtual Care Experience) standard engagement protocol. VR: virtual reality.

V-CarE Model's Design and Development Framework

As mentioned earlier, V-CarE is a conceptual model that can be used with flexibility for different situations as long as it is linked with training, learning, and maintaining good health (Table 1). The V-CarE team would involve individuals from areas of health sciences, VR, and education.



The Protocol of Introducing V-CarE to Users

A standard protocol has been laid out to introduce the V-CarE system, aiming to make users comfortable with the VR experience based on the V-CarE concept. The user would go through the proposed standard process when using V-CarE as described in Figure 2. They would be introduced to the system thoroughly, including the VR experience at first. Then, the product will be used by the users at home at their convenience. With every growing demand and experience requirement, the system would continuously improve through feedback where necessary to give the user an ultimate experience of a VR environment.

In this case, we will use the proposed general process of using the V-CarE system for COVID-19 pandemic awareness. Figure 3 shows the updated protocol that was designed toward introducing an immersive experience dedicated to providing an understanding and awareness of the current pandemic, as well as facilitating a pathway for the user to get used to the required preventive measures and the vaccination process.

XSL•FO
RenderX

Design Strategy—Educating to Combat (COVID-19) Pandemic

In this study, looking at the seriousness of the COVID-19 pandemic, we have proposed a virtual learning environment design using the V-CarE model that would help people to understand the pandemic, educate themselves, and take necessary measures consistently in a hassle-free manner. The 3 design steps for implementing the VR immersive strategy and experience are as follows:

1. From the 3 broad sets (highlighted in yellow color in Figure 1)—the V-CarE design requires understanding the elements to choose for subsets to develop a relevant VR environment. For our purpose, our final set should have these 3 components: a VR environment for an interactive experience, education about COVID-19, and exposure therapy to impact the users' lives positively.
2. From the 3 blended sets (highlighted in green color in Figure 1)—the V-CarE design requires a VR environment with an educational aspect in it. Education about what measures can reduce the chances of getting infected with COVID-19, its symptoms, information on SARS-CoV-2, and the 3D immersive experience of the measures to keep oneself safe.
3. From the core V-CarE set (highlighted in gray)—The V-CarE design requires a VR environment where users can experience the results of preventive measures at home during the lockdown through a 3D simulation. The virtual simulated environment is designed to be an indoor environment; however, it can be developed to be outdoors when required. In the 3D-immersion experience, users can safely interact with the VR environment and perceive a deep awareness of the COVID-19 virus.

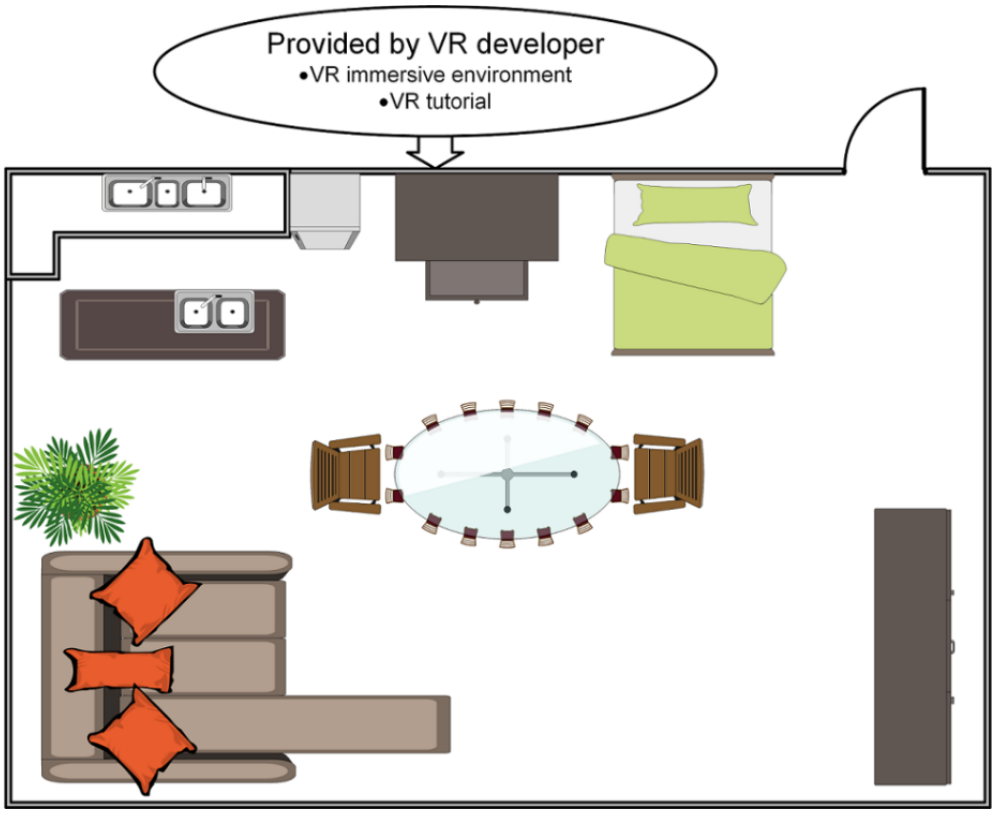
Development Strategy—3D-Simulated Experience

In this section, we provide an example of developing strategies through a simulated environment for users to practice key preventive measures and social distancing procedures. The virtual simulation will have the following different scenes in a house:

1. Scene in the bathroom where a user must wash hands thoroughly for 20 seconds (timer is active). If any part of the hand is left unattended, a red spot will be added to the simulation environment. This spot would grow if the user does not attempt to wash hands again for 20 seconds.
2. Scene in the house where there is a grocery item that is located on the table. The red spots on the item would be an indication of the possible risk of COVID-19. A wipe, and a water tap in the kitchen would be available. The user would be required to clean the item with a suitable option.
3. Someone knocks at the door and the user would be asked to take action; (1) open the door, and (2) ask the person to keep a 2-meter distance (social distancing) from the door before interacting.
4. Social distancing scene where green circles depict moving users if they are moving or standing at 2-meter distances or more. If the distance becomes smaller, the circle's color will turn red accompanied by a warning alarm.
5. To keep the immersion engaging, these proposed scenarios would undergo a slight change with each experience, which can be decided by the developers. Also, these scenarios can be easily adapted or redesigned to address different procedures and precautions (matching the rules of the

XSL•FO
RenderX

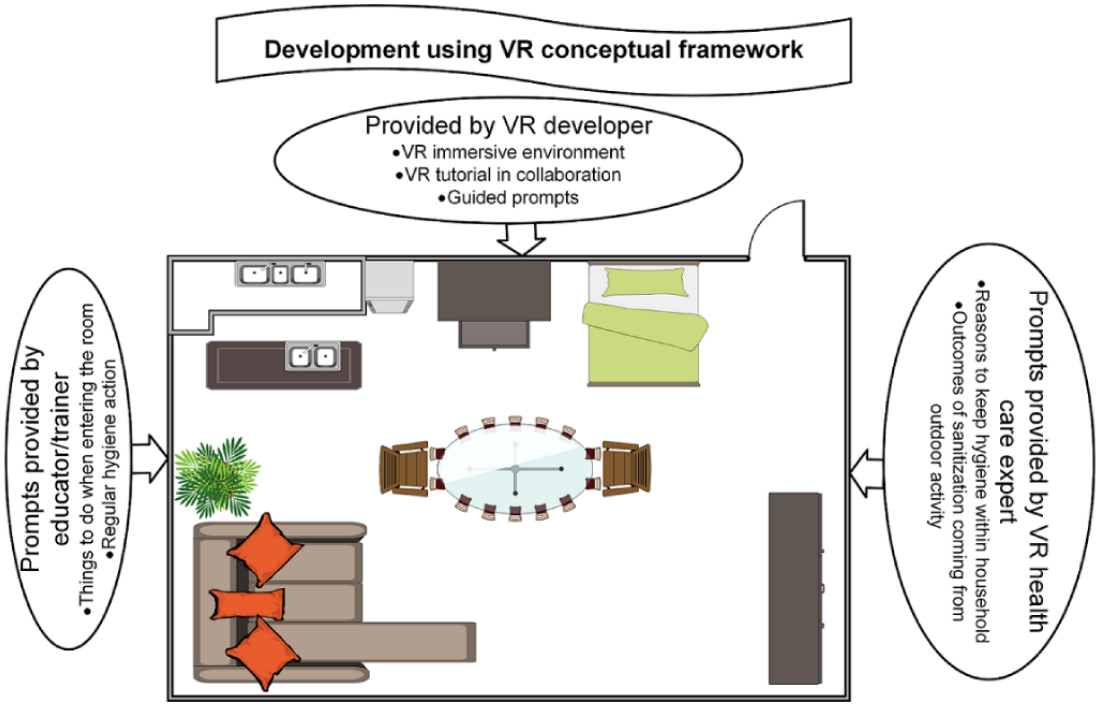
lockdown's level). Consequently, more scenes can be added to address more of the suggested and updated preventive measures for indoors and outdoors, aiming for a complete training and therapy system. Moreover, a scene can be added for understanding and getting familiar with the special polymerase chain reaction (PCR) test used to diagnose COVID-19 and for the vaccination process. With VR immersion, telepresence, and real-time interactions, people would get more engaged and motivated to use VR technology to increase their awareness about COVID-19 and practice preventive measures instead of just reading and hearing about the disease through media. User-centered tutorials and demonstrations would be used to assist the users in using the system independently and would provide further support to the users [34].



Sample Simulation Process Using V-CarE–Visual Aid

For a visual understanding of V-CarE, we have provided an example of a studio room (in 2D for simplification purposes): the VR version can be customized as needed. Users would go into a 3D simulation of the room. In a conventional VR development environment, understanding interactions with objects in the room will be decided by the VR developers, whereas in the V-Care framework, these interactions will be guided by expert judgement through guided tutorials. It is expected that the interactions in the room can either be a part of a VR-based game or solely a VR experience (Figure 4).

If the environment is developed using the V-CarE framework, the elements in the VR experience would have attributes infused by experts from different disciplines and the purpose would be narrowed down to specific yet common goals. In this study, the focus would be to understand the actions required to avoid COVID-19. As mentioned before, experts from the 3 disciplines would be involved in the V-CarE–based product development. The user would (1) interact with the environment (VR developer would be involved), (2) receive continuous input feedback (educators and trainers would be involved) to be informed of the necessary steps to avoid COVID-19, and (3) get prompts of health information on the actions they took in the immersion (Figure 5).



As the virtual environment is flexible to the users' needs, the idea of a descriptive VR environment is left to the developers. Figure 5 illustrates VR environments that can be created from different perspectives. At the same time as design layout II in Figure 5 shows, a simple environment like a studio room can be used as an insightful interactive space to tackle the spread of COVID-19 through community contribution and awareness of the pandemic. Some of the recent research work showed that the developers have started investigating strategies around creating casual VR simulations for certain groups of audiences [35-38]. In this study, we have proposed a conceptual framework to engage experts from other disciplines to keep the scope of VR simulation balanced to the needs of the users. This scope can easily be expanded to the direction of selected disciplines without compromising on the quality of the developed VR product.

Incorporating Internet of Things into V-CarE Design Strategies

The development of our proposed V-CarE model will require the involvement of people from 3 different fields of expertise including education, VR, and health. It is important to see how V-CarE can collect the users' feedback and reaction to connect them to the right resources. The IoT has been around for some time and the promising attribute is the integration and communication of several technologies [13], and it fits well with the proposed conceptual V-CarE model.

In the integration of VR and IoT, Empathic VR is an appropriate example that can support the advantages of V-CarE for its flexibility in adopting IoT. Empathic VR uses a VR head-mounted display with a mobile remote–controlled robot. This enables 2 people at distant locations to connect and move freely within a real world and virtual workspace while creating a strong sense of telepresence of actually being in the same location [39]. In the proposed V-CarE model, an IoT-based system can be designed to suit the users' needs by involving the relevant health experts to facilitate a deeper understanding of the user experience and to support users in line with health care practices.

Figure 6 depicts our proposed framework that engages both the developers and users using the V-CarE model, aiming for an efficient and dedicated IoT-based VR immersive engagement. As for COVID-19, it is evident that social distancing and isolation are necessary to alleviate the spread of the virus, and IoT-based design would be ideal to connect everyone involved in helping the society become COVID-19-free. Interestingly, modern IOT and internet of medical things technologies have been studied to assist in managing the current pandemic [35]. Therefore, our proposed model will be empowered by incorporating these promising technologies, aiming to achieve an efficient system with a variety of applications including managing the COVID-19 pandemic.

Extending V-CarE for Patients With PPPD

With V-CarE, users can immerse and experience reality through 3D simulation and learn according to their engagement preferences. The Venn diagram–based model (Figure 1) can adapt to changes and various considerations as long as the core V-CarE has all the common elements from the 3 big sets (VR, education, and health sciences). Also, we would like to stress that the V-CarE model can help people with different disorders, symptoms, and phobias. In this case, we would like to see how people with PPPD can benefit from the current setup. PPPPD is an inconsistent chronic vestibular nonvertiginous form of dizziness and unsteadiness that persists for 3 months or more [24]. It exacerbates by upright position, passive and active motion of oneself, and exposure to static and dynamic complex environments which are overwhelming to visual perception. Having entered the list of the International Classification of Disorders-11 in 2015, there are very limited research studies on the treatments and effects of PPPD and the impact on the affected people [36]. Recently, VR technology has been exploited for vestibular rehabilitation through balance and habituation exercises [37]. There are very limited studies, including this work, on using VR to understand PPPD through exposure therapy [25-28]. None of the studies discussed the encouragement and trust factors of VR technology.

Considering the triggers of PPPD and its symptoms, using VR would be a promising starting point for patients with PPPD to get used to the environments and to understand and practice immersion [28,40]. They would be able to see and feel the environment of a house where their daily activities would be similar to what they are expected to do, especially during the COVID-19 pandemic. The proposed V-CarE model with the designed strategy for COVID-19 will provide the required immersion and sense of achievement for PPPD users to practice following all preventive measures. This will make them engaged while experiencing the outcome of their actions in the real world. Not only would they have a virtual experience of learning, but they might also get comfortable with virtual headsets through habituation. This will lead to their acceptance of VR technology and, later, using it by choice for their treatment (self-therapy) under the supervision or advice of PPPD experts.

Moreover, if the simulation is similar to their home environment (that does not trigger dizziness symptoms), people with PPPD would interact comfortably, reducing fear responses. Furthermore, for the sake of knowing COVID-19 and doing their part to control the spread, they would take initiative in practicing COVID-19 preventive measures through 3D immersion. The proposed protocol introduced in Figure 3 will help in creating awareness for patients with PPPD and assisting them to overcome the symptoms. The PPPD experts would be involved in the development process of the system and introduce it efficiently to patients with PPPD. In addition, incorporating IoT into the proposed model would offer a more relaxed environment with familiar surroundings, aiming to improve habituation and adaptation. Additionally, the proposed model would help people with PPPD to understand the PCR test, as well as the vaccination process, which would assist in controlling the COVID-19 spread.

The proposed model presents a simple and feasible VR-based solution that can be applied to help patients with PPPD (besides regular users) understand the COVID-19 pandemic and practice the needed precautions and preventive measures.

Electronic Equipment for V-CarE Design and Development

VR has come a long way to get the attention of potential users and create a competitive market, with various companies putting in effort to keep their products as one of the leading equipment in the market [41,42]. HTC Vive and Oculus are keeping their gadgets accessible for consumers and developers with several models and compatible software design kit. The latest graphics cards combined with powerful machines have been the major contributors to the VR success, considering the framerates, and close to real-world development of simulation. Augmented reality has even gone one step further to cater for the necessary engagement and interactive factor which VR is providing to the users [43]. V-CarE can be applied to any design methodology using the hardware in line with the users' and participants' needs.

Ethical Considerations

The paper proposes a theoretical design conceptual model without involving any human subjects. The design element focuses on the possible development of VR interventions that can sustain positive behavior and mitigate the negative effects of the pandemic and PPPD symptoms on daily life activities.

Usability Testing

To materialize the conceptual framework, we suggest rigorous usability and user testing to make the product reliable and effective for end users. Experts in the areas of VR, health sciences, and education, can collaborate in cross-disciplinary domains to harvest quality outcomes using VR technology [10,12,27,44]. The proposed V-CarE framework suggests that for the development phase, the relevant stakeholders would be involved in testing the system's usability. The process should engage experts in their fields and select users from a group of people who would be directly impacted. It is important to involve the people at the right time for the right role in the development of the VR environment [34,45]. Tools like System Usability Scale and me CUE have been extensively used by researchers and practitioners to measure usability and user experience [46,47]. Furthermore, the agile project management approach and scrum methodology [40] would be appropriate methods to move to the development phase of the V-CarE model, considering its nature of involving researchers from different fields.

Sample Size

Although the study primarily focuses on users' COVID-19 *a*wareness, we have also emphasized that the design has the potential to cater to a broader audience, including individuals with PPPD. Preliminary research and investigation have been performed as proof of concept for using VR technology to help patients with PPPD in their journey of exposure therapy and improving symptoms. For example, in recent studies, a VR prototype has been proposed, paving the way toward an efficient VR-based intervention tool for improving exposure therapy

XSL•FO
RenderX

through immersion strategy [27]. In addition, a smart VR-based e-diary is proposed for improving PPPD therapy and facilitating habituation [28]. For appropriate sample size calculation, priori analyses were performed to estimate a suitable sample size for a reasonable power level. The G*Power (version 3.1; Universität Düsseldorf) statistical program was used for sample size calculation and power analysis [49,50]. It was calculated that 54 participants can designate 95% power of the study based on a medium effect size Cohen d=0.5, with significance level α=.05 (*2*-tailed *t* test). Therefore, we suggest including a total of 54 participants *and* patients (assuming some dropout), aiming to achieve 95% statistical power of the study. The sample of participants can include both genders (male *and* female). For gathering information and collecting feedback for the experiment, an efficient questionnaire *or* survey is required based on the standards for developing questionnaires for educational research and using the handbook of questionnaire development as a guide [50].

Results

We have proposed a model that provides a significant step toward enhancing the accessibility of VR technology. The methods section highlights that VR development using V-CarE can strengthen public awareness regarding pandemics. Also, VR development can provide effective care to individuals with PPPD without making major VR exposure training improvements. In addition, we have determined that incorporating cutting-edge technology, for example, IoT, into the model will facilitate the expansion of VR accessibility while preserving the primary purpose of the development.

Discussion

Principal Findings

The V-CarE conceptual model is a major leap forward in the strategic use of VR technology for health care; and educational purposes–at a user level. By developing a fully immersive, semi-immersive, or nonimmersive 3D simulation, researchers from the fields of education, health, and creative technology can work together to improve health care outcomes and address the challenges posed by the COVID-19 pandemic. The model provides a pathway to develop a virtual experience that helps people understand COVID-19 and the recommended preventive actions. In addition, the model has the potential to be applied in a wide range of settings, from medical clinics and hospitals to educational institutions and home-based settings. The flexibility of the model makes it accessible to a wide range of people, regardless of their location or background. By using VR technology, people with PPPD can receive effective treatment without feeling any reluctance. This is due to the proper guidance provided by the model, which enables habituation therapy to be used to treat PPPD dizziness symptoms effectively by reducing fear and anxiety as well as promoting better health outcomes. The integration of IoT is also suggested as a way to promote contemporary technology into the developed system in order to enhance the capability of the VR experience by adding a feature.

Limitations

Further investigation is needed to determine the applications of the V-CarE model in various settings, from medical clinics and hospitals to educational institutions and home-based environments. To ensure the feasibility of the study and the usability testing, a power analysis and sample size calculation can be performed using G*Power.

Conclusions

In conclusion, the purpose of the V-CarE model is to provide a tool that effectively uses VR technology for interdisciplinary collaboration between health care, creative technology (in this case, VR), and education. It lays the foundation for exploring and understanding the effects of VR technology on human behavior and cognition, with its ability to address the challenges posed by the COVID-19 pandemic. Moreover, it provides effective treatment solutions for PPPD for improvements in health care outcomes, and people's lives. As the V-CarE model has the potential to make a positive impact in day-to-day activities of the users, it is, therefore, suggested to continue to conduct further research and support interdisciplinary collaboration to help bring these innovative solutions to our lives.

Abstract

Background: Globally, over 20 million children are unvaccinated and over 25 million missed their follow-up doses during the COVID-19 pandemic; thus, they face vaccine-preventable diseases and unnecessary deaths. This is especially the case for those with HIV or living in vulnerable settings. Using cell phones to send reminders to parents has been shown to improve vaccination rates.

Objective: We aim to determine whether implementation of an automated SMS reminder will improve child vaccination rates in a turbulent, semiurban/semirural setting in a low-income country.

Methods: This will be a nonrandomized controlled trial that will be conducted at Azire Integrated Health Centre, Bamenda, Cameroon.

Results: A total of 200 parents per study group (aged over 18 years) who are registered at the clinic at least one month prior to the study will be recruited. The intervention group will receive 2 reminders: 1 week and 2 days prior to the scheduled vaccination. For those who miss their appointments, a reminder will be sent 1 week after their missed appointment. The control group will receive the regular care provided at the clinic. Baseline information, clinical visit data, and vaccination records will be collected for both groups. Descriptive statistics will be used to summarize baseline characteristics between and within clusters and groups. The Fisher exact test will be used to compare parent-child units who return for follow-up visits (as a percentage) and children vaccinated as scheduled (as a percentage) between the study groups. Finally, we will compare how many members of both study groups return for 1 follow-up visit using Kaplan-Meier survival analysis.

Conclusions: Due to limited effective child vaccination interventions in unstable settings, this study will be of high importance for suggesting a holistic approach to improve child vaccination and public health.

Introduction

Child immunization is a key component of the World Health Organization (WHO) and United Nations Children's Fund (UNICEF) child survival intervention package [1]. Immunizing children is an essential strategy in primary health care services and a crucial public health objective. Yet internationally, there are up to 19.4 million children who are still unvaccinated and face unnecessary deaths [2], including an especially high number of children living either in resource-limited settings or living with HIV. Therefore, children are considered a high-risk group for acquiring vaccine preventable diseases (VPDs) Also, the WHO and UNICEF warn of an increased number of missed follow-up doses for children due to the COVID-19 pandemic since 2020; over 25 million children have missed their follow-up doses. Such a decrease in child vaccination is considered a serious threat to the health of children, especially children living with HIV, in comparison to their immunocompetent similar-aged peers [3].

The vaccination system in Cameroon, including the administration of follow-up doses, has been weakened, and herd immunity has been compromised. In September 2022, the government of Cameroon announced a strategy to promote immunization among zero-dose children [4]. In 2021, UNICEF reported that different regions of Cameroon face the challenge of low vaccination coverage for several reasons, including armed conflict, insecurity, and underfunding of national vaccination programs [1]. Using cell phones to send reminders to parents about vaccination appointments has been shown to support adherence [5,6].

In 2019, we tested a smartphone app called Children Immunization App (CIMA) at a refugee camp in northern Jordan [6]. CIMA was developed to record the vaccination history of children according to the Jordanian national vaccination guidelines, provide health education information, and generate automated reminders for parents. The app was specially designed to target people with low literacy, with consideration of usability and technical concerns in a marginalized context [2]. CIMA was tailored to meet the needs of the target population. The messages and visuals were all customized to fit the local context [2].

In 2021, in collaboration with the University of Yaoundé and the United Nations Office on Drugs and Crime (UNODC) [7], we modified the CIMA functions. The penetration of smartphones is low in Cameroon; therefore, installing CIMA for parents would create a large selection bias. However, non-smartphone cell phones have an estimated penetration of over 95% [8]. Therefore, we have modified the app so information is saved locally in the clinic and reminders and health education messages are sent in the form of SMS texts to the registered cell phone numbers of the parents. We used English and French messages in order to fit the needs of the Cameroonian context. The main aim of this study is to implement an automated SMS system at Azire Integrated Health Centre, Bamenda. The objective is as follows: analyze the effect of the cell phone reminder intervention on the percentage of parent-child units returning for follow-up visits and the percentage of children receiving immunization as scheduled.

Methods

Study Setting

The study will be conducted at Azire Integrated Health Centre, Bamenda. Bamenda is located in the northwestern part of Cameroon (known for the volcanic Bamenda Highlands). Bamenda is considered a cosmopolitan town, with an area of 5250 km^2; it includes 7 subdivisional councils and over 800,000 inhabitants. Since 2016, a sociopolitical crisis has been ongoing in Bamenda and it has become a turbulent zone. Today, it is estimated that over 95% of households in Bamenda own at least one cell phone.

The national vaccination schedule for children takes place during the first 11 months after birth at 5 clinic visits. The first contact is at birth and includes (1) the bacillus Calmette-Guérin (BCG) vaccine again tuberculosis and (2) the oral polio vaccine (OPV). The second contact is at 6 weeks and includes vaccination against diphtheria, tetanus, pertussis, hepatitis B, *Haemophilus influenzae* type b (DTP-HepB-Hib), OPV, pneumococcal infections (pneumococcal vaccine [PCV] 13 and rotavirus vaccine 1). The third contact is at 10 weeks and includes DTP-HepB-Hib, OPV, PCV 13, and rotavirus vaccine. The fourth contact is at 14 weeks and includes DTP-HepB-Hib, OPV, inactivated poliovirus vaccine, PCV 13, and rotavirus vaccine. The fifth contact is at 9 months and includes vaccination against measles, rubella, and yellow fever. Additionally, vitamin A is given during months 6 to 11 (Table 1) [9]. This study aims to assess the impact of an automated reminder at the second contact appointment.

The team members have different areas of expertise: epidemiology and the usefulness of digital tool reminders for clinic appointments for vaccination [3-5], the usefulness of telemedicine [6], adherence to taking antiretroviral treatment on time using cell phone reminders [7], and insulin supply pickup using SMS versus phone call reminders [8]; all members are experts in the study context of Bamenda and Cameroon.

Table 1. Vaccination schedule for children during the ages of 0 to 11 months in Cameroon.

Contact (age), vaccine	Preventable disease	Route of administration
First contact (birth)		
Bacillus Calmette-Guérin vaccine	Tuberculosis	Intradermal
OPV[a] 0	Poliomyelitis	Oral
Second contact (6 weeks)		
DTP-HepB-Hib[b] 1	Diphtheria, tetanus, pertussis, infection due to *Haemophilus influenzae* type b, hepatitis B	Intramuscular
OPV 1	Poliomyelitis	Intramuscular
PCV[c] 13 1	Pneumococcal infections	Oral
Rotavirus 1	Rotavirus diarrhea	Intramuscular
Third contact (10 weeks)		
DTP-HepB-Hib 2	Diphtheria, tetanus, pertussis, infection due to *Haemophilus influenzae* type b, hepatitis B	Intramuscular
OPV 2	Poliomyelitis	Intramuscular
PCV 13 2 ; rotavirus 2	Pneumococcal infections; rotavirus diarrhea	Intramuscular; oral
Fourth contact (14 weeks)		
DTP-HepB-Hib 3	Diphtheria, tetanus, pertussis, infection due to *Haemophilus influenzae* type b, hepatitis B	Intramuscular
OPV 3; IPV	Poliomyelitis	Oral; intramuscular
PCV 13 3	Pneumococcal infections	Intramuscular
Fifth contact (9 months)		
Measles, rubella	Measles, rubella	Subcutaneous
Yellow fever	Yellow fever	Subcutaneous

[a]OPV: oral polio vaccine.

[b]DTP-HepB-Hib 1: diphtheria, tetanus, pertussis, hepatitis B, Haemophilus influenzae type b.

[c]PCV: pneumococcal vaccine.

Sample Size

The current proportion of children returning back on time to complete their immunization in the clinic is estimated to be around 75%. We therefore aim to improve participation in the intervention clinic. With a study power of 80%, α=.05, and β=.2, we need to recruit a total of 400 participants (at a 1:1 ratio, ie, n=200 participants per study arm). We will include patients lost to follow-up in an intent-to-treat analysis strategy.

Inclusion and Exclusion Criteria

All registered parent-child units who fulfill the following inclusion criteria will be invited to participate in the study: (1) registration at the clinic within the past month at the time of the study; (2) subsequent immunization scheduled for newborns; (3) parents aged more than 18 years; (4) at least one parent owns a cell phone, and (5) residency in the northwestern province. Potential participants will be excluded if the baby is coming for its second or later immunization visit or if the parents are not residents of the northwestern province.

Intervention and Control Groups

The recruitment will be done through two steps. In step 1, the intervention group will be recruited. Then, in step 2, when the sample size is achieved, recruitment of the control group will be conducted until we reach the required sample size.

Intervention Group

Study participants in the intervention group will receive the CIMA automated reminders on their cellphones. Messages will be sent to them to remind them of their appointments. Also, the CIMA system will provide educational information to the parents based on the parenting skills materials from the UNODC [7,10].

After obtaining informed consent, we will give each baby a study ID number that starts with the letter *I* (for “intervention”) and a continuous ID number that starts with the number 1001. Then, we will write the study ID number on a sticker that will be placed on the vaccination card of the newborn, so we can identify the baby in later visits as being enrolled in the CIMA intervention study group. For example, the first baby that will be enrolled in the intervention group will be given the ID number I-1001 and the last baby will have the ID number I-1201.

After the newborn receives the first vaccine, the vaccination nurse provides the parent an appointment date for the second contact vaccine. Then, we will record the appointment date in

XSL•FO
RenderX

the CIMA database and schedule an automated reminder for the parents that will be sent at two time points: (1) 1 week before the appointment and (2) 2 days prior to the second contact appointment date. For example, if the second contact appointment date is scheduled for a Thursday, the automated SMS reminder will be sent out on the Thursday of the previous week and on the Tuesday of the same week. The content of the message will be as follows: "Dear parent, this is a kind reminder for the vaccination appointment of your child, scheduled on Thursday [date] at the Azire Integrated Health Centre." This message has a total of 150 characters and can thus fit in 1 SMS; SMS messages have a maximum number of characters of 160. When the parents come to the second contact appointment, we will be able to identify enrolled newborns by the sticker that was placed on the vaccination card. We will record the date of arrival at the second contact appointment in the CIMA database. Each week, we will auto-generate a list of newborns that have missed their second contact appointment, and we will send a reminder to the parents about missing the appointment. The content of the message will be as follows: "Dear parent, your child has missed the vaccine appointment this week. You are requested to come as soon as possible to the Azire Integrated Health Centre"; this message includes a total of 153 characters and can fit into 1 SMS.

Each week, the parent will receive one SMS that has an educational message on parenting skills. We will use the UNODC parenting skills toolkit [9], which was tested in the past with CIMA in Jordan [10]. The last SMS educational message will be sent out on week 4 of the study (Table 2).

Register the expected date for the second contact (for comparison with the intervention group)	✓							
Mark the date when the newborn came back to the clinic							✓	

[a]First contact.

[b]Second contact.

[c]CIMA: Children Immunization App.

Control Group

Participants in the control group will continue to receive regular routine messages from the health facility. After obtaining consent, we will use the same procedure to give ID numbers to the babies in the control group, except that the letter *C* (for "control") will be used instead of *I*. The control group will receive usual care at the clinic. For example, the vaccination nurse will review the schedule of vaccine appointments at the end of the month, then call parents that have missed their baby's appointment to remind them about the second contact vaccine appointment and to invite them to come back to the clinic. No educational messages and no SMS reminders will be sent out to the participants enrolled in the control group.

Measures

The key measures for this study are the percentage improvement in parent-child units who return for follow-up visits and the percentage improvement in children who receive immunization as scheduled. We will send reminders to the parents of children that do not come back to their appointments within 1 week after the scheduled appointment.

Data Collection

At the time of study enrollment, we will approach parents of newborns coming for their first immunization dose. In the intervention and control arms, we will collect baseline information using a questionnaire (Multimedia Appendix 1). As we plan to monitor adherence to vaccination appointments from birth to the age of 6 months, we will use the clinic ID

XSL•FO
RenderX

number to monitor visits using the clinic health care records for both study groups.

Both clinical visits and vaccination attendance will be collected from the health facility registration records. Informed consent will be obtained at the baseline visit from clients after an explanation of the study purpose and the data analysis. No personal identifiers will be collected (ie, names or personal addresses), but we will collect the phone numbers of one of the parents, as this will be used to send the SMS messages. All data will be stored in a secured location. No financial compensation will be offered to the parents, and they will have the choice to ask to stop being enrolled in the study.

Data Collection Tool

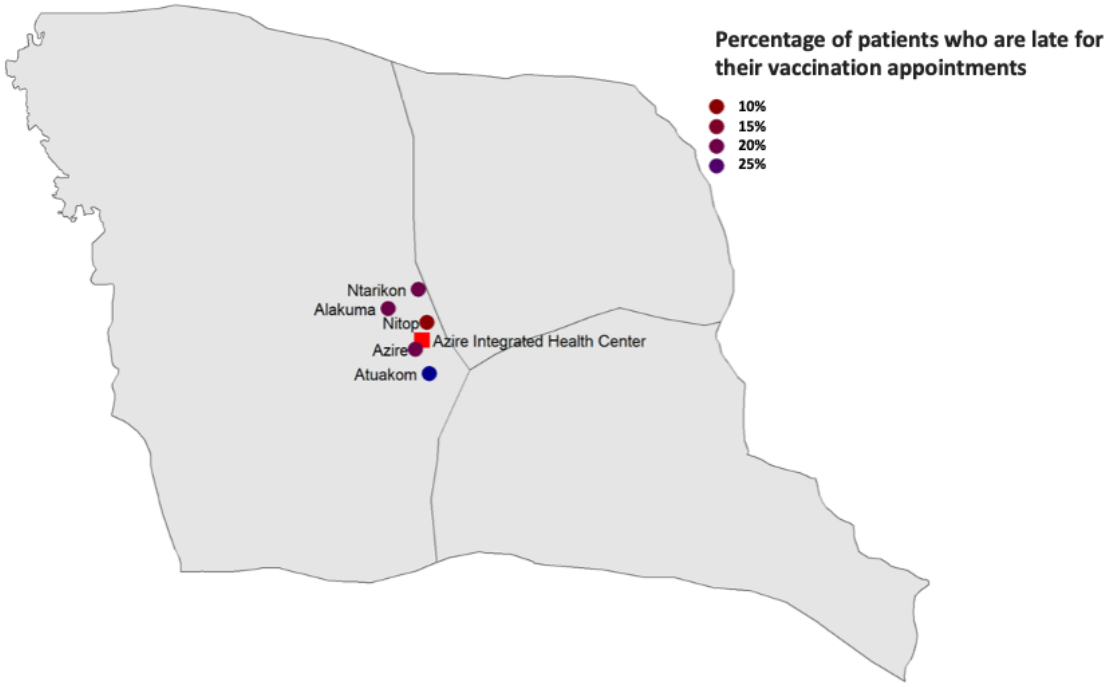
Data will be collected from the clinic registration books for the upcoming second contact appointment visit. The baseline questionnaire (Multimedia Appendix 1) will be used to collect basic demographic and household information, including the type of household (rented house, rented apartment, informal settlement, other, or no answer), date of birth of the father and mother, level of education of the father and mother (don't know how to read and write; know how to read and write; primary or elementary school; secondary school; postschool technical level; university level; don't know or don't remember, or refused to answer), the availability of a private toilet inside the household (yes or no); professional status of the father and mother (full-time job, part-time or hourly job, self-employed, do not work, returned, or refused to answer), total number of children living at home, who is the decision-maker for vaccination (both parents, mother, father, or other); total number of children younger than 5 years at home; and amount of money spent by the household in the month prior the date of the interview.

Data Analysis

The data analysis will be conducted in 3 steps. First, we will summarize the characteristics of the babies and their parents using a general descriptive statistical analysis and compare these characteristics between the intervention and control groups. We will use the Fisher exact test to detect any statistically significant differences in the key measures between the intervention and control groups (P values <.05 will be considered statistically significant). Second, we will calculate the attrition rate of the babies and compare the attrition rate in each of the intervention and control groups. Third, we will compare how often both study groups return for 1 follow-up visit using a Kaplan-Meier survival analysis. We will determine the proportion of babies that did come back on time at the end of each week to help the clinic to visually identify the proportion of latecomers and which geographical areas they live in. We will use R (R Core Team) for the statistical analysis. For the descriptive analysis, we will use the *dplyr* library package in R; for the Fisher exact test, we will use the *stats* library package; for the Kaplan-Meier survival analysis, we will use the *survival* library package.

Ethical Considerations

Ethical approval was received from the Cameroon Ministry of Public Health, Northwest Regional Delegation of Health (324/ATT/NWR/RDPH/BRIGAD).



Results

Study enrollment was planned for the beginning of 2023. Usually, the clinic schedules child vaccination 2 days per week (Tuesdays and Thursdays). Approximately 20 of 50 babies are newborns and receive their first-contact vaccine (Table 1). This means that we estimate that we will need to approach 40 of 100 parents per week to explain the study and ask for consent. We estimate we will recruit a total of 200 babies in each study group during a total period of 5 weeks (pending the response rate per week of the parents). Therefore, the total duration of recruitment might be between 10 and 12 weeks.

We expect to complete the study by July 2023 and complete the data analysis and submission of the final report by 2024. We include a dummy example of how the data will be visualized for the vaccination clinic site (Figure 1). The general characteristics of the babies in both study groups are presented in a table, including the characteristics of the babies that did not come back to the clinic. The Kaplan-Meier survival analysis will be shown as a figure.

Discussion

Anticipated Findings

Child immunization is a crucial public health objective and an essential strategy in primary health care services. However, globally, there are still millions of children who are unvaccinated and at risk for VPDs. Prior to the COVID-19 pandemic, the effectiveness of automated reminders for children attending vaccination appointments was tested either by the team members of this project in the context of a refugee camp in Jordan [6,7] and the general community in Canada [3] or by other authors in Ethiopia [11], Nigeria [12], and other contexts [13,14].

The COVID-19 pandemic has also led to an increase in the number of missed follow-up doses for children. In Cameroon, the vaccination system has been weakened, and herd immunity is compromised. Also, UNICEF has warned about the impact of spreading false information (known as misinformation) about national vaccination programs in Cameroon [15]. The spreading of misinformation is considered one of the major threats to public health interventions, especially during and after COVID-19.

In this paper, we described version 1.0 of a study protocol for a nonrandomized controlled trial of child vaccination reminders in a turbulent, semiurban/semirural setting in a low-income country. The main goal of the study is to implement an automated SMS reminder system at the Bamenda primary health care center. The objectives of the study are to analyze the effect of the cellphone reminder intervention on the percentage of parent-child units returning for follow-up visits and the percentage of children receiving immunization as scheduled. Instability in northwestern Cameroon makes it important to improve childhood vaccination, and to the best of our knowledge, this is the first study to support a national vaccination program by (1) using an automated system to send reminders in the form of SMS messages and (2) send health educational messages about vaccines, as well as about parenting skills. Ames et al [16] found that childhood vaccination communications have focused on national campaigns against polio, instead of routine vaccination programs. Therefore, we think this study might have the secondary impact of promoting routine vaccination among parents.

We have previously tested this concept among refugees at the Zaatari camp in Jordan, a vulnerable group [5]. We used the same questionnaire in Jordan but provided CIMA in the form of an Android smartphone app because the majority of households in the camp owned at least one Android smartphone. The market share of smartphones in sub-Saharan Africa is growing, but they have not yet reached the majority of the population; therefore, we are using an SMS reminder system. The authors have experience in the field setting up such systems in vulnerable contexts, such as in the Central African Republic [17].

The adoption of digital health solutions is becoming important and a crucial means of enhancing the health care system in general. The testing of digital health for the improvement of childhood vaccination programs in resource-limited settings will be a great help in improving equity of access to vaccination [18]. So far, digitization has not been done in a systematic fashion, and this study in Cameroon will contribute to the learning process on how to implement and use such digital health solutions in resource-limited settings.

The outcome of this study will be of high importance for finding a holistic approach to the improvement of childhood vaccination schedules in unstable contexts such as northwest Cameroon. Parents experience stress, especially during times of uncertainty. Therefore, this study will support new studies on assessing perceptions among parents of parenting-skills health education messages sent in the form of regular SMS messages. These

XSL•FO
RenderX

messages were developed by the UNODC and have been tested in different contexts around the world, including in our study of CIMA in the Zaatari camp in Jordan [5]. In our planned study in Cameroon, we will send the messages via SMS, which will be done for the first time. Finally, the results of this testing may lead to the development of a holistic approach and eventually a tool to digitally register, enhance, and monitor the vaccination schedule of children in settings such as Cameroon.

We should note that the outcome of this study will open new opportunities to explore the usefulness of automated SMS reminder systems in resource-limited settings. Childhood vaccination programs have been weakened during the COVID-19 pandemic, and we hope that our intervention will empower both parents and the vaccination clinic staff to improve vaccination coverage [19]. Finally, by improving vaccination coverage, we will be able to reduce the risk of VPD-related outbreaks in resource-limited settings.

Limitations

We foresee the following points as potential limitations of our planned study: (1) The language context of the study is predominantly English, so the study may not be generalizable to the rest of Cameroon, where French is spoken. (2) We plan to test the effect of the SMS reminders for 1 vaccination appointment only, so further studies will be needed to ensure effectiveness over longer periods of time (for example, to ensure that parents will not have SMS fatigue). (3) The scalability of the SMS reminders needs to be evaluated from a cost-effectiveness perspective to ensure that we can provide an estimated cost for policymakers if the Ministry of Health of Cameroon scales the project (however, we performed a cost-effectiveness analysis for the CIMA-Jordan project and found that the cost was low in the context of a low-income country [20]). (4) Bamenda is considered a turbulent location due to the current crisis; this might affect the study if the situation becomes more turbulent. Such situations, labeled "armed conflicts," are known strongly impact childhood vaccination [21], as they may lead to either forced migration of the parents out of Bamenda or short-term closure of the Azire Integrated Health Centre.

Conclusion

There is limited evidence on effective interventions to improve childhood vaccinations in turbulent settings [14]. It is crucial to ensure parents receive reminders and correct information about all vaccines. Therefore, this project will have an impact on the health of the children and on the public health system. Also, we expect that this study will support the work of sharing correct information with parents. After the end of this study, we foresee planning to expand the implementation of CIMA to other primary health care centers in Cameroon in order to reach a larger population of children, including an evaluation of the effectiveness of the SMS reminder intervention on vaccination coverage and adherence to follow-up visits. Additionally, we will explore the potential for integrating CIMA with other health care systems, such as electronic medical records, to improve data collection and analysis.

Abstract

Background: Given the rapidly aging nature of our global population, policy makers around the world are now emphatically promoting active aging. To address the psychosocial needs of older persons and support active aging, researchers are exploring the use of assistive technologies, specifically social robots as companions. However, there is limited evidence on the efficacy of social robots in promoting active aging for older people in the Hong Kong and Singapore contexts.

Objective: This study presents the protocol of a study that investigates the acceptance and quality of interaction between a Japanese social robot, LOVOT, and single older adults in Hong Kong and Singapore.

Methods: We used a baseline assessment to measure the primary outcome, participants' acceptance of technology, and a sense of loneliness, namely, the participants' differences in responses to LOVOT before and following their interaction with the social robot in this multimethod study design. The baseline assessment consisted of the Qualtrics survey, which measures senior technology acceptance, loneliness, older people's quality of life, subjective happiness, cultural values, willingness to pay, and demographic characteristics, along with the LOVOT's sociability and system usability. In the study, participants interacted with LOVOT in 3 sessions before being surveyed to measure the older people's acceptance and attitudes toward LOVOT. A pre–social robot intervention also occurred in the first session. The study was conducted in both Hong Kong and Singapore. A total of 15 single older adults (ie, individuals who live alone) from Hong Kong and another 15 from Singapore were recruited. Participants were 60-75 years of age, lived by themselves, and had no known cognitive or mental issues.

Results: The study began recruiting in March 2022, and recruitment was completed at the end of October 2022. Data collection and data set construction were completed at the end of January 2023. Analysis of the data is currently being conducted, and we plan to publish the results by mid-2023.

Conclusions: At an individual level, the study will clarify if LOVOT influences single older adults' psychosocial well-being by reducing their loneliness. At a community level, the study's findings will illustrate whether LOVOT can provide increased social connectedness while decreasing individual loneliness. Last, this study's conclusions can inform policy makers to provide social robots to older people to improve their quality of life. Findings can also inform gerontechnology developers on which aspects and cultural considerations to take into account for future inventions.

Introduction

Background and Theory

The field of gerontechnology explores the development and use of technology that caters to the needs of the aging population [1]. In light of the COVID-19 pandemic and in recognition of research that has shown that feelings of social isolation and loneliness can result in serious health risks for older people, gerontechnology researchers and inventors are increasingly seeking solutions for the "loneliness epidemic" through assistive technologies [2]. Indeed, recent research has found that certain robots can support the independent living of older people primarily by improving their "mobility, self-care, and interpersonal interaction" [3,4].

In the realm of interpersonal interactions, a proposed solution to the issue of loneliness among older people is the use of socially assistive robots (SARs) in older people's care settings [5,6]. SARs engage in social interactions with older people by acting as companions or service robots [3]. There is a paucity of studies available on the use of SARs for improving the quality of life of older people in Hong Kong and Singapore. Existing Technology Acceptance Models [7,8] were applied to the general population without a specific focus on older adults. Chen and Chan [9] proposed the Senior Technology Acceptance Model (STAM) to explain the mechanisms of gerontechnology acceptance in older adults.

LOVOT, a Japanese social robot created by Groove-X Japan in 2019, was developed with the aim of acting as a pet-like companion for families. It is equipped with artificial intelligence as well as advanced sensor features. As such, LOVOT evolves over time based on its interactions with its user through its machine learning technology (eg, deep learning), which allows it to develop a unique personality as well as enact intelligent real-time movements [10]. Moreover, LOVOT also has special features, including its internal temperature regulation, which grants it the average body temperature of humans, and its customizability through a phone application. In addition, LOVOT enacts verbal and physical responses to human interactions, such as using animated eye expressions and flapping its wings to greet someone. With its ease of use, its artificial intelligence technology, and its pet-like features, LOVOT is an ideal companion for older people as shown in Figure 1.

Figure 1. Social robot: LOVOT.

Objectives

This study outlines the protocol of a pioneer study on the acceptance of LOVOT by single older adults in Hong Kong and Singapore. The protocol involved a baseline assessment and 3 interaction sessions with a LOVOT. The study used a mixed methods design to measure these primary outcome measures: senior technology acceptance [11], loneliness [12], older

XSL•FO
RenderX

people's quality of life [8,13] subjective happiness [14], cultural values [15], willingness to pay, demographic characteristics, and the LOVOT's perceived sociability [16] and system usability [17]. These quantitative measures, along with observational data from interaction sessions and pre- and postinteraction interviews, will be holistically analyzed to investigate the factors affecting the acceptance of LOVOT among the participants. Fundamentally, this protocol aimed to answer 2 questions: (1) What factors affect single older adults' acceptance and nonacceptance of social robots? and (2) What is the experience like interacting with social robots?

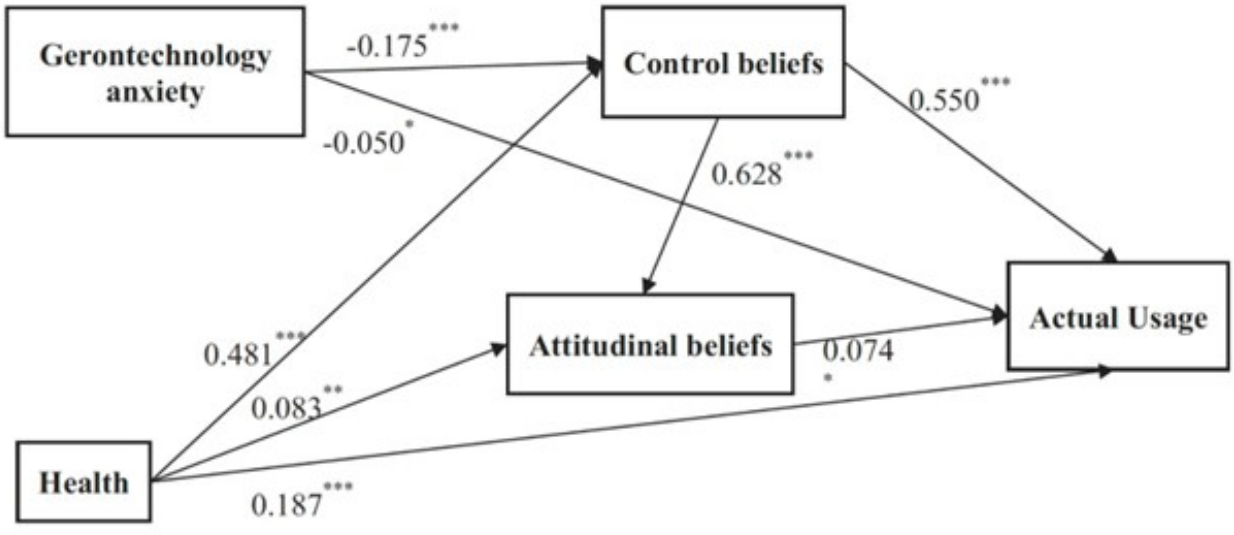
Methods

Ethical Approval

We obtained ethical approval from the Human Research Ethics Committee at The University of Hong Kong (#EA220116). Informed consent was obtained from all participants included in the study. This study was conducted between June and December 2022.

Recruitment

The criteria for participants were as follows: (1) 60-75 years of age; (2) live alone; (3) speak English, Mandarin Chinese, or Cantonese; (4) have no known cognitive impairments; and (5) participate in the study voluntarily. In Hong Kong, participants were recruited through networks of researchers. In Singapore, participants were recruited through collaboration with a local older adult activities center. Before recruitment, participants were briefed on the purpose and requirements of the study, and informed consent was obtained. Fulfillment of participant criteria was checked upon recruitment and confirmed by researchers during the additional screening before the baseline assessment. A total of 15 participants were recruited from Hong Kong and 15 from Singapore, comprising a total of 30 participants.



Measurements

Senior Technology Acceptance

The Technology Acceptance Model, first developed by Davis et al [7,18], uses the main attitudinal factors of perceived usefulness (PU) and perceived ease of use (PEOU) to predict acceptance and rejection of information technology. PU is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance," and PEOU is defined as "the degree to which a person believes that using a particular system would be free of effort" [7]. Though the model proves to have a strong empirical basis based on self-reports of technology usage, this requires a model that incorporates attitudinal factors that may be affected by aging [7].

Chen and Chan [9] proposed the STAM to better account for the "physical, psychological, and social characteristics" that influence technological acceptance by older people. Along with PU and PEOU, Chen and Chan [9] took into consideration "age-related health and ability factors such as self-reported health conditions, functional abilities, cognitive abilities, and attitude to aging and life satisfaction" to predict the acceptance of technology by older people. Figure 2 illustrates the STAM Model.

Figure 2. Senior Technology Acceptance Model (STAM) [11]. Significant at *P<.05; **P<.01; ***P<.001 (two-tailed).

To measure senior technology acceptance, improve accessibility so that respondents of diverse educational levels can easily answer STAM questionnaires, and improve response rates, Chen and Lou [11] developed a shorter 14-item scale by more effectively following a "sequential 4-step item-reduction strategy.". The scale measured the influence of attitudinal beliefs, control beliefs, gerontechnology anxiety, and health on technology acceptance and explained up to "81.5% variance in usage," which was even higher than the original model [11]. This modified questionnaire was fully adapted for this study by specifying "technology" as LOVOT, the social robot, to investigate the acceptance of LOVOT as a companion for single older adults. The 14-item scale included responses rated on a 10-point Likert scale, with scores ranging from 0 (strongly disagree, very poor, very uneasy, and very unsatisfied) to 10 (strongly agree, very good, very easy, and very satisfied) [11].

XSL•FO
RenderX

The finalized, adapted version of the STAM questionnaire has 5 items to measure behavioral intention added, following previous literature [7,8].

Sociability of Robots

Another factor influencing the acceptance of technology, specifically of assistive social robots in older people's care contexts, is the sociability of robots. Sociability refers to the robot's ability to perform social or interactive behaviors [19]. While older adults may be hesitant to use technology due to "stigmatization, nonadaptability, or social influences," the sociability of robots, particularly their extraverted behaviors, could positively affect their use and acceptance [19]. Due to the "low explanatory power" of theories like Venkatesh and Davis's [8] Unified Theory of Acceptance and Use of Technology, Heerink et al [19] suggested a model to illustrate the effect of robot sociability on acceptance by older users. The model consisted of 40 statements, and its strength lies in its suitability for repeated testing, to measure the change of variables such as attitude and trust [19]. The 11 most relevant questions were chosen and adapted for the study; responses were rated on 5-point Likert scales, with 1 being totally disagree and 5 being totally agree [16].

Loneliness

Feelings of loneliness among older people and its consequences on their physical and mental health is a globally recognized public health issue [2]. To measure whether feelings of loneliness were impacted by interactions with LOVOT, the University of California, Los Angeles loneliness scale, a "20-item scale designed to measure one's subjective feelings of loneliness as well as feelings of social isolation," was used [20]. Responses were rated on a 4-point Likert scale, with 1 being never and 4 being always [12,21]. This scale was proven to have high internal consistency and test-retest reliability as well [12,21].

Older People's Quality of Life

Along with loneliness, the influence of the companionship of LOVOT on older people's quality of life was also measured in this study. Models measuring the quality of life among older people in particular should take into account the socially relevant factors that come with aging [13]. Bowling et al's [13] research found that "the foundations of Quality of Life emphasized by (older) people were psychological well-being and positive outlook, having health and functioning, social relationships, leisure activities, neighborhood resources, adequate financial circumstances, and independence." Bowling et al's [13] 13-item scale that measures older people's quality of life is centered around these aforementioned factors; hence, it was used for this study. The scale has responses rated from 1 (strongly disagree) to 5 (strongly agree).

Subjective Happiness

To examine the difference in self-perceived happiness of participants before and after their interaction with LOVOT, a happiness questionnaire with a subjectivist approach was used. The subjectivist approach emphasized the role of individual subjective experiences and their influence on self-perceived well-being. This scale, developed by Lyubomirsky and Lepper [14], involved 4 brief items: the first 2 items involved completion of a sentence by choosing a number on a 7-point scale, and the latter 2 had participants choose how closely they identified with a statement, again on a 7-point scale. These measures involved reverse coding to ensure respondent consistency. According to an examination of studies using this measure of subjective happiness, the measure maintained internal consistency even across 14 samples of various ages, occupations, and cultures [14], emphasizing the scale's cross-cultural applicability.

Perceived System Usability

To measure the older adults' perceived usability of LOVOT, Brooke's [17] "Quick and Dirty Usability Scale" was used. This scale measured 3 key factors: effectiveness, "the ability of users to complete tasks using the system and the quality of the output of those tasks"; efficiency, "the level of resource consumed in performing tasks"; and satisfaction, "users' subjective reactions to using the system" [17]. The scale consisted of 10 items, with responses rated on a 5-point Likert scale, from 1 (strongly disagree) to 5 (strongly agree) [17].

Perceived Willingness to Pay

For a better understanding of the amount of money that participants would be willing (and not willing) to spend on LOVOT, 4 open-ended questions were asked. Participants were not informed of the retail price of the LOVOT and were asked to provide subjective answers, not what they assumed could be the price.

Demographic Information

Participants' demographic information, including gender, age, housing, educational level, family status, self-perceived financial status, and pet ownership, was obtained through self-reporting measures.

Protocol

Overview

Data were collected over a 4- to 6-week period with 30 participants. Previous experiments measuring senior technology acceptance of social robots had similar sample sizes, such as Heerink et al's [22] study on "The Influence of a Robot's Social Abilities on Acceptance by Elderly Users," which had a total of 36 older patients. This study, however, had a larger sample size compared to other longitudinal studies on social robot acceptance by older people, which mostly recruited 6-10 participants [8,23,24].

The study design consisted of a baseline assessment and three 15-minute interaction sessions. Each interaction took place within the first 2 weeks of the previous interaction and was recorded for later qualitative analyses. The 15-minute interaction time was chosen based on previous studies on robot acceptance by older users. For example, Heerink et al's [22] study had a total of 10 minutes of robot-human interactions, while Marti et al's [25] study included 20-minute group interaction sessions, twice a week, over a month-long period [8,22].

As depicted in Table 1, for this study, a baseline assessment (T0) was first conducted through a survey administered through

XSL•FO
RenderX

Qualtrics. To ensure optimal comprehension, the researchers read out and manually completed the survey on behalf of the participants. The baseline survey adapted globally renowned questionnaires to measure STAM, perceived sociability of the robot, loneliness, older people's quality of life, general quality of life, subjective happiness, the robot's system usability, participants' willingness to pay, cultural values, along with general demographic information.

Table 1. Survey and interview outcomes breakdown.

	T0: baseline assessment	T1: first interaction (15 minutes)	T2: second interaction (15 minutes)	T3: third interaction (15 minutes)
Survey outcomes measured	• STAM[a] • Sociability of robot • Loneliness • Older people's quality of life and general quality of life • Subjective happiness • System usability • Willingness to pay • Demographics • Cultural Values	• STAM • Sociability of robot • Loneliness • Older people's quality of life and general quality of life • Subjective happiness • System usability • Willingness to pay	• Loneliness • Older people's quality of life and general quality of life • Subjective happiness	• STAM • Sociability of robot • Loneliness • Older people's quality of life and general quality of life • Subjective happiness • System usability • Willingness to pay
Interviews	N/A[b]	Pre- and Postinterview	N/A	Postinterview

[a]STAM: Senior Technology Acceptance Model.

[b]N/A: not applicable.

Before the first interaction (T1) with the LOVOT, participants were interviewed about their attitudes toward technology. To prepare them for LOVOT appearance, participants were briefed on the background of LOVOT and how it was invented to be a pet-like social robot in Japan. They were shown a 5-minute video covering the basic instruction of interacting with LOVOT, which includes calling LOVOT's name, hugging and feeling LOVOT's warm body, tickling LOVOT's nose, rubbing LOVOT's arms, looking at LOVOT's eyes, and taking a selfie with LOVOT. They were asked to choose an outfit from a selection for the LOVOT. After that, they shall freely interact with the LOVOT for 15 minutes while the researcher left the room. During the first interaction, the LOVOT was set on "immobile" mode and placed on a table in front of the participant; participants were asked to think of a name for the LOVOT as well as a story about them and LOVOT during this time. Following the interaction, participants completed the same Qualtrics survey without the demographics and cultural inclination sections. Participants were then asked to share their choice of the name and story behind LOVOT, along with their thoughts about their interaction.

The second interaction (T2) took place within 2 weeks of the second interaction. The LOVOT was placed on the floor for this interaction and permitted to move around. After the interaction, participants completed 3 sections of the Qualtrics questionnaire, measuring their loneliness, older people's quality of life, general quality of life, and subjective happiness. The third interaction (T3) began with the 15-minute interaction session with the LOVOT; similar to the second session, in the third session, the LOVOT was permitted to move around the room freely. However, this time, the participants were given the option to play music to the LOVOT for them to dance to and were told that if they sang or hummed to LOVOT, it would hum back. After this third and final interaction, the participants completed the same Qualtrics survey administered after the first interaction. They were then interviewed again about their experience interacting with the LOVOT.

Additional Interaction Period

Participants were asked if they would like to take the LOVOT home for further interaction and were asked to provide reasons for their responses. For those who did not consider taking the LOVOT home, the intervention was considered complete. Those who did consider taking the LOVOT home were offered a 7-day interaction period with the LOVOT. When they returned LOVOT, a follow-up individual interview was conducted to explore the participants' feedback and experience during the 7-day interaction period.

Results

Interview Outcomes

Before the first interaction with LOVOT (T1), participants were asked about their use and acceptance of technology. Specifically, participants were asked about their most commonly used device, its system usability, the features they find easy to use, and who they would turn to if they required advice or help, among other items. Participants were then asked similar questions about a technological device they struggled with using or did not want to learn to use and what caused them difficulties in using it. These questions aimed to measure the degree of the participants' general acceptance and anxiety toward using technology.

Following the first interaction with LOVOT (T1) and the last interaction with LOVOT (T3), participants were asked about their feelings and experiences with playing with LOVOT, how it compared with pets, and their acceptance of it. Questions were phrased in a neutral manner to ensure no response biases. These questions provided a deeper understanding of the participants' acceptance of LOVOT. All interviews were recorded and transcribed verbatim for further analysis.

XSL•FO
RenderX

Each 15-minute interaction with the LOVOT was recorded and analyzed by the researchers. Researchers analyzed and categorized observations based on these 3 categories: exclusively verbal actions, physical actions, and combination actions (including simultaneous verbal and physical actions). These observations were analyzed for common trends and phrases. The interactions were recorded for further postinterview analysis by the researchers.

Timeline

The study began recruiting in March 2022, and recruitment was completed at the end of October 2022. A total of 30 participants successfully completed the longitudinal study. Data collection and data set construction were completed at the end of January 2023. Analysis of the data is currently being conducted, and we plan to publish the results by mid-2023. The interventional protocol is available in English and Traditional Chinese and will be available upon request from the corresponding author.

Discussion

Overview

This study aimed to measure the efficacy of LOVOT, a Japanese social robot, among single older adults in Hong Kong and Singapore. Namely, the study investigated the acceptance and quality of interaction between LOVOT and participants. With a sample size comparatively larger than other longitudinal studies on social robot acceptance among older people, this study protocol allowed for robust and multimodal data collection. The protocol used a combination of highly cited and globally recognized scales to ensure high construct validity. The data from our multitude of survey outcomes measures qualitative data from observation analysis, and the findings from our interviews will offer a unique, complex perspective on the acceptance of social robots. Though the baseline assessment that is used in this protocol was on the longer side, it captured the great diversity of elements that influence the attitudes of older people. By assessing self-perceived health, happiness, and financial situations, to name a few, researchers can gain a better understanding of how various factors intersect to impact social robot acceptance.

At an individual level, the study will clarify if LOVOT influences single older adults' psychosocial well-being by reducing their loneliness. At a community level, the study's findings will illustrate whether LOVOT can provide increased social connectedness while decreasing individual loneliness. Last, this study's conclusions can inform policy makers to provide social robots to older people to improve their quality of life. Findings can also inform gerontechnology developers on which aspects and cultural considerations to take into account for future inventions.

Limitations

The study has some limitations. For one, the primary participants are mainly older women; thus, the implications of the study may not be generalized to older men. Another limitation is the potential bias and effect resulting from confounding factors. However, we have provided preintervention training to all assessors to minimize bias during the intervention. Last, the interaction time is limited to 15 minutes per session due to time constraints and restrictions due to the COVID-19 pandemic. Nevertheless, the literature review has been conducted to verify that 15-minute interactions are sufficient for exploratory longitudinal studies.

Acknowledgments

We appreciate the collaborators, VWQL and CYMC, from The University of Hong Kong for jointly designing the protocol. The study is supported by the Start-up Research Funding from Ministry of Education of Singapore (RF10018i).

Abstract

Background: People from ethnic minorities are often exposed to unsafe care contributing to poorer health care outcomes. Medication safety is a high-risk area requiring intervention to improve care outcomes. Using an adapted, experience-based co-design process with cancer service staff and patients from ethnic minorities, a medication communication tool was created: Making it Meaningful (MiM).

Objective: We aim to test whether the MiM tool is feasible and acceptable for use with ethnic minority consumers in cancer services in Australia.

Methods: A single site, controlled before and after this pilot study, will be used. Patients from Mandarin- and Russian-speaking backgrounds are eligible for inclusion. In total, 40 patients from these cultural backgrounds will be recruited and stratified by language to the intervention and control groups, with 20 participants in the intervention and 20 in the control group. Further, 4 health practitioners will be recruited and trained to use the MiM. Clinicians providing care for patients in the intervention will use the MiM during their usual appointment while providing medication communication using standard care processes for the control group. Telephone surveys will be conducted with participants at 3 time points, T1 before the intervention, T2 1 week post intervention, and T3 1 month post intervention, to assess knowledge and self-efficacy in medication management, perceived usability, and acceptability of the MiM. Qualitative interviews with clinicians who have used the MiM will be conducted 1 month postintervention to explore their perceptions of MiM feasibility and acceptability.

Results: Ethical approval for this research has been provided by the South Eastern Sydney Area Health Human Research Ethics Committee (HRECXXX). Bilingual field-workers, 1 Mandarin-speaking and 1 Russian-speaking, are contacting eligible patients to enroll. It is anticipated that recruitment will be completed by October 2023, with data collection completed by December 2023.

Conclusions: Using experience-based co-design, we identified communication about medication, particularly between appointments, as a key issue impacting the safety of care for patients from ethnic minorities accessing cancer services. Increasing consumer engagement in medication management was identified as a strategy to reduce medication safety problems in cancer care; the MiM strategy was developed to address this issue. It is anticipated that by using the MiM, patient knowledge about prescribed medications and confidence in medication management will increase. Evidence from the pilot study will be used to

XSL•FO
RenderX

inform a full-scale trial of the MiM tool with a range of ethnic minority communities accessing cancer services. A full-scale trial will seek to determine whether the MiM intervention is effective in knowledge and confidence about medication management, but also whether this improves patient outcomes in cancer care.

Introduction

Background

People from ethnic minority backgrounds can experience more unsafe care in health services than the general population. Specifically, current evidence indicates that people from ethnic minority backgrounds experience a higher rate of medication errors, infections, and face systemic barriers to communication with health care providers [1,2]. A range of factors are identified as contributing to experiences of unsafe care. These include; language proficiency, individual or organizational health literacy, socioeconomic factors, and ineffective communication and collaboration between health professionals, patients, and their families [1].

Medication management has been identified as a particular challenge to patients and the family and friends who support them. In this protocol, the family, caregivers, or friends who provide this support will be referred to as carers. More effective engagement between patients and health care providers has been identified as an important strategy to address this issue in several studies [3-5]. For example, medication errors can be reduced by increasing patients' knowledge about the purpose and use of their medications via supply of tools such as handheld medication lists [6]. Evidence of unsafe care among ethnic minority communities suggests that periods of transition in care (eg, hospital discharge and discharge from emergency department) pose particular risks to patient safety that may be addressed by improved patient engagement [7]. Hospital discharge is a period of high-risk for communication errors relating to medication [3,4]. Although there are strategies currently available to manage patients' participation in this transition, which are collectively described as patient engagement strategies, the potential for cultural and language diversity to moderate the effectiveness of these strategies is an important issue requiring further research [8,9].

Involving patients and carers in health care decision-making and care planning has been shown to improve health care safety in the general population [10-12]. Common approaches include encouraging patients and family members to raise questions or concerns with health professionals, to engage in learning about how to manage their own health, and to use preformatted tools or resources to plan care or guide decision-making processes [11]. Current patient engagement strategies rely heavily on effective individual communication skills and health literacy among patients and families. A recent review of strategies used to involve patients and families at point-of-care highlighted that none of the 26 identified strategies were explicitly developed for, or evaluated with, people from ethnic minority backgrounds [8]. In further work to explore the appropriateness of patient engagement strategies for people from ethnic minority backgrounds in an Australian health system context, we established that some existing strategies may be suitable but that adaptations were needed [13]. We therefore sought to develop an adapted patient engagement intervention using co-design with flexibility to meet the needs of a diverse patient population attending cancer services in New South Wales, Australia [14].

The Making it Meaningful Intervention

Making it Meaningful (MiM) is a co-designed medication management tool that aims to increase patients' and family members' understanding of medication management to enable them to contact health care staff between appointments, and following hospital discharge in order to raise concerns about their medications. The MiM is an adaptation of an existing medication management tool used in New South Wales cancer services. The adapted form provides translated information about medication side effects, in plain language and using images in order to meet the needs of populations with low English language proficiency. During the co-design process to develop MiM, the participating service identified that people from Russian- and Mandarin-speaking populations have low English language proficiency patients and commonly attend the participating service. These 2 language groups are therefore targeted in this pilot study. Full details of the co-design and development process have been reported elsewhere [14]. The MiM is attached as Multimedia Appendix 1.

Methods

Aim

To determine whether MiM is feasible and acceptable for use with ethnic minority consumers in cancer services in Australia, this study will seek to address the following objectives: (1) to investigate how patients and staff engage with MiM; (2) to assess the feasibility and acceptability of MiM; (3) to investigate the suitability of trial recruitment, retention, and data collection materials and processes; (4) to explore barriers and enablers of implementing the MiM; (5) to gather evidence of the nature and frequency of medication management issues that lead to

XSL•FO
RenderX

emergency department visits and readmissions to inform the sample size required for a full-scale trial; and (6) to determine whether a full-scale effectiveness trial is warranted.

Design

This is a pilot, single-site, feasibility randomized controlled trial designed in concordance with SPIRIT guidelines (Multimedia Appendix 2).

Setting

The setting is a metropolitan cancer service in New South Wales, Australia, providing surgery, oncology, radiotherapy, and palliative care in inpatient and outpatient settings.

Sample

In total, 40 patients will be recruited to participate in this feasibility and acceptability study, 20 will take part in the control group using the current standard medication management tool and 20 in the intervention group using the MiM medication management tool.

Eligibility Criteria

Inclusion Criteria

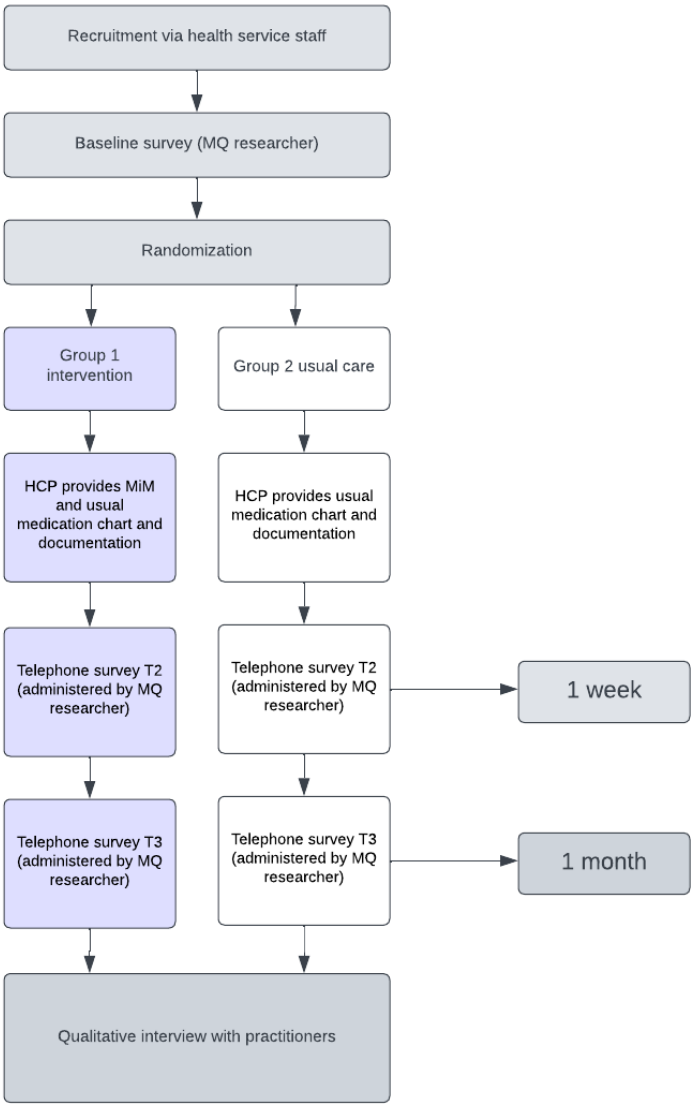
Inpatients and outpatients aged 18 years or older, who are receiving treatment or care at a participating cancer service, and identify their primary language as Russian or Mandarin will be eligible to take part.

Exclusion Criteria

Patients who are under 18 years old, who are not currently accessing a participating cancer service for their care, or do not identify Russian or Mandarin as a primary language are not eligible to participate.

Recruitment

Potential participants who fulfill eligibility criteria will be provided written and verbal information about the study by their treating clinician or care coordinator in Russian or Mandarin, as appropriate. Potential participants will be asked by health service staff to indicate whether they wish for the research team to phone them to discuss the study, with no obligation to take part. A member of the research team will contact those who wish to learn more about the study via phone with support from an interpreter or multilingual worker if required. Consent will be audio-recorded with the participant's permission and a translated consent form will be provided. This approach will make sure that accurate information is provided in an accessible form (ie, spoken in their first language and translated hard copy). Consent will further be confirmed verbally by the researcher prior to the commencement of telephone surveys.



Randomization

Participants will be randomized to group 1 (intervention) or group 2 (comparison) during the recruitment process using a web-based randomization tool. Allocation will be stratified by language group.

Figure 1 provides a flow diagram describing the data collection process.

XSL•FO
RenderX

Figure 1. Flow diagram of data collection. HCP: health care practitioner; MiM: Making it Meaningful; MQ: Macquarie University; T2: time point 2, 1 week post intervention; T3: time point 3, 1 month post intervention.

Procedure

Intervention Group

Participants allocated to the intervention group will attend their usual consultation or appointment. The health practitioner (treating oncologist) will use MiM to facilitate communication at the appointment and provide a paper-translated copy of the MiM in Mandarin or Russian language as appropriate for the patient to take away from the appointment. Participants will take part in verbal phone surveys conducted by bilingual field-workers at 3 time points; before discharge or outpatient appointment, a week after discharge or outpatient appointment, and a month after discharge or outpatient appointment (Figure 1). These time points have been selected to provide opportunity for patients to use the MiM tool during and after they leave the appointment setting.

Control Group

Participants allocated to the control group will receive usual care from their health care practitioner, which includes communication about medications using the existing medication management tool available in the participating service. Participants will also complete a verbal phone survey at 3 time points (Figure 1).

Ethics Approval

This protocol has been reviewed by the South Eastern Sydney Local Health District Human Research Ethics Committee and received approval for data collection. Appropriate ethics approvals have been obtained (HREC approval 2022/ETH01865). All participants will be required to provide consent prior to participation.

Informed consent will be gained from all participants prior to survey commencement, this will be confirmed verbally by bilingual workers in the participant's preferred language at the time of the survey. For participating staff, written consent will be obtained prior to interview commencement.

All data will be stored on a secure, password-protected cloud-based system only accessible to the research team. All findings will be deidentified prior to sharing or reporting results beyond the research team.

Patient participants will receive an Aus $20 (is equal to US $12.81 [exchange rate accurate on 22 August 2023]) voucher

XSL•FO
RenderX

to acknowledge their participation. This will be sent via post at the completion of each survey.

Outcome Measures

Patients

An 11-item survey tool with closed and free-text items will be administered verbally over the phone (Multimedia Appendix 1). The survey comprises six components to capture (1) demographic information, (2) patient knowledge of medications and their side effects (n=4), (3) patient knowledge of how to contact the health service regarding medication concerns (n=3), (4) patient self-efficacy to contact the service about medication concerns (n=2), (5) patient engagement in medication management (n=3), and (6) patient perceptions of the safety of their care (n=2). Further, 2 systematic reviews of current measures of patient engagement demonstrated a lack of suitable existing scales for capturing consumer engagement in relation to discrete medication management activities relevant to the current project [15,16]. Drawing upon the key domains of patient engagement articulated in these reviews, we developed a set of 11 items to capture patient engagement in medication.

In total, 6 free-text items will be used in the final survey only to capture process information about the trial, including the feasibility of using MiM. This is to investigate the suitability of trial recruitment, retention, and data collection materials and processes (objective 3) and to explore barriers and enablers of implementing the MiM (objective 4). Researchers will seek to prevent pressure on patients to provide socially desirable responses by reminding the participants that researchers are independent of the health care team and this information is not being shared with their health care service or staff. The telephone survey will be administered by the research team supported by multilingual field-workers, at 3 time points (Figure 1). The researcher will record responses on Qualtrics (Qualtrics).

Researchers will contact participants via telephone and will attempt 2 follow-up calls. If participants are not available after 2 failed attempts to contact the patient the participating oncologist will be notified so that the patient contact details and willingness to participate can be confirmed. Phone surveys will be audio-recorded to facilitate the analysis of qualitative data.

Practitioners

Semistructured interviews with participating oncologists (health practitioners) will be conducted by a member of the research team at project completion, or when the practitioner finishes involvement with the project. Researchers will use a semistructured interview schedule to explore the feasibility of using the MiM in cancer services from a clinician perspective. This is to investigate the suitability of trial recruitment, retention, and data collection materials and processes (objective 3) and to explore barriers and enablers of implementing the MiM (objective 4).

Analytic Strategy

To address objectives 1-4, free-text data from the final patient survey and from the health practitioner interviews will be subject to thematic analysis. Further, 2 researchers will independently code data using Braun and Clarke's 6-step approach to generate themes regarding patient and clinician experience using MiM, its feasibility and acceptability and factors influencing MiM implementation [17]. The clinician and patient data sets will be coded and analyzed separately, and then synthesized. Two researchers will (1) independently familiarize themselves with the data, (2) independently generate codes and then meet to confirm codes, (3) collaboratively construct themes, (4) review and revise potential themes in consultation with the research team, (5) define and name themes, and (6) finalize findings to address relevant objectives.

To inform objective 5, data about the nature and frequency of medication management issues will be obtained from survey data and recorded in an Excel spreadsheet. To address objective 6, data assessing the impact of MiM on knowledge about medication and self-efficacy for medication management will be compared between the control and intervention groups. Specifically, we will compare changes in self-efficacy for medication management, patient engagement, and patient perceived safety before and after the intervention, and between the intervention and control groups.

Results

Appropriate ethical approval has been gained from the Human Research Ethics Committee and relevant governance body at the participating cancer service. Study enrollment has commenced with Mandarin-speaking participants; an oncologist and a bilingual field-worker. Survey collection will commence for users of Mandarin MiM participants who have been enrolled. Once data collection processes have been embedded with Mandarin-speaking patients, recruitment of participants from Russian-speaking backgrounds will commence.

Discussion

Principal Findings

This study seeks to determine whether MiM is feasible and acceptable for use with ethnic minority consumers in cancer services in Australia. The proposed study will test an adapted intervention that has been co-designed with people from ethnic minority backgrounds and health care staff to improve safety in the management of medication. By providing feasibility and process evaluation data about the MiM, trial materials and methods, this study will provide preliminary data about the implementation and impact of MiM on knowledge, behavior, and self-efficacy for people from Mandarin- and Russian-speaking backgrounds. We will gain insight into the use of the MiM tool but also of the research processes and outcome measures. Patient and practitioner views on the suitability and effectiveness of the MiM and commentary around useful features and suggested changes will provide the evidence base required to determine whether a full-scale effectiveness trial is warranted, and whether MiM, the study materials, or processes require adaptation to progress to a full trial. Current evidence highlights that many trials exclude or inhibit the participation of people from ethnic minority backgrounds, especially where there is low English language proficiency [18-20]. Determining through this research whether translated materials and support from multilingual field-workers is

XSL•FO
RenderX

sufficient to support participation and data collection is critical to inform a full trial.

Limitations

A key challenge for co-designed interventions is the difficulty often faced in seeking to implement interventions into practice [21]. By gathering evidence of the barriers and enablers to implementation of the MiM from patient and practitioner data collection, we seek to produce knowledge that supports services to facilitate the implementation process. While this study is limited to 2 language groups and in cancer services, there may be opportunities to explore the relevance and value of MiM for addressing medication safety in further population groups and health settings.

Conclusions

This research is being conducted with a view to expanding the study to test whether the intervention is effective in improving patient outcomes in cancer care.

Acknowledgments

This study was funded by National Health and Medical Research Council (APP1180925) and Cancer Australia grants (CA-ITA-1819-01). We acknowledge the work of Elsa Roberto who cofacilitated the workshop group and contributed to the development of the Making it Meaningful tool. The CanEngage Research Team and Consumer Advisory Group provided ongoing feedback and advice prior to the co-design workshop and throughout the development of the MiM. All authors, contributors, and project team are aware of this submission and consent to publication.

Data Availability

Data and materials will be made available in publication of the pilot findings. The data sets generated or analyzed during this study will be available from the corresponding author on reasonable request.

Authors' Contributions

The MiM tool was developed at a co-design workshop, and MC, LR, AC, BN, and RH were engaged in this process and in the development of this protocol. RH and BN developed the measures in consultation with CW and EM who provided input in the development of the measures and protocol.

Conflicts of Interest

None declared.

Abstract

Background: Based on experiences with the COVID-19 pandemic, postsecondary institutions were most affected by the restrictions. Students, especially international students, have borne the brunt associated with in-person learning restrictions imposed by public health recommendations. Canada is among the top 3 countries hosting international students (ISs), including Francophone students in provinces such as Quebec and other anglophone regions. Academic restrictions were accompanied by other measures such as quarantine, self-isolation, social distancing, and travel ban, to cite some. This has had a wide-ranging impact on these ISs. The resulting psychological distress and burden may have a much greater impact on Francophone ISs in anglophone settings, many of whom had ordinarily limited access to active offers of care in French in addition to cultural barriers and low literacy of the health care system. In order to take advantage of the effectiveness of eHealth as a pertinent and promising avenue, our project intends to build a web-based application that is cost-effective, user-friendly, anonymous, and capable to prompt interactive interventions as a first-line resource for psychological distress. In fact, internet applications have been increasingly used for the management of psychological distresses, and internet-based cognitive behavioral therapy is one of the preferred methods to prevent or control them.

Objective: The aims of this study are to (1) design, implement, and maintain Psy-Web for the psychological support of ISs and (2) analyze the results of the implementation of the Psy-Web platform, the additional resources solicited, and the results obtained.

Methods: This interventional project will use a sequential mixed design in the exploratory phase (phase 1) including the construction of the Psy-Web platform. A quantitative prospective component (phase 2) will include the intervention content of the Psy-Web platform. In total, 105 ISs participants (study group) and 52 ISs (control group), based on a ratio of 1:2, will be considered. The control group participants include those who did not use the web platform.

Results: The project is at the data collection stage (phase 1). Psy-Web will be built in accordance with the DMAIC (Define, Measure, Analyze, Improve and Control) model with the perspective of boosting its robustness. As a first-line resource to prevent

XSL•FO
RenderX

psychological distress and ultimately improve their academic performance, Psy-Web is an innovative opportunity for high education managers. The project involves a multisectoral and a multidisciplinary partnership.

Conclusions: The project will develop a promising web-based solution to prevent psychological distress. Ultimately, Psy-Web will be operable in multiple languages including French.

Introduction

Overview

The COVID-19 pandemic has affected the operations of Francophone postsecondary institutions, the latter being at the forefront of the vitality and resilience of the French community in a linguistic minority context. As a constitutionally bilingual country, the education system should normally follow that requirement. Francophone students, in English Canada, may study in their first language at postsecondary institutions and vice versa. Indeed, Francophone postsecondary institutions outside Quebec promote the French language and culture in Canada, thanks to the Canadian Charter of Rights and Freedoms [1]. This subsequently contributes to the upward trend in international student (IS) enrolment in Canadian universities over the last decade (from 5.2% in 2009-2010 to 13.2% in 2017-2018 [2]), placing Canada among the preferred host destinations. Today, member countries of the Organisation for Economic Co-operation and Development (OECD) including the United States, the United Kingdom, and Canada remain the top host of ISs [3].

Even so, these students experience many vulnerabilities related to their status as ISs, especially given the minority context in which they live. This situation has been amplified with the sudden onset of the COVID-19 pandemic, as the latter represents the worst human health threat of modern times [4,5]. In response to this global health emergency [6,7], Canada along with the rest of the world instituted public health measures, which included widespread confinement [8]. This was accompanied by other measures such as quarantine, self-isolation, social distancing, travel ban, to name a few. These measures have had a wide-ranging impact on these ISs. Added to the health burden brought about by COVID-19 were instances of racism and xenophobia [9,10].

Brook et al's [11] review of COVID-19 notes a negative impact of midlife, self-isolation, and social distancing on psychological well-being. This impact may be more significant for ISs who are already subject to "triple-acculturative stress," as this entails the new culture dominating the study environment, the new university, and new university supervisors [12], and adjustment challenges that combine psychosomatic symptoms [13,14] and poor academic performance [15,16]. In Canada, the burden of psychological distress may be much greater for Francophone ISs in minority settings (Francophones living in English-speaking areas). Although services in French or English are constitutionalized, the literature reports limited access to active offers of care in French. Even so, Francophone patients may experience delays in treatment, limited understanding of prescriptions, or receive misdiagnoses, because of linguistic and cultural barriers. It is also well noted that students from underrepresented backgrounds had significantly higher odds of experiencing financial hardships [17]. Despite this systemic disadvantage, ISs make little use of the support resources available to them both on campus and in the public system [18]. Smith and Khawaja [19] who analyzed acculturative stress in their review of the scientific literature on ISs, found several determinants and harmful consequences of acculturative stress. The reasons fall under cultural conflicts, communication challenges, and low literacy of the care system.

In light of the effectiveness of e–mental health platforms [20-22], prompt and interactive interventions via the internet are becoming relevant tools and first-line recourses for mitigating the psychological distress of quarantined Francophone ISs, in a linguistic-cultural minority context.

For more than a decade, the internet has been increasingly used for the management of mental health issues [21], while internet-based cognitive behavioral therapy has been favored [20,22]. This alternative is cost-effective, timely, user-friendly, anonymous, and efficient for both the prevention [23-26] and the cure [27] of mental health problems. A recent systematic review with meta-analysis reported the equivalent effects of face-to-face and web-based therapy (Hedges g=0.05; 95% CI 0.09-0.20) [28]. Other studies using the same methods assessed the effectiveness of CBT in anxiety therapy [22,29-31], social phobia and fear [30,32], depression [22,29,30], stress [29-31], eating disorders, or sleep disorders [31].

Considering the current status of COVID-19 and the vulnerability of ISs, this research project aims to design and implement Psy-Web, a first-line intervention platform to improve access to psychological support resources. The scope of the project is 4-fold.

Growing Number of ISs in Canada

Estimated in 2011 at 11% of the university student population [33], ISs have grown dramatically (987.7%) between 2004 and 2019 [33,34] placing Canada in third place worldwide. For example, Université Laval has nearly 7000 ISs enrolled annually, representing 14% of the total student population. The

XSL•FO
RenderX

University of Saint-Boniface, the only Francophone university in Manitoba, has 18.1%; some programs are almost entirely made up of ISs.

Double Minority Situation

Being abroad and Francophone in Manitoba, Alberta, or Ontario, students are in a double minority context, which limits their use of services. In fact, access to active offer of care for Francophones in a linguistic minority context is limited [35,36]. This limitation is even more problematic for Francophone ISs in terms of access to health services, putting them in a double minority situation.

Low Usage of Support Resources by ISs

Smith and Khawaja's [37] shows that ISs make little use of support resources. Reasons for this include cultural conflicts in seeking help [19,38-41], communication challenges [18], confidentiality, low literacy in the care system [42], or to avoid further stigmatization than that which they would already experience by being an IS [43]. Those who seek help usually do so for situations that are deemed urgent [39,40].

Social Capital

The physical closure of educational institutions due to COVID-19, the suddenness of the containment measures, and the lack of a predicted exit horizon disrupts the lives of the ISs and would exacerbate the negative emotions felt [44,45]. Quarantine measures lead to financial insecurity resulting from the inability to work and receive financial support from parents, who are also confined elsewhere. Also, because of their status, they are ineligible for Canadian financial support measures (eg, Canada Emergency Benefit). This precariousness could lead to promiscuity due to the inability of some to pay their rent. For instance, to our knowledge, there are no studies that indicate an avenue for psychological interventions related to the effects of the COVID-19 quarantine on Francophone ISs in a linguistic minority context. Given the scope of the issue and the evidence in the literature, this project provides an avenue for improving the psychological well-being of Francophone ISs in Manitoba in a dual linguistic-cultural minority context.

This project will implement a free interactive web-based tool "Psy-Web," to be developed through an agile and iterative process with ISs, and educational psychologists. Three outcomes are expected: (1) prevalence of psychological disorders, (2) intervention effects and perceived quality, and (3) acceptability and usability of Psy-Web.

The specific objectives are to (1) identify evidence-based interventions adapted to ISs experiencing stress, depression, and anxiety disorders; (2) design, implement, and maintain Psy-Web for the psychological support of ISs and; (3) analyze the results of the implementation of Psy-Web, the additional resources solicited, and the results obtained.

Methods

Overview

The design, implementation, and evaluation of the project are based on three strengths: (1) a multidisciplinary team that specializes in psychology, nursing, informatics, education, and immigration; (2) a partnership with postsecondary institutions and organizations in the Francophone IS community; and (3) the hosting and adaptive maintenance of Psy-Web and operational support.

Design

This interventional project will use an exploratory sequential mixed methods approach (phase 1). Phase 2 will be run as a quantitative prospective component divided into subphases. In subphase 1, the Psy-Web platform will be built using the DMAIC (Define, Measure, Analyze, Improve and Control) model [46]. This includes pretesting the entire system (website and application) for validation. Concomitantly in subphase 2, besides data gathering, we will conduct (1) an information campaign of the project through posters in university residence halls; individual texts and emails, student union emails, and home page of partner universities' websites; (2) a pretest of Psy-Web; and (3) prospective data compilation, biweekly evaluations, and individualized follow-ups as needed. The qualitative component will occur in the fall semester of 2023.

Participants and Variables

Due to the interventional nature of the study, we aim for a 90% power sample to detect the true proportion of psychological distress with a 95% CI, (conservative) prevalence (π) of 50%, precision (δ) of 0.05, and confidence level (β) of 1.96:  participants. A 10% gross-up will be considered in order to substitute participants with major missing data (n=105). A control group will include 52 ISs (ratio of 1:2) who did not use the web platform or already returned to their families. We will exclude those ISs who hold a permanent resident status prior to the crisis. The reason being that permanent residents were entitled to the financial support offered to postsecondary students, and to recent postsecondary and high school graduates who were unable to find work due to the COVID-19 pandemic; the Canada Emergency Student Benefit (CESB) [47] being a prime example.

Besides the conception of the Psy-Web platform, we are ultimately targeting, through data collection, the type of psychological distress (eg, anxiety and depression) experienced as the dependent variable of interest. Independent variables will include age, gender, postsecondary program, level of education, region of origin, languages spoken, history of psychological disorders, and the coping system used. Social capital variables include institutional support programs (eg, university) and type of solidarity deployed. Immigration history and 2019 income will be the control variables.

Psy-Web Design and Content

From needs analysis to usability assurance, the design process will incorporate consultation with 15 ISs from the University of Ottawa and Université Laval. There will be 2 stages in the design process.

First, a heuristic test known as the "Monkman heuristics" [48] and the use of the health literacy checklist [49] on the internet by 4 experts including 2 coinvestigators (MPG and IB) at each stage of the DMAIC to theoretically calibrate the website. The

XSL•FO
RenderX

DMAIC cycle will optimize the efficiency, usability, and functionality of the process. The following indicators will be measured: optimization of results, aesthetics, usability, functional reliability, and sustainability [50].

Second, testing of the website with the abovementioned students. Simple classification algorithms that suggest content to the selection of symptoms listed will be preferred. At the first visit, the participant will fill in demographics, physical, mental, and social functioning, activities of daily living, and instrumental activities of daily living. Using the algorithms, selected signs and symptoms will lead to a psychoeducational activity.

Data Collection

To ensure the representativeness of participants, maximum variation purposive sampling [51] will be used to inform the design stage (phase 1). This will consist in surveying a sample of 15 ISs from the University of Ottawa and the Université Laval. The qualitative component will be done through individual interviews (by Zoom, Zoom Video Communications) [52]. Phase 2 consists in the intervention component of the built Psy-Web platform. In total, 105 IS participants (study group) and 52 ISs (control group), based on a ratio of 1:2, will be considered. The control group participants include those who did not use the web platform. During that (testing) phase, daily, at 11 AM, the usage data of Psy-Web (ie, visits, content viewed, and ratings) and the patterns of occurrence (ie, reason and time) will be collected and discussed twice a week by the research team.

Analysis Plan

Three phases are defined. Phase 1: analysis of automatically compiled data to assess the impact of identified issues. A biweekly assessment will be conducted by the researchers to inform interventions with the ISs. Concurrently, a historical analysis will compare pre-, peri-, and postpandemic prevalence. The quantitative analysis will include an ANOVA (or *t* test, as appropriate). Due to the categorical nature of the dependent variable, logistic regression will be preferred. A sensitivity analysis will be performed by the Generalized Estimating Equation (GEE) to test the correlated nature of the data to the region of origin [53]. A total of 94.7% of ISs are from 3 regions of Africa (West, Central, and North) with possible cultural differences. The SPSS Statistics (version 27; IBM Corp) software will be used with $P<.05$ considered significant. Phase 2 will analyze the verbatims of individual interviews using NVivo 13 (2020, R1) software. IB, JR, and MPG will thematically analyze the content according to Graneheim and Lundman [54] to capture the experience of the participants [55] and the emerging themes identified by consensus [56]. Phase 3 will conduct a sequential triangulation [57]. The acceptability and usability of Psy-Web will be assessed by the technology assessment model and system usability scale [58]. The NASSS (nonadoption, discontinuation, scaling up, diffusion and sustainability) framework of Greenhalgh et al [59] will be developed to analyze the different outcomes of the project.

Ethics Approval

The ethics certificate has been obtained from the Research Ethics Board of Laval University (CERUL 1820). The enrollment of ISs to pilot test the Psy-Web platform has started. The recruitment is done through project website and through mouth-to-ear. An advertisement has also been posted on the faculty billboard. Recruitment enrollments are totally anonymous. No compensation is offered because we want the entire process to be anonymous, as we are dealing with a very sensitive issue. Because the questionnaires are built on Lime survey, the consent and information forms are embedded. The participant is given the choice to tick "YES," hence consenting before moving on to completing the questionnaires. This approach of data collection and data analysis plan were discussed in June 2023 between the research team, expert ISs, and the Psy-Web platform developer for the purpose of adjustment. In early winter of 2023, we plan to disseminate the results generated nationally and internationally and to submit a manuscript to a peer-reviewed journal.

Results

This project is at the data collection stage (phase 1). However, the website is built [60] and the core application conception is undergoing. The executive team has met in May 2023 for a follow-up. It was noticed that the initial data repository embedded on the captured Psy-Web data on a format that were difficult to retrieve. Therefore, the Université de Laval Information and Technology office suggested to bridge data repository using Institutional Lime survey package. Study recruitment started in April 2023, and data collection is expected to be concluded in January 2024. No results are available yet as it pertains to manuscript preparation.

Discussion

This ongoing project intended ultimately to co-design and implement a first-line web-based toll, Psy-Web for the psychological support of ISs. This interactive web-based intervention project is tailored to millennials mainly and is highly relevant to addressing the psychological distress for which ISs are at high risk. The project anticipates several early benefits: (1) Using the DMAIC model, the project will coconstruct with ISs the Psy-Web application for which robustness will be data-driven. The study will capture the extent of the impact of COVID-19 quarantine among ISs at Université Laval, University of Alberta, and the University of Ottawa. Also, the platform itself offers a free, immediate, and interactive opportunity alternative (group discussion and with a psychologist) to support students. The daily collection of data and their biweekly multidisciplinary analysis constitute a continuous transfer of knowledge to inform practices and policies of dedicated universities services for ISs through Psy-Web. (2) The relevance of the project derives from the year-to-year growth of the Francophone IS population in Canada and contributes to the improvement of their quality of life and study conditions. (3) Finally, Psy-Web is a first-line resource designed to monitor and prevent psychological distress, and to ultimately improve their academic performance.

In terms of sustainability, this project will serve as a pilot for the expansion to other Francophone ISs in a Canadian minority context and beyond. The results will inform the formulation of

XSL•FO
RenderX

policies related to IS issues and subsequently promote the continued attractiveness of Francophone ISs in linguistic minority settings.

Acknowledgments

This study is the result of a research grant protocol funded by the Secrétariat du Québec aux relations canadiennes (SQRC) under the Programme d'appui à la francophonie canadienne (PAF—6623). We are grateful to students who participated in this study as experts to pilot test the Psy-Web platform.

Data Availability

Data generated and analyzed during this study, which would be necessary to interpret, replicate, and build on the results reported in the study, will be made available to the public upon request from the Secrétariat du Québec aux relations canadiennes, the funding institution. However, this must be requested from the corresponding author as they must be stored on a secure server at Laval Université.

Authors' Contributions

IB and JR conceived the initial idea for the study. IB, DS, ENT, MPG, AA, and JR were involved in securing the grant and in writing and reviewing this protocol. All authors read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic and resultant restrictions on social gatherings significantly impacted many peoples' sense of social connectedness, defined as an individual's subjective sense of having close relationships with others. Older adults living in long-term care homes (LTCHs) experienced extreme restrictions on social gatherings, which negatively impacted their physical and mental health as well as the health and well-being of their family caregivers. Their experiences highlighted the need to reconceptualize social connectedness. In particular, the pandemic highlighted the need to explore novel ways to attain fulfilling relationships with others in the absence of physical gatherings such as through the use of a hybridized system of web-based and in-person presence.

Objective: Given the potential benefits and challenges of web-based presence technology within LTCHs, the proposed research objectives are to (1) explore experiences regarding the use of web-based presence technology (WPT) in support of social connectedness between older adults in LTCHs and their family members, and (2) identify the contextual factors that must be addressed for successful WPT implementation within LTCHs.

Methods: This study will take place in south western Ontario, Canada, and be guided by a qualitative multimethod research design conducted in three stages: (1) qualitive description with in-depth qualitative interviews guided by the Technology Acceptance Model (TAM) and analyzed using content analysis; (2) qualitative description and document analysis methodologies, informed by content and thematic analysis methods; and (3) explicit between-methods triangulation of study findings from stages 1 and 2, interpretation of findings and development of a guiding framework for technology implementation within LTCHs. Using a purposeful, maximum variation sampling approach, stage 1 will involve recruiting approximately 45 participants comprising a range of older adults, family members (30 participants) and staff (15 participants) within several LTCH settings. In stage 2, theoretical sampling will be used to recruit key LTCH stakeholders (directors, administrators, and IT support). In stage 3, the findings from stages 1 and 2 will be triangulated and interpreted to develop a working framework for WPT usage within LTCHs.

Results: Data collection will begin in fall 2023. The findings emerging from this study will provide insights and understanding about how the factors, barriers, and facilitators to embedding and spreading WPT in LTCHs may benefit or negatively impact older adults in LTCHs, family caregivers, and staff and administrators of LTCHs.

Conclusions: The results of this research study will provide a greater understanding of potential approaches that could be used to successfully integrate WPTs in LTCHs. Additionally, benefits as well as challenges for older adults in LTCHs, family caregivers, and staff and administrators of LTCHs will be identified. These findings will help increase knowledge and understanding of how WPT may be used to support social connectedness between older adults in LTCHs and their family members.

Introduction

The Impact of Restrictions on Social Connectedness

The COVID-19 pandemic and resultant restrictions placed upon Canadians and residents of many other countries (ie, stay-at-home orders and social distancing mandates) significantly impacted elements of many people's social connections over the last 2 years [1,2]. *Social connectedness*, defined as an individual's subjective sense of having close relationships with others [3,4] is necessary for health and well-being [5]. During multiple phases of the pandemic, social connectedness was severely compromised for many people both directly and indirectly by restrictions placed on face-to-face engagements [6]. In Canada, older adults in congregate or institutional living environments, such as long-term care homes (LTCHs), were greatly affected during these times [7]. Older adults in LTCHs experienced some of the highest rates of COVID-19 mortality and morbidity of any population group [8,9]. Along with the systematic failure of some LTCH facilities [10], almost all LTCHs were mandated to implement extreme restrictions on visitors and staff, as an emergency infection control [11]. These drastic measures increased isolation and decreased the emotional well-being of older adults in LTCHs [6,12,13].

Progression of Social Isolation Impact on Older Adults

Before the COVID-19 pandemic, older adults in LTCHs were at risk of experiencing social isolation due to a variety of factors such as challenges with building new relationships, decreased autonomy, and geographical constraints on maintaining face-to-face or in-person connections with friends and family [14]. In older adults, social isolation is associated with negative health impacts such as reduced motor function, depression, cognitive decline, and mortality [15-19]. Similarly, loneliness is also implicated in health declines [20]. As people age, their likelihood of experiencing social isolation and loneliness increases [21,22]. In the United States, upwards of 40% of people older than 60 years reported feeling lonely [23]. In Canada, older adults also report elevated rates of loneliness and social isolation [24]. Moving to LTCHs can increase older adults' likelihood of being lonely or socially isolated with reported rates of loneliness in older adults living in LTCHs varying from 22% to 75% [20,25,26].

With the start of the pandemic, social connectedness among older adults within LTCHs was severely compromised both directly and indirectly by restrictions placed upon visitors and other infection control measures [27]. This physical isolation of older adults in their rooms thereby compounded any preexisting impacts of isolation [6]. Detrimental impacts on older adults' mental health associated with quarantine measures include emotional disturbance, insomnia, and low mood [28,29]. While these visitor restrictions were implemented in good faith as an effort to mitigate the spread of COVID-19, many older adults during the height of the pandemic died alone, with little to no connection with their family members or friends [30].

In the initial stages of the COVID-19 pandemic, research findings suggested that older adults may be less vulnerable to detrimental mental health effects of the disease and associated health measures, than their younger peers [30,31]. However, with time, additional studies indicated that the impacts of COVID-related restrictions and the resultant social isolation will have long-lasting repercussions on older adults' health and well-being [27]. Furthermore, the protracted restrictions associated with the ongoing nature of the pandemic continue to negatively impact the physical and mental health of older adults and their family caregivers [9,12,30]. In Canada, during the first wave of the COVID-19 pandemic, when families were prohibited from in-person visits, there were 7260 deaths of older adults across LTCHs and retirement homes, representing 79% of all COVID-19 deaths [7]. Consequently, during the height of the pandemic, many older adults died isolated and alone [30-33]. Since that time, the policy changed first resulting in modified visitor restrictions that allow family members to be together in palliative circumstances and then removing visitor restrictions altogether [34]. However, challenges relating to the social isolation of older adults within LTCHs remain.

As COVID-19 led to widespread limitations on in-person gatherings and for a time halted in-person visits to LTCHs, attention turned to technology as a means to communicate and facilitate social connectivity between family members and older adults [35]. As we move forward from the pandemic it is critical to develop robust systems now, to mitigate the harmful unintended side effects (eg, decreased social connectedness and well-being) of infection control policies.

Web-Based Presence Technology

Web-based presence is the use of networked digital telecommunications technology to create the impression that a user is present in another environment [36]. Digital apps (eg, Zoom [Zoom Video Communications] and FaceTime [Apple Inc]) provide web-based face-to-face connection and may support social connectedness by providing meaningful social engagement in addition to being a point of access to community environments for older adults [37]. For LTCHs, web-based presence technology (WPT) has the potential to support social connectedness as a supplement to in-person engagement or a stand-in during outbreak situations such as the current COVID-19 pandemic. Acknowledgement of this potential has been highlighted by the COVID-19 pandemic, which has been a catalyst for myriad and lasting social changes, including the vastly accelerated use of WPT for communication in people's personal and professional lives. However, the general uptake

XSL•FO
RenderX

of WPT across LTCHs has lagged behind other sectors [38] for reasons including age-related bias about older adults' physical and cognitive ability to use technology, costs of equipment, and a lack of education and support of staff, family, and older adults to use technology devices such as tablets or other mobile devices [39].

Early efforts to explore the application of technology within LTCH settings focused on aspects such as resident safety. However more recently, the role of technology to support social connectedness is also being investigated [40]. Emerging findings suggest that challenges of implementing WPT in LTCHs include limitations in staff shortages, training for staff on the use of WPT, dated LTCH building infrastructure, funding to support additional staffing and technology equipment, and processes supporting consistent use of WPT [41]. Addressing these challenges entails more than just the provision of additional funding. Instead, it asks for an enhanced systemic and context-specific understanding of technology implementation [42]. This understanding has to be cocreated with all relevant LTCH stakeholders (eg, residents, family members, staff, and administration) to effectively address user needs as well as financial, operational, and administrative constraints.

WPT can provide family members of older adults in LTCHs with the opportunity to visually observe the well-being of the older adult in real time. Visual confirmation of these older adults' well-being can contribute to family members' trust and confidence in the care being provided by LTCH staff [43]. Admittedly, WPT is not a panacea for fostering social connectedness among older adults in LTCHs [44]. However, it may be profoundly important to supplement in-person activities with *hybridized web-based and in-person approaches* for social connectedness in the context of distancing measures or other constraints on in-person engagement.

Objectives

Given the potential benefits of WPT within LTCHs and the need to understand associated shortcomings, the proposed research goal is to explore experiences regarding the use of WPT in support of social connectedness between older adults in LTCHs and their family members, and to identify the contextual factors that must be addressed for successful WPT implementation in LTCHs. This study has 3 aims. First, to explore how older adults in LTCHs, their family members, and LTCH staff members experience, benefit from, and envision the role of WPT to support social connectedness in LTCHs. Second, to interview key stakeholders such as managers and directors of LTCHs, and to examine LTCH policy, funding, management, and operations in order to identify institutional challenges and facilitators impacting the uptake and spread of WPT within LTCHs. Third, to triangulate the findings from stages 1 and 2 to develop a framework that can inform the formal implementation of WPT in support of social connectedness within LTCH**.**

Methods

Study Team

The faculty team recognizes that there is an implicit bias against some groups' progression to academia's higher ranks. Our faculty team is deeply committed to equity and diversity in recruiting, hiring, and training students. This research team will comprise emergent and seasoned scholars and researchers and a research assistant who is a graduate student at the university where the principal investigator is employed.

Approach

Overview

This study will use a qualitative multimethod research design conducted in 3 stages. The multimethod design will be informed by the Technology Acceptance Model (TAM) and entail the use of qualitative description using content analysis (stage 1) and thematic and document analysis methodologies (stage 2). The overarching objective will be to triangulate the findings from stages 1 and 2 to create a working framework to inform the implementation of WPT in LTCHs. Stage 1 is focused on data collection through in-depth interviews with stakeholders (older adults living in LTCHs, their family members and LTCH staff) to inform an initial understanding of the perceived usefulness, ease of use, challenges, attitude toward, and human resource availability to support social connectedness using WPT. Stage 2 will involve the examination of relevant documents (eg, information technology and operational policy documents, budgetary documents and training manuals) and in-depth interviews with key LTCH administrators such as directors and managers as well as salient staff (eg, information technology) that will describe the LTCH environment, its functioning, and regulations to develop an understanding of the institutional factors that have a bearing on potential web-based presence implementation. In stage 3, the data from stages 1 and 2 will be used to triangulate the findings and interpret them to develop a working framework for WPT implementation within LTCHs.

Stage 1: Interviews and Framework Development

Design

The first stage of this study will use qualitative description to explore how older adults in LTCHs, their family members, and LTCH staff experience and understand the use of WPT in support of the social connectedness of older adults in LTCHs [45]. The outcome of this exploratory enquiry will be combined with the outcome of stage 2.

Ethical Considerations

As the initial step of stage 1, ethics approval for the proposed study will be sought from the applicable research ethics boards (Western University Health Science Research Ethics Board). Once ethics approval has been obtained, data collection will be initiated. The research team anticipates beginning the participant recruitment phase in late autumn 2023.

The principal investigator will manage all data generated with this research to ensure effective data use and security. Standardized data file naming, storage (including metadata) and

XSL•FO
RenderX

backup procedures will support data sharing and protect the data against catastrophic loss. Data will be stored on a password-protected university server to protect against unauthorized access, in keeping with research ethics board requirements (ID#2023-121993-78969).

Participants

To conduct the interviews in stage 1, we will use purposeful and maximum variation sampling to recruit a range of older adults, family members (30 participants) and staff (15 participants) within several LTCH settings with a total recruitment goal of approximately 45 participants [46]. A review of the literature on sample size across 55 qualitative descriptive studies found that about half of studies (24 studies) had a sample size ranging from 8 to 20 participants and approximately 15% (8 studies) of included studies had a sample size of up to 50 participants [46]. Therefore, a total sample size of 45 for stage 1 is deemed to be congruent with other research conducted using a qualitative descriptive method. Data collection and analysis will take place simultaneously and will continue until the data provides a rich description of the participants' experience in using or supporting the use of WPT for the purposes of social connection. It is expected that data collection will conclude once data saturation has been obtained across the range of participants [47]. Participants will be recruited from 3 LTCHs (anonymized). Given the goal of gaining a holistic understanding of the role of WPT implementation in LTCHs, we hope to recruit a broad range of participants (older adults, family members and staff including, registered practical nurses, registered nurses, personal support workers, and recreation therapists).

Inclusion criteria for this stage will be English speaking and the ability to participate in a one-on-one interview using Zoom technology. Potential older adult participants with mild cognitive decline living in LTCHs or receiving outpatient care will be assessed for suitability to participate in this study by LTCH staff first before any study information will be shared with them. Exclusion criteria applied will be the inability to converse in English and advanced cognitive decline.

Screening Process

The screening process will be conducted by partnering organizational staff. As part of LTCH guidelines a regular Montreal Cognitive Assessment screening [48] is used to assess residents' cognitive dimensions such as language, memory, visual and spatial thinking, reasoning, and orientation status. Upon receiving study information, partnering staff will identify potentially suitable participants and share this study's information with them on behalf of the researchers.

Setting

Individual in-depth interviews with older adults, their family members, and LTCH staff will take place in-person, via phone, or Zoom call depending on participant preferences and applicable COVID-19 restrictions at an agreed-upon date and time.

After the screening and deeming an older adult eligible to participate in this study, a research assistant will connect with a recreational therapy department staff or a caregiver in order to assist older adult participants with setting a study interview appointment, securing a quiet room, accessing an electronic device at their LTCHs, and helping them join a Zoom meeting to participate in an interview at an agreed upon date and time.

Data Collection

We will conduct semistructured in-depth interviews with a range of older adults, family members, and staff in several LTCHs. The purpose of conducting these interviews will be to explore participants' perceptions of how WPT has been used and can be used, and to identify potential barriers to supporting social connectedness between older adults and family members within LTCH settings using WPT. Interview questions will be informed by extended the TAMs as widely applied to questions of health technology implementation [49-51]. The TAM and its extensions are based on 2 belief constructs: perceived technology usefulness and perceived ease of technology use [50,51]. Building on these constructs, a range of interview questions tailored for type of participant (staff, older adult living in LTCHs, and family member) will be posed to participants (eg, can you describe your experience with using technology such as smartphones or tablets for speaking with your family). For a full list of interview questions please see Multimedia Appendix 1. In addition to in-depth interviews, observational field notes will be kept throughout this study thereby enhancing the data set [52].

Data Analysis

Data will be analyzed using directed content analysis, a qualitative analytic technique characterized by a structured stepwise process of coding the data and organizing it into categories or themes [53]. The goal of the analysis will be to provide the initial data for a framework to guide web-based presence implementation in LTCHs. As such, the key constructs of the TAM, perceived usefulness and ease of use of technology, will serve as initial codes to guide analysis. Data that do not lie within one of the key codes will be labeled with a new code and organized into new categories or organized depending on their suitability as subcategories under the initial codes [53]. Throughout the entire sampling and data collection process, data analysis will be conducted in a concurrent and iterative process. Interviews with participants (in-person, via phone or Zoom depending on participant preferences and applicable COVID-19 restrictions) will be audio recorded, transcribed verbatim prior to analysis. Study rigor will be ensured through member checking, verifying data by contacting a subset of participants a second time to verify their intended meaning [54]. In addition, those engaged in the research process will practice reflexivity, acknowledging biases they may introduce to the research, and other strategies such as ethical conduct and ensuring the trustworthiness (eg, confirmability of data through triangulation between interviews and field notes) of this study data will be used [55].

Stage 2: Interviews With Key Stakeholders and Document Analysis

Design

To further develop insights related to the challenges and facilitators impacting the spread of WPT within LTCHs, stage 2 will consist of 2 elements: interviews with stakeholders using a qualitative descriptive approach, and document analysis. The

XSL•FO
RenderX

in-depth interviews will be analyzed using conventional content analysis, an analytic technique that will facilitate increased understanding in the absence of guiding theory [53]. Document analysis, a systematic process of evaluating documents, is often used in conjunction with other qualitative methods in order to facilitate triangulation. Including a wide variety of documents (eg, policy documents, correspondence, and institutional reports), document analysis will be used as a means to enhance this study's findings with its potential to provide greater insight, information, and understanding [56].

Participants and Setting

Approximately 10-15 stakeholder participants will be recruited using convenience sampling. Given the focused nature of the interviews in stage 2, it is expected that fewer participants will be required to reach data saturation (approximately 5 to 8 per participating LTCHs). Participants will be invited to participate through targeted outreach via the (anonymous) Long-term Care Associations and through current relationships with LTCHs and professional nursing organizations. Key stakeholders will involve a range of functions or positions including directors of care, chief executive officers, director of community connections, and director of information technology innovation. Interviews with key stakeholders will take place in person, via phone or Zoom call depending on participant preferences and applicable COVID-19 restrictions at an agreed-upon date and time.

Data Collection

A qualitative description will be the methodological approach used to conduct in-depth interviews with key stakeholders (eg, IT personnel and LTCH management) [45,53]. Purposeful sampling techniques such as theoretical sampling are commonly used to recruit individuals or focus groups and data is often analyzed using content analysis when using a qualitative description approach [46]. Prior research in health technology implementation has stressed the importance of the role that system factors play in successful technological implementation in clinical settings [57]. Insights gained during stage 1 (eg, identification of barriers to the use of WPT) will inform the development of an interview guide targeted at increasing understanding of how potential modifications in structural and institutional factors could facilitate the spread of WPT in LTCHs.

Contributing documents to the document analysis component of this stage of this study will include annual LTCH budget reports, annual reports, strategic plans, LTCH funding policy documents, and regulatory documents as well as relevant communication documents (anonymous). These documents can potentially add information that can inform understanding of WPT use in LTCHs such as resource and budgetary allocation for technology and support personnel.

Data Analysis

In-depth interviews with participants will be audio recorded, transcribed verbatim, and analyzed using conventional qualitative content analysis with codes emerging through an iterative process of data collection and analysis [53]. Identified key documents will be analyzed using *conventional content analysis.* This will be an iterative process of reading the interviews, identifying initial coding categories based on the results from the interviews with key stakeholders and then organizing the codes into categories [53].

Analysis of documents will entail an iterative process which includes scanning documents, preliminary reading in detail, and finally organizing the data using strategies such as coding and categorizing the data. Concomitant to the analysis will be ensuring that the documents are credible, accurate, and able to inform the research questions [56].

Stage 3: Explicit Between-Methods Triangulation and Conceptual Framework Development (Methods)

In the concluding stage, there will be *explicit between-methods triangulation* of the findings of the respective methodological approaches (qualitative description using directed content analysis and conventional content analysis and document analysis) used in stages 1 and 2 to develop a final conceptual framework [58,59]. Findings from the various methodological approaches used in stages 1 and 2 will be systematically gathered and sorted to allow discerning patterns of overlapping and complementing evidence to establish the emerging final conceptual framework [60].

Results

The result of this iterative analytic process will inform theoretical understanding of how older adults in LTCHs, their family members and staff experience and envision the application of WPT to support social connectedness. After stage 1, a total of 45 participants will have completed in-depth interviews and their data will have been used to generate theory related to how WPT can be used within LTCHs to support social connectivity. The findings emerging from stage 1 will be used to directly inform stage 2's data collection as well as the overall development of a conceptual framework (stage 3).

Findings emerging from key stakeholders' interviews as well as document analysis will be used to inform *explicit between-methods triangulation* in stage 3 by expanding on findings through the inclusion of data obtained through other methods [61]. Expected contributions from the document will include a greater understanding of factors such as fiscal constraints, an organizational structure including staffing complement, and controlling regulatory and policy frameworks required for the successful implementation and spread of WPT for social connectedness within LTCHs.

The findings emerging from this study will provide deeper insights and understanding about the factors, barriers, and facilitators to embedding and spreading WPT in LTCHs and benefit older adults in LTCHs, family caregivers, and staff and administrators of LTCHs. Going forward, the conceptual framework will have utility to inform approaches to embedding web-based presence as a mainstreamed communication tool to support social connectedness among older adults in LTCHs and their family members.

Discussion

Principal Findings

A growing body of literature demonstrates the benefits of various communications technologies such as social networking apps on older adults' well-being, independence, and sense of connectedness with friends and family [62]. Knowing that social connectedness is a key contributor to the well-being of older adults in LTCHs [2], it will be important to optimize communications web-based technology in an efficient and timely way to avoid compounding further unintended detrimental effects to limit transmission of COVID-19, or any other future pandemics or epidemics.

As society continues to experience evolving disruptions to the ability to engage with one another, there is a need to reconceptualize social connectedness and to identify novel ways to attain fulfilling relationships with others particularly in the context of LTCHs. In the context of LTCHs, this could be represented by a hybridized system of web-based and in-person presence. However, more evidence is required to determine whether older adults in LTCHs and their family members benefit from WPT (eg, smartphones and tablets) as an approach to support their social connectedness. Further, there is a need to better understand how WPT can be implemented in LTCHs.

While WPT may have the potential to support meaningful social connectedness among many older adults in LTCHs and their family members, to date numerous uncertainties remain regarding leveraging WPT for social connectedness. These uncertainties include (1) the effectiveness of using WPT for social connectedness by older adults with cognitive impairments, (2) best practices related to the use of WPT by older adults with cognitive impairment, and (3) the role of extra supports for older adults with cognitive impairment when using WPT [44]. Additionally, it will be important to identify how an older adults' physical condition could impact their ability to use WPT. For example, arthritis, vision impairments or neurodegenerative conditions such as Parkinson disease could necessitate the need for adaptive technology or additional assistance [63,64].

Limitations

The proposed multistage approach and methodological triangulation will require the engagement of multiple stakeholders. Potential limitations may include challenges associated with conducting interviews with older adults living in LTCHs who may have cognitive or physical conditions that could limit their participation in in-depth interviews. Additional support from family members, LTCH staff or researcher staff may be required to facilitate interviews with older adults. Researchers will use flexible approaches to interviewing including in-person and zoom interviews, accommodating interview times and an honorarium to recognize their time and contribution. Researchers will also use strategies that can support older adults' participation such as providing documentation in larger font size and providing a list of questions ahead of time.

The data obtained through qualitative description will consist of subjective perceptions and recollections of using technology for social connectedness and therefore may be biased toward a particular type of experience. Direct user observations, attained using an ethnographic approach, might be able to produce data that have a lower likelihood of being biased toward memorable experiences. However, actualizing this approach within LTCHs would be very challenging to practically implement.

Conclusions

The conceptual framework arising from this research on the role of WPT to support social connectedness between older adults in LTCHs and their family members will have a key role in informing LTCHs how to embed web-based presence as a mainstream communication tool to redefine and support social connectedness among older adults in LTCHs and their family members.

Acknowledgments

This study received funding from a Social Sciences and Humanities Research Council Grant (#430-2022-00617). The authors thank McCormick Dementia Services, Idlewyld Manor, and Mount Hope Long-term Care for their support and participation in this research.

Abstract

Background: During the COVID-19 pandemic, eHealth services enabled providers to reach families despite widespread social distancing restrictions. However, their rapid adoption often occurred without community partners' involvement and without an understanding of how they prioritize aspects of their mental health and associated service provision, both of which promote family and community-centered health care delivery. Establishing priorities in health care is essential for developing meaningful and reliable health services. As such, there is an urgent need to understand how eHealth service users, especially families who may have historically faced oppression and systemic barriers to service access, can best benefit from them. Arts-based approaches can elicit an understanding of priorities by providing an engaging and expressive means of moving beyond readily expressible discursive language and stimulating meaningful dialogue reflective of participants' lived experiences.

Objective: The purpose of this research is to determine the priorities and preferences of youth; parents or caregivers; newcomers and immigrants; and Indigenous community members regarding the use of eHealth in supporting their mental health using an innovative arts-based priority-setting method.

Methods: This study uses a mixed-methods approach combining qualitative, quantitative, and arts-based research. It follows a survey used to identify key knowledge partners who are interested in improving eHealth services for mental health support in Manitoba, Canada. Knowledge partners interested in group-based priority setting will be contacted to participate. We will facilitate approximately two focus groups across each subgroup of youth, parents or caregivers, newcomers or immigrants, and Indigenous community members using an integrative, quantitatively anchored arts-based method termed the "Circle of Importance" to understand participants' mental health priorities and how eHealth or technology may support their mental well-being. The Circle of Importance involves placing small objects, whose meaning is determined by participants, on a visual board with concentric circles that correspond to a 5-point Likert scale of importance. Following each focus group, we will evaluate participants' and focus group facilitators' experiences of the Circle of Importance using a survey and follow-up structured in-person interviews to garner how we can improve the arts-based approach used in the focus groups.

Results: The PRIME (Partnering for Research Innovation in Mental Health through eHealth Excellence) theme received institutional ethics approval on August 23, 2023. Data collection is projected for August 2023, with follow-up focus groups occurring in early 2024 as required. Data analysis will occur immediately following data collection.

Conclusions: Findings will directly inform a multiyear applied research agenda for PRIME aimed at improving mental health services through engaging key knowledge partners. The results may inform how arts-based methods in a priority setting can reflect aspects of experience beyond the capacities of qualitative or quantitative methods alone, and whether this approach aligns well with a positive experience of research participation.

Introduction

Background

As the world recovers from the COVID-19 pandemic, health service providers have increasingly turned toward digital technologies to support family mental health. Extensive research documents the disruption that COVID-19 exerted on the lives of families. These disruptions are characterized by challenges across health service access, provider availability, workplace, and home life stress, along with infractions upon coping ability [1-4]. In response to these obstacles, digital technologies, including app-based mental health supports, telehealth, and remote therapy delivery options, helped support in-person service delivery. These digital technologies, henceforth referred to as eHealth, include the provision of mental health support services through digital technology, such as conducting therapy remotely through videoconferencing platforms such as Zoom (Zoom Technologies Inc), Microsoft Teams (Microsoft Corp), or apps.

Although eHealth proved valuable during the COVID-19 pandemic by reducing the strain on health service delivery, its rapid usage made it difficult to adequately develop best practices—and for service providers to have evidence-based guidance—in their absence [5]. The urgency of health system response meant that, in many cases, families and other community knowledge partners were not engaged in determining priorities for and tailoring approaches to maximize the benefits of eHealth services. As the world recovers from the COVID-19 pandemic and in-person services resume, there remains a paucity of literature considering how eHealth services can and should be a part of mental health services for families moving forward. These are essential questions for communities that experience systemic barriers to access related to racial and ethnic oppression, geography-based proximity to care, and mobility challenges due to health status or transportation access. These marginalized communities include Indigenous and newcomer groups in Canada, as well as bedridden or homebound individuals, who benefit from the extension of particular eHealth services such as telehealth [6-9]. This paper presents a protocol for using an arts-based qualitative approach to understanding the family mental health and eHealth priorities and experiences for youth, parents, and caregivers, with particular consideration of the experiences of Indigenous and newcomer communities in the Canadian context.

Use of eHealth for Mental Health Support

eHealth is a well-accepted component of many mental health services, but during the COVID-19 pandemic, eHealth services were often used as mitigation for an absence of in-person delivery options [10]. eHealth delivery was necessary for reaching individuals in light of quarantine, social distancing, and safety protocols [11-14]. The time-sensitive nature of response mandated by service providers meant that many eHealth services were generated, and many more transformed, to meet public demand [6,8,15,16].

Reviews conducted prior to the emergence of COVID-19 highlight the promise of eHealth in preventing and treating mental health challenges and promoting mental health [15]. For instance, MacKinnon et al [17] found better self-reported mental health and improved anxiety and depressive symptoms for parents of young children, and reduced parenting stress for parents using eHealth interventions. eHealth also shows encouraging results for reducing mental health challenges at the population level, which could help address the adverse effects of the pandemic [15]. The feasibility and acceptability of eHealth are often positively assessed by end users; for example, individuals living with serious mental illness have reported eHealth interventions as feasible and accessible [18]. Additional reviews highlight the promise of eHealth interventions for improving health service delivery; however, further research is needed to identify ways to increase intervention efficacy [16,19,20].

Research conducted during the pandemic was a rapid response to lockdown protocols in the face of increasing need and often without sufficient time to build relationships and ethically engage in best practices with other professionals and knowledge partners. Thus, reviews conducted specifically on the impact of interventions used during the pandemic demonstrate that the lack of legislation, guidelines, and engagement with communities results in a lack of quality of care in some eHealth programs [21-23]. The proliferation of eHealth has outpaced the evidence base, which has functioned as a barrier to policy developments [24] and uptake within particular user groups (eg, older adults) [25], with the strength and quality of evidence being a key characteristic impacting eHealth implementation across contexts [26]. This study context provides a unique and timely opportunity to learn how communities and families want to engage with eHealth moving forward and to identify their priorities for future research and clinical services.

While eHealth services demonstrate promising results for service provision, including reducing commute and wait times, reducing the spread of infections, and improving access to health services [10], understanding how specific groups may benefit from and use eHealth supports is integral to maximizing the benefits for such services. Indeed, eHealth services failed to reach their full potential before the COVID-19 pandemic but have strong potential to enhance health service accessibility [10]. To improve eHealth services, there is a need to understand the experiences of mental health from the individuals and groups who should benefit from them. This understanding is paramount to developing eHealth programs, interventions, and services that align with user priorities.

Priority Setting and the Benefits of Arts-Based Methods

Priority setting identifies various knowledge user priorities around a topic and, from these, seeks consensus [27]. It is often used to identify and understand health care users' experiences to inform the health service of health user needs and thus is particularly useful within the context of codevelopment [27]. Priority setting can improve research credibility and practicality for real-life problems and help in developing systematic, user-centered, and applied research programs and associated projects [27]. Within the context of eHealth for mental health services, priority setting can help align eHealth supports with family experiences and needs and inform their improvement and integration within other in-person services, which are sensitive to the users' local context.

Popular priority-setting methods, such as the James Lind Alliance and the Delphi technique, begin with identifying gaps in the literature, meeting with multiple knowledge users, and voting in multiple rounds before reaching a consensus [27,28]. Consensus is obtained through scoring, ranking, voting, and ordering of items, often achieved through surveys or workshops [27]. Some authors incorporate participatory and playful methods when ranking by using colored sticky notes, cards, and stickers [29,30]. While many of these methods promote empirical ways of knowing, there are opportunities to explore other forms of knowledge that go beyond discursive communication.

Knowledge exists in various forms and can be expressed in a multitude of ways, including more experiential and embodied forms. For instance, children and youth often express themselves using the creative arts, which are regarded as developmentally appropriate in this context [31]. Arts-based methods probe into other forms of knowing—embedded, tacit, emotional, and subconscious—enabling new ways of engaging with experience, new representations, and expressions to emerge, and therefore, new insights to be constructed through and within the relational research space [32]. Despite this knowledge, most priority-setting approaches rely upon discursive knowledge (ie, asking participants to state their priorities and to complete a questionnaire on priorities). On the contrary, arts-based methods provide an opportunity to explore experiences differently and more profoundly and bring to the center what may be missed by traditional research methods. Combining arts-based methods with other narrative methods, such as focus groups, can provide a more holistic understanding of priorities than would otherwise be impossible. Further combining arts-based methods within mixed-methods frameworks can advance complementarity, extend understandings, and provide real-time integration of diverse knowledge forms [33,34]. While arts-based research is proliferating across the health and social sciences, its use in priority settings is nascent. Here, we will engage youth, parents or caregivers, newcomers, and Indigenous community members in arts-based priority setting of their mental health and technology priorities to generate deeper understandings.

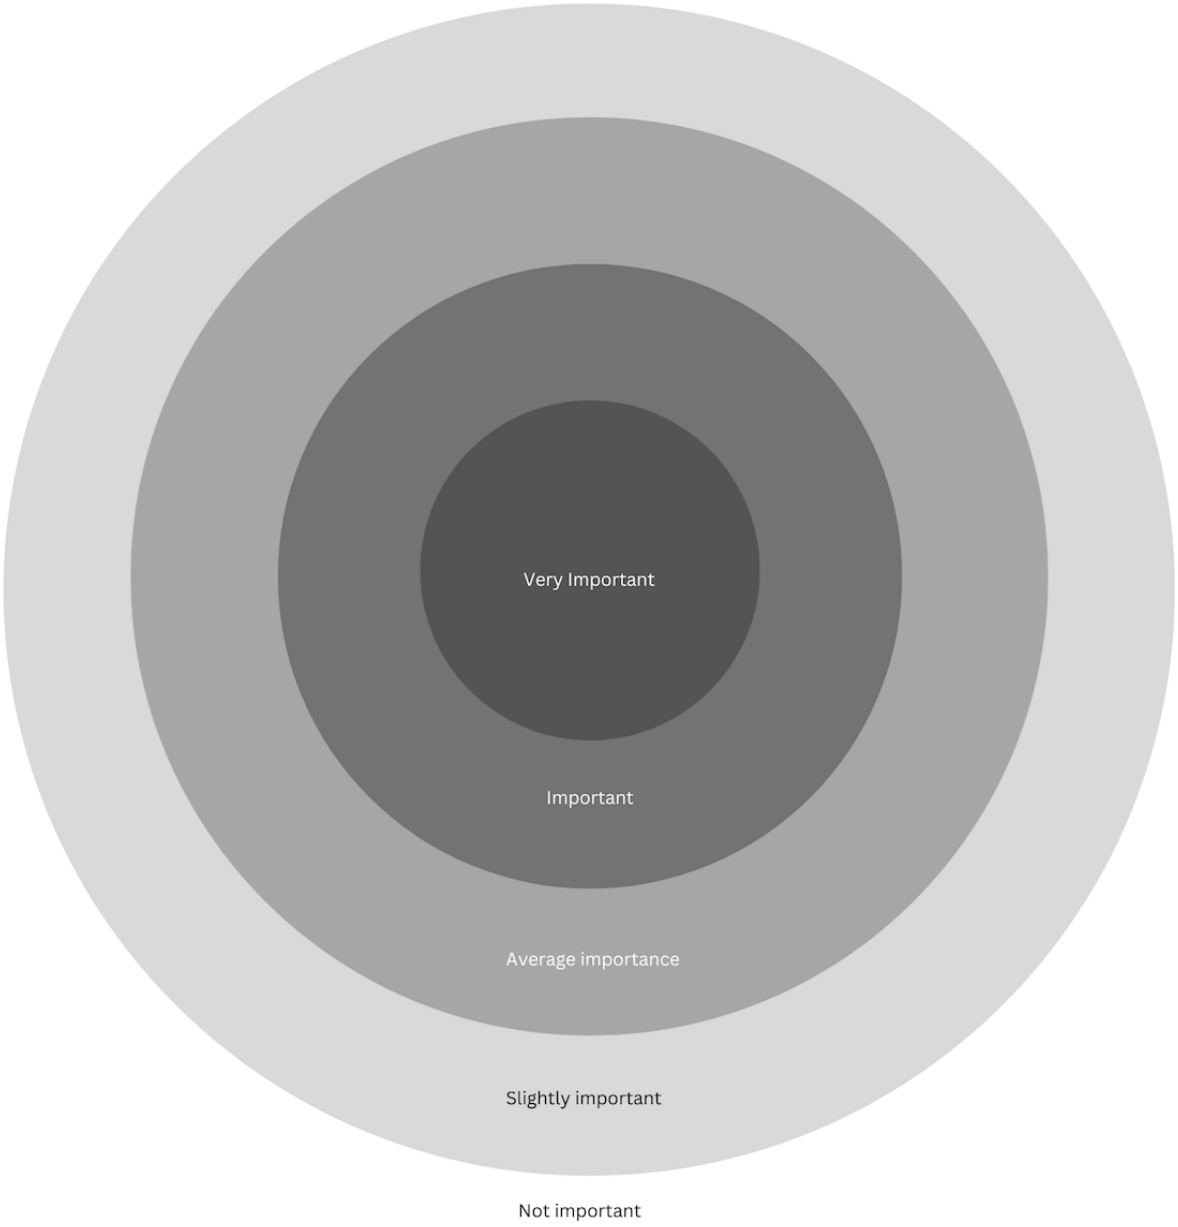
Research Context

The research theme PRIME (Partnering for Innovation in Mental Health through the eHealth Excellence) is the fourth research theme at CHRIM (Children's Hospital Research Institute of Manitoba). CHRIM is the Canadian Prairie province's first children's research facility with the overarching goal of holistically improving the health of children and youth through equitable and innovative research, policies, and interventions [35]. PRIME was developed to address the growing need for mental health services for children, youth, and families that were inflated due to the COVID-19 pandemic [35]. PRIME is developing eHealth models to address youth and children's mental health needs in Manitoba through equitable partnerships with local communities [35]. The foundational research proposed here directly addresses extant gaps to identify youth mental eHealth needs in Manitoba with broader methodological relevance, and uses and advances the methods for assessing mental health and technology priorities across a variety of knowledge user groups.

Methods

Overview

This is a convergent mixed design inclusive of arts-based priority-setting activities and focus groups across the 4 subgroups of youth, parents or caregivers, Indigenous communities, and newcomer and immigrant families [36]. It follows a survey used to identify interested parties and knowledge users in ongoing research engagement in eHealth for mental health in Manitoba, Canada. Arts-based data collection involving the innovative priority-setting approach titled the Circle of Importance will be used to concurrently gather narrative, quantitative, and visual data and will be used as a visual elicitation tool to catalyze focus group interviews. Graphic recording, wherein an illustrator is present during each focus group to visually capture emerging thematic content, will be used as a member checking and dissemination device. This study will be conducted in a large urban capital of a central Canadian province (population 749,607) [37]. We will iteratively collect data at the centrally located CHRIM and analyze the data over a 4-month period across Manitoba.



Theoretical Framing

Arts-Based Priority Setting Using the Circle of Importance

we have developed an innovative arts-based approach to priority setting entitled the Circle of Importance (see Figure 1), integrating aspects of existing priority setting, mixed methods design considerations, arts-based methodologies and theories, and professional experience across arts-based, mixed methods, and qualitative research traditions, building on the first author's (MA) extensive work in this area [33,36,38-40]. The Circle of Importance draws from a number of methodological traditions and methods applications, including the Center Stage approach. Center Stage involves positioning found objects on a blank board, wherein the center represents the core elements impacting a person's experience [41]. The participant places other objects of importance in the peripheral areas on the board, with more peripheral placement indicating less significance [42]. As such, center staging encourages participants to reflect and organize their experiences into themes that can be visualized [41].

XSL•FO
RenderX

Figure 1. The Circle of Importance, incorporating concentric circles with the embedded Likert scale of importance.

However, given our specific interest in priority setting and our orientation toward integrating multiple data sources to increase holistic understanding, we adapted the Center Stage process to strengthen the mixed-methods integration potential and mitigate analytic challenges likely to be faced in using the method [39]. Specifically, we extend the blank boards of Overs et al [41] to incorporate 5 concentric circles, which embed a visual 5-point Likert scale on the board for object placement. Participants have the option to select objects provided by the investigative team or objects they have brought themselves and assign meaning to these objects prior to placing them on the board. Each icon or object position is anchored to a quantitative indicator (1-5) aligned with their respective qualitative descriptions (very important to not important) and serves as a visual elicitation stimulus for narrative data attained through the focus group. This approach enables real-time qualitative and quantitative data integration—an area of increasing focus in the mixed methods research context wherein methodological integration and participatory integration methods are garnering interest [34,43]. Here, participants can more readily externalize change in their responses between interview questions.

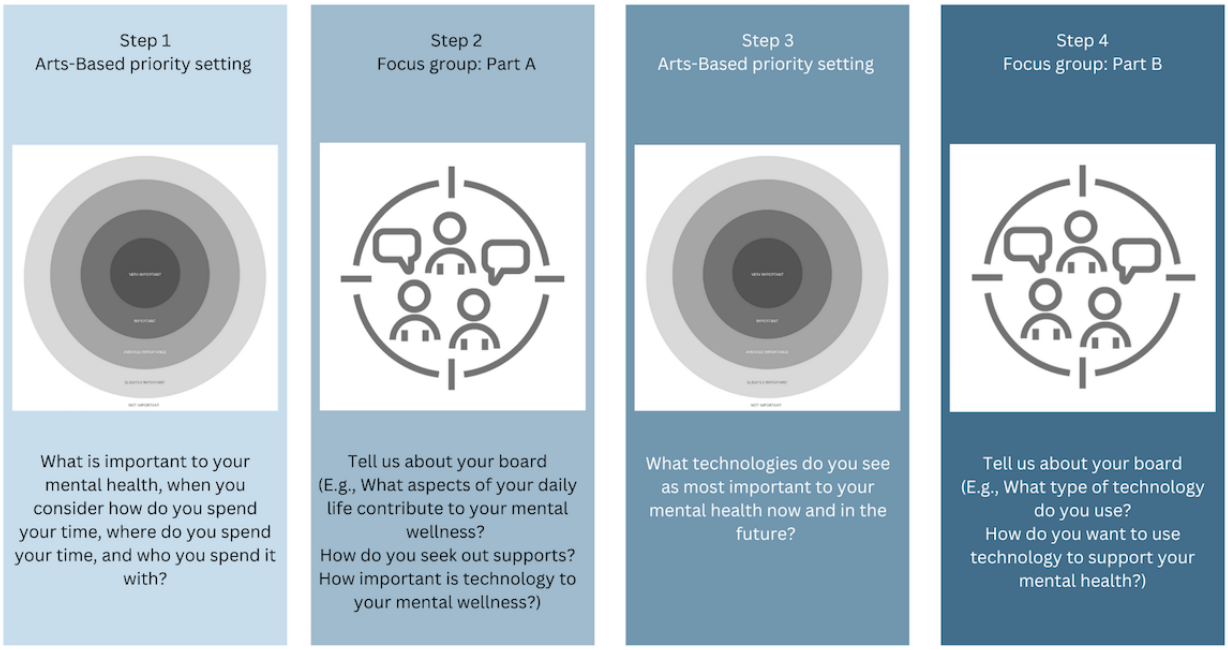
Participants and Recruitment

As foundational work to the current proposal, a survey was distributed across Manitoba to identify partners and parties interested in, experiencing, or supporting family mental health. For this study, participants will be purposively recruited from the phase 1 survey. Participants must be aged 16 or older; have experience, interests, or provide support for youth mental health; and identify with 1 of the 4 subgroups (youth, parents or caregivers, newcomer and immigrant families, and Indigenous community groups). These criteria apply to Indigenous and non-Indigenous people with lived experience of mental health and experience as a caregiver or parent of someone experiencing

XSL•FO
RenderX

mental health needs. All individuals must reside in Manitoba and be fluent in English. Recruitment will consider age, gender, location, and demographic identity. Five to eight participants will be selected for each subgroup. Youth in this study refers to individuals aged 16-20 years—a definition adopted from the United Nations [44] with modifications made to the upper age category of our sample, recognizing the changing nature of stressors and life stages beyond 20 years of age (eg, increased independence, including place of residence; higher likelihood of employment and postsecondary schooling). The research team will conduct 2 focus group sessions for each subgroup. All participants will receive a CAD $30 per hour (US $22.38) reimbursement through a gift card as a token of appreciation for their participation.

Data Collection



Focus groups spark discussions among participants and allow them to share similar and dissimilar views [45]. Aside from group restrictions (ie, youth, caregivers, Indigenous community members, and newcomers and immigrants), groups will be heterogeneous in composition to allow diverse perspectives on the topic [45]. Heterogeneity will include age, ethnicity, geographic location, sex, and gender, where appropriate. Furthermore, youth will be subdivided into focus groups reflecting more discrete age ranges (eg, group 1: 15-17 years; group 2: 18-20 years). The lead author has extensive experience in qualitative and arts-based methodologies and will play a key role in conducting the focus groups through facilitation and staff training. A graduate trainee of Indigenous ancestry and with significant qualitative experience will lead the facilitation of the Indigenous community subgroups with instruction and assistance from the lead author. Furthermore, 2-3 facilitators will be present at each focus group to ensure smooth operations and take observational notes of group interactions. Focus groups will be facilitated at CHRIM. A professional graphic recording company will graphically record each focus group to allow for a visually integrative output per subgroup to aid dissemination and member checking.

Focus Group Approach

Overview

Focus groups will involve 4 steps, including 2 cycles of the Circle of Importance method followed by semistructured focus group interviews (see Figure 2). Each respective focus group will commence with an icebreaker activity selected based on the specific group. A brief evaluation of participant and facilitator experiences of the Circle of Importance activity will directly follow the completion of each focus group (Multimedia Appendix 1).

Figure 2. Study sequence.

Step 1: Arts-Based Priority Setting Using the Circle of Importance

The first stage includes identifying what is essential to each person's mental health using the Circle of Importance (Figure 2). Participants will be instructed to select up to 10 objects that they feel represent an aspect of their life and mental health and directed to position the objects on the Circle of Importance board to reflect what is most important to them. No distinct meaning will be assigned to each object by the facilitators. Instead, participants will be advised to decide what each object represents. Approximately 15 minutes will be provided for each respective Circle of Importance board placement. Facilitators will photograph each board and label the photo with the participant identification number to allow integration with narrative responses throughout the analysis.

XSL•FO
RenderX

Step 2: Focus Group Interview—Part A

Following the selection of the items, a facilitator trained in qualitative methods will guide a discussion on the participants' boards. Two additional facilitators will be present to assist with note-taking of participant nonverbal communication and group interactions and assist with the Circle of Importance method as necessary. The focus group interview will progress from general to specific, beginning with an invitation for participants to describe their board. Participants will also be asked what aspects of their daily life contribute to mental wellness, what contributes to when things are going well, how they seek out support, the importance of technology to their mental wellness, how they use technology, and the importance of technology to receiving mental health services. A simple definition of technology will be provided to participants during the focus group introductions and icebreaker activity.

Step 3: Arts-Based Priority Setting Using the Circle of Importance

Subsequent to a break, step 3 will resume with participants reimagining their board in response to the question: What technology do you see as most important to your mental health in the future? Participants will have the option to exchange their icons before partaking in the Circle of Importance method if they so desire. As with step 1, participants will have 15 minutes to complete the Circle of Importance method. At completion, facilitators will photograph each board and label it with the participant ID.

Step 4: Focus Group Interview—Part B

After the prioritization method in stage 3, participants will again be invited to discuss their board. The facilitator will first invite participants to describe their board generally, before asking more specific questions about the use and desired use of technology in the context of mental health. Questions will center upon how participants use and want to use technology to support mental health, the types of technologies used, and the technologies regarded as most important to participants' mental health, now and in the future. Participants will then be asked about the negative impacts of technology use on their own or their family's mental health, the importance of privacy and confidentiality in the context of technology, preferences around the separation of digital spaces, and perspectives on tracking mental health in app-based technologies. The information gathered during these focus groups will be used to inform the development of a new research theme at the Children's Hospital Research Institute and associated family and community-centered research and care activities.

Evaluation of the Circle of Importance

Arts-based approaches to understanding health priorities are an emerging area [46]; as such, feedback from the participants and facilitators on this methodology is crucial for informing its ongoing development. Following the completion of the focus groups, we will evaluate participants' experiences—including benefits and challenges—of engaging with the Circle of Importance for priority setting. The experiences of facilitators will also be evaluated. We have previously used comparable methods to evaluate methodological innovations, which proved both feasible and useful to methods refinement (eg, Archibald et al [47]). Findings will be used to further refine the Circle of Importance, with sensitivity to the various contexts of its use.

The evaluation will involve descriptive statistics and brief structured follow-up interviews and last approximately 10 minutes per participant. First, participants and facilitators will be provided with a brief questionnaire containing 7 items, structured as a 5-point Likert scale. Questions will center around the feasibility, acceptability, and use of the Circle of Importance for priority setting, as well as challenges and opportunities to improve the method. Following the survey, participants will take part in brief structured interviews containing approximately 6 questions with facilitators to provide an opportunity for additional feedback and to explain the survey responses in a convergent design [45]. Evaluation interviews will occur immediately after the focus group interviews and in the same location.

Data Analysis

An integrated mixed-methods analytic approach is used in this study. MAXQDA (VERBI GmbH) will be used for data management and to support. Analysis will proceed at the individual and focus group levels. At the individual level, each participant's artboard, narrative responses, and quantitative Likert response will be analyzed holistically as a case (ie, photos of the participant's artboard will be analyzed individually as a case and in reference to the focus group context; participants' Likert scale responses will be recorded in reference to the image on their Circle of Importance, their discussions during the focus group, and in the larger contexts of the focus groups). Inductive thematic analysis will be used. Analysts trained in qualitative and mixed methods will view the photographs of the artboards in tandem while reading the interview transcriptions repeatedly to gain a sense of the whole. Codes will be constructed and applied in accordance with the research questions and assigned descriptions. Case outlines will be provided for each participant and compared within and across subgroups to generate inductive explanatory insights.

With the focus groups, data will be analyzed and organized by subgroups (ie, youth, parents or caregivers, and Indigenous communities). Likert scale responses will be pooled and analyzed descriptively once the objects have been clustered categorically. Thematic labels will be assigned to the objects and reported by prevalence across and within subgroups. Transcripts will be inductively coded; previous transcripts will be reviewed once again when new codes have been identified to ensure comprehensive coding. A variety of strategies, such as joint displays wherein data of various forms are presented in dialogue within a table, will be used to facilitate integration and aid dissemination [48].

The evaluation of the Circle of Importance method will involve data cleaning of the transcribed audio files, and uploading of the transcriptions and survey responses into the mixed-methods software for analysis. Statistical analysis software (SPSS; IBM Corp) will be used to descriptively analyze quantitative data; these will be linked with corresponding narrative explanations of responses and presented using the integrative method of joint displays.

XSL•FO
RenderX

Ethics Approval

Ethical approval was received from the University of Manitoba Research Ethics Board (HE2023-0139). To protect confidentiality during the focus groups, participants will be asked to keep all information discussed private. Participant quotations will be carefully reviewed to ensure anonymity and to ensure that identifying information is removed.

Results

Data collection will commence in August 2023. The findings from the study will be used to develop and inform numerous initiatives, including the development of a context-sensitive research theme within the Children's Hospital Research Institute, a series of publications regarding subgroup level analysis of priorities inclusive of the multiple data sources, and a methodological paper describing the use and evaluation of the Circle of Importance method. Results will be reported at each subgroup level and published approximately in August 2024.

Discussion

Priority Setting for eHealth in Mental Health

eHealth has the potential to increase access to health services and improve mental health services for various communities [15]. Every individual experiences mental health differently; therefore, people may have similar or varying values and priorities regarding enhancing their well-being. Similarly, how individuals experience and cope with mental health symptoms varies depending on several factors such as gender, ethnicity, culture, age, access to services, and the intersections of these elements. For example, newcomer and immigrant groups in Canada often face acculturation stressors that affect their mental well-being, and report distress from reporting distress from learning a new language and integrating into a different culture [49]. They experience systemic hurdles to mental health service access, such as language barriers, fear of stigma or discrimination from service providers, and difficulty finding information about accessing needed services [50,51]. Notably, there are different ways of experiencing, defining, and treating mental health and well-being across cultures. For example, spirituality can be a significant cultural factor in one's experience, with some individuals viewing mental well-being as an inner peace, while others view mental illness as an evil to be expelled [51,52]. Even when born in Canada, children of newcomers and immigrants may experience unique mental health challenges. Studies indicate that they may struggle with a sense of belongingness both in relation to their family's country of origin and the country they currently reside in [53]. Thus, it is possible that mental health experiences and priorities differ among various groups (eg, parent or caregiver, youth, newcomer, and Indigenous communities). For many Indigenous nations in Canada, well-being is defined holistically, encompassing balance between physical, mental, emotional, and spiritual components of the self. Connections to land, traditional languages, and cultural practices are additionally noted as central to wellness among Indigenous people [54-58]. Wellness also extends beyond the individual, being dependent upon the whole family and community's well-being through relational considerations [59,60]. The concept of mental illness is a western construct that does not often resonate with traditional ways of knowing, being, and doing nor does it account for systemic and social determinants that influence well-being [61,62]. Therefore, encouraging participants to self-identify priorities and needs aligned with personal and cultural values is critical in promoting safe and respectful practice in research.

Arts-based approaches are well-suited to reflect these unique experiences and priorities for mental health and eHealth that other approaches may fail to identify. Though an emerging methodology, arts-based priority setting has the potential to improve user-centered priority-setting research. Literature highlights popular prioritization methods such as the James Lind Alliance, the Delphi process, and the Nominal Group Technique for involving end users and other knowledge users [63,64]; however, these techniques demonstrate higher ontological and epistemological rigidity than creatively situated approaches. Arts-based methods, for instance, stimulate critical knowledge about human experience from the unconscious mind while provoking transformation [46]. Because of their ability to encourage authentic participation and elicit new and deeper responses to experiential questions, arts-based approaches to priority setting offer unique potential in discovering meaningful experiences and mental health and eHealth priorities across diverse subgroups [32]. There is often a lack of clarity in evaluating arts-based methods in research and priority-setting contexts [46]. This study addresses this challenge using a 5-point Likert scale with the Circle of Importance, quantifying priorities while remaining flexible enough to qualitatively convey participant priorities and experiences. Furthermore, using surveys and semistructured interviews in this study permits the evaluation of the effectiveness of arts-based methods for priority setting while enabling future tailoring of the approach to various subgroups commonly engaged in priority setting.

Limitations

The Circle of Importance method is a novel innovation, and while we will evaluate its use and acceptability, the activity may not go as planned and may not produce the anticipated results. However, related research suggests that participants will respond well to this form of visual elicitation and arts-based methodology [41,65]. Additionally, there may be some limitations in recruitment. Despite our best efforts, we may not be able to recruit equal numbers across the 4 subgroups.

Future Directions

While data collection has not yet commenced, we recommend that researchers consider the use of arts-based approaches in trying to capture complex and varying experiences among individuals. It is also important to try and be aware of the different factors (eg, ethnicity, age, and the intersection of multiple identities) that can contribute to individuals' experiences of their mental health and well-being. Thus, collecting data from various groups with differing identities can provide a richer and fuller picture of their experiences.
