Compliance to wearing the biosensor will be measured separately for youths and parents. Signals from the biosensor indicate whether the biosensor was worn while turned on. For the experiments, compliance is a binary outcome: either the participant wore the biosensor for the experiments or not. We will provide reasons for noncompliance (eg, discomfort or technical problems with the biosensor). For the observational period, we will count the number of days the participants wore the biosensor and define adherence as more than 30% of days (1 day=at least 3 hours) in 1 month of participation. The biosensor provides time data per recording session in hours, minutes, and seconds, and provides the dates on which the sessions were recorded. We will also report total time in hours that each participant wore the biosensor.

OCD Markers

Distress

During the lab visits, OCD distress is rated by youths in two ways. First, OCD distress related to each current OCD symptom is rated before ERP sessions on a symptom hierarchy on a scale from 0 (no distress) to 10 (maximum distress). During ERP sessions, the clinical researcher asked youths to rate their current distress levels after 1, 3, 5, 7, 10, and 15 minutes on the same scale as the symptom hierarchy. When OCD distress is rated during an ERP session, it is called subjective units of distress (SUDs) [56].

During the in-the-wild observational period, OCD distress is a binary measure, with patients and their parents marking events of OCD distress. Control dyads mark occurrences of youth fear to compare clinical to subclinical distress.

ERP Quality

Two major theories for mechanisms of change in ERP include emotional processing theory and inhibitory learning theory. According to emotional processing theory, ERP works by replacing an association between a stimulus and a feared outcome with a new harmless association [57,58]. Here, quality ERP sessions require habituation, defined as sessions in which distress levels decrease from the first measurement until the last measurement, and the decrease in distress occurs in the absence of avoidance, reduced task difficulty, and accommodation as defined previously [12]. This theory also assumes that there is an optimal level of distress that is neither too low nor too high for conducting effective exposures [59]. As subjective distress may not correspond to physiological levels of arousal, we will use both measures. Using SUDs and physiological measures of arousal, we will categorize low, medium, and high distress.

Alternatively, the inhibitory learning theory states that successful exposures are characterized by reduction in expectancy of an aversive outcome by creating alternative harmless associations that compete with the feared expectations [60]. A therapeutic expectancy violation occurs when an anticipated negative outcome fails to actualize and a benign or positive outcome occurs instead [60,61]. We will calculate distress-related expectancy violations in the baseline and follow-up exposure sessions in three ways. First, an expectancy violation occurs when the patient's expected distress trajectory as reported in the multiple-choice question before an ERP does not match the actual distress trajectory during ERP. Another way that we will define expectancy violation is by subtracting the actual maximum distress level during ERP by the distress level reported prior to an ERP session on the symptom hierarchy [62]. The final way that we will define an expectancy violation is by subtracting the distress level reported prior to ERP on the symptom hierarchy by the actual distress level at the end of an ERP session [62].

OCD Symptom Severity

The CY-BOCS, the gold-standard semistructured clinical interview for assessing OCD symptom severity in youths on a scale from 0-40 [63], is completed at baseline and at week 8 of follow-up. Items 1-10 are summed to obtain a total OCD severity score, with higher scores indicating higher severity. Items 1-5 can be summed to obtain an obsession severity score and items 6-10 can be summed to obtain a compulsion severity score. Change in OCD severity is calculated by subtracting the week 8 CY-BOCS score from the baseline CY-BOCS scores. Remission is defined as a 30% or greater reduction in the CY-BOCS score from baseline to follow-up. The CY-BOCS also contains information about types of OCD symptoms, such as those marked by anxiety or disgust. We expect these two mental states to have different effects on physiological signals as previously found [64].

Quality of Life

KIDSCREEN-52 is a parent- and child-rated questionnaire of child (8-18 years) health-related quality of life [39]. Higher scores indicate a better quality of life. In this study, we are particularly interested in the following subscales: psychological well-being, mood and emotions, autonomy, and parent relation and home life. These subscales provide information about the internal states of patients and controls as well as family dynamics.

Family Interactive Processes

The FAS-PR is completed by parents of patients and asks parents to rate how often they modify their routines due to their children's OCD and how frequently they help their children complete OCD rituals [43]. One item assesses how much distress the parents experience because of their accommodating behavior. Three items ask parents to rate how unhappy, anxious, angry, or violent their children become if not accommodated [44].

To obtain insight into the family interactive characteristics of patients and controls, we ask all parents to complete the following subscales on the FES-PR: cohesion, expressiveness,

XSL•FO
RenderX

conflict, independence, organization, and control. The FES-PR assesses the rater's current perception of their family environment [65].

The PSS contains 18 items that ask parents to rate how stressful they experience parenting their participating child [40]. Parents rate the extent to which they disagree or agree on a 5-point scale (1=highly disagree to 5=highly agree) to statements about their role as parents.

Parent Affective Symptoms

Parents report their symptoms of depression, anxiety, and stress on the 42-item DASS [41,66,67]. These internal states of parents will likely affect their physiological signals.

Oxytocin

Oxytocin levels are measured in youths and their parents before and after the controlled conditions during lab visits, as described in the Experiments section above. Salivary oxytocin response is defined as a change in oxytocin levels measured before and after a condition (physical activity, exposure, parent-child interaction). We ask participants to refrain from eating 2 hours and drinking 30 minutes before collecting the first saliva sample. To collect one saliva sample, participants are asked to chew on a Salivette (Sarsted, Rommelsdorf, Germany) for 60 seconds. The saliva samples are frozen at –20°C. At the biochemistry laboratory, the samples are centrifuged twice with a 2-day interval at 4°C at 1500 ×*g* for 20 minutes. The obtained liquid samples are lyophilized at –80°C/0.02 mbar overnight and stored at –20°C. On the day of the assay, the freeze-dried samples are reconstituted with assay buffer. The factor depends on the amount of saliva before freeze-drying. Samples are concentrated three times. The immunoassay is performed with the Enzo (NY, USA) oxytocin kit or a kit of comparable detection sensitivity. Measurements are performed twice, and the sample concentrations are calculated using WorkOut version 2.5 software that is provided with the enzyme-linked immunoassay reader according to relevant standard curves.

Measuring oxytocin in saliva is a noninvasive and easy way of estimating peripheral oxytocin levels [68]. Salivary oxytocin is sensitive to manipulations of stress and social interaction, as demonstrated by increases in oxytocin levels after 10 minutes of physical exercise [69], anticipation of and engagement in a socially stressful condition [70], and a 7-minute parent-child interaction task [71]. Higher oxytocin levels have been associated with parental synchrony and affect synchrony between parents and infants [72]. Higher oxytocin levels have also been linked to lower heart rate [69,73].

Synchrony

Synchrony is operationalized as two processes that are or become correlated above chance levels [74]. We will calculate synchrony between youth and parent affect, behavior, oxytocin, and physiological signals.

Data Analysis

Analysis Plan

We will summarize the demographic and clinical characteristics of the patients, control youths, parents of patients, and parents of control youths at baseline. At baseline, week 4, and week 8, we will summarize parental stress for patients and controls and family accommodation for patients in plots. At baseline and week 8, we will summarize child quality of life for patients and controls and OCD severity for patients in plots. We will also summarize physiological signals, accelerometer data, facial emotion recognition, movement, speech, and observational codes under the controlled conditions (rest, exercise, exposure, parent-child interaction) separately. Physiological and accelerometer data collected in the wild will be summarized in a plot with time on the x-axis, separately for patients and controls. Means with SDs will be reported for continuous variables and frequencies and proportions will be reported for categorical variables. We will not perform imputations of missing data. Data will be analyzed on an intention-to-treat basis regardless of protocol violations.

Model Development and Testing

Detailed statistical/ML analysis plans will be published separately. Table 2 provides an overview of the primary prediction targets and the hypothesized associations among signals and clinical endpoints. As a first step in learning the associations between signals and OCD-related parameters, we will plot the progression of endpoints (responses for future paired *t* tests) and use mixed effects models with repeated measures to assess associations between oxytocin, individual biosignal features, and outcomes such as stress-rest and case-control comparisons. Confounding factors and important interactions will be included to the extent possible. These initial statistical results will mainly serve to estimate sample sizes for future studies. Substudies will focus on assessing automating behavioral observations using audio and video data from parent-child interactions and exposure sessions.

We will test the feasibility of developing AI tools that use signals from a wearable biosensor and audio and video recordings of human interactions. Audio and video recordings are collected at two time points for each participant dyad, which will increase power of these analyses. Furthermore, the exposure tasks last for over 20 minutes and will be sliced into different events: ERP preparation, ERP, ERP debrief. These events will be segmented in 5-minute slices for analyses, which will increase the number of observations.

We will use ML models for classification and prediction of OCD-related and physical stress, as well as prediction of in-the-wild distress episodes. We will use a double-loop cross-validation for model selection and to assess model accuracy within and across subjects. Differences in accuracy within and across subjects can provide information on the needed number of observations for developing robust models in the future. We will use pretrained speech emotion recognition models and computer vision models to estimate behavioral labels from audio and video, respectively.

XSL•FO
RenderX

Table 2. Overview of clinically relevant parameters and hypothesized associations among signals and clinical endpoints.

Prediction target	Definition	Physiological signals	Paralinguistic signals	Linguistic signals	Visual/behavioral signals	Biochemical signals	Ground truth/validation
OCD[a] distress (youth)	Stress, fear, worry, disgust, embarrassment, shame, anger, sadness caused by obsessions/compulsions	Change in HR[b] depending on emotion; increased EDA[c] and temperature	High activation; negative valence	Negative emotion statements	Negative emotion facial expression; increased movement	Low oxytocin	Biosensor tags; (SUDs[d]); child negative emotions (CIB[e]); avoidance (ERP[f]); child stress (FAS[g]); consequences (CY-BOCS[h])
OCD severity	Time spent on, interference, and distress caused by obsessions/compulsions; resistance of and control over obsessions/compulsions	Change in HR depending on emotion; increased EDA and temperature	High activation; negative valence	Negative emotion statements	Negative emotion facial expressions	Low oxytocin	Symptom hierarchy; child negative emotions (CIB); avoidance (ERP); mood and emotion (KIDSCREEN-52)
OCD distress (parent)	Stress, embarrassment, worry, shame, anger, sadness caused by youth's OCD	Change in HR depending on emotion; increased EDA and temperature	High activation; negative valence	Distress statements	Negative emotion facial expressions	Low oxytocin	Biosensor tags; parent negative emotions (CIB); parent stress (FAS); parental stress (DASS[i])
Overdemanding parenting [51]	Expecting youth not to feel distressed despite lived experience [51]	HR, HRV[j], EDA; lower resting HRV; asynchrony	High activation; negative valence; asynchrony; interruptions	Example: "You must…"	Negative emotion facial expressions	Low oxytocin; low concordance between parent and child	Intrusiveness, criticism, low validation (CIB); conflict (FES[k]); low demand (FAS, item 5)
Overprotective parenting [51]	Cognitions/behaviors aimed at protecting child from distress or harm [51]	HR, HRV, EDA; lower resting HRV; asynchrony	Positive valence; asynchrony	Protective statements	Proximity; affective touch	Low oxytocin; low concordance between parent and child	Accommodation (ERP); participation and modification (FAS); autonomy (KIDSCREEN-52)
Supportive parenting [51]	Nonjudgmental, emotional and cognitive, empathy and conviction that child can cope [51]	Higher resting HRV; HR, HRV, EDA; synchrony	Positive valence; entrainment [18]	Accepting and confidence statements [51]	Movement synchrony	High oxytocin; high concordance between parent and child	Youth engagement, parent sensitivity (CIB), synchrony (ERP); discourage avoidance (FAS low score); cohesion (FES); parent relation (KIDSCREEN-52)

[a]OCD: obsessive compulsive disorder.

[b]HR: heart rate.

[c]EDA: electrodermal activity.

[d]SUD: subjective unit of distress.

[e]CIB: coding interactive behavior [48].

[f]ERP: exposure and response prevention.

[g]FAS: family accommodation scale [43,44].

[h]CY-BOCS: Children's Yale-Brown Obsessive Compulsive Scale.

[i]DASS: depression anxiety and stress scale [41].

[j]HRV: heart rate variability.

[k]FES: family environment scale [42].

Feasibility Outcomes

Study-specific feasibility criteria are defined in Table 1. Where appropriate, we will provide 95% CIs. Feasibility outcomes are binary: "success" indicates that the a priori feasibility criteria have been met, whereas "revise" indicates that the criteria have not been met. "Success" will indicate that no or small changes are needed before proceeding with a larger study and "revise" will indicate the need for major changes before proceeding.

We will also identify the clinical measures needed to validate the AI tools. Measures will be retained for further studies if they are comprehensible to the participants, do not overburden participants, and can be practically delivered to participants without overburdening research staff. EMAs about emotions should not exceed 60 seconds to complete. Questionnaires and

XSL•FO
RenderX

semistructured interviews about participant experiences with the biosensor will be used to generate hypotheses that can be tested in a larger study and, if relevant, to improve researcher scripts for introducing the biosensor to participants. We will report frequencies of responses to the user experience questionnaires.

Dissemination

Study results will be released to participants and referring clinicians upon request. Results will be published in scientific journals and conferences targeting mental health professionals and researchers within computer science. We follow authorship guides set by the National Academies of Sciences, Engineering, and Medicine [75] and the International Committee of Medical Journal Editors [76].

Results

The first participant was enrolled on December 3, 2021, and recruitment closed on December 31, 2022. Nine patient dyads and nine control dyads were recruited. Sixteen participating dyads completed follow-up assessments. We expect to submit results of our study by the summer of 2023.

Discussion

Study Overview and Significance

One percent of children and adolescents will be diagnosed with OCD before their 18th birthday [77]. Today, diagnosis and severity ratings depend on self-report and clinical observation, and no objective measures exist for OCD symptoms. ML models that detect distress levels would automate clinical severity monitoring and passively collect objective measures allowing therapists to adjust exposure treatment accordingly. Automatic, continuous distress detection may also facilitate the monitoring of treatment response across therapy sessions as well as monitoring disorder progression in individuals with subclinical symptoms. Finally, ML models that detect changes in mental states would facilitate increasing awareness of connections between thoughts, emotions, behaviors, and bodily sensations, forming an essential part of effective therapy [13].

In this protocol, we present the study design and methods of a pilot study that will evaluate the feasibility of using a commercially available wearable biosensor to monitor symptoms of OCD in youth from physiological signals. Embedded in our pilot longitudinal, case-control study are substudies of audio/visual signals and actively collected biochemical parameters from youths and parents with the goal of detecting and predicting episodes of OCD-related distress.

Potential feasibility issues involve recruiting and retaining participants, biosensor safety and functionality, participant adherence to wearing the biosensor, and logistics of collecting and processing data. The size and design of the biosensor and the lack of a substantial clinical intervention may deter participation. User experience questionnaires and interviews explore themes of stigma attached to wearing a biosensor. A previous study demonstrated that a group of 16 youth, aged 10 to 17 years, participating in a study of similar length wore a similar biosensor for an average of 11 out of 30 days and one child managed to wear the wristband 5 days per week [78]. The study aimed to develop a personalized weight management program with the E3 wristband and asked youths to wear the biosensor for at least 5 days per week for 3 months [78]. No technical difficulties were reported for the wristband [78]. Youth in the wristband condition reported a similar level of (dis)comfort as youth in the control condition [78]. Nonetheless, the researchers speculated as to whether the youths did not wear the wristband due to concerns that it would attract unwanted attention from peers [78]. Some participants expressed concern of being surveilled by the biosensor [78]. To address potential concerns in our participants, we will thoroughly explain what the wristband is and is not capable of and coach the participants in informing others about their new accessory. The E4 wristband has been used to monitor arousal in 15 children as young as 2 years with Down syndrome during 7-minute parent-child interaction sessions [15]. EDA data from children were deemed useable (90% of interactions tracked) for 27 out of 30 interactions; from parents, EDA data were useable for 23 out of 30 interactions [15]. Missing data were due to 7 instances of software malfunctions [15].

A byproduct of having up to two in-person meetings with participants to download biosensor data securely throughout the observation period may be an implicit reminder to wear the biosensor. We will examine whether participants were more likely to wear the biosensor on data collection days. Asking youths with obsessions, compulsions, and safety behaviors to tag OCD-related events may interact with or become a symptom. This theme is also explored in the user experience interview.

Strengths and Limitations

The strengths of the protocol include the ecological validity of in-the-wild passively collected physiological signals; collecting physiological signals under repeated controlled conditions; the case-control design; and supplementing with multimodal signals from audio, video, and biochemistry. One limitation of the protocol is the small sample size. The sample size limits generalizability of the statistical and ML results. The ML models risk producing false-positive predictions. In the case of high individual variation, false negatives will also be a risk. Nonetheless, we have enough observations to evaluate the feasibility of making the proposed predictions. We have up to 8 weeks of physiological signal data per participant. Moreover, previous studies indicate that these physiological signals are sensitive to strong sustained stressors [75] such as those experienced in OCD.

Conclusion

If the findings of this pilot study support our hypotheses of sufficient feasibility, subsequent larger studies will further develop and test ML models that can detect and predict OCD severity, distress, and related family processes that maintain OCD. Ultimately, these innovations will contribute to increasing knowledge about objective markers of OCD severity and OCD-related, clinically relevant family processes. Furthermore, the AI tools we aim to develop have the potential to assist in validation of assessments of the severity of psychiatric disorders and inform treatment decisions. Such AI tools would enable

XSL•FO
RenderX

monitoring disease and treatment planning. For example, automatic clinical severity classification models could be applied in the therapy room or in the patients' everyday lives while youths are on treatment wait lists to monitor symptoms or between therapy sessions to monitor and support treatment progress.

Acknowledgments

This study is funded by the Novo Nordisk Foundation (grant number NNF19OC0056795). We would like to thank the colleagues that supported this work. AR Cecilie Mora-Jensen critically reviewed this protocol. Camilla Uhre critically reviewed the full protocol to the ethics committee. Michella Heinrichsen helped obtain the data protection and collaboration agreements. Julie Hagstrøm and Klara Sofie Vangstrup Halberg reviewed the guided exposure material. Melanie Ritter helped to set-up questionnaires in the Research Electronic Data Capture (REDCap) system and translate questionnaires into Danish. Nicklas Leander Lund helped translate and prepare participant material. We would also like to thank Eli R Lebowitz, Jakob E Bardram, and Niklas Rye Jørgensen for supporting our grant application with letters of support and commitment to collaboration in terms of interpreting results, creating a mobile app for data collection, and analysis of saliva samples, respectively.

Data Availability

After results are published, we will strive to make a depersonalized data set publicly available in a legally compliant way. We will open-source the machine learning code where relevant in conjunction with publications.

Authors' Contributions

All authors made substantial contributions to the conception and design of the work. NNL and LKHC drafted the manuscript. All authors revised the work critically for important intellectual content, approved the final version, and agree to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Abstract

Background: Sustainable implementation of telemonitoring in health care is challenging, especially if one aims to scale up telemonitoring initiatives nationwide. The National collaborative eHealth program in the Netherlands is supporting the nationwide upscaling of telemonitoring in 3 clinical domains by implementing telemonitoring in all Dutch university medical centers (UMCs). The chosen telemonitoring concepts are (1) telemonitoring solutions in the domain of cardiology, (2) telemonitoring solutions providing care from a distance in obstetrics, and (3) telemonitoring solutions monitoring vital functions in hospital wards.

Objective: The aim of this study is to evaluate the upscaling of telemonitoring in Dutch university hospitals in order to gain a better knowledge of the process, methods, and outcomes of nationwide upscaling strategies. Our hypothesis is that by the completion of the Citrien program's scale-up, telemonitoring will be operational in all UMCs but not normalized in routine care.

Methods: A before-and-after study will be conducted to assess upscaling. The theoretical frameworks used are the framework for nonadoption, abandonment, scale-up, spread, and sustainability; the Normalization Process Theory; and a project management tool Project Canvas. The primary outcome of the study is the degree of normalization to which health care providers at UMCs consider telemonitoring a part of their routine practice, measured using the Normalization MeAsurement Development tool (NoMAD). Our secondary outcome is the uptake of telemonitoring at the Dutch UMCs, using management data from UMCs' business intelligence systems query.

Results: Data will be collected between May 2020 and December 2022. Results were retrieved in June 2023. UMCs' business intelligence systems are queried for data for the secondary outcome measures. There is a risk that the UMCs will not be able to provide this management information. The laws and regulations governing telemonitoring in the Netherlands are changing, with the Electronic Data Exchange in Health Care Act (Wet elektronische gegevensuitwisseling in de zorg) and the European Health Data Space Act expected to positively influence implementation and upscaling.

Conclusions: The Citrien program is a nationally coordinated change management program that is scaling up telemonitoring across contexts and settings. This study will produce original data on the uptake and upscaling of telemonitoring at Dutch UMCs. Future initiatives to implement eHealth in the health care sector may be guided by the wide range of success factors, obstacles, and experiences collected through this program. The network itself may be of great value impacting future acceleration of eHealth initiatives.

Introduction

Telemonitoring in health care can be defined as the use of IT to monitor a patient's status remotely [1-3]. Telemonitoring includes the collection, transmission, evaluation, and communication of individual health data from a patient to their health care provider from outside a hospital to the hospital record using technology [3]. Telemonitoring may not only benefit health outcomes [4-6] but also reduce workload for clinical staff and save health care resources. [7]

Significant advantages for patients, the economy, and society could result from widespread telehealth adoption [8]. For example, using a digital platform for blood pressure and symptom monitoring in antenatal care for high-risk women is related to lower costs and equal health outcomes in conventional care [9].

Hence, sustainable adoption, implementation, and subsequent upscaling of telemonitoring initiatives in hospital settings remains challenging nationwide [10-12]. Although there are systematic reviews on adopting digital care [13,14], to our knowledge, little has been published on national implementation programs or national scale-up. A scoping review on nationwide upscaling of telemonitoring revealed heterogeneity in describing nationwide uptake. According to this study, there are 89 factors influencing nationwide upscaling [10].

Implementation of telemonitoring in the Dutch medical landscape is still rather limited, focusing on use in pilots and research settings [15,16]. To date, only 19% of the Dutch medical specialists report the use of telemonitoring in their daily practice [17]. Ten percent of the Dutch medical specialists claim that the COVID-19 pandemic has increased their use of telemonitoring [18]. Only 6% of Dutch patients have reported sharing their health data with their own hospital-based physician, and only 3% of them reported sharing their health data with their hospital-based nurse for the purpose of telemonitoring [17,19].

In the Netherlands, the Ministry of Health, Welfare and Sports (HWS) has called upon the university medical centers (UMCs) to take the lead in shaping the digital health landscape, ensuring sustainable health care [20]. Over the last decade, the Ministry of HWS continues to advocate this role for UMCs [21-23], and recent policy papers continue to do so [24]. From 2014, Dutch UMCs collaborated within the "Citrien" eHealth program, which was founded by ZonMw—a health research and development organization in the Netherlands [25]. The Citrien program is now in its second term. In the first term, the Citrien program was themed "Evidence-Based eHealth." In this program, the effectiveness of eHealth was jointly studied [26]. This resulted in an increased focus on specific eHealth topics including monitoring and insights into the positive contribution of eHealth in health care and a nationwide eHealth vision [27-29]. Despite valuable projects and scientific evidence in the first term of the program (2014-2018), nationwide upscaling of these projects was not in scope. Therefore, a follow-up program was implemented, called "Citrien Implementation and Upscaling." This is the current term of the Citrien program running between 2018 and 2022 [23,30]. At this time, the Citrien program aims at scaling up 3 telemonitoring concepts in a collaborative effort at all Dutch UMCs, including many of their partnering hospitals and systems.

The UMCs in the Netherlands—8 in 2019 and 7 at the moment—act as a knowledge and network partner for nonuniversity hospitals. An effective scaling up of telemonitoring (and obtained knowledge regarding scaling up) at UMCs could affect roughly 70 additional nonuniversity hospitals in the Netherlands. Within this program, a strong implementation network has emerged, aiding UMCs in being more successful in jointly scaling up telemonitoring with other hospitals and care settings [31].

The aim of this study is to evaluate the upscaling of telemonitoring in Dutch university hospitals in order to gain a better knowledge of the process, methods, and outcomes of nationwide upscaling strategies.

Our hypothesis is that by the completion of the Citrien program's scale-up, telemonitoring will be operational at all UMCs, although it has yet to become normal practice among health care providers.

Methods

Study Design

To evaluate the success in scaling up of 3 telemonitoring concepts across settings, flexibility in vendor and concept selection is deemed necessary. This is required to better adapt to existing variations in hospital settings from a technical, organizational, financial, and cultural perspective while simultaneously safeguarding outcome end goals. A before-and-after study will be conducted to assess the degree of successful upscaling.

Theoretical Frameworks

In order to describe essential elements of the Citrien program—including the intervention, target group, application design, and implementation choices—the framework for nonadoption, abandonment, scale-up, spread, and sustainability (NASSS) will be used [32]. The NASSS framework consists of 7 domains and is designed to identify activities such as those performed by Citrien within a complex context from local adoption to sustainable national scale-up. This framework is considered to be a good fit, as it intends to be used reflexively to guide conversations and help generate ideas about barriers and facilitators [33]. The NASSS framework is intended to evaluate unfolding technology programs in real time and, in particular, to identify and manage their emergent uncertainties and interdependencies. In our study, the NASSS framework

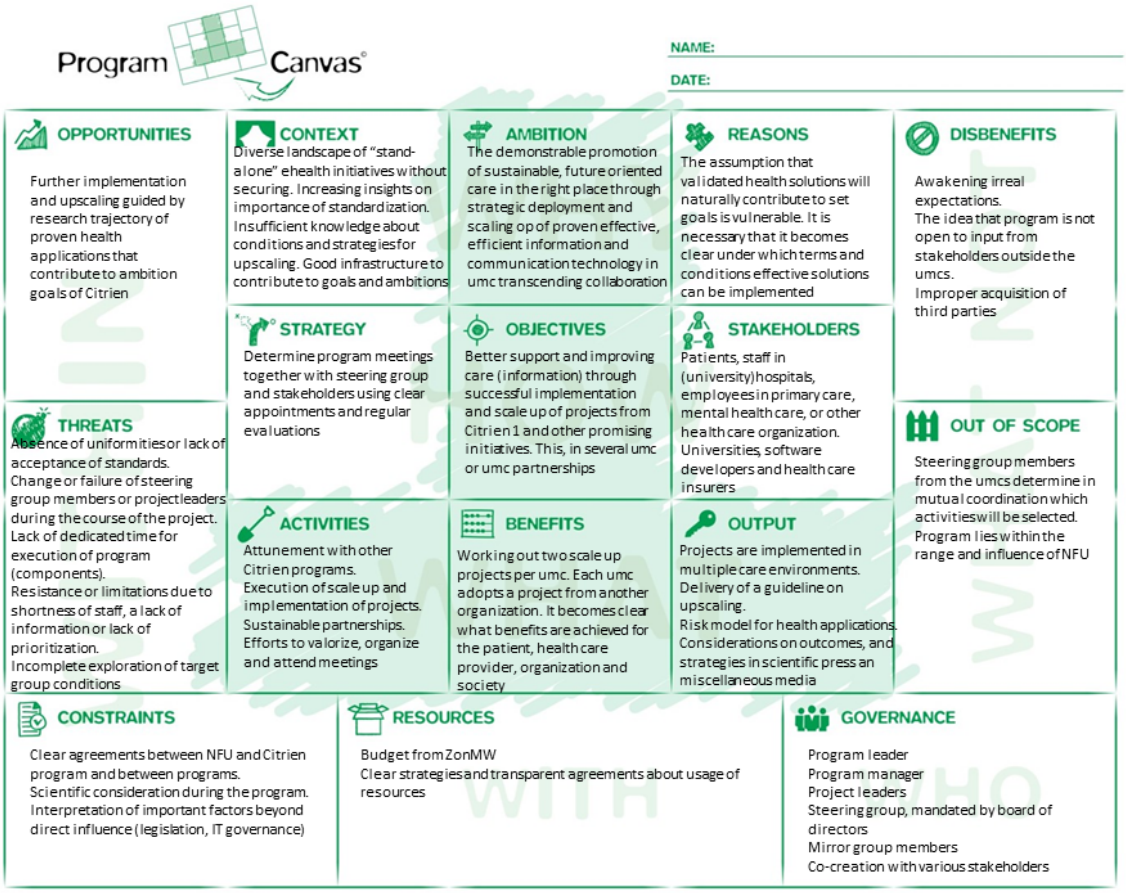
XSL•FO
RenderX

guides the estimation of the complexity of implementation and subsequent scale-up.

Given that this protocol describes the scaling up of 3 telemonitoring projects at 8 university hospitals, the descriptions of all of its essential elements are very lengthy. We, therefore, have appropriately explained the analysis of key elements in accordance with the NASSS framework in Multimedia Appendices 1-3.

Whether end users (health care providers and patients) integrate telemonitoring into daily care (normalization) is a socio-technical issue. An implementation framework such as the NASSS does not provide sufficient insight. To measure normalization, we, therefore, have used the Normalization MeAsurement Development (NoMAD) questionnaire, which is based on Normalization Process Theory (NPT). According to the NPT, a normalization process is a result of individual and group behaviors and entails the embedding and integration of health care innovations into everyday treatment.

According to the theory, 4 constructs play a central role in generating the work of implementation:



- Coherence of the innovation with the goals of daily routine
- Cognitive participation as a process of enrollment and engagement of individual participants and groups
- Collective action by individuals and groups to apply the innovation in daily routine
- Reflexive monitoring through which participants in the implementation process evaluate and appraise the use of the innovation in practice

The NPT successfully aids in the conceptual understanding of implementation processes and outcomes across a wide variety of health care settings [34].

The brief self-report NoMAD questionnaire was designed in accordance with the general approach of the NPT for the goal of detecting factors likely to influence normalization processes [35]. The questionnaire aims to (1) facilitate the evaluation of normalization progress over time in an implementation project and (2) facilitate the comparison of normalization (progress or outcomes) among sites in multicenter studies. The NoMAD questionnaire has been translated to Dutch [36]. Therefore, the NoMAD questionnaire seems suitable as a tool for tracking the progress of implementation for telemonitoring in our Citrien program.

A project-based approach (Program Canvas; Figure 1), advocated by the Netherlands Federation of University Medical Centres, was chosen as the management template for the Citrien program. Program Canvas, and the associated Project Canvas, is a simple model consisting of 16 elements from which a program is built. Project Canvas provides a universal technology to design and initiate new projects. The Canvas has been particularly created for teams involved in interdisciplinary projects, who aim at developing a common ground in an early stage of the project [37].

Figure 1. Citrien program canvas [37].

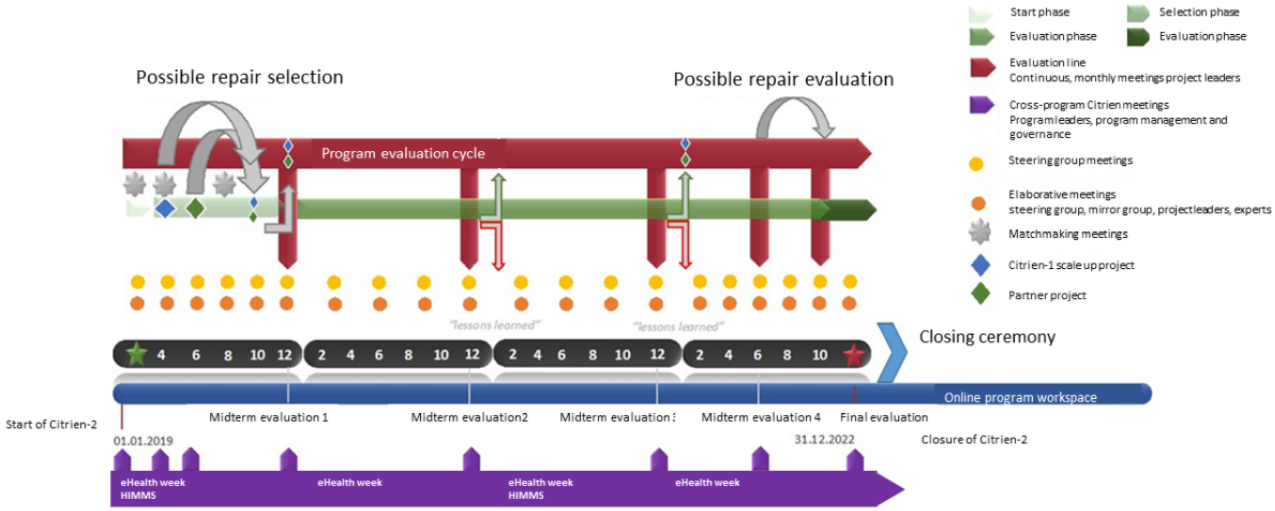
RenderX

Settings and Intervention

In 2020, a total of 1,200,000 patients were treated in all of the UMCs in total [38]. The telemonitoring concepts aim to encourage and foster adoption of (1) telemonitoring solutions in the domain of cardiology, (2) telemonitoring solutions providing care from a distance in obstetrics, and (3) telemonitoring solutions monitoring vital functions in hospital wards. In a prior Citrien initiative, these telemonitoring concepts were developed and evaluated [9,29,39-43].

The Citrien program was structured such that each UMC appointed a tripod of a steering group member, a deputy steering group member, and a project leader. Members are all professionals working at the UMCs, with expertise in the field of eHealth. The steering group members were formally appointed by their hospital boards, and the other members of the tripod were subsequently chosen by the steering group members. All members are in a key position or a management role to guide implementation within their organization. The Citrien program characteristics are outlined in Textbox 1 and Figure 2.

Textbox 1. Outline of the Citrien program.



The Citrien eHealth Program

The Citrien eHealth program focuses on nationwide upscaling of telemonitoring by actual implementation at university medical centers (UMCs) in the Netherlands. The diverse concept of telemonitoring among cardiology patients, high-risk pregnancies, and for in-patients undergoing continuous monitoring of vital signs using wearables is implemented and researched. For all concepts chosen, differences in the target population or chosen technology (or both) may exist to fit the existing infrastructures and hospital strategy. In the Netherlands, different electronic health records (EHR) are in use by the UMCs. To facilitate interoperability, different requirements must be met to accommodate upscaling of the concepts. UMCs were free to opt for stand-alone solutions, although embedding technology into the existing EHR is a well-known enabler for implementation. Although the technology supply model is open to UMCs, the participating UMCs had to comply to the vision of the Citrien program, choosing trusted suppliers with validated, reliable, secure, and scalable solutions.

Collaboration within the Citrien program supported the project leaders in preparing a business case for their own organization. To analyze barriers and enablers for scaling up telemonitoring locally, UMCs used methodologies they were most experienced with. The Citrien program supported the analysis and drafting of implementation strategies by exchanging best practices among project leaders.

This Citrien program is aligned with relevant initiatives such as information standards and regulations on secure exchange of health data. Part of the program's strategy is to strengthen and foster cooperation within the UMCs and to foster cross-UMC partnerships while implementing various telemonitoring initiatives. Overarching issues related to scaling up such as reimbursement, screening new technologies for viability and suitability, procurement of devices, and privacy aspects were tackled by the UMCs in a joint effort. Typical of the Citrien program was the monitoring of change over a period of 2 years. Project leaders kept track of progress every month during their meetings.

Figure 2. Program planning and characteristics. HIMMS: Healthcare Information and Management Systems Society.

Outcomes and Data Collection

Overview

Upscaling of telemonitoring is operationalized as the actual use (uptake) and normalization of telemonitoring. Effectiveness is expressed in the degree of uptake and normalization of the use of telemonitoring at the UMCs. Data will be aggregated in a protective collaborative web-based environment created for this purpose and managed by the chair of the steering group (MS) and the principal investigator (HG).

Primary Outcome

The primary outcome is the degree of normalization to which health care providers consider telemonitoring to be a part of their routine practice, as measured by the NoMAD questionnaire [36]. The NoMAD questionnaire has high internal consistency and has been validated in heterogeneous examples in different languages and settings [35,36].

XSL•FO
RenderX

Recruitment of Respondents

We make a pragmatic choice for a purposeful sample of respondents without performing a power calculation. Citrien program project leaders within each UMC recruited participants for each telemonitoring project to take part in the survey. The local project leader within each UMC sent a standardized invitation email to 10 self-selected health care professionals involved in the adoption of a telemonitoring project, containing the objective of the study and a link to a web-based survey. We aimed for a total of 10 respondents per project and consequently 30 respondents per UMC. This is a pragmatic choice because project leaders have noted at this stage of the scale-up that not more than 10 care providers are involved in the telemonitoring projects. Three reminders were sent. The local project leaders and the researcher were both unable to determine who had filled out the questionnaire. The questionnaire did not collect any email or IP addresses. The questionnaire responses could not be linked to specific individuals.

Secondary Outcome

The secondary outcome is the uptake of telemonitoring in Dutch UMCs, as measured by (1) the absolute number of patients using telemonitoring within each UMC and (2) the percentage of patients using telemonitoring compared to the number of patients eligible for telemonitoring.

These data are management data or business intelligence data. Patients are not actively being included. This study observes the nationwide coordination of implementation and scale-up practices carried out on a daily basis.

Statistical Analysis

The results will be presented as a summary of the outcome measures sorted by UMC and telemonitoring project, using frequencies, medians, and percentages for categorical factors and means and SDs for continuous measures in order to have as much information as possible available for exploration and nonparametric analysis. For evaluation of NoMAD data, we will use the Wilcoxon signed-rank test. To evaluate the secondary outcome measures within each UMC, we will use a 2-tailed paired *t* test. All statistical analyses will be conducted using SPSS software (version 28.0, 2021 release; IBM Corp).

Ethical Considerations

The primary outcome measure is a questionnaire administered to health care professionals. It is a nonburdensome questionnaire that is completed voluntarily and anonymously. Health care professionals are not subjected to any actions, nor are any behavioral rules imposed.

The secondary outcome measure is management information collected retrospectively. No data are collected from patients, and no actions or behavioral rules are imposed on patients. The use of telemonitoring is always and only in the context of patient care. The reason for monitoring is not different but only the method of delivery is in a digital manner.

The Medical Ethics Review Committee Amsterdam UMC exempted this study from ethical review. The study protocol is registered on the Open Science Framework [44].

Results

The baseline assessment was carried out from May 2020 to January 2021. Data on scaling up are collected quarterly. The final results were retrieved in June 2023. Data collection will be carried out under governance of the project leaders at every UMC. The findings are likely to be available in the second half of 2023.

Discussion

Anticipated Findings

This study will define the degree of uptake of telemonitoring at Dutch UMCs and elucidate how it is normalized in the daily routine of health care professionals. This protocol is important as it describes the theoretical framework that will be used and activities that will be performed. Evaluating the implementation of 3 telemonitoring projects at all university hospitals of the Netherlands provides the opportunity to provide a better understanding of the process, methods, and outcomes of a nationwide implementation of strategies.

Limitations

While launching this initiative, we thoroughly analyzed the scale-up's challenges and created tailored implementation plans and strategies for each UMC. However, we are unable to completely control all variables and influences in this real-world evaluation study. This implies that there remains a degree of uncertainty about the effectiveness of the scale-up program. If unforeseen circumstances arise despite carefully planned implementation actions and plans, the effect of the Citrien program may be underestimated. Thus, maybe the impact of the Citrien program could be overestimated if there are favorable changes in the health care environment that are unrelated to the Citrien program and accelerate the scale-up of telemonitoring. Nonetheless, it is interesting to evaluate this in a systematic approach.

Although not likely, limitations may also occur as a result of data collection; for example, when too few responses are received for the primary outcome measure. We can send additional reminders and request project leaders to exercise leadership in this situation.

The UMCs' business intelligence systems are queried for data for the secondary outcome measures. Although the outcome measures are actual fundamental parameters, there is a risk that the UMCs will not be able to provide this management information. It is crucial to acknowledge this and communicate the lesson that has been taught if this happens.

Nationwide upscaling of telemonitoring in different target groups requires a range of technologies and suppliers. The Citrien program aims to contribute to important preconditions, such as writing a business case, providing insight into barriers and enablers, and designing implementation strategies. With a pragmatic approach, Citrien aims to provide insight in, and solutions for, various barriers such as interoperability, reimbursements, adjustments in care paths, privacy policies, and procurement policies. These initiatives were carefully and

XSL•FO
RenderX

purposefully developed in light of the variables that affect nationwide upscaling, which were identified in a recent scoping review on upscaling telemonitoring [10].

The laws and regulations governing the use of telemonitoring in the Netherlands are subject to change. The legal responsibility in monitoring patients remotely was still unclear at the start of this program. From 2023, the Electronic Data Exchange in Health Care Act (Wet elektronische gegevensuitwisseling in de zorg) mandates digital data exchange among health care providers. This also affects the processing of telemonitoring data. In the near future, European Health Data Space Act will also be enacted [45]. These regulations are expected to positively influence implementation and upscaling.

Finally, there are other eHealth scale-up initiatives in the Netherlands. In order to encourage eHealth activities outside of hospitals, the government has incentive regulations for eHealth in primary care [46]. A coalition of patients, health care professionals, health insurers, and suppliers was formed by the Netherlands Patient Federation in order to advance digital care [47]. Although these programs are not aimed at UMCs, the Citrien program will include similar strategies.

Conclusions

The Citrien program is a nationally coordinated change management program in the eHealth domain, now scaling up telemonitoring across situations and settings. We expect that this study will yield unique evidence about the use and upscaling of telemonitoring in Dutch UMCs. This study protocol could serve as inspiration for others who would like to implement a similar programmatic intervention for nationwide scale-up of applications, such as a digital ward or artificial intelligence–driven decision support. The success factors, barriers, and experiences collected in this program could guide future projects that aim to implement eHealth in the health care sector. The Citrien network itself may be of great value impacting future acceleration of eHealth initiatives.

Acknowledgments

Abstract

Background: With the increasing prevalence of chronic diseases, partly due to the increase in life expectancy and the aging of the population, the complexity of the approach faced by the structures, dynamics, and actors that are part of the current care and attention systems is evident. The territory of Bages (Catalonia, Spain) presents characteristics of a highly complex ecosystem where there is a need to develop new, more dynamic structures for the various actors in the health and social systems, aimed at incorporating new actors in the technological and business field that would allow innovation in the management of this context. Within the framework of the Bages Territorial Specialization and Competitiveness Project (PECT BAGESS), the aim is to address these challenges through various entities that will develop 7 interrelated operations. Of these, the operation of the IDIAP Jordi Gol-Catalan Health Institute focuses on the creation of a Laboratory for Statistics and Analysis of Dependence and Chronic Conditions in the Bages region, in the form of a database that will collect the most relevant information from the different environments that affect the management of chronic conditions and dependence: health, social, economic, and environment.

Objective: This study aims to create a laboratory for statistical, dependence, and chronic condition analysis in the Bages region, to determine the chronic conditions and conditions that generate dependence in the Bages area, in order to propose products and services that respond to the needs of people in these situations.

Methods: PECT BAGESS originated from the Shared Agenda initiative, which was established in the Bages region with the goal of enhancing the quality of life and fostering social inclusion for individuals with chronic diseases. This study presents part

XSL•FO
RenderX

of this broader project, consisting of the creation of a database. Data from chronic conditions and dependence service providers will be combined, using a unique identifier for the different sources of information. A thorough legal analysis was conducted to establish a secure data sharing mechanism among the entities participating in the project.

Results: The laboratory will be a key piece in the structure generated in the environment of the PECT BAGESS, which will allow relevant information to be passed on from the different sectors involved to respond to the needs of people with chronic conditions and dependence, as well as to generate opportunities for products and services.

Conclusions: The emerging organizational dynamics and structures are expected to demonstrate a health and social management model that may have a remarkable impact on these sectors. Products and services developed may be very useful for generating synergies and facilitating the living conditions of people who can benefit from all these services. However, secure data sharing circuits must be considered.

KEYWORDS

chronic disease; multiple chronic conditions; primary health care; diffusion of innovation; health data; data sharing

Introduction

The prevalence of chronic diseases has increased worldwide over recent decades and is no longer a characteristic of developed countries [1,2]. These types of diseases tend to be long-lasting, generally slow to progress, and noncommunicable among people [1,3,4]. Life expectancy has increased as a result of social progress and advances in health [4]. However, this has led to an increased risk of chronic multimorbidity, especially among older adults [2,4,5].

As a result, an increase in the burden of noncommunicable and chronic diseases is being described globally [1,4,6,7]. Consequently, there is an increase in years lived with disability and eventually in situations of dependence. Altogether, this poses a challenge from multiple perspectives. Health systems, and especially primary care, must adopt a complex approach in terms of detection, care, and follow-up of cases of chronic conditions or chronic multimorbidity, in addition to the costs involved [2,4,8]. There is also a direct impact on the loss of quality of life of people with these conditions and the emerging needs they develop [2,4,5]. At the same time, the circumstances of chronic conditions increase the fragmentation and burden of care, as well as the burden on family relationships and carers [5,9-13].

The difficulty of dealing with chronic diseases often lies in the complexity of the structures, dynamics, and actors involved in care, beyond the clinical complexity that care for these conditions may entail. Given the diversity of chronic diseases and their impact on the people who have them, management that takes into account a multiplicity of factors is necessary. This requires patient identification, comprehensive needs assessments, management of needs and resources, coordination between health and social agents that can influence an optimal care response, ensuring round-the-clock care, minimizing potentially avoidable hospitalizations, and accompanying people at the end of their life trajectory when appropriate [4].

The Catalan health system (integrated within the Spanish national health system) is intended to provide universal care and is financed by citizens' taxes, based on a public model centered on personal care and a comprehensive approach to health [14]. In this context, primary care plays an important role in the clinical management of chronic diseases and cases of patients with complex conditions. Thus, the system allows for continuity and longitudinality of care, together with other levels of care (emergency, specialist consultations, and hospital admissions) [4,15]. In parallel, sociohealth and social structures provide care focused on aspects derived from clinical conditions (eg, home care and formal care) [10]. Together, the various health and social agents make it possible to respond to a series of needs of the group most affected by chronic conditions and situations of dependence [14,16].

Despite the existence of an integrated health and social system, there are shortcomings in relation to the diversity of cases for which the system is unable to respond. These include informal care and the burden on family members [9,12,17]; the impact on the quality of life of patients with chronic diseases [2,5]; the differential impact of chronic conditions according to sex and gender [18,19]; barriers to access to health or social services [20,21]; and, finally, a lack of coordination within the network of actors involved who are sometimes unaware of the extent to which all the needs are being met [20].

The population of the Bages region (Central Catalonia) shows a sustained increase in population aging and overaging [22], which favors a high prevalence of chronic diseases. Although chronic conditions are present in various stages of life, they become more complex to manage as age advances and there are more cases of multimorbidity and dependence. It is therefore crucial to have data and information on the needs of people affected by these conditions, their environment, and the services they require.

The Bages region, primarily a rural area, spans a surface of 1092 km^2 and is characterized by the presence of only 2 urban centers [23]. As of 2021, the total population of the region was 179,770 [22]. Situated within Central Catalonia, the Bages region is 1 of the 7 regions that form the Catalan health system. The Catalan Health Institute (ICS) serves as the main health care provider in the area, covering approximately 85% of the population of Bages [24].

XSL•FO
RenderX

According to data from the Central Catalonia Territorial Management of the ICS [25], the prevalence of various chronic diseases grew between 2018 and 2021 (ICS, unpublished data, 2023). The most prevalent diseases were hypertension (40.2%), chronic pulmonary diseases (26.3%), and type 2 diabetes (16.1%). At the same time, the most prevalent mental disorders were anxiety (42.6%) and depression (18.3%), which also corresponded with the continued increase in chronic conditions and as one of the most common comorbidities. At the same time, the data showed differences by age and sex in the burden of chronic conditions, which reinforces the need to differentiate the approach by taking into account a sex and gender perspective [18,26-28].

Despite the availability of this information, mainly of a clinical nature, the ICS system does not have information on the needs of people with chronic and dependent conditions. It should be considered that the Bages area has a structure of health and social health services and providers included in the public system other than the ICS [14]. At the same time, social services depend on local public administration, which is governed by different legislation from the health sector [29]. Therefore, there is a lack of a procedure to bring together all these institutions and actors that provide care to people with chronic conditions and dependence across the board.

Given these conditions, in 2019, the Territorial Specialization and Competitiveness Project-Big Data, Analytics, Management and Strategy in Health and Social (Proyecto de Especialización y Competitividad Territorial – Big Data, Analytics, Gestión y Estrategia en Salud y Social [PECT BAGESS]) project was born. It was formed by several agents of the health and social system, public administration, technological sector, and university and research sector in the Bages region. The objective of the project is to address the problems and needs arising from dependence and chronic conditions and their impact on the health and social spheres, developing solutions, products, and services that can also become opportunities for economic growth.

This protocol presents one of the operations of the PECT BAGESS, which corresponds to the creation of a Laboratory for Statistics and Analysis of Dependence and Chronic Conditions in Bages. This will serve as the basis for coordinating information from all project entities. It will also make it possible to define the chronic conditions and conditions that generate dependence in the Bages area; identify their prevalence, incidence, and main associated factors; and propose products and services that can respond to these needs.

The PECT BAGESS project is currently being developed by 7 partners, with funding from the Generalitat de Catalunya [30], and 4 collaborating entities without funding. The coordination of the project is led by Manresa Town Hall.

Methods

Theoretical Approach

In order to address such a complex challenge as the one posed by the PECT BAGESS project, the Bages Shared Health and Social Agenda was drawn up. The Shared Agendas are initiatives promoted by different agents in the area with the aim of implementing a coordinated approach to complex challenges linked to the Sustainable Development Goals and the problems and opportunities arising from them [31].

The Bages Shared Agenda aims to bring together the relevant main actors in the area who will adopt a proactive approach to the challenge. In this way, objectives, resources, and structures can be shared, and collaborative and multidisciplinary solutions can be generated. In short, it is structured to satisfy the need for applying enabling technologies in this highly complex ecosystem relating to dependence and chronic conditions, placing the person living with these types of conditions and the needs arising from their health circumstances at the center. The main actors in the area who participate in the Shared Agenda are part of the health and social sector, both from the public administration, research centers, universities, and health care centers at all levels (eg, from primary care, specialized consultations, acute care, and chronic diseases).

The structure of the Shared Agenda, and consequently the PECT BAGESS project, in this environment of chronic conditions and dependence is framed within the strategy promoted by the Research and Innovation Smart Specialization Strategy (RIS3) of the Generalitat de Catalunya in the RIS3CAT 2030 edition. This commitment to transformative and responsible research and innovation is based on shared agendas as the main drivers to guide Catalonia toward a greener, digital, resilient, and fairer socioeconomic model [32]. In addition, the use of technology and a quadruple helix structure (4H) are promoted: patients and the population, health and social system, science and technology, and business. The joint work of these sectors and agents in the region will make it possible to provide a united response to the needs associated with the chronic conditions and population with dependencies in Bages, to export the dynamics and solutions generated to other regions of Catalonia once the project is completed.

The PECT BAGESS project seeks to improve the quality of life and promote the social inclusion of people with dependence and chronic diseases, making them active agents of their own health. Furthermore, it also wants to drive the economic transformation of the county with a focus on the digital transition of the health and social sector, both public and private, to make it a more competitive, sustainable, resilient, and quality service.

To this end, one of the operations to be carried out is the definition and detection of the needs of people in these circumstances. For this reason, mechanisms need to be established for sharing data and information among the different actors involved in the project, especially among those providing direct health care or population health care. The availability of real data on chronic conditions and dependence will make it possible to go deeper into the other aspects of the project, as well as to offer subsequent analyses and evaluations in greater depth.

As part of the study, data from supplier entities will be combined. In order to have information corresponding to a single person, the data will be merged using a unique identifier for any of the provider entities. This strategy ensures that the combined data are accurate in terms of ownership, although the

XSL•FO
RenderX

problem in its implementation lies in the existence of a common unique key (Table 1).

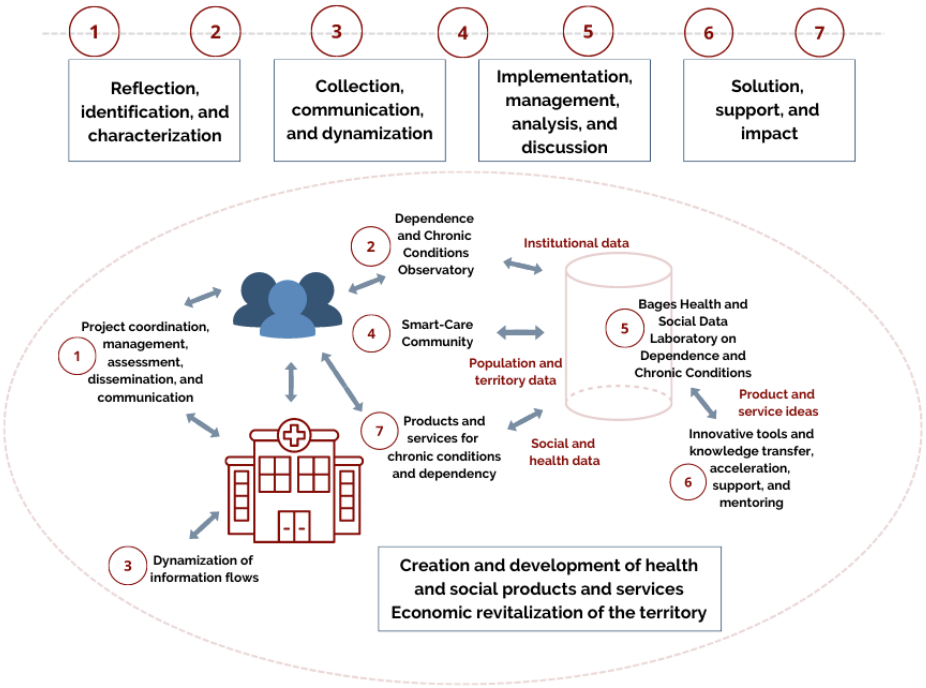
Table 1. Characterization of the data sets involved in the combination process.

Characteristics	Health data	Social services data	Context data
Unique identifier	Personal identification code (PIC), personal ID	Personal ID	Personal ID
Additional information	Sex, age, municipality, nationality	Sex, age, municipality, nationality	Sex, age, municipality, nationality
Thematic data	Diagnosis	Problem, dependence	Income, living conditions

The utilization of a unique patient identifier is a complex yet essential aspect of the data merging process. Its purpose is to prevent duplication and ensure a comprehensive understanding of regional requirements and attributes. Recent literature delves into the discussion surrounding data sharing and provides insights into the implementation of unique patient identifiers [33-35], highlighting the complexities associated with integrating data, particularly personal data, from diverse sources. Furthermore, it is essential to address the legal implications before creating the database, as outlined in the "Ethical Considerations" section.

Project Partners

The collaboration of various entities in the area, through research and implementation of comprehensive and innovative digital solutions, make the PECT BAGESS project possible. Among the partners (entities receiving funding) are Manresa Town Hall, as project coordinator; Sant Andreu Salut Fundació; Althaia Xarxa Assistencial de Manresa Fundació Privada; Fundació Eurecat; Institut Universitari d'Investigació en Atenció Primària-Institut Català de la Salut de la Catalunya Central (IDIAPJGol-ICS); Fundació Universitària del Bages-UManresa; and, finally, Fundació Ampans.



Also collaborating are the Regional Council of Bages, the Unió Consorci Formació, the Associació Catalana d'Entitats de Base Associativa, and the Fundació TIC Salut Social.

Project Structure and Interconnection Between Operations

Overview

The various entities involved in the project are key players in the 4 phases defined by the PECT BAGESS: (1) reflection, identification, and characterization; (2) collection, communication, and dynamization; (3) implementation, management, analysis, and discussion; and (4) solution, monitoring, and impact. These 4 phases group 7 operations, which are determined by the performance of each partner entity in each of them (see Figure 1).

Figure 1. Structure of the Proyecto de Especialización y Competitividad Territorial-Big Data, Analytics, Gestión y Estrategia en Salud y Social (PECT BAGESS) and interconnection of operations.

XSL•FO
RenderX

Operation 1: Coordination, Management, Evaluation, Dissemination, and Communication of the PECT BAGESS

Manresa Town Hall is leading the transverse coordination operation. This allows one to have an overall view of the rest of the operations, facilitate their management, and ensure that the project is on schedule. It also supports each individual entity in terms of administrative and economic justification, while acting as a liaison between the entities and the General Directorate of Local Administration.

Operation 2: Observatory of Dependence and Chronic Conditions in Bages

Developed by Sant Andreu Salut, the objective of this operation is to manage the information generated about chronic conditions and dependence, both for the affected person and his or her family and carer. The observatory aims to be a tool for sharing needs and resources for this group, as well as gathering new actions and relevant information in this regard.

Operation 3: Dynamization of Information Flows

Althaia, responsible for the management and dynamization of information flows, seeks to incorporate the use of technologies to contribute to the transformation of the health care model, promoting a better patient-professional relationship and improved coordination among professionals. Using support tools, shared among the different health and social care providers, the aim is to contribute to better patient stratification and predictive medicine, thus minimizing acute cases and, consequently, regulating the need for health care resources. In this way, the quality of life of patients with chronic diseases is improved, and their care is made more efficient.

Operation 4: Smart-Care Community

Eurecat develops information and communication technology (ICT) tools for the integrated care of patients with chronic diseases, in a global context that takes into account the patient, caregivers, and health care environment. The center uses technologies based on artificial intelligence and human-machine interaction interfaces. This operation involves co-designing, implementing, and validating various management, learning, and support tools for the patient-professional care and social system. Eurecat also conducts 2 pilot tests in cardiac rehabilitation and mental health (schizophrenia), which are implemented in coordination with agents using these tools.

Operation 5: Statistical and Intelligent Analysis Laboratory

The collection of chronic condition and dependence data and their analysis are carried out at IDIAP JGol-ICS Catalunya Central through the Laboratory of Statistics and Intelligent Analysis. With the legal requirements to do so, with the completion of a legal study and an impact assessment, this operation makes it possible to gather all the existing data in terms of health and social data to detect the problems and needs of people with chronic conditions and dependence and their environment. Similarly, this operation serves to validate the interventions proposed by health care institutions, as well as the products and services of companies in the sector, and to propose new solutions based on the scientific evidence identified by the analysis.

Operation 6: Transformative and Knowledge Transfer, Acceleration, Support, and Monitoring Tools

The Fundació Universitària del Bages-UManresa focuses on the creation of a platform for entrepreneurship and support for health and social initiatives (eHealthinking) in the process of developing products and services in this sector, providing expertise in this type of process from a position of knowledge of existing structures. Both initial financing (Business Angels network) and support from the business network with expertise in the health-social field (Health and Social Innovation Cluster) will be provided.

Operation 7: Dependence Products and Services

The latest operation is led by Fundació Ampans, with the aim of creating a product that offers people with chronic conditions and dependence and in need of support solutions and tools that empower and facilitate the management of their daily reality. In the form of a technological tool (mobile app and back end platform), this product will enable the concerned person to find specialized professional social and health care services for their condition. Additionally, it will provide them with access to a library of resources, tools, and knowledge from collective experiences and enhance social relationships by finding specific recreational activities. This technological solution seeks to build change, fostering empowerment, quality of life, and person-centered care and focusing on meeting the needs of the dependent population.

Creation of a Laboratory for Statistics and Analysis of Dependence and Chronic Conditions in Bages

In light of the project's overarching framework outlined previously, we will now proceed to describe the implementation of the operation assigned to IDIAPJGol-ICS, which corresponds to operation 5. This consists of the following 2 elements: (1) description of the procedures associated with the laboratory and (2) description of the implementation proposal to be carried out.

Procedures Associated With the Laboratory

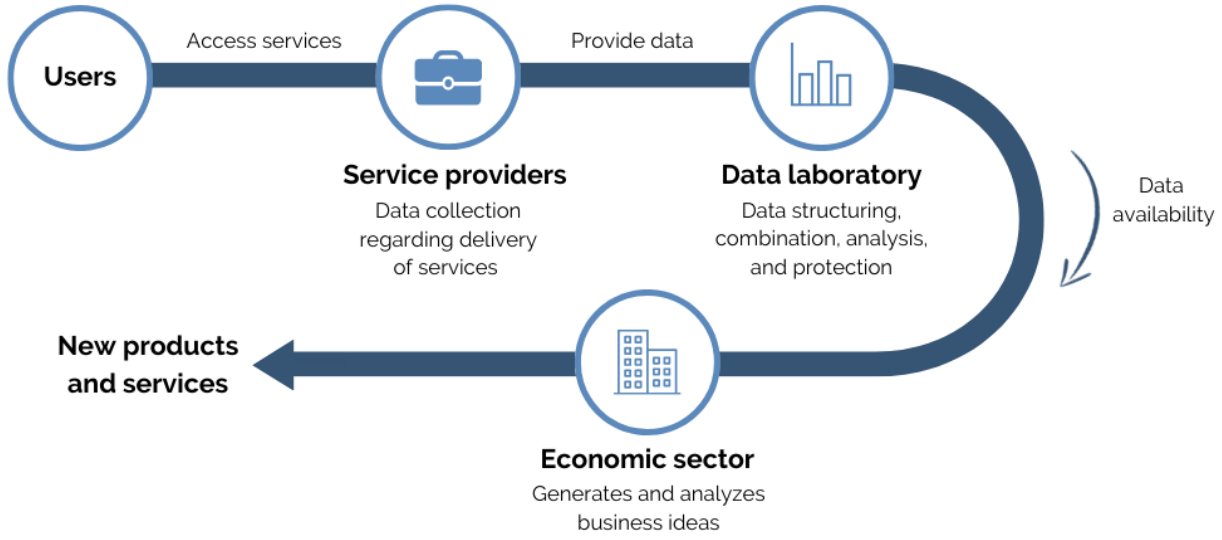
The procedures for operation of the laboratory are as described in the following paragraphs.

First, data collection in the health, social, and contextual areas covers the data life cycle from its contribution by users at the time of access to services including the generation of new services in the area of chronic conditions and dependence by the economic fabric (Figure 2).

Second, data that contribute to performing operations 4 and 6 of the PECT BAGESS project are transferred. One of the first uses of the data obtained by the statistics laboratory is to deliver data to the ICT tools developed in the context of operations 4 and 6 of the PECT BAGESS project (Figure 3).

XSL•FO
RenderX

Figure 2. Procedure 1: collection, combination, and publication of chronic condition and dependence data.



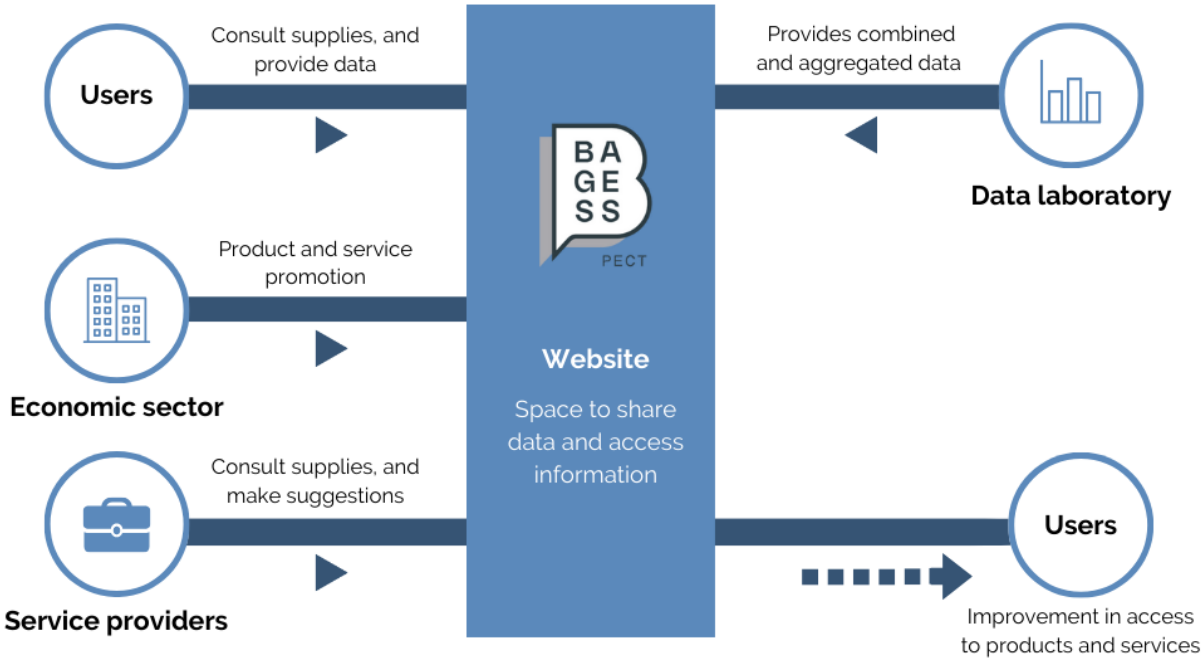


Figure 3. Procedure 2: transfer of data to contribute to the implementation of operations 4 and 6 of the Proyecto de Especialización y Competitividad Territorial-Big Data, Analytics, Gestión y Estrategia en Salud y Social (PECT BAGESS) project.

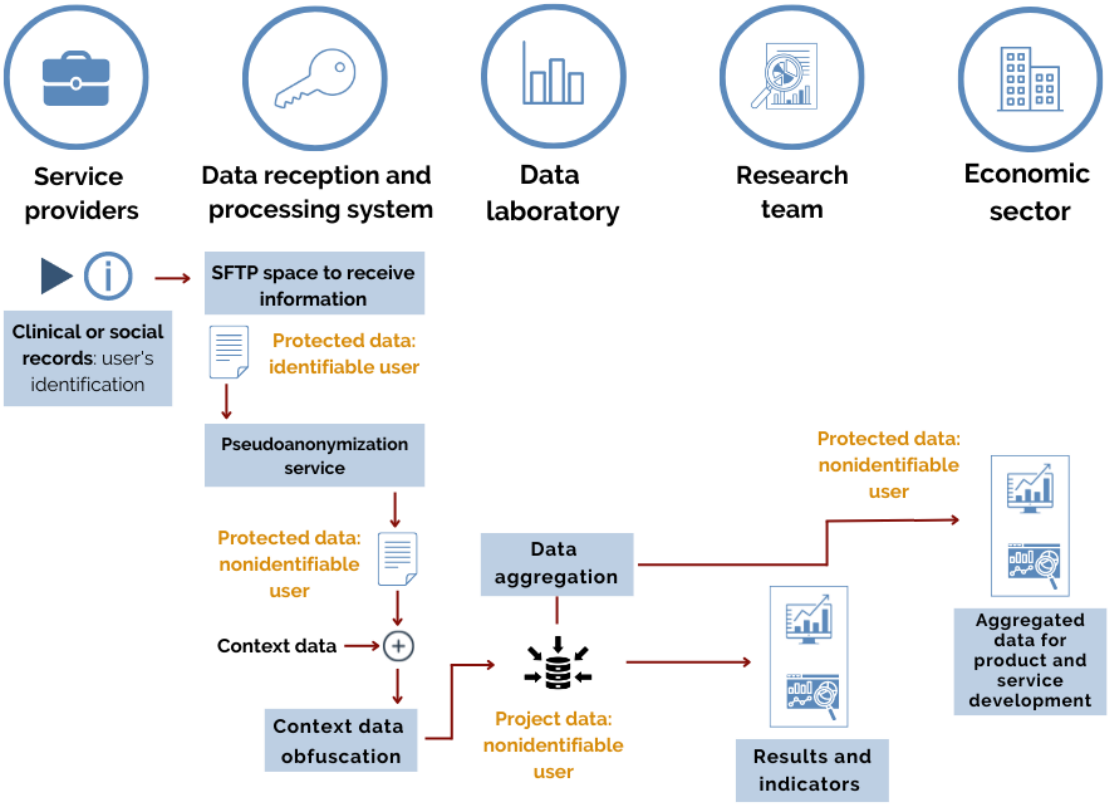
Description of the Implementation Proposal

In accordance with the previous paragraphs, the proposal involves creating the chronic condition and dependence laboratory with the implementation characteristics described in the following paragraphs.

First, the combination of the data will be carried out by combining 2 strategies: (1) use of pseudonymized data in which a unique identifier (personal ID) is used as the basis for the generation of the pseudonym combined with the person's date of birth for the combination of health and social data and (2) use of general demographic data for the combination of contextual data.

Second, IDIAPJGol separates the functions in its project according to the following 2 blocks: (1) technical block, which is part of the process of pseudonymization, combination of data, creation of the data repository, obfuscation, and aggregation and preparation of data for dissemination to third parties, and (2) research block, which involves data analysis tasks and review of scientific evidence, needs assessment, and proposal of products and services.

Third, the pseudonymization process is carried out in a distributed manner both in the generation of the pseudonym and in the custody of the translation dictionaries and consists of the following entities: (1) pseudonymization neutral point that is in charge of obtaining the hash by applying the algorithms (SHA256 hash with a fixed salt not specified in the database and a pepper of 3 characters in length) and of keeping the resulting pseudonym values and of the entity making the request and (2) provider entities that are in charge of keeping the translation dictionary of the entity's own pseudonyms.



XSL•FO
RenderX

Going into more detail on the operation, it is necessary to describe the agents involved in the process and their main function in relation to the process (except for the service users, who are not considered even though they are the ones providing the data, since they do not perform interactions at the information system level), which are as follows:

- Entity providing health or social services, which provides the data and keeps the pseudonym dictionaries of its own users
- Pseudonymization neutral point (IDIAPJGol-technical), which performs the pseudonymization process and the keys to obtain it
- Statistical laboratory (IDIAPJGol-technical), which prepares and keeps the pseudonymized data
- Research team (IDIAPJGol-research), which analyzes the pseudonymized data
- Economic fabric, which is the recipient of the aggregated data containing specially protected data but in which the individual is not identifiable

The overall model that would emerge from this description can be seen in Figure 4.

Figure 4. Global model proposed by the creation of the laboratory. SFTP: secure file transfer protocol.

Monitoring and Assessment

Monitoring will be done in cooperation with the various partners involved in the project. The various operations will be evaluated by each entity, through process and results indicators, in order to meet the project's objectives. Quality measures of the activities carried out will also be provided, assessing whether the objectives are being met and their impacts, always taking into account new needs that may arise throughout the process. The evaluation will be shared with all the participants regularly involved.

Communication and Dissemination

The results of the project will be disseminated through the following different strategies led by the various entities participating in the project:

- PECT BAGESS website and social networks
- Observatory of Dependence and Chronic conditions (operation 2)
- Citizen science meetings and events
- Elaboration of a Policy Brief that includes recommendations for better care and prevention of the needs derived from chronic conditions and dependence, based on the experience of Bages
- Reports, presentations, and meetings with policy makers, health and social professionals, and other relevant stakeholders and organizations
- Scientific publications
- Presentations at local and national conferences

Ethical Considerations

This project has been reviewed and approved by the Ethics Committee of IDIAPJGol (22/068-P). All activities carried out within the framework of this study will be conducted in accordance with existing ethical guidance, as indicated in the Universal Declaration on Bioethics and Human Rights adopted by UNESCO (19/10/2005); the Council of Europe Convention for the Protection of Human Rights and Dignity of the Human

XSL•FO
RenderX

Being with regard to the Application of Biology and Medicine (1997) and its Additional Protocol on Biomedical Research (2005); the Declaration of Helsinki (2013) and relevant European Union laws (Directive 2001/20/EC of the European Parliament and of the Council); the Spanish Law on Biomedical Research (14/2007); and the Spanish Law on Personal Data Protection (3/2018). This analysis was also carried out considering the legislative aspects in the field of health and social services provision, as well as those related to the protection of personal data.

With regard to general ethical aspects, the following have been considered: social and scientific value of research, equitable search in relation to the resources of the population, use of widespread informed consent, processing of data from vulnerable groups.

Regarding the social and scientific value of research, the aim of the study is to obtain combined data on chronic conditions and dependence of the population of Bages. From the data obtained, it will be possible to better characterize the needs of the population (regardless of their characteristics), and as a result of the new products and services that can be defined by the economic fabric, the health and well-being of people will be improved.

Regarding the equitable search in relation to the resources of the population, the result of the research should make it possible to cover the analysis of the global population regardless of its context and based on the propensity to need access to products and services linked to social and health services.

Regarding the use of widespread informed consent, in this phase of the research and under current data protection regulations, consent of the interested parties in the data processed is not obtained for its implementation.

Regarding the processing of data from vulnerable groups, the aim of the research is focused on the group of users benefiting from social and health services who, according to the definition of the project itself, are or may be in a situation of vulnerability. In this respect, the research is aimed at achieving new services to reduce the effects and, if possible, the presence of these situations of vulnerability.

In any case, one of the most relevant aspects is the one related to the processing of service users' personal data, which are combined to obtain the statistics laboratory. These specially protected data are subject to the provisions of Law 21/2000 on the rights to information concerning health and patient autonomy and clinical documentation, the basic Law 41/2002 regulating patient autonomy and rights and obligations regarding information and clinical documentation, Law 12/2007 on social services, Eropean Union Regulation 2016/679 General Data Protection Regulation, and Organic Law 3/2018 on the protection of personal data and guarantee of digital rights, General Health Law 14/1986.

To ensure that the activities to be carried out in the project are conducted in accordance with the law, prior consultation was held with the Catalan Data Protection Agency. The authority's response indicated that the project was covered by current data protection regulations, provided that it was part of a research project and worked with anonymized data, guaranteeing technical and functional separation of pseudoanonymization and the conduct of the research. Considering all the aforementioned information, the data will be stored in an ICS server, and the IDIAPJGol research team will be responsible for data processing.

Results

With project start-up in 2021, all PECT BAGESS operations have been initiated and are in progress. As of June 2023, the operation corresponding to the creation of the Laboratory for Statistics and Analysis of Dependence and Chronic Conditions reached the legal study stage, which covers the suitability of use and combination of the data necessary to create the database.

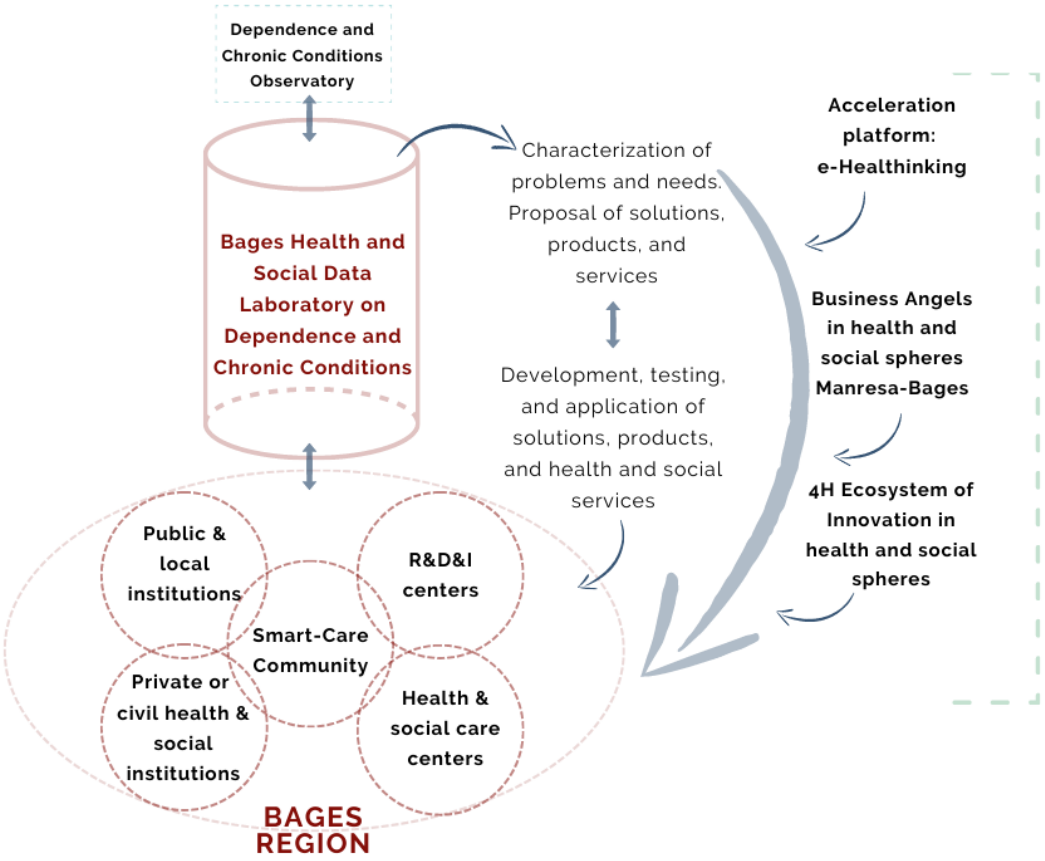
Since the laboratory will primarily consist of personal data provided by various entities offering health and social services in the region, ensuring data protection is of paramount importance. Considering that processing personal data involves the use of special data categories and entails high risk, a data protection impact assessment (DPIA) was carried out following the WP248 guide of Article 29 of the Working Party of the European Data Protection Board.

IDIAPJGol carried out this DPIA through data protection, analyzing the typology of the data included in the new treatment, collection, integration, and data processing procedures, as well as technical and organizational measures applied, in order to minimize the risk associated with their treatment. As a result of the implementation of the planned measures, the final impact of the data processing involves a low level of risk, and therefore, no additional measures are necessary. Thus, the data processing resulting from the creation of the laboratory was deemed feasible from the point of view of personal data protection.

At the same time, coordination with the rest of the operations includes monthly meetings between entities and the organization of various communication events open to the authorities and the public of the Bages region, which have made it possible to publicize the work being done within the framework of this project.

Discussion

This paper presents the project for the creation of the Laboratory for Statistics and Analysis of Dependence and Chronic Conditions in the Bages region, as part of the PECT BAGESS. As an ongoing project, the authors anticipate an improved data sharing process among partners that will be key to move toward a better understanding of the chronic conditions and dependent needs of the population in this area. This project should also provide a foundation for the scalability of this model in other regions.



The authors and agents involved in this project expect that the resulting organizational dynamics and structures will allow for a model of health and social management that may have a remarkable impact on these sectors. Products such as the Observatory of Dependence and Chronic Conditions, the "eHealthinking" entrepreneurship platform, the Bages-Catalonia

XSL•FO
RenderX

Central Business Angels organization, the Smart-Care Community citizen participation platform, or the Health and Social Innovation Cluster, as well as the websites and applications to be developed may be very useful for generating synergies and facilitating the living conditions of people who can benefit from all these services. In relational terms, the project seeks to culminate in interaction and collaboration in other health and social projects, whether they have an impact on research, innovation, or economic development (Figure 5).

To facilitate these dynamics, the backbone of the BAGESS project lies in the Health and Social database, which is fed by the different communication strategies and the information available from each entity, both from health care and other organizations related to dependence and chronic conditions. From the analysis of data from the Laboratory of Statistics and Analysis, it will be possible to extract the information that the Observatory of Dependence and Chronic conditions will collect to offer a more precise characterization of problems and needs related to dependence. As a result of these analyses, it will be possible to propose solutions, products, and services that will be shared with the BAGESS community, accompanied by research and innovation entities, and developed as business projects. These will contribute to the dynamization of the health and social structure and to the economic acceleration of the area. Previous experiences with similar projects can be found in southern Catalonia, where an integrated care model called Salut + Social was implemented. This model aimed to enhance coordination among professionals from health and social services, with a specific focus on addressing the needs of patients with chronic diseases and dependencies [36]. The program received positive acceptance among professionals and high satisfaction among users, improving the efficiency of care and preventing duplication of tasks [37]. Despite not covering the scope of the PECT BAGESS (which also includes economic and technologic agents), this experience confirms the benefits of joining forces to look after a population with potentially high health and social care needs.

Figure 5. Relationship schemes, information flows, and management of the Big Data, Analytics, Gestión y Estrategia en Salud y Social (BAGESS) project, once the Proyecto de Especialización y Competitividad Territorial (PECT) has been passed. 4H: quadruple helix structure; R&D&I: research and design and innovation.

We acknowledge, however, that this study presents several limitations. The potential risks of the implementation of this project will be detected at the time of implementing this management model, as well as the limitation of database maintenance, which will require resources beyond those that have been developed for this project, although several options are currently being considered and coordinated by the Generalitat de Catalunya. Moreover, the commitment and availability of the entities involved in taking on the current tasks and the possible continuation of the tools and products derived from the project must be taken into account, although, so far, the coordination and communication between them have been very positive. Finally, there is a risk arising from the nature of the information with which we work, since it refers to personal health and social data; therefore, it is very necessary to adhere to the corresponding regulations in order to maintain its confidentiality. Being aware of the latter, we developed a legal study within the framework of the operation presented in this

XSL•FO
RenderX

protocol, in order to rely on the necessary legal support to develop the project.

In conclusion, the proposal discussed in this study emphasizes the importance of finding a balance between the needs of the population and the protection of data privacy. Implementing secure data-sharing models in health and social care systems can lead to improved efficiency and satisfaction among both professionals and the population. It also presents an opportunity to foster synergies and develop new products and services that cater to the specific needs of individuals with chronic diseases and dependencies. Additionally, the creation of comprehensive databases plays a crucial role in generating evidence and facilitating research in these areas of increasing prevalence. However, it is essential to adhere to frameworks and regulations that ensure the secure transmission and handling of data, whether at the local or international level. By establishing robust and protected circuits, the potential benefits of data sharing can be realized while maintaining the privacy and confidentiality of individuals' personal information.

Acknowledgments

The research team would like to thank Alfonso Bataller Díaz for his legal and methodological advice.

Funding was provided by the Generalitat de Catalunya, within the framework of the European Regional Development Fund (ERDF) programme for Catalonia 2020-2024.

Data Availability

Access to the data used in this article is limited to the Catalan Health Institute due to the sensitive nature of personal data and the requirements set forth by Spanish and European regulations. As a result, the data cannot be openly shared. However, the results mentioned in the Introduction section will be presented in a forthcoming manuscript by Pujolar et al titled "A Gender-Based Approach to Chronic Conditions in Central Catalonia (Spain): A Descriptive Cross-Sectional Study" (in preparation as of 2023).

Furthermore, the creation of the laboratory outlined in this protocol aims to facilitate broader access to data within the established legal and ethical frameworks.

Authors' Contributions

This paper is based on a funded grant proposal, which was conceived and developed collaboratively by the authors and all members of the PECT BAGESS Group. GPD and JVA conceptualized the study, performed the investigation, wrote the original manuscript draft, and reviewed the final manuscript. AF, EDS, and JB reviewed the final manuscript.
The members of PECT BAGESS Group are M Lluïsa Sort-Garcia, Jullieth Suarez-Guevara, Gemma Cuberas, Juanjo Martín, David Marí, Maria Bosch Gall, Jordi Mir, Carles Clotet Vilalta. They reviewed and edited the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Intellectual disability (ID) is a neurodevelopmental disorder associated with a poorer health profile and higher mortality. Young people with ID have more sedentary lifestyles than their typically developing peers. Consequently, this group is at significant risk of developing lifestyle diseases (ie, noncommunicable diseases) later in life. Increasing physical activity and eating a healthier diet have been argued to be effective ways to improve the health of adolescents and young adults with ID. Digital interventions are a viable option for improving health behaviors.

Objective: This research protocol describes a co-design approach using workshops to develop a digital intervention that promotes healthy behaviors, including increasing physical activity and eating a healthier diet, among adolescents and young adults with ID.

Methods: A participatory design using a co-design approach will be applied as a strategy to include potential users of the digital intervention and other stakeholders in the research process, comprising research design, data collection, and data analysis. A total of 7 to 10 workshops will be conducted aimed at developing a digital intervention and will include procedures for assessing needs; facilitators and barriers to health promotion; physical, mental, and social well-being; participation; and relationships. The workshops will include 12 to 18 stakeholders with experience of clinical practice and research related to young people with ID, including relatives, as well as adolescents and young adults (aged 16-25 years) with mild to moderate ID. Participants will perform a mixture of individual and group work using whiteboards, sticky notes, felt-tip pens, cards, balls, stickers, and wireframe templates. Data analysis will take place concurrently with data collection as an iterative process. Transcribed data from the audio and video recordings of the groups' discussions will be analyzed following a qualitative methodological procedure.

Results: This study protocol provides a systematic record of the scientific methodologies used when developing the digital intervention and provides insights into the potential practical solutions and challenges when following a co-design approach in which relatives and professionals, as well as adolescents and young adults with ID, are included as research partners. Recruitment of participants started in April 2023. Data collection, analysis, and reporting will be completed in December 2023.

XSL•FO
RenderX

Conclusions: This study will explore the effectiveness of workshops at gathering rich, reliable, and valid data in a co-design approach with participants. The results will provide increased knowledge in how to use technology to develop novel, evidence-based, and scalable interventions that adolescents and young adults with ID can and want to use to motivate physical activity and a healthier diet. The project will provide a simple and cognitively accessible digital solution for promoting lifestyle behaviors tailored to the needs of adolescents and young adults with ID.

intellectual disability; lifestyle behavior; eHealth; co-design; digital intervention; lifestyle; adolescents; young adult; healthy diet

Introduction

Health of Adolescents With Intellectual Disabilities

Intellectual disability (ID) is a neurodevelopmental disorder with onset during childhood [1]. In Sweden, about 1% to 3% of the population is diagnosed with ID. ID differs from person to person but always impacts conceptual, social, and practical skills [2]. The ability of people with ID and the support they therefore need varies, as the severity of ID can be mild, moderate, or severe [1]. ID is associated with more health problems, poorer health profiles, and higher mortality rates [3]. People with ID are more likely to have a chronic illness, such as cardiovascular and respiratory disease [4] or mental illness [5,6]. Adolescence is a time of change, marking the transition from childhood to adulthood, and it is a critical life period when health-related behaviors often are set for adulthood [7]. Adolescents with ID have, in general, a more sedentary lifestyle, a less healthy diet, and greater social isolation compared to adolescents in the general population [3,8]. Consequently, this group is at significant risk of developing lifestyle diseases (ie, noncommunicable diseases), such as type II diabetes, hypertension, obesity, heart disease, stroke, and cancer later in life [4,9-11]. A recent population-based longitudinal cohort study of adolescents and young adults in Sweden found that premature mortality was significantly increased in those with ID [12].

Digital Interventions to Promote Lifestyle Behaviors

As in the general population, lifestyle behaviors have a strong impact on health for this group [13]. Establishing healthy behaviors is often easier and more effective during adolescence than trying to change unhealthy behavior during adulthood [7]. Increasing physical activity and eating a healthy diet have been argued to be the most effective ways to improve the health of adolescents with ID [14]. However, few studies have investigated health promotion interventions that target this group [13]. One viable option for improving health behaviors is to use digital interventions, called eHealth, which is defined as the use of information and communication technologies for health and can include the use of email, text messages, push notifications, websites, and mobile apps [15]. Previous systematic reviews [16,17] and our own previous randomized controlled trials (RCTs) [18-20] have shown that eHealth provides a wide range of possibilities for health-behavior promotion among young people in the general population. Digital interventions may also be useful for adolescents and young adults with mild to moderate ID, but there is a lack of such studies. Research comparing the internet use of adolescents with ID with a reference group of adolescents without ID shows that 70% of adolescents with ID have a smartphone and use the internet for entertainment purposes, compared to over 95% among adolescents without ID [21]. This is in line with other research and provides the knowledge that digital devices and internet activities are used in this target group [22-24]. Although Johansson et al [25] reported that there is a disability digital divide related to cognitive understanding and language difficulties, there is a possibility to design usable and accessible digital interfaces by using simple and logical interaction, clear design, and easy-to-understand written and audiovisual language combined with the use of clarifying icons and symbols. Digital interfaces can also be constructed to be adaptable to personal needs [26] and interoperable with personal assistive technology [27]. Combined, these measures can create a cognitively accessible digital intervention [28,29]. However, few studies have examined the feasibility or effectiveness of eHealth interventions to promote healthy behaviors (eg, a healthy diet and physical activity) in adolescents with ID. Furthermore, few studies have examined the possibility of co-designing eHealth interventions together with, rather than for, adolescents and young adults with ID. Only one protocol study for an RCT [30] has used a digital intervention to encourage youth with ID to increase their physical activity, and that study also targeted adults with ID. Clearly, there is a need to develop and design interventions that promote healthy behaviors tailored to the needs of adolescents and young adults with ID.

Participatory Design With a Co-Design Approach

The World Health Organization's Global Strategy on Digital Health (2020-2025) [15] prioritizes the development and adoption of appropriate, acceptable, and scalable health solutions to promote health and well-being worldwide. Participatory design [31] with a co-design approach [32,33] is crucial for successful development of digital interventions, as it is an effective method to understand the context, culture, attitudes, behaviors, needs, and expectations of those for whom the digital intervention is being designed. Previous research, including our own studies targeting adolescents and lifestyle behaviors [18-20,34-36], has consistently shown that the active participation of stakeholders and end users throughout the design of digital interventions supports the development of an intervention that meets the needs of its intended users. The development of a complex intervention requires several phases, although these phases do not follow a linear sequence [37]. The

XSL•FO
RenderX

developers and designers of eHealth interventions targeting people with ID should be aware that this group might have the same needs to stay or become healthy as anyone, but they will have special prerequisites to consider due to their intellectual challenges, and there will be special requirements on how to design and promote such an intervention [38,39]. Through the co-design process, all included persons are given the possibility to become active partners at different stages in the development process [31].

Objective

The objective of this research protocol is to describe a co-design approach using workshops to develop a digital intervention that promotes healthy behaviors among adolescents and young adults with ID.

Methods

Study Context

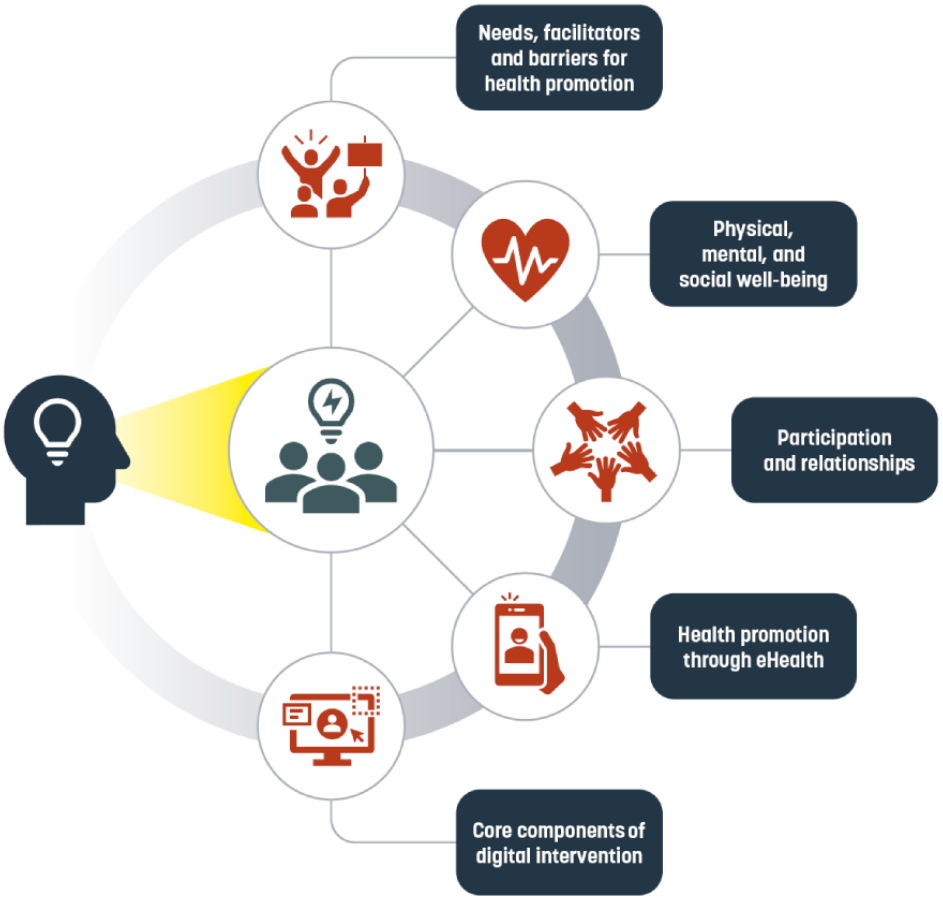
This study is part of a larger research project that aims to develop and evaluate a digital intervention to promote healthy behaviors among adolescents and young adults with ID. To accomplish the purpose of the research project, we have established an ID research forum together with adolescents and young adults with ID; stakeholders, such as professionals within the social welfare, health care, and school systems; relatives; other relevant partners; and researchers. The development of the digital intervention will be based on a review of the literature and existing evidence and will be centered on insights of stakeholders and adolescents and young adults with ID gathered through specially adapted workshops [40].

Study Design

A participatory design approach using co-design [41] will be applied, in which research is conducted together with participants instead of on them. Co-design will be applied as a strategy to include potential users of the digital intervention and other stakeholders in the research process, including research design, data collection, and data analysis. The work draws from value sensitive design [42], a theoretically grounded approach that includes ethical and moral values in the design of technology. Value sensitive design allows stakeholders to have a voice in the design process and uses a tripartite method to perform conceptual, empirical, and technological investigations. Adolescents and young adults with ID; stakeholders within the health care, social service, and school systems; designers; accessibility experts; and researchers will form a design team. The design team will use an iterative and nonlinear process to design solutions to complex and prespecified problems. Every co-design activity will be carefully planned to fit the need to involve adolescents and young adults with ID.

Workshops provide a platform that can aid researchers in identifying and exploring relevant factors in a given domain by providing a way to understand complex work and knowledge processes that are supported by technology; an example of this is eHealth [43]. Workshops have a 3-fold purpose and focus within research: as a means, as a practice, and as a research methodology [44]. This study focuses on the workshop as a means to do co-design and develop the process for participation and as a research method to generate and collect data.

Setting, Recruitment, and Participants



Adolescents and young adults with ID, as well as stakeholders living in Östergötland, Sweden, will be invited to workshops. The inclusion criteria for taking part in workshops for adolescents and young adults with ID will be as follows: (1) diagnosis of mild to moderate ID; (2) age between 16 and 25 years; (3) frequent use of either smartphones, tablets, or computers, that is, digital literacy, since we want them to use that experience in designing a digital intervention; (4) willingness to participate in a workshop; and (5) ability to provide informed consent. An equal mix of genders will be sought. Workshops with stakeholders will be divided into 2 groups with the following participants: group 1, including professionals from the areas of social welfare, health care, and the school system, and group 2, including relatives and representatives from the disability organizations. The inclusion criteria for the stakeholders will be as follows: (1) experience with clinical practice or other experiences related to adolescents with ID; (2) willingness to participate in a workshop; and (3) ability to provide informed consent. All participants will be geographically located in the region of Östergötland. Participants will be recruited with purposeful sampling to provide a representative sample of all relevant areas in collaboration with research partners in Östergötland and already established networks of the authors.

Data Collection

In total, 7 to 10 workshops [43] will be conducted between May and August 2023. Young adults and adolescents with ID will participate in a series of 3 workshops. The co-design process with specially adapted workshops will be used to gather rich, reliable, and valid data involving all participants. An overview of the included themes in the workshops is presented in Figure 1. The following themes will be included in all workshops: needs; facilitators and barriers to health promotion; physical, mental, and social well-being; participation and relationships; health promotion through eHealth; and core components of digital intervention. All workshops will be conducted in a meeting room at Linköping University or at rooms close to where young people with ID go to school or after-school clubs. The workshops will be organized in rooms with a whiteboard, internet connection, and wall surfaces suitable to tape up sheets of paper or sticky notes. Each workshop will produce rich data material, including design artifacts such as sketches, wireframe templates, screenshots of participants' phones, and lists of technological barriers and enablers. The workshops will also be documented with video and audio recordings and field notes, allowing participants to revisit important discussions and ideas. All collected data will be used in an iterative analytical process. The data will be used to evaluate the workshop as a tool for co-designing together with people with ID and to design the digital intervention for promoting a healthy lifestyle. Each workshop will last approximately 2 hours, including breaks.

XSL•FO
RenderX

Figure 1. An overview of the included themes in the co-design workshops.

Structure and Activities of the Workshops

A structure of the workshops has been outlined. The workshop phases, including preparation, introduction, the main act, and evaluation, as well as planned activities, are presented in Table 1 and further described below. Workshops with relatives and representatives from disability organizations and professionals will be initially conducted once per group of stakeholders. Adolescents and young adults with ID will take part in 3 consecutive workshops.

Table 1. Structure and activities of the workshops.

Phase	Structure and activities
Preparation	• Provide information to participants (information videos, information letters, informed consent forms) • Prepare workshop management (moderator, notetaker, video documenter) • Construct the workshops (structure, content, and length) • Prepare workshop materials (sticky notes, felt-tip pens, balls, wireframe templates of a mobile phone, stickers, colored cards) • Prepare the use of assistive technology (devices for time management, taking turns, and recording) • Prepare surveys
Introduction	• Joint meal • Presentations given by participants • Moderators introduce the workshop and the timetable • Notetaker and video documenter present assistive devices
Main act	• Moderator introduces the topics to discuss and to work with • Individual and group work (using whiteboards, sticky notes, felt-tip pens, cards, balls, stickers) • Identifying core components using own devices and wireframe templates • Tasks using colored cards to indicate agreement on suggestions (green, yellow, red) • Survey on demographic variables and expectations on participating in co-design workshops (only for participants with intellectual disability)
Evaluation	• Qualitative evaluation of the participants' perceptions of their experiences taking part in the workshop • Quantitative evaluation survey: demographic variables and perceptions of participation in the co-design process (only for participants with intellectual disability)

XSL•FO
RenderX

Preparation

The workshops will be carefully planned in line with the aim of the study. In preparation for participation in the workshops for adolescents and young adults with ID, a short video will be produced by the researchers in cooperation with relatives and representatives from the disability organizations. The video will be shown to the participants to explain the aim of the research project and ethical issues. All participants will be informed that the purpose of the workshops is to address barriers and facilitators to health promotion and to co-design components of a digital intervention. To avoid dropping out caused by, for example, issues with time management or memory issues, we will reach out and contact participants to remind them of the upcoming workshop. Workshop management will be organized to divide roles (eg, moderator, notetaker, and video documenter) between researchers. Workshop materials and assistive technology will be prepared, including cognitive adaptation to involve adolescents and young adults with ID.

Introduction

The workshops with participants with ID will be executed according to set procedures to make them cognitively accessible: start the workshop by establishing a convivial tone, present the agenda and the upcoming tasks, and present the rules for collaboration. Furthermore, to respect the timetable for the workshop, we will find a good pace and rhythm for the work, allow room and space for everyone to participate (while respecting participants who temporarily want to be silent), and give all participants time to think and reflect; we will stop and explain things that participants do not understand. We will start all workshops with a meal together to equalize differences in social status, get to know each other, and make participants feel comfortable. The participants will also give presentations. All participants (adolescents and young adults with ID; professionals from the areas of social welfare, health care, and the school system; and relatives and representatives from the disability organizations) will give oral presentations, preferably incorporating their own drawings. Moderators will introduce the workshops, including their length, schedule, and breaks. The notetaker and video documenter will explain the assistive devices.

Main Act

The moderators will present the proposed topics to discuss and work with during the workshop. The topics are (1) the health and well-being of young people with ID, (2) support for health-related activities and behaviors, and (3) the core components to include in a digital intervention to promote health behaviors. The co-design process will be implemented by giving all included participants the possibility to become active partners in all parts of the main act phase of the workshop. The goal is to both discuss the topics and create new outputs (ideas, concepts, and designs), as well as to evaluate special aspects of interest, such as drawing upon ideas for the design of a digital intervention prototype to promote healthy behaviors. Throughout the workshop, participants will make use of graphical arrangements along with verbal exchanges to express their ideas and to discuss proposals. Participants will perform a mix of individual and group work using whiteboards, sticky notes, felt-tip pens, cards, balls, and stickers. The selection of the specific materials and tools will be made in order to facilitate all participants to express themselves and hence to ensure a rich selection of data. The method of using a mix of individual work and group work encourages less talkative participants to have as much influence as more talkative participants. Additionally, the design team (ie, participating individuals and researchers) will use their own devices to discuss the apps they use that day. We will also use wireframe templates of a mobile phone for identifying core components of a digital intervention to promote health behaviors. Participants with ID will use stickers to prioritize what they perceive to be the most important components to include in a digital intervention and use green, yellow, and red cards to indicate if they agree with upcoming suggestions. An initial survey on demographic variables and expectations on participating in a co-design workshop will be provided to participants with ID.

Evaluation

The workshop will end with an evaluation of the participants' perceptions of their experiences of taking part in the workshop. In line with the co-design process, all included participants will be active oral partners in a qualitative evaluation process. Further, during the last of the 3 workshops, participants with ID will also be provided with a quantitative survey on demographic variables, their perceptions of the co-design process as implemented in the workshops, and their interest in continued participation in our research.

Data Analysis

Inspired by Sanders and Stappers [32], we use the following definition of co-design: "Co-design in a broader sense [refers] to the creativity of designers and people not trained in design working together in the design development process." In co-design, roles are diversified and potential end users are given the position of "experts of his/her experiences" and play a central role in knowledge development, idea generation, and concept development. In order for them to take on this role, appropriate tools for ideation and expression are necessary [32], which in this study will be provided throughout the co-design workshops. Co-creation will be applied across the whole span of a design process. Data analysis will be performed together and take place concurrently with data collection. By striving for concurrent data collection and data analysis, we will start the joint analysis simultaneously during the workshops. The co-design process will be an iterative process between ideation and visualizing the ideas as frameworks for a preliminary prototype of the intervention. Data collection and data analysis are, in other words, seen as an intertwined back-and-forth process used by the design team. This process draws from methods adapted from the participatory action research and participatory design approach presented by Johansson [45] and will follow the double diamond design process with discovery, define, develop, and delivery phases [46]. The discovery phase will focus on understanding relevant phenomena and discussing the prerequisites for health promotion through a digital intervention. The define and develop phases will narrow the ideas down to those that will be developed in this project. The delivery phase will end with the framework for a preliminary

XSL•FO
RenderX

prototype that the design team will use to move forward, but we will also work in iterative loops, going back and forth to co-design the prototype. This will be done by, for example, checking with participants, reflecting on feedback, and examining the processes of the included activities together with the participants. Preanalysis of quantitative aspects, for example, summarizing the colored-dot stickers, will be performed together by counting the dots and analyzing the results.

In order to analyze the workshop as a method for co-designing together with people with ID, transcribed data from the audio and video recordings of the groups' discussions will be analyzed in an approach inspired by inductive program theory development [47] following a qualitative methodological procedure [48]. As suggested in literature describing participatory design methods from process to outcome [49], we will strive to follow an approach that creates space for all partners to draw on their different, yet complementary, experiences and skills and to determine their respective analytical roles and responsibilities. Analyses of the transcribed data will therefore be led by the first author (UM) and performed together with the researchers and representatives from the design team. Given the time and skills required, the transcribed data will be analyzed initially by the researchers. The evaluation survey will be analyzed using descriptive statistics. The representatives of the participating stakeholders will be actively engaged in determining the meaning of the results and their implications for action. By capturing visual details from the filmed workshops, this analytical approach will allow us to review not only what we said, but how we expressed it and in what situations. Systematic analyses will follow a prescribed sequential process [50].

Ethical Considerations

All participants will receive written and oral information about the study, including information that participation is voluntary and that they are allowed to ask questions and leave the study at any time without giving reasons as to why. Informed consent will be obtained from all participants before participation in either written form or orally during audio recording. The study data will be deidentified before publication. Young adults and adolescents with ID will receive a diploma and a gift card of 100 SEK (US $9.77) for their participation. All procedures were approved by the Swedish Ethical Review Agency (Dnr 2022-06682-01).

Results

Recruitment of participants started in April 2023 through initial contacts with schools, after-school clubs, community-based services, and social services. The recruitment continued until the end of June 2023. Initial workshops were planned for May 2023. Data collection and analysis are planned to be completed in September 2023. The main contribution of this protocol article is a detailed description of how to conduct and analyze co-design workshops to develop a digital intervention that promotes healthy behaviors among adolescents and young adults with ID. Full results from the workshops are expected to be published in December 2023.

Discussion

This research protocol describes a co-design approach using workshops to develop a digital intervention that promotes healthy behaviors, such as physical activity and a healthy diet, among adolescents and young adults with ID. In this study protocol, we set out to describe a co-design approach using workshops to develop a digital intervention that promotes health-related activities and behaviors among adolescents and young adults with ID, who are a group that is often marginalized in society and in research regarding aspects of their own lives. However, research with the involvement of people with ID has proven to be plausible [51]. Through the co-design process, all included persons will be given the possibility to become active partners at all different stages in the development process. A description of how the participants will be involved in the co-design process has been presented. In this study protocol, needed adaptations are described and will be continuously redesigned to improve the involvement of people with ID in the co-design process.

It is well known that young people with ID have a more sedentary lifestyle compared to their typically developing peers. Specifically, they are less physically active, have a poorer diet, and are more socially isolated [3,8]. These health conditions are more prevalent due to lack of knowledge of their effects, reduced physical and behavioral skills, and lack of motivation attributed to ID [52]. As little evidence-based knowledge is available about how to promote physical activity, a healthy diet, and social participation for this group, this proposed study will identify needs, as well as facilitators and barriers to health promotion activities enabled through digital interventions. Furthermore, since few studies have examined the effectiveness of eHealth interventions to promote healthy behavior (eg, a healthy diet and physical activity) among adolescents and young adults with ID, our research aims to develop an eHealth intervention that targets this often-marginalized group. Including young individuals with ID in trials can involve challenges in many aspects of the research process. Common challenges in trials involving these individuals include informing the individuals with ID about the research process, obtaining informed consent, arranging transportation to research sites, and ensuring that instructions are followed [53]. Hence, it is particularly important to plan and conduct intervention studies for this group carefully. Therefore, by using a co-design approach when developing the intervention, we believe that we also will optimize participation in the trial and the potential uptake and reach of the digital tool.

This research project will develop an eHealth intervention that is specifically designed to address the needs of adolescents and young adults with ID. The digital intervention will be complex, especially given the variety of the intervention components needed, the degree of flexibility required, and the ability to adapt to the contextual, social, and practical skills of the individual. This research protocol describes a participatory design in order to develop a digital intervention to promote healthy behaviors. First, this protocol provides a systematic record of the scientific methodologies used when developing the intervention to enhance transparency of research and ensure

XSL•FO
RenderX

research rigor. Second, the protocol provides insights into potential practical challenges and solutions when following a co-design approach in which relatives, professionals, and adolescents and young adults with ID are included as research partners. Third, this protocol provides procedural considerations on how to use workshops as a means and research method when developing digital interventions. The protocol describes how data will be collected and analyzed in cooperation with stakeholders and adolescents with ID. We hope this study will contribute to and inspire new approaches to develop effective interventions for lifestyle behaviors for young people with ID. Further studies will examine the effectiveness of our individually tailored digital intervention to support healthy lifestyle behaviors among adolescents and young adults with ID. If successful, the project will provide a simple and accessible digital solution for promoting physical activity and a healthy diet. Hence, our research has potentially important implications for both this target group and their support networks. Since it is necessary to engage stakeholders for widespread clinical implementation, this study will also be valuable during the later stages of our project. We have established networks through our ID research forum that include adolescents and young adults with ID, stakeholders (ie, professionals within the social welfare, health care, and school systems), relatives, other relevant partners, and researchers.

Several procedures will be performed to fulfill the quality criteria (ie, credibility, transferability, confirmability, dependability) for qualitative research to verify trustworthiness [54] when designing, analyzing, and reporting the processes related to the video-recorded workshops. The research process will be clearly described and documented. The Consolidated Criteria for Reporting Qualitative Research (COREQ) 32-item checklist [55] will be followed to create a clear audit trail. Data will be analyzed in accordance with the steps following indicative program theory development [47] and qualitative methodological procedures [48] to facilitate a rigorous and systematic process. The sample size will be based on data saturation [56], and data collection will accordingly be finalized when the data reach satisfactory depth and complexity to answer the aim with sufficient confidence. Trustworthiness will be further enhanced by the use of a guide [48] during all workshops. Video recordings will yield more details and secure high accuracy since the recorded data can be reviewed indefinitely [57]. Moreover, video recordings can help guard against researcher bias because they can be analyzed by researchers other than those who led the workshops [43]; hence, researcher triangulation will be used [48]. A possible limitation of the study design is that the transferability of the forthcoming results to other study contexts may vary depending on how the care is organized. However, we consider that the results from the study will be relevant and applicable to the development of digital interventions in similar settings. We expect that the results from this study will be valuable for the development of eHealth interventions in young adults with ID.

Acknowledgments

The study is funded by grants from the Swedish Research Council for Health, Working Life, and Welfare (Dnr 2022-01303; principal investigator: UM).

Data Availability

The data sets generated during and/or analyzed during this study are not publicly available due to Swedish ethical review guidelines but are available from the corresponding author on reasonable request.

Abstract

Background: There are over 500,000 survivors of childhood cancer in North America alone. One in 4 survivors experiences chronic pain after treatment has been completed. Youths with chronic pain report increased anxiety, depression, activity limitations, and sleep disturbances. An 8-week web-based cognitive behavioral treatment for chronic pain (Web-Based Management of Adolescent Pain [WebMAP]) has demonstrated a reduction in pain in youths but has not yet been explored in survivors.

Objective: The objectives of this study are to (1) test the feasibility and acceptability of WebMAP for a sample of survivors with chronic pain and their parents; (2) assess the acceptability of WebMAP using qualitative interviews; (3) assess WebMAP's effect on activity limitations, pain intensity, depression and anxiety symptoms, and sleep disturbances; and (4) assess WebMAP's effect on parent pain catastrophizing and parental response to their child's pain.

Methods: A single-arm mixed methods pre-post intervention study design will be used. Participants will be 34 survivors and at least one of their parents or caregivers. Inclusion criteria are (1) a cancer history, (2) current age of 10-17 years, (3) >2 years post treatment or >5 years post diagnosis, (4) pain present over prior 3 months impairing >1 area of daily life and occurring >1 time per month, and (5) computer access with broadband internet. Survivors will complete a pretreatment questionnaire, which will include the following: the Child Activity Limitations Interview, the pain intensity Numerical Rating Scale, Patient-Reported Outcomes Measurement Information System (PROMIS)–Pain Interference, Anxiety, Depression, Insomnia Severity Index, and Adolescent Sleep Wake Scale. Parents will complete the Pain Catastrophizing Scale–Parent Version and the Adult Responses to Child Symptoms. Upon completion of pretreatment questionnaires (T0), survivors will begin WebMAP. After the 8-week intervention, survivors will complete the same measures (T1), and at 3-month follow-up (T2). Posttreatment interviews will be conducted to determine acceptability. Feasibility will be assessed via recruitment and retention rates. Treatment engagement will be measured by number of modules completed. Pre-post outcome data will be assessed using linear mixed models. Qualitative data will be analyzed using thematic analysis. Patient partners will be involved in study design, recruitment, interpretation of results, and knowledge translation.

Results: This study has been funded in January 2022. Data collection started in May 2022 and is projected to end in August 2023. We have enrolled 10 participants as of December 2022.

Conclusions: Investigating whether WebMAP is useful to survivors will be an important step in improving pain management in this population.

Introduction

Currently, there are over 500,000 survivors of pediatric cancer in North America alone [1]. Unfortunately, two-thirds of survivors of childhood cancer will experience late- and long-term effects from their cancer and its treatments, such as subsequent chronic health conditions and psychological difficulties [2]. Our previous work demonstrated that approximately 1 in 4 survivors of childhood cancer experiences chronic pain after treatment completion and 1 in 5 experiences moderate to severe chronic pain problems, reporting high pain intensity and interference in activities [3]. We also found survivors living with chronic pain reported significantly worse depressive and anxiety symptoms and poorer quality of life than survivors without chronic pain [3,4].

Survivors of childhood cancer are already at risk for worse mental health than their healthy peers as a result of cancer and its often toxic treatments [2], and pain could exacerbate these outcomes. Importantly, pain among survivors of childhood cancer has been shown to persist into adulthood, which among noncancer adolescents has been linked to lower educational and social attainment and poor vocational functioning in young adulthood [5]. With the growing number of survivors of childhood cancer, improving long-term follow-up care will help improve health care for these vulnerable youths by reducing their risk of continued pain and poor health into adulthood.

Chronic noncancer pain in childhood is associated with negative developmental outcomes in young adulthood including a higher likelihood of dropping out of high school, a lower likelihood of graduating from university, poor vocational functioning, and social impairments [6]. A large, longitudinal study demonstrated that chronic pain in adolescence conferred risk for lifetime anxiety and depressive disorders [6].

According to the United Nations Office on Drugs and Crime's most recent World Drug Report, approximately 585,000 people experienced drug-related deaths and the majority of these deaths could be attributed to opioids [7]. Importantly, there is little evidence for the efficacy of prescription opioids for the treatment of chronic pain, and long-term opioid use for the treatment of chronic pain can cause adverse effects such as overdose, cardiovascular events, and motor vehicle accidents [8,9]. Chronic pain is also a significant financial burden on families, society, and the health care system, costing up to CAD $60 billion (US $46.99 billion) per year in Canada [10], and is one of the most common reasons for seeking health care [11,12]. According to a recently proposed developmental model of chronic pain, strategies for pain prevention and management should begin in childhood and should leverage psychological interventions in order to prevent pain-related morbidities and promote better overall well-being in adulthood [13]. Thus, research on nonpharmacological pain management strategies is needed in general, particularly in this underserved population.

While the prevalence of pain is high in survivors of childhood cancer, no evidence-based interventions for pain are available for youth survivors of childhood cancer [14]. Most promising for this population may be cognitive behavioral therapies, as they can effectively target activity limitations, depression and anxiety symptoms, and sleep disturbances related to pain. Cognitive behavioral therapies are effective in reducing the burden of pain in youths with chronic noncancer pain conditions [15]; however, there are also significant barriers to participation in clinic-based cognitive behavioral therapy programs. For example, parents may have to take time off work and take their children out of school to visit a psychologist (the professionals most often trained and competent to deliver cognitive behavioral therapy), a psychologist may not be affordable, or there may not be a psychologist available in some areas.

In response to these limitations and barriers, internet-delivered cognitive behavioral therapy (CBT) can address these significant barriers and has demonstrated feasibility and efficacy in youths with chronic pain [16]. An 8-week web-based cognitive behavioral therapy program called web-based management of adolescent pain (WebMAP) has been rigorously developed and tested in children and adolescents with various chronic pain conditions, and is feasible and acceptable for this group, demonstrating clinically significant reductions on primary targets including activity limitations and pain intensity [17,18]. In addition, previous trials with WebMAP have shown economic benefits for both intervention and education groups, demonstrating a significant decrease in health care–related expenditures from the year before participating in the trial to the year after [19]. In other populations, WebMAP has demonstrated feasibility and acceptability in adolescents with sickle cell disease and their parents, with no indication that the program needed to be significantly tailored for those with sickle cell disease [20].

Treatment for chronic pain in youths is enhanced by the inclusion of parents, given the developmentally important role they play in their child's life. For example, unique social factors exist related to parent and family influences on pediatric chronic pain and disability such as parental responses to child pain behavior, parenting style, family environment, and overall family communication and functioning [21]. Parent pain catastrophizing has also been shown to play an important role in their child's pain interference [22,23]. Parent protectiveness is also related to important child-level outcomes (eg, child functional disability) in trials assessing family cognitive behavioral therapy for adolescents with chronic pain [24]. WebMAP includes a parent component in which parents complete modules in parallel with their child in order to target these factors. In WebMAP, parents are taught various operant strategies to respond to their child's pain behaviors. In previous

XSL•FO
RenderX

trials with WebMAP, parent distress, and parent protective behaviors predict child functional disability trajectories 6- and 12-months post treatment [25], and parent engagement in the program may also be predictive of treatment outcomes [26]. Thus, the inclusion of parents in psychological intervention trials for youths with chronic pain is recommended.

WebMAP has never been tested on a sample solely comprised of youths with a history of cancer. Thus, the primary objective of this study is to test the acceptability and feasibility of WebMAP for survivors of childhood cancer living with chronic pain and their parents, using a single-arm, pretest-posttest mixed methods design with semistructured interviews. Objective 1 will test the feasibility and acceptability of WebMAP for a sample of survivors with chronic pain and their parents. We hypothesize that the intervention will be feasible, that families will be engaged in the treatment and it will be safe. Objective 2 will assess the acceptability of WebMAP using qualitative interviews. Objective 3 will assess WebMAP's effect on activity limitations, pain intensity, depression and anxiety symptoms, and sleep disturbances. We hypothesize that survivors of childhood cancer participating in WebMAP will report significantly reduced activity limitations, pain, anxiety and depressive symptoms, and sleep disturbances from before to after the intervention. Finally, objective 4 will assess WebMAP's effect on parent pain catastrophizing and parental response to their child's pain. We hypothesize that parents participating in WebMAP will report significantly reduced catastrophizing about their child's pain, distress, and reduced protective parental responses to their child's pain. This study protocol follows the Standard Protocol Items: Recommendations for Interventional Trials Checklist for recommended items to address in a clinical trial protocol [27].

Methods

Study Design

This study will use a single-arm, mixed methods, pre-post design. Survivors of childhood cancer with chronic pain will participate in an 8-week internet-delivered cognitive behavioral therapy intervention (WebMAP). Assessment questionnaires will be collected before the intervention (T0), immediately following the intervention (T1), and 3-months after intervention completion (T2). Individual interviews will also be conducted upon completion of the intervention.

Participants

Sample Size

Based on an audit of sample sizes of combined feasibility and pilot trials in similar populations, median sample sizes ranged from 30 to 36 [28]. A sample of 34 will be sufficient to detect an effect size (Cohen *d*) of 0.4 with our preliminary outcomes with 80% power and α at .05. Therefore, we will aim to recruit a total sample of 38 to conservatively account for 10% attrition over the study duration.

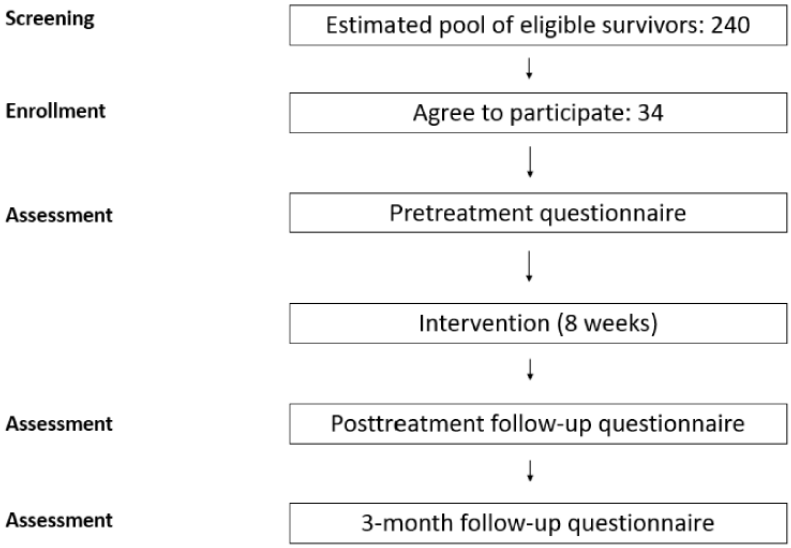
Eligibility Criteria

Inclusion criteria for participation are (1) history of any cancer diagnosis; (2) current age 10-17 years; (3) >2 years posttreatment or completed treatment and >5 years post diagnosis; (4) pain present over prior 3 months that impairs at least one area of daily life and occurs >1 per month; and (5) computer access, internet, and literacy. Survivors wishing to participate without a parent will not be excluded but will still require parental consent.

Patient Engagement

Patient engagement is an important component of health research. One systematic review found that across studies, engaging patients as partners in research increases enrollment and retention rates, and improves dissemination of results to be more meaningful and digestible for patient audiences [29]. The Canadian Institutes of Health Research Strategy for Patient Oriented Research Patient Engagement Framework [30] is a roadmap on how to engage patients as partners in health research, with the goal of improving health outcomes and creating a more enhanced health care system. The framework provides guiding principles (inclusiveness, support, mutual respect, and cobuilding of ideas), tools, and resources for researchers to use throughout their projects. It highlights that patients should be included from the start of the research project and that they should collaborate with the researchers as equal members of the team.

In this study, 3 patient partners were involved in the study design and will be involved in recruitment, interpretation of results, and knowledge translation for this study. More specifically, the patient partners have been consulted on the study protocol where they provided feedback and have approved the final version to be submitted to the institutional ethics committee. We started a group on Slack (Slack Technologies, Salesforce Inc), a web-based communication platform that allows us to share communications and materials all in 1 place. Patient partners will help with the creation and dissemination of recruitment materials, using their own connections with advocacy groups and Canadian cancer advocacy groups. Similar to previous experiences, we will discuss findings with patient partners in order to seek their interpretation of the results and how to communicate them. This work will foster inclusiveness, support, mutual respect, and cobuilding of ideas [30].



Procedures

Recruitment

Survivors will be recruited from the Long-Term Survivors Clinic at the Alberta Children's Hospital in Calgary, Alberta, Canada. The participant flowchart is in Figure 1. The study team will contact potentially eligible survivors by phone or email. Approximately 700 survivors receive follow-up care at ACH, and an estimated 240 of these survivors may be experiencing chronic pain based on our research [3]. Approximately 94% of Canadians have internet access at home [31] and recruitment rates from our previous pain-related research were 70% [3]. Conservatively, we expect 40% of these survivors to meet our inclusion and exclusion criteria, leaving a possible sample of 70. Meeting our targets would require a participation rate of 49% (34/70).

XSL•FO
RenderX

Figure 1. Participant recruitment flowchart.

Data Collection

Upon enrollment and completion of informed consent, survivors and their parents will complete pretreatment questionnaires (T0) and be given access to WebMAP. Upon treatment completion (T1), survivors and parents will complete the same questionnaire battery plus the Treatment Evaluation Inventory—Short Form [32]. In addition, we will conduct posttreatment interviews to gather feedback on the program. Patient and caregiver partners will be involved in creating the interview questions and conducting a portion of the interviews. Interviews will be recorded and transcribed. Finally, survivors will be administered the same questionnaire battery at 3 months post intervention (T2) to assess longer-term effects of the intervention. Questionnaires will be completed over internet via Research Electronic Data Capture (REDCap) tools hosted by the University of Calgary Clinical Research Unit. REDCap is a secure, web-based application designed to support data capture for research studies, providing (1) an intuitive interface for validated data entry, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for importing data from external sources. The investigator leading the trial (MP) and the sponsor (FS) will have access to the final trial data set (Table 1).

Data category	Information
Primary registry and trial identifying number	ClinicalTrials.gov NCT05241717
Date of registration in primary registry	February 4, 2022
Sources of monetary or material support	Alberta Children's Hospital Trainee Small Research Grant[a]
Primary sponsor	Fiona Schulte, PhD[a], fsmschul@ucalgary.ca
Contact for public queries	Fiona Schulte, PhD, fsmschul@ucalgary.ca
Public title	Internet-delivered cognitive behavioral treatment for adolescent survivors of childhood cancer with chronic pain
Scientific title	Internet-delivered cognitive behavioral treatment for adolescent survivors of childhood cancer with chronic pain: A pilot feasibility trial
Countries of recruitment	Canada
Health conditions or problems studied	Cancer, chronic pain
Intervention	
Active comparator	Internet-delivered cognitive behavioral therapy
Key inclusion and exclusion criteria	
Ages eligible for study	10-17 years
Sexes eligible for study	Any
Accepts healthy volunteers	No
Inclusion criteria	History of any cancer diagnosis, >2 years post treatment or completed treatment and >5 years post diagnosis, pain present over prior 3 months that impairs at least one area of daily life and occurs >1 per month, computer access and literacy.
Study type	Interventional study; intervention model: single arm; primary purpose: pain management; phase II
Date of first enrollment	May 24, 2022
Target sample size	34
Recruitment status	Currently recruiting
Primary outcomes	Feasibility, satisfaction
Key secondary outcomes	Pain intensity, activity limitations, anxiety symptoms, depressive symptoms, pain interference, insomnia symptoms, parent catastrophizing about child's pain, parent distress, parent responses to child's pain behaviors

[a]The funders will not contribute to any aspects of study design or management. The sponsor will be responsible for overseeing the study, interpretation of data, and the decision to submit the report for publication.

Intervention

Upon completion of the pretreatment questionnaires, survivors will receive access to the WebMAP program, an 8-week web-based cognitive behavioral therapy program with weekly modules including (1) education about chronic pain, (2) recognizing stress and negative emotions, (3) deep breathing and relaxation, (4) implementing coping skills at school, (5) cognitive skills, (6) sleep hygiene and lifestyle, (7) staying active, and (8) relapse prevention.

WebMAP is built using a responsive framework so that it can be easily viewed on any internet-enabled device (eg, smartphone and laptop). The program makes use of multimedia components (eg, audio and video) and interactive exercises. Support is provided through a message center, which allows asynchronous messaging with a coach over the internet. The study coach will be a member of the research team (MP) and is a clinical psychology doctoral student trained in cognitive behavioral therapy. The study coach will have access to a previously developed web-based coach's manual to standardize responses to participants in the message center. The WebMAP backend system monitors the completion of modules so treatment progress can be recorded.

Survivors will be asked to complete 1 module per week, which is approximately 20 minutes in length. Survivors and parents will be asked to spend approximately 4.5 hours each over the course of the intervention on WebMAP including 4 hours to complete the modules and 30 minutes total corresponding with a coach.

XSL•FO
RenderX

Each week, survivors will be instructed to log in to WebMAP to learn a new skill and practice that skill for 1 week to allow time for skills acquisition. WebMAP consists of 2 separate, password-protected programs including 1 for children and adolescents and 1 for parents.

Parents will also be given access to their own web-based program with weekly modules including (1) education about chronic pain, (2) recognizing stress and negative emotions, (3) operant strategies I (using attention and praise to increase positive coping), (4) operant strategies II (using reward to increase positive coping and strategies to support school goals), (5) modeling, (6) sleep hygiene and lifestyle, (7) communication, and (8) relapse prevention. The parent version of WebMAP uses the same type of multimedia and interactive elements as the teen version including access to the message center.

Measures

Clinical and Demographic Information

We will collect clinical and demographic information from parents including survivor's date of birth, gender, race, ethnicity, and household income. We will also ask about the survivor's previous medical issues (excluding cancer) including major injuries, illnesses, or surgeries as well as current or past history of pain treatments (behavioral or pharmacological). Upon receiving consent, we will also collect clinical information from electronic medical records including survivor sex, diagnosis date and description, and treatment received.

Objective 1

Feasibility

Feasibility will be assessed by considering rates of: (1) recruitment, (2) retention, (3) treatment engagement, (4) acceptability, and satisfaction. "Recruitment" will be measured by the number of survivors enrolled or consented divided by the total number of survivors invited to participate. Based on previous trials of similar nature [17], a 50% recruitment rate of eligible survivors will be used as the benchmark to determine this factor of study feasibility. "Retention" will be measured by the number of survivors who complete the study defined as those who complete the intervention and all assessments from enrollment (T0) to 3-month follow-up (T2) divided by the total number of survivors who enrolled in the study. Survivors will be considered to be enrolled in the study when they have read and signed the informed consent form. Based on previous pilot trials [17], an 80% retention rate will be considered "feasible." "Treatment engagement" will be measured by number of modules completed by survivors and parents. Based on similar trials [17], the goal to determine treatment engagement will be at least 75% of survivors completed at least 6 of the 8 modules, and the mean number of modules completed by the sample being at least 6. We hypothesize that >75% of survivors will complete assessment measures across the 3 specified time points. "Acceptability" will be measured using the Treatment Evaluation Inventory—Short Form (TEI-SF) [32], a 9-item self-report measure of acceptability of treatment, completed by both survivors and parents. The TEI-SF was originally designed to measure parents' acceptability of a treatment for children with problem behaviors but has been adapted to assess the acceptability of WebMAP in previous studies [17]. Responses are scored on a 5-point Likert scale and summed to create a total score. Higher scores represent better acceptability. Moderate to high acceptability, defined as a score of 27 or higher, has been considered sufficient for trials of similar nature [17,33]. The TEI-SF has good reliability and validity across various child treatments [32]. This study will use the adapted version and will be completed by survivors and parents.

Satisfaction

A survey including open-ended questions will be created with patients to elicit feedback on specific modules. These questions will ask about what information was helpful and what may need to be adjusted to better serve youths with a history of cancer for both patients and parents. The satisfaction survey will be completed as part of the posttreatment questionnaire by survivors and parents.

Qualitative Interviews

Semistructured interviews will be conducted with survivors and parents separately upon treatment completion to assess feasibility, acceptability, and satisfaction with the program. Patient partners will be involved in creating an interview guide. The interview guide will include open-ended questions about participants' experience with the program to facilitate self-reflection and open discussion around important aspects of their experience. Interviews will be audio-recorded and transcribed verbatim.

Objective 2

Pain Intensity

Daily surveys, administered to survivors through REDCap, will be used to assess the daily presence of pain and pain intensity for 7 days at the beginning of each assessment period (T0, T1, and T2). Pain intensity will be assessed with an item asking about the magnitude of pain experienced answered on an 11-point numerical rating scale (0=no pain, 10=worst pain). This measure of pain intensity has demonstrated to be a reliable and valid measure of pain in many populations of children 8 years and older [34-37], including those with chronic cancer pain [38].

Activity Limitations

The Child Activity Limitations Interview (CALI-9) [39] is a measure of children's perceived difficulty in completing typical daily activities because of pain. The CALI will be collected from survivors for 7 days at the beginning of each of the study timepoints (pretreatment, posttreatment, and 3-month follow-up). Survivors will choose from a list of 9 activities (eg, running, doing a hobby, playing with friends, sports, going to school), and will be asked each day whether the activity occurred and how difficult the activity was to perform because of their pain. Total scores range from zero to 100, where higher scores indicate greater functional limitations. Average daily limitation scores across each assessment period will be computed. The CALI has demonstrated reliability and validity in school-age children and adolescents with chronic pain, including those referred to pain clinics from hematology departments [40].

XSL•FO
RenderX

Anxiety and Depressive Symptoms and Pain Interference

The Patient-Reported Outcomes Measurement Information System (PROMIS) Anxiety and Depression instruments [41] (8-item short form) will be administered to survivors to screen for current symptoms of anxiety and depression. Survivors will complete the self-report instrument corresponding to their age (child: aged 8-17 years; adult: aged 18 years or older). Items (eg, "I felt worried") are rated on a 5-point scale (1=never, 5=always). Higher scores signify greater severity of symptoms. Pain interference will be assessed using the 4-item PROMIS interference scale for survivors 8-17 years of age, and the 7-item PROMIS interference scale for survivors over 18 years of age [42]. The PROMIS pediatric measures have been validated for use in pediatric oncology [42].

Insomnia

Insomnia Severity Index (ISI) is a 7-item self-report questionnaire assessing the nature, severity, and impact of insomnia [43,44] and will be administered to survivors. Items are rated on a 5-point Likert scale (0=no problem; 4=very severe problem). The scale is scored using a total sum ranging from 0 to 28 and cut scores are interpreted as such: absence of insomnia (0-7), subthreshold insomnia (8-14), moderate insomnia (15-21), and severe insomnia (22-28). The ISI is a reliable and valid measure used to detect cases of insomnia in a population sample and is sensitive to treatment response in patients presenting with sleep difficulties [43].

Catastrophizing About Child's Pain

The Pain Catastrophizing Scale–Parent Version [45] is a 13-item measure used to assess parents' catastrophic thoughts and feelings about their child's pain and will be administered over the internet via REDCap. Parents rate statements about their child's pain on a 5-point Likert scale (ie, "When my child has pain, I can't keep it out of my mind"). Items are summed to yield a total score and can also be summed to provide scores on 3 subscales: rumination, magnification, and helplessness. Lower scores indicate less catastrophizing. This scale has been found to have good reliability in parents with children who experience pain.

Parental Responses to Child's Pain Behaviors

The Adult Responses to Children's Symptoms [46,47] measures parental responses to their child's pain behaviors and will be administered over the internet via REDCap. This study will only use the Protect subscale, which assesses parents' responses that either positively or negatively reinforce pain complaints. Parents' responses are rated on a 5-point scale (0=never, 4=always). Subscale scores represent an average of the items, with higher scores indicating more frequent use of that behavioral style. This scale has demonstrated reliability and validity for use with parents of children with chronic pain [46,47].

Parent Distress

The Kessler Psychological Distress Scale [48] will be administered to parents and is a 6-item measure used to assess nonspecific psychological distress representing diagnoses of major depression and generalized anxiety disorder and also contains a positive affect domain. The measure has good precision in the 90th-99th percentile range of the population, and has solid psychometric properties across major sociodemographic populations distribution in the United States and Canada [48]. It also strongly discriminates between meeting and not meeting diagnostic thresholds for psychological disorders [48].

Data Analysis

Quantitative Data Analysis

To address objective 1, we will use frequencies and descriptive statistics to describe recruitment and retention rates, treatment adherence, and acceptability. To address objectives 2 and 3, primary efficacy end points of the study will be calculated as within-person changes in outcome measures using Cohen *d* effect sizes from T0 to T1 and T2. Outcome data will be analyzed using paired samples *t* tests in order to assess changes in outcome variables over time. Treatment effect sizes (Cohen *d*) will be calculated for changes in means, standardized by the pooled SD. All quantitative analyses will be conducted using SPSS (version 27; IBM Corp).

Qualitative Data Analysis

Qualitative data will be coded independently by 2 study team members and analyzed using reflexive thematic content analysis, consistent with Braun and Clark's thematic analysis guide [49]. Team members will first familiarize themselves with the data by reading the transcripts multiple times. The data will then be coded independently using a hybrid deductive-inductive approach whereby codes will be inductively derived from the data and codes will be deductively generated from existing literature [50]. Afterward, the 2 coders and the principal investigator (MP) will meet to discuss the codes and iteratively generate themes and subthemes. Additional team members will be invited to offer critical reflections and insight on the interpretations. Several strategies will be used throughout the data analysis to enhance rigor including having clear and extensive descriptions around the research setting and process, member checking, providing thick descriptions of themes, regular debriefing meetings, data triangulation with the quantitative analysis, and having the authors actively practicing reflexivity through notes and meetings [51].

Ethics Approval

Ethics approval was obtained from the Health Research Ethics Board of Alberta Cancer Committee (HREBA.CC-21-0272). Any changes to this protocol will be made through this ethics board. Potential survivors will be contacted and informed of study details such as the voluntary nature of participation, confidentiality, and risks and benefits of participating. Once survivors are fully informed, they will be given the opportunity to provide written consent and enroll in the study. Survivors will provide assent and will require parental consent to participate. Parents will provide consent for their own participation. WebMAP is known to be safe and previous trials reported no adverse events directly related to study participation [17]. Data will be collected using participant identification numbers to protect confidentiality. Names and corresponding identification numbers will be kept in a separate, password-protected document. Potential benefits of participating

XSL•FO
RenderX

in the intervention include a reduction in pain and an improvement in mental health.

The results will be disseminated to a range of stakeholders such as survivors of childhood cancer, parents of survivors of childhood cancer, health care practitioners, and researchers. Dissemination efforts will be made through national and international conference presentations, social media posts (eg, Twitter and Facebook), peer-reviewed academic journal publications, and cancer advocacy group newsletters (eg, Kids Cancer Care).

Results

This study was funded in January 2022. Data collection started in June 2022 and is projected to finish by August 2023. As of December 2022, we have recruited 10 participants, with zero participants completing all aspects of the protocol.

Discussion

The primary objective of this study is to assess the feasibility and acceptability of a well-studied internet-based psychological intervention developed for adolescents with chronic pain in a population of youths with a history of cancer. The strength of the study is the usage of a mixed methods design, which will provide both quantitative and qualitative information regarding the feasibility, acceptability, and potential efficacy of the intervention. Additionally, 3 patient and caregiver partners with lived experience of cancer and chronic pain will inform the study from the beginning. The web-based intervention will also be accessible for survivors who would not otherwise be able to access CBT with a psychologist. This may prove to be more inclusive for survivors living in rural or remote areas and survivors of families with low household incomes.

The proposed study has limitations. Participants for previous studies were recruited from tertiary pain clinics, which serve the most severe cases of chronic pain. One limitation of this study is that the participants may not experience a severe chronic pain problem compared to participants from other studies, though screening criteria require that they have chronic pain that affects at least one area of their daily life, similar to previous studies. This limitation may lead to smaller effects of the pain intervention on participants with mild to moderate chronic pain problems, and may also affect motivation to engage in the program if participants are generally functioning with pain. Another limitation is that the study will be conducted at a single location, in which the feasibility and acceptability of the study may not be generalizable to survivors across Canada.

The Obesity-Related Behavioral Intervention Trials (ORBIT) Model for Behavioral Treatment Development [52] is a framework for increasing the number of optimized evidence-based behavioral trials to prevent and treat chronic diseases. The ORBIT model includes several phases that serve as a roadmap for conducting behavioral intervention research in a systematic way that ensures quality and cost-efficient methods. This dynamic framework begins with a significant clinical question. This study proposes that while chronic pain is a prevalent issue in survivors of childhood cancer, no interventions to date have been empirically tested on this population. Phase I in the ORBIT Model represents the Design phase, where the goal is to design essential features of the intervention or to adapt to an existing treatment [52]. This phase has already been completed in that the intervention has been designed, refined, and tested on a different population [17]. Phase II represents the Preliminary Testing phase, where the goal is to test the ability of a fixed intervention to produce a clinically significant improvement on a behavioral risk factor [52]. While this phase has already been completed in previous studies [17], this intervention has never been tested on adolescents with a history of cancer, and thus this study aims to complete this phase. Should survivors not find the study helpful and adjustments are warranted, the trial will move back to phase I to be tailored for youths with a history of cancer. If the study finds WebMAP to be feasible and acceptable with promising preliminary efficacy, the trial will move to a phase III efficacy trial in future studies. This study will provide valuable information about the potential usefulness of WebMAP for survivors of childhood cancer with chronic pain.

Acknowledgments

Thank you to our other patient partners Madison Tutt and Nicholas Severino for providing feedback on the current project proposal. This research was funded by Alberta Children's Hospital Research Institute Small Research Grant.

Data Availability

Data and materials will be available upon request of the corresponding author after data have been collected.

Authors' Contributions

All authors participated in research conceptualization, study design, and revising drafts of the protocol. The first author (MP) completed the literature review and wrote the first protocol draft.

Conflicts of Interest

None declared.

Protocol

An mHealth Intervention to Improve Guardians' Adherence to Children's Follow-Up Care for Acute Lymphoblastic Leukemia in Tanzania (GuardiansCan Project): Protocol for a Development and Feasibility Study

Abstract

Background: Cancer is a leading cause of death during childhood and in low- and middle-income countries survival rates can be as low as 20%. A leading reason for low childhood cancer survival rates in low- and middle-income countries such as Tanzania is treatment abandonment. Contributing factors include poor communication between health care providers and children's guardians, insufficient cancer knowledge, and psychological distress.

Objective: Our aim is to respond to Tanzanian guardians' poor adherence to children's follow-up care after treatment for acute lymphoblastic leukemia with the help of mobile health (mHealth) technology. Our goal is to increase guardians' adherence to children's medications and follow-up visits and to decrease their psychological distress.

Methods: Following the Medical Research Council framework for developing and evaluating complex interventions, we will undertake the GuardiansCan project in an iterative phased approach to develop an mHealth intervention for subsequent testing. Public contribution activities will be implemented throughout via the establishment of a Guardians Advisory Board consisting of guardians of children with acute lymphoblastic leukemia. We will examine the acceptability, feasibility, and perceived impact of Guardians Advisory Board activities via an impact log and semistructured interviews (study I). In phase 1 (intervention development) we will explore guardians' needs and preferences for the provision of follow-up care reminders, information, and emotional support using focus group discussions and photovoice (study II). We will then co-design the mHealth intervention with guardians, health care professionals, and technology experts using participatory action research (study III). In phase 2 (feasibility), we will examine clinical, methodological, and procedural uncertainties associated with the intervention and study procedures to prepare for the design and conduct of a future definitive randomized controlled trial using a single-arm pre-post mixed methods feasibility study (study IV).

Results: Data collection for the GuardiansCan project is anticipated to take 3 years. We plan to commence study I by recruiting Guardians Advisory Board members in the autumn of 2023.

Conclusions: By systematically following the intervention development and feasibility phases of the Medical Research Council Framework, and working alongside an advisory board of guardians, we intend to develop an acceptable, culturally appropriate, feasible, and relevant mHealth intervention with the potential to increase guardians' adherence to children's follow-up care after

treatment of acute lymphoblastic leukemia, leading to a positive impact on children's health and chances to survive, and reducing distress for guardians.

Introduction

Overview

Cancer is a leading cause of death during childhood [1,2]. In high-income countries over 80% of children are cured [3], whereas in low- and middle-income countries (LMIC) survival rates can be as low as 20% [4]. If childhood cancer treatment inequalities are not addressed, it is estimated that 11.1 million children will not survive childhood cancer between 2020 and 2050, with 9.3 million (84%) of these cases living in LMIC [5]. Avoidable deaths from childhood cancer in LMIC result from factors including lack of diagnosis, misdiagnosis or delayed diagnosis, financial barriers, lack of essential chemotherapy, drug toxicity, poor survivorship care, reliance on traditional and complementary medicine, and treatment abandonment [4-8]. Deficiencies in pediatric cancer care are particularly pronounced within sub-Saharan Africa [9].

A major reason for low survival rates in LMIC is treatment abandonment, which is defined as failure to start (refusal) or continue curative treatment for 4 or more consecutive weeks [10-12]. Commonly reported factors contributing to treatment abandonment include dissatisfaction with health care providers' communication, guardians' lack of knowledge about cancer, preferences for traditional and complementary medicine, and psychological distress alongside limited access to psychological support [13,14]. In a Kenyan study, parents of children receiving treatment for leukemia reported anxiety, shock, fatigue, and economic challenges, which were associated with heightened family tension and increased need for emotional support [15]. Our research in Tanzania has identified that guardians report poor communication between themselves and health care providers, insufficient cancer knowledge, and emotional concerns [16], with findings suggesting that guardians have unmet needs related to health provider communication, information about childhood cancer, and emotional support. Importantly, these unmet needs can have negative consequences for guardians' adherence to the child's follow-up care, for example, medication adherence and follow-up appointments, which can have an impact on the child's health and chances of survival. However, research from Malawi suggests receiving information about treatment duration, reasons for and frequency of medical procedures, and the positive outcome in many cases of common childhood cancers can reduce treatment abandonment [17].

Mobile health (mHealth) interventions may represent a solution to address guardians' unmet needs, reduce treatment abandonment, and ultimately improve childhood cancer survival rates. Specifically, mHealth interventions may provide guardians with follow-up treatment reminders, educational information about cancer and treatment, and emotional support. Across sub-Saharan Africa, national-level digital health strategies and architectures are being implemented and are endorsed by the United Nations and the World Health Organization [18]. mHealth interventions have shown promise in improving treatment adherence among patients with tuberculosis in Tanzania [19] and young people living with HIV in sub-Saharan Africa [20]. A recent systematic review of the use of 2-way SMS text message interventions to improve appointment attendance and medicine adherence in sub-Saharan Africa found improvements in medicine adherence in comparison to standard care, but not appointment attendance. However, effectiveness differed between clinical conditions [21]. While an mHealth intervention represents a promising solution to improve adherence to the child's follow-up care, more knowledge is needed regarding the relationship between different types of mHealth interventions (eg, apps or SMS text messaging) and different outcomes including appointment attendance and medicine adherence. In addition, although mHealth technology has been piloted in many sub-Saharan African countries for various clinical and public health interventions, most of these interventions have not been scaled up due to poor design, limited stakeholder involvement, and neglecting to consider the implementation context [22].

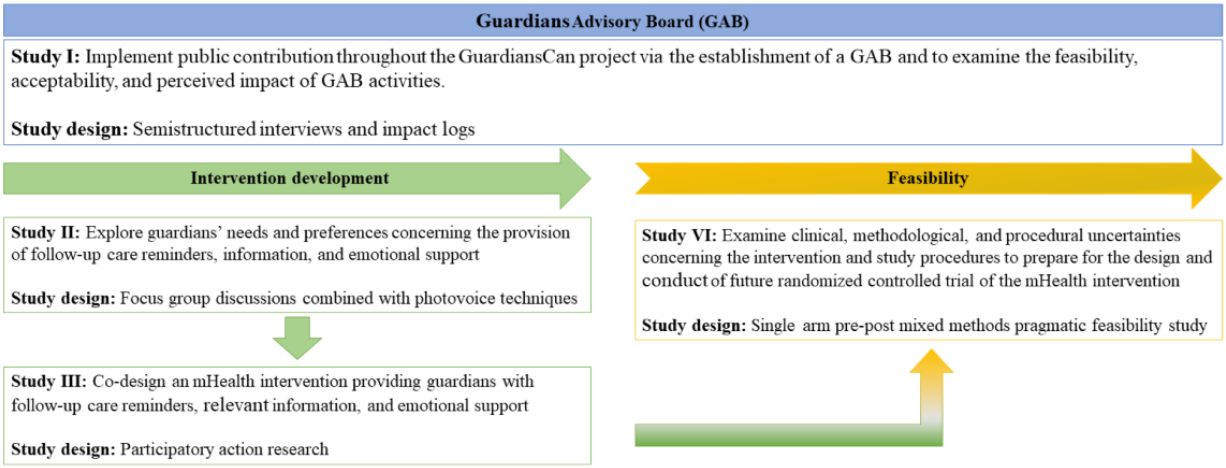
mHealth interventions could also provide emotional support to guardians. mHealth apps using cognitive behavioral therapy (CBT) principles are effective for common mental health difficulties [23], and we have successfully used internet-administered CBT to improve depression and anxiety in Swedish parents of children during [24,25] and after [26] cancer treatment. An mHealth intervention informed by CBT principles that supports guardians' unmet emotional needs may facilitate their adherence to the child's treatment and follow-up care. In addition to the uncertainties regarding which type of mHealth intervention should be used, and how to integrate CBT principles to target emotional needs, mHealth interventions should also be tailored to the target population [19]. Tailoring includes careful consideration of the population's needs and preferences, attitudes toward mHealth interventions, and perceived barriers and facilitators to intervention use. Potential barriers related to the technology, the health care system, and community factors, such as households sharing mobile phones, should also be carefully considered [27]. In addition, the acceptability and feasibility of the intervention and trial methods should be explored before undertaking a definitive randomized controlled trial (RCT) [28]. This paper describes the design of

XSL•FO
RenderX

the GuardiansCan project in which we aim to respond to Tanzanian guardians' poor adherence to children's follow-up care after treatment for acute lymphoblastic leukemia (ALL) with the help of mHealth technology.

Overall Aim and Specific Goals

Our goal is to increase guardians' adherence to children's medications and follow-up visits and, second, to decrease their psychological distress. Our overall objectives are to (1) implement public contribution activities throughout the GuardiansCan project via the establishment of a Guardians Advisory Board (GAB) and to examine the acceptability, feasibility, and perceived impact of GAB activities (study I); (2) to explore guardians' needs and preferences concerning the provision of follow-up care reminders, information, and emotional support (study II); (3) to co-design an mHealth intervention providing guardians with follow-up care reminders, relevant information, and emotional support (study III); and (4) to examine clinical, methodological, and procedural uncertainties associated with the intervention and study procedures to prepare for the design and conduct of a future definitive RCT of the mHealth intervention (study IV).



Methods

Overview

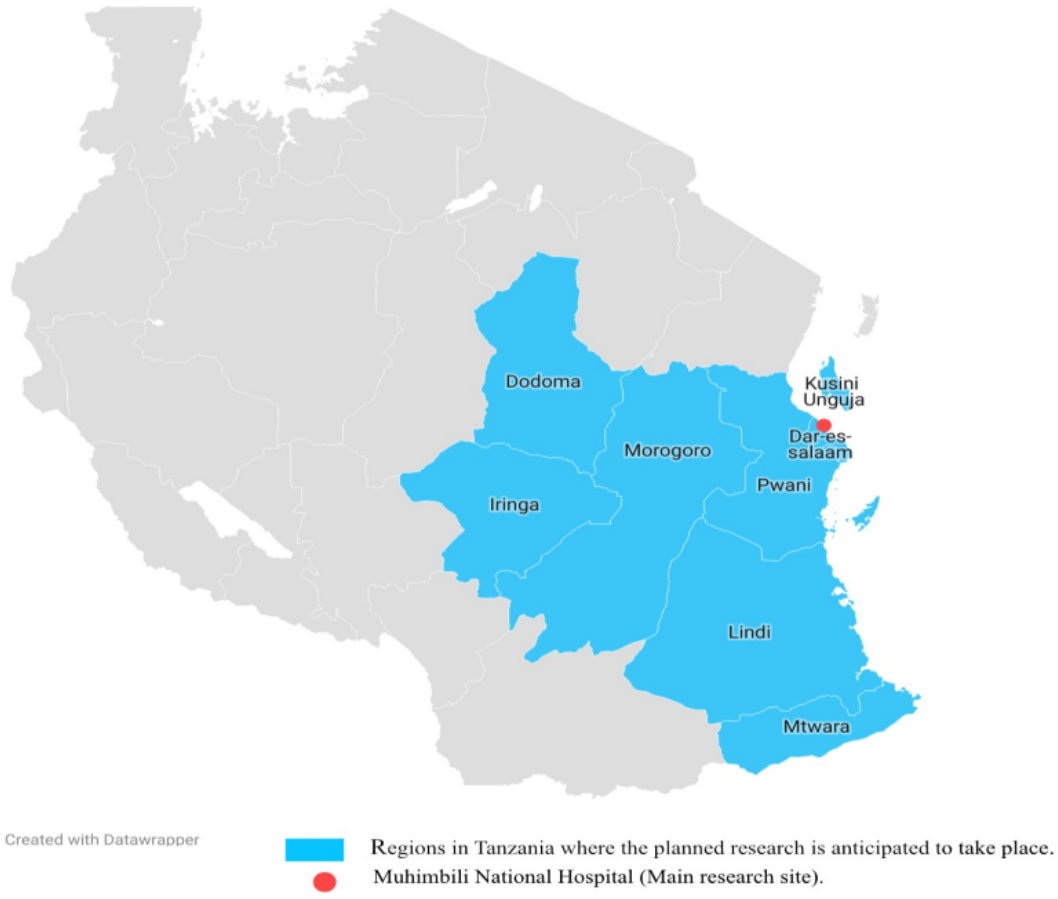
Following the revised United Kingdom Medical Research Council (MRC) framework for developing and evaluating complex interventions [29], we will undertake the GuardiansCan project in an iterative phased approach to develop an mHealth intervention for subsequent testing. The GAB will contribute to the project [30-32] and follow a study-focused framework [33] with public contribution activities planned at the managing and undertaking, analysis and interpretation, and dissemination phases of the project. As GAB members will be involved in designing the detailed research protocols for studies II-IV, we provide here an overview of the methods and study procedures as planned for now, to be further informed via GAB contribution.

The GuardiansCan project is divided into two main phases in accordance with the MRC Framework: (1) intervention development and (2) feasibility, with data anticipated to be collected over a 3-year period. We will follow published guidance to conduct the intervention development phase, paying attention to involving stakeholders, reviewing published evidence, developing a program theory, and considering future real-world implementation [29,34], and the feasibility phase regarding the design and reporting of feasibility trials [35] and supplementary guidelines for nonrandomized feasibility studies [36]. An overview of the GuardiansCan project can be seen in Figure 1.

Figure 1. Overview of the GuardiansCan project. mHealth: mobile health.

Setting

The GuardiansCan project is an international collaboration between Tanzania and Sweden. Uppsala University (Sweden) is the responsible academic institution with research primarily coordinated from Muhimbili National Hospital (MNH), a National Referral and University Teaching Hospital located in Dar es Salaam, Tanzania. MNH provides basic and advanced medical and surgical treatments, and is a strategic center for the implementation of eHealth aligning with the Tanzania National Road map of eHealth Investment 2017-2023 [37]. MNH is the main hospital for the treatment of pediatric cancer in Tanzania and the center for the pediatric oncology network that established a pediatric oncology unit at MNH in 2013 with collaborative support from the government, nongovernmental organizations, and other donors. The pediatric oncology unit includes "Upendo children's cancer ward" and the "Ujasiri house," a hostel for families. Around 100 children are diagnosed annually with ALL at the unit.



Regarding general access to mobile phones, Tanzania's mobile subscription rate per 100 population is 85%, with Android (Google) being the dominant operating system [38,39]. A study among guardians of children with cancer showed that 85% had mobile phones; however, out of these, only 9% reported having smartphones [40].

XSL•FO
RenderX

Recruitment

For each planned study, we intend to recruit guardians from 7 regions in Tanzania including Dar es Salaam, Dodoma, Iringa, Lindi, Morogoro, Mtwara, and Pwani, and the island of Zanzibar (a semiautonomous state and part of the United Republic of Tanzania). The regions represent urban and rural areas in Tanzania and have been selected to facilitate including guardians with different cultural backgrounds and accessibility to Dar es Salaam (see Figure 2). Recruitment will be conducted in collaboration with pediatric oncologists or pediatric oncology nurses at the pediatric oncology unit at MNH. Oncologists or nurses will identify potential participants for each study via MNH records. An oncologist or a nurse will call identified guardians to explore inclusion criteria and their initial interest in each study. Subsequently, a member of the research team will call interested guardians to provide more study information, undertake screening procedures, and obtain informed consent. The detailed recruitment strategy for study I will be published elsewhere. An overview of planned recruitment procedures is presented for studies II-IV as planned for now; however, recruitment strategies are subject to change via collaboration with the GAB.

Figure 2. Map of regions in Tanzania where the planned research is anticipated to take place.

Public Contribution in Research

Guardians Advisory Board: Study I

Aims

We aim to involve guardians of children treated for ALL in the managing and undertaking, analysis and interpretation, and dissemination phases of the GuardiansCan project, and examine the acceptability, feasibility, and perceived impact of GAB members' contribution to the GuardiansCan project from the perspective of GAB members and public contribution coordinators.

Methods

The full public contribution plan for the GuardiansCan project will be published elsewhere. We aim to recruit 6 to 8 guardians of children treated for ALL at MNH, representing different genders and coming from rural and urban communities, into the GAB. Workshops will be held with GAB members, facilitated by public contribution coordinators who are Kiswahili speakers with GAB members contributing to the undertaking and managing, analysis and interpretation, and dissemination phases of the GuardiansCan project. Examples of public contribution activities include, but are not limited to, designing detailed study protocols for studies II-IV, assisting in writing participant information sheets and consent forms, data collection (eg, cofacilitating or observing focus groups), data interpretation and sense-making of findings, developing a dissemination plan, and helping to distribute findings within community settings.

Data Collection

Public contribution activities will be recorded in an impact log [41] immediately after each GAB workshop. Workshop discussions will be held in Kiswahili and will be audio-recorded; however, audio-recordings will not be transcribed and only made to ensure impact log accuracy. Semistructured interviews

XSL•FO
RenderX

will also be conducted to explore the acceptability, feasibility, and perceived impact of GAB activities from the perspective of GAB members and public contribution coordinators 6 months after GAB has been formed and at the end of studies II-IV. Semistructured interviews will be conducted in Kiswahili and audio-recorded.

Data Analysis

Researchers in our group who are not involved in public contribution activities and conversant with Kiswahili will read impact logs, with impacts (eg, anticipated and unanticipated changes to the research process and potential benefits and harms) extracted and summarized. Summaries of impacts will be presented for discussion with GAB members and public contribution coordinators to aid sense-making and interpretation of results. Two members of the research team who are not involved in GAB activities will analyze semistructured interviews using manifest content analysis [42]. Descriptions of subcategories and categories will be presented for discussion with GAB members and public contribution coordinators to aid in sense-making and interpretation of results.

Phase 1: Intervention Development

Intervention Program Theory

Following the MRC Framework [29] throughout the intervention development phase we will use findings iteratively to develop and refine an intervention program theory [34]. The program theory will describe: (1) how we expect the mHealth intervention to increase guardians' adherence to children's medications and follow-up visits; (2) pathways predicted to drive the change; and (3) under what conditions the change is expected to occur [43]. The program theory will be presented diagrammatically, in the form of a logic model. Cumulative information from the intervention development phase will be used to identify intervention program inputs, activities, outputs, and the context in which they operate to deliver short- and long-term outcomes of interest [44]. We will continue to iteratively build the program theory and logic model throughout intervention development and later test and refine the developed program theory during the feasibility phase [34].

Focus Group Discussion and Photovoice: Study II

Aims

We aim to explore (1) perceived needs and preferences concerning the receipt of follow-up care reminders, information, and emotional support; (2) attitudes toward mHealth interventions; and (3) perceived barriers and facilitators of mHealth intervention use.

Study Design

An explorative qualitative design with data collected via focus group discussions combined with photovoice techniques will be used [45-47]. Photovoice is a qualitative research method whereby participants are engaged actively in the research process, using photographs or pictures to facilitate discussion and generate knowledge around a particular research topic, with an overall aim to reach policy makers to generate societal change concerning an important community issue [47,48].

Inclusion Criteria

Participants will be guardians of the children treated for ALL at MNH and health care professionals (eg, nurse practitioners, pediatric oncologists, pediatric oncology nurses, pediatricians, pharmacists, and social workers) working at the pediatric oncology unit at MNH. We will include guardians who meet the following inclusion criteria: (1) are at least 18 years of age; (2) whose child has been discharged within the last 3-36 months from MNH after receiving main treatment for ALL (ie, completion of the induction phase of treatment); (3) are able to speak Kiswahili; (4) have completed primary school education (International Standard Classification of Education [ISCED] level 1 to postsecondary nontertiary education ISCED level 4), but not tertiary education; (5) can provide written informed consent via ink signature; and (6) are able to travel to attend focus group discussions.

Recruitment

A member of the research team will speak to interested health care professionals working at the pediatric oncology unit at MNH face-to-face or over the telephone to provide more study information. Those who wish to participate will be provided with a study information sheet and consent form. Written informed consent or alternatively verbal recorded consent over the telephone or via a secure videoconferencing system will be obtained. After provision of informed consent, background and sociodemographic characteristics will be collected, that is, age, gender, profession, length of time in profession, professional qualifications, and length of time working with pediatric oncology.

An oncologist or a nurse will call identified guardians to explore inclusion criteria and their initial interest. A member of the research team will call guardians who fulfill the inclusion criteria and are interested in participation to provide more detailed verbal study information. Guardians interested in participating will be invited to the first focus group discussion. We will provide guardians with (1) a study information sheet and (2) consent form and written informed consent (via ink signature) will be obtained prior to data collection.

Data Collection

A series of 2 focus group discussions with health care professionals (n≈6-8) at MNH will be held in Kiswahili. We will hold a series of 6 focus group discussions combined with photovoice with guardians (n≈3-4 females and n≈3-4 males). We plan to conduct focus groups in Dar es Salaam at a venue where participants can share their thoughts and feelings in privacy. It is anticipated that guardians will meet approximately once every 2 weeks for a 12-week period with each focus group lasting approximately 3 hours. However, the exact venue, frequency, and duration of focus group discussions will be planned in collaboration with the GAB.

Focus groups with guardians will be combined with photovoice techniques [45-47]. We will predevelop topics for each focus group in collaboration with GAB members and they will be conducted in Kiswahili. During the first focus group with guardians, we will present study aims and participants will be trained in photovoice procedures, how to use a camera, and in

XSL•FO
RenderX

ethical considerations [49]. Next, we will introduce the topic for the subsequent focus group discussion and participants will take 3 photographs based on the topic prior to the subsequent planned focus group. During each of the focus group discussions, photographs will be used to elicit discussions around each preplanned topic. At the end of each focus group, the topic for the subsequent focus group will be introduced.

Focus group discussions will be moderated and notes taken with the assistance of an observer, a GAB member who will help facilitate discussions. We will audio-record focus group discussions and they will be transcribed verbatim by a person conversant in Kiswahili. An external translation company will translate transcripts to English and back-translate it to Kiswahili to facilitate analysis by the whole research team. Transcripts will be anonymized.

Data Analysis

Data will be analyzed using manifest content analysis [42]. Two members of the research team will individually code transcripts and perform categorization of codes into categories and subcategories. Subsequently, categories and subcategories will be discussed in the wider research team to facilitate interpretation. Descriptions of subcategories and categories will be presented for discussion with GAB members to aid sense-making and interpretation of results. Visual data from photographs will be used as supplementary data sources. Trustworthiness of the analysis will be established in accordance with a trustworthiness checklist for content analysis [50] and by adopting procedures including an audit trail, case analysis for deviant cases, and peer examination.

Participatory Action Research: Study III

Aims

We aim to identify: (1) intervention content informed by findings from study II, behavioral change techniques [51-53] and evidence-based CBT principles [23,54], and may include audio, visual, and written elements; (2) acceptable methods of intervention delivery within the health care context (eg, 1-way SMS text messaging, automatic voice message reminders, 2-way SMS text messaging, or via artificial intelligence methods, or a basic or smartphone app) which are suitable for urban and rural environments; (3) intervention delivery preferences, for example, technical elements [55,56] such as reminders and personalization and whether a professional group is needed to support intervention delivery; and (4) potential technical support and training needs of guardians and health care professionals.

Study Design

A qualitative design based on principles from participatory action research (PAR) will be used [57,58], placing key stakeholders at the center of the research process.

Inclusion Criteria

Participants include guardians of the children treated for ALL at MNH, meeting the same inclusion criteria as study II, and health care professionals working in pediatric oncology care, and technology experts, including mobile operator technicians.

Recruitment

We anticipate identifying health care professionals and technology experts via in-person networks and guardians via MNH patient records, following the same recruitment procedures used in study II.

Data Collection

Approximately 8 face-to-face PAR iterative meetings will be held in Kiswahili at a venue where participants can share their thoughts and feelings in privacy. Each meeting is anticipated to last approximately 3 hours, including a refreshment break. Before the first meeting, background and sociodemographic characteristics from participants will be collected. Some meetings will only include guardians or health care professionals and technology experts, and some meetings will be combined.

Each meeting will have a predefined theme to focus the discussions and we will predevelop topics in collaboration with GAB members. PAR meetings will be conducted in iterative cycles and each meeting will involve cycles of collaboration, discussion, reflection, and evaluation. At the beginning of each meeting, we will present the agenda and participants will be encouraged to add items to the agenda. Action plans related to the topic will be developed collaboratively and at the end of each meeting, participants will individually reflect on the group discussions by answering open-ended questions and will be encouraged to provide suggestions for the upcoming meeting [58]. An initial intervention prototype will be drafted after 6 meetings. We will discuss the initial prototype in combined meetings and come up with the proposed intervention to be tested in the feasibility phase.

PAR meetings will be facilitated and notes taken with the assistance of an observer, who will be a GAB member. Meetings will be audio-recorded and will be transcribed verbatim by a person native in Kiswahili. An external translation company will translate transcripts to English and back-translate to Kiswahili to facilitate analysis by the whole research group. Transcripts will be anonymized. Participants' input at meetings and on action plans will be discussed by meeting facilitators, the research team, and the GAB who jointly plan further actions.

Data Analysis

Data will be analyzed (meeting notes, action plans, and transcripts) using manifest content analysis [42] in a "recursive" process to reach a collaborative understanding of the data. Two members of the research team including a Tanzanian national will individually code transcripts and perform the categorization of codes into categories and subcategories. Subsequently, categories and subcategories will be discussed in the wider research team to facilitate interpretation. The analysis will be presented for discussion with GAB members to aid sense-making and interpretation of results. Trustworthiness of the analysis will be established in accordance with a trustworthiness checklist for content analysis [50] and by adopting procedures including an audit trail, case analysis for deviant cases, and peer examination. We will develop a full prototype of the mHealth intervention describing the type of intervention, information to be provided, and mode and frequency of delivery for feasibility testing.

XSL•FO
RenderX

Phase 2: Feasibility

Single-Arm Pre-Post Mixed Methods Pragmatic Feasibility Study: Study IV

Aims

We aim to determine (1) intervention acceptability from the perspectives of guardians and health care professionals; (2) feasibility of the intervention; and (3) feasibility and acceptability of study methods and procedures.

Study Design

We will undertake a single-arm pre-post mixed methods pragmatic feasibility study [35,36,59].

Inclusion Criteria

Participants will be guardians (1 per child) whose child has been discharged from MNH after receiving main treatment for ALL (ie, completion of the induction phase of treatment) with the inclusion or exclusion criteria informed by studies II and III findings and GAB member involvement.

Recruitment

Exact recruitment procedures will be informed by GAB member involvement. It is anticipated the recruitment period will take 6 months. To examine recruitment feasibility, the study invitation materials will include the possibility for guardians who decline participation to provide reasons for nonparticipation and consent to take part in an interview to explore potential decisions not to participate. Written informed consent (via ink signature) will be obtained prior to data collection and being provided with access to the intervention. In addition to the intervention, guardians will receive care from health care professionals as per normal clinical practice.

We anticipate recruiting a sample of between 20 and 40 participants, following recommendations for feasibility studies [60] and, as in other single-arm pragmatic feasibility studies [61], to provide information on feasibility outcomes and inform the sample size for a future definitive RCT [62].

Data Collection

We plan to collect data at screen, baseline, and posttreatment follow-up (12 months post intervention). In line with our feasibility objectives [35], we will collect the following outcomes: (1) intervention acceptability from the perspectives of guardians and health care professionals (eg, intervention acceptability, intervention usability, and indications for usage such as number of opened messages); (2) feasibility of delivering the intervention (eg, number of successfully delivered messages); and (3) feasibility and acceptability of study methods and procedures (eg, number of guardians eligible and enrolled, data collection completeness, and feasibility of data collection procedures). Progression criteria and stopping rules will be defined [63] to inform progression to an RCT. The exact progression criterion and stopping rules will be developed in accordance with our feasibility objectives, existing relevant literature, and input from a broad range of relevant stakeholders, including GAB members and researchers external to the research team who have relevant expertise in conducting similar research [64].

To examine the feasibility of data collection, the following clinical data will be collected: (1) adherence to child's medications as per discharge instructions (eg, amount of medication taken and successful prescription refill); (2) attendance of follow-up visits at MNH or another hospital as per discharge instructions; (3) number and types of complications after discharge, number of readmissions after discharge, and progress of children's cancer; and (4) psychological distress as measured with the Kiswahili adaptation of the Kessler Psychological Distress scale [65], cancer knowledge, and quality of life [66]. We will examine the feasibility of collecting economic data to inform a future cost-effectiveness evaluation, for example, provider costs pertaining to direct financial costs of delivering and maintaining the intervention and personnel costs [67]. Semistructured interviews at posttreatment will be conducted in Kiswahili to explore intervention acceptability, relevance, impact (eg, on medication adherence, attendance at outpatient follow-up visits, guardians' psychological distress, cancer knowledge, and child's well-being), and barriers and facilitators to intervention use. All guardians included in the study will be invited to participate in the interviews until data saturation is met. We will also interview health care professionals involved in the intervention to explore experiences of the intervention and perceived impact on guardians.

Data Analysis

Participant flow will be illustrated in accordance with the CONSORT (Consolidated Standards of Reporting Trials) diagram for feasibility and pilot studies [35]. We will calculate the percentages of participants (1) consenting, (2) screened, (3) meeting eligibility criteria, and (4) enrolled calculated with 95% CIs. Reasons for ineligibility, ambiguities regarding eligibility criteria, and reasons for nonparticipation at each stage will be reported. We will calculate follow-up rates, and the numbers of missing items relating to outcome measures are calculated with 95% CIs. We will report descriptive statistics (means and SDs or proportions with 95% CIs) for each clinical outcome at eligibility screen, baseline, and posttreatment (eg, adherence to child's medications, attendance of follow-up visits, number and types of complications and readmissions, psychological distress). We will also report frequencies of intervention activity relating to intervention adherence and use. We will analyze semistructured interviews using manifest content analysis [42] and establish the trustworthiness of the analysis in accordance with a trustworthiness checklist for content analysis [50] and by adopting procedures including an audit trail, case analysis for deviant cases, and peer examination. Quantitative and qualitative data will be analyzed separately, with findings integrated following a triangulation protocol at the participant level to explore potential relationships between mHealth intervention implementation, intervention acceptability and perceived impact, and changes in adherence to medication and follow-up visits and psychological distress. Joint displays will be used to compare quantitative and qualitative findings [68,69]. We will present the analysis for discussion with GAB members to aid sense-making and interpretation of results.

XSL•FO
RenderX

Reporting

We will report: (1) GAB activities and perceived impact of activities following the GRIPP2 (Guidance for Reporting Involvement of Patients and the Public) checklist [70]; (2) qualitative results in accordance with the SRQR (Standards for Reporting Qualitative Research) checklist [71]; (3) intervention development in line with GUIDED (Guidance for Reporting Intervention Development Studies in Health Research) [44]; (4) intervention content following the TIDieR (Template for Intervention Description and Replication) checklist [72] and the mERA (mHealth Evidence Reporting and Assessment) checklist [73]; and (5) feasibility study results in accordance with the CONSORT extension for reporting randomized pilot and feasibility [35].

Data Management

We will process data in accordance with the Swedish Patient Data Act (2008:355), the General Data Protection Regulation (EU 2016/679), and the Tanzania National Institute of Medical Research policy [74]. Tanzanian and Swedish members of the research group will have access to collected data and will be involved in data management and analysis. We will develop a detailed data management plan for each study that will be made available on DMPonline. In summary, research data will be pseudonymized and a list linking ID number and identifiable personal information (ie, participant name and contact details) will be kept separately from research data. Data will be stored on password-protected USB sticks kept in a locked fireproof cabinet at MNH and stored in ALLVIS, a secure web-based data portal used by Uppsala University for the confidential storage of research data, accessible by both Tanzanian and Swedish members of the research group. A Data Transfer Agreement will be completed between Uppsala University and MNH.

Ethical Considerations

The GuardiansCan project will be conducted in accordance with the Declaration of Helsinki [75]. Informed consent (via ink signature) will be obtained from all GAB members and study participants. We will obtain ethics approval for all studies from the Swedish Ethical Review Authority, MNH Ethics Review Board, and the Tanzania National Research Ethics Committee; and research permits for foreign researchers will be sought from the Tanzania Commission for Science and Technology for study IV. Given the iterative nature of the planned research and involvement of the GAB, ethics approval will be obtained for all 4 studies in a stepwise manner, with ethics approvals initially obtained for study I.

Members of the GAB (study I) will receive reimbursement for their contribution, which includes travel and living cost and an allowance equivalent to the government daily subsistence allowance for ISCED level 4 personnel: 75,000 Tanzanian Shillings (≈US $31). Guardians participating in study II will receive mobile phones to facilitate the use of photovoice techniques. Guardians participating in studies II-IV will also receive reimbursement for any travel and living costs incurred.

Results

Data collection for the GuardiansCan project is anticipated to take 3 years. We plan to commence study I by recruiting Guardians Advisory Board members in the autumn of 2023.

Discussion

Principal Findings

The development of interventions to address childhood cancer treatment inequalities and avoidable deaths from childhood cancer in LMIC is a high public health priority. To the best of our knowledge, this is the first study to seek to increase guardians' adherence to children's medications and follow-up visits after treatment for ALL, decrease guardians' psychological distress via the use of mHealth, and represents an opportunity to increase childhood cancer survival rates in LMIC such as Tanzania.

Despite the piloting of mHealth interventions across sub-Saharan African countries, mHealth interventions are seldom scaled-up due to factors such as lack of stakeholder involvement and consideration of the implementation context [22]. To overcome these limitations, robust methods will be adopted systematically following the intervention development and feasibility phases of the revised MRC complex interventions research framework [29], developing program theory, and involving wider stakeholder groups throughout the intervention development phases. In addition, we will implement public contribution throughout the GuardiansCan project by working alongside an advisory board of guardians with lived experience to enhance the quality and relevance of the GuardiansCan project, ensuring local applicability and acceptance, and a feasible and sustainable solution to a significant health care challenge. Consequently, important data will be generated to facilitate the development of an acceptable, culturally appropriate, feasible, and relevant intervention, as well as maximize the success of a future definitive RCT. Significant stakeholder involvement and consideration of context and future real-world implementation will enhance the future implementation potential of the intervention should it later be demonstrated to be clinically and cost-effective. In addition, we will use our developed program theory to inform future process evaluations of the intervention.

Limitations

We did not involve guardians as public contributors when developing the overall research plan, limiting our ability to plan study procedures in advance that maximize acceptability and feasibility for guardians. However, we plan to overcome this limitation by embedding public contribution via the GAB throughout the GuardiansCan project, including activities related to the managing and undertaking, analysis and interpretation, and dissemination phases of the project. As planned currently, we will only recruit guardians from 7 geographical regions of Tanzania. Therefore, results may not be generalizable to guardians located in other regions of Tanzania, including guardians located at very long distances from the pediatric oncology unit at MNH. We will not include guardians who have not completed at least primary school; therefore, the proposed

XSL•FO
RenderX

mHealth intervention may not be suitable for guardians who have not attained primary education.

Conclusions

The proposed mHealth intervention and research have significant potential to promote equitable and sustainable care for families struck by ALL in Tanzania, adding to the capacity building of health care services in Tanzania. Our research may have a positive impact on children's health and chances to survive, and guardians' ability to provide for the family as a result of reduced costs for treatments, transportation, and long periods of hospitalization. The mHealth intervention also has significant potential to be a clinical and cost-effective solution, optimally prepared alongside key stakeholders for the implementation and a real-world clinical impact. The project, and the novel and robust methodological approach being taken, will also add to the existing evidence base concerning how mHealth interventions should be developed and tested, which may be of benefit to patients and informal caregivers for a variety of different conditions and unmet needs.

Acknowledgments

This work is supported by the Swedish Research Council (Dnr: 2020-04716), the Indevelop Foundation (MEDFARM 2022/632) and funding to U-CARE, a strategic research environment via the Swedish Research Council (Dnr: 2009–1093). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript. We thank our colleagues from the pediatric oncology unit of Muhimbili National Hospital for their invaluable input to the protocol.

Abstract

Background: The risk of a large number of severe acute respiratory infection (SARI) cases emerging is a global concern. SARI can overwhelm the health care capacity and cause several deaths. Therefore, the Austrian Agency for Health and Food Safety will explore the feasibility of implementing an automatic electronically based SARI surveillance system at a tertiary care hospital in Austria as part of the hospital network, initiated by the European Centre for Disease Prevention and Control.

Objective: We aim to investigate the availability of routinely collected health record data pertaining to respiratory infections and the optimal approach to use such available data for systematic surveillance of SARI in a real-world setting, describe the characteristics of patients with SARI before and after the beginning of the COVID-19 pandemic, and investigate the feasibility of identifying the risk factors for a severe outcome (intensive care unit admission or death) in patients with SARI.

Methods: We will test the feasibility of a surveillance system, as part of a large European network, at a tertiary care hospital in the province of Lower Austria (called Regional Hospital Wiener Neustadt). It will be a cross-sectional study for the inventory of the electronic data records and implementation of automatic data retrieval for the period of January 2019 through the end of December 2022. The analysis will include an exploration of the database structure, descriptive analysis of the general characteristics of the patients with SARI, estimation of the SARI incidence rate, and assessment of the risk factors and different levels of severity of patients with SARI using logistic regression analysis.

Results: This will be the first study to assess the feasibility of SARI surveillance at a large 800-bed tertiary care hospital in Austria. It will provide a general overview of the potential for establishing a hospital-based surveillance system for SARI. In addition, if successful, the electronic surveillance will be able to improve the response to early warning signs of new SARI, which will better inform policy makers in strengthening the surveillance system.

Conclusions: The findings will support the expansion of the SARI hospital-based surveillance system to other hospitals in Austria. This network will be of use to Austria in preparing for future pandemics.

Introduction

Globally, there has been an increase in acute respiratory infections, which are considered among the major causes of morbidity and mortality across all age groups [1]. Annually, over 4 million people die from acute respiratory infections, and the majority are due to lower respiratory tract infections [1]. Mortality is high in infants, children, and older people, especially in low- and middle-income countries [2]. Therefore, public health surveillance is an essential tool for monitoring population-level changes in the incidence and burden of respiratory infectious diseases, which is essential for their prevention and targeted control [3].

The COVID-19 pandemic has shown the importance of routine syndromic surveillance of respiratory infections, especially new cases of severe acute respiratory infection (SARI) [4,5]. Currently, there is a need to invest more into systematic data collection on SARI, including the identification of risk factors associated with the SARI cases, which is going to guide policy makers in tailoring appropriate interventions to reduce the SARI public health burden.

Currently, a total of 27 countries in the European Union and 3 countries in the European Economic Area are part of a SARI surveillance network, in collaboration with the European Centre for Disease Prevention and Control (ECDC) and the World Health Organization [6]. The countries using the SARI surveillance network report to the ECDC about the population under their surveillance. This includes persons of all ages living in the catchment areas of the hospitals participating in the national surveillance systems (also, the target population tends to be representative of the general population) [6].

There is concern about the acute emergence of a large number of severe infectious cases, which can overwhelm the health care capacity and cause several deaths. Therefore, in 2022, the ECDC took the initiative to establish a hospital network sustainable infrastructure to conduct enhanced surveillance of SARI, including the performance of studies on the impact and burden of diseases. Thus, it is becoming important and crucial to have at the EU level a hospital-based surveillance system for the monitoring of incidence trends and an early detection system for epidemics, including the identification of the risk groups for severe diseases to measure the impact of these diseases [7].

Austria is participating in this network and is initiating such SARI hospital-based surveillance for the first time. In this feasibility study, we aim to investigate the availability of routinely collected inpatient health record data pertaining to respiratory infections and the optimal approach to use such data for a systematic automated surveillance of SARI. Furthermore, we aim to describe the characteristics of patients with SARI before and after the beginning of the COVID-19 pandemic. Additionally, we investigate the feasibility of identifying risk factors for a severe outcome (intensive care unit [ICU] admission or death) in patients with SARI at a tertiary care hospital in Austria.

Methods

Study Design and Setting

This will be an investigative feasibility and cross-sectional study at an 800-bed tertiary care hospital (Regional Hospital Wiener Neustadt) in the federal state of Lower Austria. The analysis will include the inventory of electronic data records and the implementation of automatic data retrieval between January 2019 and December 2022.

For inclusion, we will include all cases that meet the SARI case definition based on the ECDC surveillance definition; we will also include all patients regardless of their address of residence (ie, either inside or outside Austria). Patients not meeting the SARI case definition will be excluded.

Setting

The Federal State of Lower Austria

The Regional Hospital Wiener Neustadt is located in the federal state of Lower Austria, which is the largest federal state in Austria (area size of 19,174 km^2 and a population of over 1.6 million) [8]. The health care system in Austria is financed through health insurance subsidies provided to hospitals at the federal, regional, and municipal levels [8]. Lower Austria is the only Austrian federal state where all hospitals are legal entities of one single health care provider, the Niederösterreichische Landesgesundheitsagentur (NÖ-LGA), which offers clinical health care services, from basic to specialist, including the handling of the operative management of the hospitals.

Lower Austria is located in the northeast of Austria, where its borders are adjacent to two neighboring countries (Czech Republic and Slovakia). Since 2008, the federal state of Lower Austria has initiated six cross-border health care projects. Additionally, in 2017, The Lower Austrian Health and Social Fund launched a so-called “Initiative Health Across,” which combines all cross-border health care activities in Lower Austria. The aim of this project is to facilitate optimum and equitable usability of the health care services for the population living in the border areas through close cooperation of the health service providers in a simple and uncomplicated way [8].

Hospital

The Regional Hospital Wiener Neustadt is an 804-bed tertiary care facility located 60 km south of the Austrian capital Vienna. The hospital provides all major fields of medicine and surgery to large parts of eastern Austria, including the border regions near Slovakia and Hungary, and in Styria to the south. The Regional Hospital Wiener Neustadt is an acute and specialist tertiary referral center with 21 anesthesiology ICU beds, 14 medical intermediate care unit beds, and 21 stroke unit beds, which cares for approximately 35,000 inpatients and 390,000 outpatients, and performs more than 21,000 surgical procedures annually. The medical and nursing staff of the hospital cares for both pediatric and adult patients with respiratory tract infection.

XSL•FO
RenderX

Austrian Agency for Health and Food Safety

The Austrian Agency for Health and Food Safety (AGES) is a government-owned agency attached to the Austrian Federal Ministry of Social Affairs, Health, Care and Consumer Protection and the Austrian Federal Ministry of Agriculture, Regions and Tourism. AGES executes several federal tasks, including public health issues and research in the areas of infectious diseases (in addition to other areas, eg, agriculture, food and feed safety, veterinary medicine, radiation protection, medical devices, and pharmaceuticals). In Austria, certain infectious diseases fall under the category of mandatory reporting. Therefore, these diseases are registered in a national registry called the Epidemiological Reporting System (EMS), which is used by laboratories located at the hospitals. The EMS has a central national registry, which is hosted at the Austrian Federal Ministry for Social Affairs, Health, Care and Consumer Protection and maintained under the Institute of Surveillance and Infectious Diseases Epidemiology at AGES [9].

Data Sources and Variables: Hospital Data Management System

We will be using the data from the EMS together with medical data stored in the local hospital information system. We will include the following information from the clinical records about the patients: the *International Statistical Classification of Diseases, Tenth Revision* (*ICD-10*) code; district of residency; gender (man/woman); date of birth; SARI date onset; bronchoalveolar lavage; tissue from biopsy or autopsy, other, or unknown/not specified; clinical symptoms; existing underlying conditions (yes/no); asthma (yes/no); diabetes (yes/no); cancer (yes/no); immunocompromised (yes/no); heart (yes/no); kidney (yes/no); lung (yes/no); liver (yes/no); neurological (yes/no); obesity (no, BMI 30-40, BMI>40, clinically obese); pregnancy (yes/no); pregnancy trimester (first trimester, second trimester, third trimester); vaccination status related to SARI organisms (yes/no); antiviral prophylaxis (yes/no); antiviral treatment (yes/no); respiratory support (no, oxygen, ventilation, extracorporeal membrane oxygenation [ECMO]); pneumonia diagnosis (no; yes, clinical/abnormal chest x-ray or raised C-reactive protein level), tuberculosis (no history of tuberculosis, history of tuberculosis, positive test during hospital visit); influenza test (not performed, polymerase chain reaction, culture, immunofluorescent assay, other—not specified—test); test result (negative/positive); influenza type (A/B); influenza A subtype (A[H1N1]pdm09, A[H3N2]); ICU admission; outcome (discharged alive/death); and cause of death (not influenza, influenza as a primary cause, influenza as a secondary cause). Only cases with available data will be included in the final analysis, and we will report the proportion of variables with missing data.

Ethical Considerations

Ethical clearance will be obtained from the Ethics Committee of Lower Austria. A waiver will be requested pertaining to informed consent for this retrospective study. All data will be anonymized to ensure the privacy and confidentiality of patients' personal information, with each participant assigned a unique identifier.

No compensation is given to the participants.

Statistical Analysis

The statistical analysis will be conducted, pending the feasibility of the data quality, through the following four steps. In step 1, we will assess the existing database structure, including the exploration of the optimal methods for data retrieval. In step 2, we will conduct a descriptive analysis of the general characteristics of the patients with SARI. The percentage will be calculated by using the total number of patients identified with an underlying condition divided by the total number of patients included in the data set. In step 3, we will calculate the estimation of the SARI incidence rate by using the available data. In step 4, we will then assess the association between the risk factors and different levels of severity of patients with SARI (only cases with available data will be included in the final analysis).

The outcome will be defined as follows: patients with SARI that were discharged alive and not admitted to the ICU, patients with SARI that were discharged alive post admission to the ICU, patients with SARI that died, and patients with SARI with any severe outcome (eg, intensive care, respiratory support, ECMO). We will conduct a logistic regression analysis (backward method) to identify the risk factors associated with a severe outcome. All variables showing an association with a severe outcome at a statistical significance level of $P<.15$ will be included in the multivariable logistic regression analysis. The final variables with a statistical significance of $P<.05$ will be defined as the significant variables. R software (version 4.2.1; R Foundation for Statistical Computing) will be used for the statistical analysis [10].

Results

The main purpose and objective of this study will be to assess the feasibility of the SARI surveillance system at one of the largest tertiary care hospitals in Austria. The SARI case definition will be defined based on the ECDC SARI protocol. The sources of the SARI surveillance data will include the following: new SARI cases during the calendar week, new SARI cases in which specimens were collected during the reported week, the total number of new hospital admissions to wards under the SARI case definition, the list of *ICD-10* that were used with the number of cases per *ICD-10*, and other specimen and epidemiological data.

Discussion

As part of a first-time established European SARI hospital-based surveillance network, we will evaluate the feasibility at one of the largest tertiary care hospitals in Austria. We will explore the existing tools to gather data and evaluate the data used in the surveillance reporting and monitoring of SARI, including COVID-19 cases and influenza A. The importance of routine syndromic surveillance of respiratory infections, especially new cases of SARI, became of high importance due to the lessons learned during the COVID-19 pandemic [4,5]. We have conducted a review of the literature and identified that there are no universally agreed standards on the topic of SARI

XSL•FO
RenderX

surveillance (El-Khatib Z, unpublished data, June 1, 2023). Therefore, this study and the newly established European network will be useful for the improvement of the preparedness for upcoming pandemics, so we can recommend directions for the future evaluation of SARI surveillance systems.

As shown by the COVID-19 pandemic, early warning and access to relevant data is imperative to act appropriately to ensure the safety of the public from infectious hazards. This study will foster the alertness of public health agencies regarding future respiratory health threats. Therefore, we will be able to improve the response to early warning signs of new SARI signs and eventually better inform policy makers on strengthening the surveillance system. Finally, we should share a potential limitation of this study. The findings of this hospital may lack representativeness at the national level. We may identify additional limitations, pending the data quality, but we could not comment on it at this stage, as the data collection has not started.

The findings of this study will support expansion to other hospitals in Austria and including them in the SARI hospital-based surveillance system. Eventually, such a network will be of use to Austria in preparing for future pandemics.

Acknowledgments

This project is part of a European Union–based project where the funding is received from EpiConcept (commissioned by the European Centre for Disease Prevention and Control; EHR-SC1-SARI).

We would like to thank all staff of the hospital and the Austrian Agency for Health and Food Safety that are providing support for this study.

Data Availability

Data sharing is not applicable to this paper, as no data sets were generated or analyzed during this study.

Authors' Contributions

All authors conceptualized the study. ZEK and OA wrote and prepared the original draft. All authors reviewed and edited the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Women with a low socioeconomic status often have a vulnerable health status due to an accumulation of health-deteriorating factors such as poor lifestyle behaviors, including inadequate nutrition, mental stressors, and impaired health literacy and agency, which puts them at an unnecessary high risk of adverse pregnancy outcomes. Adequately preparing for pregnancy through preconception care (PCC) uptake and lifestyle improvement can improve these outcomes. We hypothesize that *nudging* is a successful way of encouraging engagement in PCC. A nudge is a behavioral intervention that changes choice behavior through influencing incentives. The mobile health (mHealth) app–based loyalty program *Pregnant Faster* aims to reward women in an ethically justified way and nudges to engage in pregnancy preparation by visiting a PCC consultation.

Objective: Here, we first describe the process of the cocreation of the mHealth app *Pregnant Faster* that aims to increase engagement in pregnancy preparation by women with a vulnerable health status. Second, we describe the cohort study design to assess the feasibility of *Pregnant Faster*.

Methods: The content of the app is based on the eHealth lifestyle coaching program Smarter Pregnancy, which has proven to be effective in ameliorating preconceptional lifestyle behaviors (folic acid, vegetables, fruits, smoking, and alcohol) and an interview study pertaining to the preferences of the target group with regard to an mHealth app stimulating PCC uptake. For moral guidance on the design, an ethical framework was developed based on the bioethical principles of Beauchamp and Childress. The app was further developed through iterative cocreation with the target group and health care providers. For 4 weeks, participants will engage with *Pregnant Faster*, during which opportunities will arise to earn *coins* such as reading informative blogs and registering for a PCC consultation. Coins can be spent on small fun rewards, such as folic acid, fruits, and mascara. *Pregnant Faster*'s feasibility will be tested in a study including 40 women aged 18 to 45 years, who are preconceptional or <8 weeks pregnant, with a low educational level, and living in a deprived neighborhood. The latter 2 factors will serve as a proxy of a low socioeconomic status. Recruitment will take place through flyers, social media, and health care practices. After finalization, participants will evaluate the app through the "mHealth App Usability Questionnaire" and additional interviews or questionnaires.

Results: Results are expected to be published by December 2023.

Conclusions: *Pregnant Faster* has been designed through iterative cocreation with the target group and health care professionals. With the designed study, we will test *Pregnant Faster*'s feasibility. If overall user satisfaction and PCC uptake is achieved, the app will be further developed and the cohort will be continued with an additional 400 inclusions to establish effectiveness.

Introduction

Background

Although decreasing, perinatal morbidity and mortality rates are still relatively high in the Netherlands, especially among women who live in deprived neighborhoods and have a low socioeconomic status (SES) [1-3]. These women, who represent up to 45% of the total population in the 4 largest cities in the Netherlands [4], are more likely to have adverse pregnancy outcomes based on the accumulation of health-deteriorating risk factors such as poor lifestyle behaviors (eg, smoking, alcohol consumption, and sedentary lifestyle), inadequate nutrition (consumption of unhealthy food or insufficient intake of healthy food), mental stressors, and impaired health literacy and agency [5-7]. These risk factors, some of which are modifiable, can detrimentally influence the pregnancy course and outcome in the periconceptional phase comprising the preconceptional period of gametogenesis and the first 3 months of embryogenesis and placentation [8]. Complications that occur later in pregnancy are also more common among these women, such as preeclampsia and low birthweight [9-11]. These outcomes result in increased perinatal morbidity and mortality that has its origin in the periconceptional period. Furthermore, there is an increasing body of evidence showing that these pregnancy complications increase the risk of noncommunicable diseases in mothers and their infants during their life course, such as obesity, cardiovascular disease, and diabetes [12,13]. Therefore, we categorized these women with a low SES as women with a vulnerable health status. In short, the vulnerable health status of women with a low SES leads to an increased risk of adverse pregnancy outcomes, which in turn leads to deterioration of the offspring's health, causing them to have a vulnerable health status as well, impacting the health and lives of generations (Figure 1).

Figure 1. Generational impact of the vulnerable health status in women with a low socioeconomic status.

Most clinical manifestations of adverse pregnancy outcomes, such as hypertension or fetal growth restriction, are terminal features of a cascade of events that originate in the periconceptional period (ie, the 14 weeks before conception up to the first 10 weeks of pregnancy) [14]. During this period, on which the focus is limited in research as well as in clinical practice, modifiable poor lifestyle behaviors are known to be common risk factors for subfertility and adverse pregnancy course and outcomes [15-17]. For example, ≥80% of women who are contemplating pregnancy have at least one modifiable behavior associated with adverse pregnancy outcomes, such as not taking folic acid supplements, low vegetable and fruit intake, and smoking [18,19].

Preconception care (PCC) focuses on improving women's health, including lifestyle behaviors, before pregnancy and plays an essential role in encouraging healthy lifestyle behaviors in preparation for pregnancy. Therefore, it reduces the risk of

XSL•FO
RenderX

adverse pregnancy outcomes and improves health outcomes in mothers and their children now and later in life [20,21]. PCC is usually delivered face-to-face, for example, at midwifery practices or hospitals. However, web-based PCC has been gaining popularity, which are delivered through video consultations or even combined as blended care [22].

The low uptake of PCC by the general population in the Netherlands is associated with women's perceived absence of risks and lack of awareness of PCC [23]. The delivery of PCC for women with a vulnerable health status faces even more obstacles, as these women are more difficult to reach and more difficult to motivate to engage in PCC [24]. These obstacles may lead to an ethically unjustifiable inequality in the health outcomes and life prospects of mothers and children from different socioeconomic backgrounds [24].

To encourage pregnancy preparation, our research group developed the web-based mobile health (mHealth) platform *Smarter Pregnancy* [19], an internet-based, tailored coaching platform that supports women who wish to become pregnant (and possibly their partners) to adopt healthy lifestyle behaviors (such as folic acid supplement use, adequate intake of vegetables and fruits, and cessation of smoking and alcohol consumption) before and during pregnancy. Previous research on the effectiveness of *Smarter Pregnancy* has shown that these healthy behaviors increase by at least 30% and that the chance of an ongoing pregnancy after fertility treatment increases by more than 50% [19,25,26]. Furthermore, *Smarter Pregnancy* has proven to be effective and highly valued by women from deprived neighborhoods [27]. This shows the potential of tailor-made mHealth for women with a vulnerable health status and underlines the importance of customizing an intervention that aims to overcome the obstacles associated with reaching and motivating women with a vulnerable health status to engage in PCC.

Changing behavior and lifestyle habits is challenging for all but even more so for women with a low SES, as they often endure stressful situations and deprived circumstances [28,29]. Therefore, it is advisable to offer this group more support in changing their behavior, which also follows the demands of social justice [30]. One way to support behavioral change is through *nudging*. Nudges are a class of interventions that change people's choice behavior by influencing their incentives, thereby stimulating beneficial, healthy behaviors that individuals themselves value [31]. This could be, for instance, offering fruit instead of chocolate bars at checkout counters to increase fruit consumption and lower refined sugar intake. Previous research has shown that nudging is a promising intervention to encourage the improvement of healthy eating behaviors [32]. Another example of nudging is loyalty programs, in which people can gather rewards by making healthy choices. Nudging via a smartphone app, especially designed for women with a vulnerable health status, may be very suitable to motivate them to engage in PCC due to the current wide availability of smartphones, as well as among women with a vulnerable health status.

Hypothesis

We hypothesized that nudging via the app *Pregnant Faster* is a feasible way to encourage pregnancy preparation and increase PCC uptake in women with an SES-related vulnerable health status. We expect that this will eventually lead to improved maternal health and pregnancy outcomes as well as improved health of the offspring in early and later life.

Aims

In this paper, we aimed to describe in detail the cocreation design process of the mHealth app *Pregnant Faster*, a loyalty program embedded in an app, based on the tailored mHealth lifestyle coaching platform *Smarter Pregnancy*. Furthermore, we aimed to develop a cohort study protocol to test the feasibility of *Pregnant Faster*, comprising overall user satisfaction; the number of booked and visited PCC consultations; and the course of practical conduction with regard to the inclusion process, reward allocation, and finalization. The general goal of *Pregnant Faster* is to encourage women with a vulnerable health status, in an ethically justified way, to adequately prepare for pregnancy by visiting a PCC consultation.

If the results of this study indicate that *Pregnant Faster* is appreciated by the participants and stimulates the uptake of PCC, we aim to continue this proposed study with an updated version of *Pregnant Faster* and an extended cohort, to establish the effectiveness of increasing the uptake of PCC in women with an SES-related vulnerable health status.

Our ultimate goal is to contribute to the reduction of inequalities in the health of women before and during pregnancy by (1) creating awareness regarding women's own influence on the course of their pregnancy and an increased uptake of PCC, (2) reducing perinatal morbidity and mortality, and (3) improving the long-term physical and mental health of mothers and their children.

Methods

The Cocreation Process

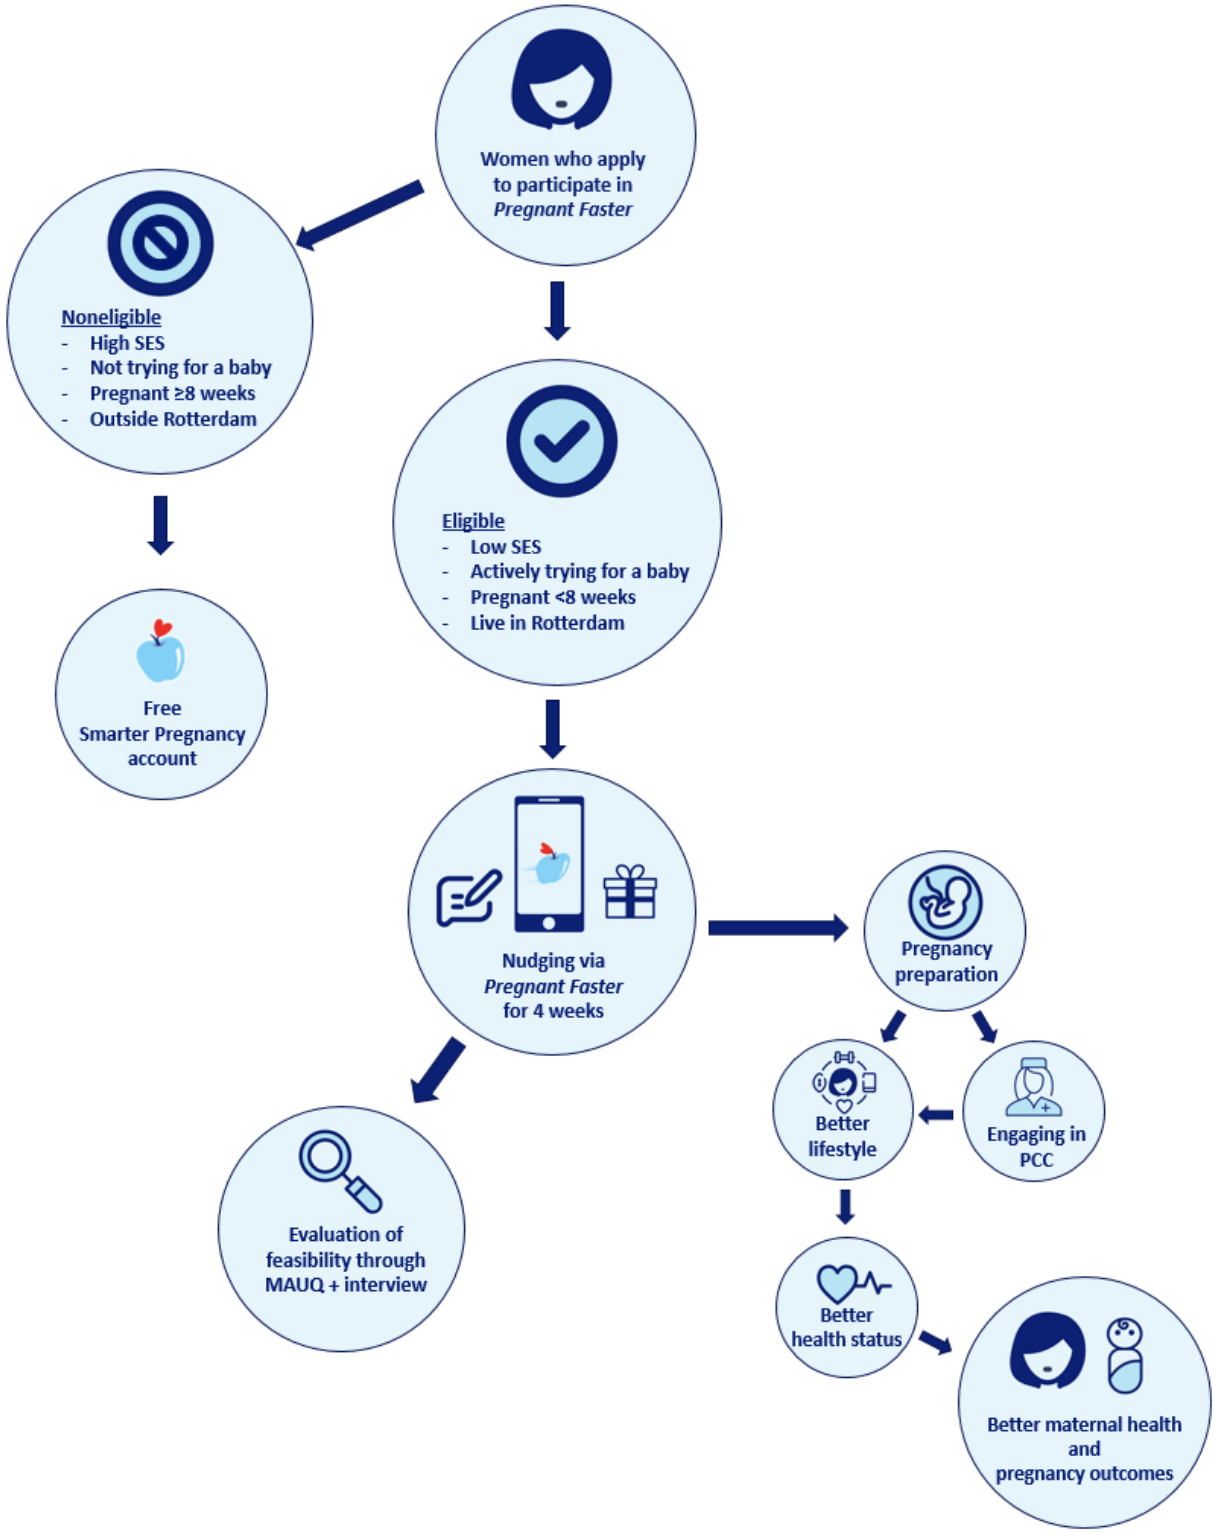
Preparation

The preparation of the design process of *Pregnant Faster* can be subsumed under 3 pillars. First, we have developed an ethical framework to assess the ethical justifiability of developing a loyalty program to stimulate PCC uptake among women with a vulnerable health status. An ethical framework can be viewed as a guideline that offers guidance on the moral permissibility of an intervention and provides suggestions on how to avoid ethical pitfalls, such as exposing susceptible participants to stigmatization based on their SES. This framework was developed by performing a literature search to identify records broadly relevant to the subject of using nudges to stimulate healthy lifestyle behaviors and extracting ethical dilemmas and pitfalls from these records. On the basis of these extracted dilemmas and pitfalls, criteria were set up to which an incentive-based intervention encouraging pregnancy preparation in susceptible women must comply to be morally justifiable. These criteria were subdivided under the 4 ethical principles of Beauchamp and Childress [33]: (1) respect for autonomy, (2)

XSL•FO
RenderX

beneficence, (3) nonmaleficence, and (4) justice. By addressing all 4 principles, an attempt was made to address as many ethical pitfalls as possible without overlooking any major aspects. This *principlist* approach is ideally suited for the topic of nudging women with an SES-related vulnerable health status because it allows for balancing between the duty to improve their and their children's health and well-being and the duty to respect them and treat them as free and equal persons.

Second, we conducted semistructured interviews with 15 women from the target group, which allowed us to gain insight into how they regard loyalty programs; which type of loyalty program they prefer; and which rewards are considered most legitimate, attractive, and effective [34]. The interviews were analyzed using a framework approach and thematic content analyses of five themes: (1) "usefulness of an app as an integral information source," (2) "permissibility and effects of offering rewards," (3) "preferences regarding content," (4) "preferences regarding the type of rewards and system of allocation," and (5) "barriers." Involving the target group in the design of the app, thereby respecting their autonomy and preferences, is an imperative criterion of the ethical framework.



Third, we based the lifestyle-related content of the app on the tailored mHealth lifestyle coaching platform *Smarter Pregnancy*. *Smarter Pregnancy* has previously proven to be effective in ameliorating preconceptional health and lifestyle behaviors and is based on over 30 years of research and the expertise of this research group regarding the influence of nutrition and lifestyle on reproduction and pregnancy course and outcome [25]. The main focus of *Smarter Pregnancy* lies in the amelioration of nutrition, including folic acid supplement use, and supporting healthy lifestyle behaviors such as reaching a healthy weight, smoking and alcohol cessation, and sufficient physical activity. The knowledge gained through these 3 pillars was combined into a first design of the app *Pregnant Faster*. The choice to develop this loyalty program as a nudge was based on the fact that women are known to wish for a healthy baby when they want to become pregnant [23,35]. Thus, the definition of nudging is that a nudge always aims to help the *nudgee* reach a goal they themselves wish for and value [31]. In addition, a nudge may not harm the nudgee. This description complies with the aforementioned biomedical ethical principles.

Iterative Cocreation

Subsequently, we conducted a strategic work session with professionals in this field (5 midwives, 2 gynecologists, and 2 general practitioners) in which we discussed our findings regarding moral permissibility, the wishes and preferences of the target group, and the first design of the app. The professionals asked to participate were known to practice in low-income areas, providing them with experience in caring for the target group of women with a vulnerable health status. The strategic work session was led by an external communication bureau specialized in transforming these types of sessions and the yielded insights into practical reports. These insights were then implemented in the app, leading to the design of a new and improved version of the app, adhering to the ethical framework. Through an iterative process (Figure 2), adjusted versions of the app were discussed by the communication bureau multiple times with 10 women in the target group who had previously participated in the interview study [34] and the aforementioned professionals, until all were satisfied with the design of the app and the app was considered morally permissible. The resulting app-based nudge *Pregnant Faster* can be viewed as an *umbrella* or a *macro-level* nudge, containing multiple *micro-level nudges*.

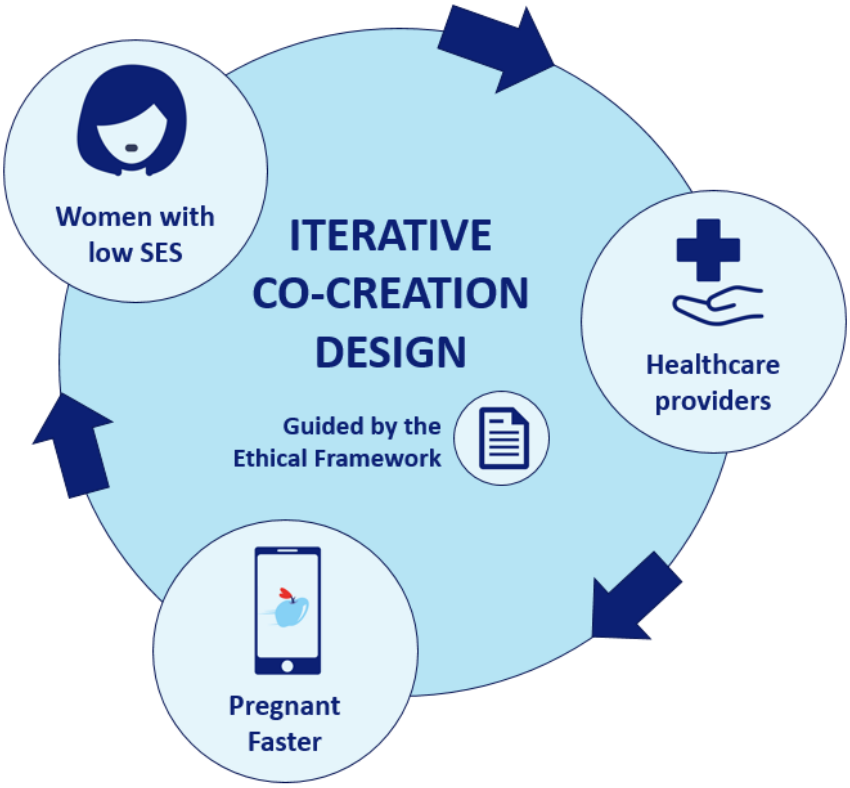
Figure 2. Overview of the intervention. MAUQ: mHealth App Usability Questionnaire; PCC: preconception care; SES: socioeconomic status.

Cohort Study Protocol

Overview

This study was set up as an open cohort to reflect the real-life situation, and it aims to assess the feasibility of the mHealth app–based nudge that stimulates PCC uptake in women with an SES-related vulnerable health status.



After inclusion (T0), the women start the intervention, consisting of using the app daily. The total duration of the intervention will be 4 weeks per participant, as we deemed a short period of active engagement more feasible than a longer period and did not expect additional engagement in pregnancy preparation or PCC consultations after 4 weeks of using the app.

After the intervention (T1), participants fill out the "mHealth App Usability Questionnaire" (MAUQ), assessing the app, as well as partake in an interview in which they may state their

XSL•FO
RenderX

opinions regarding the content of the app and how they rate their experience. At T1, we will assess the uptake of PCC as well (Figure 3). The results of this study will provide further insights to enhance the final design of the nudge and the app and can be viewed as another round in the iterative process, implementing the opinions and experiences of the target group into the final design. After this proposed cohort study, we aimed to update *Pregnant Faster* and plan to establish its effectiveness in a cohort of 400 women. Originally, the sample size of 400 was based on a power calculation for a randomized controlled trial with 2 groups using the app: one with and one without the allocation of rewards. However, the choice was made to convert the planned controlled trial to a cohort study due to the nature of this intervention and the possible disappointment women would feel if they would be randomized in a nonreward group, which could lead to disengagement and biased outcomes.

Figure 3. Iterative cocreation of Pregnant Faster. SES: socioeconomic status.

This research group has previously experienced difficulty in including women with a vulnerable health status in an interview study [34]. Although we believe that the nature of the intervention *Pregnant Faster* might encourage more women to participate, we consider these previously obtained experiences. Therefore, for this pilot study, we chose to aim for a sample size of 40 participants (10% of the larger planned cohort study), which we deemed sufficient to provide the first insights supporting further development of *Pregnant Faster*.

Participants

To be eligible, participants must meet all the following inclusion criteria: assigned female at birth, 18 to 45 years of age, living in the municipality of Rotterdam (the Netherlands), currently trying to conceive or planning to actively try within 3 months, or pregnant with a gestational age below 7+6 weeks, and having a vulnerable health status. In this study, having a vulnerable health status is defined as having a low SES based on the combination of a low to intermediate educational attainment (prevocational or vocational education) and living in a deprived neighborhood based on the zip code's median income [36].

A potential participant who meets any of the following exclusion criteria will be excluded from participation in this study: insufficient proficiency in Dutch, not in possession of a smartphone or tablet suitable for the app, living outside of the municipality of Rotterdam, refusal to fill out the questionnaires, or refusal to participate in the interview.

The choice to only include citizens of the municipality of Rotterdam is based on the plan to deliver the rewards per bike, car, or public transport.

Recruitment and Inclusion

Women from the target population will be recruited not only through midwifery practices, hospitals, and general practitioner practices but also directly through the distribution of flyers and posters and through social media, specifically Instagram and Facebook. Social media campaigns will be directly targeted at specific areas and populations, which fit our inclusion criteria. Recruitment will take place in collaboration with the Regional Consortium Pregnancy & Childbirth of the Southwest Netherlands, in particular with 5 midwifery practices located in or near deprived neighborhoods of Rotterdam. Women may enroll themselves in the study or they can be enrolled by a health care provider.

When women receive the flyer or are informed about the study by a health care provider, they may fill in their email on the

XSL•FO
RenderX

website *Getting Pregnant Faster* [37]. The researcher receives their email address and sends them a screening survey with questions regarding the inclusion criteria. This information will allow for the selection of women who fit the target group. If a potential participant is eligible, the researcher will contact her via telephone and email to provide further information about the study. If the woman is interested in participating, informed consent will be sent via email.

If women are eligible and have signed the informed consent form, they will be asked to download the app and start the intervention. If women are not eligible for participation, they will be provided with a free 26-week subscription to our mHealth coaching platform *Smarter Pregnancy*.

Randomization and Blinding

Owing to the nature of the intervention, all participants will receive the same intervention. Therefore, this section is not applicable. Blinding of the participants is not possible. Neither the participants nor the researchers will be blinded.

Intervention

The intervention consists of using the app *Pregnant Faster* (Dutch: *Sneller Zwanger*), which can be viewed as a macrolevel nudge containing a multitude of microlevel nudges. All nudges are aimed at encouraging participants to adequately prepare for pregnancy by making healthy nutrition and lifestyle choices and visiting a PCC consultation.

Outcome Measures

The main objective of this study design is to establish the feasibility of the app *Pregnant Faster* as a nudge that encourages pregnancy preparation by stimulating the uptake of PCC. Feasibility in this study pertains to overall user satisfaction, the number of booked and visited PCC consultations, and the course of practical conduction with regard to the inclusion process, reward allocation, and finalization. The outcome will be assessed in multiple ways: (1) through the number of women who registered for this study, which indicates the effectiveness of the methods used to reach women; (2) the number of women eligible to participate, which indicates the effectiveness of these methods in reaching the target group; (3) the number of participants who were included and the number who actually started the intervention, which may reveal possible barriers between inclusion and conduction; (4) the number of participants completing the intervention, which offers information on how engaging the app is; and (5) the frequency with which certain rewards are chosen that indicates which rewards are deemed the most desirable and motivating. Furthermore, the usability of the app will be assessed using the MAUQ, a validated 18-item questionnaire on user satisfaction, information arrangement, and usefulness based on a 7-point Likert scale (strongly disagree, disagree, somewhat disagree, neither agree nor disagree, somewhat agree, agree, and strongly agree) as presented in Multimedia Appendix 1 [38].

To further investigate how participants have experienced using the app, the first 10 participants will be interviewed in a semistructured manner to explore the answers they give on questions such as how often they opened the app and if this was according to how often they would have liked to open the app. A topic list and additional information on this interview is present in Multimedia Appendix 2. This topic list and participants' answers will be converted into a questionnaire offered to the remaining 30 participants. To include the first 10 participants in this questionnaire, the first author will fill in the questionnaire based on the participants' answers in the interview. The MAUQ and the interview or additional questionnaire will be offered 4 weeks after a participant has started the intervention (T1).

The number of PCC consultation requests and confirmed visits will be registered during the study period and in the aforementioned questionnaires, women will be asked why they registered (or did not register) for a PCC consultation and if they changed their lifestyle behaviors due to using the app. Descriptive statistics will be used for these outcomes, and the results will be reported in a narrative and tabular form.

Sample Size

The aim of this study is to test the feasibility of *Pregnant Faster* and explore the barriers that might be encountered. On the basis of our previous experiences with including the described target group, we are confident that 40 participants will be sufficient to reach our aim.

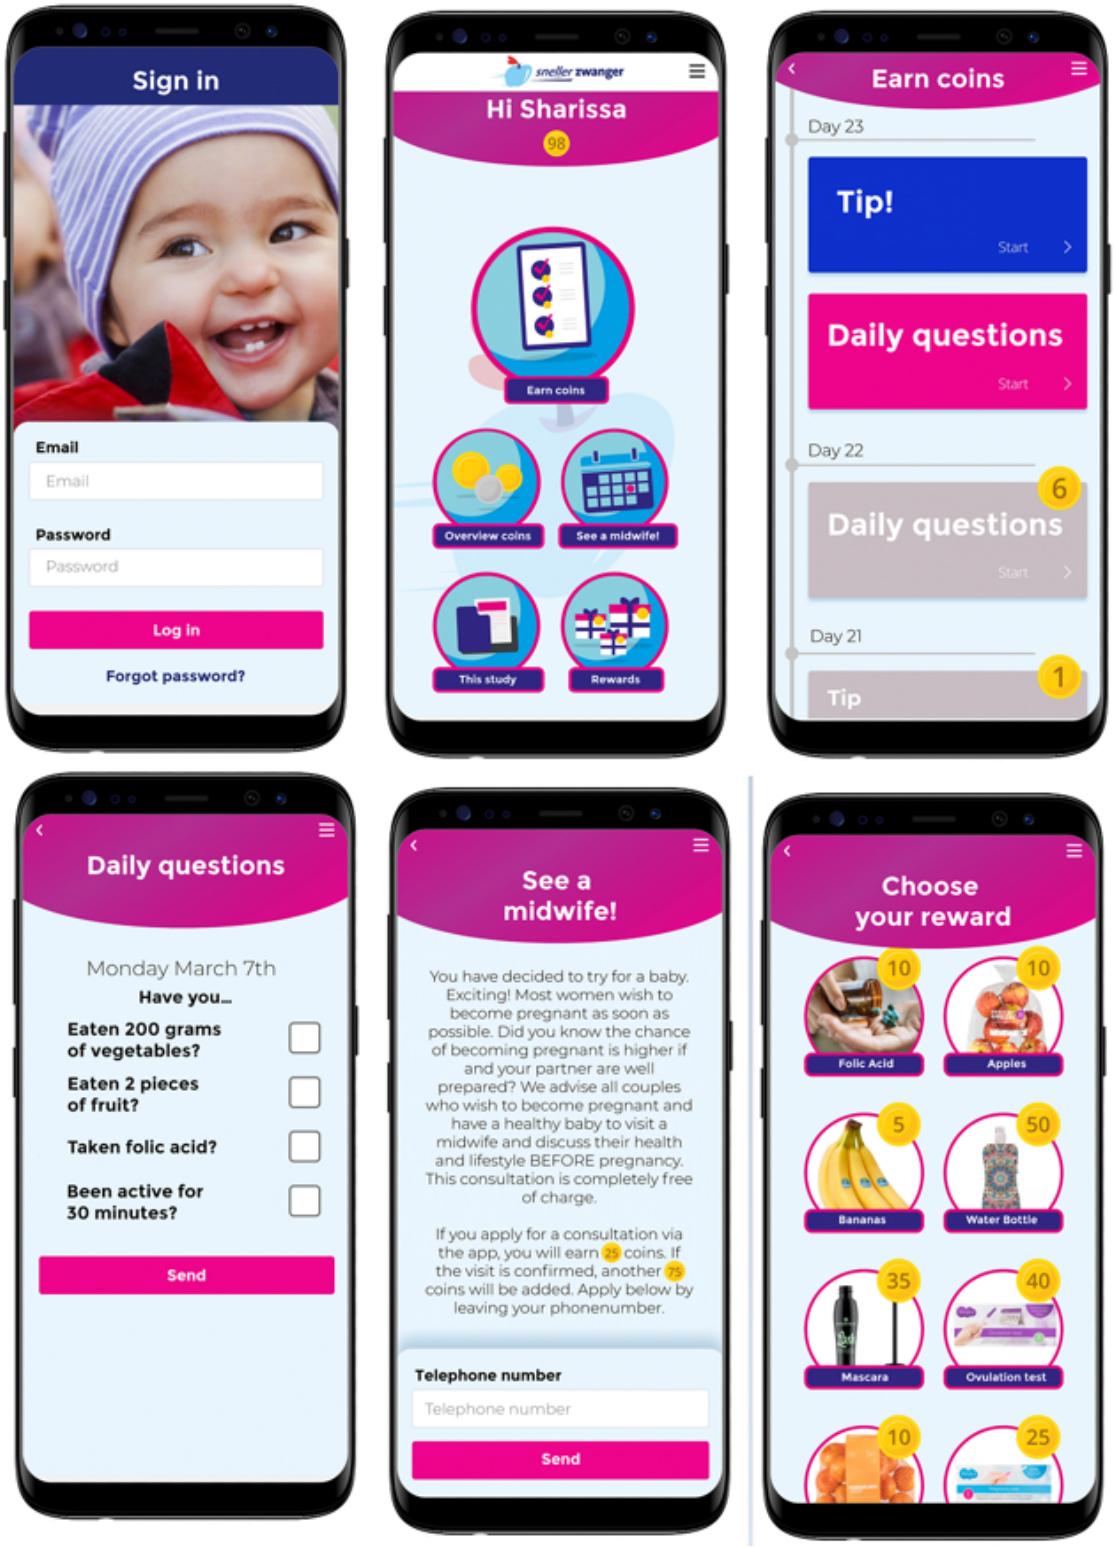
Ethics Approval

This study was assessed and approved by the Medical Ethical Committee of the Erasmus University Medical Center, Rotterdam, The Netherlands (MEC-2020-0974). Considering the low risk of this study, composing a Data Safety Monitoring Board was deemed unnecessary.

Results

The App Design

The name *Pregnant Faster* serves as a first microlevel nudge to join the study because most women who wish to have a baby often hope to become pregnant quickly. Using the app and its various components, all of which form microlevel nudges, will lead to earning so-called *coins*. Earning coins functions as a microlevel nudge because it stimulates participants to use the app.



Participants log-in with their email address and a password that yields 1 coin per day. The first log-in yields 50 coins to immediately stimulate the participants to engage with the app. After log-in, a dashboard appears, containing five buttons: (1) Earn coins, (2) Overview coins, (3) See a midwife! (4) This study, and (5) Rewards (Figure 4).

Button 1, "Earn coins," leads to a timeline in which new information appears daily in blogs or tips. Reading these yields 4 to 8 coins depending on the reading time and reading difficulty. Earning coins acts as a microlevel nudge to engage in reading relevant information about how to adequately prepare for pregnancy and ameliorate lifestyle and preconceptional health. Putting pregnancy preparation into the participant's focus stimulates active thought on this topic, which in turn may lead to increased motivation for pregnancy preparation and healthier choices. In the same timeline, a daily questionnaire

XSL•FO
RenderX

appears in which participants can tick off if they have eaten enough fruit and vegetables, exercised, and taken their folic acid supplements. Each ticked-off point yields 2 coins. This questionnaire also acts as a microlevel nudge because it serves as a reminder and motivator, which may lead to performing the behavior that can be ticked off.

Figure 4. Screenshots of the mobile health app Pregnant Faster.

Button 2, “Overview coins,” displays when and how coins have been earned and how many coins have been spent on which products. Having saved or spent a certain number of coins may nudge women to try and earn more coins, leading them back to the timeline in which they learn about properly preparing for pregnancy.

Button 3, “See a midwife!” contains information regarding what PCC entails and for whom it is meant. Here, we try to encourage participants to sign up for a consultation with a midwife in their

XSL•FO
RenderX

vicinity and offer an easy way to sign up for a consultation in their neighborhood by filling in their phone number, which yields 25 coins immediately and an additional 75 coins after the visit has been confirmed. Minimizing the effort required to register for a PCC consultation serves as a microlevel nudge by lowering the threshold to engage in PCC.

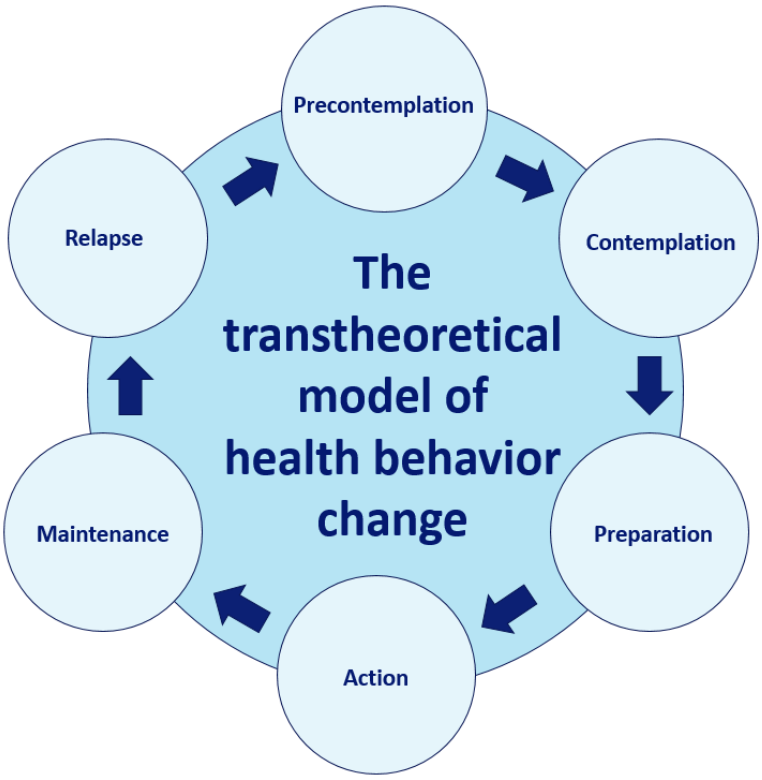
Button 4, "This study," contains information about the study itself, the researchers, and where to find additional information and contact details for questions, help, or complaints.

Button 5, "Rewards," contains a list of rewards accompanied by images that participants can spend their coins on. Participants can choose from a variety of rewards such as folic acid supplements, fruits, nail polish, mascara, ovulation or pregnancy tests, newborn clothing, water bottles, and other healthy or fun rewards that may contribute to preconceptional health.

In our earlier ethical research and interview study [34], it became apparent that adequately respecting participants' autonomy and preferences is imperative when it comes to increasing motivation for certain behaviors. Women wanted to have the option to either save up for a large reward or spend their coins on multiple smaller rewards. When participants choose their rewards freely, this will automatically lead them to choose the timing and type of reward that motivates them the most. In other words, being able to freely choose supports the app in stimulating women with different preferences regarding the timing and types of rewards to engage in pregnancy preparation and visit a PCC consultation. To satisfy this requirement, the app contains multiple types of rewards of varying value.

Another microlevel nudge lies in the varying value of the coins. One coin represents a monetary value of €0.06 to €0.26 (US $0.06 to US $0.26). By making healthy rewards, such as folic acid supplements and fruits, relatively cheap, we steer participants toward picking healthy products over luxury goods, while still allowing them to choose luxury goods if that is what stimulates them most to earn coins and engage in PCC. For instance, the mascara and folic acid supplements are of equal monetary value and cost €3.00 (US $3.00). However, the folic acid supplements can be ordered for 10 coins whereas ordering the mascara will cost the participant 35 coins.

Participants of our previously conducted interview study [34] mentioned that it might be painful for them if they could only choose pregnancy and baby-related products, in case of not getting pregnant quickly. To take this into account, we have included rewards in the app that are not relatable to pregnancy or babies, such as water bottles, a book voucher, and resistance bands for physical exercise.



The design of *Pregnant Faster* makes the app suitable for all women because it automatically matches participants' personal preferences and their current level of motivation to prepare for pregnancy and engage in PCC. This is done by allowing participants to freely choose the type and timing of their rewards and by matching their current "Stage of Change," as described by Prochaska and DiClemente [39].

The transtheoretical model of behavior change by Prochaska and DiClemente [39] describes the different and subsequent stages of changing a certain behavior: precontemplation, contemplation, preparation, action, maintenance, and relapse (Figure 5). Each stage requires a different type of approach [40]. For instance, if a woman has an unhealthy diet and is currently in the precontemplation stage, is not aware of a problem, and is not willing to change, helping her set up a detailed healthy eating plan may lead to her feeling overwhelmed or rejecting the idea that a healthy diet is important, which results in resistance and noncompliance. The first step for this specific woman would be to help her discover why a healthy diet is important to her and which benefits it could possibly yield for her. This will help her acknowledge that her current diet may be problematic and requires a change: the contemplation stage. However, if the woman has been contemplating improving her diet for a while, helping her set up a practical plan may be the exact nudge she needs to help her reach the next stages of change: preparation and action. The choice to use this model was based on the fact that it is widely used and taught in medical education and health care professions, as it provides solid instructions on how best to approach the patient or client to encourage and support them in changing unhealthy behaviors, in addition to the available evidence regarding its effectiveness [41,42] and the amount of experience of the authors in the application of this model.

It is clear that the most effective approach differs by stage and that the current stage of change is very personal. However, we chose not to assess the participants' current stage of change to minimize what participants could deem *fruitless engagement*—spending time in the app without being rewarded for it, which could diminish interest in the app. Therefore, *Pregnant Faster* was designed to passively match all possible stages, as described by Prochaska and DiClemente [39]. If a participant is currently not preparing for pregnancy and is not interested in doing so (precontemplation), it is still attractive to read the information *Pregnant Faster* offers because of the coins she can earn and spend on rewards to her liking. The blogs and tips in *Pregnant Faster* focus on conveying that healthy choices and PCC may help to have a healthy baby sooner, a goal that many women strive for. This may cause a participant to start contemplating if she too could get pregnant faster by actively preparing for pregnancy and visiting a midwife for PCC. She might even start to plan how she could take action (preparation). If a participant is already preparing for pregnancy by, for instance, eating more vegetables (action or maintenance), reading about the benefits of this behavior in the timeline of the app will act as a stimulant to maintain this behavior or maybe even make a plan to also eat 2 pieces of fruit per day (preparation). For women who already have a healthy diet and lifestyle, and are currently in the maintenance stage, the app will serve as a stimulant to sustain healthy behavior and may help to prevent a relapse (maintenance). In conclusion, the app appeals to women in each stage of change by either encouraging new healthy behavior or the continuation of preexisting healthy behavior.

XSL•FO
RenderX

Figure 5. The transtheoretical model of health behavior change by Prochaska and DiClemente [36]. (1) Precontemplation: unaware of the need for change and unwilling to change. (2) Contemplation: aware of the problem but not yet committed to change. (3) Preparation: believes change is good, intent on taking action, and planning to start. (4) Action: actively changing behavior or creating new habits. (5) Maintenance: behavior has changed, committed, and resolved; must be aware of the possibility of relapse. (6) Relapse: relapsing into old behavior; may skip precontemplation in the next cycle.

Participants in any stage of change may choose to register for a PCC consultation as the reward is high and the required action (filling in their phone number) is relatively small. This was decided consciously to meet the main objective of *Pregnant Faster*, stimulating pregnancy preparation by visiting a PCC consultation provided by a health care provider. These face-to-face consultations allow health care providers to directly apply motivational conversation techniques [43] and actively match the participant's current stage of change on the topics that are most relevant for them, for instance, smoking cessation, an unhealthy diet, or a sedentary lifestyle. Having an engaging, live conversation in which the participant can ask questions and feels heard and supported may be the greatest encouragement or nudge to engage in adequate pregnancy preparation and make healthy choices. Furthermore, a live consultation allows for relevant referrals (eg, for smoking cessation) without relying on the participant to take the first step.

This intervention is completed after 4 weeks. If women still have coins left by the end of the intervention, they will be able to exchange these for rewards within 2 weeks after the completion date or 2 weeks after their PCC consultation. The app and timeline will continue to be available for participants, so they can access its information and register for a PCC consultation whenever they please, but they will no longer be able to earn or spend coins by using the app.

The iterative developmental process has led to the detailed design of the app *Pregnant Faster*, which we have built in cooperation with the event agency Improve in Delft, the Netherlands, and the mobile app manufacturer TJIP The Platform Engineer. *Pregnant Faster* is an app of 5.2 MB and is currently only available in the research setting for Android by a download link and for iPhone through the Apple store. The app has a modern, colorful interface (Figure 4) inspired by the preferences of the target group. Overall, the app was designed to fit the user's needs and preferences concerning the content of the app as well as easy and intuitive operating.

Cohort Study

Results are expected to be published by December 2023.

Discussion

Principal Findings

In this paper, we have described the iterative cocreation design process of the app *Pregnant Faster*, an mHealth app–based nudge specifically designed for women with a vulnerable health status based on their SES who have a higher risk of adverse pregnancy outcomes. In addition, we have described the protocol of the cohort study aimed at establishing the feasibility of using *Pregnant Faster* to encourage these women, in an ethically justified way, to adequately prepare for pregnancy by engaging in PCC and making healthy nutrition and lifestyle choices.

In this proposed study, women will be nudged through an app that rewards them to encourage them to make healthy choices. The nature of an incentive-based intervention, or nudge, is such that its aim is to *influence* the participant's behavior. There is a fine line to tread between nudging and manipulation, which

XSL•FO
RenderX

we consider in this protocol. Nudging entails that alternative choices are never taken away or obstructed, and choosing differently does not require significant extra effort or create a great sense of loss, as this would count as coercion. This study does not force women to prepare for pregnancy or engage in PCC. Using the app or registering for a consultation is optional, and the offered rewards are of such value that they will not coerce participants into actions they do not value or wish to perform.

Furthermore, the aim of the nudge must be beneficial to the target group and must align with their own preferences and aims. In this case, the intervention aimed to adequately prepare women with a vulnerable health status for pregnancy to reduce the chance of adverse pregnancy outcomes. This aligns with the preferences and aims of the participants as they want to give birth to a healthy baby. For manipulation to be prevented, transparency concerning the aim of this study is crucial. Therefore, proper explanation, obtaining informed consent, and ensuring that the participant consents to being influenced is of utmost importance.

van der Windt et al [22] established that blended care is an effective method to improve lifestyle and nutrition choices. In this study, we will use an mHealth app to offer an intervention that aims to encourage women to learn about healthy pregnancy preparation via an app and visit a face-to-face PCC consultation. In other words, it aims to provide blended care while still offering important information to women who are not yet ready to engage in a face-to-face consultation.

The use of smartphones is widespread, even among women with a low SES [44]. This means that *Pregnant Faster* as an app-based nudge will be widely available and easily accessible for the target group, allowing them to use the app privately and at a time that suits them best, which reduces the burden of participating in the study. The attractive interface and overall positive outlook applied in the app are aimed at further reducing any negative feelings that may result from learning about necessary lifestyle behavioral changes, resulting in an app that is fun to have and use. A foreseen possible limitation of the app design lies in the fact that it cannot yet be altered to best suit the participant's personal situation regarding her gestational age or how long she has been trying to become pregnant. However, even though *Pregnant Faster* does not specifically target women with difficulty conceiving, it does address the experiences associated with subfertility, which means that this group may also benefit from using the app. For example, the offered information aligns with the nutrition and lifestyle advice given to couples in the fertility outpatient clinic of the University Medical Center where this study has taken place. Furthermore, attention is paid to which factors influence the chance to become pregnant and have an ongoing pregnancy, specifying which factors are within and outside one's own control. By providing clarity on what can and cannot be influenced, including the size of the expected effects, we aim to encourage healthy lifestyle behavior without possibly burdening participants with the idea that they themselves would be responsible for (possible) subfertility or miscarriage cessation. Furthermore, within the blogs and tips, advice is given on when and how to find support when trying for a baby takes longer than expected, considering women's age and medical history in line with Dutch General Practitioner guidelines on referral for fertility treatments. In addition, the stress that may accompany trying to get pregnant is acknowledged and tips are provided to cope with these experiences.

With regard to the study design, the outcomes comprising *Pregnant Faster's* feasibility allow for practical evaluation, which will form solid stepping stones to further develop the app. The design of the app is such that we aim to continue its development throughout the coming years and possibly explore its use in different target groups, with and without rewards. A possible limitation in the study design pertains to the interviews with the first 10 participants that have been used to develop the additional questionnaire on user experiences. To evaluate the group of 40 women as one, these interviews will be used to fill out the developed questionnaire. It might be more prudent to qualitatively analyze these interviews and view these 10 participants as a separate group. However, as this feasibility study mainly aims to provide holdfasts for further development of *Pregnant Faster*, we believe that this method will suffice.

A potential risk of using *Pregnant Faster* may be that providing rewards can "crowd out" intrinsic motivation to make healthy choices [45,46]. In other words, the healthy behavior that women value and display before the start of the intervention, diminishes or vanishes after the intervention ends, and rewards are no longer provided. For example, if women went to the gym before the intervention, they could maintain this habit and receive rewards for it. This influences the way they view and value this behavior by shifting their focus from health-related rewards, such as strength and fitness, to material rewards. When the intervention ends and going to the gym no longer leads to material rewards, these women might be less inclined to exercise than they were before they participated in the intervention. This is caused by increasing extrinsic motivation for a behavior at the expense of intrinsic motivation.

If a nudge only appeals to extrinsic motivation, the healthy behavior "dies out" as soon as the intervention ends [46]. However, scaffolding intrinsic motivation leads to a more sustainable change because it focuses on health-related rewards. Overall, women who want to become pregnant wish to have a healthy baby. Educating them about the control they may exercise on their pregnancy outcomes by taking up PCC and making healthy nutrition and lifestyle choices fits their wish to have a healthy baby and may increase their intrinsic motivation to make healthy choices. This cancels out the *crowding out* effect and allows for continuation of healthy behavior because the focus is not placed on limited material rewards but on continued health-related rewards, making the behavioral changes more sustainable.

Another potential risk lies in how the app makes women feel. It is known that mHealth apps may evoke feelings of guilt, shame, and stress and even discouragement when participants fail to meet the app's goals [47]. It is paramount that the tips and blogs in *Pregnant Faster* convey that small steps are worth celebrating and that women are not obliged to strive for a perfect lifestyle to have a healthy baby. Furthermore, the app must also contain information on the fact that a healthy lifestyle increases

XSL•FO
RenderX

the chance of a healthy baby but offers no guarantees. It must be stated that not all adverse outcomes can be prevented and that an adverse pregnancy outcome does not mean that the woman (or her partner) is to blame.

When this pilot study has been conducted, we expect to have obtained valuable information on how to further adjust *Pregnant Faster* to best fit the needs of women with a vulnerable health status and encourage PCC uptake in this group. In other words, this proposed study can be viewed as yet another phase of the iterative process, and the outcomes will be used to update and alter the app to further develop the design of *Pregnant Faster*. Furthermore, practical information on, for example, the number of registrations of eligible and noneligible women will provide guidance on our methods to reach the target group and evaluation of the rewards, and the frequency of allocation will provide more insight into which rewards are deemed most desirable. Finally, any barriers encountered during this pilot study will be assessed to avoid such barriers in the future.

Conclusions

We have developed an mHealth app (*Pregnant Faster*)–based nudge that aims to encourage women with a vulnerable health status to engage in pregnancy preparation by taking up PCC, to improve the high incidence of adverse pregnancy outcomes in this group.

The risks and burdens of participating in this study will be minimal, whereas the benefits for both the mother and (unborn) child are potentially substantial. Furthermore, we designed a study protocol to establish the feasibility of *Pregnant Faster*. If the results of this study indicate that using *Pregnant Faster* to increase the uptake of PCC in women with a vulnerable health status is feasible, we will implement the obtained insights and further develop the app. For example, if a specific barrier in joining the study or registering for a PCC consultation is encountered, we will attempt to overcome these barriers to improve inclusion rates and increase PCC consultation requests and continue this study with an updated version of the app and an additional 400 inclusions, thus attempting to establish the (cost) effectiveness of *Pregnant Faster* with regard to increasing the uptake of PCC.

Finally, we aim to investigate the possibility of offering *Pregnant Faster* without rewards to all women who wish to become pregnant, regardless of their health status. Earning material rewards forms just one of the multiple microlevel nudges in this macrolevel nudge and is meant to attract women with little knowledge of, or headspace or motivation for, pregnancy preparation. However, many women look for information on how to become pregnant quickly and healthily. For these women, the knowledge and motivation provided by *Pregnant Faster* may also be valuable and help them adequately prepare for pregnancy.

Acknowledgments

This research was funded by ZonMw (*Zorg Onderzoek Nederland en het gebied van Medische wetenschappen* [Healthcare Research in the Netherlands and the field of Medical Sciences], grant 543003103). Furthermore, the authors thank the women from the target group and health care providers who participated in the cocreation for their continuous and valuable input and Improve and TJIP for their expert knowledge and support throughout the development process of *Pregnant Faster*. The TOC image was provided by Klaus Nielsen via Pexels.

Data Availability

As this paper concerns a design process and proposed study, no pilot study data are available to share as yet. However, the design process of *Pregnant Faster* and the proposed pilot study are based on earlier research conducted by this group. Articles about *Smarter Pregnancy* and its development and testing have been published previously [19,26], as has the interview study on the preferences of susceptible women regarding a loyalty program [34]. Due to the ethical framework currently being submitted, we are unable to provide its data, as that would be in conflict with the conditions of submission. Further inquiry with regard to the ethical framework and reports of the strategic work session (which are written in Dutch) can be provided by the authors at reasonable request.

Authors' Contributions

RPMS-T conceived the study and provided funding. RPMS-T, SMS, and BB initiated the study design. SMS wrote the original draft and BB and RPMS-T reviewed and edited the original draft. BB, RPMS-T, HIM, and MHNS supervised this study. All authors contributed to the refinement of the study protocol and approved the final manuscript.

Conflicts of Interest

RPMS-T is an initiator and developer of the mobile health app Smarter Pregnancy. The funder had no role in the design of the study, writing of the manuscript, or decision to publish the protocol.

Abstract

Background: Following total knee arthroplasty (TKA), 10% to 20% of patients report dissatisfaction with procedural outcomes. There is growing recognition that postsurgical satisfaction is shaped not only by the quality of surgery but also by psychological and social factors. Surprisingly, information on the psychological and social determinants of surgical outcomes is rarely collected before surgery. A comprehensive collection of biopsychosocial information could assist clinicians in making recommendations in relation to rehabilitation, particularly if there is robust evidence to support the ability of presurgical constructs to predict postsurgical outcomes. Clinical decision support tools can help identify factors influencing patient outcomes and support the provision of interventions or services that can be tailored to meet individuals' needs. However, despite their potential clinical benefit, the application of such tools remains limited.

Objective: This study aims to develop a clinical decision tool that will assist with patient stratification and more precisely targeted clinical decision-making regarding prehabilitation and rehabilitation for TKA, based on the identified individual biopsychosocial needs.

Methods: In this prospective observational study, all participants provided written or electronic consent before study commencement. Patient-completed questionnaires captured information related to a broad range of biopsychosocial parameters during the month preceding TKA. These included demographic factors (sex, age, and rurality), psychological factors (mood status, pain catastrophizing, resilience, and committed action), quality of life, social support, lifestyle factors, and knee symptoms. Physical measures assessing mobility, balance, and functional lower body strength were performed via video calls with patients in their home. Information related to preexisting health issues and concomitant medications was derived from hospital medical records. Patient recovery outcomes were assessed 3 months after the surgical procedure and included quality of life, patient-reported

XSL•FO
RenderX

knee symptoms, satisfaction with the surgical procedure, and mood status. Machine learning data analysis techniques will be applied to determine which presurgery parameters have the strongest power for predicting patient recovery following total knee replacement. On the basis of these analyses, a predictive model will be developed. Predictive models will undergo internal validation, and Bayesian analysis will be applied to provide additional metrics regarding prediction accuracy.

Results: Patient recruitment and data collection commenced in November 2019 and was completed in June 2022. A total of 1050 patients who underwent TKA were enrolled in this study.

Conclusions: Our findings will facilitate the development of the first comprehensive biopsychosocial prediction tool, which has the potential to objectively predict a patient's individual recovery outcomes following TKA once selected by an orthopedic surgeon to undergo TKA. If successful, the tool could also inform the evolution rehabilitation services, such that factors in addition to physical performance can be addressed and have the potential to further enhance patient recovery and satisfaction.

Introduction

Background

Total knee arthroplasty (TKA) is a well-established and effective treatment for end-stage osteoarthritis [1]. The number of TKA procedures performed is increasing annually, both locally and globally. In both Australia [2] and the United States [3], it is projected that the number of TKAs undertaken will rise by 276% and 181%, respectively, by 2030, placing an increased burden on health care services. Surgical success rates are high and are currently based on a range of objective medical outcomes including survival, prosthesis performance, and revision rates [4]. However, despite this, there are consistent reports that up to 20% of patients report dissatisfaction with the outcomes of the procedure, reflected by enduring pain, limited function, and diminished quality of life [5-7].

Rehabilitation is an important factor that improves recovery from this surgery. However, no clinical guidelines are currently available to inform the recovery pathways. This is because there is no evidence to suggest who may benefit from rehabilitation, when and where this service should be delivered, and what services should be provided. Consequently, some patients receive inpatient (7-10 days) rehabilitation or at home rehabilitation through exercise monitoring (up to 10 weeks), whereas others are not referred to any form of rehabilitation, depending on the surgeon and the clinic. This inconsistent approach to rehabilitation may be because of the general lack of data demonstrating the effectiveness of any specific pathway. For example, a recent study demonstrated no difference in patient mobility at 26 weeks after the surgery when comparing inpatient rehabilitation with home-based monitoring [8]. Furthermore, a systematic review concluded that the setting did not significantly influence the outcomes [9].

During rehabilitation programs, the primary emphasis is on assisting patients in regaining muscle strength, enhancing joint stability, improving range of motion, restoring neuromuscular function, and recovering proprioception [10]. The approaches taken and outcomes vary widely among therapists, and to date, no clear guidelines exist for the most effective therapeutic strategies to be applied [9]. In addition, several psychological factors have also been reported to be linked to recovery following knee replacement or have the potential to impact recovery [11,12]. This includes psychological "vulnerability factors," such as depression, anxiety [13-15], and pain catastrophizing [16,17], and "protective factors," including resilience and committed action. However, despite their potential impact on recovery, quality of life, and satisfaction [12], these factors are not routinely reviewed in patients before surgery and remain overlooked in rehabilitation referral and ongoing clinical decision-making.

Determining whether rehabilitation programs are effective is also complicated by the use of inconsistent measures of "success." Many studies to date have used a single traditional outcome measure, such as a physician's or patient's report of functional mobility, pain, or quality of life [18]. Although surgical success has been characterized by a number of objective medical outcomes, including survival, prosthesis performance, and revision rates [4], there has been increasing interest in considering and combining longer-term outcomes of success, such as patient satisfaction and social integration, with these other traditional measures. Over the last decade, the integration of patient-reported outcome measures (PROMs) in the evaluation of the success of TKA has become more widespread [19]. However, the impact of PROMs on clinical practices remains limited. Although there are clear benefits of assessing the patient's perspective of recovery, including their symptoms, functional status, and quality of life [20,21], there remains a lack of consensus regarding the appropriate measures to be used, together with concerns of the cost-effectiveness involved in their application [22].

Regardless of the adopted outcome definition, no consistent set of factors that predict a successful surgery outcome have been identified. Individual studies have identified some factors associated with long-term outcomes. These include BMI, radiological arthritis severity (Kellgren-Lawrence score), mood status (eg, anxiety and depression), quality of life, and functional

XSL•FO
RenderX

mobility [18,23,24]. Nevertheless, it is important to note that the collective predictive value of these metrics has not been externally validated, nor has their generalizability been demonstrated across various settings and populations [25].

Mounting evidence suggests that it may be possible to predict, via the use of a model, which patients could benefit from a more multifaceted approach to rehabilitation, which could encompass a broad range of biopsychosocial parameters, and how this can be precisely tailored to address each patient's individual needs [26]. Importantly, if such a prediction model can be developed and validated, it would be extremely useful to guide the future provision of rehabilitation services to support superior outcomes for each patient. In a recent systematic review, we demonstrated that the number of clinically meaningful, well-validated prediction tools for recovery following total knee replacement is limited [26]. Several clinical and lifestyle factors have been linked to poor outcomes and dissatisfaction following a variety of surgical procedures, including TKA, such as female sex, obesity [27,28], lower social support level [29], and comorbidity status [15]. Indeed, predictive models have demonstrated that age and sex can predict improvement in knee function [30] and satisfaction [31]. However, few studies have reported the inclusion of psychological parameters in their model development. Moreover, many of the models developed have limited predictive success and lack external validation, which limits their implementation in routine clinical use. There are also constraints when predictive models repurpose existing data sets owing to the limitations of data quality and completeness [32].

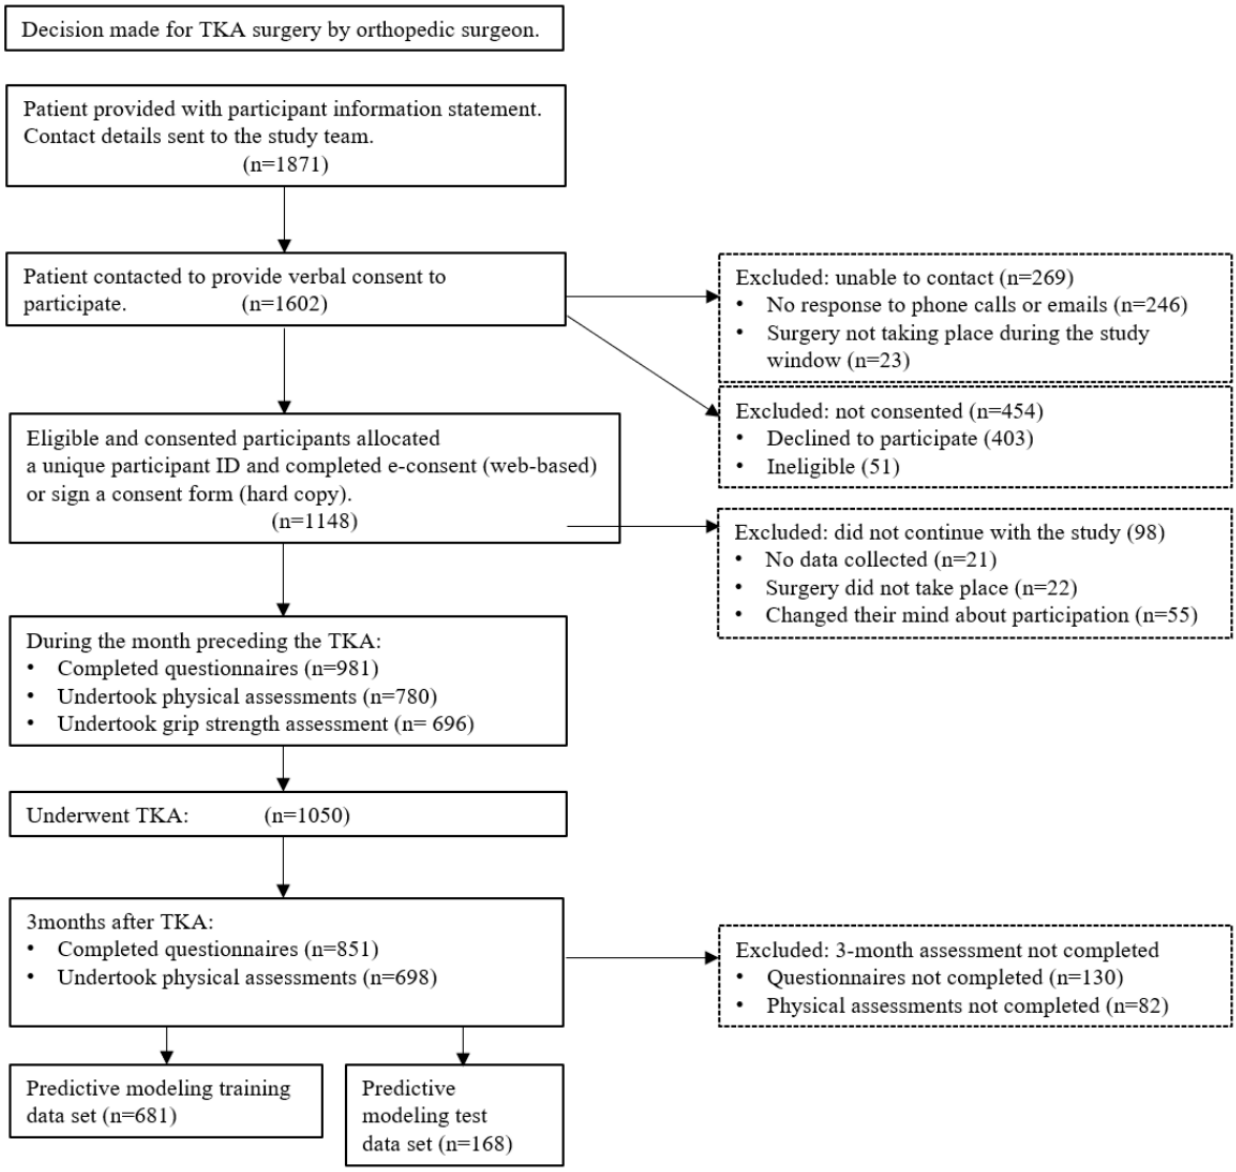
To date, there is an unmet need for the development of a clinical tool based on a comprehensive range of parameters that can assist in determining individual recovery trajectories following TKA, which can be easily adopted in the clinical setting. Through the identification of factors influencing patient recovery trajectories across a range of success outcomes, rehabilitation pathways will be better informed regarding the tailoring of services to meet patients' individual needs. This has the potential to improve long-term outcomes and satisfaction by addressing a broader range of pre- and postoperative parameters.

Aims and Objectives

The major aim of this study is to develop a clinical tool that can be used in the prediction of recovery trajectories, which can inform rehabilitative services regarding the nature of potential interventions and the timely delivery of the right services to each individual patient. Our approach will be to look beyond the impact of biomedical features alone on patient outcomes by adopting a biopsychosocial approach. The biopsychosocial model of health systematically considers biological, psychological, and socioenvironmental factors and their complex interactions in understanding illness, health, and health care delivery. It encompasses a more holistic approach to understanding illness and wellness than a purely biological vision. The tool will be constructed by assessing the predictive capacity of a comprehensive battery of biopsychosocial factors on a number of patient outcomes following TKA, including improvements in knee symptomology, quality of life, and satisfaction. This approach has the potential to facilitate the allocation of rehabilitation resources toward a more holistic approach to recovery following surgery and could improve the effectiveness of TKA across a range of success outcomes, including patient satisfaction. By supporting the delivery of rehabilitative interventions that are precisely targeted to patient needs, this clinical decision-making tool could also improve the efficiency of health care resource delivery.

Methods

Study Setting



This study was undertaken with patients who underwent TKA surgery between November 2019 and June 2022 across 4 participating Ramsay Health Care facilities in New South Wales (NSW), Australia, including Lake Macquarie Private Hospital, Gateshead; Kareena Hospital, Caringbah; Baringa Hospital, Coffs Harbour; and Wollongong Private Hospital, Wollongong. Surgical procedures were performed by 11 collaborating orthopedic surgeons.

Study Design

This study had a prospective observational design. Participants were involved in the study for a duration of 4 months, with data collection taking place at 2 time points during this period: within the month preceding their scheduled TKA and 3 months (12 weeks) following the TKA procedure. Figure 1 outlines the participants' timeline for this study and the number of participants recruited and excluded at each stage.

XSL•FO
RenderX

Figure 1. Participant timeline. TKA: total knee arthroplasty.

Study Population and Eligibility

All patients identified by the participating orthopedic surgeons as requiring a total knee replacement and who fulfilled the eligibility criteria were invited to participate in the study. Patients were included as eligible if they were aged ≥18 years, could complete the PROMs questionnaires, and confirmed to require a primary total knee replacement (bilateral or unilateral procedure). Patients were excluded from participating if they were receiving a primary total knee replacement owing to trauma, had undergone previous knee surgery within the past 6 months, were planning to undergo additional knee surgery within the next 12 months, or did not have the capacity to provide informed consent to the research.

Sample Size

For machine learning modeling, the standard required sample size used should ensure at least 10 events for each included predictor parameter [33]. In this study, we have a total of 39 input variables and 76 input events when applying the conversion of categorical variables to numerical data (one-hot-encoding). Applying the standard approach, we would require 390 participants for models without one-hot encoding and 760 participants when using one-hot encoding.

Recently, Riley et al [34] have developed a more refined calculation of the required sample size, which depends not only on the number of candidate predictor parameters but also on the total number of participants, the outcome proportion (incidence) in the study population, and the expected predictive performance of the model. Applying the method proposed by Riley et al [34] to our classification modeling with an aim of 90% accuracy and an outcome proportion of 20% (ie, 20% of participants were not expected to meet the minimal clinically important difference [MCID] improvement threshold), a predicted R^2 of 0.5, and shrinkage of 0.85, returns a required sample size of 864.

In this study, we aimed to recruit at least 1000 patients undergoing total knee replacement. This will ensure sufficient data for inclusion in our machine learning predictive modeling

XSL•FO
RenderX

analyses and allow for 13.6% (136/1000) of data to be nonevaluable owing to missing data fields.

Recruitment and Enrollment Procedures

Eligible participants were contacted by the study team through a follow-up phone call made after they received the study Patient Information Sheet from their surgeon. Eligible participants who chose not to participate when they received the Patient Information Sheet from their surgeon were not contacted. If the participant verbally agreed to participate in the study, they were provided access to study materials either on the web or by post, and if they consented to undertaking physical assessments of mobility via a video call, a time for this appointment was made at a time convenient to the participant.

If patients opted to have their study questionnaires accessed via the study-specific web-based platform, they were provided with a copy of the Patient Information Sheet when they accessed this system via a participant-specific log-in. Following a review of the Patient Information Sheet, they were asked to acknowledge their consent to participate in the study and provide electronic consent on the Electronic Letter of Consent Form. Questionnaire templates were not accessible to the participants until the consent field on this form had been completed. Participants also had the option to consent to all study assessments being undertaken or to only complete the study questionnaires.

If patients opted to have their study questionnaires posted to them, a copy of the Patient Information Sheet and Letter of Consent were included in the posted package. The participants were asked to sign the consent form before completing the questionnaires. The completed consent form and questionnaires were subsequently posted back to the study team.

Participation in this study was voluntary. Patients had the option to decline participation at any time point during the study and were informed that this would not impact their ongoing medical care. If patients decided to withdraw from the study, they could specify whether their data were to be removed from the study or if they were willing for it to be used as part of the analysis.

Data Collection Tools and Procedures

Web-Based Data Collection Platform and Centralized Data Repository

Data were entered and stored on the secure electronic platform Vision Tree Optimal Care (VTOC) developed by VisionTree Software, Inc. This platform enables the direct entry of data by participants when completing study documents and serves as a centralized data repository. The addition of an e-consent form, as the first item viewed and completed by participants when accessing the study-specific platform, enabled consent to be obtained before the collection of study data. Participants accessed the site via a unique encrypted link sent to their email. Using the encrypted link, the participants also validated their identity by entering their initials on the platform.

The electronic site is 256-bit Secure Sockets Layer (SSL) encrypted to protect the privacy of the participants. The VTOC meets all Health Insurance Portability and Accountability act of 1996 security and compliance standards, which include physical, technical, and procedural safeguards to help protect personal information. Using Thawte as a third-party encryption service, all reminders or messaging are 256-bit SSL encrypted.

The participant log-in links are encrypted using Advanced Encryption Standard-256 encryption. The participant internal identification number, only known to the VTOC application, is included in the encrypted payload, thus ensuring that it is unique to the participant. Advanced Encryption Standard is a symmetrical-key algorithm, meaning the same key is used for both encrypting and decrypting the data.

The platform can be viewed by any modern browser, whether a tablet, mobile, or computer-based system. No data were housed on the device at any point; therefore, if a device gets lost, there was no exposure of any of the data within the platform or data being collected.

VisionTree's security technologies include an F5 Load Balancer and Cisco Firewall. Software technologies include 256-bit SSL, third-party verification, command line and basic virus scanning, audit logs, and secured biometric access to the data centers. The VTOC platform firewall was OSCI level 4 compliant.

Patient Deidentification and Study Code Allocation

Unique study code or ID numbers were automatically and randomly assigned to each participant within the VTOC. Reports were available from the system using deidentified data, that is, study code or ID numbers. Members of the study team involved in data management, processing, and analysis only have access to the data that have been deidentified. Identifiable data can be accessed by study team members who need to make direct contact with participants during study visits or for the entry of additional data.

Study Questionnaires

Overview

Consented participants were asked to complete the study questionnaires either on the web using the VTOC platform or on a posted hard copy. Questionnaires were disseminated for completion at 2 distinct time points: within 4 weeks before their scheduled TKA and at 3 months after their TKA. These questionnaires are validated self-report tools that are used to measure a variety of biopsychosocial parameters associated with recovery following TKA.

Biopsychosocial measures and self-report tools used to derive each measure and administration time points are shown in Table 1. Psychosocial variables were selected following a thorough literature review that was conducted to determine the types of constructs that had demonstrated associations with outcomes that were relevant to the outcomes of interest in this study. Many of the selected variables were supported by systematic review–level and meta-analytic–level evidence. In addition, because of the innovative nature of the proposed tool, we also wanted to explore the role of other factors that had good face validity with respect to their potential to enhance or hinder someone's behavioral engagement in rehabilitative activities or general restoration of functioning [12]. Measurement tools were selected based on their psychometric properties and length (shorter scales were selected where possible to reduce the strain on participants).

XSL•FO
RenderX

Participants were also asked before their TKA if they had experienced any falls or unexpected weight loss within the last 12 months. In addition to measuring biopsychosocial parameters before surgery, participants were asked about their expectations about surgical outcomes, enabling them to perform specific activities, as well as their expectation of experiencing a reduction in knee pain.

Table 1. Biopsychosocial measures and administration time points.

[a]TKA: total knee arthroplasty.

[b]As reported by the participant.

Knee Symptomology

We implemented the Western Ontario and McMaster University Osteoarthritis Index (WOMAC) [35] to evaluate the level of knee function limitation, pain, and stiffness symptom severity. The WOMAC is a validated and widely used self-administered questionnaire [48] developed to provide a means of standardizing self-report health status and activities relevant to patients. It consists of 24 items: 5 relating to pain, 2 to stiffness, and 17 function items with ratings provided using a 5-point Likert scale. Lower scores are indicative of lesser symptoms, and higher scores are indicative of worse symptomology. The global score is the sum of the scores for all the items combined. In this study, participants were asked to complete the WOMAC before their TKA and at 3 months after their surgery.

Mood Status

The mood status of the study participants was assessed using the Depression Anxiety Stress Scales (DASS)–21 [36]. Higher scores are indicative of higher levels of depression, anxiety, and stress. All scores derived from the 21-point scale were multiplied by 2 to enable comparison with the full 42-point DASS and to determine clinical cut-offs for symptom severity. The full DASS and abbreviated DASS-21 have been validated to measure the 3 negative emotional states (ie, depression, anxiety, and stress) in research and clinical settings, but is not considered a diagnostic tool or a replacement for a comprehensive clinical interview [49]. Each of the DASS-21 subscales contains 7 items. The Depression scale assesses dysphoria, hopelessness, devaluation of life, self-deprecation, lack of interest or involvement, anhedonia, and inertia. The Anxiety scale assesses autonomic arousal, skeletal muscle effects, situational anxiety, and the subjective experience of anxious affect. The Stress scale is sensitive to levels of chronic nonspecific arousal. It assesses difficulty relaxing; nervous arousal; and being easily upset or agitated, irritable or overreactive, and impatient. Participants are asked to use a 4-point severity or frequency scales to rate the extent to which they have experienced each state over the past week. The scores for depression, anxiety, and stress are calculated by summing the scores for the relevant items. In this study, participants were asked to complete the DASS-21 before their TKA and at 3 months after their surgery.

Pain Catastrophizing

We used the Pain Catastrophizing Scale (PCS) [37] to measure the level of catastrophic thinking related to pain before TKA. PCS is one of the most widely used instruments for measuring pain catastrophizing and has been used extensively in clinical practice and research settings [50]. The self-report form consists of 13 items describing thoughts and feelings that patients may experience when they are in pain. Respondents provided ratings for each item on a 5-point Likert scale ranging from 0 (“not at all”) to 4 (“all the time”). Higher scores are associated with

XSL•FO
RenderX

higher amounts of pain catastrophizing, with scores >30 associated with a high risk of chronic pain.

Resilience

We assessed participants' resilience before their TKA using the Brief Resilience Scale (BRS) [38]. This scale assesses an individual's ability to recover from stressful events (level of resilience), and has demonstrated relationships with positive postsurgical health, satisfaction, and pain outcomes [12]. The BRS contains 6 items, including 3 positively and 3 negatively worded statements (reverse scored). Respondents rated their responses using a 5-point Likert scale ranging from 0 ("strongly disagree") to 4 ("strongly agree") for each statement. Raw scores are calculated by summing the item scores and range from 6 to 30. The BRS-weighted score is calculated by dividing the summed item scores by the number of items and ranges from 0 to 5. Higher scores are indicative of greater resilience.

Committed Action

Committed action is a component of "psychological flexibility" and is defined as a person's capacity to flexibly engage in effective and adaptive behaviors, guided by personally held values, even in the presence of challenges and discomfort [39,51]. We assessed committed action in our study cohort before their TKA because of the role this psychological process has been shown to play in an individual's health outcomes and their management of pain [12]. We used a shortened form of the Committed Action Questionnaire-8 [39], which comprised 8 statements. Respondents rate the extent to which each item applies to them, ranging from 0 ("never true") to 6 ("always true"). The total scores are calculated by summing the item scores, with a maximum score of 48. Higher scores denote greater committed action.

Capacity to Succeed in Achieving Goals

The Valued Living Scale assesses a person's goal importance, success, and confidence with respect to 8 value domains [40]. The scale was used to assess a person's rating of the importance of each of the 8 goals, their confidence in achieving these goals, and their success in achieving them following TKA.

Quality of Life

To evaluate participants' quality of life before and after TKA, we used the Short Form-12 (SF-12, version 2) quality of life questionnaire [41]. This tool is a 12-item self-administered measure of general quality of life that is widely used and has been validated in an Australian population [52]. It is a shortened and modified version of the original 36-item form [53]. Scores are transformed to generate 2 weighted summary scores for physical health, PCS, and mental health, the Mental Component Scale. Scores range from 0 to 100, with higher scores indicating a better health state. In this study, the participants completed the SF-12 before their TKA and at 3 months after their TKA.

Social Support

The amount of social support available to patients has been reported to influence physical and mental well-being [54] as well as being a key determinant of the suitable location of postsurgical rehabilitation services (ie, inpatient vs community based). The level of social support that participants felt they had available to them before their TKA was assessed using the Medical Outcomes Study Social Support Survey, 6 item [42]. The survey captures information related to perceived psychological and material support derived from interpersonal relationships. Scores ranged from 6 to 30, with higher scores indicative of higher levels of perceived support.

Physical Activity

Recent activity levels of the participants were determined using the University of California, Los Angeles Activity Index, which was developed to assess activity levels in patients undergoing joint replacement [43]. Participants were asked to indicate which of the 10 activity levels provided best reflected their current level of activity. The activity levels included being inactive (1 and 2), undertaking mild activities (3 and 4), moderate activities (5 and 6), active events (7 and 8), and impact sports (9 and 10). Activity status was evaluated before the TKA and at 3 months after the TKA.

Sleep Quality

To assess sleep quality in our study cohort, we used the sleep quality question extracted from the Pittsburgh Sleep Quality Index [44]. Participants were asked to rate their current sleep quality on a Likert scale ranging from 1 ("very bad") to 4 ("very good") on 2 occasions: before their TKA and at 3 months after the TKA.

Nutrition Status

The dietary habits of participants before TKA were assessed using the Starting the Conversion Score [45]. The Starting the Conversion Score is a validated 8-point screening tool used to evaluate dietary habits. The participants rate the frequency of ingesting a range of 8 different food types over the past few months. The total scale ranges from 0 to 16, with higher scores associated with worse dietary habits.

Alcohol Consumption

Alcohol consumption before TKA was evaluated using a modified version of the Alcohol Use Disorders Identification Test [55] related to alcohol consumption only (Alcohol Use Disorders Identification Test-Consumption) [46]. Participants were asked 3 questions related to their average alcohol consumption over the last 12 months, with a maximum total scale score of 12. Total scores <5 indicated low-risk consumption and scores >5 indicated hazardous or harmful consumption.

Smoking Behavior

Before and 3 months after the TKA, we asked participants to indicate their smoking status. Smokers were asked to provide details regarding smoking frequency.

Concomitant Health Conditions

The Charlson Comorbidity Index provides a weighting to concomitant health conditions based on the nature of the condition and age of the individual and is used to predict 1-year mortality. The higher the score, the higher the mortality risk [56]. We applied the same 10 medical conditions and weightings used by Chaudry et al [47]. Participants were asked to indicate whether they experienced any of the 10 medical conditions provided before their TKA and at 3 months after TKA.

XSL•FO
RenderX

Outcome Recovery Measures—3 Months After TKA

Table 1 shows the PROMs questionnaires completed by the participants 3 months after TKA and the parameters measured. Questionnaires related to knee symptomology (WOMAC), quality of life (SF-12), mood status (DASS-21), and lifestyle (physical activity, sleep, and smoking behavior) were also repeated at the 3 months post-TKA time point. This allowed us to evaluate changes or improvements in these factors at 3 months after TKA compared with levels measured before surgery. The primary outcome measure in our study is the improvement in quality of life 3 months after TKA (changes in SF12 physical and mental health scores).

Secondary outcome measures include knee symptomology (changes in WOMAC scores), satisfaction with the surgery, and mood status (changes in DASS-21 scores) 3 months after TKA.

We also asked questions related to satisfaction in achieving specific activities, the level of knee pain reduction, and overall satisfaction with the surgery. Information related to the type of rehabilitation they undertook and health care services used following their surgery were also collected.

Study Participation Evaluation Survey

A study participation evaluation survey was included to enable the participants to provide the research team with feedback regarding the assessments they were asked to undertake and the overall conduct of the study. It also allowed the study cohort to share their suggestions for future research areas they considered important to be addressed in the recovery from TKA surgery. The results from this survey will inform our team's future research endeavors in similar cohorts.

Physical Assessments

Overview

When participants were contacted by phone regarding their potential involvement in the study, they were also asked if they consented to undertake 2 physical tests in their home, taking 15 minutes, that enabled measurements of their mobility, balance, and strength. These assessments were undertaken via a video call between the participants in their home and a member of the study team in their office. To participate in these calls, the participant needed to have the following:

- Sufficient internet access and a mobile phone, tablet device, or computer with a movable camera
- Someone to be at home with them during the call, to assist with holding the device during the call and be there for safety support if the participant stumbles or falls during the assessments
- A dining chair or a similar chair with a firm seat and arm rests to perform assessments
- A 4-m length floor space with uniform flooring and no trip hazards to perform assessments

Physical assessments were conducted on 2 occasions during the study, within 2 weeks before their scheduled TKA and at 3 months after the TKA.

In our original protocol, we planned to conduct face-to-face physical assessments with participants at each of the 4 study sites. As these activities were restricted by the COVID-19 pandemic, we adopted the approach to undertake these measures via video calls with participants in their home. This approach enabled these assessments to be performed despite social distancing regulations being implemented at the time of the study. It also enabled the study to be managed from a central location and still involve participants located across a large geographical range.

The physical measures applied in this study were selected following a thorough literature review that was conducted to determine the types of assessments used to assess joint function, mobility, and knee; were extensively validated; and were used to assess improvements or changes associated with total knee replacement surgery. As these assessments needed to be undertaken via video calls between participants and study staff, they also needed to have the capacity to be accurately measured without supervision by a physiotherapist and, if possible, not require specialized equipment.

Timed Up and Go Test

The Timed Up and Go test is a simple, reliable, and valid test of functional mobility that can be used to monitor clinical changes over time [57]. It enabled an evaluation of the participants' capacity to engage in simple daily activities involving walking and getting up from a chair. We performed the Timed Up and Go test before the TKA and at 3 months after the TKA. On each occasion, the test was performed twice, with the fastest time for each individual to get up from a chair, walk to a 3-m mark, turn around, and come back and sit down recorded. Therefore, the shorter the time taken to perform the test, the better the performance.

30-Second Sit-to-Stand Test

The 30-second Sit-to-Stand (30 s-STS) test is a reliable and valid measure of lower extremity strength [58]. We performed the Sit-to-Stand test on 2 occasions, before the TKA and 3 months after the TKA. On each occasion, the total number of completed chair stands achieved over a 30-second period was recorded. A larger number of stands is indicative of better performance. The test is a general measure of the strength and endurance of a person's legs and is sensitive to change when a person's knee pain and function changes.

Presurgery Hand Grip Strength Assessment

Hand grip strength measures the maximum amount of static force that a person can apply by their hand while gripping a handheld dynamometer. It is a reliable proxy for overall strength and is related to the risk of frailty, falls, functional capacity, morbidity, and mortality [59,60]. Hand grip strength was assessed before the surgery. As this assessment requires the use of a calibrated dynamometer (Jamar Plus+ Hand Dynamometer, Jamar Diagnostics), a device was provided to each study site. The hospital site staff received training from a member of the research team before the start of the study to conduct these assessments.

Demographic and Clinical Information

To reduce the data collection strain on study participants, we extracted demographic data from patient hospital records at

XSL•FO
RenderX

each study site. In addition, medical data related to knee pathology diagnosis and medications were also collected from the hospital records. The scope of additional patient data used in this study is shown in Textbox 1.

Textbox 1. Demographic and medical data derived from patient hospital records.

Demographic and lifestyle behavior

- Age at the time of surgery
- Sex
- Nationality
- Suburb or postcode (rurality)
- Working status

Medical

- BMI
- American Society of Anesthesiologists score
- Surgery type (unilateral or simultaneous bilateral)
- Diagnosis
- Concomitant medications (were >5 different medications taken before surgery? What type of medications were taken before surgery?)
- Anesthetic and analgesic agents
- Length of hospital stay

Data Analysis

Overview

For prediction modeling, we are interested in whether a combination of presurgery measures can predict the change in physical (WOMAC subscores) and quality of life (SF-12 subscores) for participants at 3 months after surgery. Both the absolute improvement and whether a patient reported an MCID in improvement between the preoperative and postoperative stages will be predicted, requiring the implementation of regression and classification prediction models, respectively. The distribution-based MCID for each outcome measure will be determined according to the method outlined by Carender et al [61]. Every measure conducted before the surgery, including those from PROMs, physical measures, and medical records, will be considered as potential inputs (predictors) for the model. The data will be divided into 2 sets: a training set, consisting of 80% (840/1050) of the cohort chosen at random, and a test set, consisting of the remaining 20% (210/1050) of the cohort.

Data Cleaning

Although the web-based forms required each question set to be answered completely before the next was commenced, some participants used paper-based forms, and questions may have been missed. Moreover, some participants were unable to attend the video calls for the measurement of physical parameters, and in some cases, their medical records were incomplete. Any inputs with low variance or with >30% missing data will be discarded from the analysis. To deal with missing information in the remaining inputs, we will use multiple imputation, whereby missing measurements are replaced with the population mean (or the population mode for categorical measures). Imputation will be conducted independently on the training set without reference to the test set.

Models

We will consider standard linear models for prediction (ie, multivariable linear regression) with and without regularization and will also consider nonlinear models (decision trees, random forest, gradient boosting, neural networks, and Bayesian soft decision trees). Models will be trained both with and without one-hot encoding for the categorical variables.

Training

Models will be trained using 5-fold cross validation on the training set. The metric used to select the best classification model will be accuracy (ie, the percentage of patients classified correctly).

For each model, we will use a grid search for hyperparameter optimization. For example, a decision tree model will be trained for a range of depths and a range of minimum number of samples required at the leaf nodes, and the combination that returns the best model will be the chosen hyperparameters. We will also consider the subset of inputs used to train a model as a hyperparameter and will use exhaustive search to find the best input subset (ie, to find the best model that uses only 7 predictors; every possible combination of the 7 predictors will be tested). This avoids training a model using a “greedy” algorithm, which is not guaranteed to find the best combination of inputs.

Validation

The performance results of the chosen models will be validated on the test set containing the remaining 20% (210/1050) of the cohort. The root mean square error, R^2, and error rate will be reported on the training set, and plots showing the predicted

XSL•FO
RenderX

versus measured outputs will be included in the supplementary materials in future papers. Where the model type allows it, we will also report CIs for the parameters and predictions.

We will then apply a common post hoc method to establish if the sample size is sufficient for the reported error rate for each model as follows: taking an increasingly large subset of the data, we will train the model, calculate the error, and plot the error as a function of the number of observations in the subsample. Fitting a power law curve, will establish an estimate of the sufficient sample size. Where the model type allows it, we will also report CIs for the parameters and predictions.

All machine learning methods will be conducted using the Python programming language. The *pandas* and *numpy* packages will be used for data cleaning, with the *scikit-learn* package used for training with standard machine learning models and techniques, and custom Python code will be used for training the Bayesian soft decision trees.

Ethics Approval

This research methodology was peer-reviewed and approved by the School of Medicine and Public Health at the University of Newcastle, NSW, Australia, in accordance with the Australian Code for the Responsible Conduct of Research. This study was conducted in accordance with the National Statement on Ethical Conduction in Human Research (2007). Ethics approval was granted by the University of Newcastle Human Research Ethics Committee (approval H-2019-0109) on June 21, 2019. Approval for each study site's participation was reviewed and approved by the Ramsay Research and Governance Office in NSW, Australia (RHC RG-2019.008).

Results

This study was funded by the Ramsay Hospital Research Foundation in September 2018. Recruitment for this study occurred between November 2019 and June 2022. Data collection was completed in September 2022. The study results will be available within 12 months of the final data collection on completion of the machine learning data processing of the predictive models (ie, final results are expected by September 2023).

During the recruitment phase, 1871 individuals requiring TKA were identified by the collaborating orthopedic surgeons across all 4 study sites, with a total of 1050 eligible, consented patients undertaking at least 1 of the pre-TKA study assessments in the study cohort (Figure 1). Participants for whom a complete data set was collected (ie, responses to all study questionnaires at both time points) were included in the machine learning data processing for predictive model development (n=851). Participants were randomly allocated for analysis into 2 groups, such that 80% (681/851) were included in the model training data set and 20% (170/851) were included in the model test data set.

Discussion

Expected Findings

This study responds to an unmet clinical need to address factors that can improve outcomes in patients undergoing total knee replacement. With a substantial increase in the number of TKA procedures expected to take place over the next decade, there is the potential for a significant number of patients to be dissatisfied with their surgical outcomes, unless the issue can be effectively addressed.

We anticipate the development of a clinical predictive tool that has the potential to improve patient-centered TKA outcomes. The uniqueness of the model being used is the inclusion of a comprehensive assessment of modifiable psychological, resilience, and clinical factors that have been linked to TKA recovery outcomes.

Comparisons With Prior Work

The approach adopted in this protocol builds on existing research demonstrating the involvement of factors influencing recovery of patients following total knee replacement and the inclusion of these factors in predictive modeling of postsurgery outcomes. We are unaware of any published predictive models of patient outcomes following TKA that include such a comprehensive battery of biopsychosocial parameters as those being evaluated in our study protocol. Our systematic review of predictive models for TKA outcomes [26] and those undertaken by others [32] revealed that the most consistently used presurgical parameters included clinical and medical factors such as age, sex, BMI, and concomitant health conditions, whereas psychological factors were incorporated to a lesser extent and, when applied, were restricted to measures of mood status (depression and anxiety) or mental health quality of life. There have been several specific modifiable psychological factors, including pain catastrophizing [18,62] and resilience [63], which have been associated with recovery following TKA and could inform the optimization of patient outcomes. However, their predictive capacity for patient outcomes after TKA has not been widely explored.

Previous limitations of predictive models are associated with using data derived from existing registries or retrospectively collected data sources [26]. Such approaches can be problematic because of the need for data imputation caused by missing values or limitations in predicting specific outcomes owing to insufficient presurgery variables collected. The prospective collection of specific variables of interest, as we propose in this study, enables the collection of specific input data that have been associated with specific outcomes. This approach has the potential to inform appropriate rehabilitation interventions to improve patient outcomes.

Potential Impact and Clinical Implementation

If successful, this project will provide a tool that can help guide health professionals with respect to comprehensive rehabilitation decisions individualized to each patient. The tool will underpin and support the identification of biopsychosocial risk factors for poor postoperative holistic outcomes and facilitate the development of biopsychosocial prehabilitative and

XSL•FO
RenderX

rehabilitative interventions, which could lead to improved overall outcomes. In addition, the tool will enable efficient patient stratification according to identified individual needs, which allows a vastly more targeted service provision, maximizing the potential for impact. Currently, patients are infrequently evaluated using formal, standardized assessments for the type of rehabilitative service they would most likely need and benefit from. This project will provide a means of stratification of patients in a clinical setting, identification of "at risk" individuals early in their recovery journey, and support appropriate follow-up services to be implemented.

The scope of the factors influencing decision-making will be evolved. Typically, when patient information is collected, it generally focuses on selected medical or targeted joint parameters [64] and does not take consider parameters such as patient anxiety, stress resilience, quality of pain, social support, and sense of purpose, all of which have recently been shown to be associated with patient outcomes [12]. The model used in this study will explore the influence of these additional parameters on recovery and well-being following TKA, thereby providing evidence for a more comprehensive therapeutic strategy.

Strengths and Limitations

In this study, we are collecting data prospectively, which enables the scope of features that may impact patient outcomes to be extended beyond that routinely collected in existing data sets and provide a focus on the biopsychosocial parameters of interest. The development of a clinical decision tool that is focused on a broader scope of patient features affords the opportunity for a more holistic approach to be taken in rehabilitation programs that extend beyond physical recovery strategies alone. The design of the study has attempted to reduce surgeon and hospital bias by including patients who underwent TKA by 11 different orthopedic surgeons across 4 different hospitals. These facilities were located across a large geographical range and enabled the inclusion of participants residing in metropolitan and rural communities to take part in the study. This was further enhanced by the capacity to collect data on the web and via video calls, which enabled the study to be managed at a central location and include participants across a large geographical area.

Although the planned study will evaluate the predictive capacity of a comprehensive battery of biopsychosocial parameters on TKA patient outcomes and offer significant contributions to the existing literature, there are potential limitations. In this study, we are assessing the predictive capacity of presurgical parameters on recovery outcomes assessed at 3 months after TKA. This may be considered early on in a patient's recovery journey. It has been demonstrated that the maximal changes in patient-reported knee symptomology occur rapidly within the first 3 months, with subsequent improvements continuing, albeit at a slower rate, up to 12 months after surgery [65,66]. It is possible that the impact of psychological factors on patient outcomes may differ at later time points, as patients' circumstances and needs change, and as such, predictive modeling developed in this study may be limited to early recovery outcomes.

We recognize that our study protocol does not encompass all factors that could potentially influence outcomes after TKA. Our analyses do not include surgical factors known to impact outcomes, including factors such as the surgeon or hospital, prosthesis type, and surgical procedures [67], and radiological factors, such as the Kellgren-Lawrence score [23]. Therefore, it is important to note that our predictive models are unlikely to account for 100% of the variability in patient outcomes that we observe. Instead, they will provide insight into the extent to which the presurgical biopsychosocial factors assessed in our model contribute to the observed variance.

Future Directions and Concluding Comments

As per the data analysis plan for this study, a rigorous internal validation of the predictive models generated will be performed. Ongoing external validation of the models will also enable the suitability and specificity of the findings to be applied to a wider clinical setting than that included in this study. In addition, through future engagement with key stakeholders, including clinical care teams (surgical and rehabilitation specialists), health care providers, and patient advocates, we will develop the predictive models to optimize their clinical implementation and usefulness.

The classification models proposed will facilitate the evaluation of intervention studies, whereby biopsychosocial risk factors are identified, targeted interventions are provided, and the benefits to postoperative outcomes are evaluated. This will enable the determination of whether targeting these factors in an individualized manner leads to improved satisfaction and PROMs.

In conclusion, the findings of this study will contribute to the development of a comprehensive biopsychosocial clinical decision–predictive tool. Such a tool will have the potential to inform clinical care teams regarding individual patient outcomes, enable the stratification of potentially "at risk" individuals, and inform the evolution of rehabilitation services through the identification of potential interventions, all of which could lead to an improvement in patient outcomes and satisfaction following TKA.

Acknowledgments

The authors would like to acknowledge the collaboration and support of the orthopedic surgeons who referred patients to this study, including Dr Mathew Broadhead, Dr Ian Chan, Dr David Dewar, Dr Michael Dixon, Dr Christopher Dunkley, Dr Richard Harbury, Dr Alex Jovanovic, Dr Anthony Leong, Dr Peter Summersell, Dr Chad Todhunter, and Dr Richard Verheul. Administrative support was provided by Mrs Lucy Bailey. This research study was funded by the Ramsay Hospital Research Foundation.

Authors' Contributions

KR and SJ wrote the manuscript. All authors provided input for the study protocol design and reviewed the manuscript. SJ, AW, and JC provided insight into the machine learning and data processing for the protocol; ED provided consultation regarding psychological outcomes; TF provided insights regarding protocol design and assessments to be undertaken; GM provided guidance on the application of physical measures; and FRW, MP, and MN provided guidance on the scope and clinical aspects of the protocol. MN is overseeing the project.

Protocol

Delivery of the HIV Service and Telemedicine Through Effective Patient-Reported Outcomes (+STEP) Intervention to Increase Screening and Treatment of Mental Health and Substance Use Disorders for People Living With HIV in Alabama: Protocol for an Effectiveness-Implementation Study

Abstract

Background: The syndemic of mental health (MH) and substance use disorders (SUDs) is common among persons living with HIV and jeopardizes HIV treatment adherence, engagement in care, and viral load suppression. Electronic patient-reported outcomes (ePROs), completed through tablet or computer, and telemedicine are evidence- and technology-based interventions that have been used to successfully increase screening and treatment, respectively, a model that holds promise for persons living with HIV. To date, there is limited guidance on implementing ePROs and telemedicine into HIV clinical practice even though it is well known that these evidence-based tools improve diagnosis and access to care.

Objective: To address this, we aim to conduct a multicomponent intervention for persons living with HIV, including the delivery of HIV services and telemedicine through effective ePROs (+STEP), to increase screening and treatment of MH and SUD in Ryan White HIV/AIDS Program (RWHAP)–funded clinics in Alabama.

Methods: Through this intervention, we will conduct a readiness, acceptability, and accessibility assessment and implement +STEP to improve the diagnosis and treatment of MH and SUD at RWHAP clinics in Alabama. To describe implementation strategies that address barriers to the uptake of +STEP in RWHAP clinics, we will conduct qualitative interviews in years 1 (early implementation), 2 (scale up), and 4 (maintenance) with patients and key staff to evaluate barriers, facilitators, and implementation strategies. Our Results will enable us to modify strategies to enhance +STEP penetration over time and inform the implementation blueprint, which we will develop for both RWHAP clinics in Alabama and future sites. We will assess the impact of implementing

XSL•FO
RenderX

+STEP on diagnoses, referrals, and health care use related to MH, SUD, and HIV by comparing clinical outcomes from patients receiving these interventions (ePROs and telemedicine) with historical controls.

Results: The first study site began implementation in April 2022. A total of 2 additional sites have initiated ePROs. Final results are expected in 2026. The results of this study will provide a foundation for future research expanding access to ePROs for improved diagnosis linked to telemedicine access to accelerate patients along the continuum of care from MH and SUD diagnosis to treatment.

Conclusions: Achieving the end of the HIV epidemic in the United States necessitates programs that accelerate movement across the MH and SUD care continuum from diagnosis to treatment for persons living with HIV. Scaling these services represents a path toward improved treatment outcomes with both individual health and population-level prevention benefits of sustained HIV viral suppression in the era of undetectable=untransmittable (U=U). This study will address this evidence gap through the evaluation of the implementation of +STEP to establish the necessary systems and processes to screen, identify, and better treat substance use and MH for people living with HIV.

Introduction

Almost 10 million people in the United States are estimated to have both substance use and mental health (MH) disorders [1]. In Alabama, the burden of MH is higher than the national average with nearly 1 in 4 people meeting criteria for any depressive disorder compared to the national average of under 20% [2]. Additionally, approximately 8% of Alabama residents are diagnosed with a substance use disorder (SUD) each year [3]. The syndemic of MH and SUDs is common among persons living with HIV, with estimated prevalence rates of 39% and 48%, respectively [4,5]. This syndemic jeopardizes HIV treatment adherence, engagement in care, and viral load (VL) suppression [6]. Specifically, MH and SUD are associated with reduced antiretroviral treatment (ART) adherence, high viral load levels, and increased mortality [7,8]. persons living with HIV with MH and SUD may be reluctant to report these conditions due to stigma, medical mistrust, or social desirability bias, but diagnosis is an essential first step toward management of these comorbidities [6,9]. Following diagnosis, improving access to MH and SUD treatment has the potential to reduce HIV transmission risks by fostering sustained viral suppression.

Treating MH conditions and reducing drug use improves ART adherence and VL suppression [10-12]. Thus, MH and SUD should be monitored often and addressed rapidly, a process facilitated by real-time electronic patient reported outcome (ePRO) data. A recent Cochrane review of 116 randomized control trials demonstrated that ePROs are a successful mechanism to improve patient-provider communication, diagnosis, and disease control [13]. While there is currently insufficient evidence that ePROs improve distal clinical outcomes, research shows ePROs can improve the process of care by collecting information directly from patients, minimizing potential for judgment and social desirability bias [14-16]. ePROs completed on a laptop or tablet using validated tools, such as the Patient Health Questionnaire-9 (PHQ-9), are replicable and provide longitudinal monitoring of the overall health of persons living with HIV [6,17-19]. This evidence-based screening mechanism enables clinics to respond with individualized counseling and education, allowing resource-limited clinics to prioritize scarce resources to those with active psychosocial barriers that may impair ART adherence and VL suppression.

Alabama is 1 of 7 states with the greatest rural HIV burden nationally, and the rural, resource-limited region poses additional barriers in treating psychosocial comorbidities in persons living with HIV. Challenges include a lack of providers, especially MH and addiction treatment providers, long commutes across rural settings to clinics, and a lack of public transportation. Lack of Medicaid expansion substantially widens this treatment gap [9,20-22]. Telemedicine offers an opportunity to overcome barriers to treatment in southern and rural states, such as lack of transportation, time away from work and childcare, costs, and stigma [22,23].

There is a need for programs that improve and accelerate the diagnosis and management of MH and SUD among persons living with HIV and promote the individual health and population level prevention benefits of sustained HIV viral suppression in the era of undetectable=untransmittable (U=U). ePROs, completed through tablet or computer, and telemedicine are evidence- and technology-based interventions that have been used to successfully increase screening and treatment, respectively, a model that holds promise for persons living with HIV [24,25]. To date, there has been a lack of consensus in the field on the implementation of ePROs, with specifically limited guidance on how to implement ePROs and telemedicine into HIV clinical practice. A majority of existing implementation recommendations are for integration into clinical practice generally and are not specific to HIV settings [14,26-28]. Additionally, implementation studies to date were not based in the Deep South, where at-risk populations face unique barriers to MH, SUD, and HIV care [14,26-29]. Given that ePROs improve diagnosis and access to care, additional recommendations specific to the integration of ePROs into clinical HIV settings are necessary to improve the

XSL•FO
RenderX

implementation and dissemination of this evidence-based tool to address the HIV epidemic [6,30]. To address limited guidance specific to HIV clinical settings, we are conducting a multicomponent intervention for persons living with HIV, delivery of HIV services, and telemedicine through effective ePROs (+STEP), to increase screening and treatment of MH and SUD in Ryan White HIV/AIDS Program (RWHAP)-funded clinics in Alabama. The aims of this study are the following:

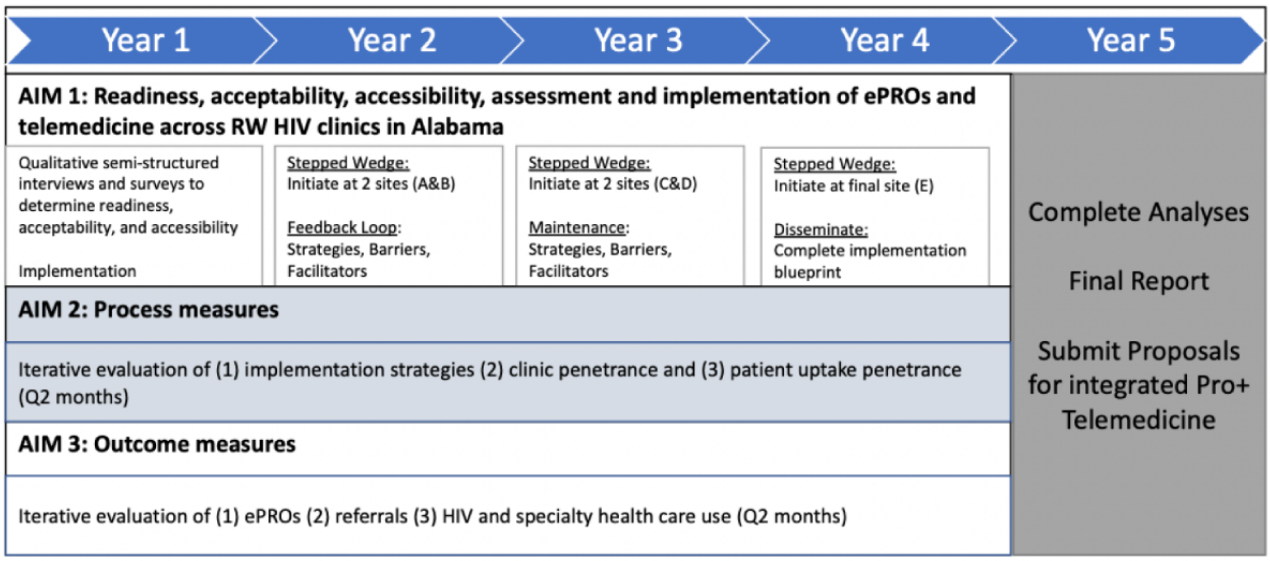
- Aim 1: to conduct readiness, acceptability, and accessibility assessments through qualitative interviews and a quantitative survey followed by the implementation of +STEP to improve the diagnosis and treatment of MH and SUD at RWHAP clinics in Alabama.
- Aim 2: to describe implementation strategies that address barriers to uptake of +STEP in RWHAP clinics. We will conduct qualitative interviews in years 1 (early implementation), 2 (scale up), and 4 (maintenance) with patients and key staff to evaluate barriers, facilitators, and implementation strategies. Results will enable us to modify strategies to enhance +STEP penetration over time and inform the implementation blueprint, which we will develop for both RWHAP clinics in Alabama and future sites.
- Aim 3: to measure the impact of implementing +STEP on diagnoses, referrals, and health care use related to MH, SUD, and HIV by comparing clinical outcomes from patients receiving these interventions (ePROs and telemedicine) with historical controls. We will complete a quantitative assessment of clinic-level diagnoses (MH and SUD) and patient-level indicators (screening, reporting, and treatment for MH and SUDs) relative to historical RWHAP reports using segmental regression (previous 3 years).

This will be the first study to evaluate integrated implementation of 2 effective evidence-based technologies—ePROs and telemedicine—in serving people living with HIV in Alabama. The results of this study will provide a foundation for future research expanding access to ePROs for improved diagnosis linked to telemedicine access to accelerate patients along the continuum of care from MH and SUD diagnosis to treatment.

Methods

Setting

+STEP is being implemented in RWHAP-funded clinics in Alabama. RWHAP-funded clinics provide medical care, medications, and essential support services to low-income persons living with HIV. In addition to providing essential care to persons living with HIV, these clinics aim to improve HIV-related health outcomes and reduce HIV transmission in their local communities [31]. Of the 9 RWHAP-funded clinics in Alabama, a total of 5 have agreed to participate in the study.



Study Design

We will conduct a stepped-wedge hybrid implementation-effectiveness type 1-design study, allowing the testing of implementation strategies while simultaneously evaluating the impact of the intervention on clinical outcomes of +STEP. Key staff from the participating sites, including clinic leadership, patient representatives, and clinicians (social workers, nurses), will participate in clinic-level trainings and assessments. Each site will identify key staff and patients who will be invited to join the advisory board. Implementation outcomes will be assessed using Proctor's Implementation Framework [32].

For aim 1, we will conduct qualitative, semi-structured interviews and surveys with key staff to assess organizational readiness and existing protocols. Specifically, interviews will explore each clinic's current resources and protocols, team structure, screening procedures, and barriers to telehealth. Surveys will measure organizational readiness. We will also survey patients with personal MH or SUD experiences to determine the accessibility and acceptability of ePROs and telehealth. We will then implement a multicomponent intervention with ePROs, targeted training to frontline providers, and telemedicine. We will assess fidelity and process measures, including clinic adoption and patient participation, as part of routine care in community-based RWHAP clinics. For aim 2, we will use the Consolidated Framework for Implementation Research (CFIR) to conduct a qualitative evaluation of implementation strategies, barriers, and facilitators to +STEP uptake. [33] Thus, Aim 2 will allow us to develop and refine an implementation blueprint. For Aim 3, we will evaluate the intervention impact on patient and clinic outcomes using patient-reported data (eg, MH, ART adherence), use of services (ie, clinical encounters and telemedicine), and retention in care, a proximal measure of VL suppression. A timeline for implementation of this study can be found in Figure 1.

XSL•FO
RenderX

Figure 1. Study timeline of specific aims. ePRO: electronic patient reported outcome; RW: Ryan White; Q: quarter.

Intervention

+STEP will combine 3 components in a novel, multicomponent intervention**:** ePROs, targeted knowledge to frontline providers and staff, and telemedicine services for the management of MH and SUD. The intervention will include ePRO surveys adapted at the clinic level based on the results of the readiness, acceptability, and accessibility assessments. The ePROs will include validated surveys of MH and SUD, and final instruments will be selected following key staff meetings in order to ensure that they meet the needs and preferences of sites. Key staff from the participating sites, including clinic leadership, patient representatives, and clinicians (social workers, nurses), will participate in clinic-level trainings and assessments. The intervention will also include ongoing targeted trainings for frontline staff emphasizing the importance of diagnosis and evidence-based treatment of MH and SUD [30,34]. We will educate participants on the role of stigma and language as barriers to MH and SUD treatment [35]. With input from clinic-level key staff, we will design training on how to respond to ePRO results, including evidence of MH and suicidal ideation, according to clinic-specific policies and procedures. Telemedicine from the University of Alabama at Birmingham (UAB) eMedicine Center allows persons living with HIV to leverage UAB's telemedicine experience and infrastructure in 55 out of 57 counties across Alabama. Patients referred to telemedicine will have access to a central contact at UAB's eMedicine Center who will arrange an appointment at the closest referral site.

Implementation strategies: we will identify and train a +STEP champion at each clinical site who will receive additional hands-on training on the +STEP protocols, technology, and troubleshooting [36]. Implementation champions are an established implementation strategy to influence and facilitate change within their organization [37]. +STEP champions will be identified at each site before implementation and join regular meetings with the +STEP research team to discuss ongoing challenges and successes. Additional implementation strategies to improve implementation will be identified and used during the evaluation of +STEP implementation and as additional sites initiate the intervention.

Study Population

Participants include staff at RWHAP-funded clinics in Alabama and the persons living with HIV receiving care at these clinics. All adult (18 years of age or older) patients will be included in the analysis regardless of race, ethnicity, insurance status, and time in HIV care based on HIV clinic use.

Recruitment

Aim 1

Clinics will identify a convenience sample of 5 staff members to participate in qualitative interviews and complete surveys at each of the 5 sites. The interviewed staff will include key staff such as the nursing supervisor, physicians, social workers, and administrators. At the conclusion of the interviews, staff participants will be sent a Qualtrics Software (Provo) survey to complete. Additionally, 5 patients, identified by key staff for their experience with MH and SUD, from each clinic will be recruited to complete an anonymous survey through Qualtrics.

Aim 2

We will work with each of the clinics to identify 3 patients and 5 key staff members in years 2, 3, and 5 of the study for individual interviews (45 patients and 75 key staff participants will be selected using purposive sampling with maximum variation to ensure diversity in perspectives. We expect representation of persons living with HIV of different races, ages, duration of engagement in HIV clinical care, education level, socioeconomic status, and insurance status. Unique patients and staff will be selected at each time point. Recruitment for each participant group will take place at each time point (years 1-4) until thematic saturation is reached.

Aim 3

Patients will be recruited to +STEP by their clinic staff. Participating patients will complete ePROs at least once per year. Their ePRO records and historical clinical data will be used for both process and clinical outcomes. The target sample

XSL•FO
RenderX

size for is 4000 participants across sites, which would allow us to detect for an odds ratio of 1.29.

Data Sources

For aim 1 of this study, we will collect data using a patient telephone survey, a staff survey, and qualitative interviews with key staff to understand current capacity and infrastructure to inform implementation. The patient survey measured the acceptability and accessibility of ePROs and telehealth services. The key staff survey included the organizational readiness to implement change instrument to determine perceived institutional readiness [38]. Interviews with key staff explored technological capacity and organizational readiness for change using the CFIR. Additional methodological details for aim 1 have been published in BMC Health Services Research [39]. The Implementation data will be abstracted from scheduling logs, training logs, and the electronic medical record (EMR) at each clinic site every 2 months to characterize the clinic and patient adoption and penetration of +STEP. We will supplement these reports with manual chart abstraction if needed to understand any gaps in the data. For aim 2, patients and staff who meet eligibility criteria will be invited to participate in an hour-long qualitative interview. All interviews will be designed to elucidate (1) perceptions of implementation strategies and (2) anticipated and observed barriers and facilitators to +STEP delivery. These data will be used to refine implementation over time. Research staff with expertise in qualitative research and program evaluation will lead in-depth interviews using standardized interview guides. Interview guides will elucidate contextual factors and will be informed by constructs from the 5 domains of CFIR, predominantly intervention characteristics and the inner setting domains, and the associated implementation strategies designed to target those factors. These factors may influence clinics' ability to implement and sustain +STEP and ultimately improve outcomes. In addition, the interviews will evaluate the acceptability of +STEP, a key component of Proctor's Implementation Framework [32]. For aim 3, clinical data will be extracted from the EMR, scheduling data, and training logs. Historical controls will be the percentage of MH and SUD diagnoses among patients and will be collected at the start of the study. We will extract ePROs, referrals for clinical encounters, visits attended and missed, and other HIV care continuum outcomes (eg, VL). We will quantify the proportion of participants with ePROs indicative of MH and SUD, and suboptimal ART adherence. We will quantify the number and proportion of clinical encounters scheduled and attended related to HIV, MH, substance use, social services, case management, and telemedicine visits.

Outcomes

Targeted outcomes for this study are outlined in Table 1.

XSL•FO
RenderX

Table 1. Outcomes including units, evaluation metrics, data source, and timing for aim 1, 2, and 3.

Outcome, concept, and unit	Evaluation metrics	Data source	Timing
Aim 1			
Outcome: readiness, acceptability, and accessibility			
Concept: organizational readiness			
Unit: key staff			
	Interviews to understand capacity and infrastructure	Interviews with key staff	Preimplementation
	Survey of organizational readiness to implement change instrument	Key staff survey	Preimplementation
Concept: acceptability and accessibility			
Unit: patients			
	Survey of acceptability and accessibility of ePROs[a] and telehealth services	Patient survey	Preimplementation
Outcome: fidelity			
Concept: degree to which an intervention is delivered as intended			
Unit: clinics			
	Review of use of intervention and implementation strategies	Implementation team	Every 2 months
Unit: patients			
	Use of implementation strategies, consistency of ePROs, telemedicine uptake	EMR[b] and ePRO data, scheduling data	Quarterly as part of reports
Outcome: process			
Concept: clinic penetration			
Unit: clinics			
	Percentage of staff taking CME[c] training, percentage of ePROs delivered and percentage generating response, number of referrals to services, number of telemedicine referrals	Implementation team, EMR, ePRO scheduling data	Every 2 months
Concept: patient penetration			
Unit: patients			
	Percentage of patients enrolled; percentage completing ≥1 ePRO report; average number of PROs completed per patient; number of MH[d], SUD[e], or telemedicine visits	EMR, ePRO, scheduling data	Quarterly as part of reports
Aim 2			
Outcome: implementation			
Concept: facilitators, barriers, and perception of implementation strategies			
Unit: patients and staff			
	Patient and staff perspective of implementation, as framed by CFIR[f]	Patient and staff interviews	Annually
Aim 3			

XSL•FO
RenderX

Outcome, concept, and unit	Evaluation metrics	Data source	Timing
Outcome: ePROs			
Concept: MH and substance use			
Unit: patients			
	Percentage of patients reporting MH, alcohol and illicit drug use, including OUD[g]; low ART[h] adherence	ePRO data	Every 6 months
Concept: ART adherence			
Unit: patients			
	Association between ePRO, intervention, and ART adherence	ePRO data	Every 6 months
Outcome: referrals for services			
Concept: counseling, psychiatry, addiction medicine, and rehabilitation			
Unit: patients			
	Referrals to specialty care	Training logs, EMR and scheduling data	Every 6 months
Outcome: use of services			
Concept: counseling, social work, MH, and addiction services			
Unit: patients			
	Percentage of patients with clinical encounters with counselor, social work, MH, addiction services	Training logs, EMR and scheduling data	Every 6 months
Outcome: telemedicine encounters			
Concept: MH and substance use			
Unit: patients			
	Percentage of encounters completed through telemedicine	Training logs, EMR and scheduling data	Every 6 months

[a]ePRO: electronic patient reported outcome.

[b]EMR: electronic medical record.

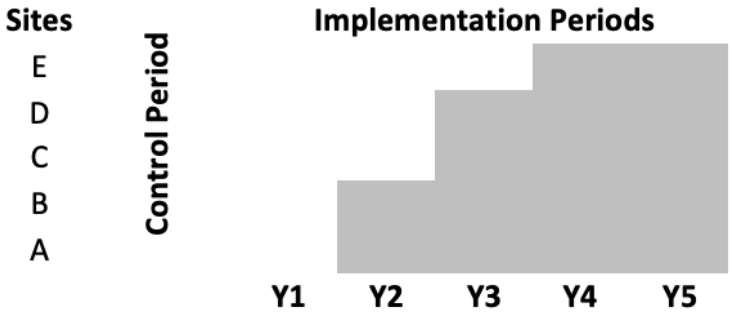
[c]CME: continuing medical education.

[d]MH: mental health.

[e]SUD: substance use disorders.

[f]CFIR: consolidated framework for implementation research.

[g]OUD: opioid use disorder.



[h]ART: antiretroviral treatment.

Analysis Plan

The analysis process will align with a stepped-wedge study design and each aim of the study (Figure 2). Aim 1 is to conduct readiness, acceptability, and accessibility assessment and implement +STEP. Data collected during the readiness, acceptability, and accessibility assessment will be analyzed using descriptive and frequency statistics for the staff and patient survey and by a rapid qualitative analysis of qualitative interviews with key staff members from the 5 participating sites. The team will use a data reduction analysis method by coding and summarizing each transcript by code before integrating the themes across all interviews [40]. This process will elucidate each clinic's protocol for completing annual screening and reporting of MH and SUD, clinic procedures for psychosocial service provision, including on-site services and details of referral options in the community and beyond, and the use of telemedicine if applicable.

XSL•FO
RenderX

Figure 2. The stepped-wedge study design in which the intervention (patient-reported outcomes) is introduced at sites across 3 years of the study (Years 2-4). Y: years.

Aim 2 is focused on describing implementation strategies addressing barriers to uptake of +STEP in 5 RWHAP clinics using CFIR. The analytic strategy for aim 2 is framework-guided rapid qualitative analysis (F-RQA) of interview transcripts [40]. We will develop an interview guide informed by the domains and constructs of CFIR and using the recommended CFIR interview questions. In alignment with F-RQA, a preliminary summary table will be developed to correspond to the domains and constructs reflected in the interview guide. Once both processes are complete, the research team will independently extract relevant data from a single transcript, including pertinent quotes, and organize them in the draft summary table. Draft summary tables from these team members will be compared to resolve discordance. A modified summary table will then be used on a second interview before finalizing the summary table, which will be used for data analysis of all subsequent interview transcripts. This analytic process will provide an in-depth understanding of implementation as it is ongoing and will allow us the opportunity to share this information with clinics during quarterly meetings with participating clinics [41].

Aim 3 includes the measurement of the impact of implementing +STEP on diagnoses, referrals, and health care use related to MH, SUD, and HIV by comparing clinical outcomes from patients receiving these interventions (ePROs and telemedicine) with historical controls. This analytic process will begin with descriptive analyses to illustrate characteristics of patients, including age, race, gender, sex, and time in HIV care for each site and overall. Historical control data will be compared to the prospectively collected ePRO data and percentages. As it will be difficult to identify certain historical values, we will note any uncollectable data and present descriptive statistics for +STEP patients alone. For all other outcomes, we will perform generalized linear mixed effects models to account for the within-clinic correlation. These models will be performed with and without covariate adjustment to determine if any potential patient population changes (eg, more persons living with HIV newly engaged in care receiving +STEP) confound the effect of STEP+ on the identification of MH diagnoses, referral to services or actual service use. We will determine if random effects are necessary and if they can be ignored, we will use logistic regression models for each outcome. For each model, all assumptions will be verified, and goodness-of-fit will be assessed.

Ethics Approval

This study received approval from the UAB's institutional review board (300005613).

Results

In 2021, at the initiation of the study, the participating RWHAP-funded clinics provided care to a total of 4065 persons living with HIV (Table 2). The number of patients at each clinic ranged from 200 to 1819 (Table 2). These clinics are situated in the some of the most disadvantaged regions of Alabama based on the area deprivation index (Figure 3). The sociodemographic traits of persons living with HIV who are receiving care at RWHAP clinics in Alabama are as follows: median age of 47 years; 2622 (76%) cisgender men; 2273 (65%) non-Hispanic Black; 372 (10%) with unstable housing or homelessness. In 2019, there were 4065 persons living with HIV receiving care at one of the participating +STEP sites.

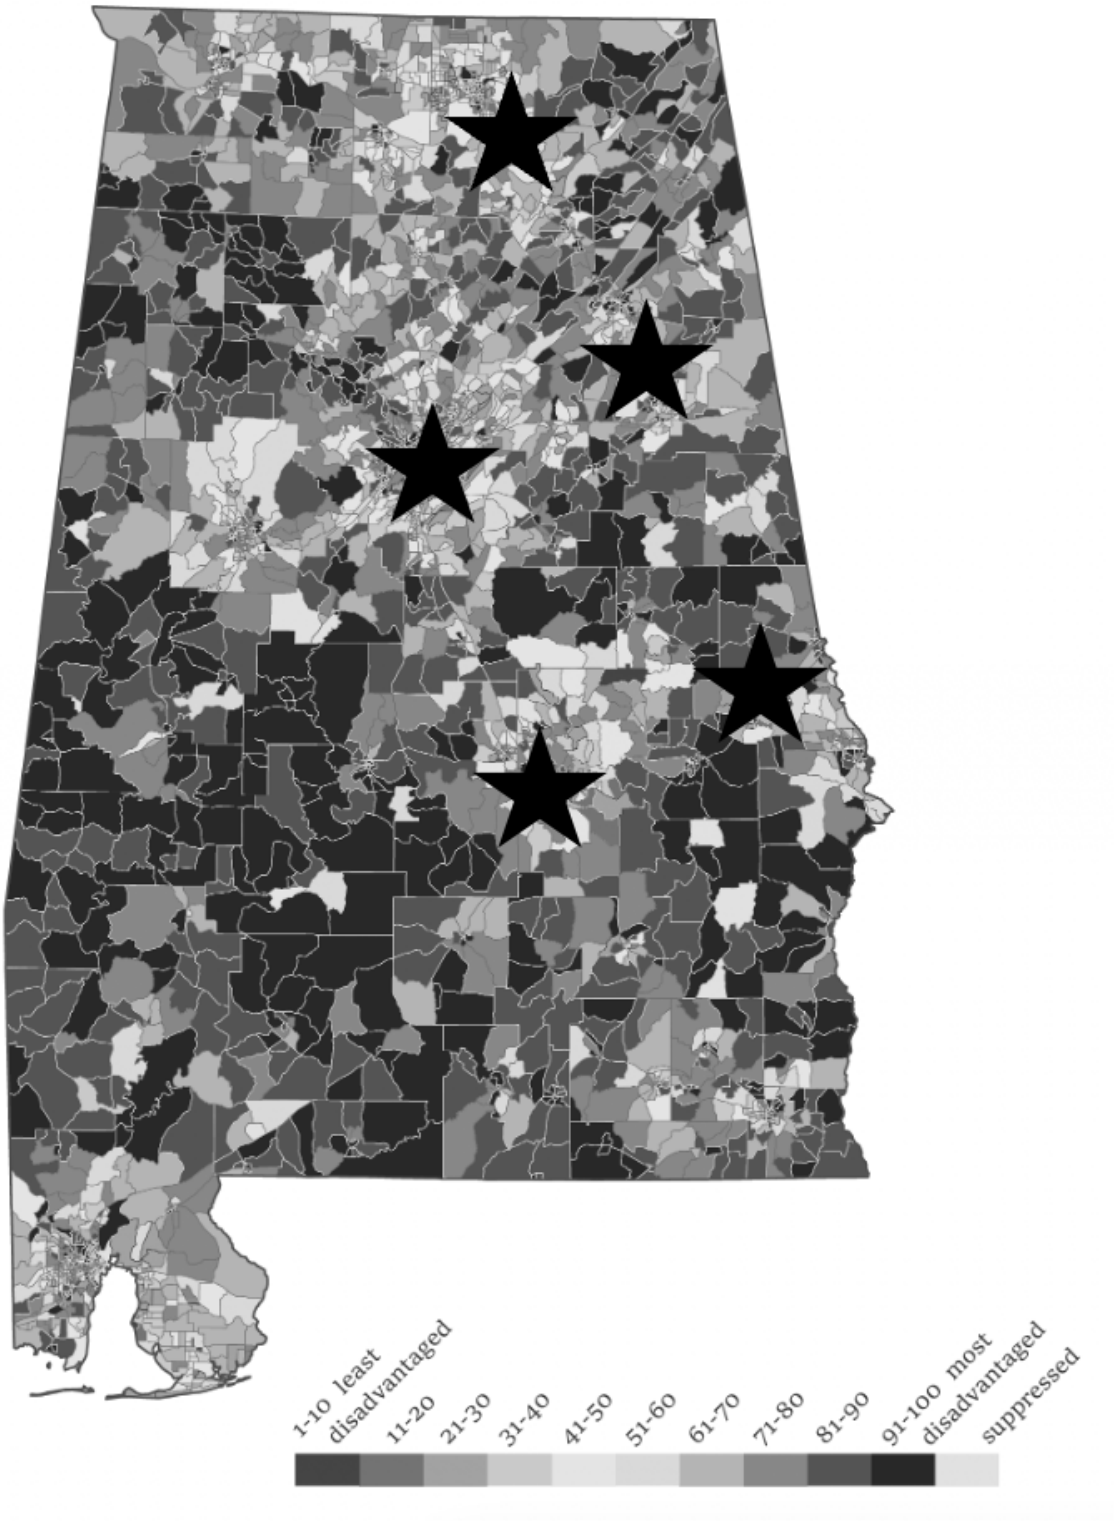


Table 2. Summary of sites participating in +STEP (N=4065).

Sites	Persons living with HIV, n (%)
Ryan White Funded Clinics in Alabama[a]	
University of AL Family Clinic	300 (7.38)
Thrive Federally Qualified Health Services Center	956 (23.52)
Health Services Center	562 (13.83)
Medical Advocacy and Outreach	1819 (44.75)
Unity Wellness Center	428 (10.53)

XSL•FO
RenderX

Figure 3. Stars indicate the location of RWHAP (Ryan White HIV/AIDS Program) clinics. Zip codes are shaded in accordance with the level of disadvantage based on the Area Deprivation Index, with White being the least disadvantaged and Black being the most disadvantaged.

Initial findings from aim 1 of this study are available at BMC Health Services Research [42]. Using data from patient surveys and key staff members' qualitative interviews, this study found that all participating RWHAP-funded clinics were ready and willing to implement and integrate ePRO screening for MH and SUD followed by telehealth services as part of their treatment strategy. Patients reported comfort with technology, such as smartphones and computers, and telehealth; however, patients expressed concerns around not having a physical examination and less in-person interaction.

Future results of this study will be collected in alignment with the study timeline (Figure 1). As part of aim 2, we anticipate the results will be used to iteratively refine the formal implementation blueprint, which includes barriers and facilitators to +STEP delivery in routine care. Results will be instructive for the continued implementation of +STEP at

XSL•FO
RenderX

RWHAP clinics and future sites. We anticipate that the results of aim 3 will demonstrate that +STEP will improve the diagnosis and treatment of MH and SUDs. We expect that +STEP will result in an increased number of referrals for evidence-based care of these conditions, an increased proportion of patients in treatment for both psychosocial comorbidities and HIV, and an increased quality of data used to monitor persons living with HIV in care at RWHAP clinics at the individual and clinic levels.

Discussion

Principal Findings

This will be the first study to evaluate the integrated implementation of 2 effective evidence-based technologies—ePROs and telemedicine—in serving people living with HIV in Alabama. We hypothesize that this study will provide foundational evidence demonstrating ePROs as an effective intervention to increase routine screening, referrals, and treatment for MH and SUDs. The results of this study will also include a refined blueprint for the implementation of ePROs at HIV clinics based on participant study–team meetings and evaluation of implementation over the course of the study.

Comparison to Previous Work

A systematic review of ePRO randomized control trials identified consistent methodological limitations in the existing literature [14]. These limitations included lack of consensus on the structure of ePRO interventions, including how questionnaire results were provided to clinical providers, limited provider training on the interpretation of ePRO results, and a disconnect between ePROs and targeted outcomes, such as exploring the impact of ePROs on distal clinical outcomes in lieu of proximal process outcomes [14,43-45]. This study will address the existing limitations by including provider training on ePROs among persons living with HIV and the measurement of process outcomes to inform an implementation blueprint for ePROs to identify MH and SUDs in HIV clinics.

Future Directions

The results of this study will provide evidence for future research expanding access to ePROs for improved diagnosis linked to telemedicine access to accelerate patients along the continuum of care from MH and SUD diagnosis to treatment. We will also use study findings to tailor future implementation research to the needs of African American communities, rural residents, historically marginalized communities, and those affected by intersectional stigmas, including gay men, transgender communities, and people who use drugs. These findings will have applicability in RWHAP-funded clinics in other parts of the Deep South and regions identified as priority sites for ending the HIV epidemic, which is a national initiative to scale up science-based strategies to diagnose, treat, prevent, and respond to HIV [46]. Implementing evidence-based services to support the mental and substance use needs of persons living with HIV is foundational to accelerating overall well-being and individual and population level viral load suppression.

Limitations

This study is not without potential limitations. The initiation of this study took place during the COVID-19 pandemic, which affected community partners capacity to fully engage in the early stages of the study. However, COVID-19 has increased patients' experience and comfort with telemedicine, aiding in the transition to ePROs and telemedicine for this study. Notably, during COVID-19, several clinics developed their own telemedicine programs out of necessity rather than waiting for the +STEP implementation. This means that many clinics are already providing MH services virtually, but few, if any, are using telehealth for addiction treatment services. Additionally, our community partners participate in others research studies and may have experienced study fatigue. Further, 1 site declined participation after the study was funded, citing COVID-19–related concerns and clinical capacity issues. Issues with clinic research saturation and COVID-19–related barriers will be monitored throughout the implementation of this study to try to mitigate overburdening our partners with research tasks when possible.

Conclusions

Achieving the end of the HIV epidemic in the United States necessitates programs that accelerate movement across the MH and SUD care continuum from diagnosis to treatment for persons living with HIV. Scaling these services represents a path toward improved treatment outcomes with both individual health and population-level prevention benefits of sustained HIV viral suppression in the era of undetectable=untransmittable (U=U). This study will address this evidence gap through the evaluation of the implementation of +STEP to establish the necessary systems and processes to screen, identify, and better treat substance use and MH for people living with HIV.

Data Availability

Since this is an ongoing study, data are not yet publicly available, but may be available upon request to principal investigator EE at eeaton@uabmc.edu.

Conflicts of Interest

GB has received honoraria from Med-IQ for medical education, and their institution has received grant funds on their behalf from Eli Lilly and Merck Foundation.

Abstract

Background: Executive function, including prospective memory, initiating, planning, and sequencing everyday activities, is frequently affected by acquired brain injury (ABI). Executive dysfunction necessitates the use of compensatory cognitive strategies and, in more severe cases, human support over time. To compensate for the executive dysfunction experienced, growing options for electronic mainstream and assistive technologies may be used by people with ABI and their supporters.

Objective: We outline the study protocol for a series of single-case experimental designs (SCEDs) to evaluate the effectiveness of smart home, mobile, and/or wearable technologies in reducing executive function difficulties following ABI.

Methods: Up to 10 adults with ABI who experience executive dysfunction and have sufficient cognitive capacity to provide informed consent will be recruited across Victoria and New South Wales, Australia. Other key inclusion criteria are that they have substantial support needs for everyday living and reside in community dwellings. On the basis of the participant's identified goal(s) and target behavior(s), a specific electronic assistive technology will be selected for application. Both identification of the target behavior(s) and selection of the assistive technology will be determined via consultation with each participant (and their key support person, if applicable). The choice of SCED will be individualized for each participant based on the type of technology used in the intervention, the difficulty level of the behavior targeted for change, and the anticipated rate of change. For each SCED, repeated measurements of the target behavior(s) during the baseline condition will provide performance data for comparison with the performance data collected during the intervention condition (with technology introduced). Secondary outcome measures will evaluate the impact of the intervention. The protocol includes 2 customizable Microsoft Excel spreadsheets for electronic record keeping.

Results: Recruitment period is June 2022 through March 2024. Trial results for the individual participants will be graphed and analyzed separately using structured visual analysis supplemented with statistical analysis. Analysis will focus on important features of the data, including both within- and between-phase comparisons for response level, trend, variability, immediacy, consistency, and overlap. An exploratory economic evaluation will determine the impact on formal and informal support usage, together with quality of life, following the implementation of the new technological intervention.

Conclusions: The study has been designed to test the cause-effect functional relationships between the intervention—in this case, electronic assistive technology—and its effect in changing the target behavior(s). The evaluation evidence gained will offer

XSL•FO
RenderX

new insights into the application of various electronic assistive technologies for people who experience executive dysfunction following ABI. Furthermore, the results will help increase the capacity of key stakeholders to harness the potential of technology to build independence and reduce the cost of care for this population.

Introduction

Overview

Acquired brain injury (ABI) refers to damage to the brain that occurs after birth and includes traumatic brain injury, stroke, infection, anoxia or hypoxia, and brain cancer to name the most common [1]. Cognitive impairments, including damage to higher-order executive functions, are frequently observed after ABI. Common executive function impairments include issues with prospective memory, flexibility, judgment, insight, planning and organization, and initiation of functional tasks [2]. Executive impairments can have a significant impact on functional outcomes and adversely affect participation in areas such as employment, leisure pursuits, relationships, and independent living [3-5].

Assistive Technology for Executive Function Support

A growing range of electronic assistive technologies is available, which may compensate for a number of challenges to participation. For instance, smartphones and tablets used by the wider population are emerging as useful tools for developing independence and participation after ABI [6-9]. To date, most studies evaluating the efficacy of assistive technology in providing support to compensate for executive impairments have focused on prospective memory compared with other components of executive function. The strongest evidence to date has come from a small number of randomized controlled trials testing the efficacy of delivering reminders to reduce prospective memory failures through text messages or other auditory cues delivered by personal digital devices or mobile phones [10,11]. To date, few studies have investigated the efficacy of assistive technology in supporting other areas of executive function, such as supporting goal-directed behavior to undertake functional therapy [12,13] or enhancing executive monitoring of daily intentions [14].

As the assistive technology field has been rapidly evolving, there are growing platforms and means for delivering support for executive functions. For example, home hubs constitute a more specialized type of multifunctional device. One example of such devices is “Sofihub,” which provides home-based movement sensing, audio-prompting technology (similar in principle to “Alexa” or “Google Home”). Sofihub was designed and marketed for people with disabilities, including those with cognitive impairment [15]. Fernando et al [15] provided preliminary evidence of the effectiveness of Sofihub in augmenting human support for people with executive dysfunction, including impaired initiation. The system provided prerecorded verbal prompts to participants at set times or triggered by sensors detecting movement. The verbal prompts targeted self-care activities (eg, showering, teeth cleaning, and medication administration), household tasks (eg, cleaning and putting out garbage), and reminders to take necessary items (eg, phone, keys, and hearing aids) when leaving the house.

In Australia, the National Disability Insurance Agency has identified that assistive technology offers the potential to reduce the lifetime care costs of people with severe disabilities [16]. Nevertheless, to date, there is limited published evidence regarding the use of technology in the delivery of support to people with ABI in a range of community settings [17]. Specific to electronic personal assistive devices, there is insufficient evidence to recommend any practice standards [18]. This limits the capacity of people with ABI and their supporters, including family, carers, and health professionals, to effectively implement and harness emerging technologies within community living.

Objectives

This paper outlines the study protocol for a series of single-case experimental designs (SCEDs) to evaluate the effectiveness of smart home, mobile, and/or wearable technologies for executive function support following ABI. The findings from the Sofihub trial [15] and other published evidence identify SCED as the principal methodology used to evaluate technological solutions for people with ABI [18]. The rigorous methodology of SCED enables it to test for cause-effect functional relationships between the intervention—in this case, smart home, mobile technology, or wearable technologies—and its effect in changing a behavior (eg, an increase in the number of steps in a specified task completed following a prompt from smart devices and a corresponding decrease in the number of verbal cues required from a support person) [19-21]. However, to date, many SCEDs have been of low scientific quality [22,23], and therefore, there is a need for more methodologically rigorous, evidence-based research to better understand the benefits of the introduction of technological aides [24]. The aim of this paper is to present a study protocol that will examine the efficacy of assistive technology (including home-based, mobile, and wearable technologies) in reducing executive function difficulties and care needs experienced by people with ABI.

RenderX

Methods

Study Design

A series of SCEDs will be used to evaluate the effectiveness of the intervention technologies. The choice of design will be individualized for each participant based on the type of technology used in the intervention, the difficulty level of the behavior targeted for change, and the anticipated rate of change. It is expected that the most common design will be a withdrawal A_1-B_1-A_2-B_2 design (where A denotes the baseline phase and B denotes the intervention phase). However, multiple baseline, alternating treatments, changing criterion, and combination designs may also be used [25]. Decisions regarding the design to be implemented will be made on a case-by-case basis by the research team.

Each SCED will be planned using the Risk of Bias in N-of-1 Trials Scale [26,27] to maximize internal and external validity and will be conducted over approximately a 12-month period. The Risk of Bias in N-of-1 Trials Scale is a 15-item critical appraisal tool that evaluates the methodological quality of intervention studies using a single-case methodology. It comprises 2 subscales: internal validity and external validity and interpretation.

The report of each case will be prepared in accordance with the SCRIBE (Single-Case Reporting Guideline in Behavioral Interventions) statement [28] using a customized Microsoft Excel spreadsheet (Multimedia Appendix 1) to enable electronic record keeping. The SCRIBE is a 26-item reporting guideline developed in the CONSORT (Consolidated Standards of Reporting Trials) tradition to facilitate clear, complete, and transparent reporting of the study.

Ethics Approval, Informed Consent, and Participation

The study design, recruitment, and data collection procedures were approved by the South Western Sydney Local Health District and Monash University Human Research Ethics Committees (Project IDs 2019/ETH14038 and 27923). The trial has been registered with the Australian New Zealand Clinical Trials Registry (ACTRN12622000835741). All participants will provide written informed consent before participating in the study. Each phase of the study will be monitored closely, and—as detailed in the procedures section—a customized Microsoft Excel spreadsheet (Multimedia Appendix 1) will be used to document and manage any adverse events or harms.

Participant Eligibility

The inclusion criteria are as follows: participants will be aged ≥18 years, experience executive dysfunction following ABI, have substantial support needs for everyday living, reside in community dwellings, and have sufficient cognitive capacity to provide informed consent (determined by a review of any available neuropsychological assessment and/or in consultation with their treating allied health professionals). Participants will not be excluded based on their living location (metropolitan vs regional) or living situation (alone or with others). Exclusion criteria included people with current severe mental health problems or challenging behaviors.

Standardized clinical measures will be used to screen for eligibility. The instruments are described in Multimedia Appendix 2 [29-39]. The Frontal Systems Behavior Scale (FrSBe) [40] will be used to screen for executive dysfunction and the Care and Needs Scale [41] will be used for support needs. The Health of the Nation Outcome Scale—Acquired Brain Injury [42] will be used to identify severe mental health problems, and the Overt Behavior Scale–Adult [33] will be used for challenging behaviors.

Setting

All data collection and assistive technology interventions of consenting participants will be carried out in the community, either their place of residence or work environment.

Measures and Materials

Overview

All screening and outcome measures are described in Multimedia Appendix 2, along with two contextual measures: (1) Assessing Needs and Supports in Relation to Assistive Technology (A-AT; an unpublished semistructured interview) and (2) the World Health Organization Disability Assessment Schedule [34]. These will be administered to better understand participants' functions, goals, and use of assistive technology. All published instruments have been used extensively in previous research in the field of ABI.

Primary Outcome Measure

Measures of Target Behavior(s)

In consultation with each individual participant, target behavior(s) will be identified based on their personal goal(s) for executive function support and/or participation in activities within home and community settings. The target behavior(s) will be tailored to each participant, and, as such, the measurement of the behavior will vary among participants. Target behaviors will be very specific, for example, frequency of occurrence or duration of a behavior, number of steps of an activity completed, or number of prompts from a support person. The frequency of measurement of the target behavior(s) will vary depending on the nature of the target behavior(s), but they will be measured, as appropriate, continuously throughout the baseline and intervention phases.

Goal Attainment Scaling

The Goal Attainment Scaling will be used to evaluate the level of goal attainment linked to the identified target behavior. Personalized evaluation scales ranging from +2 to −2 will be developed based on the framework of Krasny-Pacini et al [43] to ensure that the scales are a valid, reliable, and meaningful outcome measure.

Secondary Outcome Measures

The reason for including secondary measures is for the purpose of generalization and to determine whether the intervention has had effects on broader aspects of the participant's functioning. The secondary outcome measures are as illustrated in the following sections.

XSL•FO
RenderX

Community Integration Questionnaire-Revised

The Community Integration Questionnaire-Revised [44] is an 18-item scale, which will be used to measure changes in community integration across four domains: (1) home integration (eg, meal preparation and housework), (2) social integration (eg, shopping, visiting friends, and leisure activities), (3) productive activity (eg, full-time vs part-time work, school, and volunteer activities), and (4) electronic social networking enabled social integration.

EuroQol-5 Dimensions Instrument

The self-complete (participant rated) and/or proxy (completed by a family member or paid support person(s) (ie, support worker, house manager, and allied health professional) versions of the EuroQol-5 Dimensions Instrument (EQ-5D-5L) [45] will provide a profile of health-related quality of life for the participant. The questionnaire has two components: (1) health state description and (2) evaluation. In the description section, they will be asked to rate 5 dimensions of health (mobility, self-care, usual activities, pain or discomfort, and anxiety or depression). In the evaluation part, they will be asked to indicate their overall health status ("TODAY") using the visual analog scale from 0 to 100 with the end points labeled "the worst health you can imagine" to "the best health you can imagine," respectively.

Psychosocial Impact of Assistive Devices Scale

The Psychosocial Impact of Assistive Devices Scale [46] will be used to measure the psychosocial effects the assistive technology device has had on the participant. It is a 26-item questionnaire, which will be used to measure the impact the assistive device has had on the participants' sense of competence, adaptability, and self-esteem in daily life.

Quebec User Evaluation of Satisfaction With Technology

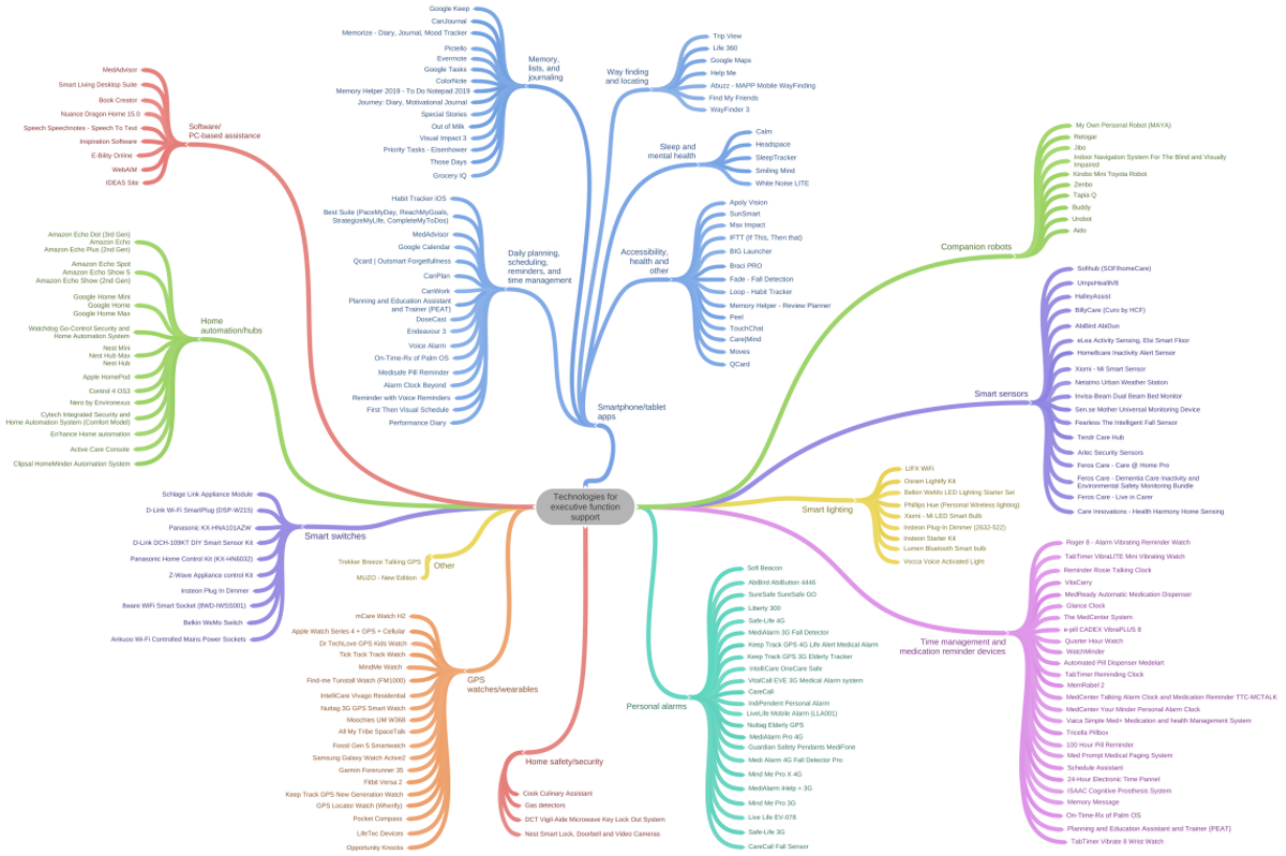
The Quebec User Evaluation of Satisfaction with Assistive Technology, version 2.0 [39], is a 12-item scale that will be used to measure the participants' satisfaction with a technology device and its related services. This includes physical properties (eg, size, weight, ease of use, and effectiveness), and, if applicable, service delivery, maintenance, and follow-up services. The final part of the measure asks participants to choose the 3 assistive technology satisfaction items that are most important to them from a total of 12 items.

Disability Support Use and Cost

If agreed by the participant as part of the consent process, disability support costs will be sourced from an administration database of their funding organization to ascertain whether the assistive technology intervention impacted disability support use and cost. These data will be augmented with discussions with the participants (and/or their proxy) using a Participant Economic Evaluation Questionnaire (Multimedia Appendix 3) to ensure that all cost data, including informal supporter costs, have been accurately captured. Data will be gathered preintervention and after the second intervention. Where costs are not available for disability support through the funding organization, market rates will be applied, with the cost of informal care based on the Australian minimum wage [47]. All costs will be inflated to 2022-2023 by applying the Consumer Price Index [48].

Blinding

Blinding in SCEDs refers to whether the participant, practitioner, and assessor are blind to the phase of the experiment. Blinding of participants will usually not be possible, given the nature of the intervention. However, the intervention is delivered by an assistive technology device, without the need for human involvement, thus eliminating human error and minimizing the risk of bias. Hence, for all intents and purposes, the "practitioner" (ie, the technology) can be considered blind to phase. Similarly, for each participant, the assessment data will be generated automatically from the assistive technology device, without the need for human involvement. Thus, the "assessor" (ie, the technology) can be considered blind to phase. In addition, data analysis will be performed by a statistician who will not be involved in discussions with the research group. The statistician will be blinded to all aspects of the intervention, including the specific phases in which data were collected.



Intervention

Electronic Assistive Technology

A scoping review identified a wide range of technologies (eg, apps, wearables, home sensors, and smart lights) appropriate for use in executive function support [49]. These are shown in Figure 1 and will be used to shortlist electronic assistive technology appropriate for addressing the individual participant's target behavior(s). The shortlist will be discussed with each participant, and through consultation with the participant and/or their proxy, assistive technology will be chosen for application and purchased using research funds.

XSL•FO
RenderX

Figure 1. Technologies identified for use in executive function support.

Customized Orientation and Training Tool

Depending on the selected electronic assistive technology, there may be a need to develop a customized orientation and training tool in either a paper or digital format. The tool will include a step-by-step guide and/or video demonstration on how to navigate to prioritized function(s) that may be controlled by electronic assistive technology. Digital information will be saved to the smartphone or tablet that the participant currently uses, and written information will be left in a prominent location in the participants' place of residence or work environment. This will ensure that they (or, where appropriate, a family member or other support person) can refer back to it if and when required.

Procedures

Initial Study Setup

The initial study setup phase with the individual participants will involve several tasks, as described below. To ensure anonymity, a pseudonym will be allocated to each participant, and no identifying information (eg, residential address) will be recorded.

Recruitment

A third-party recruitment strategy will be used to recruit up to 10 adult participants across Victoria and New South Wales in Australia. A single-page information sheet about the study, including inclusion criteria, and a "consent to contact" form will be prepared and distributed (in hard copy or via email) to community-based allied health professionals, with the request to pass the information sheet to potentially eligible clients. The consent to contact form asks whether the individual is willing to provide their own name and phone number and the contact details of the allied health professional(s) who work with them. If the individual agrees to provide contact information, the completed form can be posted or a copy emailed to the research group. Once returned, a member of the research group will make contact to invite the individual (and/or their proxy) to a face-to-face meeting to discuss their potential participation in the research.

Consent to Participate

At the first meeting, a plain English information sheet of the study and consent form will be provided and explained verbally to the participant (and/or their proxy), as will the screening process, to ascertain eligibility. The individual can either choose to review the explanatory statement and consent form during that meeting and provide written consent at that time or later. If they wish to decide later, a member of the research group will email or call the individual (and/or their proxy) within 2 weeks of the meeting to see if they would like to consent to participate. This is the only follow-up contact made with the individual unless they request additional time to make their decision.

Screening for Eligibility

Individuals who consent to participate in the study will attend a further appointment to complete the screening assessment. Except for 1 proprietary measure (FrSBe), responses to the other measures will be recorded on a Microsoft Excel spreadsheet (Multimedia Appendix 4). Measures consist of the semistructured interview (A-AT), a clinician-rated contextual

XSL•FO
RenderX

measure of functional ability (World Health Organization Disability Assessment Schedule 2.0), and 3 clinician-rated and 1 proxy-rated measures to ensure participants meet the clinical threshold (as detailed in Multimedia Appendix 2) in terms of executive function (FrSBe), have high support needs (Care and Needs Scale), and do not have mental health issues (Health of the Nation Outcome Scale—Acquired Brain Injury) or severe levels of challenging behavior (Overt Behavior Scale–Adult). Individuals who do not meet the study inclusion criteria will be thanked for their interest and time but have no further participation in the study.

Identification of Goals, Target Behaviors, and the Intervention

Overview

Several sessions will be spent working with the participants (and their proxy) to identify the goal(s), target behavior(s), and intervention to be trialed in the study. As recommended, goal(s) and target behaviors will be specific, measurable, attainable, realistic, and time limited (SMART) [50,51]. Details regarding the primary outcome (target behavior) measures will be recorded on the SCRIBE checklist: Electronic Version of Selected Items (5-21; Multimedia Appendix 1). The checklist is an interactive, fillable Excel document containing 17 of the 26 items (items 5-21) detailed in the SCRIBE guidelines [28]. A total of 2 SCRIBE items were expanded from the original SCRIBE checklist by the authors of this paper: Item 14 (measures) has added Goal Attainment Scaling (which is commonly used in neurorehabilitation) to the target behaviors to measure progress toward the goal(s); item 21 (adverse events) was slightly modified to incorporate a plan or procedure to manage adverse events. A video demonstrating the use of the SCRIBE Checklist: Electronic Version of Selected Items (5-21) is available from the authors on reasonable request.

If agreed by the participant as part of the consent process, a member of the research group will take photographs of the participant's home or work environment. The photographs will be used to help with discussions with the research team about the potential considerations regarding the layout of the house or work environment for possible technology use. A shortlist of potential assistive technologies that are appropriate to address the target behavior(s) will be developed and chosen in consultation with the participant (and/or their proxy) and the research group.

Phase 1: Baseline (A) Phase

Preintervention (secondary) measures will be administered (Multimedia Appendices 2 and 4). In addition, disability support costs will be sourced (Multimedia Appendix 3). During the baseline phase, the target behavior(s) will be measured repeatedly before implementing the intervention. Accordingly, this phase will serve as the control condition and include a minimum of 5 data points. For some technologies, it may be possible to use system-generated log reports to generate the target behavior data during the baseline (and intervention) phases. As such, the technology will be set up or installed (but during the baseline phase, it will not be activated, ie, for reminders or prompts) by either the occupational therapist to the research group or an external provider. If system-generated log reports are not possible, behavioral recordings of the target behavior(s) will be used.

Phase 2: Intervention (B) Phase

The technology will be installed, worn, and/or activated by an occupational therapist in the research group or an external provider. If required, participants (and/or their proxy) will receive a single 1-hour orientation and training session by a member of the research group on how to use the technology. Any barriers to technology use will also be identified and ameliorated if possible. The target behavior will be measured continuously throughout the intervention phase, with a minimum of 5 data points.

Depending on the specific study design for each participant, there will be subsequent phases (for A-B-A-B withdrawal designs), subphases of the intervention (for changing criterion designs), staggered introduction of the intervention across multiple target behaviors (for multiple baseline designs), or alternating interventions in rapid succession (for alternating-treatment designs). Combination designs can also be used for this purpose.

Postintervention Assessment

Following the completion of the intervention, the secondary outcome measures will be readministered (Multimedia Appendices 2 and 4). In addition, the disability support costs will be sourced (Multimedia Appendix 3). The occupational therapist in the research group will also discuss with the participant whether they wish to continue or cease using the technology following trial completion. If the participant chooses to cease using the technology, the occupational therapist will either uninstall the technology or organize for an external provider to do so at a mutually convenient time.

Results

Recruitment began in June 2022 but has been impacted by the unprecedented COVID-19 pandemic. The data collection is expected to be completed by March 2024. Only data from participants who complete all baseline and intervention phases of the study will be included in the analyses; however, reasons for withdrawal will be documented (eg, hospitalization due to deteriorating health).

Participant raw data from the publicly available contextual, secondary outcome, and screening measures will be entered into a Microsoft Excel spreadsheet (Multimedia Appendix 4). The spreadsheet contains formulas and calculations that automatically calculate scores and subscores (as per author guidelines for each measure). Test booklets will be used to enter and score the participant data from the FrSBe.

The target behavior data collected during the baseline and intervention phases will be entered or imported into SPSS statistical software (version 29; IBM Corp). Data for each participant will be evaluated separately using both structured visual analyses and statistical techniques suitable for within-subject, time-series data. Structured visual analysis will use the standard protocol of Kratochwill et al [52]. It will focus

XSL•FO
RenderX

on important features of the data making both within- and between-phase comparisons for response level, trend, variability, immediacy, consistency, and overlap. The Tau-U technique [53] or another suitable technique (depending on the individual data patterns) will be used to statistically quantify the overlap and generate effect sizes. The results will offer new insights into the application of various electronic assistive technologies for executive function support following ABI.

The SCED data analysis will be coupled with an exploratory economic evaluation analysis using Microsoft Excel (version 2306) and SPSS Statistics, delivered under the supervision of a health economist from the research team. This analysis will be completed by comparing a new intervention (ie, the assistive technology product applied during the intervention phase) against an alternative or comparator. In this study, the comparator is an intervention that would usually apply to the care of the population of interest in the absence of new technology, often referred to as standard care (ie, baseline phase). In addition, to ascertain whether the intervention had an impact on quality of life, changes in quality-adjusted life years (QALYs) will be compared between baseline and follow-up for both the participants and/or their informal support person.

The exploratory economic evaluation will determine both the incremental effect and incremental costs of the new technology intervention over those of the comparator state for each single case (each participant). The incremental costs will be presented as a "return on investment," with the return referring to the change in cost for care needs and the investment referring to the cost of the assistive technology. The incremental effect will be presented as QALYs, derived from the baseline and follow-up EuroQol-5 Dimensions Instrument utility indices. The cost difference between the "return" and "investment," together with the QALYs, will produce an individual incremental cost-effectiveness ratio for each participant.

Discussion

Expected Findings

This protocol for a series of single-case experiments delivered across 2 states of Australia (Victoria and New South Wales) offers digital tools, including the SCRIBE checklist: Electronic Version of Selected Items (5-21; Multimedia Appendix 1), a semistructured interview schedule (A-AT), and a customizable Microsoft Excel spreadsheet of screening tools and outcome measures (Multimedia Appendix 4). The single-case experiments will rigorously test the effectiveness of a suite of smart home, mobile, and wearable technologies and deliver high-quality evidence regarding technology interventions. Furthermore, an exploratory economic evaluation will determine the impact on formal and informal support use and quality of life.

This study extends the work of the Sofihub trial [15] and has been strategically designed to test the cause-effect functional relationships between the intervention (in this case, smart home, mobile technology, or wearable technologies) and its effect in changing the target behavior(s). Consequently, the results will address the current evidence and knowledge gaps for people with ABI who experience executive function issues, their formal and informal support networks (including health professionals), technology developers, smart home designers, and funders of disability services. Furthermore, the findings will be translated into a suite of freely available digital, written, and face-to-face educational resources to increase the capacity of key stakeholders to harness the potential of technology to build independence and reduce the cost of care for people who experience executive dysfunction following ABI. Dissemination of the study will also be undertaken by publishing results in peer-reviewed journals, presenting them at relevant conferences and in a final report provided to the 2 project sponsors.

Limitations

This study has some potential limitations. First, the study is limited to English-speaking participants, which limits the generalizability of the findings to culturally and linguistically diverse groups. Second, people with severe mental health problems or challenging behaviors will be excluded from participating in the study, so it will not be possible to determine the potential application of various electronic assistive technologies for executive function support following ABI in those populations.

Conclusions

The digital tools developed and made available as part of this protocol may be useful for other researchers to consider, or draw upon, when designing single-case experiments. Evaluation evidence gained from a series of SCEDs will offer new insights into the application of various electronic assistive technologies for people who experience executive dysfunction following ABI. Furthermore, the results will help increase the capacity of key stakeholders to harness the potential of technology to build independence and reduce the cost of care for this population.

Acknowledgments

The authors would like to acknowledge the support received to undertake this work through funding from the Transport Accident Commission (Victoria) and icare New South Wales (project reference T012).

Data Availability

The data sets generated during this study are not publicly available, as the study is still ongoing and analysis has not yet taken place.

Abstract

Background: Routine examination after cataract surgery, including a refraction test 4 to 6 weeks after surgery, is mandatory in most hospitals. In recent years, there has been growing interest in exploring alternative approaches to postoperative follow-up in cataract surgery patients due to the increasing number of cataract surgeries being performed, the limited availability of health care resources, and the need to optimize the use of health care services.

Objective: We aim to compare postoperative visual outcomes after a day 0 examination in patients with 2 follow-ups, one on day 7 and other on day 30, and patients with a single ophthalmic follow-up between days 25 to 30.

Methods: A prospective, quantitative, experimental control study will be carried out in Reiyukai Eiko Masunaga Eye Hospital, located in Banepa, Kavrepalanchok, Nepal. All patients undergoing cataract surgery meeting the inclusion and exclusion criteria irrespective of the type of surgery (small-incision cataract surgery or phacoemulsification) will be included in the study. The patients will be randomly assigned to 1 of 2 groups. Patients in group 1 will be examined on day 1, day 7, and day 30, whereas patients in group 2 will be examined on day 1 and once between days 25 to 30. The minimum clinically important difference (MCID) in our study will be set according to the improvement in the Snellen visual acuity chart.

Results: The study is expected to be completed within 6 to 8 months from the start of the project. Data analysis and report writing will be carried out in a 2-month period. Best-corrected visual acuity will be compared between the 2 groups to determine if the MCID is achieved. The cost-effectiveness of the new approach will also be analyzed.

Conclusions: We aim to conclude that we can safely defer the 1-week postoperative follow-up visit in patients undergoing uncomplicated cataract surgery and that, moreover, we can reduce the patient load at the hospital and decrease patient expenses by decreasing the frequency of hospital visits.

Introduction

Background

Cataract is the leading cause of blindness and visual impairment in lower- and middle-income countries [1,2]. Surgery is the only available treatment that is highly cost-effective and capable of significantly improving visual function [3,4]. Cataract surgery often achieves an excellent visual outcome with low rates of complication [5,6]. Routine examination after cataract surgery, including a refraction test a few weeks after surgery, is mandatory in most hospitals [7,8].

Limburg et al [9] investigated the benefits of postoperative follow-up in India and concluded that visual acuity at hospital discharge was not representative of visual acuity several weeks after surgery [10]. However, a study by Congdon et al [11] concluded that early vision assessment of all patients and a follow-up assessment only for patients who return to the clinic without prompting were adequate to ensure the quality of cataract surgical services. This is again countered by a study by Gupta et al [12], who presented evidence of substantial changes between visual acuity on the first postoperative day and at subsequent follow-up. Postoperative complications and uncorrected refractive errors are 2 major issues that lead to poor visual outcomes [5,13-16]. Both issues can be wholly addressed by promoting and ensuring postoperative follow-up at the designated time [17-20]. As per the National Programme of Control of Blindness, Vision 2020: Right to Sight, the recommended postoperative follow-up visit schedule is a first follow-up on the first postoperative day by the surgeon (mandatory), a second follow-up between day 7 and day 10, and a third follow-up (with refractive correction) between day 30 and day 45 [21]. Saeed et al [22] and Tinley et al [23] concluded that postoperative follow-up visits can be safely deferred up to 2 weeks after cataract surgery, thereby enhancing the efficiency of day care units. Meltzer et al [24] performed a study using data from the PRECOG (Prospective Review of Early Cataract Outcomes and Grading) trial and reported that visual acuity immediately after cataract surgery was highly correlated with visual acuity after 40 days, suggesting that for the purposes of quality assessment, follow-up of all patients is not needed. A study by Deshpande et al [25] concluded that visual outcomes after uneventful cataract surgery were comparable between patients followed up on days 3 to 7 and days 25 to 30 in comparison to patients directly followed up on days 25 to 30. Additionally, it was observed that the first follow-up visit could be safely deferred until 4 weeks after uneventful cataract surgery, including phacoemulsification or small-incision cataract surgery (SICS), in patients with no preexisting ocular or systemic comorbidity [25]. The purpose of this study is to evaluate, from a safety perspective, altering the standard postoperative management guidelines after cataract surgery so that the first follow-up visit at 1 week is deferred in patients with no significant preexisting ocular or systemic comorbidity and no intraoperative surgical complications or immediate postoperative complications at the time of discharge from the hospital.

General Objective

The general objective is to reduce follow-up visits in cataract surgery patients.

Specific Objectives

The specific objectives are (1) to compare postoperative visual outcomes after a day 0 examination in patients with either 2 follow-up visits, one on day 7 and the other on day 30, or 1 ophthalmic follow-up visit between day 25 and day 30; (2) to assess the safety of deferring the first follow-up visit at 1 week; and (3) to perform a cost-benefit analysis of the intervention.

Methods

Study Design, Setting, and Participants

This will be a prospective, quantitative, experimental, noninferiority control study of health services use. Selected patients undergoing cataract surgery at Reiyukai Eiko Masunaga Eye Hospital irrespective of the type of surgery (SICS or phacoemulsification) will be included in the study.

All enrolled patients will undergo an examination on the first postoperative day conducted by an ophthalmologist who is unaware of the patient's group assignment. Subsequently, the patient will proceed to the counselor's office, where a unique identification number will be generated and the patient will be randomized into either group 1 or group 2.

In group 1, patients will be instructed to attend follow-up visits at 1 week and 1 month postoperatively. In group 2, patients will be instructed to attend a follow-up visit at 1 month postoperatively only. During the visit, the patients will receive detailed guidance on the appropriate use of medications and be educated about the signs and symptoms they should be vigilant for. The specific date of the postoperative visit will also be communicated.

At each follow-up visit, the patient will directly visit the counselor's office. Upon arrival, they will be provided with a blank sheet of paper containing the unique identification number assigned to them on the first postoperative day. Visual acuity testing will be conducted by a blinded optometrist, while slit lamp biomicroscopy will be performed by a blinded ophthalmologist. Before leaving the hospital, the patient will return the paper to the counselor, who will then enter the necessary information into the patient's file.

Inclusion Criteria

Patients undergoing uncomplicated cataract surgery at Reiyukai Eiko Masunaga Eye Hospital irrespective of the type of surgery (SICS or phacoemulsification) will be included in the study.

Exclusion Criteria

Patients will be excluded if (1) there are complications during the surgery that warrant more frequent follow-up visits (eg, premature entry, posterior capsular rupture, zonular dialysis, postoperative hyphema, toxic anterior segment syndrome, or postoperative fibrin in the anterior chamber); (2) the surgery is for complicated cataract, traumatic cataract, ocular hypertension, or if the patient has drug allergies; (3) the patients has a history

XSL•FO
RenderX

of diseases that might affect postoperative visual outcomes, such as uveitis, glaucoma, viral keratitis, corneal scarring, hypertensive retinopathy, diabetic retinopathy, central retinal vein occlusion, branched retinal vein occlusion, or age-related macular degeneration; (4) the patient is unwilling to participate or does not provide written consent; and (5) the patient misses the follow-up visits.

Sample Size and Sampling Technique

Sample size is calculated as follows: $2[Z\alpha + Z1 - \beta] 2 \times (sd2/d2) = 2 [1.96 + 1.645] 2 \times [(0.1125)2/(0.025)2] = 263$ for one group, where reference mean values for postoperative visual outcomes are taken from the study conducted by Deshpande et al [25]. The number of participants in intervention group will be 263 and the number of participants in the control (reference) group will be 263. We will use a random sampling technique and computer-generated random numbers to assign patients to the intervention or control group. We generated randomized numbers with a commonly used method [26]. The assignment will be done by the counsellor on the first postoperative day. The researchers will be masked as to randomization at all postoperative visits.

Data Collection Technique and Tools

A proforma will be developed for data collection. A questionnaire will be prepared; counselors will ask the questions and the information will be recorded in a register. This information will be transferred to an Excel (Microsoft Corp) sheet on a daily basis.

Plan for Supervision and Monitoring

The study will be carried out by a team of investigators. The principal investigator will provide orientation for the involved staff 1 week prior to participant enrollment. The issues that might arise during the course of data collection will be resolved by mutual discussion between the investigators. The study will be supervised remotely by the Seva team.

Plan for Data Management and Analysis

Study records that identify the patients will be kept confidential, as required by law. All records pertaining to the patients' involvement in this research study will be stored in a locked file cabinet in the hospital. A case number will indicate the patients' identity on these records. This information will only be accessible to the authors.

Expected Outcome of the Research Results

We expect to determine whether we can defer the 1-week cataract surgery follow-up visit of patients to the hospital.

Primary Outcome

Visual acuity measurements serve as the most important primary outcome. This includes assessing the level of visual improvement or stability achieved by patients during the 4-week follow-up period. Visual acuity outcomes can provide insights into the effectiveness of deferring follow-up visits for achieving comparable visual outcomes to the standard practice of early postoperative visits.

Secondary Outcome

The results of the cost-benefit analysis can be considered a secondary outcome. Conducting a cost-effectiveness analysis allows for the assessment of the economic implications and potential cost savings associated with deferring postoperative follow-up visits. This outcome provides insights into the financial feasibility and efficiency of implementing the deferred follow-up strategy.

We will perform a cost-benefit analysis to compare the economic status of the intervention group and active control group. For this we have to collect financial data on direct and indirect costs. Data on direct costs will be retrieved from the hospital record system, because this is the money paid directly by patients for their treatment after the surgery is recorded, including payments for consultation, medicine, and investigation (if required) at each follow-up visit.

Data on indirect costs, that is, costs incurred to the patient in the process of coming to the follow-up visit, include the following: (1) lost productivity costs (how much money the patient could have earned if the patient hadn't come to the hospital follow-up visit), (2) transportation costs (the cost incurred while travelling), and (3) companion costs (patients will definitely have a companion, for whom we also have to calculate both costs above (lost productivity and transportation). Data on indirect costs will be obtained from interviews with the patients. We will calculate the average cost per visit, which will ultimately reveal the costs and benefits of the new approach, because the suggested new regimen will eliminate one follow-up visit.

Plan for Use of Research Findings

Research findings will be disseminated through the Reiyukai Eiko Masunaga Eye Hospital newsletter. Donors will be also informed. Results will be published in high-impact journals for better coverage.

Ethical Considerations

Ethical Approval

The Declaration of Helsinki will be adequately addressed. Ethical approval for this study has been obtained from the ethical review board of the Nepal Health Research Council (428/2022 P).

Consent

Participants will be provided with detailed information about the study, including the deferral of postoperative visits, as well as potential risks, benefits, and alternatives. A written informed consent form will be provided to all participants.

Privacy and Confidentiality

Study data will be collected and stored in a manner that ensures the anonymity or deidentification of participants. Personally identifiable information such as names, addresses, and social security numbers will be removed from the data set. Each participant will be assigned a unique identifier that is used instead of their personal information.

XSL•FO
RenderX

Results

More than 526 participants will be enrolled in the study, with a minimum of 263 assigned to the intervention group (deferred follow-up visits) and a minimum of 263 to the comparison group (standard practice of early postoperative follow-up visits). The sample will have diverse demographics, ensuring a representative population.

Visual acuity measurements will be obtained for both groups during the follow-up period. We will be able to statistically compute whether the deferred follow-up visit group demonstrates comparable visual acuity outcomes to the comparison group. This will be inferred if there are no statistically significant differences between the two groups in terms of visual acuity outcomes (P>.05).

Among the participants in the deferred follow-up visit group, the number of patients who experience postoperative complications during the 4-week follow-up period will be compared with the group with the 1-week follow up visit.

We will also determine if participants in the deferred follow-up visit group report high levels of satisfaction with the extended recovery period and reduced travel burden. The number of participants who express that deferring follow-up visits provided them with convenience and comfort during the recovery phase will be mentioned.

We will determine if reduction in early postoperative visits allows health care providers to allocate their time and expertise more efficiently, focusing on patients with immediate needs or complex postoperative care requirements.

Discussion

Expected Findings

The proposed study will investigate the feasibility and potential benefits of deferring postoperative follow-up visits up to 4 weeks after uneventful cataract surgery in a tertiary level eye hospital in Kavrepalanchok.

Deferring postoperative follow-up visits will allow patients to recover in the familiar environment of their homes, reducing the need for immediate travel and associated costs. This can have a positive impact on patient satisfaction and comfort during the recovery period. By avoiding unnecessary trips to the hospital, patients may experience reduced anxiety and stress, leading to an improved overall experience.

By spacing out follow-up visits, health care providers can optimize resource allocation within the tertiary level eye hospital. This approach will allow health care personnel to allocate their time and expertise more efficiently, focusing on patients who require immediate attention or complex postoperative care. Moreover, it can potentially reduce the burden on health care facilities, as fewer appointments are scheduled during the early postoperative period.

Deferring follow-up visits may also improve access to care, particularly for patients residing in remote areas. Traveling to health care facilities shortly after surgery can be challenging, especially for individuals with limited mobility or limited access to transportation. By extending the follow-up period, patients from distant locations can receive necessary care without the immediate need for travel, increasing the likelihood of their adherence to follow-up appointments.

One major concern related to deferring follow-up visits is the potential delay in detecting postoperative complications. Early postoperative visits allow health care providers to closely monitor patients for any signs of infection, inflammation, or other adverse events. When extending the follow-up period, it is crucial to educate patients regarding the signs and symptoms of postoperative complications so that they can visit the hospital, if required, on time. Patients should receive comprehensive information about self-care, potential warning signs, and instructions on when to seek medical attention. This will empower patients to actively participate in their own recovery and promote a sense of responsibility for their eye health.

Limitations and Challenges

There are potential challenges associated with deferring postoperative follow-up visits. It is important to carefully consider the selection criteria for eligible patients to ensure that only those with a low risk of complications are included in the study. Additionally, proper communication channels must be established to ensure patients have access to health care providers in case of emergency concerns or complications during the extended follow-up period.

Conclusion

The proposed study on deferring postoperative follow-up visits up to 4 weeks after uneventful cataract surgery in a tertiary level eye hospital in Kavrepalanchok will offer several potential benefits for patients, health care providers, and health care facilities. By prioritizing patient convenience, optimizing resource use, and ensuring appropriate support and education, this approach has the potential to improve access to care and overall patient satisfaction. However, careful consideration should be given to the selection criteria and establishment of effective communication channels to address potential challenges and ensure patient safety. The findings of this study will contribute valuable insights to the delivery of eye care services and may have implications for similar settings.

Acknowledgments

We sincerely thank Ms Shova Acharya for her active role as a counsellor in the study. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Abstract

Background: Studies exploring the impact of receiving end-of-life prognoses in patients with advanced cancer use a variety of different measures to evaluate the outcomes, and thus report often conflicting findings. The standardization of outcomes reported in studies of prognostication in palliative cancer care could enable uniform assessment and reporting, as well as intertrial comparisons. A core outcome set promotes consistency in outcome selection and reporting among studies within a particular population. We aim to develop a set of core outcomes to be used to measure the impact of end-of-life prognostication in palliative cancer care.

Objective: This protocol outlines the proposed methodology to develop a core outcome set for measuring the impact of end-of-life prognostication in palliative cancer care.

Methods: We will adopt a mixed methods approach consisting of 3 phases using methodology recommended by the Core Outcome Measure in Effectiveness Trials (COMET) initiative. In phase I, we will conduct a systematic review to identify existing outcomes that prognostic studies have previously used, so as to inform the development of items and domains for the proposed core outcome set. Phase II will consist of semistructured interviews with patients with advanced cancer who are receiving palliative care, informal caregivers, and clinicians, to explore their perceptions and experiences of end-of-life prognostication. Outcomes identified in the interviews will be combined with those found in existing literature and taken forward to phase III, a Delphi survey, in which we will ask patients, informal caregivers, clinicians, and relevant researchers to rate these outcomes until consensus is achieved as to which are considered to be the most important for inclusion in the core outcome set. The resulting, prioritized outcomes will be discussed in a consensus meeting to agree and endorse the final core outcome set.

Results: Ethical approval was received for this study in September 2022. As of July 2023, we have completed and published the systematic review (phase I) and have started recruitment for phase II. Data analysis for phase II has not yet started. We expect to complete the study by October 2024.

Conclusions: This protocol presents the stepwise approach that will be taken to develop a core outcome set for measuring the impact of end-of-life prognostication in palliative cancer care. The final core outcome set has the potential for translation into clinical practice, allowing for consistent evaluation of emerging prognostic algorithms and improving communication of end-of-life prognostication. This study will also potentially facilitate the design of future clinical trials of the impact of end-of-life prognostication in palliative care that are acceptable to key stakeholders.

Introduction

Background

Palliative care is a service provided to patients with life-limiting illnesses, such as advanced cancer, focusing on improving quality of life and symptom management through the early identification, assessment, and treatment of pain and other ailments [1,2]. It can also enable patients to understand their choices for treatment while providing physical, psychological, social, and spiritual support to patients and their families or informal caregivers alike.

Prognostication is broadly defined as the process of making predictions about the future, such as the likely outcome or course of a disease and the chance of recovery or recurrence. This research is specifically concerned with prognostication of survival, or end-of-life (EOL) prognostication. Prognostication of EOL is a vital component of patient management and decision-making in palliative care [3,4]. An accurate prognosis of the EOL allows patients and their families or informal caregivers adequate time to prepare, such as making financial plans and identifying their preferences for place of death [5]. Medically, an accurate prognosis can allow clinicians to identify appropriate treatment strategies based on individual patients' prognostic factors and symptoms [4].

Currently, there is no gold standard for prognostication of EOL. Many prognostic methods rely on clinician-estimated prognosis [5]. However, clinicians' survival predictions are often inaccurate, inconsistent, and overoptimistic [6,7]. Various prognostic tools have been validated for use in palliative cancer care, and they may provide better accuracy, consistency, or other benefits in comparison with clinicians' predictions [5]. However, the impact of such prognostic algorithms has yet to be established, and inconsistency in outcome reporting among prognostic studies makes it difficult to compare results.

Rationale for Core Outcome Set Development

The selection of appropriate primary and secondary outcome measures is an essential component of study design; a study is only as credible as its end points [8]. However, researchers may select outcomes that do not reflect meaningful end points for all stakeholders, namely patients and informal caregivers or clinicians [9,10]. Inconsistency in end points across a particular area of research can be a barrier to comparing study findings, reducing the feasibility of meta-analysis, and perpetuating outcome reporting biases [10]. Heterogeneity of outcomes has been noted in palliative care research. Previous studies have often focused on outcomes deemed important by experts, namely academics and clinicians, thereby overlooking patients' and other stakeholders' opinions and experiences and hindering the translation of findings into clinical practice [11-14].

A core outcome set (COS) promotes consistency in outcome selection among studies within a particular population, such as palliative cancer care, by providing a consensus-based, agreed minimum set of clinically meaningful outcomes to be measured and reported in all clinical trials of a specific population [15]. The Core Outcome Measures in Effectiveness Trials (COMET) initiative provides guidance for COS developers planning to construct a COS [15]. First, it is recommended that outcomes in existing published and ongoing studies be identified. Interviews with patients, informal caregivers or family, and other stakeholders can then be performed to ascertain outcomes important to them and assist research teams in understanding why particular outcomes are important [16]. Next, a Delphi process is advised, where key stakeholders such as patients, informal caregivers, and those who design and use research rank all the outcomes identified in the previous 2 phases until consensus is reached on which ones are the most important. The result is an agreed set of core outcomes.

There is as yet no consensus on which outcomes should be used to assess the impact of EOL prognostication in palliative cancer care. This study will develop a COS to assess prognostic impact, which will assist in preparing for future impact studies.

Scope of the COS

Palliative care can be provided to people living with a variety of disease types and chronic illnesses, including but not limited to cancer, cardiovascular diseases, chronic respiratory disease, diabetes, and acquired immunodeficiency syndrome [1]. This study will focus on palliative care in patients with a life-limiting, advanced, or progressive cancer to avoid confounding outcomes that might arise from including all such a wide range of illnesses. This will be the first study to investigate and define a COS for prognostic research in palliative cancer care. For the purpose of this study, the term *palliative cancer care* will be defined as treatment, care, and support provided to those with a life-limiting, advanced, or progressive cancer that cannot be cured [1,2]. This is a working definition, in that this definition has been chosen for the purpose of this study, and we recognize that it may not fully conform with established or authoritative definitions of *palliative cancer care*. Informal caregivers will include family members, friends, or other individuals who provide a wide range of unpaid assistance for someone with whom they have a personal relationship, including but not limited to physical and psychological support [17,18].

The intervention of interest in our study is EOL prognostication, defined as any process of estimating and communicating the likelihood of survival (ie, how long an individual has left to live) [5].

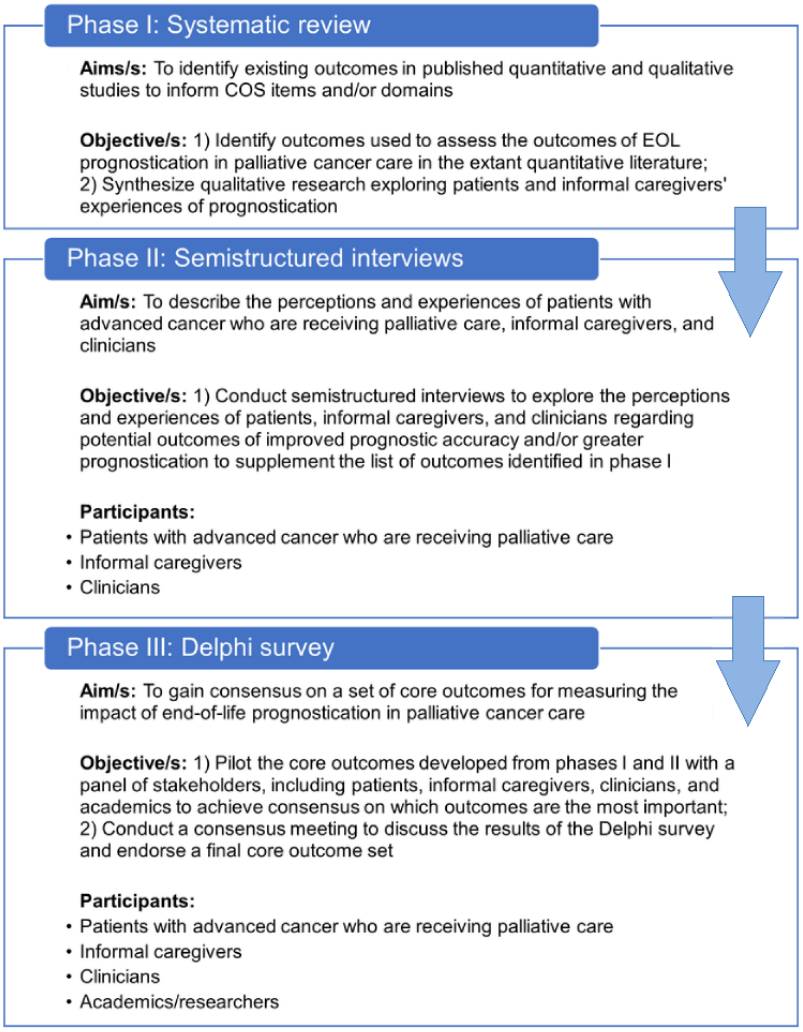
Aim and Objectives

This study aims to create a COS for measuring the impact of EOL prognostication in palliative cancer care.

The objectives for the whole study are as follows:

1. To develop a list of outcomes relevant to the impact of EOL prognostication in palliative cancer care.
2. To prioritize outcomes for measuring the impact of EOL prognostication in palliative cancer care that are important to relevant stakeholders, namely, patients, informal caregivers, and clinicians.
3. To achieve consensus on a minimum set of relevant outcomes to assess the impact of EOL prognostication in palliative cancer care.

XSL•FO
RenderX



Methods

Design

This study will adopt a multiphase, mixed methods approach suggested by the COMET guidelines [15] and will adhere to the Core Outcome Set—STAndards for Development (COS-STAD) recommendations to support the development, implementation, and evaluation of the COS [19]. This study protocol was written following the Core Outcome Set—STAndardized Protocol Items (COS-STAP) guidelines for reporting protocols of COS development [20].

The study will consist of three phases: (1) a systematic literature review of relevant outcomes reported in extant quantitative and qualitative literature to measure the impact of EOL prognostication in palliative cancer care; (2) semistructured, qualitative interviews to explore the views and experiences of patients, informal caregivers, and clinicians; and (3) a Delphi study to prioritize outcomes derived from phases I and II. Figure 1 shows a summary of the study design.

Figure 1. Phases of developing a core outcome set (COS) for the impact of end-of-life (EOL) prognostication in palliative cancer care.

Stakeholders and Setting

This study will involve four stakeholder groups: (1) patients with advanced cancer who are receiving palliative care, (2) informal caregivers, (3) clinicians, and (4) academics or researchers. We will recruit patients, informal caregivers, and clinicians through palliative care services from 3 sites in London, United Kingdom, including 2 National Health Service trusts and 1 hospice. We will begin recruitment to the study by placing posters advertising the study in public spaces of the participating sites to recruit patients (both inpatients and outpatients), informal caregivers, and clinicians simultaneously. These posters will include the researchers' contact information so that interested individuals can contact them for further details regarding the study, to ask questions, or to express their interest in participating.

Where possible, a researcher (CS) will also attend weekly multidisciplinary team meetings within the sites and be available on site to encourage clinical staff to identify patients who are eligible to participate and who are physically and mentally capable. The researcher will only attend multidisciplinary team meetings at a time point agreed with the clinical team (ie, at the beginning or the end) to discuss the study and will leave before any confidential patient information is discussed. A member of the patient's direct clinical care team (ie, someone who is currently treating them) will make the first approach to potential participants to ask them if they would be interested in participating in the study, and if so, whether they give

XSL•FO
RenderX

permission for the clinical team to provide the minimum, necessary information (name and contact details) for the researcher to approach them. The researcher will only approach participants who have consented (ie, verbally) for them to do so. The researcher or clinical staff will provide such patients with a participant information sheet and the researchers' contact information. If present at the time, informal caregivers will also be asked if they would be interested in participating in the study.

An invitation email, participant information sheet, and researcher contact information will be shared with palliative care clinicians at participating sites. We will also contact relevant organizations, such as the Association for Palliative Medicine of Great Britain and Ireland and the European Association for Palliative Care, to recruit national and international palliative care clinicians. We will ask the group or association chair to forward an email to group members that contains the participant information sheet and a link to the first round of the survey.

We will identify academics or researchers through opportunity sampling. We will ask colleagues and other contacts to suggest potential participants who have the relevant experience and are able to read and write in English. To encourage participation from a wide geographical area, we will screen academic profiles on UK and international university websites to identify individuals who have conducted relevant work. Heads of palliative care research departments may also be contacted and asked whether any members of their team have conducted research within the field of palliative care and would be willing to put us in contact. Additionally, the reference list of any relevant reviews will be searched to identify academics who have published research in the palliative care settings, and the authors who have cited relevant papers will also be screened for eligibility.

For phase II, we estimate that we will need to recruit 8 to 10 participants per group (patients, informal caregivers, and clinicians), making a total of 24 to 30 participants. This sample size is based on a previous COS study's recommendations, as well as the research team's experiences of qualitative research [21]. However, data collection will continue until data saturation is reached. Data saturation will be determined to have occurred when no new themes are being identified in analysis. Data collection will occur concurrently with recruitment to minimize attrition.

There is currently no consensus on how to determine the sample size for a Delphi survey. Balancing the sample size in a Delphi survey is crucial for achieving meaningful consensus; larger sample sizes may present challenges in terms of communication and follow-up, leading to lower response rates, whereas smaller sample sizes can restrict the scope and reliability of the survey results [22-24]. When considering sample size, it is also important to consider attrition that is likely to occur between each round. Therefore, based on previous studies' recommendations [25,26], we took a pragmatic decision to recruit a minimum of 10 participants to represent each stakeholder group, with a minimum of 40 participants in total. For pragmatic reasons, and to ensure that we include a range of perspectives, we aim to recruit a minimum of 10 international experts. For the consensus meeting, we will recruit approximately 4 participants from each stakeholder group. Maintaining a balance between stakeholder groups is important to ensure that certain voices are not overpowered. This group size will be manageable for a web-based meeting, while still permitting a range of perspectives to be heard.

Phase I: Systematic Literature Review

Phase I of the study was completed in June 2023. The complete protocol for this systematic literature review, including the search strategy and study selection criteria, was submitted for registration on PROSPERO (the International Prospective Register of Systematic Reviews) on March 29, 2022, and was subsequently published on the PROSPERO website on April 1, 2022 (CRD42022320117). This review was conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 statement [27].

The aim of this systematic literature review was to identify existing outcomes to inform COS items and domains. Retrieved papers were analyzed in two subsets: (1) quantitative studies (clinical trials and observational studies), seeking to identify the outcomes used in previous research to measure the impact of EOL prognostication in palliative cancer care, and (2) a systematic review and thematic synthesis of qualitative studies exploring patients' and informal caregivers' experiences of EOL prognostication in palliative cancer care.

We carried out searches using the following electronic databases from inception to September 2022: Ovid MEDLINE, Ovid Embase, Ovid PsycINFO, CINAHL, and the Cochrane Library (both the Cochrane Controlled Register of Trials and the Central Register). We also extended searches to gray sources and adopted snowballing techniques to identify additional papers and ensure literature saturation. Search terms included keywords related to prognostication, palliative care, advanced cancer, and outcomes and cognate terms. Search limits were applied to restrict results to a human, adult population, and studies published in English language only due to limitations in resources. Eligibility criteria included (1) patients with advanced cancer, or their informal caregivers; (2) prognostication, defined as any process of estimating and communicating the length of survival of an individual's disease; (3) quantitative studies that reported outcomes of prognostication; and (4) qualitative studies that explored experiences and perceptions of prognostication.

The search results from each database were imported and deduplicated in the Rayyan software [28]. The titles and abstracts of the studies were screened by 4 independent reviewers using the above-mentioned eligibility criteria. Those that met the inclusion criteria for either review question were read in full by at least 2 authors. Discrepancies were resolved through discussion between authors. If no consensus could be reached, a third author was consulted.

Methodological quality was assessed using the Mixed Methods Appraisal Tool [29]. A narrative approach was used to undertake the quantitative synthesis, along with tables of outcomes, their descriptions, and measures. Outcomes were categorized using the taxonomy for COS recommended by COMET [30]. For the qualitative analysis, the analysis was guided by Thomas and 'Harden's [31] framework for thematic synthesis, with 3 stages.

XSL•FO
RenderX

The COMET taxonomy was used as an external framework to support the development of analytical themes and facilitate the combination of the results of both the quantitative and qualitative studies. A narrative description of each theme in relation to the review question was provided.

The results of the review have been accepted for publication in an academic journal and will be taken forward for consideration for inclusion in the COS.

Phase II: Semistructured Interviews

The second phase of this study will be a qualitative study using semistructured interviews to explore the perceptions and experiences of patients, informal caregivers, and clinicians regarding the potential outcomes and impact of EOL prognostication.

Participants

We will use purposive, maximum variation sampling to capture a range of patients, informal caregivers, and clinicians with the characteristics shown in Textbox 1. To achieve this, we will collaborate closely with staff at participating sites and seek to identify a diverse sample, accounting for characteristics such as age, gender, ethnicity, socioeconomic status, education level, cancer diagnosis, relationship to the person with cancer, and professional role. This will enable us to ensure that our study includes a broad spectrum of perspectives and experiences, making our research findings more comprehensive and representative. For pragmatic reasons related to resource availability, we will only be able to recruit participants who are able to communicate in and understand written and spoken English.

Textbox 1. Eligibility criteria for phase II.

Inclusion criteria

- Patients
  - Aged ≥18 years
  - Receiving palliative cancer care as per the prespecified definition [1,2]
- Informal caregivers
  - Aged ≥18 years
  - Identifies as an informal caregiver, as per the prespecified definition [17,18]
  - Have provided such care within the last 12 months before study recruitment, irrespective of survival (in cases where the informal caregiver is bereaved, they will be contacted no less than 6 months after bereavement out of respect and concern) [32]
- Clinicians
  - A registered health care professional (eg, a physician, nurse, or allied health professional) employed in the palliative care services at one of the participating sites, who routinely estimates and provides end-of-life (EOL) prognostic predictions

Exclusion criteria

- Patients
  - Children (aged <18 years)
  - Individuals who, in the opinion of their treating clinician, would not be appropriate to participate in this research
  - Individuals who have previously expressed a wish not to be involved in research
  - Individuals who lack capacity to give informed consent
- Informal caregivers
  - Young informal caregivers (aged <18 years)
  - Informal caregivers who, in the opinion of the clinician gatekeeper, would be inappropriate to approach about enrollment in the study due to physical or mental illness
  - Individuals who lack capacity to give informed consent
- Clinicians
  - Clinicians whose role in palliative care is undertaken exclusively outside of the United Kingdom (to avoid varying, potentially confounding practices)
  - Clinicians who do not routinely estimate and provide EOL prognostic predictions in palliative cancer care

XSL•FO
RenderX

Data Collection

Participants will be invited to take part in one semistructured interview, which will be conducted by one researcher (CS) with individuals either face-to-face, via video call, or via telephone, depending on practical considerations, participant preferences, and any prevailing COVID-19 restrictions. Interviews are anticipated to last between 30 minutes and 1 hour and will be conducted in a quiet environment, at a convenient time for the participant. From our experience, people with advanced cancer may only be willing or able to be interviewed for 30 minutes at a time, so we will be flexible in meeting their needs and will either continue for longer if they are comfortable or take a break. Before the interview starts, the interviewer will explain the concept of the COS and the importance of measuring the impact of prognostication in palliative care. Participants will also be asked to provide basic demographic information for descriptive reasons only.

The interviews will be semistructured using a topic guide. The main topics covered will be consistent across the interviews, but the specific phrasing of questions and when they are posed during the interview will vary depending on how the conversation develops throughout the interview. Interviews will be audio-recorded with the participant's consent.

Data Analysis

Interview transcripts will be analyzed thematically using a framework analysis approach. Audio recordings will be transcribed verbatim. A researcher (CS) will independently read the transcripts and generate initial codes. A second researcher (BV) will independently read a sample set of interviews to provide a second, independent perspective and ensure that all codes capture the range and depth of data. The 2 researchers will develop initial proposals for themes and then meet to discuss and agree broad themes. CS will then review and construct a final set of themes. The data from these interviews will be analyzed alongside the data from phase I, so as to identify outcome domains to be included in the long list of core outcomes to be taken forward into phase III. Descriptive statistics will be used to present demographic information.

Phase III: Delphi Survey

Once a list of core outcomes has been developed from phases I and II, we will carry out a Delphi survey and consensus meeting to achieve consensus between disparate stakeholders, including patients, informal caregivers, clinicians, and academics or researchers, about which of these outcomes are most important. An international sample of clinicians and academics or researchers will be sought to widen the generalizability of the final COS.

Participants

The goal is to have representation of different perspectives about which are the important outcomes to include in the COS. The Delphi panel members should reflect the population that is intended to use the COS or who will be involved in subsequent research studies that use the COS [33]. Therefore, the participant panel will comprise 4 key stakeholder groups: patients, informal caregivers, clinicians with clinical experience in palliative care, and academics or researchers with research experience in palliative care. We will use convenience sampling, as well as opportunity and snowball sampling to achieve a maximum variation sample by including people with the characteristics shown in Textbox 2.

XSL•FO
RenderX

Textbox 2. Eligibility criteria for phase III.

Inclusion criteria

- Patients
  - Aged ≥18 years
  - Receiving palliative cancer care as per the prespecified definition [1,2]
- Informal caregivers
  - Aged ≥18 years
  - Identifies as an informal caregiver, as per the prespecified definition [17,18]
  - Have provided such care within the last 12 months before study recruitment, irrespective of survival (in cases where the informal caregiver is bereaved, they will be contacted no less than 6 months after bereavement out of respect and concern) [32]
- Clinicians
  - A registered health professional (eg, a physician, nurse, or allied health professional) with experience in estimating and providing end-of-life (EOL) prognostic predictions in palliative care and who is currently or was recently clinically employed (ie, not retired for >12 months or dismissed from clinical work)
  - Palliative care experience can be within the United Kingdom or international
- Academics or researchers
  - Academics or researchers who have published research, written or supervised a thesis, or contributed to a book chapter on the topic of prognostication in palliative care
  - Research experience can be within the United Kingdom or international
  - These experts may also be clinicians; however, this will not be a requirement

Exclusion criteria

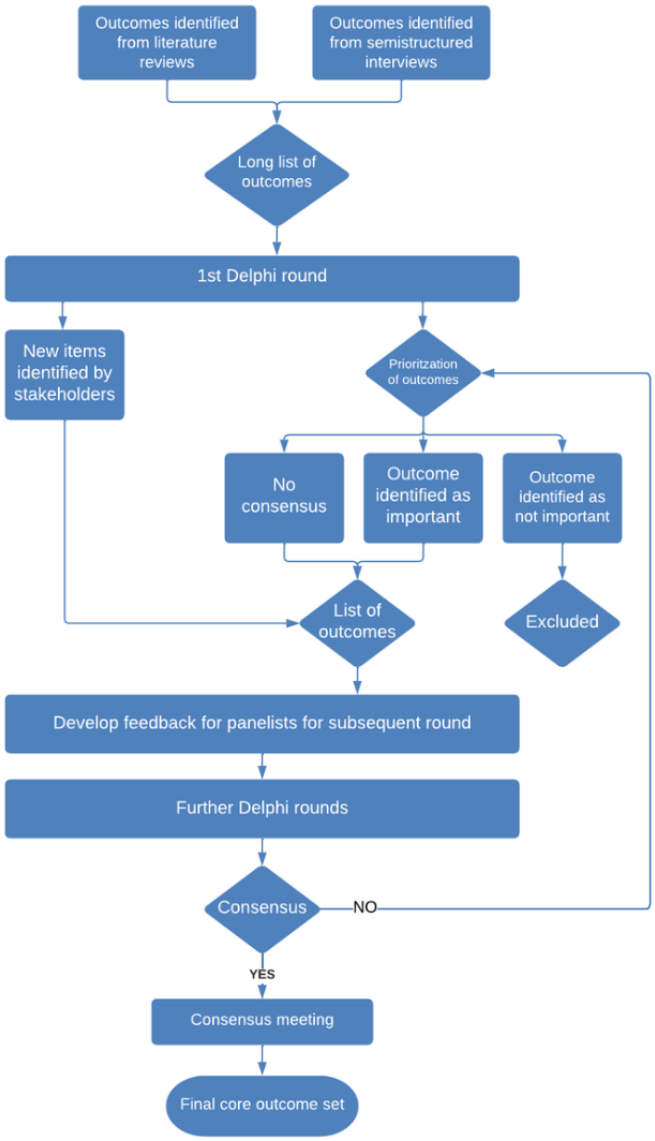
- Patients
  - Children (aged <18 years)
  - Individuals who, in the opinion of their treating clinician, would not be appropriate to participate in this research
  - Individuals who have previously expressed a wish not to be involved in research
  - Individuals who lack capacity to give informed consent
- Informal caregivers
  - Young informal caregivers (aged <18 years)
  - Informal caregivers who, in the opinion of the clinician gatekeeper, would be inappropriate to approach about enrollment in the study due to physical or mental illness
  - Individuals who lack capacity to give informed consent
- Clinicians
  - Clinicians who are not clinically employed in the last 12 months (ie, retired or dismissed from clinical work)
  - Clinicians who do not routinely estimate and provide EOL prognostic predictions in palliative cancer care
- Academics or researchers
  - Academics or researchers whose experience lies within the generic topic of palliative care without any specific experience in prognostication

Data Collection

The Delphi survey will comprise multiple web-based surveys that will be answered anonymously by stakeholders until consensus is achieved about which outcomes should be included in the COS. The outcomes resulting from the systematic review and the semistructured interviews will be prioritized by the participants in up to 3 of these web-based Delphi rounds via secure, web-based software (REDCap; Vanderbilt University) [34,35].

In round 1, participants will be asked to grade the importance of each outcome on the long list relative to the other outcomes in terms of how important they think they are in measuring the impact of improved prognostication. A 9-point Likert scoring

XSL•FO
RenderX



system will be used, where a score of 1 to 3 denotes "low importance," 4 to 6 is "important, but not critical," and 7 to 9 is "critical," as per the GRADE (Grading of Recommendations Assessment, Development and Evaluation) scale [36]. Participants will also be provided with an "unable to score" response if they consider themselves unable to rate any of the outcomes, as well as a free textbox to provide any comments.

It is anticipated that each survey will take approximately 30 minutes to complete. Participants will be given 2 weeks to respond to the survey. Participants will also have the opportunity to identify any outcomes that they think are relevant from their perspective, but which were not included in the initial list. This will facilitate the inclusion of outcomes that may be relevant but were not obtained in phases I and II of the study.

The group's ratings will be analyzed together, and outcomes removed or included depending on the group consensus. The survey will be repeated (with modifications) up to 3 times. Group descriptive statistics and a summary of comments will be generated after each round and sent to the participants during the next round of the survey. All comments and ratings shared will be anonymous.

If after 3 rounds, items remain without consensus, the Delphi survey will be terminated and the outcomes with no consensus, alongside those with consensus for inclusion and exclusion, will be presented at the consensus meeting where a final decision will be made. The aim of this meeting will be to discuss the results of the Delphi survey and vote on the final COS. Participants for the consensus meeting will be purposefully selected from the Delphi survey participants. The consensus meeting will be conducted via a web platform for practical reasons, allowing for the inclusion of international participants and accommodating any prevailing COVID-19 restrictions. This remote format is generally adopted in COS consensus meetings as it ensures accessibility, safety, and global representation, promoting a more inclusive and fruitful discussion during the meeting [37]. The panel will be asked to confirm whether they agree (or not) with the inclusion or exclusion of the outcomes in the COS. The result of this will be the final, consensus-agreed COS. Figure 2 summarizes the Delphi process proposed in this study.

Figure 2. Flow chart of the Delphi process.

XSL•FO
RenderX

Data Analysis

To determine which items should be included in the final COS, the thresholds recommended by the COMET initiative will be used [10]. Consensus for inclusion or "consensus in" will be defined as ≥70% of all participants rating the outcome as "critical" (GRADE score 7-9) and ≤15% of all participants rating the outcome as of "low importance" (GRADE score of 1-3). Consensus for exclusion or "consensus out" will be defined as ≥70% of the participants rating the outcome as of "low importance" and ≤15% of all responses rating the outcome as "critical." Outcomes meeting consensus for "not important for inclusion" will be removed and the remaining outcomes carried forward to the next round. Outcomes that are rated as "critical" or of "low importance" by one panel will be carried forward to the next Delphi round. For example, outcomes rated <70% by informal caregivers, clinicians, and academics, but with a patient rating of >70%, will be considered "patient-important" and included in the next round.

The same definitions for "consensus in" or "consensus out" will be applied to the consensus meeting.

Patient and Public Involvement

We advertised the opportunity to be involved in this research project as part of a patient and public involvement (PPI) advisory group through the National Institute for Health Research "People in Research" website and the Marie Curie Research Voices Group. Our advisory group included members of the public with experience of talking about prognosis, either as someone with advanced cancer or as one caring for someone with advanced cancer, who reviewed the protocol and all participant-facing documents. They advised on how the protocol could be adapted to ensure that the research study meets the needs and preferences of those taking part. They also made suggestions for how the documents might be made more suitable for participants, particularly for those receiving palliative care, to ensure that sensitive language was used.

In the future, we will consult this PPI advisory group regarding the format of the Delphi survey, before distributing it to participants, to ensure that it is easy to understand, access, and use. Specifically, the group will be requested to review and streamline the extensive list of outcomes intended for inclusion in the Delphi survey. We recognize that lengthy lists can be daunting for Delphi participants, potentially impacting their engagement. The PPI advisory group's expertise will be invaluable in identifying and addressing this risk, guiding us in minimizing the occurrence of overly lengthy lists and ensuring that the Delphi survey is well received and productive. We will also ask the group to review and propose outcome names and plain-language descriptions for each outcome. This step aims to ensure that all participants interpret the concepts as intended, reducing the potential for misunderstandings and enhancing the overall clarity of the survey.

During the data analysis, we will ask members to comment on the plain-language presentation of findings to ensure that this is understandable and relevant. We will also seek input from members of the PPI advisory group when disseminating results of the study to ensure that we communicate the study in a way that is appropriate for the general public.

The involvement of the PPI advisory group in these crucial aspects of the study has already made, and will continue to make, a considerable contribution to the success and impact of our research. In particular, this facilitates more meaningful participation and the likelihood of gaining valuable insights from participants.

Ethics Approval and Informed Consent

Ethical approval was obtained for this study from the London-Camberwell St. Giles Research Ethics Committee and the Health Research Authority on September 6, 2022 (reference 22/LO/0469).

Written, informed consent will be obtained from participants taking part in face-to-face interviews, the first round of the Delphi survey, and consensus meeting. Verbal, recorded consent will be obtained from participants being interviewed over the telephone or via a web platform. Participation in sequential rounds of the Delphi survey will be considered indicative of consent.

Dissemination

Promoting the uptake of the COS is paramount in preventing research waste and involves engaging key stakeholders, raising awareness, and demonstrating its value and relevance [38]. To achieve this, we will aim to disseminate findings to academic and research community audiences via publications in peer-reviewed journals and as presentations or posters at regional, national, and international palliative care conferences. After the finalization of the COS, further research will be necessary to identify the most suitable outcome measures or instruments for each core outcome. Subsequently, we will conduct a comprehensive evaluation of their quality and feasibility. To encourage adoption, we will collaborate with relevant journals and funding bodies, urging them to incorporate the COS in their guidelines for researchers and authors. Furthermore, we will actively seek feedback from researchers who pilot the COS in their studies. Being open to updates and revisions based on emerging evidence and feedback, we will continually improve the COS, ensuring its continued relevance and value over time.

The findings will be disseminated to participants in the form of plain-language summaries at the end of the study. To reach wider public audiences, plain-language newsletters, tweets, or blog posts will be published. Professional and clinical groups will also receive the findings as research summaries for participants and by engaging with palliative care representatives such as the palliative care team at the participating sites.

The final COS will be shared with the expert panel so they can verify the changes made and review what the project produced.

Results

As of July 2023, we have completed and published the systematic review (phase I) and have started recruitment for phase II. So far, we have recruited 5 patients, 10 informal caregivers, and 10 clinicians. We are still recruiting patients for

XSL•FO
RenderX

phase II. Data analysis for phase II has not yet started. We anticipate that the recruitment for the Delphi survey will begin in January 2024. We expect to complete the study by October 2024 and publish the results by June 2025.

Discussion

Anticipated Study Findings and Potential Impact

This study protocol presents what will be the first study that aims to develop a COS to measure the impact of EOL prognostication in palliative cancer care. The objective of this COS is to involve various stakeholders in its development and reach a consensus on the essential outcomes that hold significance for this population. Developing a COS for measuring the impact of EOL prognostication in palliative cancer care is an important step to improve patient care and communication of EOL prognoses. By addressing the inconsistent outcome measurement in existing studies and aligning the outcomes with those that are important to stakeholders, our COS has the potential to help standardize and improve prognostic research in palliative cancer care, such as the development of prognostic algorithms. Furthermore, the findings from this study have the potential to ensure that outcomes measured in future prognostic impact studies will reflect what is important to such stakeholders and ultimately facilitate the translation of the findings into clinical practice [39-41]. Once the COS is finalized, further research will be required to establish which outcome measures or instruments are most appropriate for each of the core outcomes, followed by an evaluation of their quality and feasibility.

Comparison With Existing Literature

Currently, research on the impact of EOL prognostication in palliative cancer care faces a significant challenge because of the measurement of different outcomes across various studies. Academic and clinical interests often dominate the selection of outcomes, potentially neglecting their meaningfulness to patients or informal caregivers [9,10]. Consequently, some studies might employ outcomes that do not resonate with those directly impacted by prognostic information. Moreover, the lack of uniformity in outcome measurement across studies hampers the ability to compare or combine results, leading to research wastage. A COS will address these issues. This COS aims to integrate the perspectives and experiences of patients and other personally affected stakeholders. By doing so, it is expected to enhance the translation of research findings into clinical practice and foster comparability in future prognostic research in palliative cancer care. Ultimately, this harmonized approach will optimize the use of research efforts and promote more effective advancements in the field.

Strengths and Limitations

This will be the first COS specifically focused on measuring the impact of EOL prognostication in palliative cancer care. The development of the COS will involve a rigorous and systematic search to gather the views and opinions of patients and other key stakeholders. Engaging with these groups will not only ensure that their perspectives are considered but will also enhance the overall relevance and applicability of the COS. By making the protocol for the COS publicly available, we will ensure the transparency and replicability of our study.

The inclusion of only adult English-speaking participants in this study might potentially limit the generalizability of the findings. Nevertheless, to mitigate this limitation, we will actively seek the involvement of international participants in the Delphi survey. Additionally, in phase I of the study, the systematic review considered international publications to minimize the risk of selection bias.

It is essential to acknowledge that conducting the Delphi survey using a web-based software may lead to underrepresentation of certain groups, particularly those who lack digital skills and access. To address this concern, we will explore alternative methods of data collection to ensure broader representation if it becomes apparent that our sample is significantly biased.

Recruiting and retaining participants may pose a challenge in our study, especially given the nature of the target population, who may face health deterioration or bereavement. To minimize attrition during phase II, we will conduct interviews concurrently with recruitment, aiming to interview participants shortly after enrollment to reduce dropouts. If a participant or caregiver cannot proceed with the interview, we will document their reasons for withdrawal and continue recruiting until reaching our desired number of interview participants or research data saturation, whichever occurs first. Attrition in Delphi surveys is a common challenge, resulting from both participant factors and reduced interest over time during multiple rounds [42]. Although we will send regular reminders and strive for timely rounds, it is challenging to minimize attrition resulting from external circumstances. Furthermore, the survey's anonymity prevents us from knowing specific reasons for dropouts or withdrawals. Despite this limitation, we will openly acknowledge its impact in any published results.

Employing stakeholder meetings to determine the final COS carries the risk of bias based on the opinions expressed by those present. To counteract this, we will make diligent efforts to encourage participation from all stakeholder groups. Despite our efforts, there remains a possibility of underrepresentation for a particular stakeholder group, and we will be transparent about this potential limitation in our study.

Conclusions

The necessity for a COS to measure the impact of EOL prognostication within palliative cancer care arises from the need to enhance outcome measurement and reporting. This COS has the potential to make a substantial impact on the field by advancing prognostication practices and aligning outcome measures with the preferences and requirements of patients and other important stakeholders. As a result, it will enable more precise comparisons and better synthesis of evidence across various prognostic studies.

The overall promise of this study lies in its potential to elevate the quality of care and decision-making for patients facing EOL care in the context of palliative cancer care. By standardizing and improving the measurement and reporting of prognostic outcomes, the COS will play a vital role in optimizing patient

XSL•FO
RenderX

outcomes and enhancing the overall care experience for those in need.

Acknowledgments

The authors would like to thank Marie Curie and the Economic and Social Research Council for supporting this proposed study via a PhD Studentship grant awarded to CS (grant number ES/P000592/1). The funder had no role in the design of the study, writing of the manuscript, or the decision to submit the paper for publication.

Data Availability

The data sets generated during and/or analyzed during this study are not publicly available due to the sensitive nature of the information, and participants' consents for public data sharing were not obtained in this study.

Authors' Contributions

PS, BV, NW, and CS contributed to the design of the review and protocol development. CS led on drafting of the manuscript. All authors contributed to revisions and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: The United States faces a nursing shortage driven by a burnout epidemic among nurses and nursing students. Nursing students are an integral population to fuel the nursing workforce at high risk of burnout and increased rates of perceived stress.

Objective: The aim of this paper is to describe WellNurse, a holistic, interdisciplinary, multidimensional longitudinal research study that examines evidence-based interventions intended to reduce burnout and increase resilience among graduate and undergraduate nursing students.

Methods: Graduate and undergraduate nursing students matriculated at a large public university in the northeastern United States are eligible to enroll in this ongoing, longitudinal cohort study beginning in March 2021. Participants complete a battery of health measurements twice each semester during the fourth week and the week before final examinations. The measures include the Perceived Stress Scale, the Satisfaction with Life Scale, the Oldenburg Burnout Inventory, the Brief Resilience Scale, and the Pittsburgh Sleep Quality Index. Participants are eligible to enroll in a variety of interventions, including mindfulness-based stress reduction, mindful eating, fitness training, and massage therapy. Those who enroll in specific, targeted interventions complete additional measures designed to target the aim of the intervention. All participants receive a free Fitbit device. Additional environmental changes are being implemented to further promote a culture that supports academic well-being, including recruiting a diverse student population through evidence-based holistic admissions, inclusive teaching design, targeted resilience and stress reduction workshops, and cultural shifts within classrooms and curricula. The study design protocol is registered at Open Science Framework (DOI 10.17605/OSF.IO/NCBPE).

Results: The project was funded on January 1, 2022. Data collection started in March 2022. A total of 267 participants have been recruited. Results will be published after each semester starting in December 2023. WellNurse evaluation follows the Rapid Cycle Quality Improvement framework to continuously monitor ongoing project processes, activity outcomes, and progress

XSL•FO
RenderX

toward reducing burnout and increasing resilience. Rapid Cycle Quality Improvement promotes the ability to alter WellNurse interventions, examine multiple interventions, and test their effectiveness among the nursing education population to identify the most effective interventions.

Conclusions: Academic nursing organizations must address student burnout risk and increase resilience to produce a future workforce that provides high-quality patient care to a diverse population. Findings from WellNurse will support evidence-based implementations for public baccalaureate and master's nursing programs in the United States.

Introduction

Background

The COVID-19 pandemic exacerbated already prominent feelings of burnout and stress among nursing students in the United States. Nursing students experienced high levels of perceived stress elicited by numerous interpersonal, intrapersonal, and community factors [1]. Nursing students' stress contributes to less academic engagement [2], and over 55% of nursing students report increased stress and worsened health after entering nursing school [3]. During the COVID-19 pandemic, economic strain, academic workload, and isolation from peers accelerated nursing students' stress and well-being [4]. Students cite limited clinical experiential learning and adjustment to web-based learning as prominent barriers influencing their intention to join the nursing workforce [4]. McKee-Lopez et al [5] found that adverse childhood experiences also contribute to mental health status among the nursing population, with nursing students experiencing a higher prevalence of adverse childhood events. Adverse childhood events have been associated with higher rates of burnout and depression among undergraduate nursing students [5]. Urban et al [6] found that nursing undergraduate students reported significantly higher stress levels than their nonnursing major peers. Moreover, COVID-19 can be seen as an adverse experience faced by all new incoming nursing students. A total of 60% of nurses younger than 35 reported an emotional, traumatic, or stressful event related to COVID-19 [7]. Nursing students are a critical component of the future nursing workforce. Currently, 55% of the nursing workforce experiences symptoms of burnout [8], contributing to an alarming acceleration of nurse turnover and shortages nationally. Stress does, in fact, predict nurses' job satisfaction and turnover intention [9]. In total, 25% of nurses left the profession in 2022 compared with 20% in 2020, and the average hospital turned over 95% of its nursing staff in the past 5 years [10].

Personal resilience, or the capacity to adjust positively to adversity to limit negative impacts, has been correlated with reduced burnout [6]. As the United States faces a critical shortage of nurses confounded by high rates of burnout and stress, nursing schools must develop interventions and strategies to reduce burnout and promote resilience among nursing students. Stress reduction interventions could promote improved stress management and mitigate burnout among students [2,3,11], which can support nursing student retention, on-time graduation, and resilience when students transition to the nursing workforce.

The health care profession's burnout crisis prompted the National Academy of Sciences to convene a committee and create a report that promotes the collective urgency to address burnout and resilience among health professionals, including nurses and students. Their vision includes a thriving health care workforce that provides high-quality care to patients in an environment that fosters their well-being [8]. The research study and project presented in this paper align with five of the seven priorities outlined by the academy: (1) create and sustain positive work and learning environments and culture; (2) invest in measurement, assessment strategies, and research; (3) support mental health and reduce stigma; (6) institutionalize well-being as a long-term value; and (7) recruit and retain a diverse and inclusive health workforce. There is a lack of substantive research that applies longitudinal analysis, large sample sizes, or randomization to support effective interventions that reduce burnout and promote resilience among nursing students [12], which this study aims to address.

WellNurse (Wellness in Nursing Education to Promote Resilience and Reduce Burnout) is a longitudinal research study implemented at a public nursing school in the northeastern United States to reduce burnout and increase resilience among nursing students. This multidimensional study examines the effect of various interventions on burnout, resilience, perceived stress, and academic performance. This paper aims to describe the comprehensive and holistic interventions and measures provided to nursing students at a public university in the northeast offering BSN and MSN education.

WellNurse Project Goals

The project's overarching purpose is to reduce burnout and increase resilience among nursing students at a public university in the northeast. Several objectives were implemented to achieve this aim, including (1) providing access to evidence-based mindfulness-based stress reduction (MBSR) to nursing students, faculty, and staff within a 3-year time frame; (2) providing evidence-based physical fitness, nutritional, and peer mentor training and support to all nursing students, faculty, and staff; (3) establishing a resilience and stress management curriculum to sustain program activities after the grant period with a credit-bearing course; and (4) creating an environment and

XSL•FO
RenderX

culture that embraces resilience, wellness, diversity, equity, and inclusion. The study design protocol is registered at Open Science Framework [13].

Methods

Participant Recruitment

Matriculated graduate and undergraduate nursing students, faculty, and staff older than 18 years who complete a web-based consent form are eligible to participate in the study. The initial phase of the study occurred from March to May 2022, and recruitment is ongoing as new students and faculty will enter the program through December 2024.

The recruitment strategy involves the WellNurse research team visiting various in-person and remote nursing classes and hosting meetings with administrative staff and faculty. The team also posts recruitment messages on the school's social media pages. Participants are offered a free Fitbit and enrollment in various interventions described below and can choose whether or not they consent to the evaluation aspect of the project. Some academic courses provide course credit, extra credit, or clinical hours to students who agree to participate. Faculty and staff are provided work time to participate in the interventions.

Measures

Comprehensive Wellness Survey

After completing a web-based consent form, participants complete a comprehensive health behavior survey. This survey is distributed during week 4 and again during week 14 (the week before finals week) in the fall and spring semesters. Week 4 was selected based on the typical nursing student's academic loads and stress. Examinations and competency testing begin each semester's third to fourth week, accelerating stress during those periods. Participants complete the comprehensive health behavior survey during designated class or work time. Additional measures are collected before specific engagement in targeted study interventions. Participants' answers are tracked through the project using unique ID codes. As listed below, several variables are assessed to capture the health of nursing students. The comprehensive measurement strategy aligns with Priority Area 2 from the National Academy of Sciences [8], which recommends the longitudinal use of valid and reliable measurements of burnout and factors that mitigate burnout to drive effective interventions and data-driven decision-making at the organizational level.

Demographics

Participants are asked several sociodemographic questions, including gender identity, sexuality, and ethnicity. Participants also provide their grade point average. Student progression status is also tracked to determine how various interventions influence retention and on-time graduation.

Perceived Stress Scale

The Perceived Stress Scale (PSS) is used to measure perceived stress. The scale includes 10 items that address experiences of distress related to "how unpredictable, uncontrollable, and overloaded respondents find their lives" [14]. Example items include "In the last month, how often have you felt that you were unable to control the important things in your life?" and "In the last month, how often have you felt difficulties were piling up so high that you could not overcome them?" The PSS demonstrates reliability and validity among healthy college populations [14].

Satisfaction With Life Scale

The Satisfaction with Life Scale is used to measure satisfaction with life. The 5-item Satisfaction with Life Scale [15] uses Likert scale responses ranging from "strongly agree" to "strongly disagree." An example item is "The conditions of my life are excellent." The measure demonstrates strong validity and reliability in past research [16,17].

Oldenburg Burnout Inventory

The Oldenburg Burnout Inventory is a 16-item measurement tool that measures the concepts of disengagement and exhaustion to assess burnout. Participants rank statements such as "When I work, I usually feel energized," with Likert responses ranging from "strongly agree" to "strongly disagree." The Oldenburg Burnout Inventory is a valid and reliable measure of burnout related to work and academics [18].

Brief Resilience Scale

The Brief Resilience Scale is a 6-item scale that measures resilience and one's ability to bounce back and recover from stress. The Brief Resilience Scale is a valid and reliable measure of resilience [19].

BMI

BMI screens for weight categories that may be associated with health problems and reflects a person's weight in kilograms divided by the square of height in meters [20]. Participants were asked to self-report their height and weight, and a BMI for each participant was derived accordingly.

Pittsburgh Sleep Quality Index

Sleep quality is measured using the 2-item Pittsburgh Sleep Quality Index [21], which assesses participants' estimated average hours of sleep per night and overall perception of sleep quality within the past 7 days. This survey has demonstrated acceptable validity and reliability in past research [21].

Nutrition Assessments

WellNurse participants have an opportunity to engage in a mindful eating cooking workshop conducted by a registered dietitian nutritionist. Before attendance, participants are required to complete a web-based registration form and relevant assessments. The assessments involve multiple health and nutrition behavior surveys, described below.

Mindful Eating Questionnaire

The Mindful Eating Questionnaire was developed to measure mindful eating, which can be described as nonjudgmental awareness of physical and emotional sensations associated with eating [22]. This 28-item scale comprises several subdomains, including disinhibition, awareness, external cues, emotional response, and distraction. Scores range from 0 to 4, with higher scores indicating greater mindful eating skills. This scale has been previously validated in adult populations [22].

XSL•FO
RenderX

Food Preparation Experience and Confidence Survey

This survey measures cooking self-efficacy and frequency of use of 13 different cooking styles (eg, boiling, baking, and microwaving). Participants are asked to rate their perceived confidence of each cooking method, ranging from confident, to uncertain, to not confident. This survey has been validated among young adults [23].

Body Appreciation Scale

Body appreciation reflects positive body image and has been previously associated with higher levels of self-esteem and lower levels of coping by avoidance. The Body Appreciation Scale is composed of 13 items, to which participants are asked in a Likert format the frequency to which they exhibit each statement [24]. Examples of statements on the questionnaire include "I respect my body" and "I do not focus a lot of energy being concerned with my body shape or weight." Scores range from 1 to 5, with higher scores indicating higher levels of body appreciation. This scale has been validated among young adults [24].

Weight Satisfaction

Weight satisfaction is measured using 3 items. The first asks, "Which of the following are you trying to do about your weight?" This gives respondents the ability to state that they are trying to lose weight, gain weight, stay the same weight, or that they are not doing anything about their weight. The second item measures how they feel about their current weight, with responses including "happy," "upset," or "don't care." The third item inquires about their desired weight in pounds. Weight satisfaction is then determined using the formula: [(actual weight – desired weight)/actual weight × 100].

Short Healthy Eating Index

Diet quality is measured using the Short Healthy Eating Index, validated in college populations [25]. Higher scores indicate greater adherence to the Dietary Guidelines for Americans, 2020-2025 [26].

Physical Activity Assessments

WellNurse participants have an opportunity to engage in physical fitness training to prepare for a 5K walk or run. Before and after the training, participants complete a comprehensive measure of physical activity.

International Physical Activity Questionnaire

The International Physical Activity Questionnaire measures participants' frequency of physical activity [27]. This 4-item instrument provides an overall estimate of physical activity levels over a week. The measure is valid and reliable in assessing college students' physical activity [28].

Fitabase Data Collection

Participants also have an opportunity to receive a free Fitbit Versa 2 (Fitbit). Because various health indices can be derived from ongoing data collection metrics within the Fitbit, participants complete an in-person consent form separate from the WellNurse consent form before receiving their device. The WellNurse research team connects each Fitbit to the web-based database, *Fitabase*. Fitabase tracks a multitude of movement and health-related behaviors, including steps taken per day, distance traveled, calories burned per day, heart rate variability (sedentary-very active minutes, logged physical activity, floors, basal metabolic rate, and resting heart rate), and sleep behavior (minutes in light sleep, deep sleep, and rapid eye movement sleep).

Mindfulness-Based Stress Reduction

Participants who sign up to participate in MBSR complete additional pre- and postintervention measures.

Five Facet Mindfulness Questionnaire

Mindfulness is measured using the Five Facet Mindfulness Questionnaire. This survey is composed of 39 questions and five subscales, including (1) observing, (2) describing, (3) acting with awareness, (4) nonjudging, and (5) nonreactivity. This survey has demonstrated good validity and reliability in past research [29].

Positive and Negative Affect Scale

Participants are asked to complete the 20-item Positive and Negative Affect Scale, which measures underlying experiences of positive or negative feelings of mood or emotion. This survey has demonstrated excellent validity and reliability in past research [30].

Massage Therapy

Short Form PSS

The Short Form PSS is a 4-item perceived stress survey that demonstrates validity and reliability [31]. Participants who receive a massage are invited to complete the Short Form PSS before the massage session and again 1 week later. Additionally, they have an option to complete a qualitative question on the follow-up survey, "Describe how massage therapy has affected your stress, anxiety, or happiness. Use specific examples if possible."

Attendance Records

When participants attend any additional workshop or activity, such as an exercise class, massage, or use of the WellNurse room, they sign in to track attendance.

Interventions Under Investigation

Holistic and comprehensive interventions are under investigation that align with 4 of the National Academy of Health's priorities areas: Priority 1: create and sustain positive work and learning environments and culture; Priority 3: support mental health and reduce stigma; Priority 6: institutionalize well-being as a long-term value; and Priority 7: recruit retain a diverse and inclusive health workforce [8].

Environmental and System Interventions

Diversity, Equity, and Inclusion

According to the United States Census Bureau [32], individuals from ethnic and racial minority groups accounted for 40% of the population in 2022. Nursing programs have a responsibility to recruit and retain a more diverse student body and more diverse faculty and staff to build a vibrant nursing workforce that reflects the diversity of the population it serves [33].

XSL•FO
RenderX

Therefore, several institutional changes were implemented and are ongoing to promote a culture that embraces diversity, equity, and inclusion (DEI).

A DEI committee was established at the school in 2021. An extensive holistic admission review training was provided to the faculty and staff who interface with the admission process. A holistic admission review process was implemented that includes objective and relational admission measures. Training and workshops about diverse populations were implemented as part of routine team meetings and class presentations. Curricular experts offered courses and programming to promote faculty transforming their courses to align with Inclusive Teaching Design. Inclusive teaching is being responsive to the diversity of the class and designing learning environments that include all students while allowing students to be engaged in an equitable learning environment and feel a sense of belonging [34]. The design begins with a clear syllabus outlining tools needed for success in a course, and transparent assignment frameworks highlighting what the learner needs to do, why they need to do it, how they should do it, and how their work will be evaluated. Faculty also include an intersectionality statement in the syllabus to state their commitment to the collective diversity learners bring to the learning environment.

Classes also include a *Getting-to-Know-You Survey* before the first class meeting that identifies learner preferences and perceived barriers to learning for early intervention. The survey is used for targeted student outreach, with an initial email offering resources specific to their concerns and a frequently asked question response to all students for commonly asked questions. Building community is a focus of the first class meeting. Students introduce themselves and share pictures from their life on the learning management software discussion board. Faculty share their social identities with the class and discuss the contexts that impact learning and teaching. Vulnerability and reflexivity are essential to breaking down real and exaggerated power differentials in the course. Ground rules are discussed and published on the learning management system during the first class. A reflection prompt completed in the first meeting allows learners to consider how they manifest their nurse role. Establishing purpose with a sense of belonging and self-confidence is threaded throughout the class meetings. Holistic admissions practices and inclusive teaching strategy training from experts are incentivized among faculty and staff and ongoing.

The faculty who teach Psychiatric Mental Health Nursing implemented wellness and resilience strategies in their classrooms. Faculty provided students with several mindfulness and wellness classroom options, such as guided meditations; mindful movement and stretching; and information about campus resources before class, during times of transition, or after emotionally taxing lecture content such as suicide. Faculty also implemented short meditations before examinations and provided extra credit to engage in any of the WellNurse programming.

WellNurse Room

A conference room in the School of Nursing was converted to a WellNurse room. The WellNurse room signals an institutional and systemic investment in supporting the resilience of incoming students, faculty, and staff. The renovation also promotes recruitment into the MBSR program by raising the profile of these activities with dedicated space for practice.

Participants are invited to attend free workshops that aim to promote healthy behavior change through evidence-based practices. Each workshop is designed and led by an interdisciplinary member of the research team. Advertisements for upcoming workshops are posted to the School of Nursing's social media pages and through email blasts. Attendance is optional. Workshops address various topics of concern, including the role of diet quality, sleep, and navigating test anxiety. Health behavior workshops are held monthly, both remote and in-person. Recordings are available to participants upon request.

Classroom Enhancements

Faculty integrate selected WellNurse interventions into their classes by offering extra credit or providing assignments attached to interventions. Additionally, faculty use class time to implement short periods of mindfulness either through guided meditations, outdoor walks, or open discussion about how students might embrace mindfulness and self-care during a rigorous schedule.

Wellness and Resilience Social Media Presence

A graduate student was hired to promote WellNurse activities and interact with students on social media. These posts highlight brief research findings about resilience, stress, and well-being among nurses and students. They also guide students through time management, test-taking strategies, community-building activities, and more.

Mindfulness-Based Stress Reduction

MBSR is an 8-week experiential program including 2.5-hour weekly class sessions and a 1-day silent retreat. MBSR engages participants in simple evidence-based mindfulness practices, including meditation, mindful walking and movement, cognitive reframing, and communication strategies. Pioneered in 1979 by Dr Jon Kabat-Zinn at the University of Massachusetts Medical Center, MBSR includes didactic and experiential training that teaches participants to cultivate self-awareness by redirecting attention away from past or future concerns and focusing instead on the present moment. With regular practice, participants learn to change habitual stress reactivity patterns and instead more flexibly respond to stress with adaptive coping. As a result, participants learn to avoid internalizing stress in reactive patterns of negative emotion [35] and, thus, reduce distress and prevent negative health and mental health outcomes.

WellNurse partnered with the University of California San Diego School of Medicine Center on Mindfulness and Brown University Mindfulness Center to provide remote, 8-week MBSR courses via Zoom and intensive week-long, in-person MBSR courses. MBSR was offered as an elective course to count toward the students' elective requirements for Nursing. Additionally, faculty and staff were provided work time to participate in the program. Selected WellNurse project personnel including faculty, staff, and graduate students completed a

XSL•FO
RenderX

multiyear teacher training certification process through the University of California San Diego and Brown University Mindfulness Center to develop a group of certified MBSR teachers to support long-term project sustainability.

MasterChef: Nursing Edition

This monthly workshop is innovative in combining gamified learning, cooking self-efficacy, mindful eating, and nutrition education for prelicensed nursing students. The course outline consists of (1) mindful eating concepts, (2) nutrition education, (3) participants designing their own healthful and accessible recipe, (4) participants mindfully eating and voting on their favorite meal, and (5) discussion and application to clinical practice. Participants are also encouraged to do 2 "homework" assignments per week, each emphasizing healthy eating or mindfulness behaviors. Participants also receive ingredients for recreating their healthful recipe at home and a "dorm-friendly" recipe book developed by a registered dietitian nutritionist. All students, staff, and faculty are encouraged to join, but students in designated courses receive credit for attendance.

Fitness Interventions

Participants are eligible to receive a free Fitbit Versa 2. Fitness trainers provide weekly 5K training in the fall and spring semesters to prepare participants for a 5K walk or run. Additionally, the campus recreation center offers nursing-specific fitness courses such as yoga and full-body workouts to promote a fitness community. Faculty are integrating fitness step challenges using the Fitbit devices as part of class assignments.

Ethics Approval

The University of Maine institutional review board reviewed and approved the WellNurse research project procedures (02-05-2-2022).

Results

Overview

The project was funded on January 1, 2022. Data collection started in March 2022. A total of 267 participants have been recruited. Results will be published after each semester starting in December 2023.

The primary study variables will be analyzed 4 times per year to track population outcomes and changes. Regression analysis will be conducted to examine the relationship of students' on-time progression, stress, resilience, and burnout with physical and emotional health variables and on-time progression. Subanalysis will be conducted for unique groups such as first and fourth year students, faculty and staff, and graduate students, as well as students from historically underrepresented populations such as first-generation college students and racial and ethnic minorities. Additionally, program retention, on-time graduation, and faculty and staff retention will be tracked over time. The cost of implementing MBSR, massage therapy, MasterChef, and fitness events will be tracked to determine cost per student. Additionally, feasibility will be measured using qualitative focus group interviews with students who complete specific interventions along with attrition rates for completing specific interventions such as MBSR and MasterChef.

MBSR Analysis

Quantitative evaluation of MBSR outcomes will be conducted by comparing MBSR participants with matched control participants at selected intervals with regard to key study variables (eg, stress, burnout, and mindfulness skills). Participants enrolled in MBSR are assessed immediately before their first MBSR session and immediately after completing the final MBSR session. Matched controls are identified for each MBSR participant by randomly selecting nonenrolled individuals from the WellNurse participant pool on the basis of identical gender identity, birth year, and role (faculty, staff, and student). Controls are assessed at the same intervals as MBSR participants.

Statistical analysis will test whether MBSR participants differ significantly from controls with regard to postintervention levels of each outcome variable, controlling for preintervention levels. ANOVA models will be used to conduct initial comparisons. With time, larger samples, and thus more statistical power and more complex models (eg, multilevel modeling), can be tested to evaluate the potential impact of instructor, delivery modality (in-person vs remote), duration (1 week vs 8 weeks), and dose (number of sessions attended), as well as individual participant characteristics (eg, gender identity and role). Ongoing assessments for all WellNurse participants will allow for longer term follow-up of MBSR and control participants with regard to distal outcomes of interest (eg, academic retention). We expect significant differences between MBSR and control participants; immediate postintervention effects may be strongest, with somewhat weaker longitudinal effects observed over time. Analyses will also be able to test whether those participants who engage in ongoing mindfulness practice after formal MBSR training may experience improved outcomes as compared with those individuals who discontinue regular practice.

Physical Activity Analysis

Data logs generated from Fitbit devices will be collected from the Fitabase platform [36], a partner to Fitbit, and raw data will be preprocessed, including merging the data of all participants in the study and purging the data set from empty cells or invalid data. The privacy-respected data set, besides participants' ID and event date, involves information on 3 major categories—sleep, activity, and wearing time—with each category covering more information in their respective parameters for a duration of fall and spring academic semesters. The sleep category provides information ranging from sleep minutes in rapid eye movement, deep, light, and total asleep minutes to sleep efficiency. The activity category is reporting time and distances traveled in very active, moderately active, lightly active, and sedentary modes, alongside calories, basal metabolic rate, and approximated heart rate levels. Analysis of the data set is done using the Python language [37] and the Scikit-learn [38], Pandas [39], Numpy [40], Matplotlib [41], and Seaborn [42] packages by applying the multiple linear regression method and also generating a heatmap of the parameters.

XSL•FO
RenderX

MasterChef Analysis

MasterChef will be evaluated initially for feasibility through a qualitative focus group design along with an expert content analysis. After modifications to the program based on feasibility analysis, the intervention will be evaluated using a matched-based cohort design with the non-MasterChef control group selected based on gender, ethnicity, and year in college matched-based design, with a focus on gender, ethnicity, and year in college. Descriptive and frequency statistics were used to analyze the sample's baseline and demographic data. A 2-way repeated-measures analysis will be used to assess significant changes in baseline and postintervention outcomes within the experimental group and as a comparison with the control. Participants will complete the aforementioned nutrition measures before the week-long Fall 2023 program delivery, directly after the program, and again at the end of the semester. A control will be recruited through a matched-based design. A 2-way repeated-measures ANOVA will be used to identify significant changes between baseline data, postintervention data, and follow-up data between the intervention and control group. The program will also be implemented in the format of monthly workshops. A multivariate ANOVA will be used to compare health outcomes between curriculum formats. Multiple linear regressions will be used to identify predictors of diet quality using the combined fall and spring samples. Significance levels will be set at $P<.05$.

Discussion

Principal Findings

Stress and burnout among nurses and students is not a new phenomenon. However, the COVID-19 pandemic has exacerbated the challenge and demonstrated the urgency in mitigating stress to improve well-being and resilience and reduce burnout. As the United States faces a looming nursing shortage and burnout crisis, more research that includes large sample sizes and longitudinal studies is needed to determine and implement resilience-building and stress reduction interventions within nursing programs [12]. Interventions that demonstrate effectiveness at improving student retention, reducing the risk of burnout, and improving resilience and well-being will be infused into a course, which will be embedded as part of the standard nursing curriculum.

Comparisons With Prior Work

WellNurse Room

Effective strategies to promote resilience and reduce burnout require system and environmental interventions [43]. The room contains floral murals, live plants, aromatherapy, meditation cushions, light therapy, coloring books, and tactile engagement. The WellNurse room is stocked with meditation cushions and a massage therapy table. Weekly mindfulness sessions are offered to support MBSR practices. A licensed massage therapist provides complimentary massage therapy in 15- to 30-minute sessions. Aromatherapy and massage therapy have shown stress-reducing effects [44,45]. This study aims to understand how environmental changes may influence nursing students' resilience, stress, and well-being.

Mindfulness-Based Stress Reduction

Extensive literature supports MBSR as an effective intervention in reducing burnout among nurses [46-52].

MBSR, meditation, and mindful movement are further effective in treating posttraumatic stress disorder and depression symptoms [35], preventing substance use relapse, and curbing binge-eating behavior [53-55]. MBSR has demonstrated better outcomes for binge-eating than cognitive-behavioral therapy [56] and is as effective as anxiolytic medication in managing anxiety disorders [57].

College students with mindfulness training have been able to better resist the negative impact of stress during challenges [58], and mindful movement and meditation are both recommended as nonpharmacologic interventions to reduce stress and anxiety among college students [43]. Among medical students, these practices were found to improve happiness, self-confidence, endurance, and patience [59]. Systematic reviews have demonstrated that MBSR decreases stress and burnout and increases resilience, coping, and job satisfaction among nurses [60,61]. Given MBSR's significant benefits with regard to physical and mental health and its demonstrated impact in nursing and college student populations, this evidence-based intervention was an ideal fit for the WellNurse nursing students. This study aims to examine the effect of MBSR on graduate and undergraduate nursing students', faculty's, and staff's resilience, perceived stress, mindfulness, and burnout.

Nutrition

Nursing students report poor diet quality and dietary behaviors elicited by high levels of perceived stress, peer influence, and academic workload [62]. The impact of mindful eating may mediate this relationship [63]. Mindful eating describes applying mindfulness practices to internal hunger and satiety cues and incorporating a nonjudgmental, self-compassion–led viewpoint in navigating dietary choices [64]. Mindful eating interventions effectively improve several health behaviors, including reducing extreme dieting behaviors, improving portion control, and weight reduction within some populations [65,66]. This study aims to examine the effect of the newly developed program, MasterChef Nursing Edition, on nursing students' diet quality, resilience, burnout, and well-being.

Fitness

Physical activity reduces stress and anxiety [67-70], and stress and anxiety are associated with increased burnout and decreased resilience among nurses [52]. A review of 37 studies on Fitbit-based interventions demonstrated the effectiveness of this wearable technology for physical fitness support; wearing a Fitbit significantly increased daily step counts and moderate to vigorous physical activity and significantly decreased weight [69]. Although students have access to healthy food and physical fitness environments, nursing programs do not systematically integrate support systems that promote physical well-being [12,71-74]. The aim of this study is to examine the effect of fitness interventions on nursing students', faculty's, and staff's burnout, resilience, fitness, and well-being.

Conclusions

WellNurse aims to examine multiple resilience-building and stress-reducing strategies while creating a culture that promotes student, faculty, and staff well-being in concert with academic and clinical preparedness and job satisfaction. Dissemination of findings will be released as they are available with an anticipated release date of initial findings in 2024.

Abstract

Background: Psychosis is one of the most disabling mental health conditions and causes significant personal, social, and economic burden. Accurate and timely symptom monitoring is critical to offering prompt and time-sensitive clinical services. Digital health is a promising solution for the barriers encountered by conventional symptom monitoring approaches, including accessibility, the ecological validity of assessments, and recall bias. However, to date, there has been no digital health technology developed to support self-management for people with psychosis in China.

Objective: We report the study protocol to evaluate the validity, feasibility, acceptability, usability, and safety of a symptom self-monitoring smartphone app (YouXin; Chinese name 佑心) for people with psychosis in China.

Methods: This is a nonrandomized validity and feasibility study with a mixed methods design. The study was approved by the University of Manchester and Beijing Anding Hospital Research Ethics Committee. YouXin is a smartphone app designed to facilitate symptom self-monitoring for people with psychosis. YouXin has 2 core functions: active monitoring of symptoms (ie, smartphone survey) and passive monitoring of behavioral activity (ie, passive data collection via embedded smartphone sensors). The development process of YouXin utilized a systematic coproduction approach. A series of coproduction consultation meetings was conducted by the principal researcher with service users and clinicians to maximize the usability and acceptability of the app for end users. Participants with psychosis aged 16 years to 65 years were recruited from Beijing Anding Hospital, Beijing, China. All participants were invited to use the YouXin app to self-monitor symptoms for 4 weeks. At the end of the 4-week follow-up, we invited participants to take part in a qualitative interview to explore the acceptability of the app and trial procedures postintervention.

Results: Recruitment to the study was initiated in August 2022. Of the 47 participants who were approached for the study from August 2022 to October 2022, 41 participants agreed to take part in the study. We excluded 1 of the 41 participants for not meeting the inclusion criteria, leaving a total of 40 participants who began the study. As of December 2022, 40 participants had completed the study, and the recruitment was complete.

XSL•FO
RenderX

Conclusions: This study is the first to develop and test a symptom self-monitoring app specifically designed for people with psychosis in China. If the study shows the feasibility of YouXin, a potential future direction is to integrate the app into clinical workflows to facilitate digital mental health care for people with psychosis in China. This study will inform improvements to the app, trial procedures, and implementation strategies with this population. Moreover, the findings of this trial could lead to optimization of digital health technologies designed for people with psychosis in China.

Introduction

Background

Psychosis is one of the most disabling mental health conditions and causes significant personal, social, and economic burden [1], which increases the risk of physical health problems and reduces life expectancy by around 20 years [2]. Within 5 years after the first episode, 80% of people with psychosis will have at least one relapse [3]. The prevalence of schizophrenia in China is the highest in the world [4]. A recent Chinese national survey showed that the lifetime prevalence rate of schizophrenia and other psychotic disorders was 0.7% [5], and schizophrenia accounted for 13.7% of all mental and substance disorder disability-adjusted life years in 2019 [6].

Accurate and timely symptom monitoring is arguably one of the essential components of quality clinical services. Conventional symptom monitoring approaches in mental health services face several practical and methodological challenges. First, conventional methods rely on clinical interviews or comprehensive assessment batteries, which can be carried out only by trained professionals and require service users to attend an in-person meeting with their health provider. However, a lack of resources means that access to in-person services is limited; the wait times between referral and assessment can range from 4 weeks to 6 months or longer [7]. Meanwhile, organizational barriers (eg, financial availability, transportation) and attitudinal barriers (eg, stigma, reluctance to seek help) prevent people with mental health problems from attending appointments regularly [8]. Moreover, accessing in-person services has been further hindered by the COVID-19 pandemic, since clinic visits have been restricted to mitigate virus transmission [9,10].

Second, the conventional approach to assessing symptoms lacks ecological validity; current methods for assessing service users' difficulties, broadly speaking, capture cross-sectional information rather than continuous information over a certain period of time [11,12]. Clinical visits tend to be scheduled mostly, at best, monthly, which means health care providers only get a snapshot of service users' conditions every 2 weeks to 6 weeks. However, clinically meaningful symptom fluctuation, such as mood or hallucinations, may occur on a daily basis [13], which conventional methods struggle to capture.

Third, recall bias has long been identified as a limitation of conventional clinical assessment methods [11,14]. Service users, especially people with severe mental health problems for which cognitive impairments are common [15], may have trouble accurately recalling their thoughts, feelings, and behaviors over a preceding period of time, making recall experiences at a granular level challenging [16]. Therefore, to optimize the quality of assessment and capture symptom fluctuation in a real-time, real-world granular manner, more ecologically valid assessment methods are needed.

The aforementioned barriers affect countries worldwide [14], even high-income countries with sophisticated mental health service systems (eg, the United Kingdom and the United States) [17,18], and China has been no exception to these challenges.

Mental Health Services in China

China has invested substantial resources to reform its mental health system to improve the accessibility and quality of mental health services in the past 15 years; however, the effort has only been partially successful, and the mental health treatment gap remains significant [19,20]. The estimated shortage of mental health professionals in China was 40,000 relative to the population need [21]. According to the WHO Global Health Observatory, as of 2015, there were only 2.20 psychiatrists, 5.42 mental health nurses, and 0.07 mental health hospitals per 100,000 population in China [22]. In contrast, in the United States, there are 10.54 psychiatrists, 4.28 mental health nurses, and 0.19 mental hospitals per 100,000 population [22]. Moreover, since the Chinese health care system is designed as hospital-centered care [23], most well-trained mental health care professionals (ie, psychiatrists, mental health nurses, and psychologists) are concentrated in psychiatric hospitals located in urban areas, which makes it difficult for people in rural or remote communities to access care [24,25].

In China, mental health services are primarily delivered through psychiatric hospitals [26-28]. Compared with other settings (ie, general hospitals and community-based settings), tertiary psychiatric hospitals are best placed to provide quality mental health services, which results in service users overwhelmingly concentrated in tertiary psychiatric hospitals causing long wait times and reduced service quality [26].

The Role of Digital Health

Digital health is a promising solution to address both the barriers encountered by the conventional symptom monitoring approach [14] and China's health care system that has a shortage of mental health care resources [29,30]. The ubiquitous accessibility of digital technologies (eg, smartphones) provides unprecedented potential to scale-up service provision. Smartphone ownership

XSL•FO
RenderX

rates in China have reached 96% [31]. Previous studies showed that smartphone ownership by people with psychosis was comparable with that of the general population [32]. More specifically, the internet access rate reached 90.9% of people with a diagnosis of schizophrenia in Hong Kong [33], and people with mental health problems in China in general were willing to accept mobile health interventions and considered them helpful [34]. Integrating digital health technologies (DHTs) into clinical workflows provides the potential to augment evidence-based care, support shared decision-making, and increase continuity of care [35]. These potential benefits are true for all countries worldwide and arguably even more so for countries with less sophisticated mental health care systems such as China. We conducted a systematic review on digital mental health in China and found that DHTs were generally feasible and acceptable among people with mental health problems, including people diagnosed with schizophrenia [29].

Among different types of DHTs, smartphones are the most advantageous tool for symptom monitoring given their ability to generate a plethora of data through active and passive monitoring methods [14]. Active monitoring is typically defined as the user self-reporting data (eg, psychological, behavioral, physiological) by ecological momentary assessment or other ambulatory assessment methods [12]. Passive monitoring refers to using the smartphone and its embedded sensors or a wearable device to measure the user's behavior pattern (eg, app usage, activity log) or contextual information (eg, location) via passive user data collection [36]. By combining active and passive monitoring, smartphone-based monitoring has the potential to provide a more dynamic, personal, and valid representation of a person's emotional and behavioral state [16,37]. Additionally, studies have shown that active self-monitoring of symptoms can reduce positive psychotic symptoms in people with recent-onset psychosis [38].

Smartphone-based symptom monitoring for people with psychosis has proved to be feasible in the Western context [39]; however, only 1 study conducted in non-Western, low and middle-income countries tested a digital platform with a symptom monitoring element [40]. To date, no smartphone-based symptom monitoring tool has been developed and evaluated for people with psychosis in China [29].

Study Objectives

The aims of this study are to evaluate the validity, feasibility, acceptability, and safety of a symptom self-monitoring smartphone app (YouXin) for people with psychosis in China.

Methods

Ethical Considerations

The study was approved by the University of Manchester (Ref: 2022-13262-24297) and Beijing Anding Hospital (Ref: [2021] Research No.58) Research Ethics Committee. The study was conducted in full conformance with all relevant legal requirements and the principles of the Declaration of Helsinki, Good Clinical Practice, and the UK Policy Framework for Health and Social Care Research 2017. Potential participants were given a participant information sheet to read. The detailed informed consent procedure is described in the Recruitment section. Participants were informed that they are free to withdraw from the study at any time and for any reason. Withdrawal from the study did not impact participants' access to standard care at Beijing Anding Hospital. The delivery of the intervention did not affect any form of clinical care participants received, and they continued to be actively supported by the hospital during their participation in the study. Study data are anonymous and were managed according to the data management plan described in the Data Management section. Participants were given a ¥100 (US $13.76) gift voucher for each completed assessment. For participants who took part in the interview, at the end, they were given a ¥100 (US $13.76) gift voucher as a thank you for their time and to cover any costs incurred as a result of their participation. This information was included in the participant information sheet and was provided to participants before they entered the study.

Study Setting

The study took place at Beijing Anding Hospital of Capital Medical University, which is one of the largest tertiary psychiatric hospitals in the Beijing metropolitan area. The hospital has 800 beds, an average 5000 inpatient admissions per year, and over 1200 daily outpatient visits.

Study Design

The study uses a mixed methods design consisting of a nonrandomized feasibility study and a nested qualitative acceptability study. The study was designed according to the Consolidated Standards of Reporting Trials (CONSORT) statement extension for pilot and feasibility studies [41]. We recruited 40 people with psychosis at a tertiary-level psychiatric hospital in Beijing, China. This number is in line with other feasibility studies and sufficient to report on response rates, follow-up rates, safety information, and attrition, as well as the clinical characteristics of our study population at the beginning of the study and at follow-up [42]. Formal power calculations for treatment effects are not appropriate for a study primarily aimed at establishing feasibility. This sample size means a monthly recruitment target of 10 participants. Moreover, monitoring the recruitment target is part of the feasibility outcomes.

Eligibility Criteria

Eligibility criteria were deliberately inclusive to fully assess feasibility and validity of the app and to reach generalizable conclusions for a wide range of service users with psychosis. Due to the limited resources, the research team could not provide devices to participants who did not own a smartphone. However, according to a recent survey study in China, 83.2% of service users and family members reported owning and frequent use of mobile devices [34]. Participant inclusion and exclusion criteria are presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Diagnosed with schizophrenia spectrum according to DSM-5 (F20-F29) or met the criteria for being at clinically high risk for developing psychosis according to the Structured Interview for Prodromal Syndromes (SIPS)
- Aged 16 years to 65 years
- Receiving care from Beijing Anding Hospital and will continue to be actively supported by the hospital over the next 5 weeks (ie, the duration of the project's participant enrollment period)
- Own and able to use a smartphone

Exclusion criteria:

- Diagnosed with organic or substance-induced psychosis
- Lack of capacity to provide informed consent
- Unsafe to participate in research as viewed by their treating clinician (ie, clinically unstable or at risk for self-harm or harm to others)

Recruitment

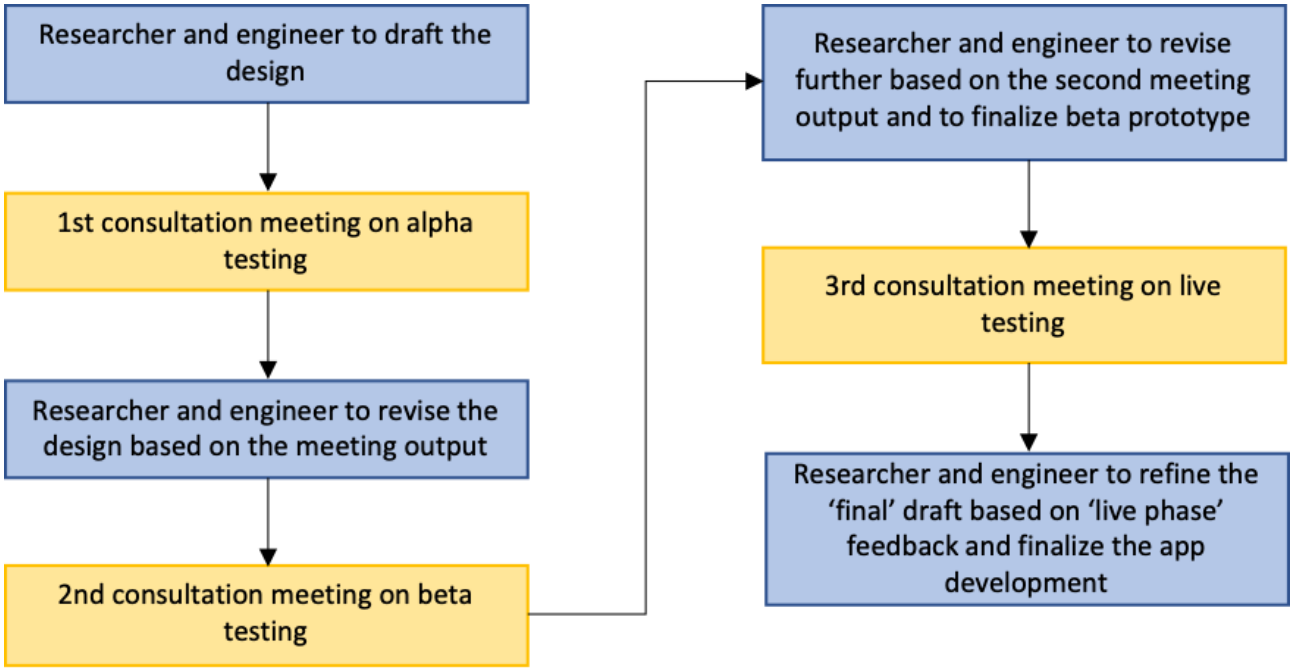
Participants were recruited from Beijing Anding Hospital, which is a major tertiary psychiatric hospital located in Beijing, China. Participants were initially approached by a clinician working at the hospital to introduce the project and assess the willingness and potential eligibility of the potential participant to participate in the study. If participants appeared to be eligible and willing to participate, they were referred to the principal researcher who confirmed their eligibility. When eligible, potential participants were given a participant information sheet to read, and their contact details were obtained by the researcher with their consent. The principal researcher followed up with a phone call to the potential participant after at least 48 hours to explain the details of the study and answer any questions that the potential participant had about the study. If the potential participant was still interested in taking part, a face-to-face meeting was arranged to obtain written consent to participate using a hard copy consent form prior to conducting the baseline assessment at the same meeting. Participants were recruited until the recruitment target was met (n=40).

Study Intervention and Procedures

YouXin is a smartphone app designed to facilitate symptom self-monitoring for people with psychosis. The app is adapted from the ClinTouch app [13], a self-monitoring app for psychosis validated against the Positive and Negative Syndrome Scale (PANSS) and the Calgary Depression Scale for Schizophrenia (CDSS) items. The PANSS and CDSS have been translated and validated in Chinese and have been widely used in practice in China [43,44]; however, app-based versions of these measures among people with psychosis have not been validated in Chinese. In this study, we translated the ClinTouch-based PANSS and CDSS items into Chinese and combined these items with passively collected data to develop the YouXin app to be tested in the Chinese context. Screenshots of the YouXin app are shown in Figure 1.

XSL•FO
RenderX

Figure 1. Screenshots of the app prototype: (A) log-in page, (B) user center, (C) assessment module.



The YouXin development team consisted of experts from various disciplines, including academics, clinicians, software engineers, and experts by experience. The principal researcher led the development of the app and was supported by members of the research team who are academic clinicians at the University of Manchester (a Professor of Clinical Psychology and a Professor of Adult Psychiatry). A psychiatrist at Beijing Anding Hospital assisted the development of the app to ensure the content reflected the Chinese context. A technology team led by a computer scientist at Beijing Jiaotong University supported software development.

To maximize the usability and acceptability of the app for end users (ie, service users and clinicians), the development process utilized a systematic coproduction approach. A series of coproduction consultation meetings was conducted by the principal researcher with service users and clinicians at Beijing Anding Hospital. We used an iterative approach to coproduction, which means the outputs of a previous meeting formed the content of subsequent consultation meetings. The framework for coproduction (shown in Figure 2) was inspired by the process of development used for the Actissist app [45,46], a cognitive behavioral therapy–informed app designed to support people in the early phase of psychosis, and the UK government user research guidelines [47]. A series of participatory design consultations involving 3 phases (alpha, beta, and live phases) was held with service users with severe mental health problems and clinicians. As the YouXin app is adapted from the ClinTouch app, we skipped the discovery phase, which is normally used to generate ideas and hypotheses for a completely new product. The remaining 3 phases are described in Textbox 2.

XSL•FO
RenderX

Figure 2. The coproduction process.

Textbox 2. The phases of the coproduction process.

Alpha:

- The alpha phase aims to understand the end users' (clinicians and service users) needs for using digital tools to monitor symptoms and demonstrate the preliminary design with users (the ClinTouch app and the user interface prototypes of the YouXin app). The design, contents, and functions of the app were further developed based on the feedback from users.

Beta:

- The principal researcher and software engineer integrated the feedback and delivered a functional prototype that users could install on their phones. During the meeting, users tested the app and provided feedback.

Live:

- A fully developed digital platform was presented to users (3 clinicians and 3 people with psychosis) to try out for a week. This meeting focused on evaluating the usability and acceptability of the app and any major issues regarding implementation.

YouXin has 2 core functions: active monitoring of symptoms (ie, smartphone survey) and passive monitoring of behavioral activity (ie, passive data collection via embedded smartphone sensors). The app is available for both Android and iOS platforms. The active monitoring uses a time-contingent design. To minimize participant assessment burden and increase compliance, in accordance with a previous similar study [38], prompts were set to alert at 2 pseudorandomized timepoints per day, during a 12-hour interval from 10 AM to 10 PM, 7 days a week for 4 weeks. A minimum 1-hour increment was set between each prompt on a particular day to avoid clustering of responses. Participants could either snooze (5 minutes or 30 minutes) or decline answering the prompt. Based on previous works by the research group, on average, it takes 70 seconds to complete each prompt. Smartphone sensors passively collected GPS data every 5 minutes. According to a recent systematic review [39], passive sensing was feasible for measuring negative symptoms; specifically, GPS indicators were associated with apathy, avolition, asociality, and anhedonia [48,49]. All collected data were uploaded to a secure server at Beijing Anding Hospital.

Participants were given a training session by the principal researcher to help them navigate the app after they consented to take part. During the training, the principal researcher helped the participant download the app onto their smartphone and gave a demonstration of the app. Participants had the opportunity to practice using the app and ask questions during the process; they had access to the app from the training session until the 4-week timepoint. An opt-out approach was applied to give participants autonomy to switch on or off the passive sensing section during the study.

The principal researcher provided technical support as needed during the study; no clinical care was provided by the research team (clinical care continued as usual from the service). The participant was referred to their treating clinician for appropriate mental health care should any clinical issues be raised to the research team. Participants were informed at the training sessions that the app is not suitable for seeking urgent medical care while in any emergency circumstance.

XSL•FO
RenderX

Data Collection

The timeline of outcome assessments is summarized in Figure 3. Participants were assessed in an in-person meeting at baseline, 1 week after baseline, and 4 weeks after baseline. To assess the validity of the remote monitoring, PANSS and CDSS were assessed at 1 week to calculate the association between the active and passive monitoring results and relevant domains of the clinical assessment. To determine which outcomes are sensitive to change in this population, participants were asked to complete an assessment of relevant outcomes of the self-monitoring intervention at baseline and the 4-week timepoint. The assessor is a clinician, has been trained in the assessment measures used, and has rich experience in conducting assessments in clinical trials. Semistructured qualitative interviews were conducted after the 4-week timepoint to explore the acceptability of the app.

Outcome Measures

Sociodemographic and Clinical Characteristics

Sociodemographic characteristics including age, gender, education level, marriage status, average income, accommodation and living situation, employment status, and ethnicity were collected. We also collected data regarding digital literacy and mental health literacy.

Data From Service Users' Electronic Health Records

Number of hospitalizations, time at first onset, number of episodes, and medication(s) or therapy used before and during the study were collected from service users' electronic health records (EHRs). At Anding Hospital, the EHR is used in both outpatient clinics and inpatient units and is shared within the hospital. All records are kept in the EHR system using

XSL•FO
RenderX

computers, and no records are written by hand; service users receive a hard copy of their record following each appointment.

Clinical Measurements

The Chinese version of the Mini International Neuropsychiatric Interview [50,51] was used to determine the DSM-5 diagnosis.

The Chinese version of the Structured Interview for Prodromal Syndromes [52,53] was used to assess the risk for psychosis.

Psychotic symptoms were rated using the Chinese version of the PANSS [54,55], a 30-item scale that assesses positive symptoms, negative symptoms, and general psychopathology. The Chinse version is comparable to the original version and has good internal consistency reliability (Cronbach α=.87) [43].

Mood symptoms were assessed using the Chinese version of the CDSS [56,57], a 9-item scale designed specifically for assessing depression for schizophrenia. The Chinese version [44] has good reliability (Cronbach α=.798-.810) and is significantly correlated with the Hamilton Depression Scale (r=0.76) and PANSS-G6 (r=0.70).

Service user engagement was measured using the Chinese Version of the Patient Health Engagement Scale [58], a self-report scale assessing service users' attitudes toward engagement in health care.

Social functioning was rated using the Chinese version of the Personal and Social Performance scale (PSP) [59,60], a 100-point single-item rating scale assessing 4 main areas of functioning, including socially useful activities, personal and social relationships, self-care, and disturbing and aggressive behaviors.

Quality of life was evaluated using the Chinese version of the EQ-5D-5L [61], a self-report questionnaire designed to assess health status and health-related quality of life. The EQ-5D-5L consists of 5 questions that assess 5 health dimensions and a visual analog scale to assess the overall current health judged by the individual respondents.

Smartphone Monitoring

Active Monitoring

Active monitoring consisted of the following 3 sections: psychotic symptoms, mood symptoms, and contextual information. The psychotic and mood symptom items were translated into Chinese from the ClinTouch app and were compared against the Chinese version of the PANSS and CDSS. Contextual questions were added to understand the context of participant responses and to validate GPS data. Examples of the items are shown in Table 1.

Table 1. Examples of the active monitoring items.

Domain	Item	Response items	Format
Psychotic symptoms	"I have heard voices."	1-7	Likert scale
Mood symptoms	"I have felt sad."	1-7	Likert scale
Contextual questions	"Where were you?"	At home; at work; at school or other educational setting; in hospital; in vehicle; in a convenience store, supermarket, or shopping mall; outside walking; inside other; outside other	Check box

Passive Monitoring

Passive monitoring used collected GPS data to measure mobility and activity level of users. GPS mobility indicators measured on the smartphone, including home time, distance travelled, and location clusters, will be extracted following the procedures by Müller et al [62]. Briefly, locations will be clustered as "unique" if a person spent at least 30 minutes within a 200-meter radius. Home location will be determined by selecting the mode of location clusters during the night (ie, 9 PM to 6 AM). Distance travelled will be computed by aggregating the distance changes between 2 successive GPS data points; however, distance changes of GPS data points in the same location cluster will be considered as zero. Time spent at each location, including time at home, will be calculated by summing the differences of the time stamps of 2 successive GPS data points in the location cluster.

Validity

The validity of active monitoring items will be assessed against relevant clinical assessments (ie, PANSS and CDSS) using Spearman correlation. An exploratory analysis will also be conducted to understand the association between mobility indicators, corresponding contextual questions in active monitoring, and PANSS negative symptom scores. We define a moderate statistically significant correlation (ie, Spearman rho>0.35) as the validity threshold.

Feasibility Parameters

To assess the feasibility of the study, we collected detailed recruitment and retention data accordant with the CONSORT statement for feasibility studies [41], including (1) number of eligible participants consenting; (2) completeness of outcome measures; (3) number of participants lost to follow-up; and (4) reason for withdrawal. We defined Green (>80%; ie, feasible and no changes needed), Amber (60%-80%; ie, additional elements required to increase feasibility), and Red (<60%; ie, not feasible) categories to indicate the levels of feasibility for the above parameters. We will explore app usage and engagement data guided by the Analyzing and Measuring Usage and Engagement Data framework [63].

Acceptability

The quantitative feedback questionnaire (QFQ) was given to participants at the 4-week timepoint to collect quantitative information regarding acceptability. The QFQ is a 27-item questionnaire designed to assess the acceptability of utilizing smartphone app interventions for service users. It has been used in previous digital mental health studies for people with psychosis [64,65].

XSL•FO
RenderX

Qualitative interviews were conducted to explore their experiences using Youxin including (1) overall impressions of YouXin, (2) positive and negative aspects of the app in terms of content and usability, (3) how it helped or did not help, (4) what changes they would make, (5) barriers and facilitators to engagement, and (6) views on the training session.

Safety

To evaluate the safety of the app, detailed adverse events and serious adverse events were collected and reported using standardized operating procedures in line with National Institute for Health and Care Research and Health Research Authority Safety Reporting procedures.

Safety Considerations, Adverse Events, and Risks

We did not expect participating in the study would cause any significant risks. Although the study involves people with severe mental health problems, the eligibility criteria for the study require the participants to be stable and at low risk for self-harm or harm to others, as judged by a clinician. There is the potential for participants to report elevated levels of distress because of taking part in assessments and digital self-monitoring. This may include the potential for increasing awareness of one's own symptoms. Participants were informed during the recruitment process that they may encounter such situations, and they were encouraged to discuss this with the research team if they feel distressed during the study.

Statistical Analysis Plan

All quantitative analyses will be performed using R (version 4.0.5) [66]. Feasibility data and safety data including (1) recruitment and retention data, (2) app usage data, (3) completeness of study measures, and (4) the number and nature of adverse events will be analyzed using appropriate descriptive statistics (mean and standard deviations for continuous data; counts and percentages for categorical data). Logistic regression and linear regression analyses will be used to explore sociodemographic and clinical characteristics and device attributes as predictors of feasibility (eg, dropouts, app usage).

The active monitoring will generate 3 levels of data, with the data entered for each "beep" as level 1, nested within the level 2 "day" level, which is nested within the level 3 subject level. Because the PANSS and CDSS measure participants' symptoms for the past week, and to minimize the impact of missing data, the subject level mean score of the first week will be used to calculate the association between active monitoring items score and relevant symptom domain scores of the PANSS and CDSS at the week 1 follow-up assessment to evaluate validity. The significance level for the study will be set to .05. Cronbach alpha will be used to calculate the internal consistency reliability of the sets of the items of active monitoring. To account for the nested structure of the data, multilevel models will be used to explore the instability of the different constructs across time and patterns of missing data.

The GPS mobility indicators will be extracted from passive monitoring data. The convergent validity of passive monitoring will be calculated by the correlation between GPS mobility indicators and the PANSS negative symptom score. Discriminant validity of passive monitoring will be demonstrated by low correlation between GPS mobility indicators and positive symptoms measured by PANSS.

Qualitative data will be transcribed verbatim in Chinese and then translated to English by the principal researcher. A framework analysis approach will be used based on the protocol by Braun and Clarke [67], which consists of the following 6 phases of thematic analysis: familiarization, transcription, generating initial codes, searching for themes, reviewing themes, and defining and deciding on meaningful themes. Nvivo software (version 12) [68] will be used to manage the qualitative data.

Data Management

Names and contact information are password-protected and stored electronically and separately with anonymous questionnaire responses in a secure, password-protected folder on the principal researcher's university drive and are kept for the purposes of contacting participants during the study. All quantitative data are stored as an anonymous electronic file and stored on the principal researcher's university drive for the purpose of analysis. Data generated from the smartphone app are stored on a secure server at Beijing Anding Hospital. The server is managed by the IT department of Beijing Anding Hospital according to the Chinese government's data protection regulations. Only the IT staff can access the data stored on the server. The principal researcher applied to download the raw data at the end of the study data collection.

Qualitative interview data recordings were anonymized as soon as practical after the interview, and anonymous transcripts were prepared by the principal researcher. Personal information was removed from the final transcripts or replaced with pseudonyms where appropriate. The file name was saved with the date of transcription and allocated a number to protect confidentiality and ensure no file names are the same (ie, DD_MMM_YYYY_SU_1). For the publication write-up, quotations may be used for which the participants will be given a pseudonym (ie, "service user1," which will be representative of the allocated number of the saved document name); however, they will not be identifiable by the research team at this point.

Results

Recruitment for the study was initiated in August 2022. Of the 47 participants who were approached for the study from August 2022 to October 2022, 41 participants agreed to take part in the study. Reasons for not participating included concerns that answering app questions would be a burden (n=1) and family member concerns that answering app questions might be triggering for the participant (n=1). Another 4 participants declined to participate without giving any reason. We excluded 1 participant for not meeting the inclusion criteria, leaving a total of 40 participants taking part in the study. As of December 2022, 40 participants had completed the study. We expect to report the validity of the app-based monitoring and results for feasibility on the (1) number of eligible participants consenting, (2) completeness of outcome measures, (3) number of participants lost to follow-up, and (4) reasons for withdrawal.

XSL•FO
RenderX

We also expect to report participants' overall impressions of YouXin, positive and negative aspects of the app in terms of content and usability, perceived helpfulness of the app, barriers and facilitators to engagement, and views on the training session.

Discussion

This study aims to test the validity, feasibility, acceptability, usability, and safety of the YouXin smartphone app for people with psychosis in China to self-monitor symptoms. To the best of our knowledge, this study is the first to develop and test a symptom self-monitoring app specifically designed for people with psychosis in China. Therefore, a feasibility study is necessary to determine if a DHT like this will be appropriate to facilitate self-management for this population.

We conducted a systematic review and series of surveys and qualitative interviews with people with severe mental health problems and mental health staff in China to facilitate the development of the app. Based on our previous findings, DHTs were generally feasible and acceptable among people with mental health problems in China [29], and mental health professionals were willing to implement such technologies in clinical practice [30]. In addition, DHTs developed in China have rarely used the coproduction approach [29]; we coproduced the app to maximize the chance it meets end user needs.

One of the concerns of utilizing DHTs is the risks related to data security and privacy, which may hinder the implementation of DHTs [69-71]. To tackle these issues, we designed and developed the app to meet the standard required by China's Data Security Law. Additionally, we discussed these issues with both the service users and mental health staff in the coproduction process, and the feedback from the coproduction process indicated that, as long as the app was designed and developed according to data security regulations, both staff and service users felt safe using it. Moreover, we conducted postintervention interviews with participants to have an in-depth understanding of their concerns and how data security and privacy issues may impact their usage of the app.

If YouXin is feasible, acceptable, and safe and brings clinical benefit, a potential future direction is to integrate the app into clinicians' workflows to facilitate a digitally enabled care pathway to support timely mental health care for people with psychosis in China. This could include a remote symptom monitoring system [38] or a more comprehensive integrated digital clinic [35]. According to views collected from mental health staff during the coproduction workshops, staff expressed positive attitudes toward implementing digital mental health care in practice and considered digital health to be the future of mental health care.

In summary, this study will provide valuable insights for evaluating the feasibility, safety, acceptability, trial procedures, and implementation strategies of a DHI with this population in the Chinese context. Moreover, the findings of this trial have the potential to inform the development of digital solutions for China's mental health services in general, and, more specifically, it could lead to optimization of DHTs designed for people with psychosis in China.

Acknowledgments

The development of the YouXin smartphone app is funded by Beijing Anding Hospital of Capital Medical University. The authors would like to thank the service users and professional advisory groups for their help developing the app.

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

XZ and SB designed the study. XZ drafted the protocol and led the development of the app. SB and SL supervised the design of the trial and the app development. LAC provided oversight of the methodology section of the trial design. XZ drafted the manuscript. All authors revised the manuscript critically for intellectual content and approved the final version of this protocol.

Conflicts of Interest

SL is the Academic Lead of Mental Health at Health Innovation Manchester. SL and SB are Directors and shareholders of CareLoop Health Ltd, a company spun out from the University of Manchester to develop and market digital solutions for remote monitoring using smartphones for mental health conditions, currently schizophrenia and postnatal depression. SB also reports research funding from the National Institute for Health and Care Research and the Wellcome Trust.

Abstract

Background: Genetic heart diseases such as hypertrophic cardiomyopathy can cause significant morbidity and mortality, ranging from syncope, chest pain, and palpitations to heart failure and sudden cardiac death. These diseases are inherited in an autosomal dominant fashion, meaning family members of affected individuals have a 1 in 2 chance of also inheriting the disease (“at-risk relatives”). The health care use patterns of individuals with a genetic heart disease, including emergency department presentations and hospital admissions, are poorly understood. By linking genetic heart disease registry data to routinely collected health data, we aim to provide a more comprehensive clinical data set to examine the burden of disease on individuals, families, and health care systems.

Objective: The objective of this study is to link the Australian Genetic Heart Disease (AGHD) Registry with routinely collected whole-population health data sets to investigate the health care use of individuals with a genetic heart disease and their at-risk relatives. This linked data set will allow for the investigation of differences in outcomes and health care use due to disease, sex, socioeconomic status, and other factors.

Methods: The AGHD Registry is a nationwide data set that began in 2007 and aims to recruit individuals with a genetic heart disease and their family members. In this study, demographic, clinical, and genetic data (available from 2007 to 2019) for AGHD Registry participants and at-risk relatives residing in New South Wales (NSW), Australia, were linked to routinely collected health data. These data included NSW-based data sets covering hospitalizations (2001-2019), emergency department presentations (2005-2019), and both state-wide and national mortality registries (2007-2019). The linkage was performed by the Centre for Health Record Linkage. Investigations stratifying by diagnosis, age, sex, socioeconomic status, and gene status will be undertaken and reported using descriptive statistics.

Results: NSW AGHD Registry participants were linked to routinely collected health data sets using probabilistic matching (November 2019). Of 1720 AGHD Registry participants, 1384 had linkages with 11,610 hospital records, 7032 emergency department records, and 60 death records. Data assessment and harmonization were performed, and descriptive data analysis is underway.

XSL•FO
RenderX

Conclusions: We intend to provide insights into the health care use patterns of individuals with a genetic heart disease and their at-risk relatives, including frequency of hospital admissions and differences due to factors such as disease, sex, and socioeconomic status. Identifying disparities and potential barriers to care may highlight specific health care needs (eg, between sexes) and factors impacting health care access and use.

Introduction

Genetic heart diseases are a significant cause of cardiac morbidity and mortality in the youth and are characterized by distinct variability in the onset and severity of symptoms [1]. The most prevalent is hypertrophic cardiomyopathy (HCM), which affects up to 1 in 500 people [2]. They are generally inherited as autosomal dominant traits, conferring a 50% risk to first-degree relatives. A diagnosis relies on clinical investigations with a cardiologist and, in some cases, genetic testing, which is ideally conducted in a multidisciplinary clinic [3].

Disease symptoms can be variable ranging from asymptomatic to episodes of unexplained syncope, palpitations, and chest pain to the most serious outcomes of heart failure and sudden cardiac death (SCD). Accordingly, some individuals with a genetic heart disease require life-saving medical intervention via emergency department presentation and hospitalization. Treatment options may include prescription medication, cardioversion, and surgeries such as implantable cardioverter-defibrillator insertion, pacemaker insertion, septal reduction therapies (eg, alcohol septal ablation and septal myectomy), or heart transplant. The implantable cardioverter defibrillator is the only proven therapy to prevent SCD in individuals with a genetic heart disease [4]. The frequency with which these individuals interact with the health care system is unknown, including for noncardiac reasons [5].

Routinely collected health data are data collected for purposes other than research or without specific a priori research questions developed before collection [6]. These data provide both population- and person-based information, meaning we can examine common patterns of health care for the population [7,8]. In jurisdictions with universal health care such as Australia, we can observe an individual's interaction with hospitals and emergency departments over time and link them to mortality data. Studies that have used routinely collected data to investigate genetic heart diseases, or their consequences such as SCD, focus predominantly on mortality data and may restrict to specific subpopulations such as infants or children [9-11]. There are limitations in correctly identifying individuals with a genetic heart disease in these data collections due to insufficient International Classifications of Diseases (ICD) codes [5], inadequate recognition of these diseases outside of specialized settings, and infrequent interaction with health facilities for many patients who remain largely well and are generally managed via outpatient clinics.

Here we report a protocol for the linkage of Australian Genetic Heart Disease (AGHD) Registry participants [12,13] with state-wide hospitalization, emergency department and mortality registries, and the national mortality registry to establish a rich and comprehensive data resource to examine the health care use of individuals with a genetic heart disease and their families for the first time.

Methods

Study Setting, Design, and Population

This is a retrospective cohort study of people in New South Wales (NSW), Australia, enrolled in the AGHD Registry from 2007 to 2019. The AGHD Registry operates nationally and has actively recruited participants since 2007 [12,13]. The goal of the AGHD Registry is to enroll every individual in Australia with a genetic heart disease and their at-risk relatives to understand and improve diagnosis, prevention, and treatment options. Eligibility criteria include a confirmed diagnosis of any inherited cardiomyopathy (HCM, dilated cardiomyopathy, arrhythmogenic cardiomyopathy, and restrictive cardiomyopathy), left ventricular noncompaction, or primary arrhythmia syndromes (long QT syndrome, Brugada syndrome, or catecholaminergic polymorphic ventricular tachycardia; Table 1) or at-risk relatives of those with a confirmed diagnosis.

Participant demographic, clinical, and genetic information (provided by the AGHD Registry data custodian) was linked with whole-population routinely collected health data, specifically hospital admissions (NSW Admitted Patient Data Collection), emergency department presentations (NSW Emergency Department Data Collection), and in the event of death, mortality registry data (NSW Registry of Births, Deaths, and Marriages; Australian Coordinating Registry Cause of Death Unit Record File; Table 2). Although the AGHD Registry is an ongoing registry, linkage to the routinely collected data is not continuous and only occurs on application to the data custodians with ethics approval.

XSL•FO
RenderX

Table 1. Classification and description of genetic heart diseases included in the AGHD[a] Registry.

Genetic heart disease type and specific condition	Definition	Diagnostic tests
Inherited cardiomyopathies		
Hypertrophic cardiomyopathy	Abnormal thickening of the heart muscle on either the left or right ventricle	Electrocardiogram, echocardiogram, cardiac magnetic resonance imaging (MRI), and Holter monitor
Dilated cardiomyopathy	Enlargement of the left ventricle of the heart affects the ability of the heart to pump blood effectively	Electrocardiogram, echocardiogram, cardiac MRI, and Holter monitor
Arrhythmogenic cardiomyopathy	A disease of the heart muscle where the normal heart muscle cells on either the left or right ventricle are replaced by fat and scar tissue. This change can lead to heart rhythm abnormalities, or the affected ventricle may become enlarged and not pump blood effectively	Electrocardiogram, echocardiogram, cardiac MRI, and Holter monitor
Left ventricular noncompaction	Characterized by deep trabeculations (finger-like projections) in the heart muscle wall of predominantly the left ventricle, but may also appear in the right ventricle	Electrocardiogram, echocardiogram, and cardiac MRI
Primary arrhythmia syndromes		
Long QT syndrome	Characterized by abnormal electrical activity in the heart that often presents in children and teenagers	Electrocardiogram, echocardiogram, and exercise or stress test
Catecholaminergic polymorphic ventricular tachycardia (CPVT)	CPVT is a rare condition often present in children and teenagers. A cardiac event can occur during periods of high emotion or exercise as these situations cause the body to release adrenalin or noradrenalin. These persons have an abnormal response to adrenaline, which causes the heart to beat fast and irregularly	Electrocardiogram, echocardiogram, exercise or stress test, and Holter monitor
Brugada syndrome	A rhythm disorder that causes the ventricles to beat abnormally fast, affecting the ability of the heart to pump blood effectively	Electrocardiogram, echocardiogram, and drug infusion study

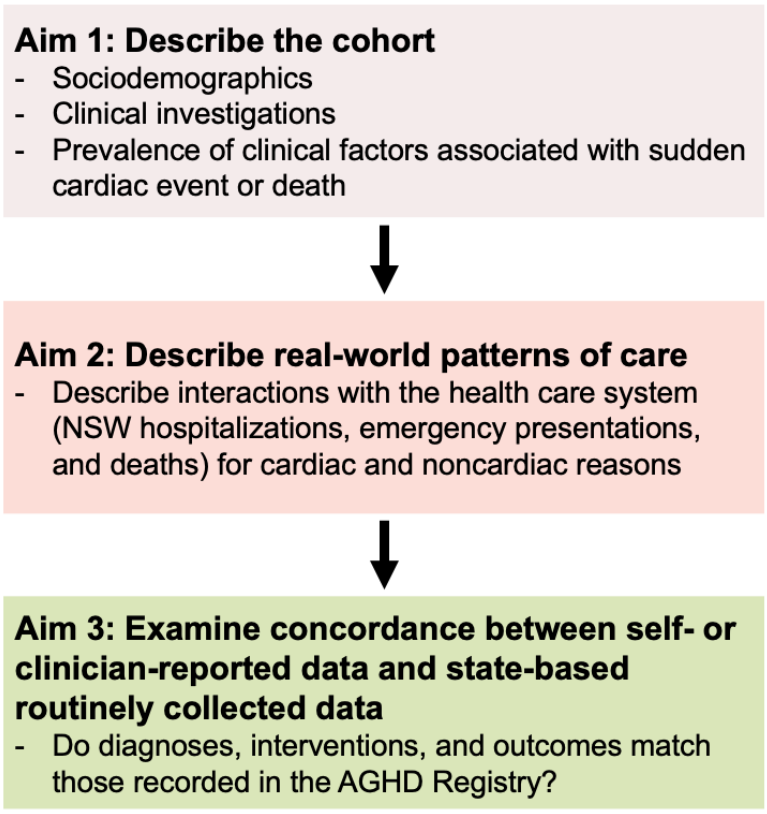
Aims

Our objective is to characterize AGHD Registry participants using routinely collected whole-population health data sets to investigate the health care use of individuals with a genetic heart disease and their at-risk relatives (Figure 1). We will also examine the concordance between data sources to see whether diagnoses, interventions, and outcomes match those recorded in the AGHD Registry. In our analyses, we will determine if patterns of care vary according to patient demographics such as age, sex, level of residential, and relative socioeconomic disadvantage of patient residence (Figure 2). We will evaluate episodes of care for any medical condition or reason.

XSL•FO
RenderX

Figure 1. Aims of the Australian Genetic Heart Disease (AGHD) Registry data linkage study. NSW: New South Wales.



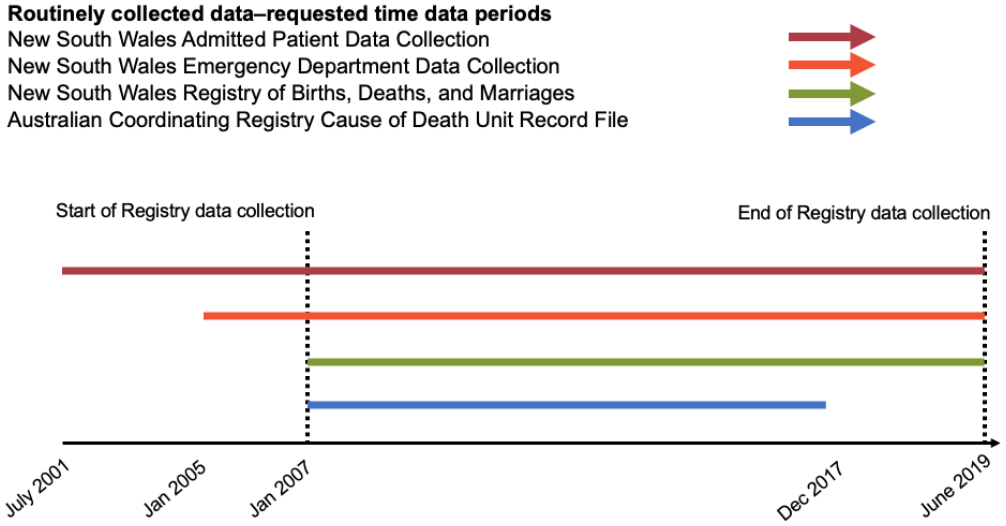


Figure 2. Period of data requested per routinely collected health data set.

Recruitment and Consent

Participants have been recruited to the AGHD Registry since 2007. Two recruitment methods were used for the data linkage aspects of the study:

1. For participants enrolled in the AGHD Registry between 2007 and April 2017, an opt-out approach was coupled with a waiver of consent. This involved sending a letter to all AGHD Registry participants outlining the study and asking them to contact us if they wish to withdraw their consent for this study. If the participant did not contact us, then the waiver of consent was applied.
2. An amendment to include permission for access to linked data sets was made to the participant information and consent form. Every person enrolled in the AGHD Registry from May 2017 provided written, informed consent for their data to be linked to the administrative data collections mentioned herein.

As part of the AGHD Registry recruitment process, extensive demographic, clinical, and genetic information was collected from the individuals and their cardiologist.

Although participants can withdraw their consent at any time for the AGHD Registry, data already included in the linkage

XSL•FO
RenderX

before their withdrawal of consent cannot be removed as all extracted data held by the researchers are deidentified.

Data Sources and Variables

Table 2 lists and describes the data sets used in this study. The AGHD Registry was used for cohort definition and linking variables with the routinely collected health data. We linked to the following data sets.

NSW Admitted Patient Data Collection

The Admitted Patient Data Collection collates information on all admitted patient services provided by NSW public (including psychiatric hospitals and multipurpose services) and private hospitals (including day procedure centers) [15]. Data include patient demographics (ie, sex, birth date, country of birth, and statistical local area of residence at admission), episodes of care (ie, date and time of admission and separation [the completion of treatment for an admitted patient because of death, discharge, or transfer to another facility or care type], referral source, diagnoses, procedures, and service referred upon discharge), and facility information (ie, hospital type, facility, and local health district [LHD]). Up to 50 relevant diagnoses and procedures were included. These are coded according to standardized codes from the International Statistical Classification of Diseases and Related Health Problems, Australian Modification and the Australian Refined Diagnosis-Related Group.

This study included data on admissions between July 1, 2001, and June 30, 2019 (Figure 2). When linked with the AGHD Registry data, this period allowed us to examine patterns of care before and after a genetic heart disease diagnosis. The requested variables will allow us to examine the frequency and type of interactions and care received during hospitalizations.

NSW Emergency Department Data Collection

The Emergency Department Data Collection provides information about patient presentations to the emergency departments of public hospitals and contracted private hospitals in NSW [15]. Each record represents a presentation to an emergency department for emergency care and treatment. Data include demographics (same as Admitted Patient Data Collection), episodes of care (eg, date of arrival and separation, diagnoses, and status at separation), and facility information (eg, facility identifier and LHD). Up to 50 relevant diagnoses are included and are coded according to standardized codes from the International Statistical Classification of Diseases and Related Health Problems, Australian Modification.

Data for the Emergency Department Data Collection were available from January 1, 2005, to June 30, 2019 (Figure 2). By combining the hospital data with the AGHD Registry data, we can analyze the emergency department episodes before and after their diagnosis during this period. These data will allow us to explore the frequency and reason for an emergency department presentation for any medical reason.

Mortality Data

Two data sets contain mortality information for deaths occurring in NSW: the NSW Registry of Births, Deaths, and Marriages death registrations and the Australian Coordinating Registry Cause of Death Unit Record File [15]. All deaths are certified by a medical practitioner or coroner (if a coronial inquiry is required) and registered by the NSW Registry of Births, Deaths, and Marriages. Details of all registered deaths are forwarded to the Australian Coordinating Registry. Details include the date of death, underlying cause, and up to 20 contributing causes of death. The causes of death are coded using the ICD, Tenth Revision, international coding system rather than the International Statistical Classification of Diseases and Related Health Problems, Tenth Revision, Australian Modification used in Australian hospitals. The Australian Coordinating Registry Cause of Death Unit Record File data are finalized considerably later than the NSW Registry of Births, Deaths, and Marriages death registration data because of the time needed to confirm details on the death certificate.

Data from the NSW Registry of Births, Deaths, and Marriages were available from January 1, 2007, to June 30, 2019, and data from the Australian Coordinating Registry Cause of Death Unit Record File were available from January 1, 2007, to December 31, 2017 (Figure 2). These variables will allow us to determine the reasons and causes of death.

Data Linkage Methods

Linkage of each AGHD Registry participant's demographic, clinical, and genetic information with whole-population routinely collected health data was conducted by the Centre for Health Record Linkage (CHeReL). The AGHD Registry data custodian (the individual responsible for the registry data and any related activities) provided CHeReL with 2 separate files. To protect privacy, identifier information, including given names, last names, and current and past residential addresses (street, suburb, postcode, and state), was separated from the content information (registry clinical and genetic information). The 2 files from each data set were stored and handled separately. CHeReL's data linkage unit applied a combination of matching methods to the identifier data to identify and distinguish between individuals. The identifier data belonging to each individual were then assigned an arbitrary person number, which replaced the name, address, and other identifying details. Using an encrypted version of the arbitrary person number, CHeReL's data integration unit created a research project-specific person number (PPN). This PPN was used to join the AGHD Registry content data to the NSW state-wide Admitted Patient Data Collection, Emergency Department Data Collection, and the mortality registries (Registry of Births, Deaths, and Marriages and Australian Coordinating Registry Cause of Death Unit Record File). Once linkages were complete, the data sets were released to the research team in a fully deidentified form, ensuring the privacy and confidentiality of all individuals. The AGHD Registry custodian does not have access to the linked data to ensure that the linked data cannot be reidentified. These deidentification measures preclude the withdrawal of any individuals included in the data linkage study after the linkage takes place. Access to the deidentified linked data is only provided to individuals named in the approved ethics protocol. The PPN combines records for the same person across different data sets.

XSL•FO
RenderX

Statistical Analysis

All data harmonization and analyses will be conducted using the R software (version 4.2.3; R Foundation for Statistical Computing). Harmonization of the data sets will involve systematic identification and removal of any duplicate records, checking for a consistent number of person-level records across the data sets, consistency across variables (eg, admission dates before discharge dates), checking for outliers, and identification and flagging of missing or invalid data. We will analyze and report each data set using descriptive statistics, including mean, median, SD, IQR, and sample size (number). We will also conduct descriptive analysis stratified by factors including age, sex, relative socioeconomic disadvantage, and advantage of patient residence and LHD of facility using the Australian Bureau of Statistics Socio-Economic Indexes for Areas [16] and genetic status (likely pathogenic or pathogenic gene identified vs no gene identified). Additionally, Cox regression models will be developed to identify independent factors associated with adverse outcomes, such as heart failure, atrial fibrillation, stroke, and death.

Patient and Public Involvement

Patients and the public have not and will not be involved in the study design.

Ethics Approval

Technical feasibility for the study was granted by the CHeReL, NSW Ministry of Health (ID#2016.38). Ethical approval has been granted by the NSW Population and Health Services Research Ethics Committee (2019/ETH0153) and Sydney Local Health District (Royal Prince Alfred Hospital zone) Human Research Ethics Committee (2020/ETHO00220). The current approval permits data storage at the Garvan Institute of Medical Research. We will disseminate project findings at scientific conferences and in peer-reviewed journals.

Results

Currently, the research team has received all deidentified data from CHeReL. The record linkage occurred in November 2019. A total of 1384 NSW-based AGHD Registry participants have been linked with 11,610 hospital records, 7032 emergency department records, and 60 death records. Data assessment and cleaning processes have been undertaken, with descriptive data analysis underway. Initial results are expected to be published by early 2024.

Discussion

This study represents the first in Australia to provide a comprehensive clinical data set on health care use patterns of individuals with a genetic heart disease and their at-risk relatives. It overcomes the limitations of previous studies, which rely on ICD codes to identify patients, by linking data from the AGHD Registry with routinely collected health data in NSW. The study will shed light on health care use among individuals with a genetic heart disease in Australia, examining hospitalizations, emergency department presentations, and mortality rates over approximately 20 years, stratified by clinical diagnosis, age, sex, socioeconomic status, and genetic status. We will investigate the impact of these factors on patterns of care, including interactions with health care providers and on disease severity and outcomes. Overall, we aim to improve the diagnosis, prevention, and treatment options for individuals with a genetic heart disease by providing a better understanding of their health care use and identifying areas for improvement in health care provision. Ultimately, the study's results will have a significant impact on the care of individuals with a genetic heart disease and their at-risk relatives.

Routinely collected data are commonly used in patterns of care studies. These studies are prolific when investigating cancer populations [17], as they provide the opportunity to describe a patient population and common treatment, as well as examine potential differences such as sex [18] and residential location [19]. In relation to cardiovascular diseases, patterns of care studies have predominantly focused on coronary heart disease or heart failure [18-22]. However, the population of individuals diagnosed with genetic heart diseases differs from those with these conditions, often being younger at diagnosis, with different risk factors and lifestyle constraints such as exclusion from high-level and competitive sports [23]. Therefore, studies such as that described here are needed to examine the unique genetic heart disease population.

By linking the AGHD Registry to routinely collected health data sets, we have overcome a significant limitation of previous studies that relied exclusively on the ICD diagnosis coding system to identify patients with genetic heart diseases [5]. A previous systematic review by our team found that for countries such as Australia, only 3 of the 12 genetic heart diseases included in the search strategy had an explicit ICD diagnosis code [5]. Codes that best match the other 9 genetic heart diseases being investigated were broad descriptive diagnoses (such as other cardiomyopathies used to describe arrhythmogenic cardiomyopathy), which also encompasses other genetic heart diseases. Additionally, the ICD diagnosis coding system fails to explicitly identify rare diseases, with only 500 of the 6000 rare diseases having an ICD diagnosis code [24].

Procedure codes may provide a little more information with specific codes for implantable cardioverter-defibrillator implantation and other interventions and surgeries associated with genetic heart diseases. However, as not all individuals undergo surgical procedures because of their condition, these codes also cannot identify all patients with a genetic heart disease. Because of these coding issues, studies to date have largely focused on those genetic heart diseases where discrimination from linked data sets is possible, that is, HCM and Marfan syndrome.

The clinical course for many patients with a genetic heart disease can be mild, meaning interactions with hospital and emergency departments could be infrequent or not required. However, when hospitalization is necessary, these patients often require urgent and potentially life-saving medical intervention. To date, there is limited research available regarding the health care system interactions of individuals with causative variants, and only one paper has used linked primary care hospital and mortality records in patients with HCM. Our study aims to address these

XSL•FO
RenderX

gaps in knowledge and provide answers to these important questions. We will be able to observe the interaction of individuals with less severe clinical course who may never require treatment at a hospital or emergency department for genetic heart disease but present for other reasons.

Because of the absence of studies exploring care patterns associated with genetic heart diseases, it remains unclear whether care varies based on specific factors. Previous studies examining nongenetic cardiac conditions have found that patient factors, such as age, sex, and residential location, impact care patterns [15,18,20,25]. It is vital to examine the impact of socioeconomic factors, as the AGHD Registry contains a significant proportion of patients seen at specialist genetic heart diseases clinics in NSW, which have been shown to overrepresent socioeconomically advantaged individuals [26]. We will be able to investigate if patterns of care or outcomes vary based on the location of the facility and the relative socioeconomic disadvantage of that location. For instance, we will examine whether areas with a relatively high disadvantage have fewer implantable cardioverter defibrillator surgeries than other facilities, as observed in other countries [27].

Among studies using more than one data source, validating the agreement between data types such as self-reporting and routinely collected health data is important. Multiple studies have examined the concordance between these data types for many medical conditions including cardiac diseases [18-21,28-31]. One study found that the agreement between self-report data and health records was substantially lower for persons with heart failure than for other chronic illnesses such as diabetes, hypertension, myocardial infarction, and stroke [28]. Patient factors associated with discordance include sex, age, education level, and socioeconomic status [30,32]. However, no studies have investigated the concordance in individuals with a genetic heart disease between self-reported and routinely collected health data.

There are limitations in coding accuracy, especially for the Emergency Department Data Collection, which could affect the validity of the data collected. The study relies on AGHD Registry participants who are predominantly from a single tertiary center, which has been shown to lack socioeconomic diversity [29]. We will be unable to ascertain the prevalence and incidence of genetic heart diseases accurately as the AGHD Registry does not include all patients in NSW with a genetic heart disease. However, even if our sample is not representative, the relationships between variables are still valid [33].

This study aims to provide valuable insights into the health care use patterns of individuals with a genetic heart disease and their at-risk relatives. By linking data from the AGHD Registry with routinely collected health data in NSW, this study has established a comprehensive clinical data set that can identify reasons for hospitalization and emergency presentation, with the potential to reveal disparities based on disease, sex and sociodemographic status, and opportunities for preventive care. Overall, this study's findings may have a significant impact on the care of individuals with a genetic heart disease and their at-risk relatives, with the potential for better outcomes and quality of life.

Abstract

Background: Correction professionals are a highly stressed workforce with heightened risks for depression, suicide, obesity, cardiovascular disease, and injury. These professionals, largely hidden from view, have received little study concerning means to improve their safety, health, and well-being. In other settings, mindfulness has resulted in lowered stress, along with other benefits. We hypothesized that a program that promoted mindfulness combined with more typical health and safety components could uniquely benefit corrections professionals.

Objective: This project will assess a novel scalable, self-administered program to enhance the mindfulness, safety, and health of a vulnerable worker group.

Methods: In partnership with the Oregon Department of Corrections, we are conducting a prospective quasi-experimental trial of a safety, health, and mindfulness program among 100 corrections professionals from 2 institutions. Survey and physiologic data will be collected at enrollment, upon weekly program completion (3 months), and at 9 months after enrollment. Primary outcome behaviors promoted by the program are being mindful, healthier eating, more physical activity, and greater restorative sleep. Secondary downstream benefits are anticipated in stress level, mood, positive feelings about the organization, vascular health, and cellular aging, along with job performance, injuries, and economic costs. Participants will meet in-person or in a Zoom-type meeting as 3- to 5-member coworker groups during their usual work hours for 30-minute sessions once a week for 12 weeks. The program uses self-guided web-based learning modules that include brief mindfulness practice, and it is accessible by smartphone, tablet, or laptop. Daily mindfulness practice is encouraged between sessions, which is facilitated by the study website and group format. The modules' structure emphasizes prerequisite knowledge, peer support, skill practice, self-monitoring, and enhancing self-efficacy for change. The program continues through self-directed use of the Headspace app following the 12 weekly sessions.

Results: Participants are being enrolled, and the intervention is ready to launch.

Conclusions: Although mindfulness training has gained traction for worker well-being, its usual format requires a skilled trainer, an initial retreat, and weekly 2-hour meetings for several weeks. The content is limited to mindfulness without safety or health promotion aspects. The need for skilled trainers and time commitment limits the scalability of the usual mindfulness interventions. The planned program is an innovative combination of technology, e-learning, and a group format to add mindfulness to a safety and health curriculum. If acceptable and effective, the format would facilitate its widespread use.

Introduction

Background and Rationale

Those working in correctional facilities experience high stress levels, which negatively impact their mental and physical health [1-5]. The US Department of Justice published a review that highlighted the many sources of stress in corrections work, such as hypervigilance, constant threats of violence, media scrutiny, a closed work environment, understaffing, organizational issues, and work or family conflicts [1]. These workers have high rates of depression [6], suicidality [7], obesity, and other cardiovascular disease risks [4]. Corrections professionals also experience twice the rates of injury, sick leave, and health care costs than other government employees [8,9]. These professionals, largely hidden from view, have received little study concerning means to improve their safety, health, and well-being.

We are conducting a prospective proof-of-concept acceptability and initial efficacy trial of a scalable, technology-enabled worksite mindfulness, safety, and health promotion program specifically designed for corrections professionals. The unique program adds to our prior worker health and safety programs [10-12] by adding mindfulness. Mindfulness is especially applicable because of its ability to mitigate the effects of stress [13-15]. Our prior National Institutes of Justice-funded work with this population provided a basis for stress mitigation in corrections [16,17]; in that project, we surveyed corrections professionals and measured their perceived stress using the Perceived Stress Scale (PSS-4 Short Form). Using a linear mixed effects regression model, we found that perceived stress increases with increased work-related stress (P=.02), work hours (P=.03), work-life imbalance (P=.002), and lack of procedural justice (P=.03) [16]. Those findings helped inform this program's content. We also stratified participants by their stress level, and the higher and lower stress subgroups completed brain functional magnetic resonance imaging assessment of decision-making under emotionally charged conditions [17]. It is known that decision-making is affected by stress [18], and the ability to make quick, thoughtful decisions particularly is relevant for corrections work. We found that the officers who have higher stress needed significantly more top-down cognitive control, suggesting that their decision-making may be impaired in certain situations. Similar alterations in executive function have been found among young adults with a history of chronic stress [19,20].

Those detrimental effects on cognitive function, as well as other stress-related mental and physical adverse effects, can be mitigated by mindfulness [14]. A 2023 systematic review of mindfulness interventions among law enforcement identified 8 studies demonstrating promising benefits on reducing stress [21]. Several years ago, the Oregon Department of Corrections (DOC) used mindfulness training within a subset of corrections professionals [22]. However, as in most worksite studies, mindfulness training required a major time commitment and skilled trainers [15]. For example, the Oregon DOC program involved 2, day-long workshops plus 2 months of 2 hours per week for its trainer-led sessions. We sought to use a new format for mindfulness training, using a strategy that would be more scalable.

We are adding mindfulness to a program that is designed to promote Total Worker Health (TWH) [23]. The term Total Worker Health, trademarked by the US Centers for Disease Control and Prevention, refers to the combination of policies, programs, and practices that integrate protection from work-related health hazards with the promotion of illness prevention. As the founding members of the National Institute for Occupational Safety & Health-funded Oregon Healthy Workforce Center, we have been at the forefront of TWH efforts and have developed programs that positively impacted first responder groups and home health care workers [10-12].

Mindfulness generally is not a component of TWH programs, and our challenge was to design a scalable TWH program that added mindfulness training. The program is called Next Level, taking the traditional TWH program up a notch with mindfulness. We also recognize that many TWH programs have not been used outside of their study setting [24], and to further maximize dissemination potential, outcome data go beyond participant behaviors and include indices of compensable injuries and work performance [25].

Objectives

Our overarching aim is to create a scalable and effective program of mindfulness and TWH for corrections professionals. We hypothesized that the intervention would result in beneficial effects related to primary outcomes of dispositional mindfulness, as well as behaviors favoring health promotion and health protection.

Design

This study will use a quasi-experimental pre-post design to compare values of outcome measures at 3 times points: baseline, immediately post intervention (3 months after baseline), and follow-up (9 months after baseline). Randomization of the intervention by site or individual is not feasible due to personnel movement and contamination effects within and across correctional facilities. An advantage of the pre-post design is that each participant will act as their own control, increasing the power of the study [26]. Each of the 2 participating corrections facilities will be enrolled sequentially and will be a new wave of the project to allow managing activities across the 2 dispersed sites.

XSL•FO
RenderX

The theoretical underpinnings of the intervention are based on our validated model of effective behavior change [27]. In establishing that model, we combined mediation analyses across our prospective randomized behavior change trials with different populations and established that effective programs included prerequisite knowledge, normative beliefs, and self-efficacy for change. Each of those features was built into this program.

Practicing mindfulness will be addressed similarly to other behaviors, such as healthy eating and achieving regular physical activity. However, unlike eating and exercise, mindful meditation will be a new ability for many participants requiring skill acquisition and practice. Accordingly, mindfulness practice is included in each session with a focus on its relationship to that session's safety or health topic. The program also emphasizes behavioral self-monitoring and peer norms to reinforce Social Cognitive Theory's tenant that observing progress toward objectives can enhance self-efficacy [28,29].

Methods

Setting and Participants

Eligible participants are corrections professionals working on units from the Oregon State Correctional Institution and Coffee Creek Correctional Facility. Corrections professionals are security and nonsecurity staff working for pay at the facility. Enrollment criteria include being employed for at least 6 months, with the exclusion criteria of not planning to leave or retire during the next 9 months. The total number of eligible participants is estimated to be approximately 600, with a budget for 100 participants. Following informational meetings with the administration hierarchy and union officials, we will use existing communication channels to inform potential participants and personally meet with them at their preshift group meetings, when information concerning the prior shift is shared. Individuals will not be directly compensated but will receive release time to participate. Enrollment is on a first-come, first-serve basis, and we expect to reach our 100-participant goal during a 6-month recruitment window. We have used similar strategies successfully in our prior studies of first responders [10,11]. We will carefully track all enrolled participants using the CONSORT (Consolidated Standards of Reporting Trials) guidelines [30].

Ethics Approval

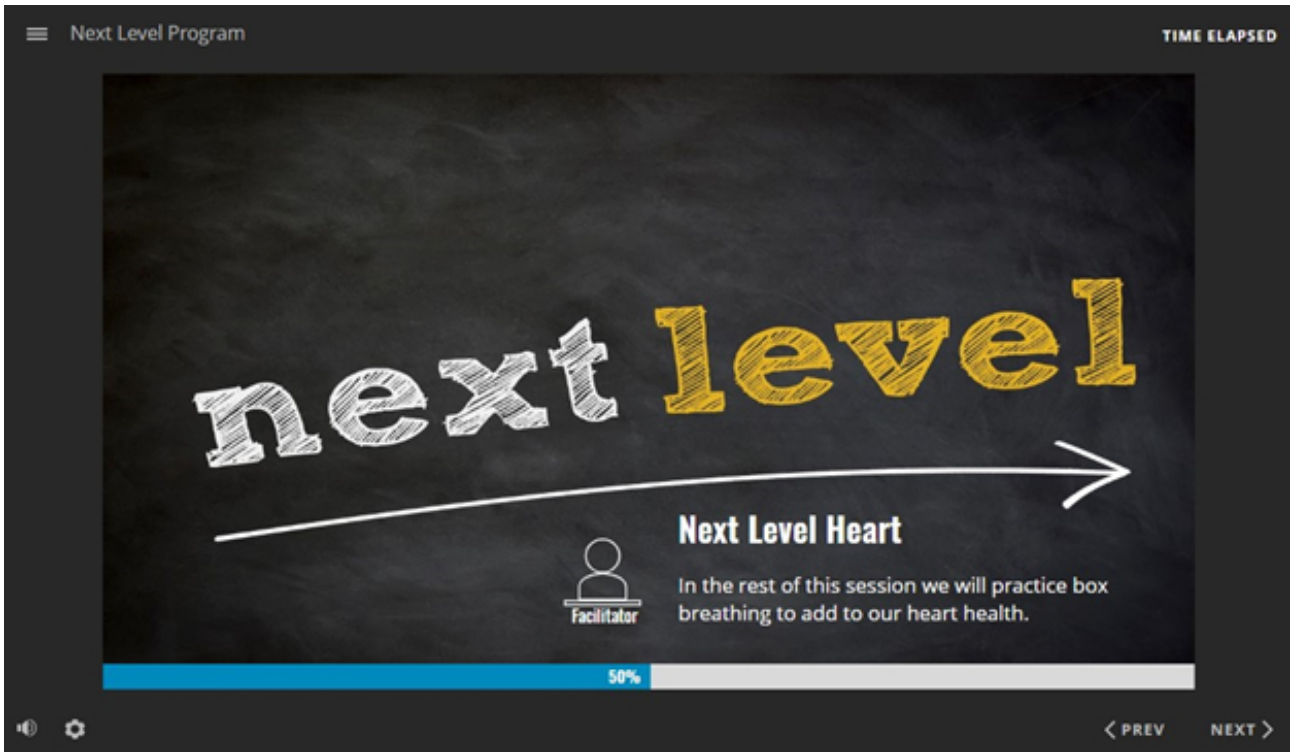
The Oregon Health & Science University (OHSU) institutional review board (IRB; #24303) has approved the study and its procedures.

Confidentiality

The OHSU IRB requires an explicit safety and monitoring plan, and it supervises project safety and reporting of any adverse events. All data and all participant responses will be confidential and stored securely. All participants will be assigned a unique, nonmeaningful identifying code number, necessary for longitudinal participant tracking that will correspond to their Headspace participant identification number, to allow merging Headspace website analytics with other data. The study data will be collected and managed using Qualtics and REDCap (Research Electronic Data Capture; Vanderbilt University) electronic data capture tools [31,32]. Qualtrics offline surveys is an application that allows securely administering surveys on a mobile device without an internet connection. REDCap is a secure web-based software platform designed to support data capture for research studies. Both are approved by the OHSU IRB for data collection. Audio files of focus groups will be recorded on OHSU password-protected devices and downloaded to an OHSU password-protected secure site. Hard copies of observation information will be stored in a locked file cabinet at OHSU. No identified individual data will be presented or published. Individual data may be shown without identifying the participant to illustrate scientific principles.

Intervention

The intervention will be delivered during twelve 30-minute weekly meetings among coworkers. The Oregon DOC supports the project by providing paid time during participants' usual work days to participate. The sessions are built using Articulate 360, which is a well-established subscription platform for e-Learning course development [33]. It includes access to authoring apps and a library with thousands of course assets. For example, it has hundreds of potential dynamic components, such as interactive games, quizzes, and reveals. It provides a consistent learner experience across all devices (desktop computer, smartphone, or tablet).



Each of the sessions contains approximately 20 wireframes. The wireframes are the baseline structure to which features (eg, games, quizzes, reveals, matching, videos, and links to other content) can be attached. Each module follows a similar format. The sessions are done with 3 to 6 coworkers positioned around a large video screen or sharing a screen when meeting in a Zoom-type meeting. Early in each session, there is a 5-minute follow-up on behavioral objectives (or practice opportunities) from the prior session (Figure 1). This provides a forum to problem-solving challenges, enhance self-efficacy for efforts, and engage in social support. Next, foundational knowledge for that session's content is presented and actively processed by completing quizzes, reading reveals, or watching a 2-minute video. The session transitions to mindfulness with a "Next Level" wireframe (Figure 2). During the second half of the session, participants either practice a seated meditation or a new mindfulness skill related to that session's topic. For example, in Healthy Heart, they learn and practice box breathing (Figure 3). The session wrap-up presents daily mindfulness practice objectives for the coming week, which will be revisited in the following session (Figure 4).

XSL•FO

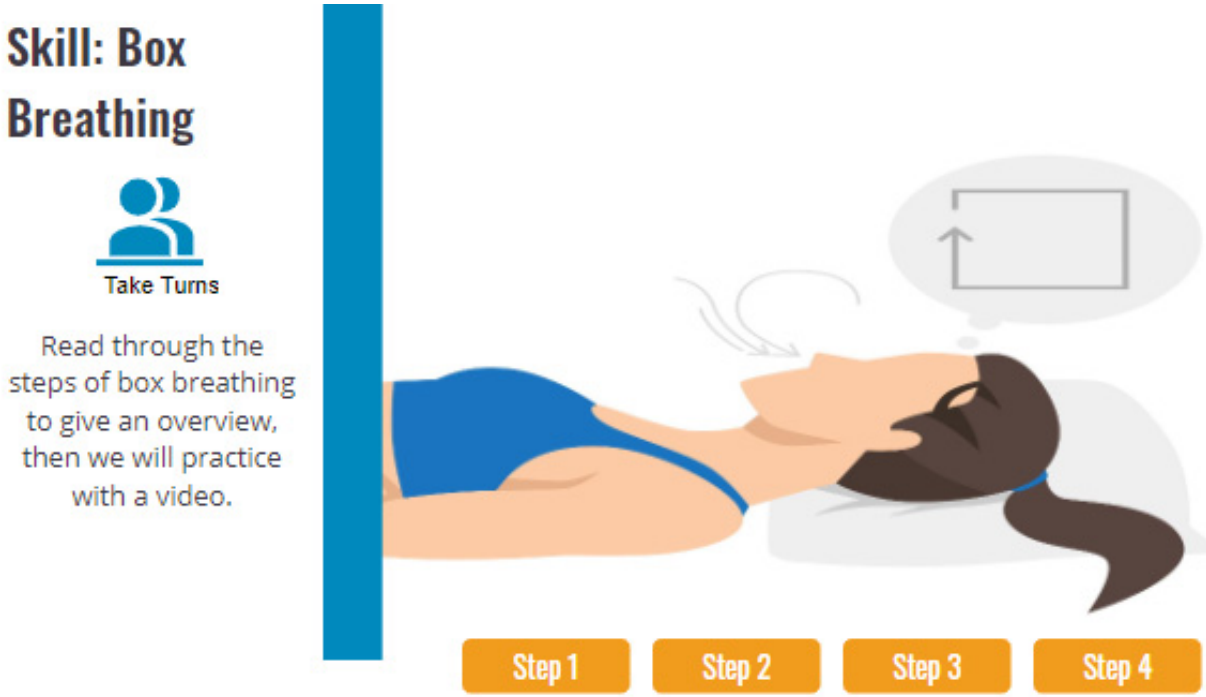
XSL•FO
RenderX

Figure 3. In-session introduction to a skill that is followed by video-led skill practice.



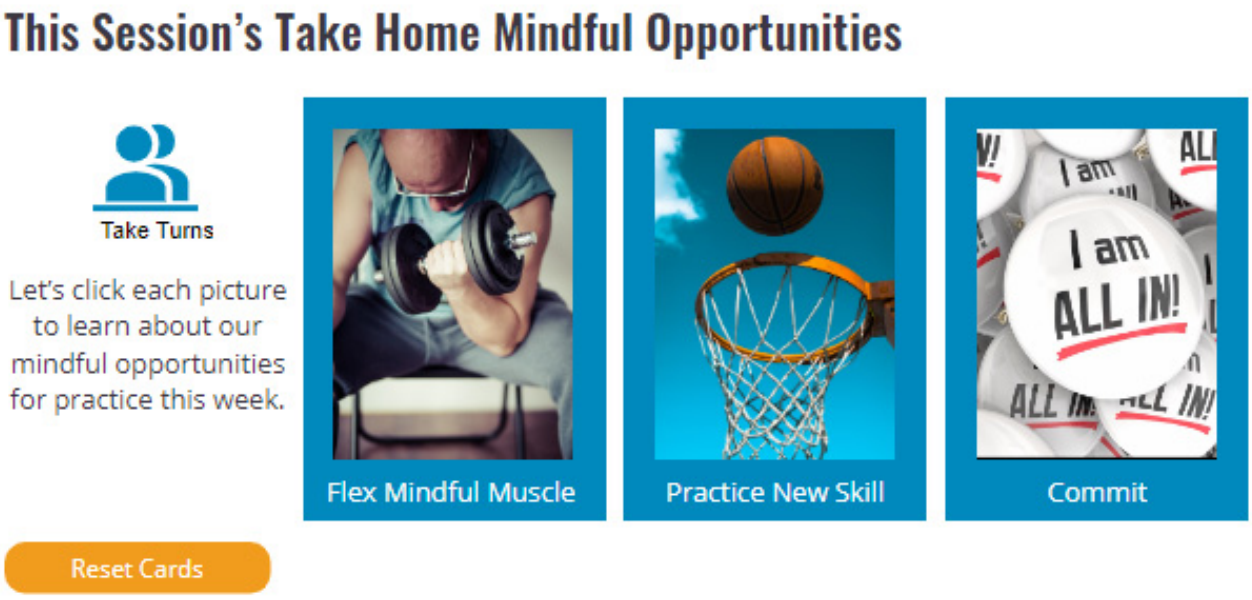


Figure 4. Participants click on each picture and read the opportunities (goals) for mindfulness practices for that week.

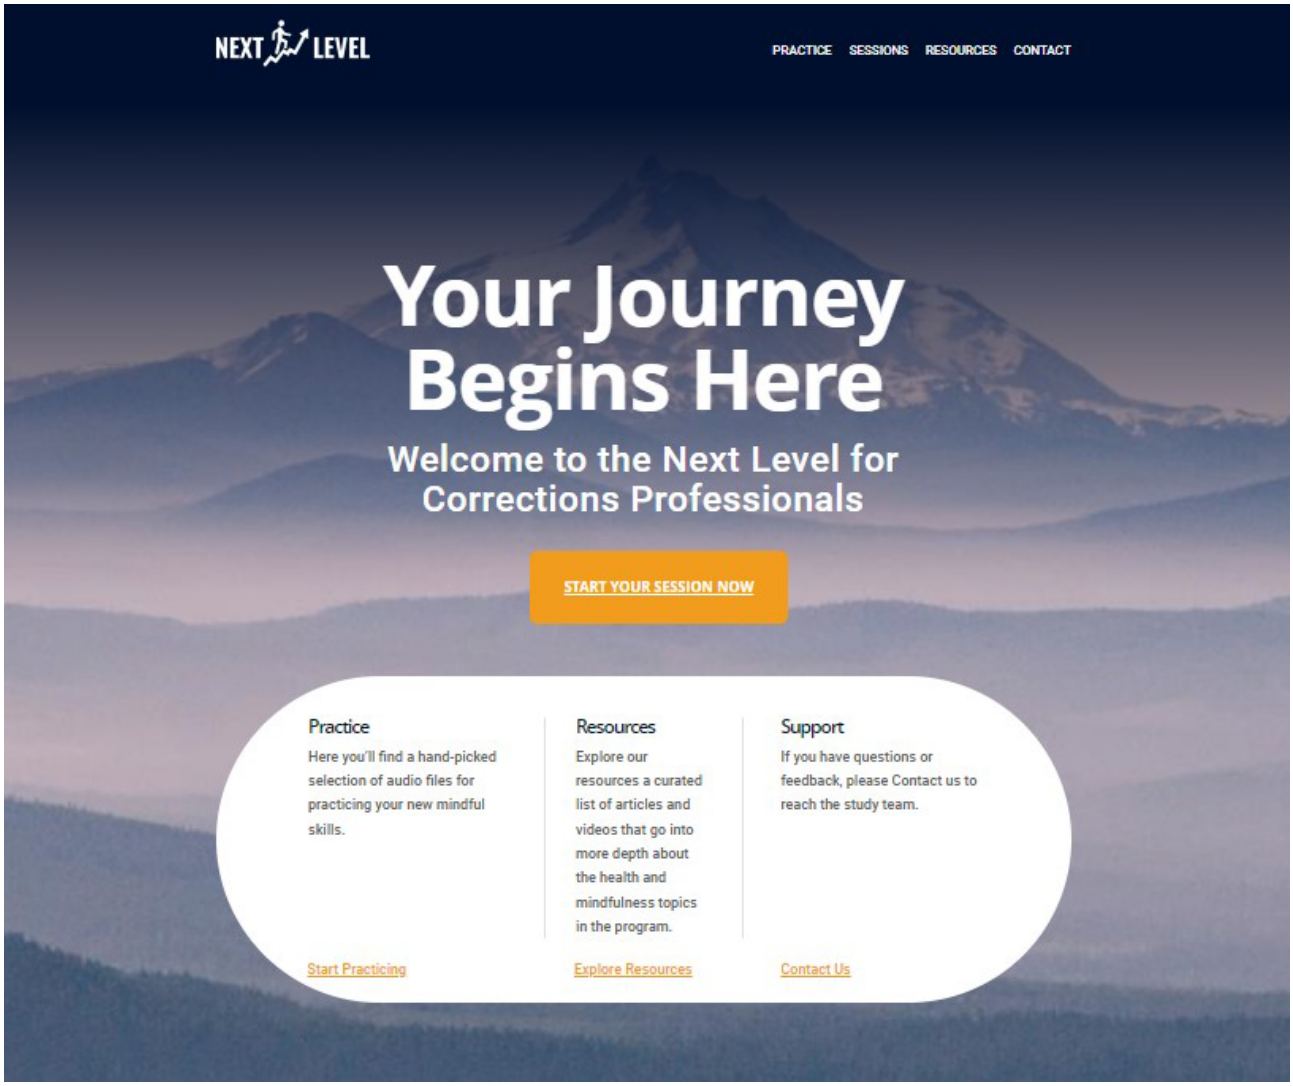
Our experience and the literature [34] emphasize that corrections professionals feel that their unique stressors require an authentic understanding of their issues, and accordingly, the content is specifically related to their profession. In addition, we believed that corrections professionals frequently lacked a background or intrinsic interest in mindfulness [35]. Consequently, the initial 2 sessions were designed to build motivation by providing background relevance, a scientific basis for mindfulness, and testimonials from corrections professionals, as well as an overview of the program's content, process, and how they will run the sessions. These sessions involve a series of videos and voiceover wireframes. Beginning in session 3, on-screen icons guide participants to run the session themselves, with 1 of them as the designated facilitator for that session. The scope and sequence of the twelve, weekly 30-minute sessions are shown in Table 1.

XSL•FO
RenderX

Table 1. Next-level scope and sequence.

Session	Content	Mindful in-session practice	Take home daily practice
1	Background and motivation building	Two-minute guided meditation	Daily 2-minute meditation+explore the website
2	Format for and running the sessions	Two-minute guided meditation	Daily 2-minute meditation+explore the website
3	Healthy heart	Box breathing	Daily 3-minute meditation+box breathing twice this week
4	Physical fitness	Three-minute guided meditation	Daily 3-minute meditation+walking meditation twice this week
5	Healthy eating	Mindful eating	Daily 3-minute meditation+mindful eating three times this week
6	Mental fitness	Three minute-gratitude meditation	Daily 3-minute meditation+gratitude meditation at least twice this week
7	Halfway check-in	Three-minute guided meditation	Daily 3-minute meditation+watch introduction Headspace video
8	Sleep	Body scan	Daily 5-minute meditation+bedtime body scan twice this week
9	Injury prevention	Three-minute guided meditation	Daily 5-minute meditation+visit Headspace app
10	Resilience	Three-minute guided meditation	Daily 5-minute meditation+visit Headspace app
11	Medical check-up	Three-minute guided self-compassions meditation	Daily 5-minute meditation+at least 2 self-compassion meditations
12	Wrap-up and next steps for next level	Three-minute guided meditation	Daily 5-minute meditation+visit Headspace app

The program does not require a trained instructor. The coworkers, guided by icons on the screen, are responsible for running the sessions. The initial session has videos and voice-over wireframes, and during session 2, the group-managed format is presented. The group is directed to identify 1 member as the designated facilitator, who follows those icons' directions. However, being the facilitator requires no preparation or special expertise and other group members can easily assume that role if that individual is not present.



We have used similar coworker-led sessions successfully with other occupational groups [10-12]. We particularly wanted to avoid a hierarchical pedagogic structure of "teaching to" corrections professionals. Peer-led programs have documented efficacy and may be as effective as professionally delivered formats [36,37]. Peers also reduce expenses, promote a sense of shared norms, enhance social support, and augment material with credible examples and personal experiences [38].

To provide a longitudinal program component, we partnered with Headspace, an established effective mindfulness app. In a recent review of mindfulness training apps, Headspace received the highest rating [39]. Individuals will have continuous access to the Headspace app beginning at enrollment for a total of 12 months. Transitioning to more Headspace use is incorporated in the latter weekly sessions to maintain mindfulness once completing the weekly sessions tailored to corrections professionals.

The program is accessible from a simple website portal designed specifically for corrections professionals. It functions on all operating systems. While corrections professionals often do not have their smartphones with them on duty, they do have access to the meeting and breakrooms with computers, tablets, and internet access. A mockup of that the website landing page is shown in Figure 5. Menu pages include (1) the sessions, (2) audio files of guided mindfulness meditations for use during their daily practice, (3) resources with PDFs and links to videos of interest and related to session topics, and (4) Headspace information. For each session, there is a link to play the session, along with buttons to review the video used in that session, and a restatement of the take-home practice opportunities for that session.

Figure 5. Landing page for the Next Level website.

Outcomes

Three types of outcome data will be collected at baseline, immediately after the 12-week intervention, and at 9 months (6 months following the intervention's conclusion): (1) Surveys using validated self-report measures for demographic variables, mindfulness indices, current (if any) mindfulness practices, healthy behaviors (nutrition, physical activity, sleep, and safety actions), work-life balance, mental health, perceived stress, and perceptions of the organization or worksite; (2) biomeasures: blood pressure, height, weight, vascular reactivity, and blood work for cellular senescence; and (3) economic outcomes: missed days, overtime, sick days, injuries, incidents, and workmen's comp claims.

These variables along with citations to the validated instruments are shown in Textbox 1.

Textbox 1. Outcome measures.

Primary outcomes

- Mindfulness (Mindful Attention Awareness Scale [40,41] and Facet Mindfulness Questionnaire [42])
- Self-compassion [43]
- Gratitude [44]
- Eating habits [11]
- Mindful eating [45]
- Physical activity [46]
- Mindful physical activity [47]
- Sleep [48,49]

Secondary outcomes

- Perceived stress [16]
- Centers for Disease Control and Prevention health days [50]
- Feelings about the organization [16]
- Mood [51-53]
- Other biometrics (height, weight, and blood pressure)
- Vascular reactivity [54]
- Telomere length [55]
- Health care costs (overtime, days missed, injuries, incidents, and worker compensation claims)

Other

- Session observations for fidelity, dose, and reach
- Application metrics
- Follow-up focus groups

The primary outcomes relate to behaviors directly promoted by the program: being mindful; healthier eating; more physical activity; and greater restorative sleep. Secondary downstream benefits are anticipated in perceived stress; negative affect; greater positive feelings about the organization; vascular health or cellular aging; and job performance/injuries/economic costs. All survey constructs have established validity, and many have been used in prior studies. In addition, the baseline survey will include demographic and work history items. The post intervention survey also will include items related to intervention usability, acceptance, enjoyment, and whether they would recommend the program to other corrections professionals.

We will track injury counts, absenteeism (used as a proxy for productivity), worker's compensation claims, and costs associated with illness and injury. We will collect data on individuals' reported illness, injury (slips, trips, falls, exposures, and incident interactions) before enrollment and prospectively during and for 2 months following the study. We will use 2-month data for participants, including 2 months prior to enrollment, months 3 and 4 after beginning the program, and a third 2-month interval after completing the study. Absenteeism will be indexed with the Institution Staff Deployment System. We will track pre- and postprogram unusual incident reporting, which is a DOC method of tracking the activity of consequence to the good order, such as inmate self-injury, uses of force, blood and bodily fluid exposure, contraband, and individual or group disturbances.

There are 2 unique biomeasures used in this study: digital thermal monitoring and markers of cellular senescence. Digital thermal monitoring is a cost-effective test of vascular reactivity and endothelial function. It is well correlated with Framingham Risk Score, Coronary Artery Calcium Score, and computerized tomography angiography. It is measured with the Endothelix DTM system, which is approved by the US Food and Drug Administration, noninvasive, and easy to use (VENDYS, Endothelix Inc). With that system, a blood pressure cuff occludes arm arterial flow for 5 minutes. Following cuff deflation, reactive hyperemia is largely dependent on endothelial cells. The healthier the artery, the larger the hyperemic response. This assessment can show changes in response to health promotion interventions and provide a proximal index of positive cardiovascular effects.

We also will assess cellular senescence. This is a measure known to be accelerated by stress and reversed by effective wellness interventions [56-58]. Changes in senescence are associated with a heightened risk for disease and mortality. At present, there is no "gold standard" for cellular senescence. We will use a combination of methods to assess cellular aging: cellular staining for senescence-associated β-gal (Senescence Cells Histochemical Staining Kit, Sigma); the presence of

XSL•FO
RenderX

senescence-associated proteins using Western blot; and senescence marker antibody sampling kits to stain for p16, p21, phospho-histone H2AX, Lamin B1, HMGB1, matrix metalloproteinase 3, cytokine interleukin 6, and tumor necrosis factor α. We also will determine the telomerase activity in cell extracts through its ability to synthesize telomeric repeats onto an oligonucleotide substrate, which is amplified by polymerase chain reaction, using the TRAPEZE RT Telomerase Detection kit (Sigma). The relative quantification of gene expression will be determined using the $2^{-\Delta\Delta Ct}$ method with control RNAs appropriate for blood, and a comprehensive senescence phenotype profile will be obtained using the Human Cellular Senescence array (SA Biosciences).

Fidelity and Adherence

We will observe approximately half of the sessions and use the session's wireframes as a checklist for fidelity, as well as note taking during session observations concerning participation, engagement, and any deviations from the planned format. When possible, observations will done be in person, and we also will join group Zoom-type meetings. We will assess fidelity (the extent to which the intervention is delivered as intended), dose (how much is delivered), and reach (the proportion of intended recipients participating). A simple email check-in will be a final session component, where participants self-report attendance and indicate session duration. In addition, participants' visits and time on the Headspace app will be tracked with that app's analytics.

Qualitative Data Collection

Following the intervention, we will conduct focus groups concerning program use and outcomes. We will offer partaking in a focus group to all participants. When possible, we will have individuals who went through the sessions together also be together in a focus group. These will last 45 to 60 minutes and will use a trained facilitator and interview guide designed to explore the study outcomes and session observations. The focus group roadmap or interview guide is included in Multimedia Appendix 1. A scribe will take notes and track participant comments.

Power and Sample Size

We expect a sample size of 100 participants from 2 facilities. We first estimated an approximate dropout rate of 20%, leaving 80 participants. For the 4 primary outcome constructs, we adjusted the α level using Bonferroni corrections by dividing .05 by 4 giving us an α level of .0125 to account for multiple testing. In order to power the change in outcomes from baseline to post intervention (3 months), we used paired *t* tests. We estimate that this sample size has 90% power to detect a moderate effect size. We estimate (Cohen *d*=.41), 85% power to detect (*d*=.43), and 90% power to detect (*d*=.46). All power analyses were conducted using PASS 2019 (NCSS, LLC). For qualitative data, rather than a specified number of groups, data gathering will continue until saturation, when no new information is obtained.

Data Analysis

Preliminary analyses will include careful examination of descriptive statistics and distributions for variables at each time point. This will include counts and proportions for categorical variables and means, SDs, and range for continuous variables, as well as 95% CIs for all proportions and means.

Primary Outcomes

Our primary criterion for determining intervention efficacy will be differences in changes in the primary outcomes listed in Textbox 1. Our primary hypothesis is that the intervention will be associated with an improvement in each of those outcomes. Repeated measures linear mixed effects models will be used to determine whether the outcome measures improved from baseline to post intervention. Models will include terms for the time points T_3 (0 vs 3 months) and T_9 (0 vs 9 months), and nested random effects for individuals within sites. Primary analyses will test the significance of the terms to determine whether outcome measures change from baseline to post intervention. Models will adjust for age and gender and follow a purposeful selection strategy to determine which other background characteristics to include. Mixed effects models have the advantage that participants do not need complete data for all 3 time points to be included in the analyses. If after data inspection it is decided to dichotomize some measures, logistic mixed effects models will be used instead.

Secondary Outcomes and Associations

Secondary outcomes will be analyzed similarly using repeated measures mixed effects models with linear or logistic links depending on whether the outcomes are continuous or binary. We will furthermore analyze whether the changes in primary outcomes are associated with changes in other selected measures. In particular, we hypothesize that (1) reduced stress and healthier behaviors (eg, nutrition, physical activity, and sleep) are associated with improvements in vascular reactivity and cellular senescence and (2) reduced stress and improved perceptions of the organization are associated with reduced injuries and incidents.

Qualitative Outcomes

We are experienced in mixed methods, having used them successfully in understanding program outcomes [48,59,60]. Analyses of the focus groups following the intervention will involve reiterative pattern analysis of comments, which avoids the substantive bias inherent in a priori categorization. Instead, we will adapt the more inductive constant-comparative method typical of grounded theory [61]. This analysis approach increases the transparency and reproducibility of qualitative research. Our aim is to further explore the findings observed in the primary and secondary outcomes, beginning with a roadmap of questions and exploring the responses. Barriers and enhancements to program impact will be sought within the dynamic contexts of actual experience. Construction of themes and interpretations rather than bounding interpretation with a prespecified list of categories for coding avoids the substantive bias inherent in a priori categorization. Instead, we will use an adaption of the more inductive constant-comparative method [62,63]. Following the identification of themes, the data set will be subjected to

XSL•FO
RenderX

microreview in a search for both confirming and disconfirming data. Quotations will be selected to exemplify and elaborate themes, support findings, and illuminate contexts, promoting reader understanding and facilitating. We will use applicable items from the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist to document and communicate our methods [64]. In addition to providing a deeper understanding of outcomes, the qualitative findings should allow the development of case studies that may be useful in sharing findings with the corrections community.

Results

As of December 2022, this study is enrolling participants and finalizing the web-based curriculum and website. We anticipate beginning the intervention in early 2023, with data collection to be completed by November of 2023.

Discussion

Fifty years ago, Kabat-Zinn et al [65] used Mindfulness-based Stress Reduction to lessen stress and distress for those with chronic pain [65]. MBSR takes time and generally includes a day-long retreat, weekly 2.5-hour classes for 2 months, and daily activities including around 40 minutes of meditation. Although its effectiveness is well established [66], its time commitment is a hurdle. Work-related stress is estimated to result in losses of up to US $300 billion annually in the United States [67]. Mindfulness training has gained some traction in the worksite setting [68,69] but still has limited use, partially due to the need for a significant time commitment and an experienced trainer. The innovative format described in this protocol overcomes 3 challenges: time, tailoring, and TWH incorporation. It is delivered in a 30-minute once-a-week, self-directed format and designed specifically for corrections professionals. Importantly, it is incorporated in a TWH context. Mindfulness and TWH are rarely combined. A literature search for TWH and mindfulness yielded only a single citation. Some evidence suggest that mindfulness training may be more effective when combined with other components [70].

Our outcome findings will include three main dimensions: (1) implementation acceptability, observations for fidelity, and adherence; (2) pre- to postsurvey measures of targeted behaviors and in particular dimensions of mindfulness along with measures of inflammation and cellular senescence, in addition to human resource data on missed work, injury claims, and incident reports; and (3) postparticipation survey items relating to program acceptability and focus group interviews concerning for a deeper understanding of practical issues, social validity, and suggestion to improve the program and its use.

The 3 listed dimensions reflect 3 components of this protocol. The first dimension relates to whether we crafted a program that was easy to use and engaging enough to sustain participation, especially in the context of the stressful and generally understaffed context of corrections. The second dimension relates to changes in behaviors with an emphasis on instruments used to assess mindfulness following the usual longer form of mindfulness interventions. The focus group aspect of the third dimension will allow a more thorough understanding of the program, as well as provide suggestions for improvement.

We recognize that each correctional system has its unique structural, organizational, and personnel factors and that our findings may not generalize to corrections professionals in other settings. In addition, this is the first evaluation of the peer-led, technology-enabled weekly session and self-directed practice format to increase mindfulness, hence the emphasis on observing sessions and formative qualitative feedback in debriefing after the trial. In addition, participants are not a random sample of these workers. However, we have site-wide data from our previous work [16], and we will be able to compare participants with other corrections professionals from these sites. Despite limitations, the innovative aspects of the program will provide outcome numbers that could inform a subsequent larger randomized controlled trial of the program in this and other settings.

Acknowledgments

We are grateful for the cooperation of the Oregon Department of Corrections. This study was funded by the National Institute of Justice (#2020_R2-CX-0006).

Data Availability

The data sets generated and analyzed during this study will be available in the National Archive of Criminal Justice Data repository.

Conflicts of Interest

None declared.

Abstract

Background: Ecological momentary assessments (EMAs) and digital wearables (DW) are commonly used remote monitoring technologies that capture real-time data in people's natural environments. Real-time data are core to personalized medical care and intensively adaptive health interventions. The utility of such personalized care is contingent on user uptake and continued use of EMA and DW. Consequently, it is critical to understand user preferences that may increase the uptake of EMA and DW.

Objective: The study aims to quantify users' preferences of EMA and DW, examine variations in users' preferences across demographic and behavioral subgroups, and assess the association between users' preferences and intentions to use EMA and DW.

Methods: We will administer 2 discrete choice experiments (DCEs) paired with self-report surveys on the internet to a total of 3260 US adults through Qualtrics. The first DCE will assess participants' EMA preferences using a choice-based conjoint design that will ask participants to compare the relative importance of prompt frequency, number of questions per prompt, prompt type, health topic, and assessment duration. The second DCE will measure participants' DW preferences using a maximum difference scaling design that will quantify the relative importance of device characteristics, effort expectancy, social influence, and facilitating technical, health care, and market factors. Hierarchical Bayesian multinomial logistic regression models will be used to generate subject-specific preference utilities. Preference utilities will be compared across demographic (ie, sex, age, race, and ethnicity) and behavioral (ie, substance use, physical activity, dietary behavior, and sleep duration) subgroups. Regression models will determine whether specific utilities are associated with attitudes toward or intentions to use EMA and DW. Mixture models will determine the associations of attitudes toward and intentions to use EMA and DW with latent profiles of user preferences.

Results: The institutional review board approved the study on December 19, 2022. Data collection started on January 20, 2023, and concluded on May 4, 2023. Data analysis is currently underway.

Conclusions: The study will provide evidence on users' preferences of EMA and DW features that can improve initial uptake and potentially continued use of these remote monitoring tools. The sample size and composition allow for subgroup analysis by demographics and health behaviors and will provide evidence on associations between users' preferences and intentions to uptake EMA and DW. Limitations include the cross-sectional nature of the study, which limits our ability to measure direct behavior. Rather, we capture behavioral intentions for EMA and DW uptake. The nonprobability sample limits the generalizability of the results and introduces self-selection bias related to the demographic and behavioral characteristics of participants who belong to web-based survey panels.

KEYWORDS

digital wearables; discrete choice experiment; ecological momentary assessment; mHealth; mobile health; remote monitoring technology

Introduction

Ecological momentary assessments (EMAs) and digital wearables (DWs) are exemplars of remote monitoring technologies that afford us the ability to monitor the individual and their environment around the clock [1]. Remote monitoring technologies are a hallmark of precision medicine, whereby medical and health decisions can be tailored to the individual based on their unique and up-to-date data [2]. Specifically, EMA is an approach where people's experiences and behaviors are repeatedly captured through brief self-report surveys [3]. DWs are electronic devices that repeatedly collect, process, store, and transmit data either directly through an internet connection or indirectly through a smartphone [4]. EMAs and DWs capture momentary contextual, sociopsychological, physiological, and behavioral data in the wild (ie, in real time and in a person's natural environment), which improves the accuracy, granularity, and ecological validity of the measurements [5].

User-generated data on behavioral and medical conditions from EMAs and DWs can be used for diagnostic, management, and treatment purposes [1]. Examples include (1) detection of smoking and alcohol use episodes and lapses [6-8] and of various medical conditions [9] (eg, seizures [10] and atrial fibrillation) [11,12]; (2) management of diabetes [13], hypertension [14], physical activity, and diet [15-18]; and (3) treatment of cigarette smoking [19], sleep [20], and mood disorders [21] by intervening whenever and wherever support is needed. Data from EMAs and DWs can improve health and clinical outcomes through various mechanisms. EMAs and DWs capture events and behaviors, their determinants, and their effects. These data relate to several cognitive processes (eg, self-monitoring) underlying the self-regulatory mechanism that motivates and guides proactive and purposeful actions [22]. Additionally, data from EMAs and DWs represent feedback information to their users that is used to form and assess self-views and goals [23], thereby reinforcing desired behaviors [24]. Indeed, evidence shows that EMA and DW use is associated with improved health outcomes [25,26] (cf [27,28]).

Real-time EMA and DW data are the foundation of intensively adaptive health interventions and personalized medical care. Intensively adaptive interventions use ongoing information about the user to disseminate (or not) an appropriate treatment type and dose at the right time and place, relying on predefined decision rules that accommodate between- and within-user characteristics and other tailoring factors (eg, intrapersonal state and contextual cues) that change by the day, hour, or second over the course of an intervention [29,30]. For example, in Text2Quit, an interactive text messaging smoking cessation intervention, users' data are periodically updated throughout the intervention (eg, number of cigarettes smoked) and subsequently integrated in pre- and postquit support messages [19]. In Sense2Stop, users wear chest and wrist DWs and answer smoking- and mood-related EMAs, both of which trigger digital prompts for users to engage in exercises to manage stress, a known antecedent of smoking lapse [31]. Although evidence on the efficacy and effectiveness of intensively adaptive interventions is largely based on pilot studies [32], they often outperform nonadaptive interventions [33]. Similarly, in clinical settings, continuous input from remote monitoring tools can be integrated into a patient's electronic health record, which subsequently informs medical decision-making and improves clinical outcomes [34,35].

To reap the benefits associated with the use of remote monitoring technology, end users must uptake and continually use these digital tools. Uptake refers to the likelihood that an individual is willing to take part in an EMA or use a DW [36]. Continued use refers to the likelihood that an individual consistently completes the EMAs or uses DWs as prescribed [37]. Rates of EMA and DW uptake and continued use are frequently low or variable. For example, health and fitness mobile apps have a mere 3.7% retention rate 30 days post installation [38] and a third of DW owners stop using their devices within 6 months [39]. When reported, EMA completion rate varies across studies, between 20% and 90% in substance use studies [8] and between 44% and 96% in diet and physical activity studies [16]. Compounding these issues, the operationalization of uptake and continued use is often absent or inconsistent across research studies. For example, some studies report percentages of participants who engage in an activity or a previously set threshold of that activity, while others report averages or the exact number of times or number of days participants engage in a given activity [40]. Researchers have documented some of the facilitators of and barriers to the uptake and continued use of EMAs and DWs. Facilitators of use include perceptions of utility, usefulness, ease of use, usability, and having the motivation and ability to use the technology, to name a few [40]. Barriers include technical (eg, technology malfunction and incompatibility) and nontechnical (eg, digital literacy and cost) factors [40].

Uptake and continued use may be improved when the features of EMAs and DWs match the preferences of potential users. However, there is scarce evidence on the relative importance of different attributes and attribute levels of EMAs and DWs that might affect uptake and potentially continued use, although uptake and continued use are driven by different factors [4]. Indeed, the design of EMAs varies greatly regarding key attributes. For instance, the length of EMA studies ranges from 1 to 182 days, with a median of 7 days, whereas the number of daily prompts ranges from 1 to 42 [41]. Additionally, user preferences for specific attributes are rarely examined across sociodemographic and behavioral subgroups, despite well-documented differences in uptake and continued use of remote monitoring technologies between these groups [41,42]. There is also little evidence on the relationship between EMA and DW preferred attributes and intentions to use remote monitoring technologies.

XSL•FO
RenderX

Using a discrete choice experiment (DCE) [43], this study aims to identify the optimal attributes of EMAs and DWs that may increase uptake and continued use. A DCE is a quantitative survey-based methodology that elicits preferences by presenting participants with alternatives and asking them to make a choice. The process is repeated with different combinations of attributes, and the resulting data are used to calculate the relative importance each participant places on each attribute [44]. In previous studies, this method has been used to elicit preferences for health mobile apps [45-47], sharing health data [48,49], and health interventions [50]. In this study, 2 DCEs will elucidate preferences for EMAs and DWs, examine how these preferences vary across demographics (ie, sex, age, and race and ethnicity) and behaviors (ie, substance use, physical activity, dietary behavior, and sleep duration), and assess whether specific preferences are associated with attitudes toward or intentions to use EMAs and DWs in the future.

Methods

Aims

This study aims to (1) quantify the relative importance of 5 EMA attributes (ie, prompt frequency for surveys, number of questions per prompt, prompt type, health topic, and assessment duration) and 30 DW features centered around 6 domains (ie, device characteristics, effort expectancy, social influence, and facilitating conditions related to technical, health care, and market factors); (2) identify the relative importance of EMA and DW attributes within demographic (ie, sex, age, and race and ethnicity) and behavioral (ie, those who meet vs who do not meet predefined criteria or guidelines for a given behavior) subgroups; and (3) examine the associations between users' preferences and EMA and DW uptake intentions.

Design

The focal point of the study is 2 DCEs (Multimedia Appendix 1). Each participant will complete only 1 DCE.

The first DCE will assess EMA preferences using a choice-based conjoint design [51,52] in which 5 attributes (eg, number of surveys per day) are presented as a package. Each attribute is assigned one of several levels (eg, 2-3 surveys or 6 or more surveys). Participants choose between 2 packages or neither package. Attributes and levels (Table 1) were selected from previous research on EMAs [15,16,18,41,53]. Collectively, over 1500 unique packages can be constructed from these attribute levels. However, a balanced fractional factorial design will be implemented in Qualtrics so that each participant only needs to repeat the task 9 times and evaluate 18 packages.

The second DCE will measure DW preferences using a maximum difference scaling design [54,55] in which participants view a subset of 4 features from a larger set of 30 features (Table 2). Participants choose which feature in the subset they value the most and which they value the least. The attributes and corresponding statements were adapted and developed from previous research on DWs [4,56-60] and digital health tools more broadly [40,46,48,50,61-65]. Attribute domains correspond to constructs derived from technology acceptance theoretical frameworks [66]. The attributes and corresponding statements center around effort expectancy, defined as the level of ease in using the technology; social influence, defined as the level of support the user of the technology receives from important others; and facilitating conditions related to technical infrastructure, health care, and market factors that can prohibit or support the technology use [66]. We also include device characteristics as an external factor associated with technology acceptance [59]. Although over 24,000 combinations of attributes are possible, each participant will only be required to complete the task 23 times.

RenderX

Table 1. Attributes and attribute levels in an ecological momentary assessment discrete choice experiment.

Attributes and attribute levels	Descriptions
Prompt frequency	
0-1 per day	None or only 1 survey
2-3 per day	2-3 surveys
4-5 per day	4-5 surveys
≥6 per day	6 or more surveys
Number of questions per prompt	
1 question	1 question
2-3 questions	2-3 questions
4-5 questions	4-5 questions
≥6 questions	6 or more questions
Prompt type	
Event-contingent	Self-initiated when a predefined event has occurred (eg, smoking a cigarette, snacking between meals, or being in a specific location such as a bar)
Signal-contingent	At random times
Time-contingent	On fixed times
Mixed	Combination of random and fixed times
Health topic	
Nicotine or tobacco use	Nicotine or tobacco use
Alcohol use	Alcohol drinking
Marijuana use	Marijuana use
Physical activity	Exercise
Nutrition	Diet or nutrition
Sleep	Sleep
Assessment duration	
≤1 month	1 month or shorter
>1 but <6 months	More than 1 month but less than 6 months
≥6 but <12 months	More than 6 months but less than 1 year
≥1 year	1 year or longer

XSL•FO
RenderX

Table 2. Attributes examined in the digital wearables discrete choice experiment.

Domains and attributes	Statements
Device characteristics	
Type	• The device collects nonmedical data (eg, steps) • The device collects medical data (eg, blood glucose)
Point of contact	• I must wear the device on my chest or ankle
Battery life	• The device must be charged every 48 hours
Display	• The device has a touchscreen interface
Memory	• The device has a memory chip to prevent data loss
Cellular data	• The device must be always connected to the internet
Personalization	• I can personalize the device to my individual goals and preferences • I can change the look and feel of the device (eg, by using different strap styles and colors)
Added features	• The device provides information in languages other than English (eg, Spanish) • The device allows me to interact with other users if I want to
Effectiveness	• The accuracy of the device has been proven in scientific studies
Effort expectancy	
Ease of use	• The device is easy to use
Data sync	• The device syncs automatically with a smartphone
Comfort	• The device fits with my lifestyle and daily activities • The device can cause skin irritations
Social influence	
Peer recommendation	• A friend or family member recommended the device to me
Facilitating technical factors	
Compatibility	• The device is compatible with all smartphones (eg, Android and Windows) • The device is compatible with popular health apps
Data security and privacy	• I can enable or disable location tracking on the device • I get to choose when and how the device shares data • My data are encrypted • My data will be sold to third parties for profit
Facilitating health care factors	
Insurance	• The device is covered by health insurance
Doctor recommendation	• My doctor recommended the device to me
Data exchange	• I can share the data with my doctor
Facilitating market factors	
Costs	• The device is under US $150
Customer reviews	• The device has a high customer rating
Warranty	• The device comes with a 2-year warranty
Customer service	• There is a number I can call if the device stops working

XSL•FO
RenderX

Sample

A nonprobability sample of 3260 US adults, 18 years and older, will be recruited nationwide to participate in a web-based survey. The sample will be equally split across biological sex, age groups, and race and ethnicity to allow comparisons of users' preferences within demographic subgroups (Table 3). Sample size calculations were performed using standard DCE formulas [67,68]. A sample of 333 participants is required for the EMA DCE based on the formula n≥1000(x)/yz, where *x* is the maximum number of levels of any attribute, *y* is the number of choices per task excluding the option none, and *z* is the number of times the task is completed per participant [ie, 1000(6)/(2 × 9) = 333]. A sample of 163 participants is required for the DW DCE based on the formula n≥500(w)/yz, where *w* is the number of features and *y* and *z* are defined identically to the previous formula [ie, 500(30)/(4 × 23) = 163]. However, the minimum sample for the DW DCE will be set at 300 participants in accordance with recommended guidelines [68]. Based on these calculations, the study should be well powered even when the sample is further stratified by demographic and behavioral subgroups.

Table 3. Target sample characteristics (N=3260).

Characteristics	Participants, n (%)
Sex	
Female	1630 (50)
Male	1630 (50)
Age (years)	
18-29	815 (25)
30-44	815 (25)
45-59	815 (25)
≥60	815 (25)
Race and ethnicity	
Non-Hispanic American Indian, Alaska Native, Native Hawaiian, or Pacific Islander	652 (20)
Non-Hispanic Asian	652 (20)
Hispanic or Latino	652 (20)
Non-Hispanic Black	652 (20)
Non-Hispanic White	652 (20)

Recruitment

Through its research panels, Qualtrics will send an invitation email to individuals with demographic characteristics that match the target sample. The email includes links to 2 identical surveys: the first has the EMA DCE, and the second has the DW DCE. The email also includes an estimated time to complete the survey and the incentive offered. Qualtrics will compensate participants and distribute the incentives at a rate equivalent to surveys of similar scope, burden, and duration. Data collection will continue until the desired sample size and composition are reached.

Procedures

Participants will consent before proceeding to any survey questions. Consenting participants will respond to inclusion and exclusion questions. To be included in the study, participants must be adults residing in the United States. Inclusion questions include zip code, age, biological sex, and race and ethnicity. The latter 3 questions are the basis of built-in hidden quotas for sample characteristics (Table 3). When a quota is met (eg, 50% females already recruited), participants who belong to that subgroup will not be allowed to take the survey. The only exclusion criterion is when participants respond yes to "Do you use any fitness tracker, smartwatch, or electronic medical device to monitor or track your health?" [69]. Participants who use a DW are excluded to improve inferences about preferences among nonusers. Ineligible participants receive a thank you message and are not allowed to proceed any further. Eligible participants will proceed to the remainder of the study questions. Except for completing 1 of the 2 DCEs, all instructions and questions are identical for all participants. The survey will take about 30 minutes to complete.

Measures

We will collect sociodemographic (ie, zip code, biological sex, age, race and ethnicity, sexual orientation, education, household income, employment, marital status, and English language proficiency) [69,70] and health (ie, weight and height [69], general health [71], emotional health [72], perceived susceptibility to disease [73], underlying health conditions [70], having a regular health care provider [69], and health insurance [69]) data. We also collect behavioral data on nicotine and tobacco use [74,75], marijuana use [76], alcohol use [77], fruit and vegetable intake [69], physical activity [69], and sleep [69], all of which are risk factors for chronic conditions and are thus the focus of health and medical interventions. These behavioral data allow comparisons of users' preferences within behavioral subgroups. Where each participant can demonstrate any number of the 6 behaviors examined in the study, we follow public

XSL•FO
RenderX

health guidelines to group each participant into 1 of 2 groups, one where participants do (vs do not) meet those guidelines and thresholds for each behavior as follows: (1) Nicotine and tobacco use is defined as current use of any nicotine or tobacco product [78]. (2) Marijuana use is defined as current use of marijuana or cannabis [78]. (3) Alcohol misuse is defined as daily consumption of >1 drink per day for women and >2 drinks per day for men, or as total consumption of >7 drinks per week for women and >14 drinks per week for men [79,80]. Alcohol use questions are asked only of participants 21 years or older. (4) Insufficient physical activity is defined as <150 minutes or 2.5 hours of physical activity per week [81]. (5) Inadequate fruit and vegetable intake is defined as <5 servings of fruit and vegetables total per day [79]. (6) Insufficient sleep is defined as <7 hours of sleep per night [82].

We also collect data on digital technologies access and use [69,83]; phone affinity [84]; previous use of [69], attitudes toward [85], and satisfaction with health applications [86]; attitudes toward wearable devices [85]; technology acceptance [59,87-89]; and willingness and intentions to use EMAs and DWs.

Data Analysis

Data from both DCEs will be analyzed using hierarchical Bayesian multinomial logistic regression models [90,91]. These models will generate subject-specific utilities quantifying the relative importance of each attribute to each participant. EMA and DW attribute preferences will be characterized among all participants and within subgroups defined by sex (female or male), age group (18-29 years, 30-44 years, 45-59 years, or 60 years or older), race and ethnicity (Non-Hispanic American Indian, Alaska Native, Native Hawaiian, or Pacific Islander; Non-Hispanic Asian; Hispanic or Latino; Non-Hispanic Black; or Non-Hispanic White), or health behavior (meeting vs not meeting established public health guidelines for each behavior). Differences between subgroups will be evaluated using *t* tests, analysis of variance, or linear regression, as appropriate. The association between each utility and each measure of attitude toward or intention to use EMAs and DWs will be depicted in correlation matrices generated from data comprising all participants or data from specific demographic or behavioral subgroups. A latent profile analysis [92,93] of individual-level utilities will be performed to detect segments of individuals who share common preferences. The extent to which demographics or behavioral characteristics predict membership in these segments will be quantified using the 3-step method [94,95]. The Bolck, Croon, and Hagenaars method [96] will evaluate whether specific segments are associated with specific attitudes or intentions.

Ethical Considerations

The study was deemed exempt on December 19, 2022, under category 2: research that only includes interactions involving educational tests, survey procedures, interview procedures, or observation of public behavior [§45 CFR 46.10(d)(2)], National Institutes of Health Institutional Review Board (001208).

Results

Data collection started on January 1, 2023, and concluded on May 4, 2023. Data analysis is ongoing.

Discussion

This protocol outlines a survey-based DCE to identify attributes that are associated with the uptake of EMAs and DWs. EMAs and DWs are remote monitoring technologies that capture real-time data in users' natural environments that are foundational to precision medicine. These data-driven approaches to health and medical care are the face of an increasingly digital ecosystem and align with the emphasis on person-centered care [97].

The study will generate insights on the optimal attributes and features that users value to maximize the uptake of EMAs and DWs. Such insights have significant health and medical implications given the ubiquitousness of mobile technologies. In 2021, smartphone ownership was at 85% in the United States [98] and there were approximately 100,000 health care apps on the Apple App Store and Google Play Store [99,100]. As of 2022, wearables penetration was at 25.3% among US adults [101] and is forecast to reach 628.3 million devices globally by 2026 [102]. Additionally, mobile health technologies enjoy acceptance and demand from users and patients [103]; interest of commercial, research, and health care entities [104,105]; and support of national and international policies and initiatives [106,107]. These technologies have given rise to terms like digital biomarkers, digital diagnostics, digital therapeutics, and digital treatments [1]. They are becoming common in medical research as well as available directly to users who can engage in self-care within (eg, electronic health records) [108] or outside (eg, faith organizations) [109] the traditional health care system. This is especially relevant given the prevalence of chronic conditions (eg, heart disease) and associated modifiable risk factors (eg, tobacco use) that are suited for remote monitoring [110]. Programs for the integration of telemonitoring in clinical and medical care for managing and treating chronic conditions in patients are developed and piloted [26,34], providing a far-reaching platform for health care delivery that can benefit underserved populations such as those with limited access to health care or those who disproportionally bear the highest burden of disease and risk factors [111].

The study has several limitations. Participants belong to web-based survey panels, rendering the results nongeneralizable to the US population and raising concerns about self-selection bias. The Qualtrics platform does not permit the inclusion of 2 DCEs in the same survey. Accordingly, participants received an invitation email with links to both surveys but were permitted to take only one. Although current use of a wearable device is an exclusion criterion for this study, the sample can include ex-users of wearables who may hold preexisting attitudes toward DWs based on previous experiences. Because of the cross-sectional nature of the survey, we capture behavioral intentions rather than EMA and DW use behavior. To avoid survey burden, we limited the number of EMA attributes and DW features. The study has several strengths, including a robust

XSL•FO
RenderX

sample size that allows for subgroup analysis by sociodemographic and behavioral groups. The study also examines the preferences-intentions relationship that provides actionable information to increase the uptake of EMAs and DWs, especially among at-risk or disadvantaged populations.

Acknowledgments

This work and the effort of SE, GZ, and PH were supported by the Division of Intramural Research of the National Institute of Minority Health & Health Disparities, National Institutes of Health.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

SE conceptualized the study and drafted the manuscript. JP developed the statistical analysis plan. GZ and PH built and tested the web-based surveys. All authors approve the manuscript as submitted.

Conflicts of Interest

None declared.

Abstract

Background: The clinical usefulness of cognitive behavioral therapy (CBT) for patients with depression who do not remit with pharmacotherapy has been recognized. However, the longer time burden on health care providers associated with conducting CBT and the lack of a system for providing CBT lead to inadequate CBT provision to patients who wish to receive it.

Objective: We aim to evaluate the feasibility of introducing virtual reality (VR) into CBT for patients with depression.

Methods: This is a single-center, interventional, exploratory, single-arm, nonrandomized, open, pre-post–comparative feasibility study of an unapproved medical device program to evaluate the acceptability, preliminary efficacy, and safety of the study device. Eligible patients meet the diagnostic criteria of the DSM-5 (Diagnostic and Statistical Manual of Mental Disorders, 5th Edition) for major depressive disorder, have a 17-item Hamilton Depression Rating Scale (HAMD-17) score of ≥12, and are aged 18-65 years. The sample will comprise 12 patients. VR-based CBT (CBT-VR) sessions will be conducted once a week in an outpatient setting. CBT-VR has been developed in accordance with 6 stages and 16 sessions in the current CBT therapist manual. VR contents and other components correspond to the themes of these 16 sessions. The flow of CBT-VR treatment is similar to that of normal CBT; however, this product replaces the in-person portion of CBT. The primary end point will be the change in the HAMD-17 score from baseline up to 16 sessions. Secondary end points will be treatment retention; psychiatrist consultation time; satisfaction with the equipment or program; ease of use; homework compliance; change in the HAMD-17 score from baseline up to 8 sessions; change in Montgomery-Åsberg Depression Rating Scale (MADRS), Quick Inventory of Depressive Symptomatology Self-Report (QIDS-SR), EQ-5D-5L, and Clinical Global Impressions (CGI) scores from baseline up to 8 and 16 sessions; and change in remission and response rates and HAMD-17, MADRS, QIDS-SR, and EQ-5D-5L scores from baseline to 3 and 6 months post intervention (or discontinuation). CBT-VR's feasibility will be assessed at baseline, after 8 sessions, after 16 sessions, or treatment discontinuation, by measuring the time required for testing and medical care during each session and with a patient questionnaire. After intervention discontinuation, a follow-up evaluation will be conducted unless the patient withdraws consent or otherwise discontinues participation in the study after 3 and 6 months.

XSL•FO
RenderX

Results: Participant recruitment started on November 30, 2022, and data collection is ongoing as of September 2023.

Conclusions: This study is the first step in testing the acceptability, feasibility, and preliminary efficacy and safety of CBT-VR for patients with depression without controls in an open-label trial. If its feasibility for depression treatment is confirmed, we intend to proceed to a large-scale validation study.

KEYWORDS

depression; cognitive behavioral therapy; virtual reality; CBT; feasibility study; open trial; VR

Introduction

Depression is a common disorder, with a lifetime prevalence rate of over 10% [1,2].

It is generally treated with antidepressant medication. However, some patients with depression do not respond to those medications, and depressive symptoms may persist for a long period without adequate improvement [3], resulting in a significant emotional and financial burden on the patients and their families [4-6].

Cognitive behavioral therapy (CBT) is a structured psychotherapy that modifies cognitive biases and assists problem-solving since mood is influenced by how one perceives and acts. CBT comprises several components: cognitive restructuring, behavioral activation, assertion, problem-solving, and relaxation [7,8]. CBT for patients with depression consists of 16-20 sessions of at least 30 minutes each, mainly through face-to-face sessions.

The efficacy of CBT for patients with depression who do not remit with pharmacotherapy has been tested in a randomized controlled trial in Japan [9]. Eighty patients with drug-resistant major depressive disorder were randomized to CBT or no-CBT groups. The change in the 17-item Hamilton Depression Rating Scale (HAMD-17) score from baseline to 16 weeks later was compared, with a significant improvement in the HAMD-17 score in the CBT group compared to that in the no-CBT group (between-group difference: –5.4 points; $P<.001$). Although the clinical usefulness of CBT has been recognized and insurance coverage is available when performed by a physician or nurse, the provision of CBT to patients who wish to receive it is currently inadequate. This can be attributed to the prolonged time burden on health care providers when performing CBT and the lack of a system to provide CBT. Therefore, developing a delivery system that uses information and communication technology is a challenge that must be overcome to enable the widespread use of CBT.

Web-based CBT has the same content as face-to-face CBT; however, it is more flexible and cost-effective treatment than face-to-face therapy for depression. Web-based CBT significantly improved patients' depressive symptoms and quality of life, similar to face-to-face CBT [10]. Mixed treatment integrating face-to-face CBT and web-based CBT has also been shown to be effective in treating patients with depression [11]. CBT can also be delivered through virtual reality (VR), a technology that immerses users in a computer-generated virtual world [12]. VR is considered a powerful educational tool because it allows people to experience, rather than merely perceive, what they need to learn [13].

However, several previous studies of VR interventions for mental health have focused on treating anxiety disorders [12,14], pain distraction [15,16], and relaxation [17,18], with surprisingly few VR interventions for depression [19].

In a joint study conducted in 2020 by the National Center for Cognitive Behavioral Therapy, Jolly Good Inc, and the National Center of Neurology and Psychiatry, the impact on depressive symptoms and safety of VR technology in providing CBT for patients with depression were evaluated (University hospital Medical Information Network [UMIN] Clinical Trials Registry; UMIN000040864). As a result, 4 of 7 patients included in the study had improvements in 2 or more Beck's Depression Inventory-II depression rating scale severity categories. One of 7 patients showed an improvement in 1 severity category compared to the previous treatment. No adverse events were observed, suggesting that using VR technology during CBT for patients with depression is well tolerated. However, this previous study has yet to be published. This previous study aimed to increase positive emotions in 7 patients with depression. The VR content comprised images of landscapes, animals, and a woman laughing, but not the CBT content.

The newly developed VR-based CBT (CBT-VR) uses VR to deliver CBT content to patients with treatment-resistant depression. CBT-VR for depression in this study aims to help patients acquire CBT skills, become aware of their own automatic thought patterns through the examples of others, and guide them toward solutions. Therefore, the VR content in this study is different from that in the previous study.

The newly developed CBT-VR follows the 16-session agenda in the therapist's manual and is intended to treat patients with depression in the same way as current CBT. CBT-VR can replace a part of the CBT conducted face-to-face by a health care provider and reduce the longer time burden. It is expected to expand opportunities for the treatment of depression and improve patient benefits through CBT.

In this study, we will evaluate whether it is possible to reduce the intervention time of medical personnel while retaining the effects of CBT by replacing part of the CBT conducted in person with VR and videoconferencing, using information terminals. By incorporating VR into CBT, patients can learn CBT skills

XSL•FO
RenderX

and become aware of their own automatic thought patterns through the examples of others. Changing one's mindset is important in CBT for depression, and the advantage of VR is that it provides an immersive experience that puts one in another person's shoes. The CBT-VR system to be used in the study is an unapproved medical device program under development by Jolly Good Inc, which intends to apply for the relevant manufacturing and marketing approvals in collaboration with Teijin Pharma Limited.

This study aims to evaluate the feasibility of introducing VR into CBT for patients with depression. In this study, 16 sessions of CBT-VR will be conducted, its acceptability will be assessed, and its efficacy and safety will be preliminarily examined by measuring and collecting data on the participants' usability and the time required for psychiatrist consultation.

If the feasibility of CBT-VR for depression is demonstrated in this study, we may proceed to a confirmatory study. In addition, if further work shows that CBT-VR is effective, it may provide a new option for patients who do not respond adequately to conventional treatment and have not had the opportunity to receive CBT.

Methods

Study Design

This is a single-center, interventional, exploratory, single-arm, nonrandomized, open, pre-post–comparative study involving a feasibility study of an unapproved CBT-VR device intervention to evaluate its acceptability, preliminary efficacy, and safety among patients with depression.

Participant Selection Criteria

Inclusion Criteria

Patients who meet all the following criteria will be enrolled in the study: (1) those who meet the DSM-5 (Diagnostic and Statistical Manual of Mental Disorders, 5th Edition) diagnostic criteria for major depressive disorder; (2) those with a HAMD-17 score of ≥12 at screening; (3) those who do not respond adequately to ≥1 antidepressants or are unsuitable for pharmacotherapy due to intolerance, comorbidity, pregnancy, or refusal of medication; (4) those who are aged between 18 and 65 years when consent is obtained; and (5) those who provide written informed consent.

Exclusion Criteria

Patients meeting the following criteria will be excluded from the study: (1) those with comorbid or preexisting manic, hypomanic, or psychotic episodes; personality disorders or posttraumatic stress disorder; or alcohol or substance use disorders; (2) those with active suicidal ideation; (3) those who have not responded to CBT in the past; (4) those who have difficulty using VR devices and applications; and (5) those deemed inappropriate for this study by the principal investigator.

Sample Size Determination

The sample size will be 12 patients. This sample size was not determined on the basis of the distribution of any end point or statistical power.

In order to evaluate the acceptability of CBT-VR in this study, it is necessary to obtain data on use and satisfaction from a wide range of patients (based on parameters such as sex, age, and severity). In addition, a certain number of patients is necessary to evaluate efficacy and safety. A similar pre- and postintervention comparative study of CBT using VR for patients with depression (UMIN000040864) was conducted with 12 patients, and the number of patients was deemed to be sufficient for feasibility evaluation.

Study Outline

Screening tests will be performed for patients who have obtained consent to participate in the study, and baseline testing will be performed for eligible participants before the start of the intervention. In principle, 16 CBT-VR sessions will be administered weekly in an outpatient setting. The feasibility of CBT-VR will be assessed by testing at baseline, at the end of 8 sessions, at the end of 16 sessions, or treatment discontinuation, and by measuring the time required for testing and medical care during each session and by patient questionnaire. The duration of the intervention, including allowance, will be a maximum of 24 weeks, with no interruption of more than 8 consecutive weeks from the end of each session to the implementation of the next session. In addition, no more than 1 session will be conducted on the same day. If a patient is hospitalized during the intervention period, participation in the study will not be discontinued if it is possible to continue. After the intervention is terminated, follow-up assessments will be conducted unless the patient withdraws consent or otherwise discontinues participation in the study. After 16 sessions or after the intervention is terminated, patients will be treated as usual; however, they will continue to view the VR and use the application for 6 months during the follow-up period.

Information on Drugs, Medical Devices, and Treatments to be Used in the Study

A CBT-VR device (Jolly Good Inc) will be used in this study. CBT-VR is an unapproved medical device program developed to support CBT for patients with depression.

The system structure of this product is shown in Table 1. This product is a system that integrates 6 components consisting of VR contents installed on general-purpose commercial VR goggles, 3 applications used by patients or health care providers, and progression support tools with CBT-VR content management system in the cloud.

CBT-VR has been developed in accordance with 6 stages and 16 sessions described in the current CBT therapist manual, and the VR contents and other components correspond to the themes of each of these 16 sessions. The treatment flow using CBT-VR is similar to that of the normal CBT protocol; however, this product replaces a part of the CBT conducted face-to-face by a health care provider with VR and videoconferencing. The homework app will be downloaded to the patients' smartphone.

Adverse events anticipated from CBT-VR include pain in the area where the VR goggles are worn and discomfort from viewing the VR images (VR sickness), both of which are expected to be mild and tolerable.

[b]CBT: cognitive behavioral therapy.

[c]CBT-VR: virtual reality–based cognitive behavioral therapy.

[d]CMS: content management system.

Dosage and Administration of Drugs, Applications, or Equipment Used in This Study

In this study, 16 sessions of CBT-VR will be conducted once a week in an outpatient setting. The flow of each session of CBT using this product is described in Table 2.

When participants arrive at the clinic, they will review their homework using the progression support tool and experience the theme by viewing the VR content corresponding to each session. While using the progression support tool again, they will use the VR experience as a guide to practice the themes. The participant will then interact with the physician and conduct homework at home using the Homework App and the progression support tool [20,21].

If depressive symptoms exacerbate and require hospitalization after each session, the principal investigator will decide whether or not to continue the treatment.

Table 2. The flow of each session.

Session	Progress of the session	Components	Implementor
1	Introduction	Progression support tools	Patient
2	Theme experience	VR[a] goggles (includes content and other programs)	Patient
3	Theme practice	Progression support tools	Patient
4	Dialogue on the theme (medical treatment by a physician)	Progression support tools	Physicians and patients
5	Homework (conducted at home)	Homework app and Progression support tools	Patient

[a]VR: virtual reality.

Rules for Concomitant Medications and Concomitant Therapy

The type and dosage of concomitant antidepressants will not be changed during the intervention period from baseline to the examination at the end of the 16 sessions or at the end of the intervention. Dosage and administration will be in accordance with the package insert of each antidepressant. If no concomitant antidepressants are used, no new antidepressants will be initiated during the intervention period. No structured psychotherapy, repetitive transcranial magnetic stimulation, or electroconvulsive therapy will be administered during the intervention period, and treatment will not be restricted during the follow-up period after 16 sessions or after discontinuation of the intervention.

End Points and Evaluation Methods

The primary end point is a change in the HAMD-17 score from baseline to the end of 16 sessions. The secondary end points are the treatment continuation rate (ie, the proportion of participants who completed 16 sessions); the time required for psychiatrist consultation; patient satisfaction and usability of the equipment and programs and compliance with homework; change in the HAMD-17 score from baseline to the end of 8 sessions; change in the Montgomery-Åsberg Depression Rating Scale (MADRS), Quick Inventory of Depressive Symptomatology Self-Report (QIDS-SR), EQ-5D-5L, and Clinical Global Impressions (CGI) scores from baseline to the end of 8 and 16 sessions; remission rates (ie, the proportion of participants with a HAMD-17 score of ≤7 and a <ADRS score of ≤10); response rates (ie, the proportion of participants with

XSL•FO
RenderX

a ≥50% reduction in the HAMD-17 and MADRS scores from baseline); change in HAMD-17, MADRS, QIDS-SR, EQ-5D-5L, and CGI scores from baseline to 3 and 6 months post intervention (or discontinuation); the proportion of participants with a decrease in the number of prescriptions or doses of psychotropic drugs from baseline to 3 and 6 months post intervention (or discontinuation); adverse events; and equipment failures.

For the safety evaluation, pain, discomfort from wearing or viewing VR, manic and hypomanic episodes (meeting the DSM-5 criteria), and suicidal ideation will be assessed during the intervention and observation periods. Suicidal ideation will be assessed using HAMD-17, MADRS subitems, and clinically. The interviewer will check for the presence and worsening of suicidal ideation at each session.

Observation and Examination Items

The following items will be collected per schedule: patient background (age, sex, height, weight, comorbidities, medical history, educational history, employment experience, and VR viewing experience); depression treatment history (date of diagnosis, number of previous episodes, duration of the current episode, number of antidepressant failures due to Antidepressant Treatment History Form, and history of CBT treatment); concomitant therapy (including medications, repetitive transcranial magnetic stimulation, and electroconvulsive therapy, and whether they were hospitalized); satisfaction with CBT-VR, feeling of use, and compliance with homework; time required for consultation by health care providers; HAMD-17, MADRS, QIDS-SR, EQ-5D-5L, and CGI scores; adverse events; and equipment failures.

The observation schedule is shown in Figure 1. In total, 16 CBT-VR sessions will be performed weekly in an outpatient setting. The intervention period will be a maximum of 24 weeks, including allowance, with no interruption of more than 8 consecutive weeks between the end of each session and the implementation of the next session. No more than 1 session will be conducted on the same day. The day of the week will not be fixed, and only 1 session will be carried out per week. If a session is held on Friday, the next session will be held on any day from Monday to Friday the following week. Therefore, the minimum interval between sessions will be 2 days (Friday to Monday).

Figure 1. Observation and inspection schedule. Combined therapy during the 6-week tracking period after 3 and 6 months post intervention include continuous use of VR or applications. CGI: Clinical Global Impressions; HAMD-17: 17-item Hamilton Depression Rating Scale; MADRS: Montgomery-Åsberg Depression Rating Scale; QIDS-SR: Quick Inventory of Depressive Symptomatology Self-Report; VR: virtual reality.

Statistical Analysis

The study objective is purely descriptive. We do not intend to decide the efficacy and safety of CBT-VR based on statistical tests.

Population for Efficacy and Safety Analysis

The population for efficacy analysis includes all participants who have used CBT-VR at least once and at least 1 end point is measured. The population for safety analysis consists of all participants who have viewed CBT-VR at least once.

Analyses

Baseline characteristics will be assessed using descriptive statistics.

As a primary analysis, original scores and changes in the score on the HAMD-17 from baseline to the end of 16 sessions will be summarized, the latter depicted as mean and 95% CI values. A 1-sample *t* test against the null hypothesis that the mean change in score equals 0 will be performed. The threshold for statistical significance will be set at 5%, and multiplicity will

XSL•FO
RenderX

not be adjusted since this study is exploratory by nature. Missing data will be imputed using the previous measurement.

As secondary analyses, original scores and changes in the scores on the HAMD-17 from baseline to other time points will be summarized, and mean and 95% CI values will be estimated. The same analyses will be performed for changes in MADRS, QIDS-SR, EQ-5D-5L, and CGI scores. The frequency and proportion of the patients in remission at each measured point and those with a decreased number or dose of psychotropic medications will be summarized. The frequencies and proportions of the patients who completed the 16 sessions, patient satisfaction, and usability (the Japanese version of Client Satisfaction Questionnaire-8 and other answers to questions) will be summarized for feasibility assessment. The time required for psychiatric consultation and the number of homework assignments done will be tabulated and summarized for each session. In addition, missing data will be excluded from the analysis at each measured point.

Detailed definitions for classification will be determined on the basis of the distribution before data fixation. The stratification variables for subgroup analyses are as follows: sex, duration of the current episode (<2 years and ≥2 years), age, work experience, previous CBT treatment, baseline HAMD-17 score, concomitant medications, homework compliance, time spent at the doctor's office, continued viewing of VR content and use of applications (during follow-up).

As a safety analysis, the frequency of adverse events and failures will be tabulated for each event.

Ethical Considerations

The clinical study will be conducted in compliance with the Clinical Trials Act. It was registered with the Japan Registry of Clinical Trials (trial ID jRCTs032220481) and approved by the Japan Certified Clinical Research Review Board. The study's details will be fully explained to all patients, and face-to-face informed consent will be obtained before starting the study. After obtaining informed consent, the participants' data will be deidentified before analysis.

If the obtained data are used in the future for purposes other than those indicated in this study, the following conditions will need to be met: (1) the study will be reviewed again and approved by the center's ethics committee or clinical research review committee, and (2) the willingness of the participants to cooperate in the study will be confirmed through reconsent or information disclosure regarding the conduct of another study.

Results

This study was registered with the Japan Registry of Clinical Trials (trial ID jRCTs032220481). Informed consent will be obtained before enrollment in the study. Participant recruitment started on November 30, 2022, and data collection is ongoing as of September 2023. The results will be published in a peer-reviewed academic journal, presented at scientific conferences, and communicated to the participants and patient organizations. International Committee of Medical Journal Editors criteria on contributorship and authorship are applied.

Discussion

This study is a first step toward testing the acceptability, feasibility, and preliminary efficacy and safety of introducing CBT-VR to patients with depression.

The efficacy of CBT for patients with depression who do not remit with pharmacotherapy has been verified in randomized controlled trials in Japan [3]. However, the provision of CBT to patients who wish to receive it is currently inadequate due to the large time burden on health care providers when conducting CBT and the lack of a system to provide CBT. In this study, we will evaluate whether it is possible to reduce the intervention time of health care providers while maintaining the therapeutic effects of CBT by replacing a portion of CBT conducted in person with VR and videoconferencing, using information terminals.

If this study confirms the feasibility of CBT-VR for depression, we may proceed to a confirmatory trial. Furthermore, if a future trial confirms that CBT-VR is effective, it may provide a new option for patients who have not had an adequate response to conventional treatment and have not had the opportunity to receive CBT.

As a limitation, the study will have a small number of cases, is not blinded, and will have no controls. In a future study, we would like to conduct a randomized controlled trial with appropriate controls.

Treatment options for CBT are expanding to include face-to-face, web-based, and VR components. Future developments may lead to new techniques, increasing access to CBT for more patients.

Acknowledgments

We would like to thank the patients who participated in this study. We are grateful to Hideki Oi, Ryoko Tsuno, Kenji Hatano, and Atsuko Asano (Department of Clinical Data Science, Clinical Research and Education Promotion Division, National Center of Neurology and Psychiatry) for assistance with monitoring and data management. We are grateful to Yuriko Takagishi, Yukinori Kanekawa, Naoto Kitani, and Hirotaka Kitazume (Jolly Good Inc) for developing CBT-VR (virtual reality–based cognitive behavioral therapy).

This study will be conducted as joint research between Jolly Good Inc and Teijin Pharma Limited, with research funding and equipment, including unapproved medical device programs, to be used in the research provided by the manufacturer, Jolly Good Inc.

Data Availability

The data sets generated or analyzed during this study will not be publicly available but will be available from the corresponding author upon reasonable request.

Authors' Contributions

SK contributed to this study's conceptualization, protocol development, and project management. AI and FH contributed to this study's design and the manuscript's preparation. MSO made significant contributions to the protocol of this study, especially in the statistical analysis section. AK and AM contributed to the development and design of the CBT-VR. All authors participated in reviewing and revising the manuscript and approved the final manuscript.

Conflicts of Interest

AK and AM are employees of Jolly Good Inc.

Abstract

Background: The internet of things (IoT) is recognized as a valuable approach to supporting health care to achieve quality and person-centered care. This study aims to identify the facilitators and barriers associated with implementing IoT solutions in health care within a Scandinavian context. It addresses the pressing need to adapt health care systems to the demographic changes occurring in Scandinavia. The vision of "Vision eHealth 2025," a long-term strategic direction for digitalization in Sweden, serves as the background for this project. The implementation of IoT solutions is a crucial aspect of achieving the vision's goal of making Sweden a global leader in using digitalization and eHealth opportunities by 2025. IoT is recognized as a valuable approach to supporting health care to achieve quality and person-centered care. Previous research has shown that there is a gap in our understanding of social and organizational challenges related to IoT and that the implementation and introduction of new technology in health care is often problematic.

Objective: In this study, we will identify facilitating and hindering factors for the implementation of IoT solutions in social and health care.

Methods: We will use an explorative design with a case study approach. The data collection will comprise questionnaires and qualitative interviews. Also, a literature review will be conducted at the start of the project. Thus, quantitative and qualitative data will be collected concurrently and integrated into a convergent mixed methods approach.

Results: As of June 2023, data for the review and 22 interviews with the stakeholders have been performed. The co-design with stakeholders will be performed in the fall of 2023.

Conclusions: This study represents a unique and innovative opportunity to gain new knowledge relevant and useful for future implementation of new technology at health care organizations so they can continue to offer high-quality, person-centered care. The outcomes of this research will contribute to a better understanding of the conditions necessary to implement and fully use the potential of IoT solutions. By developing cocreated implementation strategies, the study seeks to bridge the gap between theory and practice. Ultimately, this project aims to facilitate the adoption of IoT solutions in health care for promoting improved patient care and using technology to meet the evolving needs of health care.

Introduction

Overview

There is a growing movement toward distributed care, wherein health care services are increasingly offered in the home environment to foster a close and person-centered approach to health care delivery. In addition, an increasing number of older adults often live longer at home, even with cognitive and physical disabilities [1,2], and extensive support is usually required to maintain autonomy and independence in daily life [3]. The increase in the older population and their health care needs has put health care under extra pressure. For example, increased costs and a shift from the traditional single-disease paradigm to a more holistic patient-centered approach are considered among the greatest challenges for society in this century [4]. At the same time, personnel and financial constraints may reduce health care services or the quality of care for older adults. Due to this, there is a need to use technology to provide more efficient health care services. IT can support health care organizations in providing high-quality, person-centered care [5-7]. Information technology can reduce the burden on health care and its resources, enable better health care and cost savings, support more care at home, and thus reduce costs [8,9]. Examples of such technologies are the Internet of Things (IoT) and wearable technologies that could offer promising solutions for the care of older people. It also has the potential to improve the quality of life of older adults and allow them to maintain their independent lifestyles [10]. In addition, IoT is suggested to be crucial in transitioning care and rehabilitation from the hospital to care and rehabilitation at home [11]. IoT technology can also contribute to health promotion initiatives, reducing the need to provide treatment and hospitalization [12,13]. The implementation of IoT is a vital aspect of Sweden's Vision eHealth 2025, which aims to make Sweden a global leader in digitalization and the opportunities provided by eHealth.

There is no unified definition of IoT, and many suggestions are put forth in the literature. One definition that is useful for our project is that IoT is "a network that connects uniquely identifiable devices (or things) to the internet, enabling them to collect, send, store, and receive data" [12]. From a technical point of view, an IoT architecture consists of several "layers." Again, there is no unified agreement describing the IoT architecture, and the number of layers varies. For example, Nord et al [14] propose three layers: (1) sensing layer, (2) network layer, and (3) application layer, while Kashani et al [10] propose four layers: (1) perception layer, (2) network layer, (3) middleware layer, and (4) application or business layer. This means that in an IoT architecture, first, there is the "thing" that collects data; then, the data are sent somewhere via the internet; and lastly, the data are analyzed and used in or by some kind of application. IoT approaches can also be divided into the following five categories depending on their technological focus: (1) sensor-based IoT (eg, wearable sensors and environmental sensors), (2) resource-based IoT (eg, scheduling and resource allocation), (3) communication-based IoT (eg, technological approaches and algorithmic approaches), (4) application-based IoT (eg, monitoring systems and recommender systems), and (5) security-based IoT (eg, privacy, access control, and confidentiality). The definition of IoT in this research project is a network that connects uniquely identifiable sensor-based things to the internet, enabling them to collect, send, store, and receive data, as shown in Figure 1.

Figure 1. Illustration of how Internet of Things is defined in this study.

Previous research shows that most IoT-related research within the health care domain has a technological focus. Dantu et al [15] analyzed keywords for IoT research in the health care domain in a systematic literature review. They found 5 topic clusters: security and privacy, data, application, wireless network technologies, and cloud and smart health. The authors found

XSL•FO
RenderX

that the social and organizational challenges (eg, factors related to users, health care professionals, and health care organizations) of IoT within health care have received little to no attention in existing research. They conclude that there is a gap in our understanding of social and organizational challenges related to IoT.

These are important perspectives when an IoT product is to be implemented in an ongoing business. Nord et al [14] have conducted a study of factors that influence IoT implementation. In that study, they state that theories related to IoT adoption and implementation appear to be nonexistent [14]. This can be troublesome when previous research has shown that implementing and introducing new technology in general in health care is often problematic [16,17]. However, there may be factors at several different levels that prevent or facilitate implementation. Flottorp et al [18] systematically reviewed factors that hinder and facilitate implementation in health care. They identified factors at seven different levels that influence implementation in health care: (1) innovation, (2) health care staff, (3) patients, (4) professional interaction, (5) incentives and economics, (6) capacity for organizational change, and (7) the surrounding society [18]. Venter et al [19] found several factors that hinder the implementation of welfare technology, such as (1) high costs, (2) lack of competence and knowledge of available solutions, (3) organizational issues, (4) resistance to change, (5) communication and cooperation across stakeholders, (6) legal complications, and (7) technological problems. As is visible in these studies, most of the factors influencing implementation are nontechnical. In line with this, Kashani et al [10] argue that one of the biggest challenges around IoT in health care right now is its implementation in the health care environment, thus underlining the need for research on these aspects.

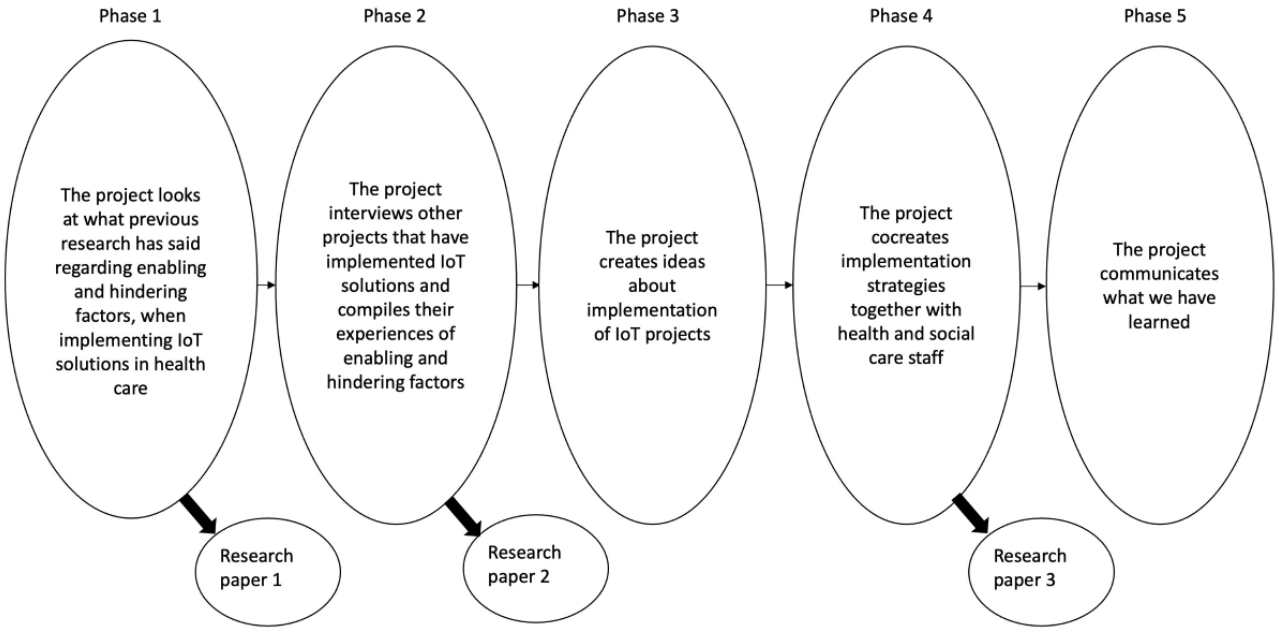
Identifying and addressing factors that influence implementation is, however, only the first stage of actually implementing new solutions such as IoT and, through this, improving care. The factors will tell us what should be changed or addressed to achieve implementation. In order to make use of the factors, they need to be connected with relevant implementation strategies, that is, methods that target specific factors and aim to change these or underlying behaviors [20]. For instance, if health care practitioners do not use IoT solutions because they forgot, then a suitable implementation strategy would focus on forgetting and improving conditions to remind them to use the solution [21]. To our knowledge, studies on IoT have not examined or focused on implementation strategies. However, existing research on implementation in health care has identified a multitude of implementation strategies that fit with specific factors at the individual, organization, and system levels [20]. Technology-related factors do not have their own strategies as the technology is often given, allowing only slight local adjustments, and thus one should target other levels such as the individual's interaction with the technology and the organizational fit of the technology. Still, on many occasions, connecting factors with suitable implementation strategies is rare [22], and the usual approach has long been to study factors and implementation strategies independently from each other, which implies that our knowledge of effective implementation strategies is incomplete [23].

Furthermore, we can state that a cocreation between researchers and concerned personnel in developing strategies for how new solutions should be implemented creates good conditions for the strategies to be well adapted and implemented [24]. We use this fact in this research project and intend, as a part of the project, to cocreate with staff to develop strategies based on the researched insights and the staff's knowledge of the local context.

Aim and Research Questions

The aim of the project is to contribute to an increased ability to use the potential of IoT solutions in society. In this study, we will identify facilitating and barrier factors for the implementation of IoT solutions in health care, including home care. To contribute to this aim, the study intends to answer the following two questions:

1. Research question 1: What are the barriers and facilitators when implementing IoT solutions within distributed care?
2. Research question 2: How to address barriers and facilitators when implementing IoT solutions within distributed care?



Methods

Design

The study will be performed in 5 phases (Figure 2). The aim of the first phase is to identify and categorize existing knowledge about barriers and facilitators for the implementation of IoT solutions in health care, including home care. The first phase will build on a systematic review. In the second phase, we will broaden the empirical base with more experiences from facilitating and barrier factors when implementing IoT solutions in Sweden. This will be done through a qualitative data collection from ongoing implementation projects of IoT solutions in care in Sweden. In the third phase, the project will analyze and draw conclusions from phases 1 and 2 and, based on this, formulate recommendations to strengthen facilitators and mitigate barrier factors when implementing IoT solutions in health care. In the fourth phase, these recommendations are to be applied in 2 implementation cases within the framework of ongoing safety-creating technology development. In this phase, there will also be a compilation of what we learned from these 2 implementation projects. In the fifth phase, the project will work on the use and dissemination of the generated results.

XSL•FO
RenderX

Figure 2. The 5 phases of the research process. IoT: internet of things.

The knowledge generated by this project has the potential to benefit the fulfillment of Vision eHealth 2025. An important prerequisite, however, is that the knowledge generated by the project be communicated and used. Therefore, in phase 5, the researchers will collaborate with municipalities, regions, and the Swedish Association of Local Authorities and Regions to communicate results. Throughout the project, learning and experiences are shared through regular project meetings where new knowledge and experiences are shared between the project participants. Furthermore, new knowledge and experiences from a work package are applied and used in subsequent work packages. Experience is gained within the project's parties by holding internal seminars and meetings where the project participants' colleagues can take part in the experiences gained and the new knowledge that is developed within the project.

Context

Many health care providers in Sweden realize that they face major demographic and resource challenges. To a certain extent, there is high confidence that digital solutions will help deal with these challenges. There is therefore relatively big support within municipalities and health care provider organizations for carrying out research promoting the implementation of IoT solutions. At the same time, several of the private companies that work on developing new IoT solutions perceive that there are major challenges in making use of their solutions. All in all, this means that the organizational context is expectant and generally positively disposed to this type of research project.

To run this research project, a research project committee has been created. The committee consists of researchers at the Department for Industrial Engineering and Management at Uppsala University; researchers at the School of Health and Welfare at Dalarna University, the Division of Assistive Technology in Council Regional Dalarna Healthcare Administration, Dalarna Science Park, and Falun's and Rättvik's municipalities; and a representative for producers of goods and services within IoT. The majority of these are also represented in a regional steering group for digitization and welfare technology in Dalarna.

Data Collection

Data Collection to Respond to Research Question 1

We will conduct a systematic literature review to study what has already been written about implementing IoT technology. We will search for relevant articles in 4 databases: CINAHL, PubMed, Web of Science, and Scopus. A combination of Medical Subject Headings terms and keywords in titles and abstracts will be used, such as IoT and health care.

Data will also be collected from stakeholders' experiences of implementation challenges, facilitators, and barriers in implementing IoT solutions in health care, including home care. Data are collected from ongoing projects on the implementation of IoT solutions. Empirical data are collected from IoT projects aimed at the implementation of IoT solutions in Sweden in health care, including home care. Interviews will be conducted with stakeholders involved in the implementation project. In total, it is estimated that between 20 and 30 respondents will be interviewed. Data collection takes place through semistructured interviews. The interviews are planned to take place digitally. Audio recording will be used if respondents accept this and then transcribed.

Data Collection to Respond to Research Question 2

To answer this question, conclusions will be drawn from research question 1. On the basis of these conclusions, support will be developed to create implementation strategies for IoT solutions within 2 pilot projects. These implementation strategies will be developed in cocreation with employed health and social

XSL•FO
RenderX

care staff within the county Dalarna and municipalities in Dalarna within the 2 pilot projects. These pilot projects will be selected during the work on answering research question 1. The criteria for selecting pilot projects are that they must consist of projects offering health or social care and be ready to implement IoT-based solutions in accordance with this project's definition of IoT. Data will be collected through a participative study in workshops for the development of implementation strategies and through interviews with representatives of key stakeholders involved in the implementation of the IoT solutions.

Data Analysis

The following analysis method will be used to answer both research question 1 and research question 2.

Bibliometric and content analysis of previous literature will be used in the systematic literature review.

The analysis of barrier and facilitating factors from previous research will constitute the analytical framework in the research process, which means that the identified barrier and facilitating factors will be deductively categorized on the basis of existing research. Previous implementation research has generated a spectrum of perspectives that focus on barrier and facilitating factors for implementation, for example, Flottorp et al's [18] previously identified seven different groups of barrier and facilitating factors: (1) guidelines, (2) care staff (eg, current knowledge), (3) patients (eg, preferences), (4) professional interaction, (5) incentives and finances (eg, remuneration), (6) capacity for organizational change (eg, mandate), and (7) society (eg, laws).

The categorization of the empirical data will be made on the basis of Flottorp et al's [18] framework. The analysis also takes into account unique contextual conditions for implementation, which means that the analysis allows the identification of new factors and strategies that can complement previous research. The deductive approach is thus complemented by an inductive approach.

Relation to Sustainable Development

The project contributes to Sustainable Development Goal (SDG) number 3 by increasing the ability to implement IoT-based technology, which creates better conditions for a continued or increased cost-effective health service to citizens. The project contributes to SDG number 5 by focusing on IoT solutions that create conditions for both men and women to enjoy good, individualized care. The project contributes to SDG number 9 by taking place in collaboration with industrial stakeholders working with developing products and services within IoT technology. The project is expected to contribute with an increased ability to develop products, test them, and implement solutions.

Ethical Considerations

The Helsinki Declaration will be followed. The most overriding ethical issue in this type of research is of an integrity-infringing nature, as the researcher, during an interview, asks employees' own thoughts about barriers and facilitators. Issues that may be discussed, such as fears, concerns, and difficulties related to barriers and facilitators, may be perceived as personal and private. The results will not be reported so that the respondents' age, gender, profession, and other characteristics can function as identity markers. When presenting individual quotations, the research group will not use quotations where identity markers or other information are named or mentioned in such a way that the respondent risks being identified.

An application about the need for ethical review of the research has been submitted to the Swedish Ethical Review Authority. The authority has announced that ethical review is not necessary in this research, given that the questions do not regard any personal data.

Results

As of June 2023, data for the review and 22 interviews with the stakeholders have been collected. The co-design with stakeholders will be performed in the fall of 2023. All data will be analyzed and disseminated during 2024.

Discussion

Overview

As one of the first studies to identify facilitators and barriers for implementing IoT solutions in health care in a Scandinavian context, we hope this project will contribute to better conditions to implement and thus use the potential of IoT solutions to contribute to the changes that need to take place in health care given the demographic changes we see in Scandinavia.

Sweden has a vision for digitalization in health care, Vision eHealth 2025. The vision sets out a long-term strategic direction for the digitalization area. It constitutes a joint collaboration platform between the Swedish Association of Local Authorities and Regions and the governmental stakeholders in the field. The vision is that by 2025, Sweden will be the best in the world at using the opportunities of digitalization and eHealth. Complementing the vision, there is also a national 3-year strategy for implementing it. The implementation is largely about developing new working methods and learning how new technology can be used operationally. In this context, implementing IoT solutions is an upcoming major issue.

Therefore, we hope that this research project will not just identify facilitators and barriers but also make use of those findings in cocreative workshops with health and social care staff in order to develop cocreated implementation strategies. The study will give insight into how knowledge from former implementation projects can be integrated into new implementation projects. Namely, we contribute knowledge about how a process for developing a strategy can be performed based on the experiences of other projects. In other words, we can also learn from what is easy and what is difficult in the transformation from gained insights into concrete actions in a new context.

Strengths and Limitations

This project has a strong design with several phases that build on each other, validating and expanding the knowledge gained in previous phases. Additionally, the study includes 2 pilot cases in real-world health care settings, providing valuable insights

XSL•FO
RenderX

into the implementation of IoT. While patients and older adults at home (end users) are important for understanding the full impact of IoT, they are not included in the sample as their perspectives are beyond this project's scope. Future research needs will indeed include end users.

Conclusions

This study represents a unique and innovative opportunity to gain new knowledge that is relevant and useful for implementing new technology in municipalities and health care organizations. By identifying and understanding the barrier and facilitating factors associated with implementing IoT solutions in health care, including care and service at home, the study can provide valuable insights into the challenges that need to be overcome and the strategies that can be used to facilitate successful implementation. The study can also help identify best practices and key success factors that can be used to guide future implementation efforts. Additionally, the study can contribute to developing person-centered care by using new technology in municipalities and health care organizations.

Abstract

Background: Over 10 million newborns worldwide undergo resuscitation at birth each year. Pediatricians may use electrocardiogram (ECG), pulse oximetry (PO), and stethoscope in determining heart rate (HR), as HR guides the need for and steps of resuscitation. HR must be obtained quickly and accurately. Unfortunately, the current diagnostic modalities are either too slow, obtaining HR in more than a minute, or inaccurate. With time constraints, a reliable robust heart rate detector (HRD) modality is required. This paper discusses a protocol for conducting a methods-based comparison study to determine the HR accuracy of a novel real-time HRD based on 3D-printed dry-electrode single-lead ECG signals for cost-effective and quick HR determination. The HRD's HR results are compared to either clinical-grade ECG or PO monitors to ensure robustness and accuracy.

Objective: The purpose of this study is to design and examine the feasibility of a proof-of-concept HRD that quickly obtains HR using biocompatible 3D-printed dry electrodes for single-lead neonatal ECG acquisition. This study uses a novel HRD and compares it to the gold-standard 3-lead clinical ECG or PO in a hospital setting.

Methods: A cross-sectional study is planned to be conducted in the neonatal intensive care unit or postpartum unit of a large community teaching hospital in Toronto, Canada, from June 2023 to June 2024. In total, 50 newborns will be recruited for this study. The HRD and an ECG or PO monitor will be video recorded using a digital camera concurrently for 3 minutes for each newborn. Hardware-based signal processing and patent-pending embedded algorithm-based HR estimation techniques are applied directly to the raw collected single-lead ECG and displayed on the HRD in real time during video recordings. These data will be annotated and compared to the ECG or PO readings at the same points in time. Accuracy, F_1-score, and other statistical metrics will be produced to determine the HRD's feasibility in providing reliable HR.

Results: The study is ongoing. The projected end date for data collection is around July 2024.

Conclusions: The study will compare the novel patent-pending 3D-printed dry electrode–based HRD's real-time HR estimation techniques with the state-of-the-art clinical-grade ECG or PO monitors for HR accuracy and examines how fast the HRD provides reliable HR. The study will further provide recommendations and important improvements that can be made to implement the HRD for clinical applications, especially in neonatal resuscitation efforts. This work can be seen as a stepping stone in the development of robust dry-electrode single-lead ECG devices for HR estimations in the pediatric population.

Introduction

Background

Each year, over 10 million newborns require resuscitation worldwide, representing more than 10% of all global births [1]. Neonatal resuscitation is the set of interventions at the time of birth to support the establishment of breathing and circulation. These interventions include providing warmth to the infant using a heat source, placing the head in a sniffing posture with neck flexion and upper cervical extension (a position to open the airways), drying the infant, and simulating breathing. Multiple metrics—respiration, infant color, and heart rate (HR)—are measured every 30 seconds to ensure successful neonatal resuscitation [2]. Out of these indicators, HR is identified as the most important for an effective resuscitation process [3]. HR guides decision-making and escalation of care, including positive pressure ventilation, endotracheal intubation, chest compressions, and administration of epinephrine.

Despite the importance of HR in neonatal resuscitation, HR determination is challenging due to a lack of evidence regarding the most rapid and accurate method to assess it. Clinically accepted methods of HR assessment include pulse palpation (umbilical, brachial, and femoral), auscultation with a stethoscope, pulse oximetry (PO) monitoring, and 3-lead electrocardiogram (ECG) monitoring [2]. It is important to note that neonatal resuscitation efforts should be performed within the first minute of life, known as the "golden minute," to ensure a high success rate and avoid neurodevelopmental disorders and hypoxic injury [4].

A systematic review compared these different methods in terms of expense, intermittent or continuous HR assessment, and other strengths and weaknesses. Auscultation and pulse palpation are rapid and easily accessible approaches due to their low cost. However, both approaches are highly inaccurate and unreliable, resulting in errors of omission, which causes failure or delay in resuscitation steps and commission through inappropriate intervention [5]. Auscultation requires a pause in resuscitative efforts, which can disrupt the flow of resuscitation and result in a delay in stabilization of the newborn. This method is the most used approach compared to other HR determination approaches, due to its quick and easy accessibility as well as its cost-effectiveness. However, auscultation accuracy is reliant on health care professional experience and can be inconsistent from one practitioner to the other, resulting in inequitable care [6]. On the other hand, PO is relatively inexpensive and noninvasive, and it displays continuous HR and oxygen saturation to the entire team in the delivery room. However, a pulse oximeter can be inaccurate due to motion artifact, ambient light, or poor tissue perfusion, and it takes several minutes to apply and achieve the first data display, potentially delaying resuscitative efforts [4,5].

Current guidelines suggest a 3-lead ECG monitor as the gold standard for HR determination in neonates due to its high speed and accuracy and because of its capabilities to provide continuous visual and auditory data compared to the other modalities, such as PO and auscultation. However, 3-lead ECG has its disadvantages. Errors in the placement of the 3 leads can yield inappropriate ECG signals that cannot be used for HR detection [7]. Additionally, similar to PO, wet electrode ECG placement takes time to apply, surpassing the golden minute of life [5]. ECG adhesive wet electrodes can cause skin damage to premature infants. Moreover, motion artifacts may be present with ECG leads. In rare scenarios, ECG-derived HR may fail to correspond with the effective mechanical contraction of the heart [8]. Most importantly, both PO and 3-lead ECG require additional equipment, which needs to be purchased and maintained, accumulating significant expenses for health care systems [7,8]. Both technologies may not be feasible or accessible in areas with limited health care resources [9].

Recent rapid scientific advancement in sensing technology have driven the development of novel technologies to assess HR, including camera-based photoplethysmography, reflectance PO, laser Doppler technology, capacitive sensors, piezoelectric sensors, electromyography, and electronic or digital stethoscope (DS) [10]. Although a systematic review of these novel technologies concluded that none are ready for widespread clinical adoption, DS offers the greatest potential [10]. Currently, DS is at the forefront in the field of "computer-aided auscultation," as advances in acoustic sensor design, digital signal processing and filtering, auditory enhancement, and machine learning can enable automated diagnoses of cardiac dysfunction [10,11]. In neonates, DS used for HR measurement is more accurate than auscultation or pulse palpation and faster than PO in "time to first HR display"; DS also correlates appropriately with ECG HR in noncrying infants [10-12]. Furthermore, DS is most similar to existing smart device technologies that are rapidly adopted, in both high- and low-resource settings. These technologies include smartphones, wearables, and other devices in the Internet of Medical Things. Although DS represents a significant improvement in neonatal resuscitation HR monitoring, further refinement and evaluation is necessary before clinical implementation, along with optimization of the existing technologies in a user-centric manner [13]. DS has severe disadvantages, including short battery life, low clinical adoption due to training requirements [14], and its nonstandardized variable sensor technologies, such as the differences between Littman Eko DUO with an ECG module, Littman CORE with analog and digital amplification, and Thinklabs' One DS with a nonstandard headphone jack. It is important to note that none of the current DS technologies take neonatal ECG into consideration during their development.

It is evident there is a lack of cost-effective and fast signal acquisition technology that uses the gold-standard ECG for quick HR measurements and display in newborns. This study focuses on the deployment of a single-lead ECG handheld monitor capable of using dry-electrode ECG for signal acquisition and HR measurements in a quick and efficient manner. The following protocol study is structured as follows: the study significance, its impact on the current technologies in single-lead ECG devices for neonatal HR monitoring, and the objectives of this study. The Methods section is presented next, and it covers an in-depth look into the ethics-approved protocols through Study Design, Study Personnel, Recruitment, Inclusion and Exclusion Criteria, Ethical Considerations, and Study Procedures sections. Study Procedures section includes the

XSL•FO
RenderX

subsections of Data Collection, Debrief, Data Management, Data Analysis, and Data Maintenance and Security. These sections are followed by the Results section, which offers the current progress of this study. Lastly, the final section provides a brief discussion of the protocol and the limitations of the current study, providing future steps to further improve neonatal single-lead ECG monitoring.

Study Significance and Impact

Given that no single method of HR assessment is clearly superior to others, finding the optimal method to delineate HR within the golden minute after birth remains elusive. Pediatric guidelines recognize this knowledge gap and identify the opportunity to develop new technologies for the rapid, accurate assessment of HR after birth, ideally integrating newborn ECG. Currently, there are no novel medical devices that have been specifically developed to provide rapid and accurate HR immediately after birth. The proposed research study will address several gaps in the scientific study of device development, vital signs measurement and monitoring, and neonatal resuscitation. Recent advances in biomedical sensors and wireless communication technologies have enabled us to develop a novel HRD, targeted to outperform the traditional HR assessment in neonatal resuscitation. The rapid application, measurement, and display of HR on a device located on the neonate addresses significant gaps in the provision of optimal neonatal resuscitation. The HRD is undergoing rigorous design and development, and this study aims to assess its feasibility in quickly detecting accurate HRs in infants using 3D-printed dry electrodes. This early proof-of-concept HRD study will establish the basis for using 3D-printed dry electrodes and determine whether novel HR estimation algorithms are appropriate for neonatal HR applications.

Objectives

The overall aim of this research study is to evaluate a novel HRD that may enable timely and appropriate neonatal resuscitation. This study is being completed using a phased sequential user-centered approach. We completed the first phase of this research to determine end-user requirements and preferences for HR assessment in neonatal resuscitation. This phase resulted in the current design and features of the HRD.

The second phase outlines the creation of the HRD conceptual design and proof-of-concept prototype to be used in the final phase of feasibility mentioned in this study.

In the final phase, the focus of this proof-of-concept research study is to examine the functionality, speed, robustness, and reliability of the prototype HRD.

Specific research questions to be answered through this phase are the following:

- How long does it take to place the HRD on an infant?
- Can the prototype HRD detect the HR of newborns?
- How fast can the prototype detect the HR of newborns?
- How accurate is the HR detection when compared to PO or ECG?

Methods

Study Design

A prospective observational study will be used to measure the performance of the HRD prototype, as shown in Figure 1, in terms of time required to place it on an infant, its ability to detect HR, the speed of detection, and its reliability (accuracy) in comparison with clinical HR monitors. Given the paucity of data on infants regarding the HRD, there is insufficient evidence to support the feasibility and performance of a randomized controlled trial. The study setting will be in the postpartum unit (PPU) and neonatal intensive care unit (NICU) of a large community teaching hospital in Toronto, Canada. Specifically, the study will take place within 2 physical settings at the hospital: PPU and NICU. As shown in Figure 2, a digital camera will be used to record the HRD concurrently with either an ECG or PO monitor, depending on their availability at the time, for 3-minute durations per newborn. It is important to note that although both 3-lead ECG or photoplethysmogram technology are compared to single-lead dry-electrode ECG, both clinical devices are considered acceptable for neonatal resuscitation efforts, which is the targeted use of the HRD in later versions and research studies.

The HRD uses two 3D-printed dry electrodes to collect 3-minute single-lead neonatal ECG signals with a 500 Hz sampling rate. The HRD's electrodes are placed approximately in the V1 and V2 locations on the newborn's chest, as shown in Figure 3. The electrodes are developed using conductive polylactic acid filaments (Proto Pasta) and a 3D printer with printing settings of nozzle temperature at 215 °C, print speed of 35 mm/s, heated bed temperature of 60°C, and a design fill ratio of 100% [15]. These settings are chosen as specified under the datasheets provided for the conductive polylactic acid filament. As shown in Figure 4, the electrodes are connected to an ECG analog front-end circuitry, which provides analog signal processing and filtering. A 3-48 Hz analog bandpass filter is applied to attenuate the powerline and electromagnetic interference noise in the 50-60 Hz range [15]. The single-lead ECG signal is later transmitted to a microcontroller, where patent-pending embedded heart estimation techniques are used to calculate HR. HR is displayed on an OLED screen on the HRD. At the same time, the HR and raw ECG information are transmitted using Bluetooth to a nearby computer interface for data storage.

Study Personnel

A pediatrician and graduate student will be conducting all the study tasks.

Recruitment

All Infants admitted to the PPU after routine delivery, regardless of method, and all infants admitted to the NICU will be eligible if their clinical status is stable and not at high risk of deterioration. In total, 50 newborns will be recruited based on previous accepted research studies that focused on examining long-term neonatal ECG and HR monitoring applications using proof-of-concept novel ECG acquisition devices [14-19].

The two groups of infants are identified as follows:

1. Infants admitted to the PPU who are at least 24 hours of age and are undergoing routine critical congenital heart disease (CCHD) screening with PO.
2. Infants admitted to the NICU who are routinely placed on 3-lead ECG or PO monitors.

Recruitment steps include the following:

Infants will be identified by a pediatrician for eligibility 5 days a week (Monday to Friday) between 8 AM and 8 PM. Recruitment on Saturday and Sunday will be done if feasible. Recruitment will happen on random days when a pediatrician is available and time permits.

Once an infant is identified based on eligibility (ie, inclusion and exclusion criteria), mentioned below, the pediatrician will ask the bedside nurse to ask the parents if they would be willing to speak to the pediatrician as shown in the recruitment script in Multimedia Appendix 1.

The pediatrician will then meet the parents in a face-to-face meeting to discuss the study, provide the written consent form, and potentially obtain consent. The parents will be given at least 15 minutes to review the consent form prior to being asked to sign it. When the parents are not available at the bedside, the pediatrician will inquire the nurse about a suitable time for the parents to meet. The infants will not be under the care of the researcher pediatrician as their primary admitting health practitioner to avoid a conflict of interest.

Inclusion Criteria

The inclusion criteria for the PPU infants are as follows:

- Corrected gestational age (35 weeks + 0 days)
- Infants undergoing routine CCHD screening with PO at 24 hours of life or later
- Stable clinical status
- Parental consent

For the NICU infants, the inclusion criteria are as follows:

- Corrected gestational age (30 weeks + 0 days)
- Infants undergoing routine 3-lead continuous ECG monitoring or PO
- Infants with at least 24 hours of life
- Stable clinical status, as defined by the following: stable requirement for supplemental oxygen and stable respiratory rate on at least 2 measurements, a respiratory rate <70 breaths per minute, HR <180 beats per minute, oxygen supplementation <0.5 L/min via nasal prongs, and not being on heated high-flow oxygen
- Parental consent

Exclusion Criteria

The exclusion criteria include high-risk clinically unstable newborns who might show unstable requirements for supplemental oxygen and unstable respiratory rates, congenital malformations that interfere with the placement of the HRD, and nonconsent.

The criteria mentioned above are standardized points used in multiple studies pertaining to neonatal noninvasive physiological monitoring. These criteria have undergone rigorous ethics review, as specified in the approved ethics proposals.

Ethical Considerations

The study was approved by the research ethics boards of the Toronto Metropolitan University (2023-070) and Scarborough Health Network (PED-21-025) in April and June of 2023, respectively. Parents will complete a detailed written informed consent prior to infant enrollment. Recruitment procedures are described under the Recruitment subsection in Methods. A number of measures will be taken to protect the rights of eligible infants, including the following: (1) using an intermediate approach—a neutral person, a bedside postpartum or NICU nurse, will seek initial permission to approach potential participants about the study; (2) ensuring anonymity, privacy and confidentiality of the participant's information; and (3) proceeding through the formal ethical review process at both the participating hospital and the university conducting the collaborative research. As per institutional policies, consent forms will be kept in a secured location, with access provided to only the primary principal investigator and then shredded. Finally, participants will be assured that the study reports, video recordings, and paper-based data collection forms will not contain identifying information in keeping with the Canadian privacy legislations—Personal Information Protection and Electronic Documents Act and Personal Health Information Protection Act.

Study Procedures

The PPU infants will be placed in the supine (face up) position. The conventional PO will be connected to the right hand as per the device's instructions and CCHD screening protocol. In the usual standard of care for CCHD screening, PO is placed on the right hand and right or left foot for 1 to 2 minutes. The change in the standard of care will include the data collection protocol during the time of CCHD screening, which includes video recording of the HRD and PO simultaneously. The HRD will be held in place by a pediatrician on the thorax for 3 minutes. This will prolong CCHD screening by an additional 1-3 minutes. On the other hand, as per the usual standard of care, NICU infants will be placed in the supine (face up) position prior to their usual feeding time; they will be unbundled and have their diaper changed. An already attached conventional 3-lead ECG will be placed on the infant's chest, as per the conventional 3-lead ECG device's instructions. The change in this standard of care will involve the thorax to be exposed, if

XSL•FO
RenderX

not already exposed, and the HRD will be held in place by a pediatrician on the thorax for 3 minutes during simultaneous video recording of the HRD and the 3-lead ECG monitor. It is important to note that the 3-lead ECG electrodes will not be in contact with the HRD's dry electrodes.

The displayed HR from the HRD will be compared to 1 or 2 reference monitors, depending on the infant's clinical setting (PPU or NICU). The PPU uses a conventional PO (Nellcor Portable SpO2 Patient Monitoring System; Medtronic) with an accompanying sensor wrap, while infants in the NICU are attached to a conventional 3-lead gel electrode ECG (Intellivue Bedside Patient Monitor; Koninklijke Philips) monitor. In both clinical-grade devices, PO and ECG biosensors and algorithms detect and display HR based on pulse peak or QRS peak detection. An internal algorithm in each device designed by the manufacturer determines how pulse or QRS peak detection is transformed into the HR displayed on the screen. Depending on the sensing technology—PO (a light-emitting diode-based pulse detection) or the 3-lead ECG (an electric activity sensing transducer that detects electrical heart activity)—a different HR may be displayed. Differences in the PO and ECG algorithmic HR estimation techniques may also influence the HR displayed on both devices. However, both technologies are known as clinical-grade HRDs and are used extensively in medical settings, which justifies their use as the ground truth state in this HRD proof-of-concept study.

Data Collection

The displayed HR from the HRD and the PO or ECG monitor will be video recorded for 3 minutes within the same video frame, as shown in Figure 1. Video recording will take place using a dedicated research digital camera mounted on a stand. Video recording will start once the infant is settled and the PO or ECG readings are stable. Stable readings are defined based on the device's instructions on waiting for an appropriate amount of time after sensor placement for clinical HR determination. The HRD will then be placed on the infant's chest until a consistent HR is displayed for 3 minutes, at which point video recording will start. After 3 minutes, the HRD will be removed, and then, the recording will be stopped. After the recording is completed, the entire HRD, including electrodes, will be wiped down with a surface disinfectant towelette (CaviWipe; Metrex). HRD device failure will be considered if no HR is displayed on the HRD within 60 seconds of application to the thorax.

Debrief

After video recording has concluded, parents will be asked of their perceptions of the HRD, and their answers will be written by the primary researcher on a paper data collection form, as shown in Multimedia Appendix 2.

Data Management

Video recordings will be individually analyzed by 2 health professional researchers to determine the time it takes to apply the HRD to the thorax and the time from HRD placement to a steady HR display. Each researcher will review and record the HR from the HRD and PO or ECG at 2-second intervals for 3 minutes, providing approximately 90 HR notations per device per patient. For 50 newborns, the total number of HR annotations will be approximately 4500 data points. This will result in multiple HR data points to compare. To avoid human error in the annotation process, discrepancies in the HR of more than 5 beats per minute between the 2 researchers will lead to a reexamination of the video recordings until a consensus can be reached regarding the correct HR. The annotations from the 2 researchers will be averaged for the subsequent analyses.

Additionally, the HRD will record raw ECG signals for the duration of the device being in contact with the infant. Raw ECG data will be collected at 500 Hz sampling rate and transmitted to a research-dedicated laptop. The raw ECG and HR information from the HRD will be stored on different CSV files with a randomized identification number.

Data Analysis

HR and raw ECG data will be analyzed using MATLAB (the MathWorks). Infant demographics will be analyzed using summary statistics. Continuous variables will be expressed as mean (SD) values, and categorical variables will be expressed as numbers (percentages), unless otherwise stated. The HR from HRD will be compared to PO or ECG using a paired *t* test. The Bland-Altman method will be used to compare the HR derived from each device—the HRD and the PO or ECG monitor, used as reference. The correlation between devices will be assessed using Pearson *r* statistic. Data will be first analyzed using all data points available, and outliers will be defined as 20 beats per minute rate difference between the methods. These discrepancies will be further analyzed to find the likely reason for deviation, including reexamination of the video recordings.

Data Maintenance and Security

Each infant will be assigned a participant identification number using a random number generator [20]. No personally identifying demographic information, such as name or parents' names, will be collected. Confidentiality will be maintained throughout the study, in accordance with the Personal Health Information Protection Act. Paper-based data collected will be electronically transcribed into a CSV file. The paper-based data collection form will then be disposed in a confidential document bin at the hospital. The data, video recordings, CSV files with raw ECG data, the CSV files with infant demographics and characteristics as well as parental perceptions will be downloaded to a research-dedicated laptop for analysis. The data will be stored in a password-protected folder and will not be emailed nor transmitted on the web. Data transfer among the research team (the primary researchers) will occur through an encrypted flash drive, if necessary. The laptop will be stored in a locked cabinet in a locked room in the research lab at the university, with access provided to only the primary research investigators. All the study investigators will have access to all the data, except the consent forms, which will be only accessible by the principal investigator.

Results

The study is currently ongoing. The projected end date for data collection is around July 2024.

Discussion

This paper discussed a research protocol for conducting accurate and reliable HR estimation using a novel real-time HRD based on 3D-printed dry-electrode single-lead ECG signals. Recent advances in biomedical sensor and wireless information and communication technologies have enabled us to develop a novel HRD, aimed at potentially disrupting the traditional assessment of HR in neonatal resuscitation efforts. The rapid application, measurement, and display of HR on a device mounted directly on the neonate addresses significant gaps in the provision of optimal neonatal resuscitation. The main objective of this study is to examine the novel HRD's ability and feasibility in obtaining an accurate HR in newborns, using dry electrodes, and comparing it to the state-of-the-art clinical-grade HR monitors at the hospital.

However, this study is limited to the feasibility of HR detection on a healthy population of newborns using dry electrodes, and it does not cover in-depth analytical metrics of ECG and HR for disease diagnosis. It is apparent that further studies should focus solely on ECG abnormalities in neonates, including bradycardia, pulseless electrical activity, and long QT syndrome. The work is also limited to the use of certain 3D-printed conductive plastic-based dry electrodes for single-lead ECG acquisition, limiting its applicability when ECG quality is compared to other dry-electrode materials, such as stainless steel and textiles. Furthermore, the proposal does not include clinical-grade ECG acquisition for comparison with the HRD's raw ECG signals due to the restraints in obtaining access to HR monitor raw ECG information. In addition, the use of algorithms on clinical-grade devices cannot be accessed, limiting this work to the examination of HR information between the HRD and clinical HR monitors. However, the raw ECG obtained through the HRD can be used to derive novel hand-crafted features that assist in quick HR estimation and prediction using artificial intelligence.

Ideally, this study will lead to critical improvements in the HRD prototype's accuracy and speed of detection, ensuring its robustness prior to further clinical testing. This preliminary work is essential to form the foundation of a larger programmatic endeavor to transform this HRD into a relevant and robust novel medical device for neonatal resuscitation efforts. It is critical that new clinical technologies be evaluated with methodologic rigor to help inform clinicians and parents on the reliability, feasibility, and ultimately, the effectiveness of new technologies. This is an early proof-of-concept study to assess the reliability of the value behind this HRD and its goals of ultimately saving infant lives through widespread clinical adaptation and implementation.

Acknowledgments

This study was conceptualized by AA, SK, and NM. AA and SK are involved in the heart rate detector (HRD) prototype design and production. AA and NM are involved in direct data collection. All authors contributed to the writing and obtaining of the ethics-approved proposals. All authors read and approved the final manuscript.

Data Availability

The anonymized data pertaining to this study will be available upon request from the corresponding author, except for video recordings, which are not available in accordance with the ethics approvals of the participating hospital and academic institution.

Conflicts of Interest

SK is the founding Chief Scientific Officer of Nanu Health, the company involved in commercializing the infant heart rate detector prototype discussed in the paper. He is also a coinventor of a patent application under review for the prototype discussed in the paper. NM is the cofounder of and owns stock in Nanu Health.

Abstract

Background: The *Health for Every Veteran Study* is the first Veterans Health Administration–funded, nationwide study on lesbian, gay, bisexual, transgender, queer, and other sexual and gender minority (LGBTQ+) veterans' health that relies exclusively on primary recruitment methods. This study aimed to recruit 1600 veterans with diverse sexual and gender identities to study the mental health and health risk behaviors of this population. A growing body of literature highlights the health inequities faced by LGBTQ+ veterans when compared with their heterosexual or cisgender peer groups. However, there is little to no guidance in the health disparities literature describing the recruitment of LGBTQ+ veterans.

Objective: This paper provides an overview of the recruitment methodology of *Health for Every Veteran Study.* We describe the demographics of the enrolled cohort, challenges faced during recruitment, and considerations for recruiting LGBTQ+ veterans for health research.

Methods: Recruitment for this study was conducted for 15 months, from September 2019 to December 2020, with the goal of enrolling 1600 veterans evenly split among 8 sexual orientation and gender identity subgroups: cisgender heterosexual women, cisgender lesbian women, cisgender bisexual women, cisgender heterosexual men, cisgender gay men, cisgender bisexual men, transgender women, and transgender men. Three primary recruitment methods were used: social media advertising predominantly through Facebook ads, outreach to community organizations serving veterans and LGBTQ+ individuals across the United States, and contracting with a research recruitment company, Trialfacts.

XSL•FO
RenderX

Results: Of the 3535 participants screened, 1819 participants met the eligibility criteria, and 1062 completed the baseline survey to enroll. At baseline, 25.24% (268/1062) were recruited from Facebook ads, 40.49% (430/1062) from community outreach, and 34.27% (364/1062) from Trialfacts. Most subgroups neared the target enrollment goals, except for cisgender bisexual men, women, and transgender men. An exploratory group of nonbinary and genderqueer veterans and veterans with diverse gender identities was included in the study.

Conclusions: All recruitment methods contributed to significant portions of the enrolled cohort, suggesting that a multipronged approach was a critical and successful strategy in our study of LGBTQ+ veterans. We discuss the strengths and challenges of all recruitment methods, including factors impacting recruitment such as the COVID-19 pandemic, negative comments on Facebook ads, congressional budget delays, and high-volume surges of heterosexual participants from community outreach. In addition, our subgroup stratification offers important disaggregated insights into the recruitment of specific LGBTQ+ subgroups. Finally, the web-based methodology offers important perspectives not only for reaching veterans outside of the Veterans Health Administration but also for research studies taking place in the COVID-19-impacted world. Overall, this study outlines useful recruitment methodologies and lessons learned to inform future research that seeks to recruit marginalized communities.

KEYWORDS

lesbian, gay, bisexual, transgender, queer, and other sexual and gender minority; LGBTQ+; veteran; recruitment; health disparities

Introduction

Background

People who identify as lesbian, gay, bisexual, transgender, queer, and other sexual and gender minority (LGBTQ+) make up a sizable portion of US military service members and veteran populations. As of 2015, it has been estimated that 6.1% of current US military personnel have an LGBTQ+ identity [1]. This is a higher proportion than the overall US population; in the same year, 3.9% of US adults identified as part of the LGBTQ+ community [2]. Among male veterans, 1.9% were identified as gay, 2% as bisexual, and 0.5% as transgender. Among female veterans, 7% were identified as lesbian, 9.1% as bisexual, and 1.2% as transgender [1]. Both lesbian and bisexual women and transgender people have been shown to be overrepresented in military and veteran populations compared with the general population [3,4]. LGBTQ+ people join the military for a number of reasons, many of which may be similar to non-LGBTQ+ service members. However, LGBTQ+ people may be more likely to face violence, lack of acceptance from family, or socioeconomic challenges, leading them to choose the military as a career path [5,6].

These statistics are likely an underestimate, given the rising numbers of LGBTQ+ identification in the general population and the impact of homophobia, transphobia, and sexism in and out of the military [1,2,6]. In particular, “Don’t Ask, Don’t Tell,” established in 1994, prevented a generation of nonheterosexual service members from serving openly [6]. Over 14,000 service members were less-than-honorably discharged due to the policy until its repeal in 2011 [6]. LGBTQ+ veterans still face the aftereffects of the policy, continued attacks against transgender service members, and other forms of structural stigma [6]. Given the pressure to hide their identities, there could be more veterans identifying as LGBTQ+ than the current statistics describe.

A growing body of literature has highlighted the health inequities faced by LGBTQ+ veterans, both in comparison with their fellow veterans and the general population. LGBTQ+ veterans as a group demonstrate disparities in suicide mortality, depression, alcohol use, posttraumatic stress disorder, intimate partner violence including sexual violence, chronic obstructive pulmonary disease, asthma, stroke, and physical health [6-14]. Disparities can be found within specific LGBTQ+ subgroups. Research indicates that compared with non-LGBTQ+ female veterans, LGBTQ+ female veterans were more likely to feel unwelcome or unsafe within the Veterans Health Administration (VA) health care system and miss needed care [15]. A national study of transgender veterans found that 46% reported delaying medical care and that 36% delayed mental health care in the past year when they thought they needed it [16]. However, there has been limited research on more detailed subgroups. LGBTQ+ veterans are a diverse group across sexual orientation and gender identity, and research is still needed to identify additional physical and mental health disparities, as well as the causal pathways for these inequities. In particular, structural stigma in the form of homophobic and transphobic policies, practices, and norms plays a significant role in causing health disparities among LGBTQ+ populations [17].

Therefore, it is crucial to better understand how to reach and recruit LGBTQ+ veterans in health research. As with other marginalized populations, LGBTQ+ veterans’ unique social contexts and lived experiences are shaped by their intersecting identities. However, there is little to no guidance in the health disparities literature describing the recruitment of LGBTQ+ veterans.

VA electronic medical records (EMRs) do not yet have readily accessible self-identified fields for sexual orientation or gender identity [18]. Although this is starting to change, it has been difficult for researchers studying LGBTQ+ veterans to monitor target populations for research or clinical care purposes through administrative records, as is often done for other groups, such as women [18]. Past research with transgender veterans has relied on the International Classification of Disease, 9th and 10th Revisions diagnosis codes in EMR data, rather than self-identified gender [19-21]. Such data can be obtained through

XSL•FO
RenderX

VA EMRs [22]. Although these diagnostic codes have shown concordance with self-identification [20], they also rely on terms or diagnoses that may be outdated, stigmatizing, or misaligned with how transgender patients identify [23]. As such, veterans may choose not to disclose their gender identity to their VA providers. In addition, these diagnosis codes are specific to gender identity, meaning that sexual minority veterans cannot be identified using EMR data. Moreover, recruitment methods that rely solely on VA EMR data exclude veterans who are not connected with VA care. Veterans who were dishonorably discharged are not eligible for VA health care benefits, and others may choose not to enroll. LGBTQ+ veterans may decide not to engage with VA because of their previous experiences with discrimination in the military, VA, or other health care settings. Anticipation or fear of such experiences may also prevent LGBTQ+ veterans from connecting with the VA. As such, EMR-based recruitment methods for research are not yet sufficiently inclusive for the recruitment of a diverse sample of LGBTQ+ veterans.

In civilian communities, the recruitment of LGBTQ+ populations for health research often occurs through community-based sites [24] and social media [25]. Historically, emphasis has been placed on men who have sex with men, with less information on the recruitment of sexual minority women and other groups [24,26]. For instance, a systematic review of the psychology literature on LGBTQ+ populations found that sexual minority women comprised only 4.8% of the study samples [26]. Therefore, the civilian LGBTQ+ health research recruitment literature may also have limited applicability for researchers hoping to recruit a wide range of LGBTQ+ veterans in health research. Literature on the web-based recruitment of gay and bisexual men describes the use of social media websites (eg, Facebook), gay news sites, and dating and sexual networking mobile apps [25]. Web-based recruitment has also been paired with in-person community-based recruitment at places targeted toward gay and bisexual men [25]. The literature on recruiting transgender people into health research also describes the use of social media ads, in addition to partnering with transgender individuals with similar lived experiences as the desired study population to conduct outreach [27,28].

Finally, race and ethnicity are other dimensions of identity that are important for researching the health of LGBTQ+ veterans. Little research exists on the recruitment of participants across the intersection of these identities (race, ethnicity, sexual orientation, gender identity, and veteran status). Structural racism and the ways in which it intersects with homophobia, transphobia, and sexism affect health [29-31]. As such, it is important to recruit LGBTQ+ racial and ethnic minority veterans into health disparities research, who have lived experiences with these intersectional forms of discrimination both in and out of military service.

Thus, gaps remain in the health research literature regarding the recruitment of individuals at the intersection of LGBTQ+ and veteran identities. Further knowledge is needed to effectively reach veterans in and out of the VA and across sexual orientation and gender identity; this paper addresses these gaps. To our knowledge, no previous study has focused on the recruitment of people who identify as LGBTQ+ *and* as veterans. In addition, we have described the efforts to recruit LGBTQ+ racial and ethnic minority veterans. By more effectively recruiting a diverse group of LGBTQ+ veterans, researchers can conduct health research that informs targeted interventions, treatments, and prevention strategies tailored to the specific needs of this population.

Objectives

The *Health for Every Veteran Study* is one such study that aims to better understand the health of LGBTQ+ veterans (VA Health Services Research & Development Study, Investigator Initiated Research 17-089). This is the first VA-funded nationwide study on LGBTQ+ veteran health that relies exclusively on primary recruitment methods, meaning that the data were collected directly from individuals prospectively. The *Health for Every Veteran Study* offers a unique opportunity to learn more about the recruitment of LGBTQ+ veterans for health research, particularly through web-based methods.

This paper describes the following: (1) the recruitment methodology of the *Health for Every Veteran Study*, (2) demographic characteristics of the enrolled cohort, (3) challenges faced during recruitment, and (4) considerations for recruiting LGBTQ+ veterans in health research.

Methods

Overall Recruitment Methodology

The *Health for Every Veteran Study* is a web-based, national, VA-funded, prospective cohort study on health disparities among LGBTQ+ veterans. The objectives of this study are as follows: (1) identify the extent of sexual orientation and gender identity disparities in mental health problems (eg, depression, posttraumatic stress disorder, anxiety, nonimminent suicidal ideation or attempt) and health risk behaviors (eg, alcohol misuse and smoking) among veterans; (2) examine risk and protective factors associated with these outcomes guided by a conceptual model informed by the minority stress theory and the self-medication hypothesis; and (3) assess LGBTQ+ veterans' experiences with and preferences for treatment, including VA health care use, barriers to access, and preferences for tailored care. This study aims to include a wide range of veterans, including those who are and are not enrolled in VA health care.

Recruitment was conducted over 15 months, from September 2019 to December 2020, with the goal of enrolling 1600 veterans evenly split among 8 subgroups (200 veterans/subgroup): cisgender heterosexual women, cisgender lesbian women, cisgender bisexual women, cisgender heterosexual men, cisgender gay men, cisgender bisexual men, transgender women, and transgender men. Male and female heterosexual cisgender participants are included as comparison groups to assess the disparities. The transgender groups include veterans of all sexual orientations because splitting those groups further by sexual orientation was not seen as feasible due to sample size concerns, budget, and timeline. Although not explicitly targeted in recruitment efforts, several interested participants indicated a gender identity not represented by the above groups. As such, an exploratory subgroup comprising nonbinary and genderqueer

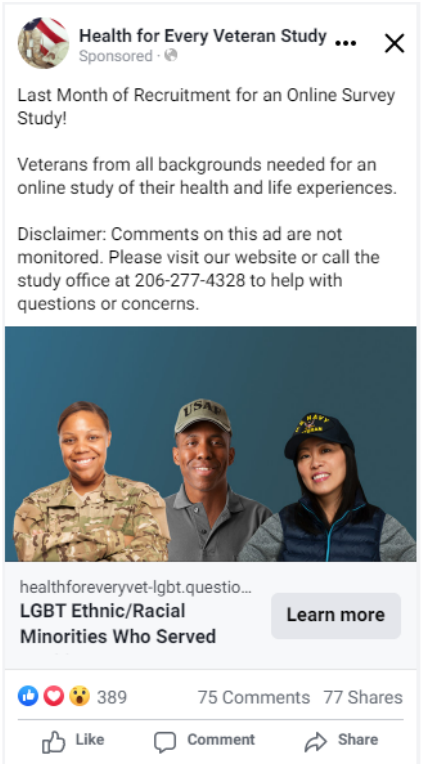
XSL•FO
RenderX

veterans and veterans with other gender-diverse identities was added after the recruitment had begun.

Three primary recruitment methods were used in this study: (1) social media advertising conducted by staff, predominantly through Facebook ads; (2) outreach to community organizations serving veterans and LGBTQ+ individuals across the United States; and (3) contracting with a research recruitment company, Trialfacts.

Social Media Advertising

On the basis of previous research on recruitment experience using social media to reach female and transgender veterans [32,33], the study team created several ad sets for use on social media platforms. Facebook was the primary social media platform used; Google and Instagram ads were tested for 6 and 12 weeks, respectively, but were discontinued for cost-effectiveness reasons.



Several Facebook ad sets were created by the study staff and approved by the VA Puget Sound Institutional Review Board (IRB), each with targeted images and language carefully selected to reflect the various recruitment subgroups (Figures 1-4). The staff selected photos for ads from Adobe stock photos, and the VA Medical Media Department assisted in editing and tailoring images for certain subgroups, such as LGBTQ+ racial and ethnic minority veterans.

Although the Facebook policy does not allow for the explicit targeting of users by sexual orientation or relationship status, other audience parameters were used to reach the target population. For instance, gender, military service, and affiliation with LGBTQ+ and military organizations were used to further target the individuals through ads.

The most successful ads, determined by the number of views and clicks, were shown more often as part of Facebook's ad-optimization algorithm. The use of separate ad sets also allowed the study staff to fine-tune the budget on a given ad set to adjust to the study's changing recruitment goals across subgroups. This gave staff the opportunity to prioritize a larger percentage of the study's budget toward harder-to-reach subgroups such as bisexual veterans. Geographic parameters of audience viewers were also adjusted to improve representativeness across geographic regions (eg, limiting ad audiences to underrepresented states in the study sample).

Facebook ads were initially placed as right-column ads and were later expanded to newsfeed ad placements to reach both desktop and mobile app users. Due to the VA Puget Sound IRB policy, direct interactions with veterans on social media were prohibited. Commenting cannot be disabled on newsfeed ads; therefore, an IRB–approved disclaimer was included on those ads to inform viewers that all questions or concerns should be relayed to the study staff directly by phone. Comment sections on all ads were monitored for influxes of negative and derogatory comments. Filtering tools available on Facebook were used, and manual staff reviews were conducted daily to block or hide all comments.

Community Organization Outreach

The community organization outreach recruitment method served two purposes: (1) to reach veterans who do not regularly use social media and (2) to establish more trust with populations who may otherwise not feel comfortable participating in research. For this recruitment method, the study staff created a database of community organizations serving veterans and LGBTQ+ individuals across the United States. Community organizations were identified through internet searches by the study staff, and their information was added to the study recruitment database. These community organizations included nonprofit, grassroots organizations and other community-based organizations at the national, state, and local levels. For instance, organizations that shared the study advertisements included the Modern Military Association of America, a nonprofit dedicated to LGBTQ+ service members, veterans, and their families, and SPART*A, an organization of transgender (including nonbinary and gender nonconforming) service members and veterans. Local organizations across all 50 states were included, as were organizations representing various subgroups (eg, transgender groups and bisexual groups). The search ultimately expanded to LGBTQ+ and veteran groups at universities, community colleges, and large employers (eg, Microsoft, Starbucks, and health care companies).

The size, demographics (age, race, ethnicity, sexual orientation, gender identity, etc), and locations of these organizations were intentionally diversified. In particular, a concerted effort was made to recruit veterans who identified as racial and ethnic minority veterans in the study. Organizations serving racial and ethnic minority veterans, whether LGBTQ+ focused or not, were included in the internet search and contact process. Nonveteran groups serving LGBTQ+ veterans, racial and ethnic minority veterans, and LGBTQ+ racial and ethnic minority veterans were also included in recruitment efforts in recognition that civilian groups may also include veteran members.

The final database included 2942 community organizations. Staff sent initial emails to the main contact listed for each of these organizations by using “mail merge,” which is an email feature that allows users to send personalized emails to large batches of recipients by uploading spreadsheets with appropriate contact information. After the first email contact, up to 4 follow-up reminders were sent via email if there was no initial response. Those who agreed to participate were recontacted at future time points and asked to reshare study information and tailored ads.

The initial email message shared background information about the study, with a request to directly share study ads and contact information with members via email distribution lists, bulletin boards, the organization’s social media platforms, or other communication methods regarding their preferences. The email messages and ads were tailored to the community organization’s membership base. For instance, the language of a contact email to an organization serving transgender veterans was adjusted to highlight how the study sought to better understand the experiences of transgender veterans, and ads designed for transgender veterans were attached with the email.

Ultimately, 10.47% (308/2942) of the organizations responded to the study staff and agreed to share the study information with their membership bases. Organizations that assisted with the recruitment were publicly acknowledged on the study website with their permission. After the completion of the full study, the participating organizations will receive an update on the study findings.

Given the nature of community outreach, there were, at times, high-volume surges of interested participants from a single organization. These surges occurred after large organizations sent out study information to their membership bases, resulting

XSL•FO
RenderX

in many members completing the web-based screener. All high-volume surges were manually reviewed, and screening decisions were discussed by the study team and documented to ensure that the study sample was not biased by a single organization or geographic region. When surges occurred, the study's current enrollment profile was reviewed, and subgroups requiring additional participants were prioritized. Oftentimes, surges were comprised of predominantly White cisgender male heterosexual veterans. Therefore, LGBTQ+, female, and racial and ethnic minority veterans were prioritized for screening.

Trialfacts

In the first 9 months of recruitment, enrollment numbers had not yet reached the target goals. Therefore, in May 2020, the study team decided to contract with an outside company to bolster its recruitment efforts by the study team. Trialfacts, a company that specializes in recruitment services for the clinical trial industry [34], was chosen due to its due diligence process and prior success with recruiting veteran populations.

Trialfacts was paid to use Facebook advertising to reach potential participants, as well as reaching out to a pool of participants from previous Trialfacts recruitment efforts in their internal database. These Facebook ads were run by Trialfacts employees, who were able to use their marketing and social media expertise to monitor and optimize ads consistently. The study team shared ad images and language that were shown to be successful in the study team's own social media ads, and Trialfacts also created their own IRB–approved ads with staff input and guidance.

Typically, Trialfacts guarantees a minimum number of participant referrals when contracting with study teams. However, Trialfacts had no prior experience of specifically recruiting LGBTQ+ veterans. As a result, Trialfacts proposed approaching this study as a pilot program. As such, the study team worked closely with the Trialfacts staff during the recruitment process. In addition to cocreating ads, the eligibility of Trialfacts referrals was relayed back to Trialfacts on a regular basis to help Trialfacts fine-tune its recruitment methods.

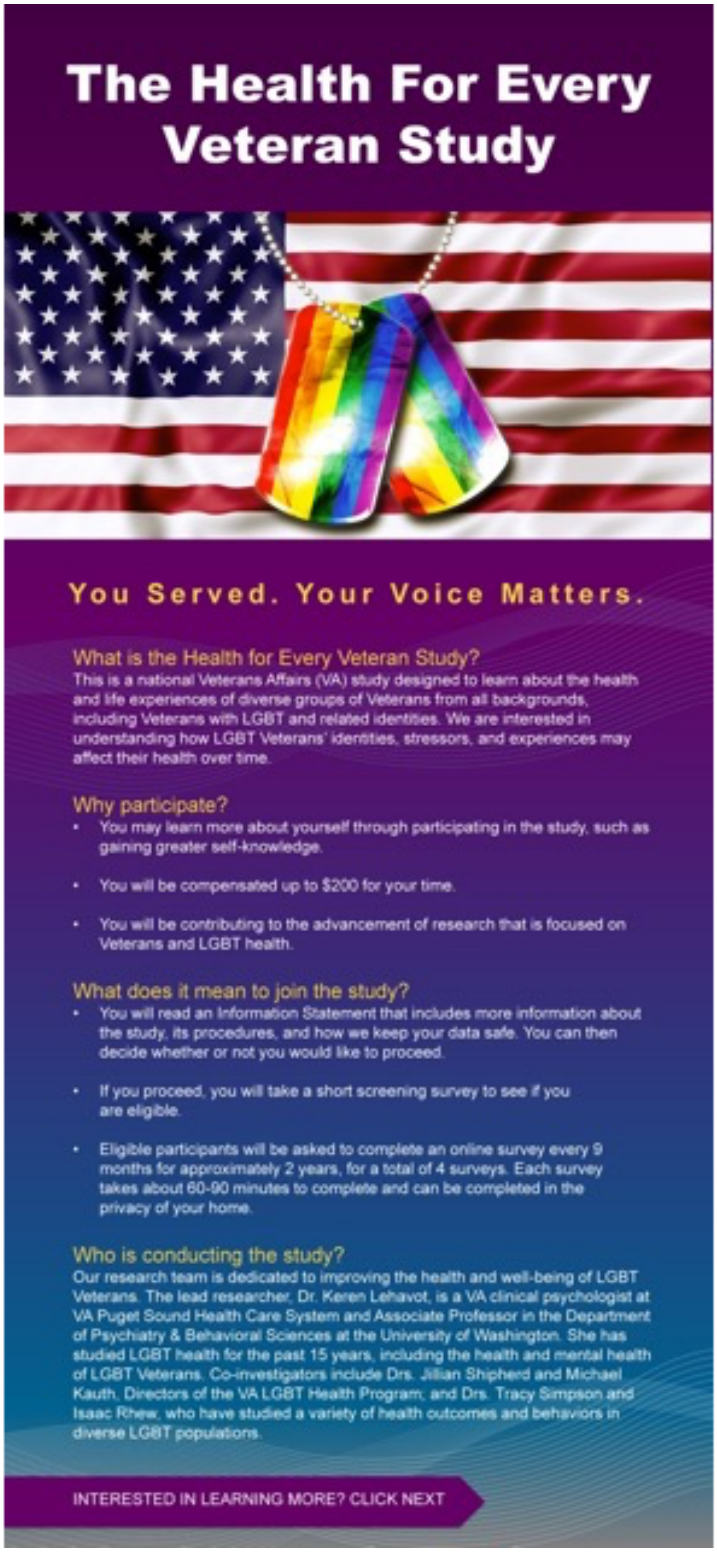
Trialfacts helped recruit participants across all study subgroups, although certain subgroups were prioritized in the study budget based on recruitment needs. In particular, the study team requested Trialfacts to focus on the recruitment of bisexual female and male, transgender male, and racial and ethnic minority veterans. In addition, Trialfacts used geotargeting and other advertising strategies to increase overall demographic diversity, with the goal of increasing the national representativeness of the enrolled sample.

Screening and Enrollment

Interested participants who were recruited via staff social media ads, community outreach, and Trialfacts were directed to an information landing page hosted by QuestionPro. These landing pages were tailored based on the ads on which the interested participant clicked; unique language and images were displayed based on the tailored subgroup for that ad. For example, ads for LGBTQ+, female, and general veteran audiences would link to LGBTQ+, women, and general landing pages, respectively (Figures 5-7). These landing pages contained relevant information about the *Health for Every Veteran Study* for interested participants, including benefits of participation, number of follow-ups (every 9 mo for 27 mo), and a description of the study team.

If participants indicated that they were interested in participating, they would then be directed to the study information statement, screening consent form, and the study screener (which were all the same across participants and hosted in QuestionPro) to determine eligibility. The eligibility criteria mandated that the veteran must be aged ≥18 years; be currently nonincarcerated; and have prior service in the US military, US residence, routine internet access, valid contact information, and willingness to answer questions about key demographics. Individuals recruited through Trialfacts underwent the same screening procedures, although the landing pages and study screeners were housed and conducted by Trialfacts.

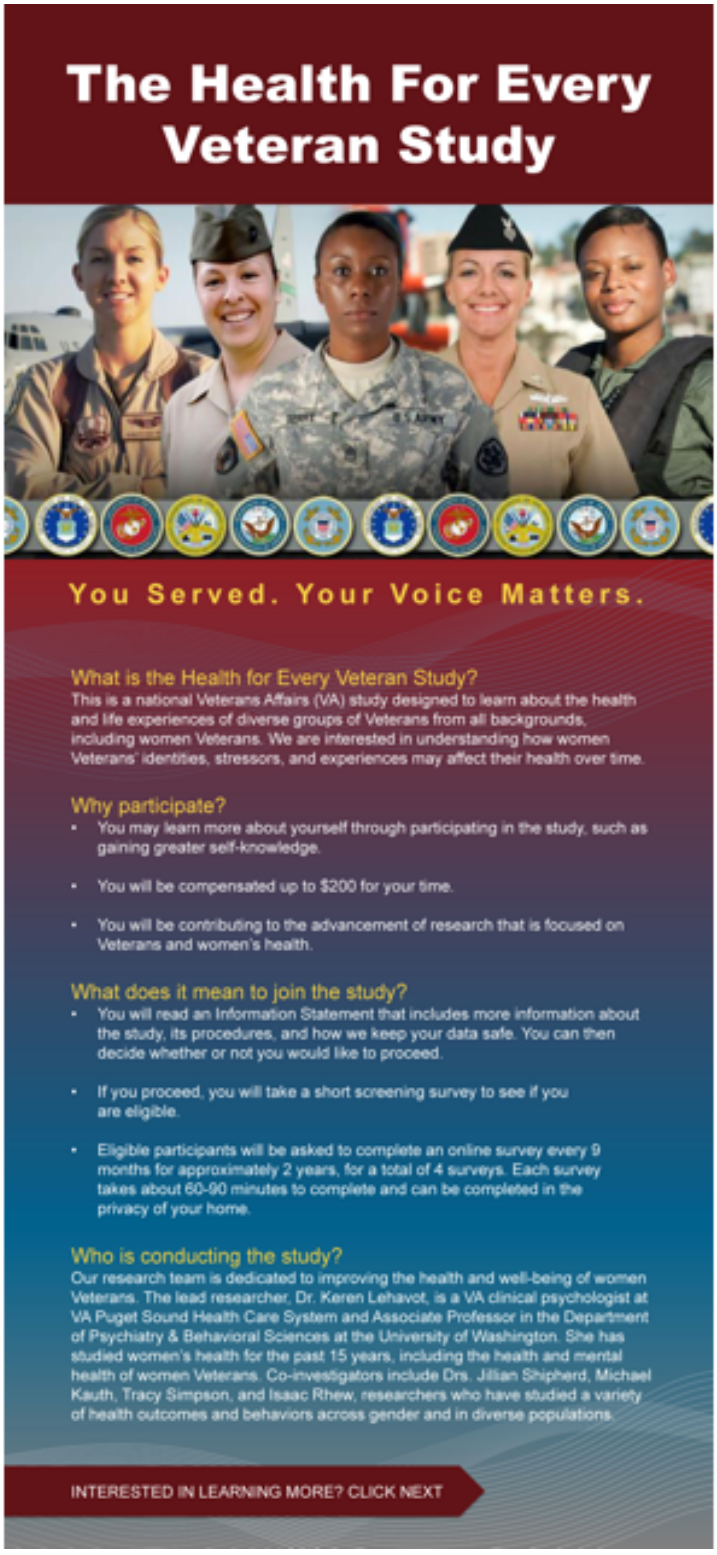
All prospective participants underwent a manual review to gauge veteran "insider knowledge" to ensure authentic veteran status. In this manual review, the study staff reviewed responses to questions regarding military branches, job fields and acronyms, and rank to determine the validity of the prospective participant's veteran status. In addition, a statement was also included on the screener as a deterrent to falsifying responses saying the following: "Per the Stolen Valor Act of 2013, it is a federal crime to obtain money or other benefits by falsely representing prior military service." Additional screening precautions are detailed in our paper elaborating the baseline results [35]. Those who did not pass the screener or manual review were deemed ineligible and provided with a link to a detailed resource page that included contact information for emergency crisis services, mental health services, sexual assault and domestic violence support, substance use support, organizations serving specific populations such as female and LGBTQ+ veterans, and information on VA benefits.



Eligible participants were emailed a link to the 60- to 90-minute web-based baseline survey to be completed on a website developed by the VA Cooperative Studies Program. If completed, the participants were considered to be enrolled and compensated US $30. Additional compensation was provided for follow-up surveys as follows: US $35 for the 9-month follow-up, US $40 for the 18-month follow-up, US $45 for the 27-month follow-up, and an additional US $50 bonus for the completion of all surveys. As such, participants could earn up to US $200 for their time. According to the VA policy, payments were issued by the Department of Treasury via physical checks or electronic fund transfers.

Weekly reporting of screening and enrollment was conducted by the study team to track the recruitment process. Screened and enrolled participants were examined by the subgroup and demographics to better understand the enrollment needs and tailor recruitment strategies across all recruitment methods. Demographic characteristics from national research surveys, such as the Behavioral Risk Factor Surveillance Survey, National Epidemiologic Survey on Alcohol and Related Conditions-III, and Millennium Cohort, were reviewed and compared by demographics (ie, age, race, marital status, education, income, and geographic region) to improve national

XSL•FO
RenderX



representativeness. Additional strategies were used to optimize validity, such as not including study compensation amounts in advertising and monitoring for duplicate identifying information.

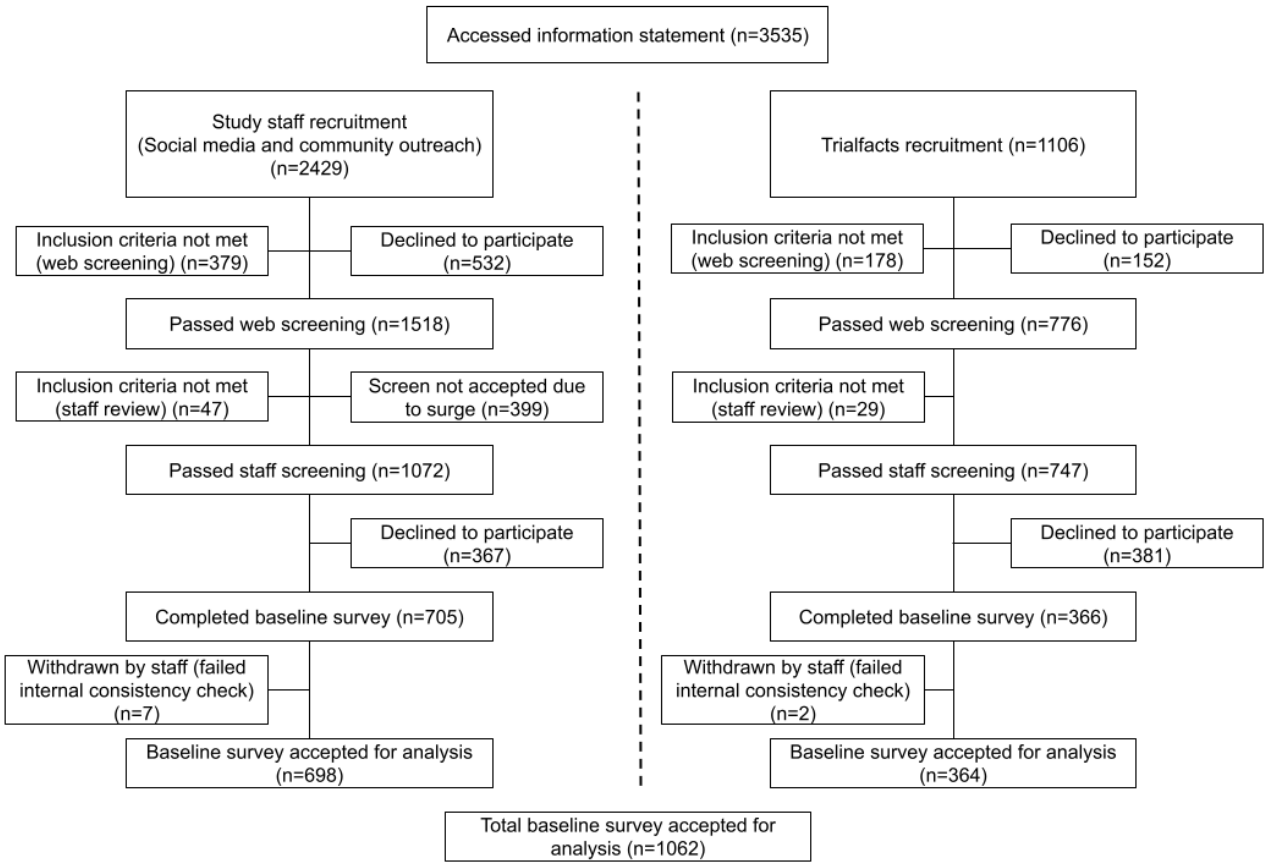
Ethical Considerations

This study was approved by the VA Puget Sound Health Care System IRB (01672) and granted a waiver for the documentation of informed consent. Potential participants were provided with an information statement comprehensively describing the nature of the study as well as its risks and benefits upon visiting the study website. All study data in this paper have been deidentified to protect the privacy and confidentiality of the participants.

Results

Enrollment in the *Health for Every Veteran Study* concluded in December 2020. A total of 3535 participants accessed the study information statement to begin the screening process, and 1819 (51.46%) participants passed screening; of these 1819 participants, 1062 (58.38%) completed the baseline survey to enroll. The CONSORT (Consolidated Standards of Reporting Trials) diagram [36] demonstrates the flow of recruitment, from

XSL•FO
RenderX



screening to enrollment, divided across study staff recruitment methods (ie, social media advertising and community outreach) and Trialfacts recruitment (Figure 8). All descriptive results were calculated using R (R Foundation for Statistical Computing) [37].

Of the enrolled participants (n=1062), 25.24% (n=268) were recruited from staff Facebook ads, 40.49% (n=430) from community outreach, and 34.27% (n=364) from Trialfacts. Trialfacts proved to be instrumental for the study, providing one-third (364/1062, 34.27%) of the participants despite being initiated 9 months after the recruitment had begun. Notably, all 3 methods of recruitment contributed to substantial portions of the enrolled cohort, indicating that a multipronged approach was a critical and successful strategy for the recruitment of hard-to-reach populations in our study of LGBTQ+ veterans.

Of the 8 subgroups targeted for recruitment, 5 subgroups neared the target recruitment goal of 200 participants per subgroup: cisgender gay men, cisgender heterosexual women, cisgender heterosexual men, cisgender lesbian women, and transgender women. However, cisgender bisexual men, cisgender bisexual women, and transgender men did not reach recruitment goals. Table 1 describes the enrollment by subgroup, including the percentage of the target enrolled. Of note is the subgroup of gender-diverse veterans; although they were not an a priori recruitment group, they were enrolled as an exploratory group after recruitment began to be inclusive of the experiences of veterans not encompassed by the other a priori subgroups.

Table 2 demonstrates the demographic breakdown of the study sample by recruitment method. Various recruitment methods were effective at recruiting different subgroups; however, it should be noted that the methods were tailored to target specific subgroups based on needs at various points of the recruitment period. For instance, because community outreach methods were extremely successful in recruiting cisgender heterosexual male and cisgender female veterans (at times resulting in recruitment surges; see the *Discussion* section), only a small fraction of Trialfacts ads focused on these populations. Instead, Trialfacts purposefully focused on the recruitment of cisgender bisexual men, cisgender bisexual women, and transgender men. This proved critical; 68% (42/62) of cisgender bisexual men were recruited through Trialfacts, compared with 11% (7/62) through Facebook and 21% (13/62) through community outreach (Table 2). Similarly, Trialfacts recruited 48% (29/61) of cisgender bisexual women and 49% (22/45) of transgender men (Table 2). To speak to the broader demographic representativeness of participants gleaned from each recruitment method, information on age, race, ethnicity, education, income, and marital status of the enrolled sample by recruitment method is also included in Table 2.

Discussion

Recruitment Methods

The Health for Every Veteran Study is the first study to specifically recruit a diverse sample of LGBTQ+ and heterosexual cisgender veterans nationwide to examine health disparities among these subgroups of veterans. Recruitment results indicated that all 3 recruitment methods, namely, Facebook ads, community outreach, and contracting with a recruitment company, were crucial for the recruitment and enrollment success. Each method contributed to at least a quarter of the enrolled participants.

In addition to the number of participants recruited, the study staff found unique benefits and costs for each method. Because recruitment strategies were continuously adjusted to best meet the study needs, all final recruitment numbers (both overall and for specific subgroups) should be interpreted within the context of this study's time period, population, and aims. However, lessons learned from the study's recruitment methodology and strategies can be applied to a wide range of researchers who work with hard-to-reach populations. To capture this, Table 3 describes various strengths and challenges of all 3 recruitment methods based on the study team's experience.

In particular, a company that specializes in recruitment strategies for research may be an attractive option for researchers with limited abilities or staff resources to manage or optimize social media ads. Despite launching this partnership 9 months after recruitment had begun, Trialfacts brought in 34% of the enrolled participants. Using Trialfacts at the start of the study recruitment period may have allowed the study to achieve full enrollment. However, researchers should consider whether they wish to have a single source for recruitment or whether a diversified recruitment strategy is desired. Depending on the study's aims and the desired target population, different strategies and methods may be beneficial.

Notably, each VA health care system has a designated LGBTQ+ Veteran Care Coordinator (VCC). VCCs serve as the point persons for LGBTQ+ veteran affairs at their respective sites. However, we intentionally chose not to engage with VCCs for recruitment to reduce bias that would have been introduced had we recruited veterans who were already engaged in VA services. For other researchers, connecting with VCCs for recruitment may be an ideal option for the recruitment of LGBTQ+ veterans.

XSL•FO
RenderX

Table 3. Strengths and challenges of study recruitment methods.

Recruitment method	Strengths	Challenges
Facebook ads	• Reach those not affiliated with the VA[a] or connect with wider audience • Can target audience by some parameters to optimize reach • Can adjust ads and targeting in real time, improves cost-efficiency, and can follow recruitment needs for specific subgroups • Provides a variety of metrics to track performance, such as reactions to and engagement with ads	• Takes experience to get audience parameters correct • Negative comments need frequent monitoring; negative comments and hate speech can have negative impacts on study staff as well as on potential study participants • Not able to reach those not on Facebook • Little to no direct customer service if ads were deemed to violate Facebook policy • Takes significant staff time to optimize • Learning platform requires time and research • Requires thoughtful budgeting due to varied and somewhat unpredictable costs and efficacy of ads
Community outreach	• Reach those not affiliated with the VA or connect with wider audience • Can reach those not on social media • Establish trustworthiness and credibility with leaders of community organizations who hold closer personal relationships with organization members	• Little control to how or when organizations shared study information • High-volume surges of interested participants to manage; surges may cause recruitment bias by geographic region or demographic group • May be biased toward those involved with community groups (eg, those who publicly identify as LGBTQ+[b] vs those who do not) • Some organizations may be hard to reach or may not have up-to-date contact information • Researching, compiling, contacting, and following up with organizations may require significant time and energy • Some relevant local groups may be missed if study team is not connected or familiar with the region
Trialfacts or similar recruitment service company	• Expertise and resources solely dedicated to recruitment and social media advertising • Reduces burden on study staff • Typically offers a recruitment number guarantee—will prorate a refund if numbers are not achieved • Familiarity with institutional review board protocols • Affordable or cost-efficient for this study • Provides a tailored recruitment plan and study timeline	• Can be expensive • Less control over advertisements • Requires establishing secure information exchanges with Trialfacts to meet all VA information security guidelines • May lack content area expertise for specific populations, such as LGBTQ+ veterans • Difficulty recruiting some subgroups • Quality checks needed to review data or reports • May overlap in reach if study is already conducting separate social media recruitment • Not able to reach those not on social media

[a]VA: Veterans Health Administration.

[b]LGBTQ+: lesbian, gay, bisexual, transgender, queer, and other sexual and gender minority.

Population Subgroups

Despite the overall success in recruiting LGBTQ+ veterans in this longitudinal study, there were areas where the recruitment underperformed. In particular, the number of bisexual veterans of any gender and transgender male veterans recruited was lower than the study aims. The reasons for underrecruitment likely differed between the groups.

Transgender men appear to be less prevalent in the veteran population compared with transgender women, although more accurate population estimates are needed [3,38]. This may be one reason why the study team had greater difficulty reaching a target goal of 200 for transgender men compared with other LGBTQ+ subgroups. In addition, transgender men face the barriers of stigma and invisibility [39,40]. For instance, a national study of transgender men found that 14.1% of participants were refused care by a provider due to their gender identity, and 32.8% delayed needed care due to fear of discrimination because of their gender identity [39]. These obstacles may reduce participation in health research.

Difficulties in recruiting bisexual veterans into research studies may be due to biphobia within and outside the LGBTQ+ community. Although bisexual people represent a large proportion of the LGBTQ+ community among both veterans and civilians [41], structural, interpersonal, and internalized biphobia may result in the exclusion of or decreased sense of belonging among bisexual people from the LGBTQ+ community [41,42]. This may make it difficult to recruit bisexual veterans through broadly targeted LGBTQ+ ads or through LGBTQ+ community groups. In addition, changes in sexual orientation identity labels over time also mean that veterans with same-gender or different-gender attractions do not necessarily identify as bisexual. Although the screening survey included other sexual identity options (eg, pansexual), the screener also required the selection of a single sexual orientation that best represented the interested participants' sexual identity (choosing from 1 of the following: gay or lesbian, bisexual, or

XSL•FO
RenderX

heterosexual) for study stratification purposes. Ultimately, improved methods for recruiting bisexual veterans and other veterans with both same-gender and different-gender partners in health research deserve further investigation. This is particularly important because the literature indicates that bisexual community members, especially bisexual women, experience health inequities in mental and physical health compared with lesbian and heterosexual women [43,44].

Notably, the study enrolled 66 gender-diverse veterans (a category that included nonbinary, gender nonconforming, and genderqueer veterans and veterans of other gender identities with any sexual orientation) despite not being an a priori recruitment category. This indicates a promising future area of research and engagement. There is limited research on the health of gender-diverse populations in general. Current literature shows that gender-diverse individuals face a number of inequities in health and social determinants of health, including increased risk of poverty, uninsurance, homelessness, discrimination in the health care system, suicide attempts, and psychological stress [45] compared with their cisgender peers.

Finally, racial and ethnic minority veterans were difficult to recruit across the subgroups in the study. The enrolled sample was less racially diverse compared with the overall veteran population, with 21.4% of the study sample identifying as racial and ethnic minority people compared with 26% in the wider veteran population [46]. Racial and ethnic minority veterans were intentionally included in targeted recruitment efforts, including through representation in ad images, outreach to community organizations specifically centering on racial and ethnic minority veterans, and Trialfacts' advertising strategies. It is possible that a deeper community-based partnership building ahead of study recruitment would improve the perceived trustworthiness of the study and increase outreach to racial and ethnic minority veterans, particularly those within the LGBTQ+ community. Generally, the multiple layers of marginalization experienced by LGBTQ+ racial and ethnic minority veterans may add structural and interpersonal barriers. For example, racism within LGBTQ+ and veteran communities may also result in further marginalization of LGBTQ+ racial and ethnic minority veterans from both communities, resulting in fewer chances to hear about or less desire to participate in this study. In addition, recruitment for this study occurred during the COVID-19 pandemic and a wave of ongoing violence and racism against Asian American, Black American, and other racial and ethnic minority individuals. This could have made it more difficult for racial and ethnic minority veterans to hear about or participate in research studies, even with study compensation.

Other Recruitment Challenges

It is impossible to know whether the COVID-19 pandemic increased or decreased participation in the study and for whom. Potentially eligible veterans may have been prevented from participating due to COVID-19–related stressors, such as physical, mental, emotional, and social health needs, as well as socioeconomic stressors such as lost work, housing instability, childcare responsibilities, financial uncertainty, and loss of access to internet or technology. By contrast, the entirely web-based nature of the *Health for Every Veteran Study* may have facilitated participation during a time of social distancing and stay-at-home orders, particularly compared with other research studies requiring in-person recruitment and enrollment.

Other factors that impacted the study recruitment process were as follows: (1) US congressional budget delays impacting VA research processes, (2) high-volume surges of heterosexual participants from community outreach, and (3) negative comments on Facebook ads. Congressional budget delays caused 2 pauses in social media advertising during the study recruitment period: from October 5, 2019, to October 25, 2019, and from October 1, 2020, to October 5, 2020.

On several occasions, the study team experienced high-volume surges of screeners from interested participants, which primarily occurred when conducting community outreach with large veterans' organizations. This resulted in large numbers of heterosexual veterans completing the initial screener, which necessitated manual screening by staff to reduce bias in the sample toward one particular community organization (see the *Methods* section). Underrepresented subgroups in the sample were prioritized for enrollment, including women, LGBTQ+ subgroups, and racial and ethnic minority veterans. This may have introduced sampling bias, including for racial and ethnic minority, cisgender, and heterosexual veterans, who had a greater likelihood of being enrolled. However, this type of manual review was necessary to create a balanced study sample, reduce overall bias, and meet enrollment goals.

Finally, the study staff encountered a large volume of negative and derogatory comments on Facebook ads, up to dozens per day. These comments were predominantly anti-LGBTQ+ and often expressed opposition to the content of the ad images. Automatic filters allowed the study staff to hide comments immediately with certain keywords and phrases. In addition to these filters, the staff monitored the ad accounts throughout the day to manually hide the comments to minimize any potential negative impact on the LGBTQ+ study participants. Unfortunately, it is possible that some potential participants may have been exposed to and adversely affected by negative and derogatory comments before the study staff members were able to manually delete them. Filters and monitoring also served to discourage commenting in general, keeping recruitment in line with the VA institutional review board protocols, which do not allow direct social media interactions between the study team and veterans. Some ad images were adjusted based on constructive criticism shared in comments (most commonly, viewers criticized any images that altered the standard US military uniform). In addition, recognizing that health disparities research may attract scholars and study staff who hold one or more marginalized identities, it was important for the study team to build support mechanisms around social media monitoring. The study team regularly discussed recruitment topics in weekly meetings, which included conversations about the emotional and cognitive labor involved in monitoring derogatory Facebook comments. The team decided to rotate the task of moderating Facebook ads to ensure that a single person would not be overwhelmed by regular exposure to hate speech.

Limitations and Strengths

There are limitations to this study, one of which is generalizability. To some extent, our processes and experiences were influenced by VA regulations, which reduces generalizability to non-VA researchers. Although we made concerted efforts to improve the national representativeness of our enrolled cohort, there were participant characteristics that we did not collect (eg, rurality) and could not be used to fine-tune our recruitment methods.

Importantly, our specific study design and subgroup stratification affected the recruitment methodology described in this paper. Because different recruitment strategies were used to attract different subgroups of participants, it was not possible to analyze which subgroups responded best to various types of recruitment methods. Consequently, it is difficult to draw concrete conclusions on whether specific methods are favored by certain subgroups. Overall, the nonprobability manner of recruitment is a significant limitation of this study. Therefore, the study results may not be generalizable to other populations. However, the lessons learned and general recruitment methodology are pertinent to a wide variety of research. In addition, our subgroup stratification still offers important disaggregated insights into the recruitment of specific LGBTQ+ subgroups.

The completely web-based methodology of the study served as both a strength and a limitation. Crucially, web-based recruitment allowed the recruitment to continue, even when the COVID-19 pandemic began. As such, this study offers tested recruitment options for other health research studies that will begin or continue recruitment during the pandemic or for other studies using solely web-based methods. However, the recruitment methodology could also have resulted in selection bias in the sample, as there are veterans who may not use social media and who may not be connected with community organizations. In addition, the social media platforms used may also have caused selection bias based on the user base (eg, age of users). However, our widespread community-based organizations targeted veterans across a variety of age ranges and other demographics.

Overall, this study contributes to the current literature on both LGBTQ+ and veteran health research recruitment. In the LGBTQ+ recruitment literature, this study offers insights into the recruitment of multiple LGBTQ subgroups. In addition, we add to the current literature on web-based recruitment through social media. Uniquely, we used community outreach in a completely web-based manner, offering opportunities for community-based recruitment efforts when face-to-face recruitment is not feasible. We add to the veteran recruitment literature by relying on methods that do not use VA administrative or EMR data. This improves the study's generalizability by using recruitment methods that are inclusive of veterans outside the VA health care system.

Conclusions

We share our descriptions and findings of the recruitment process of the *Health for Every Veteran Study* to convey the lessons learned during the web-based recruitment of LGBTQ+ veterans. As the first study to recruit a large and diverse group of veterans that varies across gender identity and sexual orientation, important insights were gathered that have implications for the web-based recruitment of LGBTQ+ veterans and potentially other hard-to-reach populations. The multipronged recruitment plan that consists of social media advertising, outreach to community organizations, and partnering with a recruitment company offers 3 viable options for researchers who plan to conduct web-based recruitment for health research studies.

Abstract

Background: Timely recognition of cancer progression and treatment complications is important for treatment guidance. Digital phenotyping is a promising method for precise and remote monitoring of patients in their natural environments by using passively generated data from sensors of personal wearable devices. Further studies are needed to better understand the potential clinical benefits of digital phenotyping approaches to optimize care of patients with cancer.

Objective: We aim to evaluate whether passively generated data from smartphone sensors are feasible for remote monitoring of patients with cancer to predict their disease trajectories and patient-centered health outcomes.

Methods: We will recruit 200 patients undergoing treatment for cancer. Patients will be followed up for 6 months. Passively generated data by sensors of personal smartphone devices (eg, accelerometer, gyroscope, GPS) will be continuously collected using the developed LAIMA smartphone app during follow-up. We will evaluate (1) mobility data by using an accelerometer (mean time of active period, mean time of exertional physical activity, distance covered per day, duration of inactive period), GPS (places of interest visited daily, hospital visits), and gyroscope sensors and (2) sociability indices (frequency of duration of phone calls, frequency and length of text messages, and internet browsing time). Every 2 weeks, patients will be asked to complete questionnaires pertaining to quality of life (European Organization for Research and Treatment of Cancer Core Quality of Life Questionnaire [EORTC QLQ-C30]), depression symptoms (Patient Health Questionnaire-9 [PHQ-9]), and anxiety symptoms (General Anxiety Disorder-7 [GAD-7]) that will be deployed via the LAIMA app. Clinic visits will take place at 1-3 months and 3-6 months of the study. Patients will be evaluated for disease progression, cancer and treatment complications, and functional status (Eastern Cooperative Oncology Group) by the study oncologist and will complete the questionnaire for evaluating quality of life (EORTC QLQ-C30), depression symptoms (PHQ-9), and anxiety symptoms (GAD-7). We will examine the associations among digital, clinical, and patient-reported health outcomes to develop prediction models with clinically meaningful outcomes.

Results: As of July 2023, we have reached the planned recruitment target, and patients are undergoing follow-up. Data collection is expected to be completed by September 2023. The final results should be available within 6 months after study completion.

Conclusions: This study will provide in-depth insight into temporally and spatially precise trajectories of patients with cancer that will provide a novel digital health approach and will inform the design of future interventional clinical trials in oncology. Our findings will allow a better understanding of the potential clinical value of passively generated smartphone sensor data (digital

phenotyping) for continuous and real-time monitoring of patients with cancer for treatment side effects, cancer complications, functional status, and patient-reported outcomes as well as prediction of disease progression or trajectories.

Introduction

Cancer continues to be the leading cause of morbidity and mortality worldwide and a serious public health challenge [1-3]. Early cancer detection as well as increased effectiveness and availability of novel treatment approaches such as immunotherapy and targeted therapies have resulted in a steadily growing number of cancer survivors [4-7]. Continuous monitoring of patients undergoing treatment for cancer and cancer survivors is important for timely identification of cancer treatment complications and cancer progression that is important for optimized long-term prognosis [8]. Therefore, there is an urgent need for developing widely available, automated, and evidence-based monitoring systems of patients with cancer [9].

The COVID-19 pandemic continues to be a serious public health challenge [10]. Patients with cancer are vulnerable to SARS-CoV-2 infection due to immunosuppression, frequent hospital visits [11,12], and lower efficacy of the COVID-19 vaccines [13]. The mortality risk of patients with cancer infected with SARS-CoV-2 was greater than that of the general population and was shown to exceed by 33% among patients with thoracic and hematologic malignancies [14-16]. A meta-analysis of 52 studies and 18,650 patients estimated the probability of death at 25.6% in patients with cancer infected with COVID-19 [17]. Furthermore, the COVID-19 pandemic caused major delays and interruptions in cancer treatments [18,19], and they are estimated to have caused over 15% increase in additional cancer deaths [20]. Finally, patients with cancer were vulnerable to adverse mental health and quality of life sequalae during the COVID-19 pandemic [21,22].

Although there is no standardized definition for mobile health (mHealth), the World Health Organization defines mHealth as "medical or public health practice that is delivered with the support of mobile phones, patient monitoring devices, and other wireless devices." mHealth encompasses the use of mobile phones and other wireless technologies for health care and is a promising approach for improving health monitoring and delivery of health interventions [23-25]. The adoption of telehealth and mHealth solutions is growing [26]. The number of digital health apps currently exceeds 300,000, with hundreds of apps being introduced every day [27]. The market size of digital health apps will grow exponentially in the coming decade [27]. However, the adoption of digital health apps in clinical practice is limited due to numerous obstacles such as unclear clinical value because they are often not developed by health care professionals and not tested in clinical environments [28]. Thus, there is an urgent need to develop evidence-based personalized telehealth or mHealth solutions and test them in real-word clinical environments that would allow evidence-based monitoring of vulnerable patients with cancer and would ideally consider the clinical, functional, and patient-reported health outcomes [29-31].

Digital phenotyping allows continuous and spatially and temporally precise quantification of individual's phenotype in his or her natural environment by using passively harnessed data from personal digital devices, including smartphone sensors [32,33]. Digital phenotyping approaches have been increasingly tested across mental health and somatic conditions [34], including amyotrophic lateral sclerosis [35], multiple sclerosis [36], posttraumatic stress disorder [37], depression [38], schizophrenia [39], sleep disorders [40], and spine disorders [41]. There is a growing body of evidence that passively generated data can allow identification of treatment complications and disease trajectories of patients with cancer. For example, the Helping Our Patients Excel study of 10 patients (mean age 60 [SD 11] years and mean Eastern Cooperative Oncology Group performance status of 1 [SD 0.66]) with gynecological cancer undergoing palliative chemotherapy found that passively acquired accelerometer data using wearable devices enabled the identification of high-risk patients and complications [42]. In another prospective observational study, 62 individuals undergoing elective cancer surgery were followed up using a smartphone app for a median of 147 (IQR 77-179) days after the surgery [43]. They found that exertional physical activity in patients who experienced postoperative events (27%) was lower than that in those who did not experience postoperative events, suggesting that this approach can allow to quantify recovery after cancer surgery [43]. However, these studies are limited by small to moderate sample sizes and consideration of a snapshot of cancer journey. Numerous barriers remain for implementing mobile-sensing data into the care of patients with cancer due to ongoing challenges related to raw data analysis and interpretation as well as integration of results in the clinical workflow [44]. Interpretation of passively collected data within clinical contexts requires multidisciplinary collaboration to identify potential clinical values of the mobile-sensing data. The analysis of passively harnessed sensing data is another important challenge, and it has been shown that deep learning approaches can be used to anticipate complications of patients undergoing treatment for hematologic malignancies [45]. Therefore, future studies are warranted to better understand the potential clinical values of mobile sensing data in oncology.

The aim of our study is to evaluate the usefulness of passively generated smartphone sensor data streams (as in digital phenotyping) for monitoring patients with cancer. We will evaluate if novel cancer trajectory biomarkers that integrate

XSL•FO
RenderX

high-resolution passively acquired data streams from smartphone sensors with actively collected data can enable real-time data analytics and monitoring of patients with cancer in their natural environment. We will (1) develop and adapt a monitoring system tailored for patients with cancer that integrates passively and actively acquired data streams, (2) investigate if continuous monitoring of patients with cancer using passively collected data acquired through personal smartphones correlates with objective and patient-reported health status and therefore can be used as actionable digital phenotype, and (3) develop prediction models anticipating disease trajectories as well as functional and reported outcomes of patients with cancer. This study will allow to better understand the potential clinical value of passively generated smartphone sensor data (digital phenotyping) for continuous and real-time monitoring of patients with cancer for treatment side effects, cancer complications, functional status, and patient-reported outcomes, as well as prediction of disease progression or trajectories.

Methods

Study Design

This is a prospective observational cohort study with a 6-month follow-up of patients diagnosed with cancer who will use a smartphone app to acquire continuously generated data from smartphone sensors (passively generated data) and deploy questionnaires (actively generated data). This study is conducted at the Department of Oncology, Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania, in collaboration with Vytautas Magnus University, Kaunas, Lithuania, and ProIT, Vilnius, Lithuania.

Patient and Public Involvement

Patient involvement in this study will last for the duration of the study and will include continuous collection of smartphone sensor data, actively collected questionnaire data via LAIMA app, and 3 in-person visits. The patients and the public were not involved in the design of this study.

Recruitment

The study inclusion criteria are (1) diagnosis of cancer, (2) current active treatment (radiation therapy, chemotherapy) for cancer or surveillance, (3) ability to comprehend Lithuanian, (4) ownership of a smartphone device (Android or iOS platform) that can support the smartphone apps, (5) age of 18 years or older, and (6) ability to provide informed consent. Patients will be excluded if they have cognitive, visual, or functional impairment or any other clinically significant medical condition that in the opinion of the study investigators could affect participant safety, preclude evaluation of responses, or interfere with the ability to comply with the study procedures.

Ethics Approval

Ethics approval was obtained from the Kaunas Regional Bioethics Committee on April 14, 2022 (protocol BE-2-31). All participants will provide informed consent before inclusion in this study. Identifying data will be available for the study oncologists and will be deidentified for other members of the research team. Patients will not receive compensation for participating in this study.

Sample Size

The sample size was calculated using the Digital Phenotyping Power Calculator tool [46]. We plan to recruit 200 patients diagnosed with cancer undergoing active treatment and actively follow-up with them for at least 3 months, with expected missing data of <50% that will allow to achieve power (type 1 error .05) of .971 at effect size (β_1) of .03 and power of 1 and effect sizes (β_1) of .05 and .07.

Primary Outcome

We will examine changes in each of the collected digital biomarker data streams during the 6-month follow-up period in relation to progression-free survival. Cancer progression will be defined based on clinical, laboratory, and radiological data in accordance with guidelines and criteria for the specific cancer type. Cancer progression will be determined by the treating oncologist according to relevant clinical guidelines.

Secondary Outcome

We will examine temporal changes in questionnaire data trajectories collected using the LAIMA app and will examine the association of passively harnessed digital biomarkers with actively collected questionnaire data. We will also examine the association of passively acquired digital biomarker data with clinically relevant outcomes of patients with cancer, such as overall survival, cancer-related complications (type of complication, unexpected presentation to emergency department or hospital admission), and cancer treatment–related adverse events. The precision of digital biomarker data to identify and predict clinically relevant outcomes of patients with cancer will be examined.

Digital Data

Data will be collected using the LAIMA app that was developed by the researchers based on the open-source Beiwe platform [47]. The LAIMA app is supported by iOS and Android operating systems. We also developed a corresponding digital platform that is linked with the smartphone app and will be used for patient registration and remote monitoring by the study investigators.

The LAIMA app and digital platform will be used to collect and integrate (1) passively generated data streams from smartphone sensors that will be uploaded to the LAIMA platform and integrated with questionnaires and clinical data, (2) actively collected questionnaire data that study participants will be prompted to answer in predefined days at 2-week intervals after inclusion in this study, and (3) sociodemographic and clinical data that will be entered by the study investigators at initial and follow-up study visits. In this study, we will include questionnaires that are commonly used for clinical and cancer research and were validated in Lithuanian as well as clinical data that are relevant for patients with cancer. The data will be uploaded to the server and aggregated. We utilize cloud services for secure data storage as well as data preparation and predictive modeling using generated data. The LAIMA platform has several data preparation methods such as classification,

XSL•FO
RenderX

clustering, regression, and ranking. The platform also has a built-in artificial intelligence algorithm function. The LAIMA app and platform are compliant with the European Union General Data Protection Regulation requirements [48]. Continuously and passively generated data from smartphone sensors will be collected during the course of this study that will take from 3 to 6 months for each patient included in this study. The following smartphone sensor data will be considered for this study:

1. Mobility data will include continuous collection and aggregation of passively generated data streams from the accelerometer (mean time of active period, mean time of exertional physical activity, distance covered per day, duration of inactive period), GPS (places of interest visited daily, hospital visits), and gyroscope.
2. Sociability indices will include continuous capture and aggregation of frequency of duration of phone calls, frequency and length of text messages, and internet browsing time.

Questionnaires

Eastern Cooperative Oncology Group Questionnaire

The Eastern Cooperative Oncology Group questionnaire will be used for the assessment of the functional status of patients with cancer during their clinic visits [49]. It is a widely used measure of the functional status of patients with cancer in clinical practice and in clinical trials.

European Organization for Research and Treatment of Cancer Core Quality of Life Questionnaire

The European Organization for Research and Treatment of Cancer Core Quality of Life Questionnaire (EORTC QLQ-C30) will be used for the assessment of quality of life of the study participants [50,51]. The EORTC QLQ-C30 will be deployed during study visits and via the LAIMA app. The EORTC QLQ-C30 consists of 9 multi-item functional scales and 6 single-item symptom scales that evaluate global health status, functional status, role functioning, emotional functioning, cognitive functioning, social functioning, fatigue, nausea and vomiting, pain, dyspnea, insomnia, appetite loss, constipation, diarrhea, and financial difficulties. Scores are linearly transformed to a scale ranging from 0 to 100, with higher scores indicating better health-related quality of life on global health status and functional status scales and worse health-related quality of life on symptom scales.

Patient Health Questionnaire-9

The Patient Health Questionnaire-9 (PHQ-9) will be used for the assessment of depressive symptom severity during study visits and via the LAIMA app [52,53]. The PHQ-9 consists of 9 symptoms of depression that respondents rate based on their severity during the preceding 2 weeks, with a greater score indicating greater depressive symptom severity and with scores of 10 or greater indicating moderate to severe depressive symptoms.

General Anxiety Disorder-7 Questionnaire

The General Anxiety Disorder-7 (GAD-7) scale will be used for the assessment of anxiety symptom severity during the study visit and via the LAIMA app [54,55]. The GAD-7 includes 7 questions pertaining to generalized anxiety disorder, with higher scores indicating greater anxiety symptom severity.

COVID-19 Fears Questionnaire

The COVID-19 Fears Questionnaire for chronic medical conditions will be used for evaluating fears related to the COVID-19 pandemic [56,57]. This questionnaire includes 10 items. Respondents are asked to select the response that reflects how much each statement describes their experience on a typical day in the last week on a 5-point numerical scale ranging from 1 (not at all) to 5 (extremely). The total score is the sum of all items and ranges from 10 to 50, with higher scores reflecting greater COVID-19 fear. The questionnaire has been validated in Lithuania [56] and will be administered during the study visits.

Questionnaire Administration

The Eastern Cooperative Oncology Group questionnaire, EORTC QLQ-C30, PHQ-9, GAD-7, and the COVID-19 Fears Questionnaire for chronic medical conditions will be administered by trained clinicians. Deidentified data will be entered into a database, and hard copy documents are kept on-site under lock and key. EORTC QLQ-C30, PHQ-9, GAD-7 will also be deployed via the LAIMA app to study participants in predefined 2-week intervals via text messages and a secure link to the website. Participants will have 2 days to complete each questionnaire. The data will be uploaded to the LAIMA digital platform and integrated with other data sources for each patient.

Sociodemographic Data

We will consider patients' age at the time of cancer diagnosis and study inclusion, gender, education, job, and marital status. The type of smartphone device and operating system (Android, iOS or other) will be recorded.

Clinical Data

Information about cancer diagnosis, cancer location, presence of distant metastases, and tumor, node, metastasis stage at time of study inclusion, date of cancer diagnosis, and pathology results, including relevant molecular data, will be recorded at the initial study visit. We will record information regarding currently active cancer treatment(s), including radiation therapy (dose, target, and number of fractions) and chemotherapy (chemotherapeutic agent and dose and treatment start and finish dates). We will also gather information about all previous cancer treatments (surgery, radiation therapy, and chemotherapy), including their date, radiation dose, and chemotherapeutic agent(s). Information about comorbidities and currently used medication will be considered.

At 2 follow-up visits that will take place at 1-3 months and 3-6 months after patient inclusion in the study, we will record information pertaining to cancer treatment (chemotherapy, radiation therapy, and other) that is ongoing or that the patient has received during the follow-up period. Disease progression

XSL•FO
RenderX

and its date will be evaluated using standard clinical assessment studies and relevant criteria. Treatment complications (date and description) and unanticipated visits to the emergency department (date and description) will be recorded for all study patients. Disease progression and complications of patients who will not be able to attend the follow-up visit will be evaluated by reviewing medical records or via phone interviews. All clinical and sociodemographic data will be recorded and entered into the LAIMA platform by the study investigators who are board-certified oncologists.

Detailed Procedure

Baseline Visit

At the baseline visit, the study investigator will inform the patients about the study and procedures, and informed consent will be obtained. Participants will complete a battery of questionnaires that will be administered by the study investigators (Table 1). The LAIMA app will be installed into the participant's personal smartphone device, and an account will be created. Participants will be provided with a personal password and informed about the procedures in case he or she decides to withdraw from the study. The study investigators will ensure that the passively acquired data are being properly collected from a smartphone device by registering in the LAIMA platform.

[a]EORTC QLQ-C30: European Organization for Research and Treatment of Cancer Core Quality of Life questionnaire.

Follow-up Visits

All study patients will complete follow-up visits at months 1 to 3 and months 3 to 6 after the study inclusion. Follow-up visits will take place during routine clinical visits or via telephone encounter. We anticipate that most follow-up encounters will take place during in-person clinic visits. At follow-up visits, patients will complete the study questionnaires, and relevant clinical, laboratory, and imaging data will be reviewed for assessment of disease progression and treatment-related adverse events (Table 1). Given the observational nature of this study, patients will undergo clinical, laboratory, and imaging evaluation as clinically indicated and per appropriate guidelines because we will include patients with different cancer diagnoses undergoing different treatments. At the end of month 6 of the study or in case of patient death, the app will be remotely uninstalled from the device. Monitoring of passively generated data via smartphone sensors and actively collected questionnaire data via LAIMA app collection and upload in the platform will be conducted daily. Patients without passively generated or uploaded data for 3 days or more will be contacted by the study investigators, and problems will be resolved.

Data Analysis

Data cleaning will be performed on both active and passive data. The main cleaning tasks will be removing errors,

XSL•FO
RenderX

identifying outliers, and filling the missing data. Moreover, data will be transformed using aggregation and normalization methods. Missing data from smartphone sensors will be restored using data recovery extension (Firebase Cloud Messaging). For small numbers of missing observations, the missing values will be inputted using linear or polynomial interpolation methods (data imputation will not be used for mixed effects regression models). Cases with more than half of the smartphone sensor data missing will be excluded from the analyses. Missing answers in a questionnaire will not be considered in the analyses, and data imputation will not be performed as it could skew the results of the analyses. A descriptive analysis (mean, SD, median, relative frequencies for qualitative variables) of all the variables will be performed. To investigate associations among digital, clinical, and patient-reported health outcomes, χ^2 test (qualitative characteristics) or 2-sided *t* test or Mann-Whitney (quantitative characteristics) *U* test will be conducted. To visualize data, boxplots, bar plots, and heatmaps will be used. In the initial exploratory analyses, we will analyze each digital biomarker separately that will be followed by their aggregation to identify the most informative biomarkers and their sets for different clinical and patient-reported outcome measures of patients with cancer. Mixed effects regression models will be used for the analysis of longitudinal data obtained from smartphone sensors. For all hypotheses, statistically significant differences will be evaluated at a significance level of .05, and multiple comparison adjustments will be performed. Statistical analysis will be employed using SPSS software (version 27; IBM Corp) and RStudio (version 2022.12.0+353; Posit, PBC).

Results

Patient recruitment and data collection are expected to be completed by September 2023. As of July 2023, we have reached the planned recruitment target, and patients are undergoing follow-up. The final results of this study should be available within 6 months after the study completion.

Discussion

In this prospective observational cohort study, 200 patients with cancer will be followed up for 6 months by using (1) continuously and passively generated data from sensors (accelerometer, gyroscope, GPS) of smartphone devices (digital phenotyping) and (2) actively collected data using questionnaires for assessment of quality of life, symptoms, depression, anxiety, and COVID-19 fear. Disease progression and treatment complications will be evaluated during clinic visits. This study will allow to better understand the potential value of passively generated data from smartphone sensors for remote real-time monitoring of patients with cancer and anticipation of disease progression or trajectories, treatment complications, and unfavorable patient-reported outcomes.

Digital phenotyping is a promising approach in oncology that enables utilization of data that are passively generated by patients in their natural environments. It is a user-friendly approach because it uses personal digital devices, thus causing limited interruption of daily routine and device use habits. High and growing adoption of smartphones across age groups underscores the scalability of digital phenotyping approaches [58]. However, the barriers for deploying and integrating the digital phenotyping approach in oncology workflow should be considered and addressed, including data privacy and security concerns and participant willingness to share data. Caveats of analysis of passively generated data and its integration with routinely collected clinical and patient-reported data should be overcome to provide clinically meaningful digital biomarkers that can provide additional clinical value above and beyond the standard of care of patients with cancer. Emerging evidence suggests that this approach can be promising to predict the complications of cancer treatment [42,43]. However, it remains largely unclear if this approach can accurately prognosticate disease and treatment trajectories of patients with cancer. Our findings will allow us to better understand the potential clinical value of digital biomarkers for the prediction of clinical and patient-centered trajectories of patients with cancer.

The limitation of this study is the inclusion of patients with different cancer diagnoses and undergoing various treatments that can have a direct impact on the digital biomarkers included in this study. However, this will allow us to better understand which patients could potentially benefit the most from such a monitoring approach. The use of sensors of personal smartphone devices will provide real-world data with regard to patient behavior in their natural home environment but is subjected to individual differences of smartphone use habits. We hope that our study will provide further insights regarding the value of digital biomarkers and will be used to inform the planning and implementation of interventional clinical trials in oncology.

Acknowledgments

This work was supported by the Research Council of Lithuania grant 01.2.2-LMT-K-718-05-0085.

Data Availability

Data will be available 6 months after study completion.

Conflicts of Interest

None declared.

Abstract

XSL•FO
RenderX

Background: Since treatment with immune checkpoint inhibitors (ICIs) is becoming standard therapy for patients with high-risk and advanced melanoma, an increasing number of patients experience treatment-related adverse events such as fatigue. Until now, studies have demonstrated the benefits of using eHealth tools to provide either symptom monitoring or interventions to reduce treatment-related symptoms such as fatigue. However, an eHealth tool that facilitates the combination of both symptom monitoring and symptom management in patients with melanoma treated with ICIs is still needed.

Objective: In this pilot study, we will explore the use of the CAPABLE (Cancer Patients Better Life Experience) app in providing symptom monitoring, education, and well-being interventions on health-related quality of life (HRQoL) outcomes such as fatigue and physical functioning, as well as patients' acceptance and usability of using CAPABLE.

Methods: This prospective, exploratory pilot study will examine changes in fatigue over time in 36 patients with stage III or IV melanoma during treatment with ICI using CAPABLE (a smartphone app and multisensory smartwatch). This cohort will be compared to a prospectively collected cohort of patients with melanoma treated with standard ICI therapy. CAPABLE will be used for a minimum of 3 and a maximum of 6 months. The primary endpoint in this study is the change in fatigue between baseline and 3 and 6 months after the start of treatment. Secondary end points include HRQoL outcomes, usability, and feasibility parameters.

Results: Study inclusion started in April 2023 and is currently ongoing.

Conclusions: This pilot study will explore the effect, usability, and feasibility of CAPABLE in patients with melanoma during treatment with ICI. Adding the CAPABLE system to active treatment is hypothesized to decrease fatigue in patients with high-risk and advanced melanoma during treatment with ICIs compared to a control group receiving standard care. The Medical Ethics Committee NedMec (Amsterdam, The Netherlands) granted ethical approval for this study (reference number 22-981/NL81970.000.22).

Introduction

In recent years, the introduction of immunotherapy with immune checkpoint inhibitors (ICIs) has significantly improved the clinical outcome of patients with melanoma and has become the standard of care [1-4]. However, treatment with ICIs is associated with short- and long-term immune-related adverse events (AEs) [5-7], most commonly fatigue [7,8], and a deteriorated health-related quality of life (HRQoL) [6,9,10]. Some studies have reported that inadequate symptom monitoring and reporting (eg, under detection) can lead to worsening of AEs and more frequent emergency department visits and hospitalizations [11-13]. Therefore, enhanced symptom monitoring in the general cancer population as well as in this specific patient population is necessary. Furthermore, enhanced symptom monitoring is associated with improved clinical outcomes (eg, survival and adverse event management) and improved HRQoL in patients with cancer treated with chemotherapy [14-17].

One approach to monitoring symptoms and potentially enhancing patient-centered care can be the periodic collection of symptom information through patient-reported outcome measures by using eHealth tools [18,19]. Results from several studies show that web-based symptom monitoring tools are also beneficial for patients with cancer receiving ICIs [20-22]. However, in one study specifically, the use of an electronic patient-reported outcomes tool alone in patients with melanoma treated with ICIs could not reduce the number of severe AEs. Despite there being no impact on reducing the number of severe AEs, the intervention group had significantly better HRQoL outcomes compared to the control group as measured by the utility scores of the EQ-5D (P=.05) [22,23]. Furthermore, home monitoring by biometrical sensors could have the potential to detect symptoms (complementary) and monitor physical activity in outpatient oncology settings, although this has not been extensively researched [24,25].

As cancer-related fatigue (CRF) is the most common symptom experienced by patients with melanoma during and after ICIs [8] and a common problem in patients with cancer in general [26,27], much effort has been made to develop interventions to address this, as CRF negatively impacts HRQoL [26,28]. Current recommendations for all patients with cancer suggest encouraging physical exercise and providing psychosocial interventions and psychoeducation [28]. Multiple studies investigating these interventions have shown a decrease in fatigue and an increase in HRQoL [29-34]. Furthermore, mindfulness-based clinical interventions and yoga appear to be feasible interventions, and beneficial effects have been reported on several physical and psychosocial symptoms in patients with cancer, such as patients' psychosocial adjustment to their disease and improvement of biomarkers of stress, inflammation, and immune function [35-37]. Encouraging physical exercise, psychoeducation, mindfulness-based interventions, and yoga have therefore been included in web-based programs and eHealth apps targeting CRF, with promising results [38-41].

XSL•FO
RenderX

eHealth apps may also contribute to addressing the unmet care and information needs of patients [42,43]. Patients with melanoma during and after targeted therapies or ICIs have extensive needs for supportive care, information provision, and symptom management, specifically with regard to clinical- and self-management topics, CRF management, and available supportive care services [43]. By providing remote monitoring and information provision through an eHealth tool, patients believe this will positively affect their HRQoL and symptom burden [43].

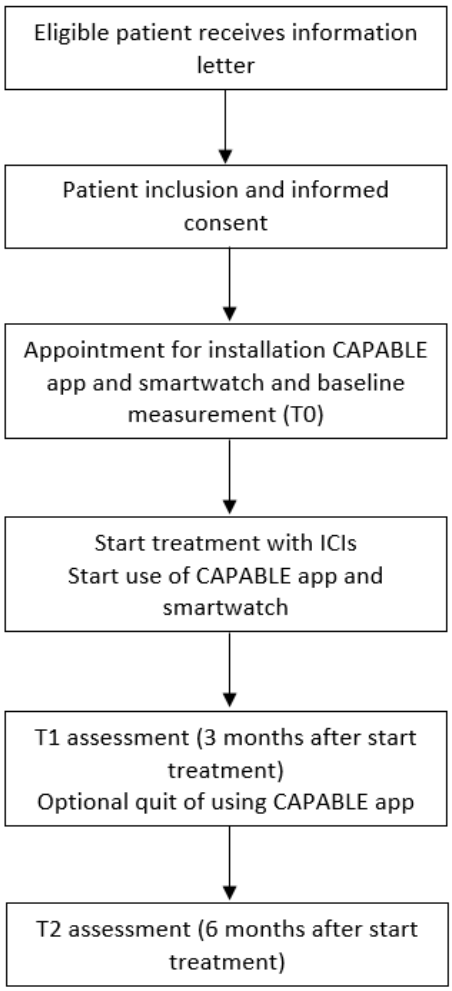
This study will investigate the extensively pretested (manuscript in preparation) CAPABLE (Cancer Patients Better Life Experience) eHealth app providing information and supportive care, symptom monitoring, and well-being interventions (as part of the European Union's Horizon 2020 research and innovation program under grant agreement number 875052). CAPABLE functionalities are accessible for patients through a mobile app, connected to a smartwatch, and available for health care professionals (HCPs) through a web portal. In this pilot study, we will explore the effect of using CAPABLE on HRQoL outcomes such as fatigue and physical functioning and patients' acceptability of using a system like CAPABLE. The results of this pilot trial will be compared with a historical prospective cohort of patients with the same characteristics but without CAPABLE. We hypothesize that patients using the CAPABLE app will have a reduced increase in fatigue in the first 3-6 months of treatment compared to patients in the control cohort.

Methods

Overview

The CAPABLE study is a prospective, exploratory pilot study in which we compare an exploratory cohort that receives the CAPABLE smartphone app and a multisensory smartwatch (intervention) to a historical prospective cohort that did not receive the CAPABLE app and smartwatch (control group). The control group (NL75996.031.20) consists of patients with the same inclusion criteria and self-reported data collection as the intervention group but receives standard care without the CAPABLE app (eg, the patient calls the hospital when a symptom is experienced and has a blood analysis and follow-up appointment with a nurse practitioner before every ICI infusion). The initial plan of the CAPABLE consortium was to perform a randomized trial, but due to time constraints in the project, development issues, and the COVID-19 pandemic, we were not able to set up a randomized study and include the needed number of patients because of the limited numbers of patients with melanoma in the restricted and foreseen time period. No data safety monitoring board is in place due to the low risk of the intervention, as assessed by the internal data security team. The results of the study will be published in international peer-reviewed journals.

Study Population



This study aims to include 36 patients with histologically confirmed stage III or IV melanoma eligible for starting treatment with ICIs (anti-PD1 or anti-CTLA4) according to standard clinical practice. In order to be eligible to participate in this study, a subject must be >18 years of age, have a sufficient understanding of the Dutch language, and be able to use a smartphone. Patients are excluded if they are included in an experimental clinical trial.

Recruitment and Data Collection

Patients will be recruited over a period of 6 months at the Netherlands Cancer Institute (NKI) in Amsterdam, a comprehensive cancer center. Eligible patients will be invited to participate in the study by their treating physician approximately 2 weeks before the start of treatment during an outpatient visit. Patients will then receive an information letter about the study from the physician or coordinating researcher. After receiving written informed consent from the patient, the patient will be enrolled in the CAPABLE system. Consenting patients will have an intake appointment with the research team before their first ICI infusion to install and set up the CAPABLE app and smartwatch. Furthermore, patients will receive a verbal explanation and an instruction manual on how to use the CAPABLE app. Patients will be asked to use the smartphone app for a minimum of 3 to a maximum of 6 months after the start of ICI treatment. In case the patient is not using the system or is not wearing the smartwatch for at least 2 weeks, the research team will contact the patient to assess possible technical issues or drop out for other reasons. Research data are collected at the intake appointment at baseline (T0), 3 (T1), and 6 months (T2) after the start of treatment (Figure 1). Data will be extracted from medical records and validated questionnaires. The patient will receive a link to a digital platform (ALEA, FormVision) through email to fill out the questionnaires. Reminders will be sent to patients' emails if the questionnaires are not completed after 2 weeks or if they are asked to fill them out during a follow-up visit in the hospital. Clinical data (eg, staging, treatment details, and demographics) will be extracted from the medical record during the study. Data will be coded and only accessible by the NKI research team on a secured server. Patient recruitment and data collection started in April 2023 and are currently ongoing.

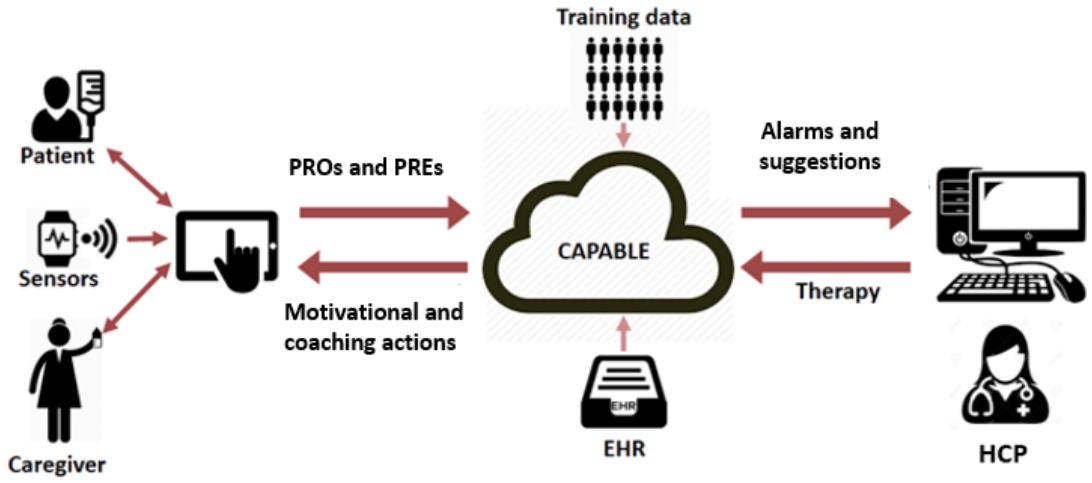
CAPABLE Intervention

Overview

CAPABLE is an eHealth tool consisting of front end and backend components (mobile app and smartwatch for patients, web-based dashboard for HCPs) that users interact with and that provide functionality related to decision support and coaching. CAPABLE monitors treatment-related symptoms and well-being and provides patients with extensive educational material and nonpharmacological evidence-based interventions called Virtual Capsules (VCs). VCs are developed using Fogg behavioral model [44] to help patients turn the proposed interventions into healthy habits. CAPABLE consists of several components that run on the backend of the system. Patient-reported information is made available to HCPs through the physician web dashboard, which can only be accessed by users in the private network of the hospital using personal credentials to login. Around 15 HCPs (medical oncologists and nurse practitioners in training) involved in the treatment of enrolled patients have access to the CAPABLE dashboard. Compared to usual clinical care, the CAPABLE dashboard is checked daily by the HCPs to see new alerts for entered symptoms or questionnaires. Besides this, existing care structures stay in place and symptom management is the same as in usual care. Figure 2 shows the overall structure of the CAPABLE system. CAPABLE will be connected 1-sided to the electronic health record (EHR), meaning the CAPABLE system can extract EHR data but cannot write back data into the EHR. Each component of the CAPABLE system will be deployed on a Virtual Machine provided by the hospital. Access to the Virtual Machines for the CAPABLE software developers will be possible through dedicated virtual private networks set up by NKI's information technology staff.



During the use of the CAPABLE system, the patient will be able to perform the following set of activities through the smartphone app:

- Report symptoms using a self-developed 130-item list derived from and based on the National Cancer Institute's (NCI) Common Terminology Criteria for Adverse Events (CTCAE) version 5 [45] and the Patient-Reported Outcome version of the CTCAE (PRO-CTCAE) standard term lists [46], which are considered self-reportable by the CAPABLE clinical expert team;
- Tracking and viewing activities and vital signs when wearing the smartwatch;
- Answer to periodic questionnaires concerning mental well-being;
- Work on well-being goals (eg, sleep improvement, improving physical or mental well-being, accepting the cancer journey) through interventions delivered by VCs;

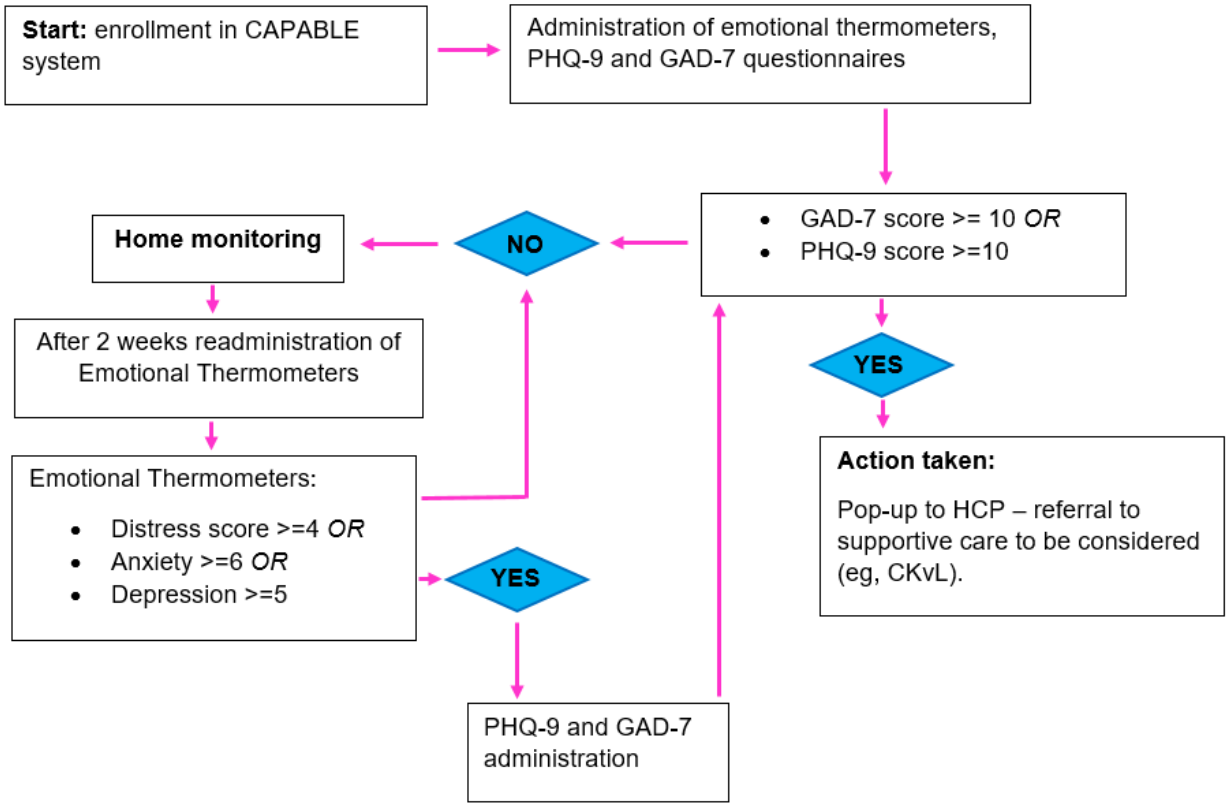
XSL•FO
RenderX

- Access evidence-based educational material regarding disease, treatments, side effects, lifestyle, well-being interventions, supportive care, and links to peer support.

Figure 2. Overall structure of the CAPABLE system; the CAPABLE backend (depicted as a cloud) is shown in the middle and connects to the mobile app on the patient side and the web-based dashboard on the HCP's side. CAPABLE: Cancer Patients Better Life Experience; EHR: electronic health record; HCP: health care professional; PRE: patient-reported experience; PRO: patient-reported outcome.

Symptom Monitoring

The CAPABLE smartphone app facilitates patient symptom reporting at any moment in time, based on when a symptom occurs for this patient. Patients can access their app, choose a symptom from the symptom list, and select the symptom description that matches their experience of the symptom. For each symptom, the patient can select the symptom description that matches the patient's experience of the symptom in terms of severity and impact on activities of daily living. These descriptions allow the CAPABLE app to get specific information about the experienced symptom and give appropriate feedback and advice to the patient and HCPs. Since the NCI's CTCAE grading system is intended for use by HCPs, it cannot be directly exploited as a symptom reporting system for patients. Furthermore, NCI's PRO-CTCAE list was not considered fully suitable for the purposes of CAPABLE. Therefore, we created a symptom list based on the full CTCAE list, from which we removed AEs that were not detectable by a patient or his or her caregiver, used a priority scoring system of involved HCPs, and made the remaining symptom list patient-friendly, when possible exploiting the PRO-CTCAE descriptions. The descriptions were constructed by following the structure of the PRO-CTCAE monitoring, namely, defining the symptom severity as "mild," "moderate," "severe," or "very severe" and defining interference with usual or daily activities as "a little bit," "somewhat," "quite a bit," and "very much." In addition, the CTCAE terms of the symptoms and information from the CTCAE grades were incorporated in the symptom description to help the patient distinguish between a "mild," "moderate," "severe," or "very severe" symptom. Symptoms can be mapped to grades in CTCAE version 5.



After a patient reports a symptom, the CAPABLE clinical decision support system provides feedback that is based on implemented computer-interpretable clinical guidelines for immunotherapy toxicity management (based on CTCAE version 5) and contact levels defined by participating clinicians. For example, the CAPABLE system can assign self-care instructions to the patient after reporting low-grade skin toxicity and will also send an alert to the HCP [5]. After clinical assessment of the entered symptom, the HCP can further decide how to manage the symptom [5]. The HCP will be able to report symptoms after seeing the patient during an outpatient visit. The list of symptoms provided to HCPs on the dashboard includes the full list of CTCAE terms and the related grading. Furthermore, the HCP receives specific recommendations related to the management of the reported symptoms. The dashboard is checked every workday by the HCPs. During the weekends, patients are instructed to call the hospital in cases of severe symptoms.

Monitoring Mental Well-Being

Besides the symptoms related to immunotherapy, the CAPABLE app also facilitates home monitoring of mental well-being through Distress (Emotional) Thermometers [47] and 2 protocolled and validated questionnaires: the Patient Health Questionnaire-9 (PHQ-9) [48] and Generalized Anxiety Disorder-7 (GAD-7) scale [49]. The management of the questionnaire outcomes is also performed by the CAPABLE clinical decision support system and is based on clinical cutoffs [49,50]. The management strategies have been thoroughly discussed with support consultants in the hospital and will allow a possible earlier referral to supportive care in the Center for Quality of Life in the hospital for further follow-up. The complete workflow for psychological follow-up is shown in Figure 3.

XSL•FO
RenderX

Figure 3. Psychological workflow in the CAPABLE system. CAPABLE: Cancer Patients Better Life Experience; CKvL: Center for Quality of Life; GAD-7: Generalized Anxiety Disorder-7; HCP: health care professional; PHQ-9: Patient Health Questionnaire-9.

Educational Material

In a previous study, we identified unmet information needs in patients with melanoma treated with ICIs and how this could be integrated into an eHealth tool [43]. Based on this study, we have developed a content list of information that should be provided in the CAPABLE app as educational material [43]. In more detail, the content of the educational material in the CAPABLE app consists of extensive information on the following topics:

- General melanoma content (diagnosis, diagnostic methods, causes, and prevention)
- Treatment with ICIs (information on the different immunotherapies)
- Side effects of ICIs (detailed descriptions per side effect)
- Experiences from fellow patients and peer support
- Supportive care options
- Nutrition
- Work and cancer
- Intimacy, sexuality, and cancer
- Adolescence and young adult care
- Other relevant topics (with links to external resources)

The content is created from evidence-based information leaflets already offered by the hospital and the European Society for Medical Oncology. Medical specialists and supportive care consultants from the hospital checked all content that was embedded in the CAPABLE mobile app.

Well-Being Interventions

CAPABLE offers patients a set of functionalities to set goals to work on various aspects of mental, physical, and social well-being at home. The interventions added to the CAPABLE system are nonpharmacological, evidence-based interventions that have been shown to improve the mental and social well-being of patients with cancer, as well as other stress-related conditions such as sleep problems and fatigue. The process works by setting specific goals for the patients (eg, sleep improvement) and selecting specific interventions to achieve those goals. Goal setting and intervention selection will be done together by the patient and HCP during the intake appointment, which facilitates shared decision-making. Interventions can serve multiple goals at once. It is always possible for the HCP to contraindicate an intervention for the patient if the conditions to perform the related activity are not met. The interventions available in the CAPABLE app and their related goals are listed below:

- Thai Chi (goals: improve sleep and insomnia, mental well-being, physical well-being) [51]
- Yoga Hatha or Nidra (goals: improve sleep and insomnia, mental well-being, physical well-being) [28]
- Walking in nature (goals: improve sleep and insomnia, mental well-being, physical well-being) [28]
- Breathing exercises and mindfulness (goals: improve sleep and insomnia, mental well-being)
- Imagery meditation (goals: improve sleep and insomnia, mental well-being) [52]

XSL•FO
RenderX

- Photo diary (goals: mental well-being, accepting the cancer journey) [53]
- Gratitude journal (goals: mental well-being, accepting the cancer journey) [54,55]

Smartwatch

Patients will also be provided with a smartwatch (the ASUS VivoWatch 5 HC-B05), which will be set up during enrollment. To ensure proper communication with the ASUS Life cloud platform (OmniCare), an additional app (OmniCare Hub, provided by ASUS Life) needs to be installed on the patients' smartphones. The smartwatch will collect data on heart rate and blood pressure, sleep (stages, hours, and performance), physical activity, and stress. However, data from the smartwatch is treated as ancillary data and will not be used for symptom monitoring or diagnosis.

Study End Points

Primary Outcome

The primary end point of this study is the change in fatigue between baseline and 3 and 6 months, as measured by The European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire-Core 30 (QLQ-C30) [56]. The changes in fatigue over time in the intervention cohort will be compared to the changes in fatigue over time in the control cohort. Fatigue is constructed out of 3 questions: "Did you need to rest?" "Have you felt weak?" "Were you tired?" Responses range from 1 (not at all) to 4 (very much) and are linearly transformed into a fatigue scale ranging from 0 to 100, with higher scores representing more experienced fatigue.

Secondary Outcomes

Secondary end points of this study are changes in physical symptoms and functioning scales [56], melanoma-specific HRQoL [57], utilities used for establishing quality-adjusted life years [58], anxiety and depression [59], patient-reported immune-related AEs and information needs [60] (Table 1). Furthermore, we will assess feasibility and patient-reported usability outcomes [61-63] at different time points (Table 1). Additionally, component-specific technical end points (clicks or completion of content in the patient app, accepted recommendations or clicks in the HCP dashboard), referrals to additional care, and the number of emergency visits will be measured.

HCPs using the CAPABLE system will retrieve extensive self-developed usability questionnaires consisting of questions about expectations, overall satisfaction, perceived impact, technical errors, ease and usefulness, efforts and resources, and the validated System Usability Scale (SUS) [64]. HCPs will receive these questionnaires after the first patient enrollment, after 1 month of using the system, and at the end of the study. They are covered in a different approved study protocol (P23CAP; IRBd23-012).

[a]CAPABLE: Cancer Patients Better Life Experience.

[b]PROM: patient-reported outcome measure.

[c]EORTC: European Organization for Research and Treatment of Cancer.

[d]QLQ-C30: Quality of Life Questionnaire-Core 30.

[e]HRQoL: health-related quality of life.

[f]Of the FACT-M, we use the Melanoma Subscale and the Melanoma Surgery Subscale, items specific to quality of life in patients with melanoma. High scores show a high quality of life. Testing has shown that the FACT-M is a reliable and valid instrument to assess quality of life in patients with melanoma.

[g]The EQ-5D is a standardized 5-level, 5-dimensional multi-attribute utility questionnaire that measures mobility, self-care, usual activities, pain/discomfort and anxiety/depression, using a five dimension scale.

[h]Psychological distress will be assessed with the Hospital Anxiety and Depression Scale (HADS). The HADS, a 14-item questionnaire, assesses symptoms of mood disturbance, yielding separate scale scores for anxiety and depression, as well as a total score.

[i]Immunotherapy-specific questionnaire. In assessing quality of life in patients with cancer, it is recommended to use a generic and cancer-specific measure of quality of life plus a treatment-specific questionnaire. However, to date the available validated measurements do not include the problems and symptoms of immunotherapy. Therefore, we identified, based on literature and expert opinion, 19 symptoms and created a symptom list based on items of the EORTC item Library.

[j]Fulfilment of information needs will be measured by the EORTC QLQ-INFO25 questionnaire. This validated 25-item questionnaire incorporates four information provision subscales: perceived receipt of information about the disease, medical tests, treatment and other care services.

[k]QLQ-INFO25: Quality of Life Questionnaire-Information 25.

Sample Size Calculation

As this is an exploratory study, a rough sample size calculation was performed based on preliminary changes in fatigue in the control cohort and feasibility parameters. In the control cohort (currently composed of 70 patients with melanoma that started with ICIs), an increase of 15 points in fatigue is shown in the first 3 months of treatment (nonpublished data). When providing the CAPABLE system to patients in the pilot study, we expect

XSL•FO
RenderX

significantly less worsening of patients' fatigue levels (by 5 points less increase in fatigue). With a 10-point difference and an SD of 20, the selected effect size is 0.5. Since the inclusion period is restricted to 6 months due to project obligations, we use an enrollment ratio of 0.3 (two-third of the control cohort and one-third of the CAPABLE cohort). Together with a 2-sided α of .05 and an accepted power of 70%, the needed sample size would be 139 patients, of whom 107 will be enrolled in the control cohort and 32 will be enrolled in the CAPABLE pilot study. We anticipate a dropout rate of 5%-10% because of unforeseen rapidly progressive diseases that might occur in this patient population. Questionnaire dropouts are considered minimal because the research team will see the patient around their 3- and 6-month follow-up at the patient's hospital appointments. A compliance rate of 60% to participate in and use the CAPABLE system is considered feasible and clinically acceptable, meaning 36 patients have to be included to meet this feasibility end point. Therefore, we need to have 60 eligible patients in the 6-month inclusion period.

Statistical Methods

Descriptive statistics will be calculated to provide information about the patient population. The mean scores of fatigue and other questionnaire outcomes will be calculated using algorithms in the existing literature, and these scores will be used as end points for analyses. Summarizing and visualizing methods such as line graphs will be used to make the data more interpretable. Effect sizes will be calculated using standard statistical procedures. The difference in fatigue (improvement or worsening) over time (baseline and follow-up moments) will be analyzed either using a linear mixed model or generalized estimating equation analysis. We will adjust for baseline patient-reported outcome scores and other covariates such as sociodemographic variables, disease, and treatment characteristics. To compare the mean fatigue scores between the group receiving the CAPABLE intervention and the control group at each individual time point, we will use *t* tests or Mann-Whitney U tests. Patients will be individually matched on sex, age, tumor staging (stage III or IV), and treatment (mono- or combination therapy). For differences in fatigue between the groups over time, we will use repeated measures ANOVA. A *P* value of <.05 will be seen as statistically significant; however, according to Cocks et al [65], a mean difference in change scores (per subdomain) can be seen as clinically relevant even if this is not statistically significant. Therefore, statistical and clinically meaningful differences will be analyzed. However, as this is an exploratory study, analysis will mostly consist of descriptive statistics, as *P* values are expected to render most outcomes nonsignificant.

Missing items from the questionnaires will be imputed according to the corresponding guidelines. The scale scores of the EORTC QLQ-C30 will be set to missing if fewer than half of the items on a given scale are answered. Where at least 50% of the relevant scale scores will be present, the missing values can be replaced by the mean of the present values. Statistical analyses will be done using R (R Core Team) [66].

Patient and Public Involvement

One of the CAPABLE consortium members is an Italian patient association that was involved in the development of the CAPABLE app. Furthermore, the development of CAPABLE went through multiple research phases. Patient and clinician interviews were held to establish baseline needs and wish for the CAPABLE system (P20CAP; IRBd20-085), of which a paper is published [43]. HCPs provided valuable input for the clinical validation of the implemented guidelines. Furthermore, multiple patients and HCPs provided their valuable input to enhance the quality of the system during the development of the CAPABLE app through multiple usability testing rounds (P21CAP; IRBd21-139). The results of the study will be communicated to participants if wish.

Ethics Approval

Ethical approval was granted by the Medical Ethical Committee of NedMec (Amsterdam, The Netherlands) under reference number 22-981/NL81970.000.22. Any amendments will be reviewed by this Medical Ethical Committee. CAPABLE is registered as a medical device trial according to the Medical Device Regulation, article 62. The trial is prospectively registered at ClinicalTrials.gov (NCT05827289). Original informed consent signed by patients allows for the analysis of the primary and secondary outcomes of this study. In case additional data needs to be analyzed, additional informed consent will be asked. Subject data will be pseudonymized and key-coded. No compensation is provided to participating patients. This study is conducted in accordance with the principles of the Declaration of Helsinki, version 9, October 2013, and the Medical Research Involving Human Subjects Act (WMO), including International Organization for Standardization (ISO) 14155 (medical device use).

Results

Inclusion in this trial started late in April 2023 and is currently enrolling. We expect to finalize inclusion by the end of August 2023. The expected last follow-up measurement will be collected in February 2024, after which data cleaning and data analysis will start. Preliminary data analysis will be carried out in December 2023 due to a project deliverable deadline by the end of December 2023.

Discussion

In this pilot study, we will explore the effect of using the CAPABLE app immediately after melanoma diagnosis in 36 patients, providing symptom monitoring, education, and well-being interventions during their first phase of treatment with ICIs, on 3- and 6-month HRQoL outcomes such as fatigue and functioning, and the patient acceptability of using a system such as CAPABLE. Since treatment with ICIs is becoming standard therapy for patients with high-risk and advanced melanoma, more and more patients experience treatment-related AEs. One of the most common symptoms of this treatment is fatigue. Consequently, a decrease in short- and long-term HRQoL can occur in these patients. An approach to improving symptom control and HRQoL outcomes is to use an eHealth

XSL•FO
RenderX

tool. eHealth apps may contribute to improving HRQoL by addressing the unmet supportive care and information needs of these patients by enabling autonomy and self-management. Moreover, eHealth tools have shown promising results in improving fatigue by stimulating physical exercise, psychoeducation, mindfulness-based interventions, and yoga. However, previous studies focused on eHealth apps providing either symptom monitoring or interventions targeting fatigue.

It is hypothesized that the CAPABLE intervention will limit the increase in fatigue in patients with melanoma receiving ICIs by 10 points at 3 months after the start of treatment compared to a similar patient group receiving standard care. Furthermore, it is hypothesized that the system will be feasible to implement during ICI treatment in clinical practice. This system will be evaluated by 36 patients for 3-6 months from the start of their ICI treatment. End points of the study will be measured at baseline, 3 months, and 6 months after the start of treatment.

Several limitations of this pilot study should be noted. First, the intervention period will be 3 to maximally 6 months due to the limited number of well-being interventions in the mobile app and information provision focusing on the first period of treatment. Therefore, we will not be able to evaluate the long-term effects of the CAPABLE mobile intervention. Second, the inclusion period will be restricted to 6 months, as the time frame of the study is limited by project restrictions and available funding. Third, the control group is collected before the intervention group (ie, the CAPABLE cohort). Because of time restrictions in the project and the limited number of patients available in the hospital, it was necessary to create 2 separate prospective cohorts instead of using a randomized design. Moreover, the control group was collected during the COVID-19 pandemic, and this might have negatively influenced the HRQoL outcomes. Furthermore, we chose the short EORTC QLQC30 fatigue scale to measure our primary outcome, as we already use this questionnaire in our daily clinical routine, facilitating future implementation. As it is short, it minimizes patient burden. Furthermore, it was previously shown that there was no difference in chronic fatigue as measured by the EORTC QLQ-C30 and the validated Fatigue Assessment Scale (FAS) in Hodgkin lymphoma survivors [67]. Lastly, this pilot study does not include the possible relevance of supportive care provided for patient's informal caregivers. It is well-known that informal caregivers or relatives of patients with cancer experience high caregiver burden and distress [68]. eHealth interventions could offer a convenient approach for providing support to the informal caregivers of individuals facing cancer [69]. Future studies with the CAPABLE app should focus on including support for informal caregivers.

Nevertheless, this pilot trial has several strengths, including the prospective study design of the CAPABLE group and the control group. Furthermore, both study groups are collected from a population receiving standard care and do not participate in experimental trials. The CAPABLE smartphone app is developed following user-centered design principles and in close collaboration with patients, app developers, component developers, and technical and clinical staff. Initial prototypes were built after content-generating interviews with patients and HCPs, following 3 rounds of user experience and user interface testing in both target populations. Consequently, the content offered in the CAPABLE app is of high quality and reviewed by the local medical staff in collaboration with patients. Last, although not primarily focusing on evaluating the change in care structures, it is worth mentioning that an eHealth tool such as CAPABLE may lead to earlier intervention for immune-related AEs and psychological complaints. A future and larger trial should focus on the impact of the implementation of such tools and their effect on existing care structures.

In conclusion, the CAPABLE pilot study will provide preliminary evidence about the effect, usability, and feasibility of the CAPABLE system, which may encourage further studies with this eHealth app. A similar pilot trial with the same CAPABLE system but for another population is currently enrolling patients in an Italian hospital. These studies will be the first to provide a system containing symptom monitoring, information provision, and well-being interventions in one eHealth tool. When positive results are generated on the primary outcome, outcomes should be validated in a larger randomized controlled trial, keeping end points for possible implementation in mind. Adding the CAPABLE system to active treatment is hypothesized to decrease fatigue in patients with high risk and advanced melanoma during treatment with ICIs compared to a control group receiving standard care.

Acknowledgments

This work was supported by the European Union's Horizon 2020 research and innovation program (grant 875052). The CAPABLE system was developed during the first 3 years of an EU project funded under the Horizon 2020 Research and Innovation Program. CAPABLE is a 4-year project coordinated by the University of Pavia, Italy, and carried out by 12 partners in Europe and Israel. We would like to thank all the partners and participants involved in this and previous CAPABLE-project studies.

Data Availability

The data sets generated during or analyzed during this study are not publicly available due to the sensitive information of patients in this data set, but are available from the corresponding author on reasonable request.

Abstract

Background: Sexual assault (SA) can lead to a range of adverse effects on physical, sexual, and mental health, as well as on one's social life, financial stability, and overall quality of life. However, not all people who experience SA will develop negative functional outcomes. Various risk and protective factors can influence psycho-socio-judicial trajectories. However, how these factors influence trauma adaptation and the onset of early posttraumatic stress disorder (PTSD) is not always clear.

Objective: Guided by an ecological framework, this project has 3 primary objectives: (1) to describe the 1-year psycho-socio-judicial trajectories of individuals recently exposed to SA who sought consultation with a forensic practitioner; (2) to identify predictive factors for the development of PTSD during the initial forensic examination using artificial intelligence; and (3) to explore the perceptions, needs, and experiences of individuals who have been sexually assaulted.

Methods: This longitudinal multicentric cohort study uses a mixed methods approach. Quantitative cohort data are collected through an initial questionnaire completed by the physician during the first forensic examination and through follow-up telephone questionnaires at 6 weeks, 3 months, 6 months, and 1 year after the SA. The questionnaires measure factors associated with PTSD, mental, physical, social, and overall functional outcomes, as well as psycho-socio-judicial trajectories. Cohort participants are recruited through their forensic examination at 1 of the 5 participating centers based in France. Eligible participants are aged 15 or older, have experienced SA in the last 30 days, are fluent in French, and can be reached by phone. Qualitative data are gathered through semistructured interviews with cohort participants, individuals who have experienced SA but are not part of the cohort, and professionals involved in their psycho-socio-judicial care.

Results: Bivariate and multivariate analyses will be conducted to examine the associations between each variable and mental, physical, social, and judicial outcomes. Predictive analyses will be performed using multiple prediction algorithms to forecast PTSD. Qualitative data will be integrated with quantitative data to identify psycho-socio-judicial trajectories and enhance the prediction of PTSD. Additionally, data on the perceptions and needs of individuals who have experienced SA will be analyzed independently to gain a deeper understanding of their experiences and requirements.

Conclusions: This project will collect extensive qualitative and quantitative data that have never been gathered over such an extended period, leading to unprecedented insights into the psycho-socio-judicial trajectories of individuals who have recently

XSL•FO
RenderX

experienced SA. It represents the initial phase of developing a functional artificial intelligence tool that forensic practitioners can use to better guide individuals who have recently experienced SA, with the aim of preventing the onset of PTSD. Furthermore, it will contribute to addressing the existing gap in the literature regarding the accessibility and effectiveness of support services for individuals who have experienced SA in Europe. This comprehensive approach, encompassing the entire psycho-socio-judicial continuum and taking into account the viewpoints of SA survivors, will enable the generation of innovative recommendations for enhancing their care across all stages, starting from the initial forensic examination.

Introduction

Background

In recent years, sexual assault (SA), defined by French law as any form of sexual abuse involving violence, coercion, threats, or surprise, and occurring without clear and explicit consent, has gained recognition as a public health issue. Research indicates high prevalence rates of SA [1] and highlights its association with numerous negative outcomes, including effects on physical, sexual, and mental health; social life; financial stability; and overall quality of life [2]. It is recognized as one of the most traumatic events [3-5]. However, not everyone who experiences SA will necessarily develop negative functional outcomes. Various protective and risk factors can influence their psycho-socio-judicial trajectories. One of the most comprehensive models for categorizing these factors is the ecological model developed by Campbell, Dworkin, and Cabral [6]. This model is based on Ecological Theory [7], which classifies factors according to the environment in which they develop in relation to the individual.

Although there is a growing body of literature on the characteristics associated with negative outcomes and the utilization of medical, social, and legal resources, the precise manner in which these characteristics influence trauma adaptation remains unclear and does not enable the prediction of psycho-socio-judicial trajectories. Following an ecological framework, this project aims to advance research in this area using mixed longitudinal data and artificial intelligence (AI) to delineate the 1-year psycho-socio-judicial trajectories of individuals who recently experienced SA. Additionally, it seeks to identify predictive factors for the development of posttraumatic stress disorder (PTSD). Furthermore, it serves as an exploratory study of the needs and experiences of people who experienced SA and the available resources for them in France.

Sexual Assaults and Negative Functional Outcomes

Data from the Global Burden of Disease study revealed that the global prevalence of SA in 2017 was 11.6% for men and 27.5% for women [1]. However, prevalence rates vary greatly depending on the definition of SA adopted by researchers, the research settings, and the study populations. A review of literature on SA prevalence outside of North America since 2010 revealed that past-year prevalence rates ranged from 0% to 59.2% for women, 0.3% to 55.5% for men, and 1.5% to 18.2% for individuals identifying as lesbian, gay, bisexual, and gender-diverse [8].

The literature demonstrates that SA can have a substantial impact on the quality of life and functional outcomes, affecting physical and sexual health, behaviors, financial stability, social life, as well as psychological and psychiatric well-being [2,9-11]. Among the various outcomes of SA, psychological and psychiatric effects have been extensively studied, with a particular focus on PTSD due to its strong association with SA. Indeed, US and international population–based studies indicate that the lifetime prevalence of PTSD ranges from 4% to 7% among individuals who have experienced any type of traumatic event [3-5]. However, for those who have endured rape and other forms of SA, these lifetime prevalence rates vary significantly, ranging from 17.4% to 65% [3-5], highlighting SA as one of the most profoundly traumatic experiences.

Factors Associated With SA Negative Outcomes

Functional outcomes can vary considerably and are influenced by a multitude of protective and risk factors. Campbell, Dworkin, and Cabral [6] developed a framework to examine the diversity of these factors [6]. This framework is based on Bronfenbrenner's Ecological Theory [7], which states that human development "evolves as a function of the interplay between person and environment" [7]. The authors adapted this framework to comprehend "how factors at multiple levels of the social ecology contribute to (...) deleterious mental health effects" [6]. It is one of the most comprehensive models to date as it classifies protection and risk factors into 7 levels depending on the environment in which they interact with the person. Using the same levels as defined by Campbell, Dworkin, and Cabral [6], we included in this review factors associated with negative mental health outcomes, overall recovery, and quality of life.

Individual-level factors represent the intrinsic characteristics of individuals that can affect their mental health and recovery after SA [6]. These are sociodemographic factors [6,11-16], preexisting mental health conditions and family history of mental health problems [6,17-19], and coping strategies [6,20-23]. Coping strategies encompass both positive strategies such as religious coping [24,25] and maladaptive strategies such as self-blame, which is related to more PTSD and depressive symptoms [6,20,26]. Campbell, Dworkin, and Cabral [6] conceptualized this last factor as a meta-construct, arguing that

XSL•FO
RenderX

it transcends any single level of the model as it is influenced and enhanced by factors across all other levels.

Characteristics of the assault, such as the perceived life threat during the assault and the perceived dangerousness of the assailant, have been linked to negative mental health outcomes, as evidenced by research on SA [6]. These factors are also associated with general trauma [18,19]. Peritraumatic factors, including peritraumatic distress and dissociation, may also serve as moderate to strong predictors of PTSD, especially in cases of interpersonal violence [18,19], although documentation of these factors is relatively scarce.

The microsystem level is defined as the "face-to-face interactions and interrelations between individuals and others in their immediate setting" [6,7]. It encompasses factors such as a lack of social support, which is considered one of the most important risk factors for mental disorders [18,19,27]; and negative reactions following disclosure, which can severely impede recovery [6,27] and are associated with posttraumatic distress [28] and self-blame [29]. By contrast, positive social reactions are shown to lower psychological distress [6] and are associated with positive life changes [28].

The meso/exosystem level, as defined, involves interactions with the formal system [6]. This encompasses both positive formal support and instances of secondary victimization within the legal, medical, and mental health systems, as well as within the advocacy community. Perceptions of social reactions from formal responders have been associated with psychopathology [6,27]. However, results are not always consistent between studies: the only study to our knowledge to compare formal and informal support showed that reactions from formal providers, regardless of whether the reaction was positive or negative, were not associated with more general psychological distress; however, positive reactions were associated with benefits in the aftermath of trauma [28]. Regarding various forms of formal support, the literature indicates that the legal system tends to have the most adverse impact on mental health due to the prevalence of questions blaming the impacted individual. Additionally, the medical system has been shown to exacerbate PTSD symptoms [6,30]. By contrast, the mental health system and the advocacy community have been found to be supportive and beneficial for individuals who have experienced SA, especially those who have had negative experiences with the legal and medical systems. These entities can help mitigate the adverse effects of such experiences [6].

The macrosystem level is defined as "consistencies, in the form and content of lower-order systems (…) that exist, or could exist, at the level of the subculture or the culture as a whole, along with any beliefs systems or ideology underlying such consistencies" [7]. It includes sociocultural factors such as race/ethnicity when explored from a sociocultural perspective [6,15]. Given that the definitions of "victim," "survivor," and "trauma" are influenced by societal imaginaries or representations [31], we have placed the impact of labeling individuals who have experienced SA as "victim" or "survivors," and the SA event itself as "trauma," within the macrosystem. Research has demonstrated that such labeling can have detrimental effects on their social life and their sense of self [32-35].

The chronosystem level examines "the cumulative effects of multiple sequences of developmental transitions over the life course" [6]. Research has shown that a prior history of SA and a history of other forms of violence exposure and reexposure are related to more negative psychological outcomes, which may be cumulative [6,36]. Besides, it is well-established that a history of trauma is a predictive factor for PTSD, regardless of the type of trauma experienced [18,19].

The multitude of factors and their complexity could explain the heterogeneity observed in the trajectories of individuals who have experienced SA [6,19].

Limits of the Current Literature

Despite a growing body of literature, how these characteristics impact adaptation to trauma remains unclear [36,37] and does not provide us with the means to characterize psycho-socio-judicial trajectories [38]. Similarly, some factors remain unexplored, such as the impact of formal support on mental health outcomes [19,27,36,37]. Consequently, given that the conventional approach of predicting the development of PTSD using bivariate analyses and traditional multiple regression analysis has shown limited success, it is pertinent to investigate new predictive methods, such as AI. There are several reasons why AI might outperform conventional regression analyses: it automates the identification of hidden interactions and nonlinearities among features, enables the handling of larger and more complex data sets, and facilitates the integration of information from highly diverse sources. Additionally, it reduces the likelihood of overestimating prediction performance when dealing with numerous highly correlated independent variables [39,40]. Moreover, AI statistical algorithms represent an inductive approach, in contrast to traditional approaches that are hypothesis driven [41]. This makes AI useful for discovering unknown mechanisms [41] and uncovering relationships between data that may not be discernible through traditional statistics [39].

To date, fewer than 100 studies have used AI for predicting PTSD following a traumatic event using clinical and biological data. These studies have demonstrated a good predictive ability, with area under the curve values ranging from 75% to 98% [42,43]. However, to the best of our knowledge, only 1 study [44] has specifically included adults who experienced SA in its sample, and it reported poor predictive ability (area under the curve 64%). Moreover, other useful indicators, such as sensitivity (ie, the capacity to give a positive result when the hypothesis is verified) and specificity (ie, the capacity to give a negative result when the hypothesis is not verified), appear necessary to judge the usefulness of AI algorithm in routine clinical practice but seem to be missing in these studies, hindering the interpretation of the results and evaluation of relevance. It is therefore necessary to explore in more detail the utilization of AI to predict the onset of PTSD for people who experienced SA and to measure its usefulness for forensic services.

XSL•FO
RenderX

Furthermore, there has been minimal research conducted on the accessibility and effectiveness of support services, including psychiatric and psychological follow-ups, legal assistance, and support from associations, in Europe [38]. Thus, conducting an assessment of the functionality and quality of available resources in France is essential to describe psycho-socio-judicial trajectories accurately and to offer services that are better aligned with the needs of individuals who have experienced SA.

Study Objectives and Aims

This study is structured into 3 major components, each fulfilling a distinct primary objective. Our first objective is to delineate the 1-year psycho-socio-judicial trajectories of individuals who have recently encountered SA and sought consultation with a forensic examiner. We hypothesize that there exist several typical psycho-socio-judicial trajectories among individuals who have recently experienced SA and sought assistance from a forensic practitioner in France. However, we also believe that a multitude of individual and contextual factors and circumstances play a crucial role in conjunction with the characterization of these trajectories [19,30].

Our second objective is to use AI to identify predictive factors for the development of PTSD. We posit that AI may be a more effective method for this prediction compared with traditional statistical methods such as multiple regression analysis [39]. A secondary goal within this primary objective is to develop an algorithm capable of screening for PTSD symptoms based on clinical criteria that are accessible during the initial forensic examination.

Our third objective is to examine the concepts of "victim" and "trauma" and enhance the understanding of SA from the perspective of individuals who have experienced it. We hypothesize that the significance and representation associated with the terms "victim" and "trauma" are either socially imposed on individuals who have experienced SA or ascribed by those involved in their recovery. However, these representations are expected to differ significantly and qualitatively from the perceptions held by the individuals directly affected by them [31,34]. Additionally, this investigation will enable us to assess the functioning and quality of available resources.

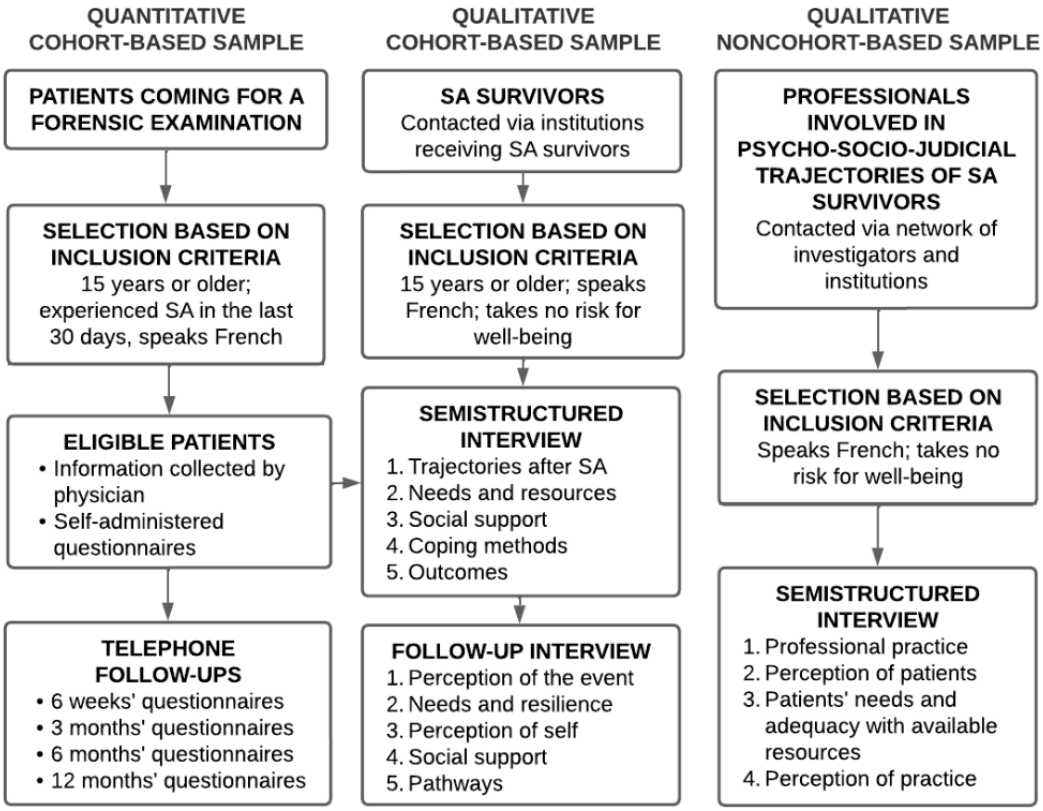
Methods

Overview

The research team consists of 14 professionals with expertise in forensic sciences, anthropology, psychiatry, law, criminology, and data sciences. Together, they are involved in the development and execution of our research project, named "Intelligence Artificielle, Dépistage et trajectoires psychosociojudiciaires des victimes de Violences Sexuelles" (IADViSe), which translates to "Artificial Intelligence, Screening, and Psycho-Socio-Judicial Trajectories of Sexual Violence Victims".

Overall Study Design

Our study is a longitudinal multicentric cohort study that uses mixed methods. Quantitative data will be gathered through repeated questionnaires administered over the course of up to a year following the SA. Qualitative data will be obtained through semistructured interviews conducted with members of the cohort, individuals who have experienced SA but are not part of the cohort, and professionals involved in their psycho-socio-judicial care. Similar to many medical and epidemiological studies [2], and given that our primary sample comprises individuals who have reported recent SA and have been referred to a medical practitioner for a formal examination, our study focuses solely on nonconsensual sexual acts that involve physical contact. This includes the legal concepts of SA (sexual contact committed by force, coercion, threats, or surprise without the clear and explicit consent of the person) and rape (SA with penetration), but excludes harassment and exhibitionism.



Participants

Cohort Participants

An integral component of our project involves establishing a cohort of individuals who have recently experienced SA and have undergone a forensic examination, whether it was court ordered or not. This cohort will serve as the source for longitudinal quantitative and qualitative data collection (Figure 1).

XSL•FO
RenderX

Figure 1. Inclusion and follow-ups stages of participants. SA: sexual assault.

Participant Recruitment

Participants are being recruited during their examinations for recent SA by physicians at 1 of the 5 participating forensic medical centers or medico-legal units in Île de France, which include Hotel-Dieu Hospital in Paris, Jean Verdier Hospital in Bondy, the Inter-communal Hospital Center of Créteil, the Sud Francilien Hospital in Corbeil-Essonnes, and the Versailles Hospital Center. During these examinations, physicians provide patients with consent forms that outline the purpose and methodology of the research. If patients choose to sign the consent form, their initial information and contact details are shared with one of the investigators (EF, VT, TS, or JO) responsible for follow-ups at 6 weeks, 3 months, 6 months, and 1 year after the SA. Additionally, participants are asked if they are willing to participate in interviews. If they agree, we arrange 1-3 meetings in a private setting of their choice to review the responses provided in the questionnaires and to discuss any other topics they wish to address, including their self-representations and perceptions of the SA.

Inclusion Criteria

We will include all individuals who undergo an SA forensic examination at 1 of the 5 forensic centers where the study is conducted, provided they consent to participate, are aged 15 or older, and have experienced SA within the last 30 days. The 30-day limit is set because one of our main objectives is to investigate the onset of PTSD, which can be formally diagnosed if symptoms persist for more than 1 month, in accordance with criterion F of the 5th edition of the Diagnostic and Statistical Manual of Mental Disorders [45].

Exclusion Criteria

We will exclude individuals for whom callbacks are challenging or impossible and those who do not possess sufficient proficiency in French to independently complete the questionnaires.

Feasibility

The potential number of participants to be included will vary depending on the clinical activity of each forensic center where the study is conducted. When considering all participating centers, there is the potential to include between 500 and 650 individuals annually. As participation in this study is entirely voluntary and offers no immediate benefits to the patients, we anticipate that not everyone will choose to participate. As a result, our recruitment period is expected to extend over a minimum of 2-3 years.

Noncohort Participants

Overview

The data gathered from the cohort are supplemented with qualitative interviews involving individuals outside the cohort (Figure 1). These interviews include individuals who have experienced SA but were recruited through alternative methods, as well as professionals engaged in the psycho-socio-judicial care of SA survivors.

Participants Recruitment

We are recruiting noncohort participants through the networks of our investigators and by promoting our study in various organizations that assist individuals who have experienced SA, such as survivor support associations, police stations, forensic

XSL•FO
RenderX

centers, regional psychotrauma centers, and more. In each organization, our designated contact person is responsible for disseminating a recruitment poster containing the investigators' contact details, both within the organization and throughout its network where applicable. This information is shared via their website, mailing lists, in their offices, or on their social media platforms. Individuals who are interested can then reach out to the investigators to arrange a meeting. We will continue to add participants until we reach saturation.

Inclusion Criteria

To be eligible for participation, individuals must be aged 15 or older, have a history of experiencing SA or work closely with individuals who have experienced SA, provide their consent to participate in the research, and possess sufficient proficiency in French to be interviewed without requiring a translator.

Exclusion Criteria

Individuals who are unable to arrange a face-to-face or video meeting in a location that ensures their privacy and does not jeopardize their well-being will be excluded from participation.

Ethical Considerations

All procedures, including the process of obtaining informed consent, underwent a thorough ethical review and received approval from the Research Ethics Committee of Paris Cité University (institutional review board approval number: 00012022-14, date: April 5, 2022). All experiments and methodologies are conducted in strict accordance with the principles outlined in the Declaration of Helsinki**.**

Informed consent is obtained from all study participants through the signing of a printed consent form. This form explicitly outlines the study's objectives, methodology, and associated risks. The consent process is facilitated either by the physician during the forensic examination or by one of the investigators at the commencement of the first interview for noncohort participants. Physicians and investigators are readily available to address any questions or concerns that participants may have regarding the study. Furthermore, participants are informed of their right to withdraw from the study at any point in time.

Participants may be experiencing latent psychological distress, with or without PTSD, either in the usual aftermath of the events or potentially triggered during the forensic examination or telephone contacts and interviews. However, most of these risks are not attributable to the research project itself. The security of participants during the forensic examination is the responsibility of the medical examiner, who follows the safety guidelines required by their department. To ensure the security of participants during and between follow-ups, investigators, all of whom are trained in dealing with people who have been exposed to SA, remind participants that some questions may be triggering, emphasize their right to stop their participation at any moment and ensure that participants are not in distress at any time during the call. As they are already part of an identified medical and psychological care system, participants will be asked to contact the forensic medical center where they were received if necessary. A list of professionals and resources is also provided to all participants for information and guidance. Participation is voluntary and does not include compensation, but it can be beneficial to participants who need to discuss their experiences.

Each participant is assigned an inclusion number to anonymize the database entries and questionnaires. Physicians or investigators record identifying and contact information in tables outside the database, allowing each participant to be linked to their inclusion number and recontacted. The audio of the interviews is recorded, transcribed, and anonymized with the same embedding code where applicable. All documents allowing the identification of the participants are securely stored and located in each participation center and will be destroyed as soon as the data collection is completed. After the data collection is completed and the database is appropriately anonymized and cleaned, the data and all necessary materials for their use will be uploaded to a public archive, such as HAL (Hyper Article en Ligne, which translates to Online Hyper Article), under a CC (creative commons) license, in compliance with the FAIR (Findable, Accessible, Interoperable, Reusable) principles and GDPR (General Data Protection Regulation) regulations.

Quantitative Measures

Quantitative measures at each time point are presented in Table 1. Initial data are collected during the forensic examination. The physician completes a questionnaire (see Multimedia Appendix 1) based on information that forensic practitioners routinely collect for their report to the criminal justice system. The questionnaire is adapted from a previously constructed questionnaire [46], which is still in use today by forensic practitioners in the Department of Forensic Medicine at the Jean Verdier Hospital (Bondy, France). Participants are also asked to complete 2 self-assessment questionnaires on peritraumatic dissociation and distress. Investigators contact the participants again at 6 weeks, 3 months, 6 months, and 1 year after the SA so that they can answer follow-up questionnaires regarding their health, support, and the status of their judicial proceedings. These follow-up sessions do not exceed 40 minutes.

Individual Factors

Sociodemographic Variables

Sociodemographic data are first collected during the initial examination. These include participants' age (in years) and gender (1=female, 2=male, and 3=other), the name of the forensic center in which the examination took place, the anonymized identity of the practitioner, and the time between the assault and the examination (in hours). Complementary sociodemographic variables are collected during follow-ups. These include marital status (0=never married, 1=married, 2=separated, 3=divorced, 4=widowed, and 5=cohabitation) and employment status (1=employee, 2=independent worker, 3=unpaid worker, 4=student, 5=housewife/husband, 6=retired, 7=unemployed due to health reasons, 8=unemployed for another reason, and 9=other), which are based on sociodemographic information measured in the World Health Organization Disability Assessment Schedule 2.0 (WHODAS 2.0) questionnaire [47]. The level of education (from 0=no diploma to 10=master's degree; and 11=other) is based on the sociodemographic questions in the 2019 Health Barometer Study [48]. Sexual identity (1=heterosexual, 2=gay or lesbian, 3=bisexual or pansexual, and 4=other) is based on an item recommended by the University of California (UCLA) Sexual Minority Assessment Research Team (SMART) team [49]. We created an item to collect information about gender diversity identification (0=no and 1=yes). The last sociodemographic variable collected is ethnicity/race (1=White, 2=Black, 3=Middle Eastern, 4=Hispanic/Latinx, 5=Asian, and 6=other) and is based on the recommendation from Public Health Ontario [50] and adapted to a French context.

Medical and Psychiatric History and Treatments

We will collect data recorded by the practitioners during the initial examination, including a history of serious or chronic diseases, personal and familial psychiatric history, and current medical treatments that could impact psychological well-being (eg, mood stabilizers, anxiolytic, hypnotic, antidepressant, neuroleptic, analgesic drugs).

Coping

Coping strategies are measured at each follow-up (6 weeks, 3 months, 6 months, and 1 year) using the French version [51] of the Brief-COPE [52]. This 28-item instrument measures the frequency with which an individual uses different positive and maladaptive coping strategies on a 4-point Likert scale ranging from 0=not at all to 3=a lot. The Brief-COPE and the COPE inventory are widely used tools for assessing coping strategies and have been translated and validated in at least seven languages, facilitating international replication and comparisons [51]. The French version of this instrument demonstrates good psychometric properties [51].

Follow-Up Substance Use

Tobacco, alcohol, delta-9-tetrahydrocannabinol, and benzodiazepine use since the assault is assessed at each follow-up (6 weeks, 3 months, 6 months, and 1 year) by inquiring whether participants use each substance and whether their consumption has increased or decreased since the assault [53]. If participants report using these substances, follow-up questionnaires are administered to assess whether their use of each substance is problematic. This assessment is performed using the 2-item simplified Fagerström test [54], a French version of the Heaviness of Smoking Index (HSI) [55], the French version of the Cut Annoyed Guilty Eye-Opener (CAGE) test (Diminuer Entourage Trop Alcool; DETA) [56], the French version of the Cannabis Abuse Screening Test (CAST) [57], and the Echelle Cognitive d'Attachement au Benzodiazépine (Benzodiazepine Cognitive Attachment Scale; ECAB) [58]. All of these instruments are validated and recommended by the French High Authority for Health.

Assault Characteristics

Standard consultation information about the assailant (ie, number, gender, age, relation to the impacted individual, and alcohol or substance use), the aggression (ie, location of the assault, types of violence, and context of the assault), and the impacted individual (ie, physical defense reaction, amnesia, chemical submission, and substance or alcohol use) is collected during the initial forensic examination as part of the physicians' routine screening.

Microsystem (Informal Support System)

We will assess social support during follow-ups at 6 weeks, 3 months, 6 months, and 1 year using the *Questionnaire sur les réactions nuisibles et aidantes de l'entourage lors d'un dévoilement de violences à caractère sexuel – Version francophone adaptée* (RNAE-22) [59]. This questionnaire is a French version of the Social Reaction Questionnaire–Short (SRQ-S) [60] adapted to be applicable to all genders. This instrument measures the frequency of positive and negative social reactions to an SA disclosure on a 5-point Likert scale ranging from 0=never to 4=always. Items are split into 3 subscales describing the behavior of people receiving the disclosure: Turning against, Unsupportive acknowledgment, and Positive support, which have been validated in their original [60] and French versions [59].

Exosystem (Formal Support System)

Use of Judicial, Medical, Mental Health, and Community Services

The use of different formal services (judicial, medical, psychological, and community) is measured at each follow-up (6 weeks, 3 months, 6 months, and 1 year) with questions built by the research team based on empirical findings and the perspective of care providers and legal professionals, such as "Have you filed a complaint with the police department?" We inquire about the evolution of medical, psychological, and community care, as well as the progress of the legal procedure at each follow-up.

Quality of Contact With the Exosystem

The quality of the contact between the physician and the patient is initially measured during the initial examination, where the physician is asked to rate it on a scale ranging from 0=very bad to 6=excellent. Participants are subsequently asked to evaluate the quality of their contact with each formal system during follow-ups, including their interactions with the medical system.

XSL•FO
RenderX

Negative Perceived Social Support by the Exosystem

The participant's negative perceived support from each formal service they used is assessed at each follow-up (6 weeks, 3 months, 6 months, and 1 year) using 5 items adapted from a study by Campbell and Raja [30]. These items examine various negative feelings the participant may have experienced after their interaction with each system, including guilt, depression, anxiety, distrust, and reluctance to seek further help.

Secondary Victimization

We will assess secondary victimization at each follow-up (6 weeks, 3 months, 6 months, and 1 year) by inquiring whether participants have experienced any guilt-inducing or unhelpful behaviors from justice system officials. Examples of such behaviors are "being pressured to withdraw your complaint" or "questioning your words." The list of these secondary victimization behaviors was developed by the research team, drawing from empirical findings and insights from legal system professionals.

Chronosystem

History of Violence During Childhood

We will measure participants' history of psychological, physical, and sexual violence exposure (by the same aggressor or by another); history of intrafamilial psychological, physical, and sexual violence exposure; and instances of witnessing domestic violence in their childhood. These questions are administered during the initial forensic examination.

Sexual Violence Reexposure

We will assess instances of physical, psychological, and sexual violence reexposure at each follow-up point (6 weeks, 3 months, 6 months, and 1 year) by inquiring whether the participant has experienced any of these forms of violence, by the same assailant or another, since the initial assault.

Functional Outcomes

Peritraumatic Distress

Peritraumatic distress is measured during the forensic examination using the French version of the Peritraumatic Distress Inventory (PDI) [61]. This instrument measures the frequency with which participants experienced various negative feelings, such as "feeling helpless" or "feeling like dying" during or directly after the assault, on a 5-point Likert scale ranging from 0=not at all to 4=extremely, and shows good psychometric properties [61].

Peritraumatic Dissociation

Peritraumatic dissociation is measured during the forensic examination using the French version of the Peritraumatic Dissociative Experience Questionnaire (PDEQ) [62]. This instrument measures 10 symptoms of dissociation during and immediately after an event on a 5-point Likert scale ranging from 0=not at all to 4=extremely and shows good psychometric properties [62].

State at the Time of Examination

We will gather information on physical complaints and injuries, the participant's psychological state, and the duration of "total or temporary work incapacity" (a legal term used in France to evaluate the severity of the SA) as reported by the physician during the consultation.

PTSD Symptoms

We will assess PTSD symptomatology at each follow-up (6 weeks, 3 months, 6 months, and 1 year) using the French version of the Posttraumatic Stress Disorder Checklist for DSM-5 (PCL-5), which has been validated both in French and in its original version [63]. This 20-item instrument evaluates the PTSD symptoms experienced by participants during the past month. It uses a 5-point Likert scale ranging from 0=not at all to 4=extremely. A total score of 31-33 or higher suggests that the participant may meet the criteria for PTSD and could benefit from PTSD treatment.

Quality of Life

The Short Form 12-item version 2 Health Survey (SF-12v2) [64] will be used to assess the physical, mental, and social quality of life during the past month. This survey is administered at each follow-up (6 weeks, 3 months, 6 months, and 1 year). Each item contributes to the scores of the Physical and Mental Component Summary. Both indexes are converted to a scale from 0 to 100, and the mean score of the sample can be compared with the national norm (where the national mean is 50 with an SD of 10).

Impact on Daily Life

We will assess the impact of the assault on daily life, including personal activities, social activities, and work, at each follow-up (6 weeks, 3 months, 6 months, 1 year) using the WHODAS 2.0 questionnaire [47]. This 12-item instrument measures the extent of these impacts on a Likert scale ranging from 0=none to 4=extremely.

Qualitative Interviews

Semidirective interviews are conducted with both cohort participants and individuals who have experienced SA in the past but are not part of the cohort (see Multimedia Appendix 2). These interviews will complement our quantitative data collection. The initial 1-hour semidirective interview covers topics such as the individual's perception of the event, formal and informal support, coping methods, and the event's impacts. After establishing a good rapport between the participant and the interviewer, additional interviews (second or third) can delve deeper into topics discussed in previous sessions. These interviews explore the participant's value system, their integration of the event into their life course, and their perceptions of themselves and the SA in relation to the concepts of "trauma" and "victim."

Other semidirective interviews are conducted with professionals involved in the pathways of people who have experienced SA (see Multimedia Appendix 3). These interviews cover various aspects: first, professionals discuss their practice and the needs of their patients or clients; second, they share their perceptions of the help they provide, the adequacy of available resources,

XSL•FO
RenderX

and the needs of SA survivors; finally, they provide insights into their definitions of the notions of "trauma" and "victim," and discuss the utility of these terms in their field and for SA survivors.

Statistical Analysis Planned: Quantitative Analysis

Descriptive analyses of participant characteristics will be conducted. The total population initially included and the follow-up cohort will be compared to understand the differences between patients who abandon their participation and those who complete their follow-up.

Bivariate and multivariate analyses, including trajectory analyses, will be conducted to examine the associations between each variable and mental, physical, social, and judicial outcomes at 6 weeks, 3 months, 6 months, and 1 year after the SA. Results regarding the presence or absence of PTSD will serve as the basis for our predictive analyses.

We will conduct predictive analyses using multiple prediction algorithms, such as meta-learners and support vector machines, to predict PTSD at the initial examination. The testing phase will be carried out in a subsequent study to validate the algorithms using a subset of our cohort. Initially, we will select relevant variables automatically, either through feature selection or manual selection based on the results of multivariate analyses. We will assess the internal validity of the prediction model through cross-validation. To quantify the performance of the algorithms, we will use metrics such as precision (accuracy and area under the precision-recall curve), sensitivity, specificity, positive predictive value, and negative predictive value. Additionally, we will explore tools for visual explanation, feature relevance explanation, and explanation by example [65] to provide elements of explainability.

Qualitative Analysis and Data Integration

Interviews conducted with individuals who have recently experienced SA, with those who have experienced SA in the past, and with professionals will be transcribed before performing coding and thematic analysis. The results of interviews with recent SA survivors included in the cohort will be integrated with the quantitative data, following best practices for mixed methods research [66]. This integration will enable us to add or enhance existing variables to be used in constructing our predictive model for PTSD using AI. Furthermore, it will provide more comprehensive information on the 1-year psycho-socio-judicial trajectories of participants, allowing for a more precise characterization of these trajectories, particularly concerning the judicial aspect and the role of the exosystem (formal support system), which have not been extensively analyzed in quantitative literature.

The data concerning the perceptions of the significance and utility of the concepts of "trauma" and "victims" will be analyzed separately to gain deeper insights into the representations and definitions of SA and individuals who have experienced it. This data will be conducted from the perspectives of recent SA survivors (cohort participants), those who have experienced SA in the past, and professionals who provide assistance to individuals impacted by SA (noncohort participants).

Results

Data collection commenced in September 2022 and is anticipated to conclude by 2026. Data analysis will commence before the conclusion of data collection, with several articles expected to be prepared and submitted for publication between 2023 and 2026.

Discussion

Anticipated Findings

Our first 2 study objectives involve delineating the psycho-socio-judicial trajectories over 1 year of individuals who undergo forensic examinations after a recent SA and using AI for early detection of those at risk of developing PTSD. Third, using mixed methods and conducting interviews with both individuals who have recently experienced SA and those with nonrecent experiences, in addition to professionals engaged in their care, we aim to assess the functionality and attributes of the available resources in France. This approach will contribute to a deeper understanding of SA, its integration into the life course, and the perceptions of "victim" and "trauma" as perceived by those who have experienced it.

Limitations

Our study has certain limitations. In France, the majority of forensic centers require a court order to admit patients, and this order is typically granted once the alleged impacted individual files charges. However, only 7%-8% of people who experience SA choose to press charges [67], and it is possible that this small percentage may not accurately represent the experiences of all individuals who have been subjected to such violence. As a result, individuals who undergo a forensic examination following SA represent a specific subset of individuals and types of assaults. In our study, the forensic center at Jean Verdier Hospital is the only one that does not require patients to have a court order for examination. Consequently, only a small portion of our cohort sample will consist of individuals who have not pressed charges. This limitation could potentially affect the representativeness of our sample.

Furthermore, our specific age and temporal criteria necessarily exclude individuals under the age of 15 years and those whose experience of SA occurred more than 30 days ago. This exclusion limits the participation of individuals who have experienced certain types of sexual violence, such as incest or child sexual abuse. This criterion is necessary to study the onset of PTSD, which typically occurs 1 month after the trauma according to DSM-5 criterion F [45]. Additionally, it facilitates the inclusion of participants, as individuals aged 15 years and older can provide consent for matters related to their sexual health. However, this criterion introduces a potential selection bias, as it excludes individuals under the age of 15 years.

There is also a potential for interviewer bias in the qualitative part of the study. However, several measures have been put in place to minimize interviewer bias. These include using a standardized interview guide for all participants, predesigning codes based on the framework used, ensuring the interviewer is trained in qualitative interviews with crime offenders and

XSL•FO
RenderX

impacted individuals, adopting an inductive approach, maintaining long-term monitoring of participants to enable reflexivity on practice, and allowing for reformulation of hypotheses and material as the fieldwork progresses. Additionally, inclusions are based on specific criteria and are not made by the interviewer but by different forensic practitioners, further enhancing reflexivity and limiting this bias.

Lastly, it is important to note that part of our study involves the use of AI, which can be more complex to implement and manipulate compared with standard statistical methods [39]. Previous research has highlighted several challenges associated with the integration of AI into studies on psychiatric disorders and its application in clinical settings. These challenges include issues related to model validation; computational resources; data quality; multimodal data; nonstationary data distributions; the heterogeneity of clinical diagnoses; the interpretability of AI models; conservative health care funding practices; and ethical concerns such as data privacy, anonymity, and the potential impact of predictive models on individuals [68].

Despite these limitations, this study plays a crucial role in filling knowledge gaps concerning the psycho-socio-judicial consequences of recent SA, the development and progression of PTSD symptoms, and the requirements of individuals who have experienced SA.

Strengths and Expected Implications

On the quantitative aspect of the project, the systematic data collection process across multiple forensic medicine centers, each with its own unique practices and recruitment patterns, will offer unparalleled insights into individuals seeking consultation for SA across various dimensions, as well as into the practices of professionals involved in these cases. This will enable us to monitor the emergence of significant psychological disorders, including PTSD, and assess their consequences on the life trajectories and functional outcomes of the participants. Furthermore, our quantitative design uses well-established and commonly used scales to assess psychological trauma and the functional consequences of trauma, facilitating comparisons with other national and international research.

Another significant quantitative advantage of our study is its emphasis on predicting the development of PTSD through the application of AI. Indeed, the data gathered during the initial forensic examinations will serve as the foundation for developing initial AI algorithms to identify individuals at risk of developing PTSD. This study will serve as the foundation for a second study, which will be integrated into the project, aimed at investigating the contribution of AI in the early detection of PTSD, as well as the reception and integration of this tool by medico-social services. We hope to develop tools to better guide individuals who have experienced SA from their initial forensic examination, particularly in terms of psychotrauma. This could potentially yield novel findings, as there is promising evidence that AI can be of great assistance in medical services [42,43], although it has not, to our knowledge, been tested in the context of forensic examinations following SA.

Regarding the qualitative aspect of the project, it stands as one of the few endeavors exploring the characteristics and challenges of French infrastructures and the requirements of individuals who have experienced SA in France. This will enable us to map the existing, accessible, and deficient resources within their paths. It is also uncommon in medical and public health research to longitudinally follow individuals who have experienced SA while placing them at the center of the study, enabling us to redefine the representations of their experiences. We aspire to gain a deeper understanding of the individuals seeking help after experiencing SA, their perceptions, and the appropriateness of the support services available to them across various contexts and timeframes. By comprehensively examining how individuals who have experienced SA perceive and incorporate this event into their life course, we can gain valuable insights into their needs and work toward enhancing their support and care. This involves considering the entire medico-social infrastructure in France and its capabilities to address these needs effectively.

Conclusions

This project will allow us to collect numerous data never before collected over such long periods in medical sciences not only in France but also globally. The wealth of data collected is expected to yield unprecedented insights and findings. First, our project will advance research on the impact of risk and resilience factors on trauma adaptation and the characterization of trajectories using innovative methods and extensive quantitative and qualitative longitudinal data. Second, it is a first step toward a functioning AI tool for early diagnosis of PTSD, which will enable us to prevent the chronicization of PTSD and provide better guidance to individuals during their first forensic examination. Third, this study will help bridge the existing gap in the literature regarding the accessibility and effectiveness of support services for individuals who have experienced SA in Europe by comprehensively mapping the currently available resources while also identifying areas where resources may be lacking. This assessment will be based on the needs and perspectives of individuals who have experienced SA, considering the impact of the events on their lives. Furthermore, this innovative research, which encompasses the entire psycho-socio-judicial chain, places a central emphasis on the perspectives of those who have experienced SA. This approach will enable the formulation of novel recommendations aimed at improving the quality of care and support provided at all levels of the system, commencing with the initial forensic examination.

We hope our approach may fuel further research to investigate psycho-socio-judicial trajectories via the creation of cohorts of people who experienced SA in other settings to have a more representative view of all people who have been sexually assaulted. Future research should also continue to focus on the use of AI to help medical examiners refer their patients toward more adapted services by testing the algorithms that will be developed in this project on several samples with different sociodemographic and trauma characteristics.

Abstract

Background: Telepsychiatry is the use of virtual communication, such as a video link, to deliver mental health assessment, treatment, and follow-up. Previous studies have shown telepsychiatry to be feasible, accurate compared with in-person practice, and satisfying for psychiatrists and patients. Telepsychiatry has also been associated with reduced waiting times for evaluation and, in some studies, lower admission rates. However, most previous studies focused on using telepsychiatry in community settings and not on involuntary admission.

Objective: The aim of this study is to examine the effectiveness and implementation process of patient assessment for involuntary admissions in the psychiatric emergency department (ED) using a video link.

Methods: This type 1 hybrid implementation study will examine telepsychiatry effectiveness and the implementation process, by comparing telepsychiatry (n=240) with historical controls who had a face-to-face evaluation (n=240) during the previous, usual care period in 5 psychiatric EDs in Israel. A temporary waiver of the standing policy requiring in-person evaluations only, for the purpose of research, was obtained from the Israeli Ministry of Health. During the telepsychiatry phase, clinical staff and patients will join a video call from the ED, while the attending physician will log in elsewhere. The Promoting Action on Research Implementation in Health Services (PARIHS) framework will guide the evaluation of the telepsychiatry implementation process in the ED. PARIHS has the following 3 constructs: (1) *evidence*: staff's opinions regarding the innovation's viability and practicality, their satisfaction levels with its use, and patients' perceptions of the change; (2) *context*: level of approval of new strategies in the ED, decision-making processes, and the manner in which clinical teams converse and work together; (3) *facilitation*: adequacy of the facilitation efforts using champions reports. Primary clinical outcomes include ED length of stay and violent incidents obtained from medical records.

Results: This study received Helsinki approval from the Ethics Committee of Abarbanel Mental Health Center (174; March 13, 2023), Jerusalem Mental Health Center (22-21; November 6, 2022), Lev-Hasharon Mental Health Medical Center (LH12023; February 12, 2023), Tel-Aviv Medical Center (TLV-22-0656; January 3, 2023), and Sha'ar Menashe (1-4-23; April 18, 2023). Data collection began in July 2023 in 2 study sites and will begin soon at the others.

XSL•FO
RenderX

Conclusions: Telepsychiatry could have significant benefits for patients in the psychiatric ED. Examining telepsychiatry effectiveness in the ED, in addition to identifying the facilitators and barriers of implementing it in different emergency settings, will facilitate better policy decisions regarding its implementation.

Introduction

Telepsychiatry is the use of email, chats, telephone, or video link for mental health assessment, treatment, and follow-up [1,2]. In this paper, we focus exclusively on 2-way communication using a real-time video link. There is evidence for the feasibility and effectiveness of telepsychiatry in certain settings, including for children and adolescents [3], adults and older adults [4], postpartum depression [5], developmental disorders like autism [6], and bipolar disorder [7]. Telepsychiatry can be used in different cultures [8] and health settings [9].

Although telepsychiatry is feasible and effective in various situations [1,9], there is less evidence and experience regarding its use for decisions about involuntary admission. Such decisions require the input of an attending psychiatrist, who may currently be required to physically come to the hospital for a face-to-face assessment. Making the patient wait until the attending psychiatrist arrives may increase the risk of additional decompensation, as the patient is already in a vulnerable state. This waiting period and possible decompensation may contribute to violent incidents and worsen the patient's condition.

In this paper, we discuss the use of telepsychiatry to streamline this process. By allowing an expedited assessment via video link, even when the attending physician is away from the hospital, telepsychiatry can facilitate quicker decisions about involuntary hospitalization. This protocol outlines the evidence supporting a research project to examine this issue empirically and the methods we plan to use.

Although previous studies have discussed the basic conditions to support telepsychiatry in other settings, it does require certain conditions to work well [3]. To conduct a 2-way video conference, one must have adequate internet speed, video and audio quality, and video meeting software [3,10]. It is important to address the security of the video link to prevent malicious intrusions or loss of confidentiality [11]. Both the psychiatrist and patient must be able to operate a computer, join a conference, and operate basic functions such as mute and unmute [3]. Quiet and private rooms must be arranged for both [3,10,11]. Videoconferencing also requires patients to be more active and cooperative than during face-to-face meetings, especially if they are in an unsupervised setting, including home [11,12]. The need for an active and cooperative patient should be considered, especially for patients with cognitive impairment, substance abuse [11], or active psychosis [13]. In our study, a trained staff member, usually a psychiatry resident or a nurse, will be physically present with the patient to support the video chat [3].

Those who wish to use telepsychiatry should be convinced of its accuracy. In fact, a narrative review of 134 articles, mostly from community settings, showed that telepsychiatry can be just as accurate as in-person meetings [9]. However, we are aware of only 2 studies that examined the accuracy of telepsychiatry in emergency settings. In one study from 2014, the authors examined the concordance between clinical impressions via telepsychiatry or in-person evaluation of 73 patients in the psychiatric emergency department (ED) in the United States. A second psychiatrist was present in the room with the patient and completed the assessment independently. In that study, there were no significant differences between raters regarding the recommended disposition, strength or confidence of the disposition recommendation, provisional diagnosis, or the rating of dangerousness [14]. In 2022, our research group published a study of 38 Israeli patients who were referred to the ED for possible involuntary admission. All patients were evaluated both face to face and by video link by 2 different clinicians. The main finding was that there was an extremely high degree of concordance between impressions arrived at under the 2 conditions, especially regarding the need for involuntary admission [15].

In addition to being convinced that telepsychiatry is accurate, one also must be convinced that it is feasible. The question of feasibility can be divided into whether it is feasible for patients as well as for health care providers. For patients, previous work has shown that telepsychiatry is acceptable and highly satisfying in community-based settings [2,9] and in the ED [15-17]. Regarding health care providers, the evidence for feasibility is also generally positive, although more limited. In one study, health care providers had mixed feelings about telepsychiatry before using it [18]. In other studies, after using telepsychiatry, they perceived it to be acceptable [1,17].

In addition to this generally positive impression by clinicians, telepsychiatry has advantages for the health care system. Several studies have documented positive system effects. For example, the use of telepsychiatry contributed to decreased waiting times for patients awaiting psychiatric input in clinical setting (EDs and community clinics), reducing workloads [9,19], and reducing medical costs [20].

In addition to using telepsychiatry in the ED, some studies have examined professionals' impressions of the process of

XSL•FO
RenderX

implementing telepsychiatry in the ED. Saurman et al [21] evaluated the perceptions of hospital staff regarding a new telepsychiatry program at a rural ED in Australia. The staff reported that they were satisfied with the program, felt confident in managing patients' cases, and valued the accessibility to mental health experts, which they otherwise would not have in such a remote location. An additional study examined the views of 17 staff members from Canadian EDs, and participants reported that telepsychiatry can improve patient experience and expedite service but can also introduce challenges for an already overloaded ED [22]. According to a 2009 report for the California Health Care Foundation, providers and patients who participated in ED telepsychiatry programs reported high satisfaction from the video meetings and stated that, in their opinion, patient outcomes, such as hospital admission or length of stay, were improved using this method [16].

One study that is worth noting was not conducted in an ED setting but does support the use of telepsychiatry for psychiatric emergencies. A university hospital in Norway developed new telepsychiatry services for emergencies in rural areas that lack psychiatric service availability. The findings showed that having access to experts through telepsychiatry was beneficial for patient involvement, reduced nurses' uncertainty, and served as a safety net for the health care team [23].

Unfortunately, previous studies regarding the feasibility of using telepsychiatry in an ED setting have limitations. These studies examined the practical implementation of telepsychiatry in relatively few settings and with relatively small samples and only characterized a relatively limited range of process outcomes. Additional information about the feasibility of using telepsychiatry in ED settings and the outcomes of patients managed using telepsychiatry would help support decisions by policymakers to adopt this strategy.

Although the previous literature has important gaps, we do already know that there are some barriers to the increased use of telepsychiatry. For example, Cowan et al [19] found that health care providers noted technological challenges, the need for guidance and training on how to use this method, and concerns regarding patients' privacy and safety. Other studies documented the unequal degree of comfort with the use of telepsychiatry by patients, with some patients adapting to the new technology relatively easily and others having more difficulty [24]. Last, several studies documented legal or procedural challenges with using telepsychiatry [3,12].

In some cases, restrictive laws may make it difficult or impossible to use telepsychiatry. In Israel, for example, it is the law that, before they can be hospitalized involuntarily, patients must be evaluated in person by a senior psychiatrist [25]. It is worth noting that such policies were created before it was possible to evaluate patients by video link. Although policy is difficult to modify, a number of jurisdictions around the world found ways to change these rules during COVID-19 lockdowns. This led to a rapid expansion of the use of many kinds of telemedicine, including telepsychiatry [26,27].

Although most previous efforts to use telepsychiatry have been in the relatively low-stress setting of delivering outpatient care, the use of telepsychiatry for ED triage could have great benefits, at least theoretically. Patients with acute psychiatric decompensation may pose a danger to themselves and those around them [28]. Their vulnerable state is complex, as they may be agitated and have poor reality testing [28]. Decompensation is more likely to happen when psychiatric patients are staying in settings that are not well-suited to their needs, such as the ED [29]. The ED is a relatively uncomfortable environment for any patient but is even more stressful for patients with psychiatric emergencies [28]. This can result, ironically, in the patient's condition worsening, violent incidents directed toward medical staff, and starting the hospitalization with precisely the reverse of the intended therapeutic benefit [29]. To the extent that incorporating telepsychiatry could help move such patients out of the ED faster, this could decrease the strain on the patients, bringing them to a quiet and controlled environment sooner, where they can begin to heal. Thus, introducing telepsychiatry in this setting, although possibly challenging, could also have great benefits.

Although the idea of using telepsychiatry in triage decisions is not entirely novel, relatively few studies on patients' outcomes have been published in this setting. A national survey in the United States in 2016 examined the extent to which telepsychiatry is already in use in some ED settings. The study found that 20% of the EDs used telepsychiatry, with the most common use being to decide which patients to admit and which to send home [30]. Additional studies examined patient outcomes with telepsychiatry in the ED. Narasimhan et al [31] examined 7261 patients who arrived at the ED and underwent a real-time video visit with a remote psychiatrist. Compared with a matched control group, the telepsychiatry group had significantly more outpatient follow-up care and fewer hospitalizations. This, in turn, was associated with a significant reduction in hospital costs. An additional study from the United States examined the use of telepsychiatry in the pediatric ED. The findings showed a significant reduction in patients' length of stay for nonhospitalized patients (ie, for those sent home from the ED) [32].

Previous studies described the use of telepsychiatry in an ED setting but did not specifically examine its use for the purpose of deciding which patients require involuntary admission. In fact, only 1 observational study examined involuntary admissions to the ED via telepsychiatry [33], but this study did not directly compare patient outcomes between telepsychiatry and face-to-face approaches.

To broaden our understanding of successful telepsychiatry implementation in the ED, further studies guided by implementation science frameworks are needed. One example of an implementation science framework is the Promoting Action on Research Implementation in Health Services (PARIHS) framework [34]. PARIHS posits that successful implementation (SI) is a function of 3 inputs: *evidence*, *context*, and *facilitation* [35]. SI is the extent to which the innovation is completely implemented and adopted as part of standard practice, as opposed to being incompletely adopted or resisted. *Evidence* refers to end users' assessments of the strength of the evidence for the innovation, including their expectations that it will be feasible to use in their setting. *Context* refers to the factors in the environment that support (or resist) the

XSL•FO
RenderX

implementation of changes in practice. *Facilitation* refers to the efforts of the research team or champions within the clinical team to promote the change.

Our study will examine the implementation of telepsychiatry in Israeli EDs for involuntary admissions using the PARIHS framework, with attention to characterizing which aspects of *evidence*, *context*, and *facilitation* contributed to SI, or the lack thereof. We will also examine the impact of telepsychiatry on patient outcomes and health care utilization, compared with historical controls managed without telepsychiatry.

Methods

Ethics Approval

Our study is being performed in accordance with all relevant guidelines and regulations. Helsinki approval was obtained from the Ethics Committees of Abarbanel Mental Health Center (174; March 13, 2023), Jerusalem Mental Health Center (22-21; November 6, 2022), Lev-Hasharon Mental Health Medical Center (LH12023; February 12, 2023), Tel-Aviv Medical Center (TLV-22-0656; January 3, 2023), and Sha'ar Menashe (1-4-23; April 18, 2023). Any changes in the study protocol will be promptly communicated to the ethic committees, and if necessary, approval for the change will be obtained. Patients will provide verbal assent for telepsychiatry evaluation.

Since the care provided during the study will be the same standard of care for all patients, at least for the duration of the study, it was not deemed necessary to have a data safety monitoring committee. The most easily foreseeable adverse consequences of the change in practice are being measured by the study, and the duration of the intervention period (4 months) is brief. In addition, study data are being collected via chart review and not necessarily contemporaneously within the study period itself. There is not sufficient time during this brief study period to conduct interim analyses. Following an analysis of the study outcomes, a policy decision will be made on the part of Israel's Ministry of Health whether to continue or end the change in practice. There are no formal plans to compensate patients for any harms that may occur during the study, which are likely to be similar to whatever harms could occur under usual care.

Study Design

We will implement a multisite study in 5 Israeli EDs to evaluate the use of telepsychiatry compared with the regular face-to-face method. Under the Mental Health Act regarding involuntary hospitalizations in Israel, all involuntary hospitalizations require an in-person evaluation by the attending psychiatrist [25]. Our study received a limited waiver of this policy for the purposes of research, after which the results of our study will be used to re-evaluate whether the current policy should be changed.

In our study, there will be clinicians, including psychiatry residents and nurses, physically present. However, using the innovation, the attending physician will evaluate the patient via video link, with the conversation facilitated by another provider who is physically present. This has numerous potential advantages, in that the patients may enter a calmer environment (ie, the psychiatry ward) or be sent home sooner if they are not admitted. Less time spent in the ED has the potential to reduce violent incidents and improve the patient's hospital course, by minimizing exposure to a noxious stimulus.

Our study will be a type 1 hybrid implementation study. Hybrid implementation studies aim to shorten the process of translating clinical innovations into practice by simultaneously collecting data about effectiveness as well as the implementation process [36]. A type I hybrid study emphasizes the collection of effectiveness data, often because there is limited previous evidence of effectiveness. However, the team also collects information regarding the contextual factors that supported or impeded implementation, with an eye toward improving the future implementation of this strategy.

Our study will compare the innovation with historical controls. During the pre-intervention period, we will collect data about patient outcomes during a period of 4 months when attending physicians continue to evaluate patients in person, as they have been doing (usual care). During the intervention period, attending physicians will evaluate the patients and make decisions based on a video link. Seasonality would be one possible threat to study validity [37]. To address this, we will collect data using the same 4 months of the year, both in the pre-intervention and intervention periods.

Evaluation of process implementation will be guided by the PARIHS framework [34]. We will characterize the extent to which staff members believe that the innovation will be effective and will be feasible to use in their context and how this belief contributes to SI [34]. We will characterize how the context, including relationships among staff, styles of administrative leadership, and organizational attitudes toward change and quality improvement, at each of our 5 medical centers contributes to or detracts from SI. Finally, we will characterize how the efforts of champions within the clinical staff, known as internal facilitators, did or did not help promote SI [35].

Study Settings

The study will be conducted in 5 psychiatric EDs in Israel. One of the study sites is a general hospital, so psychiatric emergency patients are evaluated and treated in a special section of the general ED. The other 3 hospitals are dedicated psychiatry hospitals, meaning that the ED is only used for psychiatric emergencies. All sites are located in the densely populated center of Israel, in or near Tel Aviv and Jerusalem, where most of the country's population lives [38]. All 5 hospitals are moderate to large in size.

Participants

This study will include 2 population groups: patients and hospital staff.

Patients

We anticipate that our 5 hospitals will collectively evaluate at least 60 patients per month for involuntary admission. Given that each hospital will have a 4-month pre-intervention period and a 4-month intervention period, we plan to enroll at least 240 patients in each study period. To be included, patients must be 18 years or older and arrive during hours when the attending physician is not at the hospital (evening and night shifts). Due

XSL•FO
RenderX

to the waiver we received for this study and the limitations that were placed on the waiver, we will exclude patients who are brought for evaluation by police after being detained or charged with a crime. Only patients needing an attending assessment under the Mental Health Act regarding involuntary hospitalizations will be included. Patients will provide verbal assent to be evaluated by video link; patients who do not agree will be evaluated in person. Although we will endeavor to support patients who have difficulty participating in a video link, there may be some patients who are unable to communicate adequately by video link, and we will exclude them from the study. To maximize study generalizability, no other exclusion criteria exist.

With an anticipated 240 patients in the control arm and 240 patients in the intervention arm (4 X 60), we will have statistical power to show a relatively small effect size for most outcomes. For example, we will be able to show a difference of as little as 15 minutes of ED time.

Hospital Staff

We will collect data about implementation from all those who are involved with administrating, supervising, or staffing the psychiatric ED. Key staff will include the hospital director, department director, unit director, service manager, senior physicians, psychiatry residents, and nursing staff.

Clinical Outcomes

Clinical outcomes are explained in detail in Table 1. Data will be collected in the same manner from the medical record both before and during the intervention. Baseline patient variables will include sex, age, marital status, city of residence, ethnic group (Jewish or Arab), and known psychiatric diagnoses. We will also collect information about the patient's arrival at the ED, including mode of arrival, legal status, violent incidents pre-arrival, and chronic medications. The primary outcomes for the ED stay, for patients who are admitted involuntarily and for those discharged home, will include time in the ED and violent incidents. Secondary outcomes will include the psychiatric diagnosis given by ED staff, psychiatric status (eg, judgment intact or not intact), and legal status upon release. For patients admitted to hospital, we will also collect information on hospitalizations reversed within 72 hours, which implies that the hospitalization was not necessary, and length of hospital stay. For patients discharged home, we will collect information on those admitted within 7 days, which implies that the patient should have been hospitalized.

XSL•FO
RenderX

Table 1. Planned collection of outcome variables for a 6-month pilot study comparing telepsychiatry with usual care (historical outcomes during the pre-intervention period) in the emergency department (ED) setting, for assessment of the need for involuntary admission.

Variable	Data collection method
Background characteristics	Patient sex, age, family status, residence, ethnic group, known psychiatric diagnosis; as well as, for both ED arrival and hospitalization: involuntary arrival or by police or emergency services, legal status, violence incidents pre-arrival, and prescribed medications and dosages
Primary outcomes	
ED length of stay	Measured from the time of arrival in the ED until the patient physically leaves the ED to go home or for hospitalization
Violent incidents in the ED	As recorded by ED staff and adjudicated by blinded review of the chart by a senior psychiatrist; violent incidents defined as one of the following: (1) degree of restlessness: calm, moderate restlessness, severe agitation, or catatonia; (2) violence type: verbal violence, violence toward property, violence toward others (eg, escort, staff member, other patients)
Duration of hospitalization (hours)	From the time of ED release until the time of leaving the hospital
Violent incidents in the ward	As recorded by the hospital staff and adjudicated by blinded review of the chart by a senior psychiatrist
Secondary outcomes	
Psychiatric diagnosis in the ED and hospitalization in case of admission	Psychiatric diagnosis categorized as one of the following: (1) neurodevelopmental disorders, (2) schizophrenia spectrum and other psychotic disorders, (3) bipolar and related disorders, (4) depressive disorders, (5) anxiety disorders, (6) obsessive-compulsive and related disorders, (7) trauma and stressor-related disorders, (8) somatic symptom and related disorders, (9) substance-related and addictive disorders, (10) neurocognitive disorders, (11) personality disorders, (12) adjustment disorder, (13) diagnosis deferred
Psychiatric status in the ED and hospitalization in case of admission	Psychiatric status to include the presence or absence of the following: (1) disturbed thinking, (2) disturbed perception, (3) disturbed judgement, (4) dangerousness
Release from the ED and hospitalization in case of admission	Release from the ED and hospitalization in case of admission to include one of the following: (1) discharge to home, (2) discharge to the institution from which the patient came, (3) hospitalization in a general hospital, (4) hospitalization in another psychiatric hospital, (5) police, (6) runaway, (7) other place
Legal status upon release from the ED and hospitalization in case of admission	Legal status upon release to include one of the following: (1) with consent, (2) compulsory follow-up visits in a community clinic, (3) involuntary hospitalization order, (4) other
Reversal of admission	Unnecessary admission: involuntary admission that is reversed within 72 hours; measurement of the proportion of admissions reversed within 72 hours
Admission within 1 week of ED discharge	A patient sent home from the ED without being admitted, who is then admitted within 1 week and should have been admitted the first time
Implementation process outcomes	
Evidence construct	
SHEMESH[a] questionnaire	A validated tool to evaluate organizational change and identify its barriers; evaluation of the evidence construct achieved via 4 online questions administered to the medical and nursing staff about the strength and feasibility of psychiatric assessment via video link at the ED and how preferable it is compared with the face-to-face method; items rated from 1 (strong disagreement) to 5 (strong agreement)
Patient satisfaction with ED course	As they are leaving the ED, patients asked to rate their overall satisfaction with 4 items (overall ED experience, interactions with nurses, interactions with residents, interactions with the attending physician), rated using a visual analog scale from 1 (very dissatisfied) to 5 (very satisfied)
Staff satisfaction with the ED work	Medical and nursing staff asked to rate their overall satisfaction with their work in the ED on a scale from 1 (very dissatisfied) to 5 (very satisfied)
Medical staff confidence with evaluation	Medical staff asked to rate their overall confidence with evaluating patients sufficiently well to make appropriate decisions about whether they need to be admitted on a scale from 1 (very uncertain) to 5 (very confident)
Context construct	
SHEMESH	Evaluation of the context construct achieved via 6 online questions administered to the medical and nursing staff about the acceptability of initiatives, the way decisions are made, and the way medical and nursing teams are communicating and collaborating in the ED; items rated from 1 (strong disagreement) to 5 (strong agreement)
Measurement of successful implementation	
Staff's impression of the implementation process	Measured via an open-ended questionnaire to all staff members at the conclusion of the intervention period, to gather their thoughts on the advantages and the challenges of using telepsychiatry; its fit for a variety of patient groups; and in their opinion, the necessary conditions for the use of telepsychiatry

XSL•FO
RenderX

Variable	Data collection method
Feedback from clinical champions	Solicitation of ongoing feedback from clinical champions located within each site who are responsible for promoting the intervention; feedback to be recorded in a research diary by the researchers and include their impression of success and failure of the implementation process, what would help improve it, and how fully the innovation is being adopted

[a]SHEMESH: acronym of "SHE'elon Muchanut Ergunit le'SHinuy" in Hebrew, translated from the English name of "Organizational Readiness to Change Assessment."

Implementation Outcomes

Evaluation of the implementation process of telepsychiatry will be guided by the PARIHS model. We will collect information on SI and the 3 factors that contribute to it: *evidence*, *context*, and *facilitation*. SI will be assessed according to feedback from site champions at each of the 5 sites, who will share impressions with our team about what is going well or less well in the implementation effort. This feedback will also be used to support tailoring of the intervention across each of the 5 sites. SI will also be investigated by open-ended questionnaires administered to all staff members to understand providers' impressions of which parts of the intervention succeeded and which should be modified.

The *evidence* construct includes staff perceptions of the strength and feasibility of psychiatric assessment via video link at the ED, how preferable it is compared with the face-to-face method, and psychiatrist confidence in the accuracy of admission decisions made using video link. The *context* construct includes the acceptability of initiatives in the ED, the way decisions are made, and the way medical and nursing teams are communicating and collaborating in the ED. Information on the *facilitation* construct and the adequacy of our facilitation efforts will come mostly from the site champions.

Data Collection

Data collection will include patient outcomes and implementation outcomes. Patient outcomes will be collected through hospital medical records using trained assessors. Process outcomes will be collected using questionnaires. The Organizational Readiness to Change Assessment survey is a validated tool created to evaluate organizational change and innovation and identify the barriers through the prism of the PARHIS framework [35]. For the purpose of this study and initially for the use of others, our group developed and validated the Hebrew version of this questionnaire, named "SHE'elon Muchanut Ergunit le'SHinuy" (English: Organizational Readiness to Change Assessment) and abbreviated as SHEMESH. The SHEMESH will examine medical and nursing staff perceptions about the evidence of telepsychiatry and its implementation in the ED context. The SHEMESH has high Cronbach alpha scores for the 2 scales (total of 10 items on a 5-point Likert scale): *evidence* (4 items): α=.887; *context* (6 items): α=.852 [39]. The questionnaire will be administered online once before implementing telepsychiatry and again 3 months after the implementation. Staff will be asked to rate their overall agreement with statements on a scale from 1 (strong disagreement) to 5 (strong agreement).

Data about the *evidence* construct will be also collected through the following questionnaires: patient satisfaction questionnaire, staff satisfaction survey, and medical staff confidence in psychiatric evaluations survey.

The patient satisfaction questionnaire will be used to compare the patient experience under usual care with that under the intervention condition. ED patients will be asked 3 questions about their overall experience at the ED and their interactions with medical and nursing staff. Patients will be asked to rate the questions using a visual analog scale from 1 (very bad) to 5 (very good). During the telepsychiatry phase, they will also be asked about their satisfaction with the video link.

The staff satisfaction survey will be administered online for all ED medical and nursing staff, once before implementing telepsychiatry and 3 months after the implementation. Staff will be asked to rate their overall satisfaction with their work in the ED from 1 (very dissatisfied) to 5 (very satisfied)

The medical staff confidence in psychiatric evaluations survey will be administered online before the telepsychiatry implementation and 3 months after the implementation. Staff will be asked to rate their overall confidence in patients' evaluations from 1 (very uncertain) to 5 (very confident) for admission decisions.

Data regarding the SI outcome will be collected using an open-ended questionnaire administered to all staff members at the end of the intervention phase. Staff will be asked about the advantages of and challenges with using telepsychiatry in the ED, its fit for patients from different backgrounds, and their opinion of the necessary conditions for the use of telepsychiatry.

All data collected during the research will be anonymized, entered, and stored in password-protected files on a researcher's (LS) computer.

Data Analysis and Dissemination of Results

All data will be analyzed using SPSS (version 27.0). Baseline characteristics will be compared between the intervention and historical controls to ensure that the 2 groups are balanced. All normally distributed data will be analyzed using *t* tests or ANOVAs. Data found to be non-normally distributed will be analyzed using Mann-Whitney *U* tests or Kruskal-Wallis *H* tests. Comparisons of percentages between different groups will be analyzed using chi-square tests. Close-ended questions using Likert scale responses will be grouped as negative (1-2), neutral (3), or positive (4-5).

The results of the study will be disseminated to the public via published manuscripts in the peer-reviewed literature, and we also plan to brief the Israeli Ministry of Health on our study findings. Authorship will include all study investigators, including, at a minimum, all site principal investigators and likely others who participated in collecting data. Manuscripts

XSL•FO
RenderX

and reports will be written by study investigators, and we will not rely on medical writers. The study protocol is being published with this manuscript, and we intend to share the statistical code with those who request it. Data from the study cannot be made available due to the terms of our study approvals by the relevant research ethics committees of the hospitals involved.

Results

This study has been funded by the Israel National Institute for Health Policy Research (grant number 2021/77). Data collection began in July 2023 in 2 study sites and will begin soon at the others. Data collection for the pre-period will be performed from the previous year, to match the months during which the pilot program was implemented at that site.

Discussion

Overview

We propose an innovative approach to evaluate the impact of telepsychiatry on involuntary admissions, as well as the barriers and facilitators to implementing this method in the ED. Using telepsychiatry for ED assessment is currently not allowed as part of standard Israeli practice. With a waiver of the usual policy from the Ministry of Health, for the purpose of evaluation, we will implement telepsychiatry in 5 EDs throughout Israel. We will examine the effectiveness and implementation of telepsychiatry for involuntarily committed cases. We will compare administrative and clinical outcomes from the implementation phase with those from historical controls, as well as evaluate process outcomes using questionnaires. This study provides an opportunity to understand the feasibility of using this approach, as well as the impact of using this method on patients' outcomes. Our results will also help to provide policymakers with data to reassess the current policy.

This study is a response to the lack of evidence for telepsychiatry use in the ED. Other studies have examined telepsychiatry effectiveness in the outpatient setting [1,9]. There are some mixed studies from community and emergency settings examining telepsychiatry's effectiveness [40] or its implementation process [24]. To date, there are no studies that evaluate the use of telepsychiatry specifically for clinicians to evaluate the need for involuntary commitment. The issue of involuntary commitment involves some of the most vulnerable patients in the entire medical system, and there is a strong impetus to evaluate these patients promptly and help them reach a quieter and more stable environment more quickly. To the extent that telepsychiatry may help accomplish this goal, the study we present in this paper is crucially important to the telepsychiatry field.

This study has the potential to directly impact patient care and welfare as well as health systems. Our proposed study could improve patient safety and well-being by preventing long waits and, thus, opportunities for decompensation. We expect to show that this approach allows patients to be put in a safer place faster and spend less time in uncontrolled settings. We hypothesize that this will be expressed as fewer violent incidents and shorter hospital stays. There may also be an impact on ED crowding, which we will not directly measure. Patients may also receive direct therapeutic benefit. Telepsychiatry may be used to initiate psychiatric evaluation faster, reduce the length of the ED wait, and reduce decompensation. In turn, implementing telepsychiatry in the ED could reduce the costs and workload in the ED by moving patients out quicker. To the extent that we are able to show such an outcome, this will constitute a compelling argument for its widespread adoption.

Limitations

This study has several potential challenges. There may be barriers to implementation, such as difficulty using video equipment or software, adequacy of Wi-Fi, or inability to reach the attending physician. There may also be resistance to change, as could occur with any change in practice. Since this is a “real world” study, another challenge is matching telepsychiatry to a variety of patients' backgrounds and contexts. Since motivation and intention are required on behalf of the patient in a video session [11,12], the ability of patients to fully cooperate may be an issue, especially since these are patients in the midst of a psychiatric emergency. By conducting this study, we will be able to identify such gaps and address them accordingly, or at least to quantify them.

Conclusions

The implementation of telepsychiatry in the ED setting has the potential to improve care for patients. Although its efficacy has been noted in community settings, its application in emergency contexts remains largely uncharted territory. This study aims to shed light on the effectiveness of telepsychiatry for evaluations of involuntary commitment in the ED, as well as exploring the facilitators and barriers to its implementation in this setting. If our hypotheses are confirmed, it will not only demonstrate the accuracy of telepsychiatry but also pave the way for a more patient-centered and efficient approach in the psychiatric ED.

Abstract

Background: Caregivers of patients with severe acute brain injuries (SABI) that lead to coma and require intensive care unit (ICU) treatment often experience chronic emotional distress. To address this need, we developed the Coma Family (COMA-F) program, a mindfulness-based resiliency intervention for these caregivers.

Objective: We will conduct an open pilot trial of COMA-F (National Institutes of Health Stage IA). Here we describe our study protocol and proposed intervention content.

Methods: We will enroll 15 caregivers of patients with SABIs during their loved one's hospital course from 3 enrollment centers. A clinical psychologist will deliver the COMA-F intervention (6 sessions) over Zoom (Zoom Video Communications, Inc) or in person. We will iterate COMA-F after each caregiver completes the intervention and an exit interview. English-speaking adults who have emotional distress confirmed by the clinical team and are the primary caregivers of a patient with SABI are eligible. The adult patient must have been admitted to the neuro-ICU for SABI and (1) have had a Glasgow Coma Scale score below 9 while not intubated or an inability to follow meaningful commands while intubated at any point during their hospitalization for >24 hours due to SABI; (2) will be undergoing either tracheostomy or percutaneous endoscopic or surgical gastrostomy tube placement or have already received one or both; and (3) have a prognosis of survival >3 months. We will identify eligible caregivers through screening patients' medical records and through direct referrals from clinicians in the neuro-ICU. During the intervention we will teach caregivers mind-body and resilience skills, including deep breathing, mindfulness, meditation, dialectical thinking, acceptance, cognitive restructuring, effective communication, behavioral activation, and meaning-making. Caregivers will complete self-report assessments (measures of emotional distress and resilience) before and after the intervention. Primary outcomes are feasibility (recruitment, quantitative measures, adherence, and therapist fidelity) and acceptability (treatment satisfaction, credibility, and expectancy). We will conduct brief qualitative exit interviews to gather feedback on refining the program and study procedures. We will examine frequencies and proportions to determine feasibility and acceptability and will analyze qualitative exit interview data using thematic analysis. We will also conduct 2-tailed *t* tests to explore signals of improvement in emotional distress and treatment targets. We will then conduct an explanatory-sequential mixed methods analysis to integrate quantitative and qualitative data to refine the COMA-F manual and study procedures.

XSL•FO
RenderX

Results: This study has been approved by the institutional review board at 1 of the 3 enrollment centers (2023P000536), with approvals at the other 2 centers pending. We anticipate that the study will be completed by late 2024.

Conclusions: We will use our findings to refine the COMA-F intervention and prepare for a feasibility randomized controlled trial.

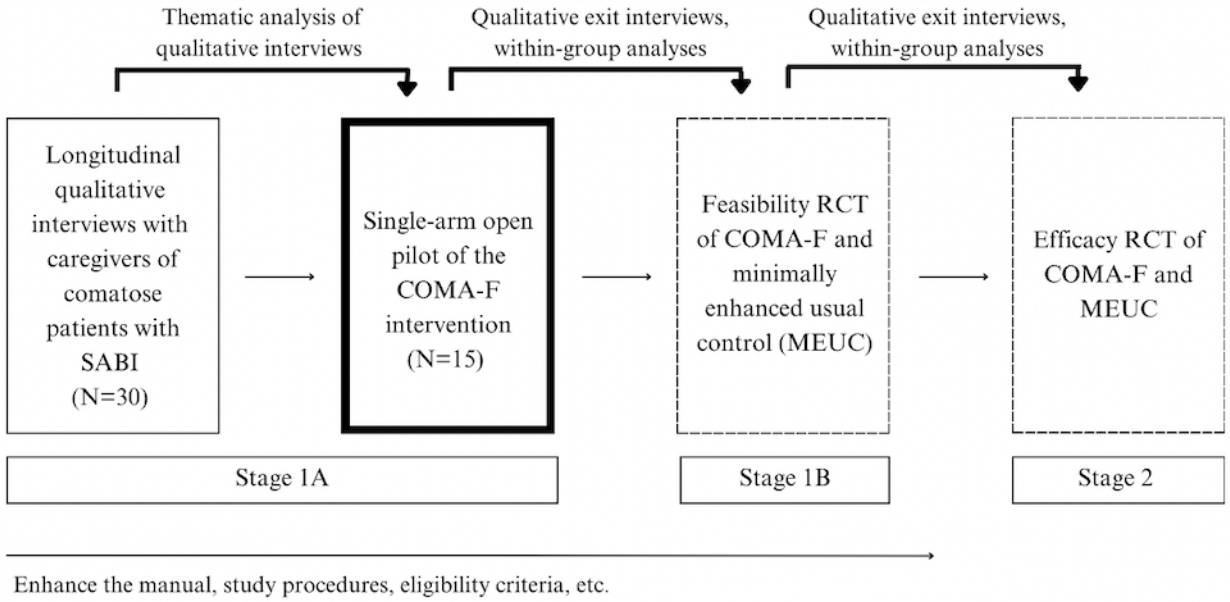
Introduction

Background



Severe acute brain injuries (SABI) such as ischemic stroke, hemorrhagic stroke, traumatic brain injury, or hypoxic-ischemic encephalopathy are sudden catastrophic events for both patients and their families [1]. The majority of patients with SABI cared for in an intensive care unit (ICU) are incapacitated, and many are comatose [2]. Caregivers of patients with SABI who survive their ICU admission nevertheless experience high rates of emotional distress, which, if untreated, becomes chronic [1,3]. These caregivers grapple with the uncertainty of their loved one's long-term prognosis, the stress of making decisions on their loved one's behalf, grief over their loved one's loss of neurological function, and the stress of managing their own life outside of the ICU [1,3,4]. While the stay in an ICU itself can be quite lengthy, ultimate recovery from SABI can be prolonged and uncertain, and caregivers often endure these stressors beyond the acute hospitalization [5,6].

Caregivers of hospitalized patients with SABI have unmet needs for emotional support. Prior work shows that they feel overwhelmed, underprepared for caregiving, unable to manage basic self-care, isolated, and lonely, and that they deal with ambiguous loss [5-8]. Despite these needs, a recent systematic review found that among 22 interventions for caregivers to general ICU patients, none led to long-term improvements in emotional distress, and many actually increased caregiver burden [9]. Further, there are few interventions specific to the needs of SABI caregivers. Those that do exist focus mainly on crisis management and decision-making during the initial 48 hours of admission [3,10,11] rather than addressing prolonged uncertainty, grief, and stress. Taken together, there is a critical need for effective interventions for caregivers of surviving patients with SABI that extend into the period following the ICU stay.

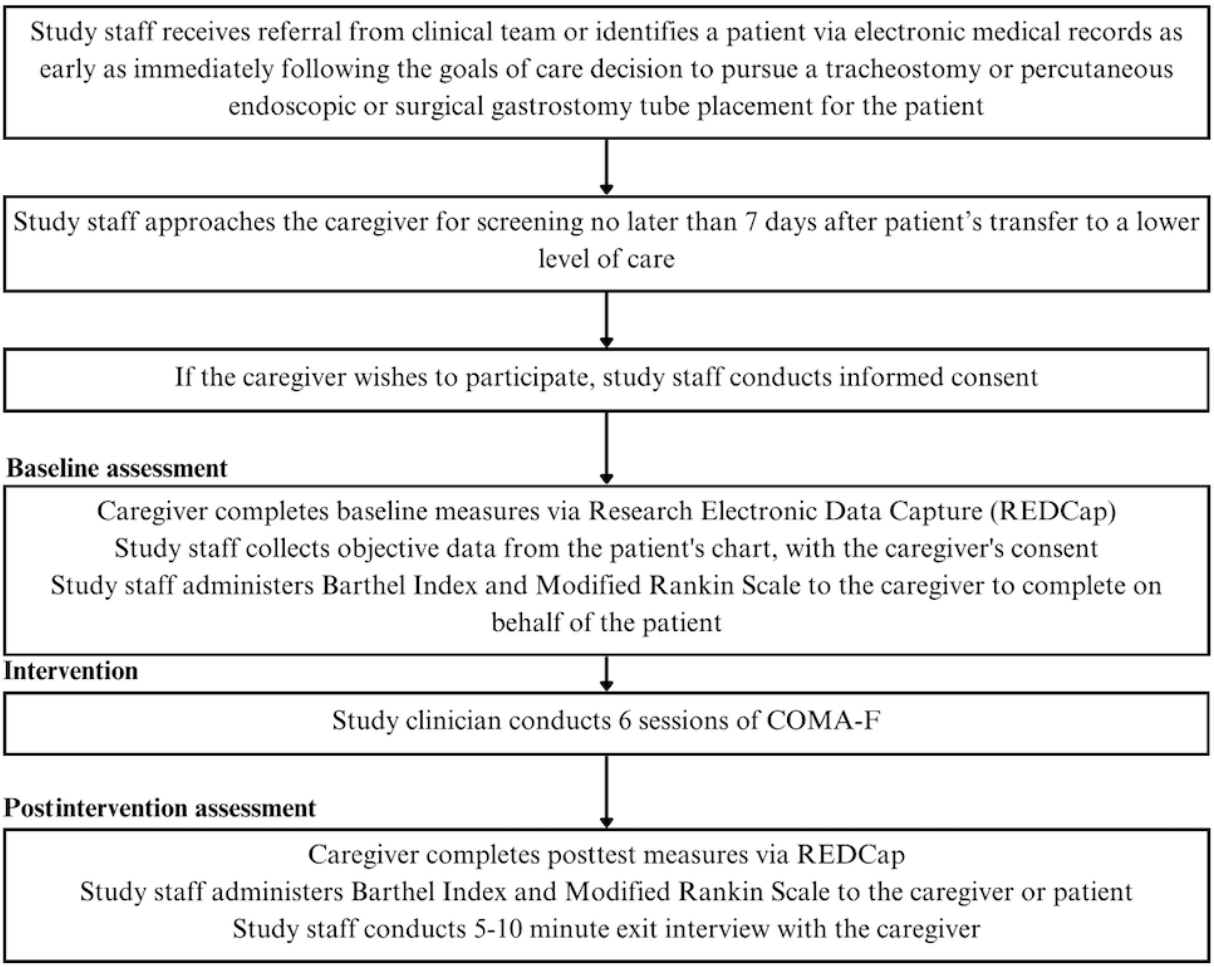
Our team has followed the National Institutes of Health (NIH) Stage Model for behavioral intervention development [12] to develop the Coma Family Program (COMA-F), a mindfulness-based resiliency program for caregivers of patients with SABI transitioning out of the ICU (Figure 1). We developed preliminary COMA-F content based on adaptations of our intervention for patients and caregivers hospitalized in the neuro-ICU (Recovering Together) [13] and from qualitative interviews of caregivers of surviving patients with SABI. For the latter, we conducted longitudinal qualitative interviews with 30 caregivers across 14 ICUs in the United States to better understand their stressors, coping methods, and treatment preferences [14,15]. Nearly all caregivers discussed using avoidance or distraction as initial coping strategies [14]. They also expressed a desire to learn adaptive coping skills, learn communication skills for interacting with the patient's care team and other family members, and for support with making difficult decisions (Hwang et al, "Psychosocial support needs and preferences among family caregivers of ICU patients with severe acute brain injury: a qualitative thematic analysis," manuscript under review). We have used this feedback and adapted content from Recovering Together to develop the first version of the COMA-F intervention. We plan to deliver COMA-F through a single-arm open pilot trial outlined in this paper (N=15 caregivers). We will use the findings from the open pilot to iteratively refine COMA-F. We will then conduct a feasibility randomized controlled trial (RCT) of COMA-F versus minimally enhanced usual control (MEUC).

XSL•FO
RenderX

Figure 1. Iterative stages of the development of a mind-body resiliency program for caregivers of patients with severe acute brain injury (the COMA-F program). The open pilot trial described in this protocol is outlined in bold. The subsequent feasibility RCT and efficacy RCT are outlined by dashed lines. COMA-F: Coma Family program; MEUC: minimally enhanced usual control; RCT: randomized controlled trial; SABI: severe acute brain injury.

Objectives

Here we describe our procedure and delivery of the COMA-F open pilot trial. We will explore the preliminary feasibility and acceptability of COMA-F. Further, through exit interviews at the end of the intervention, we expect to elicit feedback on program procedures (hybrid in-person and Zoom format), treatment manuals, support from study staff, and expectations of the program. We will use this feedback to inform each iteration of COMA-F. After completion of the open pilot trial, we will then proceed to test the feasibility of the refined COMA-F program versus the MEUC.



Methods

Study Design and Setting

We will deliver our open pilot of COMA-F for caregivers of comatose patients with SABIs enrolled from 3 academic medical centers in the United States. If we encounter recruitment challenges, we will also plan to enroll from collaborators' institutions in the northeastern and mid-Atlantic regions of the United States. We present our study design and procedure in Figure 2.

XSL•FO
RenderX

Figure 2. Open pilot trial design and procedure for the development of a mind-body resiliency program for caregivers of patients with severe acute brain injury (the COMA-F program). COMA-F: Coma Family; REDCap: Research Electronic Data Capture.

Ethics Approval

This study has been approved by the institutional review board at 1 of the 3 enrollment centers (Mass General Brigham Institutional Review Board, 2023P000536), with approvals at the other 2 centers pending. We will conduct informed consent with all caregivers enrolled in the study. We will deidentify all data and provide subject ID numbers to participants. We will compensate participants US $20 via check for completing baseline assessments and US $40 via check for postintervention assessments, for a total of US $60 per participant.

Recruitment and Screening

Overview

We present our study inclusion criteria in Textbox 1. We will recruit caregiver subjects through 2 concurrent mechanisms.

XSL•FO
RenderX

Textbox 1. Open pilot trial inclusion criteria for the development of a mind-body resiliency program for caregivers of patients with severe acute brain injury (the Coma Family program).

- Age 18 years or older
- English-speaking
- Screens for emotional distress on either depression or anxiety subscales (>7) of the Hospital Anxiety and Depression Scale
- Confirmed by the primary clinical team as the primary caregiver for a patient who has the following characteristics:
  - Age 18 years or older
  - Admission to the intensive care unit with a severe acute brain injury for one of the following: ischemic stroke, intracerebral hemorrhage, subarachnoid hemorrhage, traumatic brain injury, or hypoxic-ischemic encephalopathy
  - Glasgow Coma Scale score below 9 (in the judgment of the medical team) while not intubated or an inability to follow meaningful commands while intubated at any point during their hospitalization course for more than 24 consecutive hours due to the brain injury itself and not a confounding factor (ie, sedation and seizures)
  - Still alive in the intensive care unit at the time that the clinical team approaches the primary caregiver about possible recruitment
  - Either will be undergoing tracheostomy and percutaneous endoscopic or surgical gastrostomy tube placement or has already received one or both
  - Has a prognosis for survival of greater than 3 months and does not have a concurrent diagnosis of a terminal illness or injury, as judged by the clinical team

Referrals From the Clinical Team

ICU medical and nursing team members who are caring for patients with SABIs will identify eligible caregivers and notify the study team, as they currently do in 1 of our enrollment centers for our ongoing Recovering Together trial of patients and caregivers in the neuro-ICU [13]. Notably, COMA-F will capture caregivers of patients with SABI as described in Textbox 1, whereas Recovering Together exclusively focuses on dyads of caregivers and patients who are cognitively intact.

Study Staff Screening

We will conduct daily prescreening of electronic health record admission reports to identify patients that meet the SABI criteria discussed below. Study staff will then inquire with the clinical team if the identified patients have a caregiver that meets inclusion criteria.

Enrollment

Once a potential caregiver has been identified and approved by the clinical team, a member of the study team will approach the caregiver in person or call them via phone no later than 7 days after the patient's transfer to a lower level of care.

Caregivers who wish to participate will complete consent. During the consent process we also inform caregivers that we will collect patient data from the medical record (eg, demographics, diagnosis, and procedures). Prior to the intervention, caregivers will complete self-report baseline assessments through Research Electronic Data Capture (REDCap) either in person on a tablet, or they will be emailed a link to the REDCap survey. We plan to enroll 15 caregivers.

COMA-F Intervention Content

The intervention will have 6 sessions and be presented as a hybrid program. Caregivers will have the option for any number of initial sessions to be delivered in person within the hospital (until the patient is discharged). If the patient is discharged at any point in the intervention, the remaining sessions will be delivered via live video using Zoom. We will also give caregivers the option of completing the intervention completely over Zoom. Zoom is a free and secure internet-based videoconferencing software program that is currently used to provide care for patients at each of the recruiting centers.

Sessions focus on developing mindfulness-based resiliency skills to cope with and manage caregiver-related stressors. The sessions were developed based on caregiver feedback in our qualitative interviews [14,15] and from adapted Recovering Together content [13]. Caregivers will choose 6 modules from a selection of 7 modules. The 7 modules are presented in Table 1.

XSL•FO
RenderX

Table 1. Session outline for the COMA-F[a] program. The program will be delivered to caregivers of patients with severe acute brain injuries. The program will take place over 6 weeks.

Session	COMA-F topic	COMA-F skills and session content
1	Coping with the here and now	Deep breathing, mindfulness, 24-hour block, and mindfulness meditation
2	Coping with uncertainty	Dialectics, hands as worries, and support with difficult decisions
3	Adjusting to new roles	Identify the distress spiral and challenge unhelpful thoughts
4	Engaging social support	Effective communication with other family members and friends and care team
5	Engaging with positive activities	Behavioral activation, using social support, and setting daily goals
6	Managing fear and worry	Observing fear and worry and acceptance and change
7	Making meaning from our experiences	Making meaning: finding purpose and meaning in new caregiving role

[a]COMA-F: Coma Family.

Feasibility and Acceptability Outcomes

The feasibility and acceptability markers are presented in Table 2.

Table 2. Feasibility and acceptability outcomes for our open pilot trial of a mind-body resiliency program for caregivers of patients with severe acute brain injuries. Outcomes will be assessed at the end of the program.

Outcome	Definition
Feasibility (>70% acceptable; >80% excellent)	
Recruitment	Percentage of eligible caregivers who participate
Assessments	Percentage of enrolled caregivers with no measures missing
Adherence	Percentage of caregivers that complete 4 of 6 sessions
Therapist fidelity	After randomly selecting 20% of sessions, percentage of sessions with 100% of content delivered
Acceptability (>70% acceptable; >80% excellent)	
Treatment satisfaction	Percentage of caregivers who score above the midpoint on the Client Satisfaction Questionnaire-3 [16]
Credibility and expectancy	Percentage of caregivers who score above the midpoint on Credibility/Expectancy Questionnaire [17]
Adverse events	Mild adverse events reported in <10% of caregivers; no adverse events linked to program participation

Assessments

We selected quantitative measures based on those collected in Recovering Together and from our qualitative interviews during COMA-F development (Textbox 2). We will administer the same measures at baseline and after the intervention.

Textbox 2. Quantitative measures administer at baseline and after the intervention.

Emotional distress

Hospital Anxiety and Depression Scale—measures anxiety and depression symptoms [18]; Posttraumatic Stress Disorder Checklist–5—measures posttraumatic stress symptoms [19].

Resiliency factors

Measure of Current Status Part A—measures adaptive coping abilities [20]; Cognitive and Affective Mindfulness Scale Revised—measures inclination toward acting mindfully [21]; Toronto Mindfulness Scale–Trait—measures trait mindfulness [22]; ENRICHD Social Support Instrument—measures perceived availability of social support [23].

Functional status of patient

Barthel Index—measures functional independence in activities of daily living [24]; Modified Rankin Scale—measures level of disability in patients after a SABI [25].

XSL•FO
RenderX

Exit Interview Procedures

Caregivers will complete the postintervention measures listed above immediately after the end of session 6. We will then conduct a brief 5-10 minute exit interview. We will ask caregivers to provide feedback on the program procedures, hybrid in-person and Zoom format, treatment manuals, support from study staff, and expectations of the program. We will also ask caregivers to discuss their responses on the pre- and postintervention assessments.

Data Analysis

For quantitative data, we will calculate frequencies and proportions of the feasibility and acceptability outcomes. We will also conduct exploratory analyses to examine differences in emotional distress outcomes and feasibility or acceptability outcomes by the sex of the caregiver. For qualitative data, we will examine exit interviews using thematic analysis following the Framework Method [26]. We will then conduct mixed methods analysis using an explanatory-sequential design which will allow us to integrate quantitative and qualitative data to refine the COMA-F manual and study procedures. Specifically, we will use the exit interviews to explain the quantitative findings and to elicit feedback on the program.

Results

We have received funding by the Neurocritical Care Society to begin recruiting in January 2024. Based on our recruitment data from our qualitative interviews [14,15] we expect to enroll 15 caregivers by November 2024. Following this timeline, our last enrolled caregiver would complete the program in December 2024.

Discussion

Scientific Contribution

Chronic emotional distress is common in caregivers of comatose patients with SABIs, which in turn undermines their caregiving ability and the patient's own health and recovery [27,28]. As novel neurocritical care interventions seek to pursue exciting and more aggressive measures to "cure coma," [29-31] caregivers of more patients may potentially endure lengthy periods of uncertainty and distress. As such, the COMA-F program is timely, aiming to prevent the development of chronic distress in these caregivers by teaching them mindfulness-based resiliency skills. These skills will help caregivers manage the severity of their distress.

This protocol provides the framework of our open pilot trial of COMA-F. The intervention is novel and flexible, offering hybrid delivery methods to bypass geographical barriers to participation. Following the NIH Stage Model for behavioral intervention development [12], we will use the open pilot results to refine the program and inform a future feasibility RCT of COMA-F versus MEUC.

Limitations

Our pilot trial has limitations that we hope to address in future iterations and adaptations of COMA-F. First, our recruitment will be restricted to the demographic distribution of our 3 enrolling centers. In our future feasibility RCT we will focus specifically on recruiting a representative racial and ethnic sample of the United States. Second, we are targeting caregivers caring for patients who are undergoing prolonged life-supporting therapy as opposed to transitioning patients to comfort care only. In future trials, we do plan to adapt COMA-F to be offered to caregivers potentially transitioning their loved ones to comfort measures.

Conclusions

We will use the results from this open pilot trial to inform the development of a mind-body resiliency program for caregivers of patients with SABIs. Our study will provide quantitative and qualitative data that we will use to refine the current iteration of the program. We will then test the refined intervention in a feasibility RCT.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Conflicts of Interest

None declared.

Abstract

Background: With an increase in both the number of mental health disorders people are experiencing and the difficulty in accessing mental health care, the demand for accessible mental health care services has increased. The use of mobile devices has allowed people to receive care in their daily lives without restrictions on time or location. However, the majority of publicly available mobile health apps are not evidence-based, and the top-rated apps are not always safe or user-friendly and may not offer clinically beneficial results.

Objective: This study aims to create a cultural adaptation of the American Psychiatric Association's comprehensive app evaluation framework in Japan using a web-based modified Delphi expert consensus.

Methods: A web-based modified Delphi study includes developing the Japanese version of the comprehensive app evaluation framework and 3 Delphi rounds. In the first round, our working group sends a questionnaire to the panelists, who then complete it. In the second and third rounds, the working group sends a questionnaire and a summary of the panelists' answers based on each of the previous rounds. The panelists answer the questionnaires based on this summary. The summarization procedure is automated to help reduce the biases that can be generated when panelists' answers are summarized and when the panelists receive them. The working group sends only the result of the summarization with the next round's questionnaire. All interactions between the working group and the panelists will be conducted on Qualtrics (Qualtrics Japan LLC), a questionnaire platform. To culturally validate the comprehensive mental health app evaluation framework, participants from the following three categories will be recruited in Japan: (1) researchers, (2) practitioners, and (3) app developers.

Results: This study received funding from a crowdfunding campaign in Japan (April 2023). The Delphi study began in January 2023 and will be completed in December 2023. We had already completed the translation of the 105 original app evaluation item questions by December 2022.

Conclusions: While the need for treatment using mental health apps is increasing, no framework that can be used to develop a centralized database for health apps is available or accessible, and no consensus has been reached among stakeholders in Japan about an appropriate framework. The results of the web-based modified Delphi method presented in this paper may provide direction for the development and use of mental health apps in the future among the relevant stakeholders. Furthermore, this study will enhance recognition of the framework among researchers, clinicians, mental health app developers, and users, in addition to devising new instruments to help users or practitioners efficiently choose the right app for their situations.

Introduction

Problems with mental health, such as mental health disorders, affect people internationally. According to the Global Burden of Diseases, Injuries, and Risk Factors Study, the 2 most disabling mental disorders, depression and anxiety disorders, ranked among the top 25 leading causes of burden worldwide in 2019 [1]. In addition, the COVID-19 pandemic has had an enormous impact on mental health. For example, the World Health Organization [2] indicated that there was a remarkable increase in mental health problems in the general population; loneliness and a positive COVID-19 diagnosis increased the risk of suicidal thoughts. The COVID-19 pandemic led to a 27.6% increase in cases of major depressive disorders and a 25.6% increase in cases of anxiety disorders in 2020 [3]. Furthermore, COVID-19 has made it more difficult for people facing mental health problems to access outpatient mental health services [2].

With the rise of mental health problems and the increasing difficulty in access to in-person mental health care services, the demand for accessible mental health care services has significantly increased. The use of mobile devices, which are now owned by a majority of people, has made it possible for individuals to access care in their daily lives without being restricted by place and time [4-6]. As of 2017, more than 318,000 health apps existed worldwide; this is twice as many as were available in 2015. Of 318,000 health apps, 490 apps targeted mental health and behavioral disorders [7]. In Japan, a systematic search of the Google Play Store and Apple App Store between June 4 and June 11, 2021, found that 172 mental health apps are available [8]. Moreover, a previous study of Japanese university students found that the mobile health (mHealth) apps usage rate was 32.1% [9]. Considering that 36% of adults who owned smartphones or tablets in a national sample of the United States [10] had mHealth apps on their devices, the usage rate of mental health apps in Japan is estimated to be about the same as in other countries.

Recent reviews have found that mHealth apps could be effective in reducing symptoms of depression and anxiety in adults and youth [11,12]. Unfortunately, some of the apps available are unreliable or harmful. Most publicly available mHealth apps are not evidence-based, and top-rated apps on the app store are not always safe or user-friendly and may not offer clinically beneficial results [13,14]. Similar problems have been reported in Japan [15].

It is difficult for service users (eg, clinical therapists, patients, the general public, and those without mental health concerns) to ensure that apps are safe, evidence-based, usable, and offer clinically beneficial results [16]. Multiple scales and frameworks have been developed to evaluate mHealth apps [17,18]. These scales and frameworks include scales for evaluating the quality, safety, usability, and importance of apps [19]. However, the majority of scales have been developed for app developers to evaluate their own apps [19], and more inclusive tool apps are necessary to help users select the right app based on their conditions and preferences.

The App Evaluation Model framework proposed by the American Psychiatric Association (APA) is useful for addressing this issue [20]. This framework was constructed via a 6-step process that involved harmonizing the 961 app evaluation questions included in 45 existing app evaluation frameworks, removing duplicate, redundant, and nonrelevant questions, and then grouping the remaining 357 questions into 5 priority levels: background information, privacy and security, evidence-based, ease of use, and data integration [21]. Even then, there was no centralized database where users can glance at how various health apps perform when assessed via the framework. Therefore, Lagan et al [16] translated APA's framework for evaluating apps into a set of objective questions that can be published on the internet; the questions from the APA model were operationalized into the 105 objective questions that are either binary or numeric. The 105 objective questions are aligned with the levels of the APA framework, with the 5 levels arranged in a pyramid format to reinforce the need to first consider access, safety, and privacy. There were some additions and alterations to several questions to reflect ongoing feedback from stakeholders after a 2-day summit in December 2019 [16]. The main difference between the user version of the Mobile App Rating Scale, which is the most used mHealth apps evaluation scale, and the app evaluation model is that the app evaluation model does not score questions or produce summary scores about the quality of app safety, usability, etc, but instead allows the user to judge what is important and a good match for them.

Currently, no framework that can be used to develop a centralized database for health apps is available and accessible, and no consensus has been reached among experts and clinicians in Japan about an appropriate framework. The aim of this paper is to describe the study protocol that will be used to validate the adaptation of the 105 objective questions in Japan and develop a Japanese version of the framework among stakeholders involved in mental health apps. In the absence of empirical evidence to reach such a consensus, various methods can be used to synthesize opinions based on expertise and scientific background. In this study, we will use the Delphi method, which ensures anonymity and allows opinions to be expressed without group pressure. The Delphi method has been used to formulate various guidelines and models [22,23]. Our Delphi study is conducted to examine whether the 105 objective questions are comprehensive, content-appropriate, and relevant to this domain as criteria for evaluating mental health apps. The target audience for this framework includes people involved in the research, clinical practice, and app development of health apps throughout Japan. The reason for targeting these people whose native language is Japanese is also to identify difficulties in understanding items that were not noticed during the Japanese translation process.

Methods

Ethical Considerations

Participation in this study is voluntary. The emailed Delphi survey invitation includes the following information for potential panelists: presentation of the researcher responsible for the study, description of the study, reasons for the selection of the expert, procedures to be followed to participate, estimation of the time required, expectations regarding the expert (including the importance of participating in all rounds of the consultation), the promise of anonymity and participation recognition, and rewards for participation (payment of 20,000 JPY [approximately US $143] at the end of the study). Before participation in this study, informed consent was obtained from all panelists.

Design

This research procedure is planned with reference to the Conducting and Reporting Delphi Studies (CREDES) guidelines [24] and reviews of the Delphi study [25,26]. The classic Delphi techniques have the following characteristics [27]: (1) a working group organizes the Delphi study; (2) the working group recruits a panelist's group of individuals with some expertise on the topic; (3) the group compiles a questionnaire with a list of statements that the experts rate for agreement; (4) the group collects responses from the panelists using the questionnaire; (5) the group gives anonymous feedback to each panelist about how their responses compare to the rest of the panelists; (6) each panelist is able to revise their responses to the questionnaire after receiving the feedback; and (7) responses converge across rounds of questionnaires, with some statistical criterion being used to define consensus. Since developing a Japanese version of the comprehensive app evaluation framework serves as a starting point for the modified Delphi technique, we refer to our Delphi study as a modified Delphi study. The expected duration of the study is 12 months, which began in January 2023. To culturally validate the comprehensive mental health app framework in Japan, Japanese participants will be recruited from three categories: (1) researchers, (2) practitioners, and (3) app developers.

Procedure of the Web-Based Modified Delphi Study

Table 1 shows the procedure of developing the Japanese version of the comprehensive app evaluation framework. The Delphi method includes 3 rounds, with evaluation panelists answering anonymously in each round. In each round of the Delphi survey, the working group will pilot the round with 1 researcher, 1 practitioner, and 1 app developer prior to initiation. The individuals who participate in the pilot will not participate in the Delphi process. In the first round, our working group will send a questionnaire to the panelists, who will complete it within 4 weeks. If any panelist does not complete the evaluation within 4 weeks and does not respond to communications from the working group, the panelist would be considered to have dropped out of the study and will be excluded from the analysis. In the second and third rounds, the working group will send a questionnaire and a summary of the panelists' answers based on each previous round. The panelists answer the questionnaires based on this summary. The summarization procedure is automated to reduce biases that may occur when summarizing panelists' answers and providing those summaries to the panelists. The working group sends the result of the summarization with the next round's questionnaire. Each round's summary includes the following: the quantitative result for each item's question and explanation, the qualitative comments and explanation for each evaluation, and suggestions for modifying (revising, removing, and adding) items. When the panelist suggests revision or addition of items, the working group members will review the proposals within 3 weeks after the panelists' response. The working group would discuss the items and judge whether each revised or added item's expression is adequate. An independent liaison from the working group will make contact with the panelists, and the information about the panelists will be masked to the working group members who are participating in the discussion. These discussions will be conducted by 2 or more members.

Final round	• Conducting the pilot study • Providing feedback on the summary of the second round • Final analysis and publication	Judging the appropriateness of items in the final version of the 105 objective questions and suggesting notations for each item

[a]N/A: not applicable.

Develop Questionnaires

The 105 original evaluation items were translated in accordance with the guidelines provided by the International Society for Pharmacoeconomics and Outcomes Research task force [28]. First, forward translation from English to Japanese was performed independently by 2 of the authors (KY and HNT). Then, a professional English translator who was English-Japanese bilingual and blinded to the 105 objective questions translated the provisional app evaluation item back into English. The 2 English versions of the app evaluation item questions (ie, the original and back-translated versions) were reconciled by KY, HNT, and John Torous (original 105 objective questions' author), and only minor discrepancies were found. These discrepancies were discussed until a consensus was reached. The original author (John Torous) evaluated the finalized English version of the app evaluation item questions and confirmed that the original meanings of the items, instructions, and responses had been maintained throughout the translation procedure.

Administer Questionnaires

Panelists will complete evaluations in a 2-stage structure (the 105 items and the 11 key levels). The 105 objective questions are constructed by the following key levels: app origin, functionality, app store attributes, accessibility, privacy and security, inputs, outputs, clinical foundation, features, engagement style, and interoperability and data sharing. At the beginning of each key level, the questionnaire explains the key level, and panelists will be asked to assess the appropriateness of the item that comprises the key level. At that time, we will ask panelists to suggest additional items if needed. After the evaluation of key level, panelists will assess 105 objective questions and descriptions. Panelists will be asked to respond on a 9-point scale (1=not at all appropriate to 9=quite appropriate) regarding whether the item is appropriate to evaluate apps. When the panelists assign a score of 1-5, they will be asked to provide free-text feedback that includes suggestions for changing the wording.

Synthesize Answers

In keeping with the described methods, satisfactory agreement for each round will require both (1) all responses >5 (ie, no participant disagreement) and (2) 60% (n=31) participation in voting in each round. These criteria were conservatively set with reference to several previous studies [29,30]. In addition, satisfactory consensus for each round will require the following: the smaller the IQR, the greater the consensus; an IQR of 0 or 1 indicates a very strong consensus, while an IQR of 2 indicates a strong consensus [31]. IQR includes the difference between the 75th percentile (third quartile) and the 25th percentile (first quartile). The items that meet these criteria will be removed for the next round of the Delphi. In addition, for free-text feedbacks, 2 or more people of the working group would discuss the panelists' responses regarding the addition or modification of items, whether to adopt the responses in the next round, and in case of adoption, how the items should be added or modified. If no conclusion is reached through discussion, the working group members who were not able to participate on the discussion day will be asked for their opinions. For this reason, the discussions will be recorded on video and via the minutes of the meeting.

XSL•FO
RenderX

Elaborate Selection Criteria for Evaluation Panelists

Overview

The panelists will consist of 51 researchers, practitioners, and app developers. Inclusion and exclusion criteria of the panelists in each category are as follows.

Researchers who have experience contributing to at least 1 study for psychological assessment or treatment with mHealth apps will be included. The number of relevant publications, the manner in which they contribute to the research, and the degree of contribution are not required; however, if they are involved in assessment, treatment, development, usability or feasibility studies, protocol studies, reviews, preprints, conference papers, etc, they will be considered candidates for panelists.

Any practitioner who has experience with at least 1 app that assists in the treatment of procedure to a patient or client who is facing mental health issues will be considered a candidate. Practitioners include psychiatrists and clinical psychologists. Clinical experience related to mental health care is not required. Given the state of app development in Japan, we anticipate that the panelists would be limited, which would undermine their inclusiveness. Therefore, we include those who have used an app for patients for treatment or assessment purposes, regardless of the mental health app.

For app developers, candidates must have experience developing at least 1 app related to mental health care. There is no minimum requirement for years of experience in mental health app development that must be met. However, panelists who participated in the development of mental health app items will be excluded.

Make a List of Panelists

Panelists will be recruited based on the inclusion and exclusion criteria that will be considered in the primary list. Subsequently, snowball sampling will be conducted to expand the pool of panelists.

Dissemination

The preponderant involvement of various stakeholders throughout the study will offer the possibility of disseminating the results and progress of this study during the conduction of this study. Following that, diverse activities will take place to transfer knowledge. For example, scientific papers will be published, and conferences will be held to share the results with researchers. These activities could include working with the media to produce commentary papers, features, and stakeholder interviews on research findings. Workshops will be organized with professionals. A podcast will also be available for people interested in delving deeper into the results and related topics and listening to interviews and discussions with experts. Public lectures for citizens are also planned to disseminate the results of the study and explain how to use the app evaluation items to the general public. These activities will be conducted both on-site and on the internet, and records of the activities will be made available through the website and social networking sites developed for the study.

Results

We have already completed the translation of the 105 original app evaluation item questions in December 2022. We compiled a list of panelists willing to participate in the Delphi study. We anticipated the first Delphi round to commence in January 2023, and that all Delphi rounds will be completed by December 2023. Finally, the results of each Delphi round will be anonymously reported, and the report will be distributed among all panelists who participated in the Delphi study. This report will include an indication of the distribution of panelists' ratings, including their comments and suggestions. The results will be presented both quantitatively and qualitatively. We expect this study to be published in a peer-reviewed journal and presented at national and international conferences.

Discussion

Principal Considerations

While the need for treatment using mental health apps and the development of mental health apps to meet this need are increasing [32], no framework which can be used to develop a centralized database for health app is available and accessible, and no consensus has been reached among stakeholders in Japan about an appropriate framework. The web-based modified Delphi method presented in this paper aims to reach a consensus on an app framework, and thus ensure the direction of use and development of mental health apps in the future.

We expect that this web-based modified Delphi method will incorporate many different stakeholders involved in mental health apps (researchers, clinicians, and mental health app developers), facilitate the application of the comprehensive app evaluation framework in Japan, and provide valuable insights that will contribute to future developments in this field.

Furthermore, we expect that this work will raise awareness of the framework among some stakeholders involved in mental health apps, in addition to leading to the development of tools that will enable users or practitioners to efficiently choose the right app for their situations.

Strengths and Limitations

The majority of studies aiming at cultural adaptation of a survey have thus far failed to follow the CREDES guidance. This study is the second CREDES-based cultural adaptation of a scale in Japan. Furthermore, the panelist group in this Delphi study includes clinical experts, researchers, and developers to use diverse perspectives. This limitation will be due to the diversity of panelists, as there will be only 51 panelists in total, which is 17 participants for each domain. The CREDES prefers 50 participants for Delphi studies; therefore, the planned number of participants is acceptable. On the other hand, since this study plans to conduct the first round for 51 panelists at the time of study participation, it is possible that the number of panelists will decrease over time.

Conclusions

This study will develop the Japanese version of the comprehensive app evaluation framework that has reached a

XSL•FO
RenderX

consensus among some stakeholders involved in the mental health app. It will generate useful insights for people involved in research, clinical practice, and app development regarding mental health apps throughout Japan and suggest the direction of use and development of mental health apps in the future. Furthermore, this study will enhance recognition of the framework among researchers, clinicians, mental health app developers, and users, in addition to developing new instruments to help users or practitioners efficiently choose the right app for their situations.

Acknowledgments

The authors would like to acknowledge the financial contributions of over 150 individuals via the crowdfunding. They provided us with the opportunity to conduct this study. We also thank Editage for the English language review.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study.

Abstract

Background: Academic procrastination is a widespread problem among college students. It is linked to poor academic performance and increased college dropout intentions, as well as several mental health problems such as depression, anxiety, and stress. Guided web-based interventions can help reduce procrastination. However, guidance by professional clinicians draws upon valuable and limited societal resources, and a more efficient, scalable form of guidance is needed. Guidance by trained clinical psychology students has not yet been examined.

Objective: The aim of this open trial is to examine the feasibility and acceptability of a web-based procrastination intervention for college students under the guidance of student digital coaches (e-coaches).

Methods: We developed a single-arm trial of a guided web-based intervention targeting procrastination for the Dutch student population. Guidance is delivered by trained clinical psychology students asynchronously in the form of textual feedback on intervention progress, with the aim of supporting and motivating the participant. Participants are recruited at 7 Dutch universities. Primary outcomes are intervention satisfaction, usability, and adherence, which are assessed by the Client Satisfaction Scale (CSQ-8), System Usability Scale (SUS-10), and number of completed modules, respectively. The primary outcomes will be examined by calculating descriptive statistics. Secondary outcomes are e-coach satisfaction and changes to procrastination, depression, stress, and quality of life from pre- to posttest and follow-up.

Results: The project was funded in 2019, and recruitment began in January 2021. As of May 2023, a total of 985 participants were enrolled, of which 372 had completed the posttest and 192 had completed the follow-up. The expected date of analysis and publication of the results is 2024.

Conclusions: The results are expected to contribute to the body of literature regarding eHealth in 3 ways. First, we will examine whether students who procrastinate adhere to and are satisfied with an eHealth intervention targeting this problem. Second, we will explore whether an intervention targeting procrastination can also decrease depression and stress. Lastly, we will investigate whether trained psychology students can effectively guide their peers in web-based interventions. Given the shortage of licensed psychologists, exploring alternative sources of guidance is much needed in order to provide students with the mental health support they need.

Introduction

Academic procrastination is a widespread problem among college students, with studies reporting prevalence rates ranging from 29% to 67% [1-4]. Procrastination, which is defined as the tendency "to voluntarily delay an intended course of action despite expecting to be worse off for the delay" [5], is linked to poor academic performance [6] and increased college dropout intentions [7]. Procrastination is also associated with several mental health problems, such as depression [8], anxiety, stress [9,10], maladaptive coping, and low self-esteem [11]. Negative long-term consequences associated with procrastination include poorer overall health, difficulties with social relationships, financial struggles, and limited career opportunities [10,12,13].

Effective treatments to target procrastination are available. A recent meta-analysis reports that psychological treatments are effective in reducing procrastination [14]. When comparing different types of treatment, cognitive behavioral therapy (CBT) was found to be the most effective in reducing procrastination when compared with self-regulation training, strengths training, and acceptance-based behavior therapy [15].

Still, it is uncommon for students to seek or receive help for mental health complaints due to several barriers. The most common barriers are the perception that help is not needed, as students view their problems as minor or temporary, and a perceived lack of time. Other barriers include a preference for self-management, a fear of stigmatization, and low awareness of available resources [16,17]. Lastly, the detection and treatment of students with mental issues in general is hampered by limited available resources and a limited number of available student psychologists or student counselors, resulting in long waiting lists [18]. One solution to several of these barriers may be eHealth interventions, consisting of web-based treatments such as CBT. They offer quick access to treatment, anonymity, flexibility, and improved cost-effectiveness compared to face-to-face treatment [19,20]. These interventions are effective in improving mental well-being for a wide range of psychological complaints such as depression, anxiety [21,22], and stress [23]. Guided eHealth and face-to-face treatment have been found to be equally effective in treating depression and anxiety [24,25].

Studies examining the effectiveness of eHealth interventions targeting procrastination specifically show that eHealth is also effective in reducing procrastination [26-28]. When comparing eHealth to traditional treatment, chat-based counseling and face-to-face counseling resulted in a comparable decrease in procrastination [29]. Similarly, a group intervention and self-guided internet-based treatment produced comparable levels of improvement for procrastination behavior after the treatment period [30].

However, there are also drawbacks to eHealth. An often-mentioned reason for a lessened intervention effect is the problem of nonadherence, meaning participants do not make optimal use of the intervention [31-33]. For procrastination specifically, the problem of nonadherence could be exacerbated, as individuals with procrastination tendencies can struggle to adhere to the treatment [28].

Adding therapist guidance to eHealth interventions could offer a solution to this problem. Meta-analytic evidence suggests that guidance from professionals increases eHealth treatment effectiveness when compared with unguided treatment [24,34]. This may be explained by the positive effect guidance has on motivation, engagement, and adherence [35-37]. However, the addition of professional guidance in eHealth draws upon valuable and limited societal resources, and there is a scarcity of properly trained professionals.

The question arises whether there is a more efficient, scalable form of guidance without lowering therapy effectiveness. There is evidence suggesting guidance by nonclinicians (eg, peers, research assistants, or other laypeople) has comparable effects compared to guidance by clinicians in eHealth interventions [38]. What has not specifically been examined yet is whether guidance by trained clinical psychology university students can be equally effective. Were this to be the case, it could greatly reduce the load on the health care system as trained clinical psychology students could offer eHealth guidance for significantly lower costs compared to clinicians. Finally, most clinical psychology students welcome the opportunity to gain hands-on experience guiding real clients during their studies.

The main objective of this study is to evaluate the acceptability and feasibility of a new eHealth intervention targeting procrastination in college students that is guided by clinical psychology students by assessing its usability, adherence, and client satisfaction. The secondary objectives are to explore differences between pre- and posttests for procrastination, depression, stress, and quality of life.

Methods

Study Design

This study is a single-arm open trial of a guided eHealth intervention (GetStarted) aimed at decreasing procrastination in college students. It uses a single-group pretest (T0), posttest (T1), and follow-up (T2) design in which T1 and T2 are administered 4 weeks and 6 months after T0, respectively. The study is conducted within the Caring Universities consortium, a Dutch project that is part of the World Mental Health International College Student Initiative (WMH-ICS) of the World Health Organization (WHO) [39].

Participants and Recruitment

Participants are undergraduate, graduate, or PhD students enrolled in the abovementioned 7 universities across the Netherlands. These 7 universities are situated in 10 cities across the Netherlands and have a combined total of approximately 190,000 domestic and international students. Participants may be both domestic and international students.

The aim of this study is to recruit a minimum of 50 students, and recruitment is conducted in 3 ways. Firs, through a yearly web-based survey of the WMH-ICS. This survey canvasses the mental well-being of students and is sent by email to all the students of the participating universities. At the end of the survey, students who want to receive feedback are provided feedback on their mental health. Students who show increased procrastination tendencies (ie, a score >28 on the Irrational

XSL•FO
RenderX

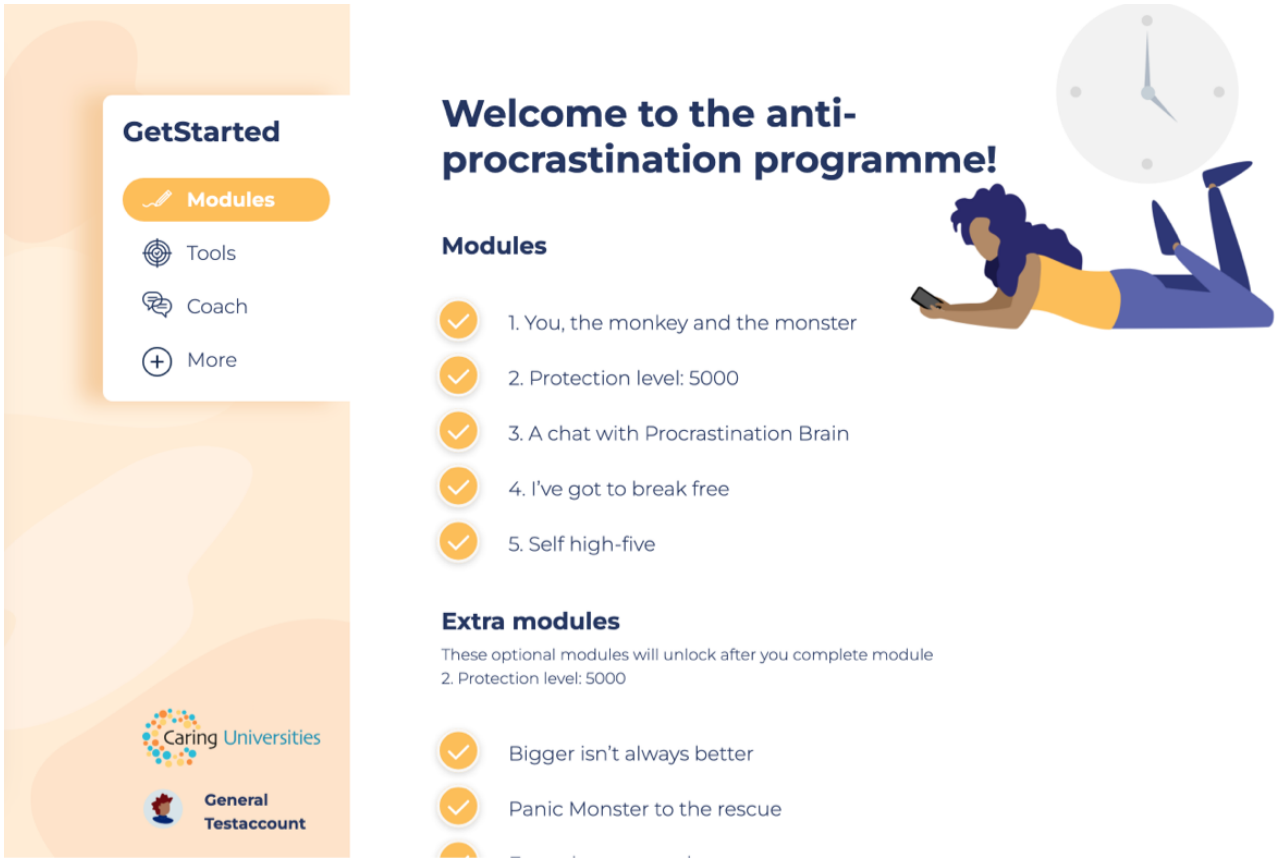
Procrastination Scale; IPS) are invited to sign up for the Caring Universities procrastination program. Second, marketing activities are conducted on the web through social media and on campus through posters, flyers, and other advertisements. Third, we recruit participants through the staff at participating universities. Staff members who work directly with students, such as student psychologists, study advisors, and lecturers, are informed of the program and can recommend it to students who might be interested.

Students are not offered compensation for participation.

Eligibility Criteria

Participants will be included if they meet the following criteria: (1) being aged 16 years or older; (2) being enrolled as a bachelor, master's, or PhD student; and (3) having given informed consent.

The sole exclusion criterion is suicidal risk. Participants will be asked if they have had thoughts of killing themselves or made plans to kill themselves in the past 12 months. If they answer yes, the follow-up question, "How likely do you think it is that you will act on this plan in the next 12 months?" is asked. Participants that respond to this question with "somewhat likely" or "very likely" are excluded from the intervention.



Intervention

The guided eHealth program aimed at reducing procrastination behavior (GetStarted) is developed based on the principles of CBT. Students are involved in the development of the program by giving their opinions and feedback on the program content as well as the layout of the website that contains the program. The feedback is implemented to ensure that GetStarted meets students' needs and preferences.

GetStarted (Figure 1) consists of 9 modules, of which 5 are mandatory main modules and 4 are optional modules. The modules consist of psychoeducation, reflective questions, interactive exercises, and homework assignments. The content is delivered both textually and visually, including through the use of pictures, infographics, and videos. Each module takes approximately 30 to 45 minutes to complete, and students are advised to complete 1 main module a week. The duration of the program will therefore be approximately 4-5 weeks, though students are allowed to go at their own pace and can access the intervention for 2 years. Students will be able to access the program from any device that allows internet access.

The first module offers an introduction to the program and its contents. Students are recommended to continue with the second module right away, which covers information on the psychological processes behind procrastination. The third module will allow students to identify the negative thoughts and feelings that accompany certain tasks, causing them to procrastinate. The fourth module will contain a cognitive restructuring exercise in which they will challenge their negative thinking patterns. The fifth and final main module will let the student reflect on their progress, prepare for the future, and include a summary of all the modules.

Figure 1. Screenshot of GetStarted, an eHealth intervention targeting procrastination.

XSL•FO
RenderX

In addition to the main modules, students will be able to choose to do 1 or several of 4 optional modules. The topics of the optional modules will be (1) breaking a big task into smaller parts; (2) creating and sticking to a plan; (3) motivational techniques; and (4) increased productivity. All optional modules will become available upon completion of the second main module.

The intervention will be created based on the following principles of optimized user interface [40] in collaboration with a user experience designer: a menu containing several main sections, presentation of content in small chunks, stepwise exercises with separate instructions at each step, examples presented in expandable containers, and showing responses given by the participant in previous exercises when relevant.

Digital Coaches

During the registration process, participants select a digital coach (ie, e-coach) to support them during the program. The e-coach provides asynchronous, textual feedback through the platform after the completion of every module by the participant. While doing the intervention, participants respond to questions about the subject of procrastination. The e-coaches read these answers, which form the basis of the textual feedback. In this feedback, e-coaches respond to the participant's answers, show empathy, encourage the participant to apply the techniques, and ask reflective questions with the aim of deepening the participant's understanding of their procrastination. The feedback contains the following elements:

- an opening statement containing positive feedback for the participant's completion of the module;
- selecting 2 to 3 points of note in the participant's answers to provide empathy, encouragement, reiterate the goal of the module, or ask a follow-up question; and
- a closing statement regarding the next module.

Writing feedback for a single module takes around 30 minutes on average, and e-coaches provide feedback within 3 working days of a module being completed by the participant. E-coaches also send reminders about the intervention to participants who have been inactive for a while. E-coaches who cannot provide feedback within 3 working days due to a short temporary absence (such as a holiday) write an explanatory message to the participants explaining the absence and informing them of a return date. In the event that an e-coach cannot adequately perform their duties in the long term, the participant is assigned a different available e-coach. The reason for the change, as well as an apology, are provided to the participant by the new e-coach. A member of the research team monitors the e-coaches and the quality of the coaching.

E-coaches are (research) master students in clinical psychology and third-year clinical psychology bachelor students who meet a number of requirements in the area of low-intensity treatments for common mental health problems. E-coaches are recruited by making third-year bachelor and master students aware of the opportunity to coach as an (extracurricular) internship. They can apply for the position with their curriculum vitae and motivation. Based on their previous experience and motivation, certain students are then invited for an interview with the research team, and selected students are offered the position. These students complete 6 hours of coach training before starting their coaching activities and are required to attend weekly 1-hour intervision meetings, which are supervised by the research team.

Possible Harms

Several meta-analyses show that internet-based programs might be beneficial for college students [41] and that there are no indicated risks to internet-based programs. Moreover, individual patient data meta-analyses showed that participants who received an internet-based program for depression had a lower risk of clinical deterioration when compared with the control group [20,42]. These findings seem to indicate minimal to no risk of possible harm. However, in the event that a participant shows signs of more severe mental health problems, which include but are not limited to self-harm or suicidality, in their responses to the questions in the intervention, the protocol for (emerging) crisis situations will be applied: the e-coach (under the supervision of and in collaboration with a certified mental health care psychologist) will reach out and assess the student's current situation in more detail through the platform. In cases of mild to moderate risk of a worsening of psychological symptoms, we will advise the student to seek professional help aside from participating in the study. In cases of high risk, we advise the student to seek out professional help and resolve the current situation before continuing participation in the study.

Platform

The intervention is embedded within the Caring Universities platform. This platform was developed by Caring Universities specifically to deliver eHealth interventions to college students. The platform allows researchers to create interventions, add and arrange the contents (eg, text and visuals), and add questionnaires. Students of participating universities can freely register for the intervention by creating an account on their device (eg, computer or mobile phone). Participants can log into the platform to view its contents 24-7 for a total duration of 2 years, even upon completion of the program. During registration, each participant is presented with a random selection of 3 e-coaches out of all available coaches to choose from based on a name, short biography, and profile picture. Within the platform, participants and e-coaches can interact using textual messages. The platform complies with the General Data Protection Regulation (GDPR) guidelines.

Assessment Measures

Primary Outcomes

Satisfaction With the Intervention

To measure participants' satisfaction with the overall intervention, the Client Satisfaction Questionnaire–8 (CSQ-8) [43] is used. The CSQ-8 is commonly used to measure satisfaction with web-based interventions. It consists of 8 items on a 4-point scale with a total score ranging from 8 to 32, where a higher score indicates greater satisfaction. The CSQ-8 showed high reliability and validity for web-based interventions [44]. Similar properties were found in the Dutch translation of the CSQ-8 [45].

XSL•FO
RenderX

Usability

The System Usability Scale–10 (SUS-10) [46] is used to measure the usability of the intervention. It consists of 10 items on a 5-point Likert scale, with a total score ranging from 0 to 40. Total scores are then multiplied by 2.5 to achieve a total score of 0 to 100, where a higher score indicates greater usability. The SUS-10 has become the most widely used standardized questionnaire to assess perceived usability and has shown good psychometric properties (reliability and validity) [47]. The Dutch translation of the SUS-10 has previously been used [48], though publications on its specific psychometric properties could not be found. However, several other translations of the SUS-10 were found to have similar psychometric properties as the English version [47].

Adherence

Adherence refers to "the degree to which the user followed the program as it was designed" [32]. This study measures adherence by dividing the number of main modules completed by a participant at the time of posttest by the total number of main modules in the program and multiplying this by 100. The resulting percentage will indicate the completion rate. Participants who have not completed a single module will be excluded from these analyses as they did not start the treatment.

Secondary Outcomes

Procrastination Tendencies

The IPS is used to assess procrastination tendencies [49,50]. This scale contains 9 items on a 5-point Likert scale. The scale aims to assess the extent to which participants procrastinate. Higher scores indicate higher levels of procrastination. The IPS is used to assess the changes from pre- to postscores. The IPS showed good internal consistency (Cronbach α=.91) [50] as well as a high level of reliability (r_{pm}=0.58-0.74), and good content, structural, and substantive validity [51].

Depressive Symptoms

Depression is assessed with the Patient Health Questionnaire–9 (PHQ-9) [52]. It consists of 9 items on a 4-point Likert scale, with a total score ranging from 0 to 27. Higher scores indicate higher levels of depression. The scores of 0-4, 5-9, 10-14, 15-19, and 20-27 are indicative of no depression, mild depression, moderate depression, moderately severe depression, and severe depression, respectively [52]. The PHQ-9 was found to have high sensitivity (0.71-0.84), specificity (0.90-0.97), internal consistency (Cronbach α=.86-.89), test-retest reliability (r=0.84), and validity [53,54].

Perceived Stress

Stress levels are assessed using the Perceived Stress Scale–10 (PSS-10) [55,56]. This self-report scale consists of 10 items on a 5-point Likert scale with a total score ranging from 0 to 40, where a higher score indicates higher perceived stress. The PSS-10 was found to have high validity, internal consistency (Cronbach α=.74-.91), and test-retest reliability (r=0.74-0.88) [56,57].

Quality of Life

Quality of life was measured using the Mental Health Quality of Life questionnaire (MHQoL) [58]. It contains 7 items on a 4-point Likert scale that cover the dimensions of self-image, independence, mood, daily activity, physical health, relationships, and future. The total score ranges from 0 to 21, where a higher score indicates a better quality of life. The MHQoL was found to have good validity, test-retest reliability (r=0.85), and internal consistency (Cronbach α=.85) [58].

Digital Coach Evaluation

The Working Alliance Inventory for guided Internet interventions (WAI-I) [59] is used to evaluate participants' satisfaction with the e-coach. The WAI-I consists of 12 items on a 5-point Likert scale with a total score ranging from 12 to 60, where higher scores indicate higher satisfaction. The psychometric characteristics of the WAI-I yielded adequate results [59].

Additional Measures

The following sociodemographic information is collected to examine sample characteristics: age, gender, marital status, nationality, attending university, faculty, education level (bachelor, master's, or PhD), and whether psychotherapy and medication are received.

Assessments

An overview of the assessments can be seen in Table 1.

XSL•FO
RenderX

[a]Pretest.

[b]Posttest (4 weeks).

[c]Follow-up (6 months).

Sample Size

There is no clear method to calculate the sample size of an open feasibility study. Studies have suggested sample sizes ranging from at least 12 participants [60,61] to 35 or more participants [62]. In this study, no power calculation was conducted to determine the sample size, as the main focus is on the feasibility and acceptability of the intervention. Based on these rules of thumb and similar previous studies [63], we anticipate that a minimum of 50 participants will be sufficient to examine our main objectives. However, as the intervention will remain accessible to students for several years as part of the service offering of the Caring Universities project, we anticipate more than 50 participants will make use of the intervention. We will analyze the data of all participants who have used the intervention at the time of data analysis to be able to draw stronger conclusions.

Statistical Analysis

Participants' satisfaction with the intervention, usability, and adherence will be examined by calculating descriptive statistics.

Satisfaction

Each of the 8 items on the CSQ-8 has 4 answering options, of which 2 indicate dissatisfaction (scored 1 or 2) and the other 2 indicate satisfaction (scored 3 or 4). Our goal is for participants to be satisfied or very satisfied with the intervention, meaning a score of 3 or 4 per item. This corresponds with an average total score between 24 and 32. We will consider the intervention a success if average CSQ-8 scores reach a minimum of 24.

Usability

Bangor et al [64] have found that SUS-10 scores above 70 are passable, with scores above 90 indicating superior products. We will consider the intervention a success if average SUS-10 scores reach a minimum of 70.

Adherence

A recent meta-analysis looking at internet interventions for mental health among university students found dropout rates between 11.84% and 50.33% [65]. Given the nature of procrastination, dropout is expected to be on the higher side. We will consider the intervention a success if adherence reaches 50%.

Secondary Outcomes

We will conduct 2-tailed paired *t* tests using a significance level of α=.05 to assess changes in the scores of IPS, PHQ-9, PSS-10, and MHQoL. Average WAI-I scores will be calculated to assess satisfaction with the digital coach.

Ethical Considerations

This study protocol was approved by the Scientific and Ethical Review Board of all universities that participate in Caring Universities on May 15, 2020 (Vrije University, Leiden University, Maastricht University, Utrecht University, Erasmus University, University of Amsterdam, and Inholland University of Applied Sciences; reference number 2020.088). Participants in the study provide informed consent to the collection, storage, and viewing of their personal data. If the researchers want to use the data later for further research and scientific education, or if interim interventions require new data to be processed or used in other ways than for which they were originally collected, this will be communicated to the participants, and permission will be asked again. Research data are collected by the platform, which complies with GDPR guidelines. These are then coded and shared with Vrije Universiteit Amsterdam, which will be responsible for the data processing. Identifying information, such as name and contact information, is stored separately from all other data that are collected. Each participant is assigned an ID code to which the collected data are linked. This ID code is stored separately and is only accessible to the researcher if it is necessary for linking data for contact or permission. The coded data will be analyzed within the study.

Results

This study was funded in 2019, and recruitment began in January 2021. As of May 2023, a total of 985 participants were enrolled, of which 372 had completed the posttest and 192 had completed the follow-up. The expected date of analysis and publication of the results is 2024.

Discussion

Overview

This study aims to examine the feasibility and acceptability of a new, guided web-based intervention for procrastination in college students. The main outcomes are client satisfaction, usability, and adherence to the intervention. In addition, we will explore any changes in the secondary outcomes of procrastination, depressive symptoms, stress levels, and quality of life from pretest to posttest. We expect the intervention to be perceived as feasible and acceptable by college students. An improvement in the secondary measures upon receiving the treatment is also expected, though not all may reach significance.

Strengths and Limitations

eHealth interventions targeting procrastination for students show promising results [26-30]. Guidance from professionals seems to increase the effectiveness of eHealth treatment when compared with unguided treatment [24,34]. However, to our knowledge, research on guidance by clinical psychology students in eHealth interventions is scarce in the literature. Therefore, it is our belief that this study will be informative in the development and implementation of eHealth interventions targeting procrastination among students in the Netherlands.

There are some limitations to be taken into consideration. First, the recruitment method must be mentioned. The main recruitment channel will be through a yearly web-based mental health survey of the WMH-ICS, which is a voluntary survey that is sent out to all students of participating universities. This may result in a selection bias, as not all students are equally likely to fill out the survey and subsequently participate in a voluntary web-based intervention. The sample in this study may therefore not be entirely representative of the Dutch student population. However, it is important to note that participants are not offered course credits or any other form of compensation. As a result, this study will provide an opportunity to examine the real-life demand and use of the intervention by students in 7 different universities across the Netherlands. While the sample may not be representative of the Dutch student population, it is still likely a good representation of students that seek help and are open to eHealth solutions.

Second, this study is a feasibility and acceptability study without a control group. As a result, any findings on the secondary measures of procrastination, depression, stress, and quality of life cannot be directly attributed to the intervention. Further research and randomized controlled trials will be necessary to draw conclusions on intervention effectiveness.

Lastly, nonadherence is a known problem in eHealth, which may be exacerbated by the nature of procrastination [28,31-33]. To increase adherence to the intervention, participants will receive guidance from trained clinical psychology students. This is expected to increase engagement, motivation, and adherence to the intervention [35-37].

There are also several strengths of this study. First is the design of the intervention, which is done in collaboration with students. The visual style of the intervention as well as its contents are discussed with students during the development. Student feedback is implemented to ensure that the intervention meets the needs of the student population. To further promote engagement and adherence, we design the intervention based on principles of optimized user interface [40] and work closely with a user experience designer. This resulted in a highly user-friendly platform, which is expected to promote students' satisfaction and engagement with the intervention. Lastly, we include automated reminders as well as personal ones by the e-coaches to increase adherence [66].

The comprehensiveness of assessment is a second strength. While this study examines the acceptability and feasibility of a new eHealth intervention targeting procrastination, extensive secondary outcomes are also measured. Procrastination is linked to many mental health issues, such as depression, social anxiety, stress, and low self-esteem [8-11]. In this study, we will explore any changes in procrastination, depression, stress, and quality of life, as well as assess the main outcomes of adherence, client satisfaction, and usability. In doing so, we will gain a more comprehensive understanding of the intervention. It also allows us to explore potential moderators and mediators of intervention adherence and effectiveness.

Finally, we believe the use of trained clinical psychology students is a strength of this study. Guidance by nonclinicians such as peers, research assistants, and laypersons has been found to be equally effective as that by clinicians [38]. To our knowledge, no studies have been conducted on guidance by trained clinical psychology students. The use of student coaches is highly cost-effective, as clinical psychology students are often required to gain work experience through extracurricular internships during their studies. Therefore, student coaching would be a more scalable form of guidance. If student guidance in eHealth interventions was found to be feasible and acceptable, it could greatly reduce the load on the health care system and offer more timely access to mental health support to those in need.

Conclusions

This study aims to examine the feasibility and acceptability of an eHealth intervention for procrastination specifically designed for college students and under the guidance of clinical psychology students. The results are expected to contribute to the body of literature regarding eHealth in several ways. First, the nature of procrastination might intensify the known problems of eHealth, such as nonadherence. This study examines whether students who procrastinate will adhere to and be satisfied with eHealth interventions targeting this problem. Second, this study explores whether an intervention targeting procrastination can also decrease depression and stress. Lastly, this pilot investigates whether trained psychology students can effectively guide their peers in web-based interventions. Given the shortage of licensed psychologists, exploring alternative sources of guidance is much needed in order to provide students with the mental health support they need.

Abstract

Background: Chronic fatigue is a common symptom among patients who have been treated for cancer. Current psychosocial interventions typically target the patient alone, despite growing evidence suggesting that a couples' approach can increase and broaden the efficacy of an intervention. Therefore, based on an existing web-based mindfulness-based cognitive therapy for patients, the couple intervention COMPANION was developed.

Objective: The primary objectives of this study are to determine the acceptability of COMPANION and its potential efficacy in reducing fatigue in patients with cancer. Our secondary objectives are to examine the feasibility of the trial procedures and the potential working mechanisms of the couple intervention.

Methods: We will conduct a single-arm pilot trial for couples (ie, patients with cancer with chronic fatigue and their partners). All couples are allocated to the web-based couple intervention that consists of psychoeducation, mindfulness, and cognitive-behavioral exercises. The 9 sessions of the intervention are supervised remotely by a trained therapist. Patients and partners will complete questionnaires before starting the intervention (T0), 2 weeks after completing the intervention (T1), and 1 month after T1 (T2). They will also fill out weekly diaries during the intervention period. A subsample of patients (n≈5) and partners (n≈5) as well as all the therapists providing COMPANION will participate in the final focus groups. Benchmark values have been defined to determine the acceptability (ie, ≥60% of couples complete the intervention and/or ≥70% of the participants are satisfied with the intervention) and potential efficacy (ie, a significant improvement in fatigue and/or a clinically relevant improvement in fatigue in 45% of the patients between T0 and T1) of the intervention. The trial procedures are deemed feasible if an average of at least three couples are included per recruiting month and/or adherence to the assessments is at least 65% for T1 and the diaries and 60% for T2. To establish potential working mechanisms, changes in affect, sleep, catastrophizing, partner communication and interactions, self-efficacy, mindfulness, and closeness will be examined. Quantitative outcomes will be interpreted along with the results from the focus groups.

Results: Data collection is expected to be completed by March 2024.

Conclusions: This pilot trial will test the first web-based mindfulness-based cognitive therapy for couples targeting chronic cancer-related fatigue. Findings will indicate whether proceeding with a randomized controlled trial is warranted.

Introduction

Background

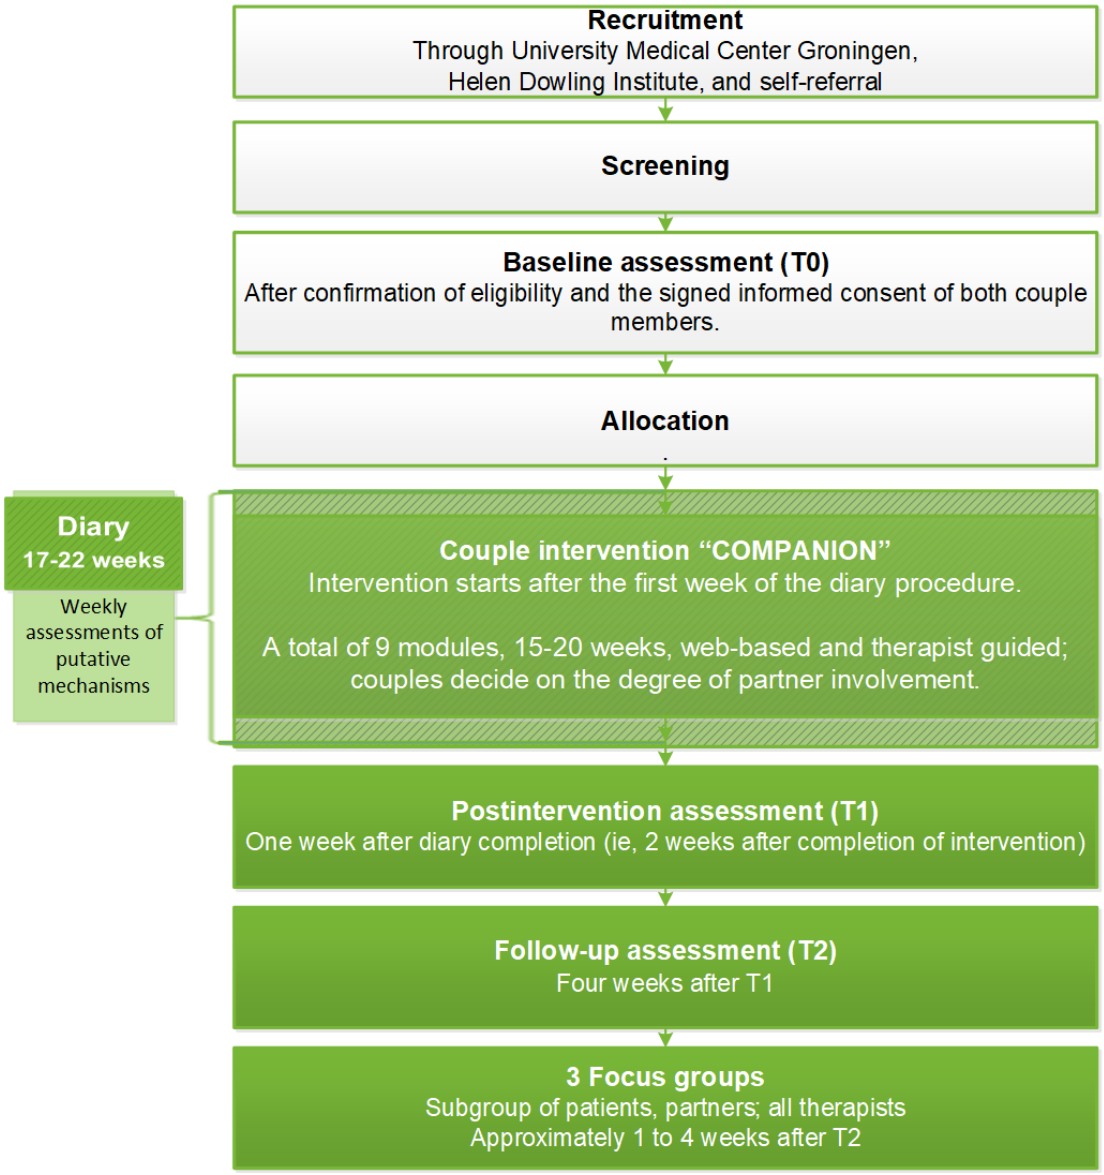
Chronic cancer-related fatigue (CCRF) is a common symptom among patients treated with curative [1-4] as well as palliative intent [5-7]. It can persist for many years and has a profound negative impact on patients' quality of life [2,8,9]. Its etiology is likely multifactorial and includes several biological pathways [10,11]. According to the cognitive-behavioral model of CCRF, cancer and its treatment initially trigger fatigue, while cognitive-behavioral variables (eg, negative cognitions about fatigue and disrupted activity patterns) explain its persistence after completion of treatment [12-14]. Based on this model, cognitive-behavioral and mindfulness-based therapies have been developed to address CCRF. While these and other interventions have been shown to effectively alleviate patients' fatigue [15-19], they are directed at the patient with cancer alone, despite growing evidence for the importance of involving patients' partners in the treatment of CCRF (ie, a couples' approach to treatment).

CCRF is experienced in the context of patients' close relationships in multiple ways. First, the way patients and their partners interact in daily life is related to patients' fatigue outcomes. For example, a daily diary study among survivors of cancer and their partners showed that partners' facilitative reactions (eg, encouragement to be active) were related to better fatigue outcomes, while solicitous reactions (eg, taking over the patient's chores) as well as ruminative conversations—fueled by patients and their partners maladaptive cognitions—were related to worse outcomes during the day [20,21]. This suggests that interventions encouraging adaptive daily interactions between couple members have the potential to contribute to better fatigue outcomes for the patient. Second, the degree to which patients benefit from cognitive behavioral therapy for fatigue appears to be related to partner and relationship variables. That is, a recent study [22] among patients with chronic fatigue syndrome showed that relationship dissatisfaction among patients and high fatigue in their partners are associated with less improvement in fatigue severity after therapy. Third, ample research shows that the cancer experience also impacts intimate partners. In particular, partners have been shown to experience substantial distress [23,24], which is positively related to patient fatigue [25,26], suggesting that an effective fatigue intervention can also benefit partners. Fourth, the aforementioned diary study [20] suggests that the way a partner deals with fatigue in the couple's daily life is not only related to fatigue outcomes but also patients' relationship satisfaction, with solicitous and facilitative responses being related to higher relationship satisfaction. Jointly, the evidence suggests that targeting the couple instead of the patient alone has the potential to increase the intervention's effect on patient fatigue and broaden its impact to alleviate partner distress and benefit the couple's relationship.

Based on this and studies indicating beneficial effects of interventions for couples coping with cancer in general [27-30], the study team has developed a couple intervention for dealing with CCRF called COMPANION (Dutch: Samen Minder Moe). The intervention is based on a web-based mindfulness-based cognitive therapy (eMBCT) that has been shown to be effective in reducing patient fatigue [31].

Research Aims

Given the relative novelty of this interventional approach, conducting a pilot trial is warranted. The primary aims of this pilot trial are (1) to determine the acceptability of the couple intervention and (2) to investigate its potential efficacy in reducing patient fatigue. Secondary aims are (3) to examine the feasibility of the trial procedures and (4) to determine the potential working mechanisms of the couple intervention.



Methods

Design

This study is a single-arm pilot trial among patients with cancer with CCRF and their partners. All included couples will be allocated to receive the COMPANION intervention, with a planned duration of 15-20 weeks. Couples will complete questionnaires and weekly diaries. Trial participation is estimated to take 6-8 months in total. Figure 1 presents a flowchart of the study.

XSL•FO
RenderX

Figure 1. The study flowchart.

Participants

Eligible participants are couples in which one member was diagnosed with cancer, completed cancer treatment for at least 3 months (excepting hormone therapy), and has been experiencing severe fatigue for at least 3 months. See Textbox 1 for an overview of all inclusion and exclusion criteria.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for the study.

Inclusion criteria

- The patient has received a cancer diagnosis (all malignancies are included).
- The patient completed cancer treatment with either curative or palliative intent ≥3 months earlier. Patients who currently receive hormone therapy are eligible.
- The patient experiences severe levels of fatigue (a score of ≥35 on the Checklist Individual Strength, subscale fatigue severity) at the screening.
- The patient has been experiencing severe fatigue for ≥3 months (as self-reported by the patient).
- The patient was 18 years of age or older at disease onset.
- The partner is 18 years of age or older.
- Both couple members live together.
- Both couple members have good command of the Dutch language (checked implicitly during registration).
- Both couple members have adequate computer literacy and have access to an internet-connected computer, laptop, or tablet (based on self-report).
- Both couple members agree to participate in the research.

Exclusion criteria

- The patient is currently following an evidence-based therapy for chronic cancer-related fatigue (ie, cognitive behavioral therapy, mindfulness-based therapy, exercising, or physiotherapy) as self-reported at the telephone screening.
- The patient has a condition that can explain his or her fatigue and is potentially treatable (eg, anemia).
- The therapist decides, based on information collected during the intake session, that the intervention is not suitable for the couple. Criteria that will be considered include, but are not limited to:
    - The presence of severe psychiatric morbidity such as suicidal ideation or psychosis (as assessed by the therapist at the intake session). Mild depression is not an exclusion criterion. A score of ≥20 on the hospital anxiety and depression scale at T0 is considered indicative of depression [32]. Therefore, if the patient or the partner scores ≥20, the therapist will determine at intake whether the participant has suicidal ideation or has another severe psychiatric morbidity. A participant (and thus the couple) will be excluded if, according to the therapist, that is the case.
    - The presence of substance abuse, except for smoking.

Recruitment

Recruitment will take place at the University Medical Center Groningen (UMCG), the Helen Dowling Institute (HDI), and through self-referral. At the UMCG, patients will be invited to the study by their oncologist or nurse, either at a follow-up appointment or during a phone call. Couples who indicate interest will be contacted by the research assistant. At the HDI, the research assistant will contact patients who are on the waiting list to receive patient-centered eMBCT and have given permission to be contacted for research purposes. Recruitment through self-referral will be encouraged by social media posts, newspaper articles, the panel of Kanker.nl [33], and flyers to be distributed at psychosocial care centers for people affected by cancer (Dutch: IPSO centra). Interested couples will be directed to the project website [34], where they can register.

Screening

The research assistant will schedule a web-based call with all interested couples to further inform them about the study and screen their eligibility. During the screening process, reasons for ineligibility and decline of participation will be recorded in the recruitment log as they inform our secondary aim (ie, feasibility of trial procedures). Upon obtaining informed consent from the patient with cancer and their partner, the patient will receive a link through email to a survey to confirm fatigue- and cancer-related eligibility criteria.

Assessments

Participants will complete questionnaires before starting the intervention (T0), 2 weeks after completing the intervention (T1), and 1 month after T1 (T2). Patients and their partners will also complete weekly diaries, starting 1 week before the intervention and ending 1 week after the intervention is completed. All questionnaires and diaries will be provided on the web through a secure, web-based application called REDCap (Research Electronic Data Capture) [35]. Patients and their partners will receive a link sent to their personal email and will be encouraged to respond independently from each other. In the event of nonresponse to the questionnaire, participants will receive a reminder email after 7 days and a second reminder after another 7 days of nonresponse. In case a diary assessment is missed, participants will receive a reminder the next day, and if 2 consecutive diaries have not been responded to, the assistant will call the participant to discuss possible problems. Therapists will also keep a therapist log to register data on intervention delivery, and the research assistant will keep a recruitment log to register data on recruitment and study adherence. A subsample of 5 patients with cancer and 5 partners (anticipated sample sizes), as well as all therapists providing the COMPANION intervention, will be invited to participate in separate focus groups. Patients and partners will be sampled purposefully (ie, based on high vs low levels of adherence or

XSL•FO
RenderX

intervention satisfaction) and can be invited independently from each other.

Sample Size Calculation

The study is powered to test the potential efficacy of the couple intervention in reducing patient fatigue (ie, the second primary research aim). Patients' baseline (T0) and postintervention (T1) scores on the Checklist Individual Strength, subscale Fatigue Severity (CIS-fatigue) will be analyzed with a 1-tailed matched pairs *t* test. G*Power analysis indicated that 27 patients are required to detect a medium effect (0.5) with an α of .05 and a power of 0.8 (1-tailed). We expect CIS-fatigue scores at T1 to be significantly lower than CIS-fatigue scores at T0. We will conduct a 1-sided test given the gain in power as compared to a 2-sided test and evidence that an increase in mean fatigue is unlikely to occur [31]. Based on the drop-out rate in our previous trial [31] and a recent review of the attrition rate in couple-based interventions for cancer [36], we assume a 20% drop-out rate. Hence, we will aim to include a total of 34 couples.

Intervention

COMPANION is a couple intervention developed from an evidence-based patient-centered eMBCT that aims to change the patient's behavioral and cognitive reactions to cancer-related stressors, including fatigue [31]. Like the patient-centered eMBCT, COMPANION is web-based and guided remotely by a trained therapist. However, COMPANION also involves the patient's partner in the treatment. The intervention consists of 9 sessions, which take approximately 15 to 20 weeks to complete (ie, the intervals between sessions are flexible to accommodate holidays and other commitments). Patients will have access to a secure web-based platform where they will receive written information about a specific theme for each session. Partners will have access to these materials through the patient. Table 1 provides an overview of all 9 sessions. Participants will be provided with audio files to practice different mindfulness-based cognitive-behavioral exercises each session. Patients will document their experiences in their personal log and perform exercises for approximately 30 minutes, 6 days a week. The exercises comprise topics such as relaxation, eating with awareness, moving with awareness, 3-minute breathing exercises, or meditation. Apart from the video call consultations, communication with the therapist will be mostly asynchronous, meaning that the therapist reads the experiences in the logs and provides feedback once a week. Adaptations compared to the patient-centered version were based on the findings from the preceding needs assessment among patients, partners, and therapists (van Dongen et al, unpublished data, 2023). These adaptations mainly concerned: 3 video call consultations between patient, partner, and therapist; psychoeducation for the partner; additional exercises for patient and partner (to be performed together or independently); and an extra session focused on the couple's mutual relationship and mindful communication about fatigue. Together with their therapist, couples can decide how and to what extent their partner will be involved.

XSL•FO
RenderX

Table 1. Modules of COMPANION.

Theme of module	Web-based psychoeducation	Exercises
Module 1: Fatigue and the automatic pilot	• Automatic pilot • Coping with fatigue • Patients formulate treatment goals	• Practice relaxation and awareness of the body with an audio file "bodyscan" • Register experiences with the "bodyscan" • Register experiences with eating with awareness
Module 2: Practice being open-minded	• Coping with pain and fatigue • Handling thoughts during breathing exercise • Tips for better sleep quality	• "Bodyscan" with muscle tension • Breathing exercise • Register experiences with these exercises • Register awareness during a specific activity • Register awareness during pleasant moments
Module 3: Dealing with boundaries	• Awareness of handling physical and emotional boundaries • Cultivating acceptance	• Moving with awareness and a 3-minute breathing exercise, alternated with previous exercises • Register experiences with these exercises • Register awareness about what happens when meeting boundaries
Module 4: Dealing with stress	• Patience • Recognizing automatic negative cognitions • Recognizing daily stress-inducing experiences and their emotional impact	• Using the senses (hearing, seeing, and feeling) with awareness • Alternating with previous exercises
Module 5: Communication	• How to communicate about cancer-related fatigue • How to communicate mindful of your own and others' thoughts and feelings	• Mindful communication exercise • Alternating with previous exercises
Module 6: Dealing with feelings	• Accept things as they are • Coping with negative emotions through acceptance	• Allowing intense feelings by focusing on present awareness of sensations in the body • Alternating with previous exercises
Module 7: Dealing with thoughts and anxiety	• Dealing with thoughts and fears • Interaction between thoughts, emotions, and behaviors • Physiology of fear	• Becoming aware of automatic negative thinking • Making a list of these thoughts • Alternating with previous exercises
Module 8: Self-care	• Self-care	• Compose own practice schedule by choosing from previous exercises • Making a list of helpful cognitions
Module 9: From stress and fatigue to strength	• Patients continue practice with their own practice schedule	• Writing about what helps their practice • Formulation of potential pitfalls in the future and composition of self-management strategies

Therapist Training and Treatment Integrity

Therapists at the HDI will deliver COMPANION. They all fulfill the criteria established by the United Kingdom Mindfulness-Based Teacher Therapist Network Good Practice Guidelines for teaching mindfulness-based interventions [37]. They will be trained in providing the couple intervention by an experienced therapist and a researcher from the COMPANION project team. This training starts with a preparatory self-study assignment using the web-based COMPANION treatment environment (a web portal for therapists). Next, therapists participate in an interactive training session addressing the content of the new therapy, the role of the therapist within this new therapy (including exercises and suggestions for involving the partner and giving therapeutic feedback [38]), and the design and procedures of the COMPANION pilot trial. All information is documented in a detailed written manual for therapists. Regular supervision will take place during the pilot trial, led by a member of the COMPANION project team who is a registered supervisor at the Dutch Society for Cognitive Behavioral Therapy. This supervisor has 15 years of experience in psycho-oncology, including 12 years of work experience with the patient-centered eMBCT for CCRF.

Measures

Table 2 provides an overview of all the constructs to be assessed. For conciseness, we have only described the key measures. Where possible, we chose validated and widely used instruments

XSL•FO
RenderX

in the field. Table 2 provides references for measures not described here.

Table 2. Overview of instruments, questionnaires, and assessment time points. Unless otherwise indicated, both patients and their partners complete questionnaires, and they report on their own health, perception, and state. Partner version of scales are own adaptations.

[m]HADS: Hospital Anxiety and Depression Scale [47,48].
[n]MMQ: Maudsley Marital Questionnaire, subscale Marital Satisfaction [49,50].
[o]Partner only.
[p]ICQ: Illness Cognition Questionnaire [51].

XSL•FO
RenderX

Demographic characteristics will be assessed at the screening and T0 and include self-reported age, sex, level of education, occupational status, relationship status and duration, cohabitation status and duration, and comorbidities.

Patients' cancer-related variables are self-reported and include cancer type, prognosis, presence of metastasis, treatment received, time since diagnosis, and time since treatment completion.

Intervention adherence will be assessed at T1, as self-reported by the patients and as registered by the therapists in their therapy log. The item used reads: "Did you/your client complete all sessions of the COMPANION therapy?" Answer categories are (1) "Yes, I/my client completed all sessions of the intervention" and (2) "No, I/my client stopped after session ____ (fill in the blank)." Reasons for stopping can be recorded in a free text field. By design, partners' involvement in the intervention is flexible, as this was an important requirement derived from the preceding needs assessment study (van Dongen et al, unpublished data, 2023). We consider receiving 6 sessions to be the minimal therapeutic dose. Therefore, intervention completion is achieved when a patient receives ≥6 out of 9 sessions, as reported by the patient at T1 and/or in the postintervention therapist log, and the partner did not drop out from the intervention.

Intervention satisfaction will be assessed with items based on those of other pilot trials for patients and their loved ones [39,40]. For both patients and partners, a total of 2 items will be used to assess satisfaction with the intervention overall (ie, "Overall, how satisfied are you with the COMPANION therapy?") and satisfaction with the couple approach (ie, "How satisfied are you with the possibility of jointly participating in the COMPANION therapy?"). Additional items assess satisfaction with specific aspects of the intervention. Items are scored on a 7-point Likert scale; scores 5 to 7 represent (high) satisfaction.

Fatigue severity will be assessed using the CIS-fatigue. A total of 8 items assess fatigue severity during the past 2 weeks (eg, "I feel tired") and are scored on a 7-point Likert scale, ranging from (score 1) "Yes, that is true" to (score 7) "No, that is not true." A higher sum score indicates more severe fatigue (range 8-56), with a score of ≥35 indicating severe fatigue in patients with cancer [42,43]. A clinically relevant change is operationalized as a difference of 6 points [52].

Recruitment rates: the research assistant will complete a recruitment log. The following information will be collected: (1) number of patients approached for recruitment (through the UMCG and HDI); (2) number of participants (ie, patient and/or their partner) interested in participation; (3) number of included couples; and (4) number of couples dropping out from the intervention and study. Along with these rates, reasons will be recorded. The recruitment rate is defined as the average number of couples included per month.

Adherence to the study protocol will be recorded by the research assistant in the recruitment log in terms of the number and percentage of questionnaires completed. Completion is defined as having responded at least to the items assessing the outcome measures.

Potential mechanism variables will be assessed in the weekly diary and include affect, sleep, catastrophizing, partner communication, partner interactions, self-efficacy, mindfulness, and closeness. Items are based on and adapted from a daily diary study among survivors of cancer and their partners [20,21,53] and existing scales. Table 3 provides an overview of the items.

XSL•FO
RenderX

Table 3. Concepts assessed with the diary method. Participants complete weekly diaries starting the week before the intervention, during the course of the intervention, and the week following the end of the intervention (ie, a total of 17-22 weeks) to assess potential working mechanisms of COMPANION.

Constructs	Items and instruments	Time frame
Outcome variables		
Fatigue severity[a]	1 item, as in [20,21,53]	Momentary[b]
Fatigue severity[c]	4 items based on SFQ[d]	Last week[e]
Intervention adherence	1 developed item	Last week
Partner involvement	2 developed items	Last week
Potential mechanism variables		
Affect	5 items, shortened from [53]	Momentary
Sleep	2 items, as in [53]	Last night[f]
Catastrophizing	4 items, as in [21,53]	Last week
Partner communication	3 items, based on [21]	Last week
Partner interactions	6 items, shortened from [20]	Last week
Self-efficacy	3 items, based on the SES[g]	Last week
Mindfulness	4 items, based on the FMI[h]	Last week
Closeness	2 developed items	Last week

[a]Patient only.

[b]Items ask the participants to report their current state (eg, "How fatigued do you feel right now?").

[c]Partners report on their perception of patients' fatigue.

[d]SFQ: Short Fatigue Questionnaire [54].

[e]Items ask the participants to report their state from the previous week.

[f]Items ask the participants to report their state from the previous night.

[g]SES: Self-Efficacy Scale [44].

[h]FMI: Freiburg Mindfulness Inventory Short Form [46].

Weekly fatigue severity in patients will be assessed with the 4-item Short Fatigue Questionnaire (SFQ) [54], a shortened version of the CIS-fatigue. The time frame has been adapted from the original past 2 weeks to the previous week, and items are formulated in the past tense (eg, "I felt tired").

Current fatigue severity will be assessed in the weekly diaries with 1 item, "How fatigued do you feel right now?" that is scored on an 11-point Likert scale ranging from (score 0) "not at all" to (score 10) "as fatigued as I could be" [20,21,53].

Analyses

Analyses will be conducted in SPSS (IBM Corp) and Mplus (Muthén & Muthén).

Descriptive Statistics

Descriptive statistics will be presented in a table. Data for patients with cancer and their partners will be presented separately (with the exception of couple characteristics such as relationship status). A study flowchart will show the number of couples screened, eligible, and included, as well as reasons for noneligibility and dropout.

Benchmark and Critical Values

This pilot trial is designed to assess the acceptability, potential efficacy, and potential working mechanisms of COMPANION and to determine the feasibility of trial procedures. To establish whether a subsequent randomized controlled trial (RCT) is justified, we have set benchmarks and critical values. Benchmark values represent the lower values of what we deem desirable to achieve. Critical values are defined as half of the benchmark values and represent potential problems with the outcome assessed. These benchmarks and critical values are based on comparable literature and our clinical and research experience. As each trial is unique (eg, in terms of study design, target population, intervention content, and duration), benchmark values are set rather conservatively (ie, similar to or lower than in comparable studies). The benchmark and critical values will not serve as definitive thresholds to determine whether a larger RCT is justified but will be interpreted along with the other outcomes, focus group data, and the recruitment log. Table 4 provides an overview of the key outcomes, their operationalizations, benchmark, and critical values.

XSL•FO
RenderX

Table 4. Overview of outcome measures, their operationalizations, benchmark, and critical values.

Outcome	Operationalization	Data	Benchmark values	Critical values
Acceptability of COMPANION				
Intervention adherence	Percentage of couples in which the patient completed the intervention, that is, followed at least 6 out of 9 sessions, and the partner did not drop out	T1 (patients) and/or therapist log	≥60% of couples completed the intervention	<30% of couples completed the intervention
Intervention satisfaction	Percentage of patients and partners responding to T1 who are satisfied with the couple approach and the intervention overall (score ≥5 on a 7-point Likert scale)	T1 (patients and partners)	≥70% of patients and ≥70% of partners are satisfied with the intervention overall and/or the couple approach	<35% of patients and <35% of partners are satisfied with the intervention overall and/or the couple approach
Potential efficacy for patient fatigue				
Significant change in patient fatigue	Statistically significant decrease from CIS-fatigue$_{T0}$[a] to CIS-fatigue$_{T1}$ (intention-to-treat).	T0 and T1 (patients)	Significant improvement in patient fatigue (P<.05, intention-to-treat)	N/A[b]
Clinically relevant improvement	Percentage of patients in which CIS-fatigue$_{T0}$–CIS-fatigue$_{T1}$≥6.	T0 and T1 (patients)	≥45% of patients improved (intention-to-treat)	<23% of patients improved (intention-to-treat)
Feasibility of trial procedures				
Rates related to the recruitment procedure	Recruitment rate: average per month, averaged across recruitment strategies.	Recruitment log	≥3 couples included per month	<1.5 couples included per month
Adherence to the T1 and T2 questionnaires	Percentage of patients and partners completing and returning T1 and T2.	T1 and T2 (patients and partners), recruitment log	≥65% of patients and partners completed T1 and ≥60% of patients and partners completed T2	<33% of patients and partners completed T1 and <30% of patients and partners completed T2
Adherence to the diary protocol	Percentage of diaries completed by patients and partners.	Diary (patients and partners), recruitment log	≥65% of diaries completed by patients and partners	<33% of diaries completed by patients and partners
Potential working mechanisms				
Changes in fatigue and potential mechanisms over time	Co-occurrence of time slopes of potential mechanisms with time slope of fatigue.	Diary (patients)	Targeted cognitions and behaviors improve (ie, time slopes are significantly different from 0); improvements co-occur with improved fatigue (standardized covariance is significant, P<.05)	N/A

[a]CIS-fatigue: Checklist Individual Strength, subscale Fatigue Severity.

[b]Not applicable.

Primary Aims

Acceptability of the couple intervention will be determined in terms of adherence to and satisfaction with the couple intervention. The benchmark value for adherence is based upon the rates of the trial that tested the patient-centered intervention (ie, 38% of intervention dropout [31]) and on comparable web-based couple interventions [55,56]. Couples will not be considered in cases where the investigator decides to withdraw the couple or a change in health status occurs that interferes with participation. The benchmark value for satisfaction is based upon the couple intervention trial by McDonnell et al [40], in which acceptability with different intervention components ranged between 75% and 100% for patients and family members.

The potential efficacy of the couple intervention will be determined in terms of a statistically significant decrease and a relevant improvement (≥6-point decrease on CIS-fatigue) in patient fatigue between T0 and T1. Both intention-to-treat analyses (ie, including all couples allocated) as well as per-protocol analyses (ie, including only couples who completed COMPANION as defined above) will be performed. The benchmark value for the percentage of clinically relevant improvement is based on our previous trial, in which 49% of the patients allocated to patient-centered eMBCT benefitted in terms of reduced fatigue (intention-to-treat; using a stricter criterion to define improvement as used here) [31].

XSL•FO
RenderX

Missing values will be replaced with multiple imputations using chained equations. The imputation model will include demographic and clinical variables as assessed at baseline. In sensitivity analyses, completer analyses will be performed (ie, including only cases with nonmissing CIS-fatigue$_{T0}$ and CIS-fatigue$_{T1}$ values). Of note, the study evaluating the patient-centered intervention included only curatively treated patients. It might be that the formulated benchmark values for efficacy are too strict for patients with cancer recurrence or reinitiation of treatment. If applicable, we will therefore calculate the efficacy outcomes with and without these patients included.

Secondary Aims

The feasibility of the trial procedures will be determined in terms of the recruitment rate. In our trial testing patient-centered eMBCT, on average, a total of 6 patients were included per month [31]. Given the known challenges in recruiting dyads for interventional research [36,57-59], the benchmark value is set lower, even lower than the number required (ie, 3,8) to reach our target sample size within the planned 9-month recruitment period.

The feasibility of the trial procedures will also be assessed in terms of adherence to the study protocol. In our previous trial, 73% of patients completed T1 and T2 [31]. In this trial, the follow-up period is shorter than in comparable trials (ie, 4 weeks). Still, given the intensity of the diary assessments (ie, up to 22 diaries), we set our benchmark value for completion of both assessments conservatively. In our observational diary study among fatigued survivors of cancer and their partners, compliance with the evening diary exceeded 90% [21]. While assessments in this study were also performed in the morning and noon, the diary period lasted only 2 weeks. It seems likely that the completion rate in this study is lower as the diary procedure is embedded in intensive treatment and the diary period covers several months; a study that had a diary duration of 6 months had a completion rate of 69% [60].

Based on the cognitive-behavioral model of fatigue and previous research [20,21,53,61], the potential mechanism variables are affect, sleep, catastrophizing, partner communication, partner interactions, self-efficacy, mindfulness, and closeness. A variable is established as a potential working mechanism of the couple intervention if its change (ie, improvement) over the course of the diary period covaries with decreases in weekly fatigue. Multilevel growth curve analysis will be applied to model the time slopes of the potential mechanisms and weekly fatigue over the entire diary period. We will explore both linear and nonlinear time trends and consider modeling random intercepts and random slopes. An improvement in fatigue and maladaptive constructs such as catastrophizing is indicated by a decrease over time. An improvement in adaptive constructs such as self-efficacy and mindfulness is indicated by an increase over time. For mechanism variables pertaining to partner communication and partner interactions, an improvement might be indicated by a decrease or increase. For some couples, talking (temporarily) more about fatigue is adaptive, while for others, talking (temporarily) less is adaptive. Covariances between the time slopes of the presumed mechanisms and the time slope of daily fatigue will be estimated to identify whether the temporal changes co-occur. A variable is established as a potential working mechanism in case the standardized covariance between the slope change factor for the outcome and that of the presumed mediators is significant (using a *z* test where ±1.96 is significant at the .05 level). Models will be run for weekly fatigue as well as weekly-reported momentary fatigue.

Explorative Analyses

First, we will explore whether there are differences between couples with low versus high partner involvement. A comparison will be performed on personal and couple characteristics. Second, we will explore whether the degree of partner involvement is related to the potential effect on patient fatigue, intervention adherence, and satisfaction. Please note that in cases of little variation in partner involvement, we might not be able to conduct these analyses. Third, we will explore the potential efficacy for fatigue severity as assessed at T2. For these analyses, the scores from the T0 and T2 assessments will be used for the statistical test (ie, CIS-fatigue$_{T0}$ and CIS-fatigue$_{T2}$). Fourth, we will explore whether the couple intervention had a positive effect on cancer patients' and partners' well-being (as assessed with the Hospital Anxiety and Depression Scale [HADS]) and on couples' relationship outcomes (as assessed with the subscale marital satisfaction of the Maudsley Marital Questionnaire [MMQ]) at T1 and T2. Lastly, we will explore whether the diary data of partners also show the expected improvement in targeted variables and partner outcomes over time.

Analysis of Focus Group Data

Focus groups are held to assess participants' experiences with following the intervention (patients and their partners) and delivering the intervention (therapists). Barriers and facilitators, as well as ideas for improvement of the intervention and trial procedures, are discussed. The data will be analyzed following the principles of thematic analysis, using open, axial, and selective coding [62]. A total of 2 researchers will independently familiarize themselves with the transcripts of the focus groups and identify initial codes (open coding). These initial codes will be collated into potential themes, described in relation to the coded extracts, and organized into a preliminary coding scheme (axial coding). Emergent themes will subsequently be reviewed and organized according to the main themes, resulting in a final coding scheme (selective coding). Using the constant comparative method [63], we will compare intervention experiences and ideas for improvement both between and within groups (ie, patients, partners, and therapists). Codes, themes, and their interpretations will be regularly discussed within the project team. The qualitative data will be interpreted along with the quantitative data.

Monitoring

This study is subject to on-site monitoring based on the risk classification "negligible."

Ethical Considerations

This study has been approved by the medical ethics committee of the University Medical Center Groningen (registration

number 2022/203, NL80201.042.22). The study is registered on ClinicalTrials.gov (NCT05636696). Written informed consent will be obtained from all participating patients with cancer and partners. A separate consent form will be signed by those who participate in the focus groups.

Results

Data collection is expected to be completed by March 2024.

Discussion

This pilot trial is designed to assess the acceptability, potential efficacy, and potential working mechanisms of COMPANION, a web-based couple intervention targeting CCRF. The feasibility of the trial procedures will also be determined. Together with qualitative data, a priori benchmarks and critical values for the key outcomes will inform whether conducting a future RCT to test the efficacy of COMPANION as compared to a control condition is warranted. If all or most benchmark values are achieved and qualitative data are reflective of this, progression to a larger RCT without adjustment to the intervention and/or trial is indicated. In the case of less positive results, progression with some adjustments to the intervention and/or trial procedures might be indicated. If few or no benchmark values are reached and qualitative data are reflective of this, it may be decided not to progress to an RCT.

Interventions directed at patients with cancer and their close relatives are becoming increasingly common. However, of those relevant to the proposed pilot study, most either apply a couple's mindfulness-based approach [64,65] or target cancer-related fatigue [66]. To the best of the authors' knowledge, there is not yet a mindfulness-based intervention for couples that primarily targets fatigue. There is 1 mindfulness-based (ie, yoga) intervention for patients and their family members that focuses on symptom reduction, with 1 outcome being fatigue reduction [40]; yet, due to the pilot design and small sample size, no conclusions about change in fatigue can be drawn. This lack of studies examining mindfulness-based interventions for couples that primarily target fatigue is surprising given the large evidence base supporting the efficacy of patient-centered mindfulness-based interventions for reducing cancer-related fatigue [16-19,67]. Therefore, the main strength of the proposed pilot trial is that it is the first to test a couple mindfulness intervention primarily targeting CCRF. This couple intervention is based on a patient-centered mindfulness-based intervention that also primarily targets CCRF and has been shown to be effective in reducing it. Further, the adaptation of the patient-centered intervention to the couple was performed with input from relevant stakeholders. Therefore, we expect that the intervention will likely meet the needs of patients and partners. Moreover, the intervention is web-based. Patients, and to a varying degree, their partners, walk through the sessions themselves while being guided remotely by their therapist. This delivery format facilitates the scalability of the intervention due to reduced participant burden and therapist time.

Another strength pertains to the collection of diary data. By measuring potential mechanism variables throughout the treatment, we make the first step toward understanding through which processes the expected beneficial effect may be reached. With this knowledge, the intervention could be made more efficient in the future. Another strength pertains to the collection of qualitative data. These data will be helpful in interpreting quantitative findings and, if needed, providing insight into how the intervention and trial procedures could be improved for a subsequent RCT. Furthermore, applying different recruitment strategies allows us to estimate the most effective ways of including couples. Lastly, we also include patients treated with palliative intent (provided they completed treatment ≥3 months ago; reinitiation of treatment after inclusion is not an exclusion criterion) and we do not exclude participants with comorbidities (barring cases as outlined in Textbox 1), increasing the external validity of the trial.

Several limitations of the pilot trial need to be mentioned. It is a single-arm, uncontrolled trial. Accordingly, results regarding the potential efficacy of COMPANION on patient fatigue and exploratory outcomes will need to be interpreted with caution. Furthermore, due to time constraints, the T2 follow-up assessment is planned only 4 weeks after T1. In a subsequent RCT, a longer follow-up period is needed to assess whether the expected treatment effect will be sustained over time. Adherence to the T2 assessment in this pilot study will therefore likely overestimate adherence to the long-term follow-up in a subsequent RCT.

The authors hope that COMPANION has the potential to positively contribute to CCRF care and benefit patients as well as their partners.

Abstract

Background: Artificial intelligence (AI) has the potential in health care to transform patient care and administrative processes, yet health care has been slow to adopt AI due to many types of barriers. Implementation science has shown the importance of structured implementation processes to overcome implementation barriers. However, there is a lack of knowledge and tools to guide such processes when implementing AI-based applications in health care.

Objective: The aim of this protocol is to describe the development, testing, and evaluation of a framework, "Artificial Intelligence-Quality Implementation Framework" (AI-QIF), intended to guide decisions and activities related to the implementation of various AI-based applications in health care.

Methods: The paper outlines the development of an AI implementation framework for broad use in health care based on the Quality Implementation Framework (QIF). QIF is a process model developed in implementation science. The model guides the user to consider implementation-related issues in a step-by-step design and plan and perform activities that support implementation. This framework was chosen for its adaptability, usability, broad scope, and detailed guidance concerning important activities and considerations for successful implementation. The development will proceed in 5 phases with primarily qualitative methods being used. The process starts with phase I, in which an AI-adapted version of QIF is created (AI-QIF). Phase II will produce a digital mockup of the AI-QIF. Phase III will involve the development of a prototype of the AI-QIF with an intuitive user interface. Phase IV is dedicated to usability testing of the prototype in health care environments. Phase V will focus on evaluating the usability and effectiveness of the AI-QIF. Cocreation is a guiding principle for the project and is an important aspect in 4 of the 5 development phases. The cocreation process will enable the use of both on research-based and practice-based knowledge.

Results: The project is being conducted within the frame of a larger research program, with the overall objective of developing theoretically and empirically informed frameworks to support AI implementation in routine health care. The program was launched in 2021 and has carried out numerous research activities. The development of AI-QIF as a tool to guide the implementation of AI-based applications in health care will draw on knowledge and experience acquired from these activities. The framework is being developed over 2 years, from January 2023 to December 2024. It is under continuous development and refinement.

Conclusions: The development of the AI implementation framework, AI-QIF, described in this study protocol aims to facilitate the implementation of AI-based applications in health care based on the premise that implementation processes benefit from being well-prepared and structured. The framework will be coproduced to enhance its relevance, validity, usefulness, and potential value for application in practice.

Introduction

Artificial intelligence (AI) has the potential to revolutionize health care delivery [1]. AI refers to the simulation or approximation of human intelligence in machines, such as perception, reasoning, and decision-making [2]. It can be used for a variety of applications in health care, for example, diagnosis, treatment planning, disease prediction, and personalized medicine [3-5]. AI can analyze large amounts of data quickly and accurately. This can be especially useful in health care for screening and diagnosis; AI can identify patterns and anomalies in medical images or laboratory results that human clinicians might miss or overlook [6]. AI can also be used to predict disease progression and recommend treatment options based on a patient's individual characteristics and medical history [7]. AI can also be useful in the development of digital tools and interventions in health care [8]. AI-powered mobile apps and wearables such as smartwatches can provide patients with personalized health recommendations, monitor vital signs, and alert health care providers to potential problems. This can help to reduce the burden on health care systems and improve patient outcomes by enabling more proactive and personalized care.

Expectations for the use of AI-based applications to improve health care delivery and efficiency are high. However, this sector has been slow to make use of AI compared with other sectors of society, such as banking, transport, and retail [9-12]. The implementation of AI in health care has encountered various technological, individual, social, and organizational barriers. These barriers have been classified in different ways, for example, data related, methodological, technological, regulatory or policy related, human factor related, environmental, and organizational [13-15]. Several studies have concluded that the implementation of AI-based applications tends to be unstructured [16,17]. Research on strategies to overcome these barriers or how to best implement AI-based applications in health care is scant [17].

Research in implementation science on the introduction and use of technological innovations and other new practices has shown that implementation is often suboptimal [18]. Implementation tends to be a complex and challenging process because it requires changes in existing behaviors, practices, and routines, many of which are well established or ingrained [19]. There may also be competing priorities or resource constraints that make it difficult to prioritize the implementation of new practices. To address these challenges, implementation science emphasizes the importance of planning for implementation from the outset to create conditions conducive to implementation and carrying out implementation processes in a structured, well-planned, and orderly way [20]. Process models are a key tool in implementation science, providing guidance for well-prepared and structured implementation by describing the key considerations and activities that are important to take into account during the implementation process [21]. These models help to ensure that implementation proceeds in a way that is systematic and focused on achieving the desired outcomes.

Interest in using AI in health care has increased in recent years, but there is a lack of knowledge to guide the process of implementing various AI-based applications in this setting. Therefore, the aim of this protocol is to describe the development, testing, and evaluation of a framework ("Artificial Intelligence-Quality Implementation Framework"; AI-QIF) intended to guide decisions and activities related to the implementation of various AI-based applications in health care. The target group of the framework are those who make decisions about, lead, or are involved in change processes in connection with the implementation of AI-based applications in health care.

Methods

Overall Design

This project will use a cocreation design [22] to develop, test, and evaluate a framework to guide the implementation of AI-based applications in health care. This will be carried out in 5 phases by Halmstad University researchers in collaboration with various stakeholders (Table 1). Cocreation involves collaboration between researchers and stakeholders for a creative problem-solving process, from design, production, and implementation to evaluation of solutions [22]. Cocreation has been found to improve the quality, usability, and social acceptance of new solutions [23]. In this project, participants with different roles in relation to AI implementation will offer diverse insights by means of interviews and informal conversations. The aim of the cocreation approach is to obtain a more holistic view of the form, content, and potential value of the framework that will be developed and to ascertain its usability in health care practice.

Table 1. The 5 phases of the project to develop, test, and evaluate the AI-QIF[a].

Phase and time period	Aim of the phase	End product of the phase	Data collection	Data analysis	Cocreation aspects
I: January to June 2023	To produce an AI[b]-adapted version of QIF[c]	A preliminary version of a Swedish-language AI-QIF (AI-QIF 1.0)	Inspection of the Swedish QIF version developed by the Public Health Agency of Sweden; consultations with QIF experts at the Public Health Agency of Sweden.	No formal analysis. Discussions in the research team regarding the adaptation of QIF for AI purposes.	QIF experts at the Public Health Agency of Sweden
II: June to December 2023	To enrich a preliminary version of AI-QIF and to make sure it is grounded in empirical AI research	An initial version of a Swedish-language AI-QIF (AI-QIF 1.2) presented as a mockup of a web-based application	Secondary data in the form of published studies concerning AI implementation and transcripts of 120 interviews conducted by Halmstad University researchers.	Deductive mapping of information to the 14 steps of QIF.	Managers, practitioners, and developers from health care as well as individuals from academia and the business sector with AI knowledge
III: September to December 2023	To incorporate organization- and management-relevant AI aspects	A prototype AI-QIF with an intuitive user interface (AI-QIF 1.3)	Individual interviews with managers in Region Halland involved in AI-relevant decision-making, national AI experts, and patients. Estimated interviews, n=20.	Qualitative content analysis.	Managers in Region Halland involved in AI-relevant decision-making and national AI experts
IV: January to June 2024	To investigate the usability of an AI-QIF prototype under real-world conditions	A proposed final version of the framework (AI-QIF 2.0)	Individual interviews with managers and AI-users in Region Halland involved in 3 AI cases. Estimated interviews, n=20.	Qualitative content analysis.	Managers and AI users involved in 3 AI cases in Region Halland
V: August to December 2024	To evaluate the real-world use of the final AI-QIF and investigate barriers and facilitators to using the AI-QIF when implementing various AI applications	A description of the development of the AI-QIF and guidelines for its use in practice based on the key barriers and facilitators to its use in routine practice that have been identified	Individual interviews with approximately 20 users of the AI-QIF in 5 regions in Sweden.	Qualitative content analysis, inductive and deductive, the latter based on Capability-Opportunity-Motivation-Behaviour.	Users of AI-QIF in 5 regions

[a]AI-QIF: Artificial Intelligence-Quality Implementation Framework.

[b]AI: artificial intelligence.

[c]QIF: Quality Implementation Framework.

Quality Implementation Framework as the Basis for the Initial Development of the Framework

The AI implementation framework will be based on the Quality Implementation Framework (QIF), a process model in implementation science aimed at guiding implementation processes. The QIF describes a number of activities and considerations that should be undertaken when implementing new practices. It was developed by Meyers et al [24] to achieve an improved understanding of "the nature of the implementation process." Meyers et al [24] posited that "quality implementation" is "putting an innovation into practice in such a way that it meets the necessary standards to achieve the innovation's desired outcomes." In total, 25 theories, models, and frameworks across multiple research and practice areas were examined. A synthesis of the frameworks yielded 14 activities (referred to as steps) to be carried out in the implementation process. These steps are clustered into a 4-phase temporal sequence [25].

The first phase of the QIF is an initial consideration regarding the host setting, with work focusing primarily on making sure there is a fit between the innovation and the host setting. The second phase involves creating a structure for implementation and emphasizing the importance of creating an organized structure to oversee the implementation process. This can involve, for example, having a clear plan for implementing the innovation and identifying a team of qualified individuals who will take responsibility for the process. The third phase is aimed at creating an ongoing structure once implementation begins, for example, providing required technical assistance, coaching and supervision, and creating supportive feedback mechanisms for the users of the innovation. The fourth phase is aimed at learning from the implementation of the innovation to improve future applications [25].

The QIF has many strengths that were important for choosing this process model as a starting point for the AI-QIF. It has been widely used and shown to be feasible in many different types of settings, for example, studies on the implementation of a

XSL•FO
RenderX

primary health care system improvement initiative in South Africa [26], electronic medical records for clinical and research purposes in Malaysia [27], an oral screening tool for pediatric cardiologists in the United States [28], and a mindfulness-informed social and emotional learning program in elementary schools in England [29]. The flexible application of the QIF underscores the model's adaptability and usability. Furthermore, the QIF has a broad scope and is not restricted to any specific "implementation object." Rather, the "object" can be any practice (innovation, intervention, program, routine, service, etc) that is introduced into an organization. Other process models in implementation science have a considerably narrower scope, for example, focusing on how research findings are used by nurses in their everyday practice [21].

The QIF is comprehensive, yet it provides fairly detailed guidance concerning important activities and considerations for successful implementation. This is in contrast to many other process models in implementation science that provide considerably more generic guidance, for example, describing an overarching process of how research is transformed into action [21]. A further strength of the QIF is that it has been translated into Swedish and used in Swedish health care by the Public Health Agency of Sweden [30]. The agency is an expert state authority under the Government's Ministry of Social Affairs with national responsibility for public health issues. The agency aims to protect the population against communicable diseases and other health threats, developing general guidelines and recommendations [31]. Agency staff tasked with developing an updated Swedish version of the QIF have recently collected feedback from QIF users in various settings, which they have used for some modifications to the Swedish version.

Phase I: Repurposing the QIF for Use in an AI Implementation Context

The first phase is aimed at verifying the validity of the QIF process model as the starting point for producing the first version of an AI-adapted version of the Swedish-language AI implementation process model (AI-QIF 1.0). This work is similar to the psychometric investigation of content validity and face validity that is done for various assessment instruments [32]. This preliminary version will be collated from the original QIF (in English) and current Swedish versions of the QIF.

Data will be collected in 2 ways. First, we will examine the Swedish QIF translation developed by the Public Health Agency of Sweden, comparing and contrasting the original QIF with the Swedish version item by item. Potential differences will be discussed with representatives of the team at the Public Health Agency of Sweden, who developed the Swedish version.

Second, we will draw on feedback documented by the Public Health Agency of Sweden from testing of the QIF by Region Dalarna and 15 municipalities in Dalarna. The framework is also used by other regions, but the Public Health Agency has not yet received feedback from them. Comments and suggestions for revisions have been collected by the team (n=3) at the agency who are in charge of the QIF. We will consult with QIF-knowledgeable experts in this team concerning lessons learned from this hands-on use of the QIF, for example, in terms of potential difficulties in interpreting items or whether important aspects were perceived to be missing from the Swedish QIF model.

Phase II: Developing a Mockup of the AI-QIF

The aim of the second phase is to enrich the preliminary version of the Swedish-language AI-QIF and to make sure it is grounded in empirical AI implementation research. The work is largely similar to face and content validity evaluation that is part of instrument development [32]. This is achieved by accounting for and integrating empirical findings from two sources: (1) AI implementation cases described in studies identified through literature reviews [17,33] and (2) interview studies involving various stakeholders involved in or affected by the implementation of AI applications in health care [34]. The end product of phase II will be an adapted version of a Swedish-language AI-QIF (AI-QIF 1.1) presented as a mockup of a web-based application.

First, we will examine AI literature of relevance for the AI-QIF by identifying AI implementation cases in studies identified in literature reviews of AI implementation studies [17,33] and examining the studies in question. This will enable us to identify overlap between the AI-QIF and existing knowledge about barriers and strategies concerning the implementation of AI in health care as well as possible differences and other aspects to take into account when implementing AI in health care.

Second, we will draw on a secondary analysis of 120 interviews conducted with stakeholders such as managers, practitioners, and developers from health care as well as academia and business sector individuals with AI knowledge [34]. The interviews will focus on, among other AI applications, mortality prediction in the emergency department, prevention of mental health problems among young adults, digital triage in primary care, and reducing the risk of readmission of heart failure patients. The purpose of analyzing these interviews is to identify AI-specific implementation barriers and strategies that might be relevant to integrate into the framework. The interviews address experiences and perceptions held by stakeholders concerning the implementation of AI in general and various specific AI-based applications.

Findings from the 2 sources (ie, AI implementation cases in the literature and interviews) will be combined and analyzed in a deductive mapping process [35] to the contents of the 14 steps of the first version of the AI-QIF (from phase I). In the first step of the analysis, an inductive approach will be undertaken to identify barriers and strategies for the implementation of AI in practice. In the second step, a deductive approach will be undertaken to map these barriers and strategies to the 14 steps in the AI-QIF. If deemed necessary, parts of AI-QIF can be adjusted to fit the needs of stakeholders by adjusting, adding, or removing steps or changing the wording in the framework to fit AI implementation. All authors will be involved in the entire analysis process, thus enabling a variety of interpretations of the material before consensus is reached among all authors.

Third, the results of phase II will be used to further adapt the Swedish-language AI-QIF (AI-QIF 1.2) and will be presented as a mockup of a web-based application.

XSL•FO
RenderX

Phase III: Developing a Prototype of the AI-QIF

The aim of phase III is to incorporate organization- and management-relevant AI aspects based on input from national AI experts and health care managers in Region Halland who are involved in AI-relevant decision-making and deployment of AI-based applications in health care in this region (regions are responsible for the provision of health care in Sweden). The goal is also to achieve a comprehensive face-validity check [32] of an intuitive and user-friendly prototype of the AI-QIF (AI-QIF 1.3).

We will develop an interview guide and conduct interviews with AI experts and managers on usability and feasibility issues around the potential use of the AI-QIF in practice. Purposive sampling will be used to identify and select individuals who can provide rich information to achieve the objective of developing the AI-QIF prototype. Approximately 20 interviews are tentatively planned, but the actual number of interviews will be guided by the information power principle [36], meaning that the larger information the sample holds relevant for the study, the lower amount of interviews is needed, and vice versa. The interviewees' experiences and perceptions will improve the fit of the framework within the context in which it will be used. The interviews will potentially function as a needs assessment, thus adding to our understanding of which organizational actors could be involved in the implementation of AI.

The interviews will also cover which terminology is experienced as appropriate, clear, and concise enough for users in these organizational capacities. The interviews will also invite participants to highlight their preferred order of the steps, which AI-QIF steps are perceived as more or less important, and which steps might be missing or redundant.

The interviews will be analyzed using qualitative content analysis [35], and the information from the interviews will be applied to the development of the prototype, which will be tested and verified iteratively with the informants to ensure that consensus is reached on how the steps should be understood and acted upon.

Phase IV: Usability Testing of the AI-QIF Prototype

Phase IV involves usability testing of the prototype of the AI-QIF developed in phase III [37]. The aim is to investigate experiences from and functionality of its use under real-world conditions. Usability testing at the prototype stage presents opportunities to check the user experiences and functionality before a final version is developed. The end product of phase IV will be the proposed final version of the framework (AI-QIF 2.0) for investigation in phase V.

For this purpose, 3 real-world AI implementation cases will be selected in close collaboration with relevant managers in Region Halland to ascertain that appropriate cases are chosen to enable timely testing of the framework before implementation starts. The following cases are planned: (1) optimized work practices and patient flows for improved care of patients with heart failure based on the implementation of an AI-based application that enables prediction of readmission risk; (2) new tools for documentation, follow-up and optimization of care flows, and management of patients with long-term wounds based on an AI-based application for analysis of and guidance for optimization of individualized wound care; and (3) introduction of interventions and resources for increased accessibility to primary care and specialist mental health care for young individuals with mental health problems based on AI-based applications for health monitoring, identification of risk groups, and mediation of care.

Key informants in each AI case will be recruited for structured interviews focusing on usability issues [38], with both Region Halland managers and users involved in any of the 3 selected cases. The aim is to investigate their experiences of using the prototype framework when implementing AI-based applications in health care. Approximately 20 interviews (managers and users) are tentatively planned, but sampling will be based on the information power principle [36]. The interviews will be analyzed using qualitative content analysis [35]. Information from these interviews will provide input for potential modifications of the framework and the prototype for the digital web application.

Phase V: Evaluating the Use of the AI-QIF

The aim of the final phase is to evaluate the real-world use of the final version of the AI-QIF and to investigate barriers and facilitators to using the AI-QIF when implementing various AI applications. The users will be asked to reflect on how they used the AI-QIF. The end product of phase V will be a description of the development of the framework and guidelines for its use in practice based on the key barriers and facilitators to its use in routine practice that have been identified.

A qualitative explorative design will be used based on individual semistructured interviews with a sample of approximately 20 framework users in 5 regions. The regions will be purposively selected with regard to geographical location (regions in different parts of Sweden) and size in terms of populations (small and large regions). A combination of conventional (inductive) and directed (deductive) approaches to qualitative content analysis will be used [35]. The deductive analysis will use 3 predefined categories of the widely used implementation determinant framework, COM-B (Capability-Opportunity-Motivation-Behaviour). COM-B posits that behavior (B), for example, using the AI-QIF, is influenced by the person's capability (C), opportunity (O), and motivation (M) to perform that behavior [38].

Ethical Considerations

The study conforms to the principles outlined in the Declaration of Helsinki [39] and will fulfill the following requirements for research: information, consent, confidentiality, and safety of the participants, guided by the ethical principles of autonomy, beneficence, nonmaleficence, and justice. Ethical approval by the Swedish Ethical Review Authority (2020-06246, 2023-02581-02) is available for required parts in phases I and II. Ethical approval will be applied for the work to be conducted in phases III, IV, and V. All participants will receive written and oral information about the studies in which they are directly or indirectly involved. Participants will also be given information about the voluntary nature of the studies,

XSL•FO
RenderX

confidentiality, and the ability to withdraw their consent at any time without having to justify why. All personal data will be registered according to the General Data Protection Regulation (GDPR2016/679), and the data will be stored in accordance with the Archive Act in Sweden (SFS1990:782). The results will be communicated to the participants and partners, and key findings will be fed back to participants and study sites to enable refinement of the developed framework. The results will be disseminated via publications in peer-reviewed journals and presentations at national and international conferences.

Results

This project will be conducted within the frame of a research program "Toward Successful Implementation of Artificial Intelligence in Health Care Practice" [34] with the overall objective of developing theoretically and empirically informed frameworks to support AI implementation in routine health care. The program was launched in 2021 and has carried out numerous research activities, including scoping reviews, mapping of different stakeholder perspectives, and initiation of several case studies. Thus, the development of AI-QIF as a tool to guide the implementation of AI-based applications in health care will draw on knowledge and experience acquired from these activities.

The development process of the AI-QIF started in January 2023 (phase I) through collaboration with the Public Health Agency of Sweden, and the plan is to finish the tool in December 2024. The AI-QIF is under continuous development and refinement. Reporting will be done through scientific papers and various formats for more practical application in health care and in national efforts on promoting and supporting AI implementation in health care.

The insights gained during the development and refinement of the framework will be used as the foundation for parallel investments in regional capacity to increase the practical resources, competencies, partnerships, and organizational structures required to facilitate the implementation of AI-based applications. This work will be carried out in collaboration with representatives from academia, strategic partners from the business sector, and political and operational leaders and teams from the regional and municipal health care systems. The framework will be an integral part of a strategy toward the use of AI in health care (described as a "roadmap"), which is planned with strategic investments to support AI implementation and quality improvement in clinical health care practice [34].

Discussion

There is little doubt that AI will play an important role in the future of health care, yet research has documented that the use of AI in health care faces many challenges in the "last mile" of the AI research and development process, that is, the introduction and routine use of AI-based applications in health care settings [40,41]. Numerous barriers to the implementation of AI in health care have been identified [9-14,17]. The AI-QIF described in this study protocol aims to facilitate the implementation of AI-based applications in health care based on the premise that implementation processes benefit from being well-prepared and structured [42]. We have not been able to identify any AI-related studies that have investigated how or to what extent the quality of the implementation process influences the outcomes.

The starting point for the AI-QIF is the QIF, a widely used process model in implementation science. Process models have been developed in this field to facilitate implementation processes [21]. There are many process models, but most share key characteristics with the QIF. To some extent, process models present an ideal view of implementation processes as a structured, linear process that proceeds stepwise in an orderly fashion. Process models aim to create favorable conditions for implementation processes [21]. However, researchers behind many models emphasize that the actual process is not necessarily sequential. The researchers behind the QIF [24] observed that "quality implementation does not always occur in the exact sequence of [the steps]."

The importance of planning ahead of the actual implementation is evident in the QIF; 10 of the 14 steps described in this model are to be carried out before the actual implementation begins. Another common feature of process models is the recognition that context matters; hence, there is a need for adaptation of implementation to local conditions and circumstances [21]. The AI-QIF does not describe specific solutions or pinpoint particular actions. The focus of the framework is on "what" should be done and considered, not on exactly "how" this should be done. Contextual conditions and the characteristics of various AI-based applications are likely to differ considerably, making it difficult to provide a cookbook-style guide.

Following on from repurposing the QIF for use in an AI implementation context (phase I), 2 development phases (phases II and III), and pilot-testing of a prototype (phase IV), we will investigate the barriers and facilitators to using the AI-QIF under routine conditions in health care (phase V). Numerous studies have documented barriers to AI implementation, but we have not identified any studies exploring how AI implementation processes can be supported by using a framework such as the QIF. The use of the QIF can be seen as an implementation strategy intended to facilitate the implementation. Strategies in implementation science are defined as "methods or techniques used to enhance the adoption, implementation and sustainability of a clinical program or practice" [43]. There is wide recognition in implementation science that successful implementation requires efficient strategies to support implementation processes [18].

The development of the AI-QIF will be guided by cocreation principles to create new value together with stakeholders [30] and by incorporating lessons learned from cases of AI implementation in health care practice. The development of the AI-QIF will involve stakeholders such as QIF experts (phase I), health care practitioners and developers (phase II), AI experts (phase III), health care managers (phases II and III), and presumptive health care users of AI-based applications (phases IV and V).

The cocreation process of the project will draw on both research-based and practice-based knowledge. Research-based

XSL•FO
RenderX

knowledge is explicit, primarily articulated in different types of text, with the aim of achieving improved understanding or explanation of problems. Practice-based knowledge, on the other hand, tends to be tacit, gained through experience, and expressed through action rather than words, with finding solutions to problems an important aim [44]. Research-based knowledge makes it possible to move beyond the specific "here-and-now" circumstances of a current situation, for example, AI implementation in health care. At the same time, practice-based knowledge is important to account for practical judgment and contextually adapt solutions, for example, the AI-QIF, thus facilitating flexibility and usability. Integrating the 2 forms of knowledge makes it possible to challenge taken-for-granted assumptions, thus broadening the views and enabling unexpected, creative solutions [44].

Some methodological considerations must be accounted for. The framework development is based on data from Sweden, which might negatively affect the generalizability of the results to other countries. Furthermore, much of the development of AI-QIF will take place in the regional setting of Region Halland by researchers from Halmstad University, potentially further restricting the generalizability of the framework. However, national AI and health care developers and experts will be involved in phase III, while phase V is based on the use of AI-QIF in 5 regions in Sweden, thus increasing the generalizability in a Swedish context. In addition, the framework development will be carried out by an experienced multidisciplinary research team, which will strengthen the feasibility of the study and ascertain a comprehensive and robust process. It is also a strength that AI-QIF will be based on the existing and widely used and versatile QIF process model. Cocreation is a guiding principle in the project that will benefit the development since research has shown that cocreation tends to improve the quality, usability, and social acceptance of new solutions [23]. However, there are also challenges with cocreation processes. The literature on the implementation of new technologies in health care suggests that the complexity of technologies can slow down cocreation processes [22,23].

In conclusion, the AI-QIF described in this study protocol aims to facilitate the implementation of AI-based applications in health care based on the premise that implementation processes benefit from being well-prepared and structured. The framework will be coproduced to enhance its relevance, validity, usefulness, and potential value for application in practice.

Acknowledgments

This project has received funding from the Swedish Innovation Agency and the Knowledge Foundation.

Abstract

Background: Increasing the dose of therapy delivered to patients with stroke may improve functional outcomes and quality of life. Unsupervised technology-assisted rehabilitation is a promising way to increase the dose of therapy without dramatically increasing the burden on the health care system. Despite the many existing technologies for unsupervised rehabilitation, active rehabilitation robots have rarely been tested in a fully unsupervised way. Furthermore, the outcomes of unsupervised technology-assisted therapy (eg, feasibility, acceptance, and increase in therapy dose) vary widely. This might be due to the use of different technologies as well as to the broad range of methods applied to teach the patients how to independently train with a technology.

Objective: This paper describes the study design of a clinical study investigating the feasibility of unsupervised therapy with an active robot and of a systematic approach for the progressive transition from supervised to unsupervised use of a rehabilitation technology in a clinical setting. The effect of unsupervised therapy on achievable therapy dose, user experience in this therapy setting, and the usability of the rehabilitation technology are also evaluated.

Methods: Participants of the clinical study are inpatients of a rehabilitation clinic with subacute stroke undergoing a 4-week intervention where they train with a hand rehabilitation robot. The first week of the intervention is supervised by a therapist, who teaches participants how to interact and train with the device. The second week consists of minimally supervised therapy, where the therapist is present but intervenes only if needed as participants exercise with the device. If the participants properly learn how to train with the device, they proceed to the unsupervised phase and train without any supervision during the third and fourth weeks. Throughout the duration of the study, data on feasibility and therapy dose (ie, duration and repetitions) are collected. Usability and user experience are evaluated at the end of the second (ie, minimally supervised) and fourth (ie, unsupervised) weeks, allowing us to investigate the effect of therapist absence.

Results: As of April 2023, 13 patients were recruited and completed the protocol, with no reported adverse events.

Conclusions: This study will inform on the feasibility of fully unsupervised rehabilitation with an active rehabilitation robot in a clinical setting and its effect on therapy dose. Furthermore, if successful, the proposed systematic approach for a progressive transition from supervised to unsupervised technology-assisted rehabilitation could serve as a benchmark to allow for easier comparisons between different technologies. This approach could also be extended to the application of such technologies in the home environment, as the supervised and minimally supervised sessions could be performed in the clinic, followed by unsupervised therapy at home after discharge.

KEYWORDS

technology-assisted rehabilitation; unsupervised therapy; self-directed therapy; stroke; neurorehabilitation; neurocognitive rehabilitation; robot-assisted therapy; rehabilitation technology; robot.

Introduction

Stroke survivors often do not entirely recover upper limb function [1], which severely impacts independence and quality of life as remaining upper limb impairments may limit their ability to perform activities of daily living. Increasing evidence shows that therapy dose is a key factor contributing to sensorimotor recovery and that administering a higher dose of upper limb therapy to people after stroke could improve their functional outcome even long after stroke [2,3].

However, due to factors such as unfavorable therapist to patient ratios [4], high rehabilitation-related costs, and the overall frailty of health care systems (as highlighted, for example, by the COVID-19 pandemic [5,6]), increasing the dose of high-quality therapy for both inpatients and outpatients is challenging as long as it relies on hospital visits and supervised therapy.

Unsupervised technology-assisted rehabilitation, defined here as patients training with rehabilitation technologies without any supervision by an external person, is a promising solution to increase therapy dose without dramatically weighing on the health care system [7]. Relying on novel digital approaches, such as wearable sensors or robotic tools, offers new ways to promote motivation and engagement for specific therapy exercises. It promises to go beyond the conventional set of exercises prescribed for patients to train independently, which may lead to low adherence [8,9]. A range of upper limb rehabilitation technologies have been tested in unsupervised settings, such as the home environment, with varying results regarding acceptance, satisfaction, success, and amount of use [10-15]. Besides the use of different technologies, these outcomes may also be influenced by the different methods applied to teach the patients how to use a rehabilitation technology in an independent way. A key step for the successful and safe use of a rehabilitation technology without supervision is the progressive transition toward unsupervised use, where users first learn how to correctly use a technology. This becomes especially critical in the case of active technologies, such as rehabilitation robotics, whose use without any external supervision has rarely been reported.

Unfortunately, most existing studies only report little information on these methodological steps or use very different protocols (eg, from multiple training sessions in supervised settings [11] to a single explanation session directly at home [12]). Similarly, there is a lack of agreement on objective measures to evaluate and document the feasibility and success of unsupervised training.

In this protocol paper, we report on the study design of a single-group, interventional clinical study to test the feasibility of fully unsupervised therapy with an active hand rehabilitation robot in patients with subacute stroke. More specifically, we describe in detail a study protocol with the following aims: (1) to evaluate the feasibility of unsupervised therapy assisted by an active rehabilitation robot and a standardized approach for the progressive transition from supervised to unsupervised use based on a set of well-defined and objective criteria, (2) to investigate the effect of unsupervised therapy on achievable therapy dose during rehabilitation, and (3) to evaluate user experience as well as the usability of the rehabilitation technology.

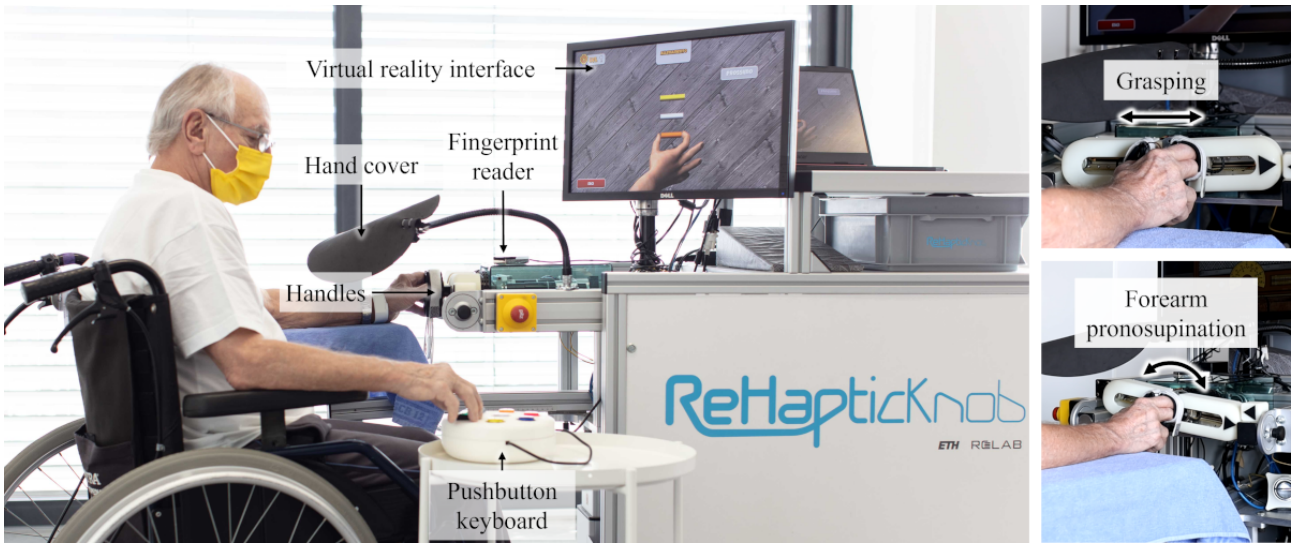
The secondary objective of this study is to identify patient-related parameters (eg, age, cognitive abilities, level of impairment) that might influence the ability of a user to transition to unsupervised therapy and the dose of self-administered therapy.

Methods

Study Population and Recruitment

For this study, we aim to recruit patients in the subacute phase after stroke that are currently undergoing rehabilitation (inpatients). To be eligible for the study, patients must fulfill all the following inclusion criteria: (1) be between 18 and 90 years old, (2) be within 6 weeks from stroke onset, (3) have a prestroke Modified Rankin Score [16] ≤1, (4) have a National Institutes of Health Stroke Scale [17] score ≥1 in at least one of the items concerning motor or sensory function and ataxia, and (5) have provided informed consent as documented by a signature.

Patients are excluded if one of the following exclusion criteria is present: (1) moderate to severe aphasia (Goodglass-Kaplan scale [18] <3), (2) moderate to severe cognitive deficits (levels of cognitive functioning-revised [19] <8), (3) functional impairment of the upper limb due to other pathologies, (4) severe pain in the affected arm (visual analogue scale [VAS] for pain ≥5), (5) other pathologies that may interfere with the study, (6) pacemakers and other active implants, and (7) a modified Ashworth Scale [20] >2 for one or more of the following muscles: shoulder adductors, forearm pronator and supinator, and flexors and extensors of the elbow, wrist, and fingers.



The study is recruiting inpatients with stroke from the Clinica Hildebrand Centro di Riabilitazione Brissago, a rehabilitation clinic in Switzerland where the rehabilitation technology used in the study is available. One of the medical doctors of the rehabilitation clinic involved in the study proposes to patients potentially meeting the eligibility criteria to participate in the study, explains the protocol, and obtains informed consent from them. Compensation is not provided.

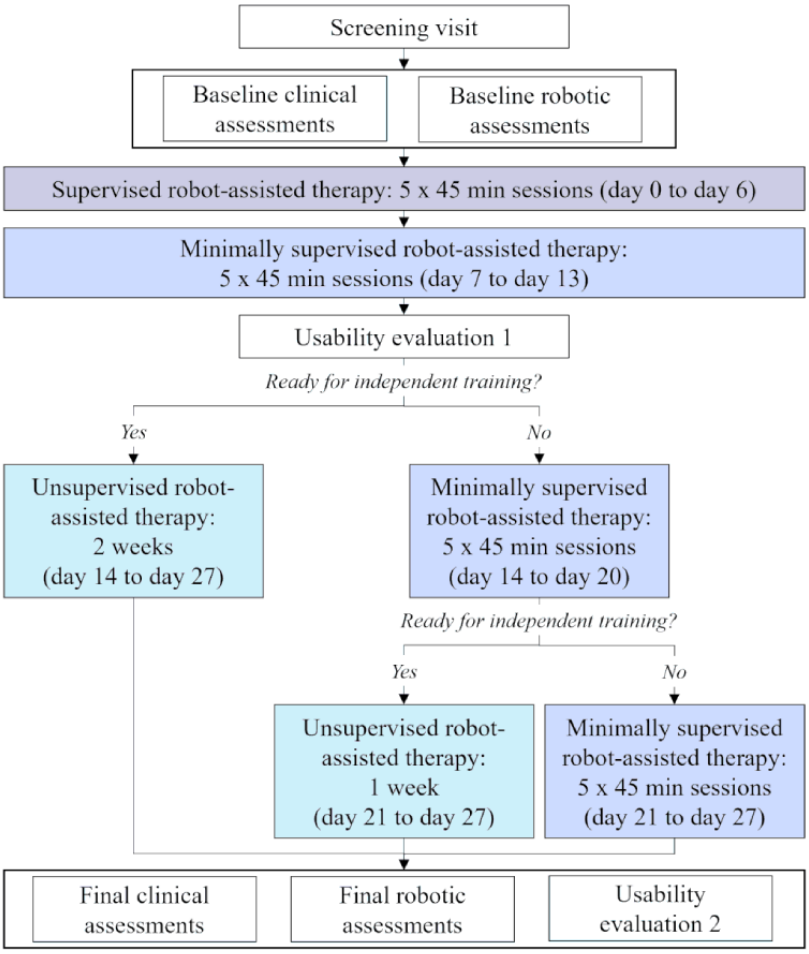
The ReHapticKnob

The rehabilitation technology used in this study is the ReHapticKnob (RHK; Figure 1), which consists of a haptic device for the rehabilitation of hand sensorimotor function after stroke with 2 active degrees of freedom, allowing for hand opening and closing and forearm pronosupination [21].

Figure 1. A patient with stroke performing an exercise with the ReHapticKnob. During a therapy session with the device (left), users first log in to their personal therapy account with a fingerprint reader; then, when performing the exercises, they place their fingers on the handles and interact with the virtual reality interface by using a colored pushbutton keyboard. As the exercises implemented on the ReHapticKnob require the user to solve tasks by relying on the sensorimotor information coming from the impaired limb and not on visual information, view of the impaired hand is blocked with a hand cover. The ReHapticKnob allows for grasping (top right) and forearm pronosupination (bottom right) movements.

The rehabilitation exercises implemented on the RHK follow the neurocognitive therapy approach [22-24] and promote motor learning by focusing on sensorimotor integration, as they require patients to use kinesthetic and proprioceptive information from their impaired upper limb and cognitively process it to solve the therapy tasks in the correct way. Assessment-driven exercises ensure an optimal difficulty level from the beginning while ensuring dynamic difficulty adaptation based on the user's performance [25]. Therapy with the RHK was previously shown to be as efficient as dose-matched conventional therapy [26] when performed in supervised settings.



To make the device suitable for unsupervised use, design changes, such as the implementation of a new graphical user interface and pushbutton keyboard to allow direct interaction between the user and the device, were implemented and tested in a previous usability study [24]. Building on that work, the usability of the platform was further improved by implementing minor graphical changes and audio instructions for the exercises. Furthermore, the platform was improved by integrating clinically inspired algorithms to automatically monitor, control, and adapt therapy in a personalized way [27,28]. This set of algorithms was evaluated in a pilot study with 5 patients with subacute stroke, demonstrating its ability to guide them through several therapy sessions with the RHK and to automatically adapt the difficulty level of the exercises to keep therapy challenging.

Intervention

This trial is a single-group, interventional clinical study. The study protocol lasts for about 4 weeks for each patient (Figure 2), which is compatible with the duration of an inpatient stay at the rehabilitation clinic and comparable to our previous studies with the RHK [26]. The data collected and procedures performed at each time point are listed in Table 1.

XSL•FO
RenderX

Figure 2. Design of the interventional study for each of the study participants. All participants undergo a screening visit, baseline assessments, 1 week of supervised therapy, and 1 week of minimally supervised therapy. After the first week of minimally supervised therapy, the therapist checks whether the patient properly learned how to use the technology and is ready for unsupervised training. If yes, the patient proceeds to 2 weeks of unsupervised use. If no, an additional week of minimally supervised therapy is performed. At the end of this second week, the therapist checks again whether the patient can train independently. If yes, the patient proceeds to 1 week of unsupervised therapy. If no, an additional week of minimally supervised therapy is performed. In total, each patient performs 4 weeks of technology-assisted rehabilitation. At the end of the protocol, the clinical and robotic assessments as well as the evaluation of the user experience and usability are repeated for all patients.

[p]Robotic therapy data includes, for example, time of logging in and out, duration of sessions and breaks, number of task repetitions, correct answers, difficulty level of the exercises, and muscle tone data.

[q]Conventional therapy data includes the number and type of standard therapy sessions performed by the patient while participating in the clinical trial.

Before starting the intervention, patients undergo a screening visit with a medical doctor at which the eligibility criteria are checked and demographic and medical data relevant for patient characterization are collected. At the beginning and end of the study, patients undergo a visit with an experienced therapist where clinical assessments are performed to characterize upper limb sensorimotor deficits. Before the first robot-assisted therapy session and at the end of the study, robotic assessments are performed. The baseline robotic assessments are used to tailor the initial difficulty level of the therapy exercises. As robotic therapy is an addition to conventional therapy and this protocol does not comprise a control group, functional recovery is not used to evaluate the efficacy of unsupervised robot-assisted therapy, as it is not possible to infer how much of the recovery is due solely to the addition of robotic therapy, but rather to investigate the possible relation of different impairment profiles on the observed increase in therapy dose.

During the first week of intervention (ie, the supervised phase), a therapist familiarizes the participants with the therapy platform and teaches them how to perform the therapy exercises. During the second week (ie, the minimally supervised phase), participants try to perform the therapy exercises with the device by themselves. A therapist is still present in the room but intervenes only upon request or if deemed to be needed. The first 2 phases consist of 5 sessions of about 45 minutes each, performed on consecutive days (weekends excluded). These sessions are an addition to standard therapy. Therefore, during the study, participants are allowed to fully follow the conventional interdisciplinary rehabilitation program provided by the clinic.

During the last session of the minimally supervised phase, a checklist (Multimedia Appendix 1) is used by the therapist to record whether participants learned how to correctly perform each assigned therapy exercise. The checklist is also used to assess the patient's functional independence in ambulation and in positioning in front of the device and to decide if the patient meets the requirements to train with the technology in a safe and effective way without supervision. If the requirements are met, the participant can proceed to the unsupervised phase, which lasts for 2 weeks. During the unsupervised phase, patients can independently exercise with the rehabilitation platform during their free time, during dedicated sessions indicated on their therapy schedule, as well as after 5 PM and during the weekend. Specific guidelines on how much to train are not provided. Even though a possible time to train with the device is suggested on the patient's daily therapy schedule during weekdays, patients are clearly told that they do not necessarily need to attend the session but can rather freely decide when to seek additional therapy within the offered slots or whether to go at all (ie, as a way to simulate home settings).

If, at the end of the first week of minimally supervised therapy, the patients do not meet the requirements to transition to the unsupervised phase, they continue with minimally supervised therapy for an additional week. At the end of the second minimally supervised week, the checklist is performed again. If the patients are now ready for unsupervised training, they can proceed to 1 week of unsupervised therapy; if they are not ready, they undergo a third week of minimally supervised sessions (Figure 2).

During the entire study, the device is placed in an open-access room and an emergency call system is available next to it. Trained personnel of the clinic turn on the device in the morning and turn it off in the evening. If needed, patients are taken to the device by the personnel of the clinic responsible for patient transportation. The personnel might also help patients to position themselves in the correct way in front of the device but do not help with placing the patient's hand on the handles or operating the device.

The usability of the platform and user experience during robot-assisted therapy is rated a first time at the end of the first week of minimally supervised therapy and a second time at the end of the study. The difference in the ratings between the 2 time points is used to investigate the effect of unsupervised training (ie, of the therapist's absence) on the perceived usability of the therapy platform and on the user experience during technology-assisted rehabilitation.

Adverse events and device deficiencies are monitored throughout the whole study protocol. The intervention can be discontinued after consultation with medical doctors and therapists or if the participant decides to quit.

For each patient, attendance to the robot-assisted therapy sessions is registered. As attendance to robot-assisted therapy is one of the study outcomes, strategies to increase adherence are not implemented. Reasons for nonattendance are registered

XSL•FO
RenderX

a posteriori for each missed supervised or minimally supervised session as well as if patients train for less than 50% of the possible days (ie, less than 7 of 14 days when the patient undergoes 2 weeks of unsupervised therapy or less than 4 of 7 days in cases where the patient undergoes only 1 week of independent training) during the unsupervised phase.

Outcome Measures

Primary Outcomes

The primary outcomes of this study are the feasibility of the proposed protocol, the dose of unsupervised robot-assisted therapy performed by participants, and the difference between usability and user experience between the phases where a therapist is present (ie, supervised and minimally supervised phases) and the unsupervised phase.

Feasibility is measured as the number of patients who could transition to the unsupervised phase out of the total number of tested patients, attendance during the unsupervised phase, and safety of use. Attendance is defined as the percentage of days out of the total number of offered days where the patient trains with the device at least once, while safety is defined as the number of adverse events and device deficiencies throughout the entire protocol.

The different metrics used to characterize therapy dose are therapy duration in minutes, number of task repetitions (ie, the number of target movements performed), and percentage change in physical therapy time with respect to the conventional therapy program. Total conventional physical therapy time is estimated from the sum of the duration in minutes of the physiotherapy (without differentiating between upper limb and lower limb) and occupational therapy sessions regularly performed by each patient at the clinic.

Platform usability is assessed with the System Usability Scale [29], the raw Task Load Index [30], and the Post-Study System Usability Questionnaire [31]. User experience during robot-assisted therapy is assessed with the Net Promoter Score [32] and the Customer Satisfaction Score, as well as by evaluating the reasons (if any) for not attending the therapy sessions with the device.

The results of the checklist used to define which patient can proceed to unsupervised therapy are also used to identify specific aspects of the platform that might need to be further improved.

Secondary Outcomes

The difference in intensity (ie, number of task repetitions per minute) and task performance during supervised or minimally supervised therapy and unsupervised therapy is used to evaluate if the content of the therapy varies when the therapist is no longer present. A task repetition corresponds to the target action that the patient must perform in a given exercise (eg, a movement or combination of movements, such as one opening and closing of the hand or interacting with one virtual object rendered by the robot). A third metric to evaluate the difference in therapy content is the ratio of effective therapy time (ie, net therapy time without breaks) to total duration of a therapy session during supervised or minimally supervised therapy and unsupervised therapy.

Functional recovery, assessed as the difference between the baseline and final scores in the clinical and robotic assessments, is another secondary outcome. Clinical assessments comprise the Fugl-Meyer Assessment for upper extremities [33], ABILHAND [34], the Box and Block Test [35], the Motor Evaluation Scale for Upper Extremities in Stroke Patients [36], and the modified Ashworth Scale [20]. Robotic assessments comprise active range of motion, hand proprioception, and haptic perception (A1-A3 in [25]).

The scores of the cognitive assessments performed during the screening visit (Goodglass-Kaplan scale and levels of cognitive functioning-revised) are used to gain more insights into the effect of cognitive function on the ability to transition to the unsupervised phase.

Other parameters possibly influencing therapy dose or attendance are also evaluated. These comprise age, baseline assessment scores, functional recovery, the number of total conventional therapy sessions, and functional independence and mobility, as assessed with the Barthel index [37] and custom questions every time the checklist is performed (ie, at the end of each week of minimally supervised therapy).

Sample Size

The study includes 13 patients; 10 patients are expected to be sufficient to perform a feasibility study and gather information on the potential of unsupervised therapy to plan a subsequent larger study targeting efficacy, and a dropout rate of around 20% is accounted for based on our previous studies [26]. The selected sample size guarantees the execution of the study within a relatively short time (ie, 2 years) such that improvements to the device, if needed, can be implemented in a timely manner for follow-up studies. Furthermore, this sample size is comparable to previous studies performed by our group with the RHK and to other studies with similar goals [10,11,15].

Data Collection, Management, and Confidentiality

All the data listed herein are collected by trained personnel. For withdrawn participants, the clinical and robotic data collected until withdrawal are kept, and no further clinical or robotic evaluations are performed after that. A specific follow-up phase is not needed.

At the beginning of the study an ID is assigned to each patient and the saved data are coded according to this ID. Study data are reported on a paper case report form (CRF), 1 for each patient, and then entered in an electronic CRF with the help of an electronic database, namely Research Electronic Data Capture (REDCap) [38,39], hosted on a secure server at the Swiss Federal Institute of Technology Zürich. REDCap promotes data quality via functions and settings, like audit trails, field type restriction, range checking, and definitions of required fields. Data automatically saved by the RHK are stored on the connected laptop. Backups of the data saved on the laptop and of the electronic CRF are saved monthly on the protected server of the sponsor institution. To promote security, the laptop is password protected and participants can only access the therapy interface. The data will be archived for a minimum of 10 years after study termination or premature termination of the clinical trial.

XSL•FO
RenderX

Data Analysis

Descriptive statistics will be used to describe the study population (eg, demographics, initial clinical scores, and changes in clinical scores, such as functional recovery), attendance and therapy dose in the unsupervised phase, user experience, and platform usability.

Normal distribution of the data will be checked with the Shapiro Wilk test. For each usability metric, a paired *t* test (normal distribution) or a paired samples Wilcoxon test (for data not normally distributed) will be performed to compare the data collected during the usability evaluation 1 and usability evaluation 2 sessions.

To evaluate the content of unsupervised therapy, 1-way repeated measures ANOVA or its nonparametric version (Friedman test) with post hoc tests will be run to compare intensity (average block intensity for each patient), performance, and ratio of effective therapy time to total session duration during supervised, minimally supervised, and unsupervised therapy. The same tests will be used to compare the answers to the VAS-smiles, a 5-point VAS represented by different emoticons, performed at the end of each therapy session during the 3 phases. For these comparisons, we expect therapy content and VAS-smiles not to vary significantly depending on the level of supervision, as ideally the absence of the therapist should not impact these outcomes. Patients who did not reach the unsupervised phase will be excluded from this analysis.

Linear mixed-effects models will be used to investigate parameters (eg, demographics and baseline data) possibly influencing the achieved dose of unsupervised therapy.

Relevant qualitative data will be summarized and reported accordingly.

Data analysis will be performed with MATLAB R2021b (MathWorks).

Monitoring

Monitoring is performed by a study nurse employed at the sponsor institution. An initiation visit on-site is performed to check the suitability of the infrastructure and staff. Routine monitoring is then performed through on-site or web-based visits depending on the needs of the investigators (eg, on request or for safety reasons). A close-out visit is performed after the completion of the study. Interim analysis is not foreseen.

Observed or spontaneously reported adverse events are collected and assessed by one of the medical doctors involved in the clinical study and recorded on the CRF. Adverse events are then reported in the annual safety report and final report. Serious adverse events are reported to the ethics committee and to the competent authority within 7 days.

Auditing may be conducted at any time by the ethics committee or the competent authority, both independent from the sponsor and investigator. The study documentation, CRF, and informed consent are accessible for auditing.

Ethical Considerations

This study protocol follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) reporting guidelines [40]. The study follows the guidelines on good clinical practice and the Declaration of Helsinki. The protocol (Version 2, 17.03.2020) has been approved by the cantonal ethics committee (“Comitato etico cantonale Ticino,” CE TI 3577) and by the Swiss Agency for Therapeutic Products (Swissmedic, 102681300) and was registered at ClinicalTrials.gov (NCT04388891) and on the portal for clinical trials in Switzerland (SNCTP000003850). Substantial amendments have to be submitted and approved by the cantonal ethics committee and Swissmedic before being implemented and distributed to the study staff both orally and in writing.

Ancillary and post-trial care is not needed. An insurance was stipulated to compensate for eventual harm from trial participation.

The sponsor and investigators will have access to the final trial data set. The study results will be presented among the collaborators of the Clinica Hildebrand Centro di Riabilitazione Brissago and of the sponsor institution. Results are planned to be published in peer-reviewed journals or conferences. The use of a professional writer and public access to the data set and statistical code is not foreseen.

Results

Recruitment started in November 2020. As of April 2023, 13 patients were recruited and completed the protocol. Data analysis is ongoing, and publication of the results is expected for 2023.

Discussion

This paper describes the details of a single-group, interventional clinical study investigating the feasibility of unsupervised robot-assisted therapy of hand function in inpatients with subacute stroke and its effect on the dose of therapy. In particular, we propose a systematic approach for a progressive transition from supervised to unsupervised use of an advanced rehabilitation technology.

Unsupervised technology-assisted rehabilitation is seen as a promising avenue to increase therapy dose for stroke survivors without increasing the workload for therapists. As opposed to most telerehabilitation interventions, whose development was fueled, for instance, by the COVID-19 pandemic and the need for neurorehabilitation services to decrease reliance on hospital presence (eg, by proposing remotely supervised physiotherapy sessions [41,42]), robot-assisted therapy may not rely on the presence of a therapist [7]. Such a fully unsupervised approach to neurorehabilitation might therefore provide a more sustainable answer to the unfavorable patient to therapist ratio [4,43].

The absence of supervision during rehabilitation certainly raises challenges with respect to adherence and motivation to train, understanding of tasks to be achieved, and safety. We expect that an initial standardized training procedure can help patients to learn how to use a rehabilitation technology in a controlled way so that the risk of adverse events during unsupervised

XSL•FO
RenderX

therapy is reduced and patients feel comfortable and motivated in using the technology on their own. Despite the many feasibility studies describing unsupervised technology-assisted rehabilitation, there exists no consensus on how to optimally achieve the transition from supervised to unsupervised use of such technologies, nor is there an agreement on how to define and evaluate feasibility. The systematic approach outlined in this protocol paper provides a way for patients to progressively transition from supervised to unsupervised use of a rehabilitation technology based on objective data (ie, a checklist). Furthermore, it allows for the collection of information on the feasibility of unsupervised therapy and its effect on therapy dose, user experience, and the usability of the rehabilitation technology used. We expect this systematic approach to allow patients to transition to unsupervised use of a rehabilitation technology in a safe and comfortable way, meaning that usability and user experience do not drop during unsupervised use. High perceived usability and user experience are essential and increasingly investigated aspects [11,24,44] as they may increase adherence, and therefore, therapy dose, in the unsupervised phase, potentially leading to an improvement in functional outcomes.

While designed here for a specific robotic technology (ReHapticKnob), the proposed methodological approach could be generalized to other rehabilitation technologies with minor adjustments, such as the goals reported in the checklist, which need to be adapted to the specific rehabilitation platform as they depend on the practical actions that users need to learn to use a given technology. Furthermore, depending on the complexity of the technology, the number of supervised and minimally supervised sessions might be adapted. All other outcome measures, such as the usability and user experience questionnaires, adverse events, device deficiencies, and clinical assessments, can be collected independently from the technology used. Outcomes used to characterize therapy dose, namely, therapy duration in minutes or the number of repetitions, should be parameters that most rehabilitation technologies automatically record, as one or both of them are already reported by many research groups working in the field [13,45-47]. Given its generalizability, the proposed methodological approach could serve as a benchmark to allow for better and easier comparisons between different technologies for unsupervised rehabilitation.

The proposed interventional study of patients with subacute stroke aims to demonstrate the feasibility of fully unsupervised robot-assisted rehabilitation in a clinical setting. While no supervision is provided during the use of the device in the unsupervised phase of the study, the fact that it takes place in a clinical environment may still influence adherence and the achieved dose. However, if successful in terms of feasibility, the approach outlined in this paper could, as a next step, also be applied to the home setting. For example, the supervised and minimally supervised (and even the unsupervised) phases can be implemented in the clinic, and after discharge, the patient could continue training with the technology in an unsupervised way at home. The purpose of the progressive transition approach we propose here would be to guarantee that enough training in the use of the device is provided before discharge to later allow for safe and high-quality unsupervised use of the robot at home, which could help keep patients engaged in rehabilitation and maintain or even further increase functional recovery.

Abstract

Background: Hospital-induced delirium is one of the most common and costly iatrogenic conditions, and its incidence is predicted to increase as the population of the United States ages. An academic and clinical interdisciplinary systems approach is needed to reduce the frequency and impact of hospital-induced delirium.

Objective: The long-term goal of our research is to enhance the safety of hospitalized older adults by reducing iatrogenic conditions through an effective learning health system. In this study, we will develop models for predicting hospital-induced delirium. In order to accomplish this objective, we will create a computable phenotype for our outcome (hospital-induced delirium), design an expert-based traditional logistic regression model, leverage machine learning techniques to generate a model using structured data, and use machine learning and natural language processing to produce an integrated model with components from both structured data and text data.

Methods: This study will explore text-based data, such as nursing notes, to improve the predictive capability of prognostic models for hospital-induced delirium. By using supervised and unsupervised text mining in addition to structured data, we will examine multiple types of information in electronic health record data to predict medical-surgical patient risk of developing delirium. Development and validation will be compliant to the Transparent Reporting of a multivariable prediction model for Individual Prognosis Or Diagnosis (TRIPOD) statement.

Results: Work on this project will take place through March 2024. For this study, we will use data from approximately 332,230 encounters that occurred between January 2012 to May 2021. Findings from this project will be disseminated at scientific conferences and in peer-reviewed journals.

Conclusions: Success in this study will yield a durable, high-performing research-data infrastructure that will process, extract, and analyze clinical text data in near real time. This model has the potential to be integrated into the electronic health record and provide point-of-care decision support to prevent harm and improve quality of care.

Introduction

Background

Hospital-induced delirium, defined as any episode of acute decline or fluctuation in attention, awareness, or other cognitive function, affects up to 56% of hospitalized older adults [1-3]. The experience of delirium can result in higher likelihood of hospital mortality, increased length of hospital stays, greater risk of 1-year mortality after discharge, functional decline, and increased caregiver burden [2-4]. The costs of hospital-induced delirium have ranged from US $16,000 to over US $64,000 per patient hospitalization, resulting in an estimated US $152 billion in national direct annual expenditures [5].

Clinicians, aging experts, patient advocates, and federal policymakers agree that there is a need to enhance the safety of hospitalized older adults through identification and reduction of iatrogenic conditions (ICs), such as hospital-induced delirium [6-8]. Advances in computing technology and availability of electronic health record (EHR) data—both structured, such as billing codes, and unstructured, such as clinical notes—present opportunities to assist health care systems and providers in more accurately identifying ICs and at-risk older adults [6,9,10].

Automated identification of conditions from EHR or other health data is not straightforward, even when biomedical ontologies such as the World Health Organization's International Classification of Diseases (ICD) or the Systemized Nomenclature of Medicine–Clinical Terms are used [11,12]. Previous studies have shown that ICD code data captures a low percentage of delirium cases [13-16]. The notion of "computable phenotype" has been introduced to provide standardized, automated algorithms that make use of both structured and unstructured health data to identify conditions [11,12]. Automated methods, such as text mining, have shown promise for medical record reviews and retrospective identification of ICs, including delirium [17-23].

Computable phenotypes are vital to identification of conditions that can be used as "dependent variables" or "targets" for prediction models to discern high-risk patients. The use of clinical notes, such as nurses' notes, has been shown to improve both computable phenotyping and prediction modeling [24]. There has been discussion about the importance of appropriately defining the outcome when developing a prognostic model for delirium; training a model to identify patients with a diagnostic code, as opposed to all patients with a condition, can result in a biased model. Researchers have suggested that incorporating clinical notes would increase the accuracy of a computable phenotype for delirium and improve a prediction model [25-27].

Registered nurses' (RNs) progress notes, a type of clinical note, often contain important contextual factors and information related to patient safety that are not found in structured data fields [28]. The ability to process and analyze text data can fill gaps in practice-based evidence, provide contextual information, and improve the accuracy of prediction models [22,29,30]. The development of a research-data infrastructure that supports the use of both structured data and text data is critical for a learning health system aimed at improving care and patient outcomes [20,22].

Despite the value in text data, few hospital-induced delirium prediction models have included nurse-generated data, such as assessments and progress notes [2]. Prior studies have also emphasized patient factors which are not mutable, such as age and gender, even though clinical interventions can only be implemented with regard to variables that can be changed. Moreover, existing prediction models tend to have a high risk of bias, and the predictive value and generalizability of these models have rarely been validated using an external data source [31,32].

Objective

Our long-term objective is to enhance the safety of hospitalized older adults by reducing ICs through a reliable and efficient learning health system. This will involve optimization of text and structured electronic data in a way that increases the reuse of clinical and administrative data for aging research, risk identification, and ultimately development of point-of-care technologies; and identification of the best ways to process and analyze text data generated by RNs to inform prospective identification of ICs in real or near–real time.

In this study, we will develop prediction models for hospital-induced delirium. In order to accomplish our objective, we will need to create a computable phenotype for hospital-induced delirium to be used as our outcome measure, design an expert-informed traditional logistic regression model to be used as a baseline model, leverage machine learning techniques to generate a model using structured data, and use machine learning and natural language processing (NLP) to produce an integrated model with components from both structured data and text data.

Building on our previous work with hospital-acquired falls [33,34], our study constitutes the first research effort to generate automated risk models of hospital-induced delirium by integrating RN-generated text data with existing structured patient, clinical, and administrative data.

Methods

Study Design

The study will use data from 2 academic medical centers in North Florida. Leveraging data from 2 medical centers will allow us to use data from 1 center for training and data from the other center for testing. Specifically, 1 medical center has

XSL•FO
RenderX

about 1095 beds and 54,757 admissions per year, and the other medical center has about 603 beds and 23,685 admissions per year. We will include older adult (≥65 years) admissions to a medical-surgical unit between January 2012 and May 2021. We will obtain the data from the Integrated Data Repository (IDR).

The IDR was created to serve as a common source of information for clinicians, executives, researchers, and educators. The IDR enables new research discoveries as well as patient care quality and safety improvements through a continuous flow of information between the clinical enterprise and research community. The IDR currently consists of a clinical data warehouse that aggregates data from various clinical and administrative information systems, including the Epic electronic medical record. The clinical data warehouse contains demographics, inpatient and outpatient clinical encounter data, diagnoses, procedures, lab results, medications, select nursing assessments, comorbidity measures, and select perioperative anesthesia information system data.

IC Task Force

We will develop a nurse-led IC task force whose purpose is to provide relevant clinical and technical expert knowledge to translate the use of electronic clinical data. In addition to focusing on delirium, members of the IC task force will also be involved in evaluating the expanded research-data infrastructure.

Outcome

We aim to develop a computable phenotype that has greater sensitivity to identify patients with hospital-induced delirium than ICD codes alone. Along with using ICD code and medication data, we will incorporate nursing assessment documentation from structured data fields as part of our phenotype. Examples of the different types of data we will use include the ICD-10 code F05, the medication haloperidol, and the nursing assessment "observed/expressed feelings: agitated." Expert clinicians will validate the phenotype; after evaluating performance, we will iteratively refine the phenotype and use it as our outcome measure.

Structured Data Modeling

We will develop a clinical model to predict hospital-induced delirium, as defined by the (validated) computable phenotype.

We will compile a list of structured data variables to be used as candidate predictors of hospital-induced delirium, on the basis of a systematic review of the literature regarding model development and validation studies [32].

Clinical experts from our IC task force will help to select which predictors to use in a logistic regression model. We will also use machine learning methods, including decision tree, bagging, random forest, and adaptive boosting, to develop prediction models of hospital-induced delirium [35-39]. We will compare the performance of the models from machine learning techniques with our expert-informed logistic regression model. We are going to evaluate both discriminative ability and calibration; measures will include area under the receiver operating characteristic curve, balanced accuracy, sensitivity, specificity, and Brier score. We are going to use 1 admission event (encounter) per patient in order to avoid corelated instances.

Text Mining

Supervised and unsupervised text mining approaches will be used to identify concepts related to risk factors, signs, and symptoms of delirium. For risk factors, we will be reviewing and adapting NLP pipelines developed to extract concepts related to risk factors for hospital-acquired falls. To identify and extract signs and symptoms of delirium, we will start by creating a reference thesaurus of keywords and phrases (ie, n-grams and sequence of consecutive keywords) thought to indicate signs and symptoms of delirium based on domain expertise and review of the literature. New themes that emerge from the data will be added to the reference thesaurus, which will be used to develop a guide for the manual annotation process. In total, 2 practicing bedside nurses will be trained as annotators to review progress notes and label phrases related to signs and symptoms of delirium. The entire process will be overseen by text-mining experts and clinicians.

We will use clinical named entity recognition (NER) to identify text patterns and attributes related to the signs and symptoms of delirium. The NER approaches are based on conditional random fields (CRF), a statistical method of sequence modeling [40,41]. The NER identifies the boundary (start and end positions) and semantic type for each clinical concept (eg, whether the concept is a laboratory finding, a medical condition, or something else). To develop the NER system, we will recruit annotators to manually identify the signs and symptoms of delirium from clinical notes as the gold standard. We will divide the annotations into a training set and a test set. The training set will be used to train the NER model and the test set will be used for performance evaluation. The performance of the NER model will be evaluated based on measures of precision and recall, including the F-measure. The model will also become a component of a text-mining pipeline to automatically extract and analyze RNs' progress notes.

We will also develop a semiautomatic (unsupervised) method to discover previously unknown terms related to delirium from RNs' progress notes using topic modeling which can support the generation of new hypotheses of risk factors or early signs of hospital-induced delirium. A topic refers to a cluster of similar words; for example, "confused, agitated, disoriented" could emerge as a cluster with the label "patient mental status." We will apply latent Dirichlet allocation (LDA), a state-of-the-art topic modeling method which represents text files or documents as a collection of topics and assumes that each word is contained within one of these topics [42]. This probability-based approach will allow us to determine the optimal number of topics based on metrics of model performance. We will train an LDA model using the full collection of RN progress notes from one of the medical centers. The team will review the clusters of words generated by the LDA model and assign a clinical topic label based on the most frequently occurring words (this will allow us to organize the results and facilitate interpretation). Additionally, the results will be the foundation of an LDA model in our delirium text-mining pipeline. We will then generate a composite model of text and structured predictors by leveraging the structured data prediction modeling portion of our study.

XSL•FO
RenderX

In case more than 1 model has similar performance, the most parsimonious will be chosen. In order to integrate text data and structured data into 1 model, we will translate text into vectors (ie, a numerical representation) using Word2Vec models [43]. Word2Vec is a collection of models developed and widely tested to process a large body of text to produce a vector space, with each unique text attribute being assigned a corresponding vector in that space [43]. This mathematical representation enables the inclusion of text patterns in statistical and machine learning predictive models.

Finally, we will prepare a single data set that contains the converted textual data, and significant empirical and clinical factors from the structured data modeling. We will assign a vector value to each of the unstructured text variables. This way, the structured data variables and the text attributes will all be represented in the same format and can be fitted into the same vector space for prediction model development. We will then apply logistic regression methods with a LASSO (least absolute shrinkage and selection operator) feature selector and machine learning approaches including naive Bayesian classification, decision trees, and support vector machines. Interpretability and clinical significance are critical to understand the impact of different attributes on the overall prediction and clinical translation and will be carefully considered in choosing the best fitting model [44]. The performance of the prediction models will be evaluated by calculating sensitivity, specificity, and area under the curve using 10-fold cross-validation. To minimize false negatives (ie, failing to identify a person that truly is at risk of developing hospital-induced delirium), we will prioritize sensitivity; we will also aim to maintain a specificity of at least 0.9.

Once an integrated model is developed, we will externally validate it using a sample of patients hospitalized from January 2012 to May 2021 at the medical center which was not used for training the model. All work will be completed and results will be reported in accordance with the rigorous reporting and validation standard, the Transparent Reporting of a multivariable prediction model for Individual Prognosis Or Diagnosis (TRIPOD) statement, and its 22 associated items [45].

Pipeline Infrastructure

We will integrate the clinical text pipelines by adding and linking them into existing components of the IDR. To evaluate the text-mining pipelines, we will carry out a testing procedure with two phases: (1) “white-box” testing—evaluating code coverage or the internal structures of modules within the research-data infrastructure, and (2) “black-box” testing—evaluating the functionality and scalability of the research-data infrastructure. For “white-box” testing, we will examine whether branch, path, and statement programming in the expanded IDR infrastructure is functional and error free. For “black-box” testing, RN members of the IC task force (see section above) will be asked to complete a series of tasks that involve querying clinical text data in the IDR instance of the Informatics for Integrating Biology and the Bedside (i2b2) computerized platform. These tasks might include identifying patients at high risk for delirium or patients with signs or symptoms of delirium. Tasks could focus on pulling data from structured EHR data fields, structured data derived from the NLP, or both. To assess functionality, we will measure perceived ease of use, processing speed, and errors reported. To determine scalability, we will assess memory usage and processing time of all “black-box” testing to identify bottlenecks or problem areas that could increase system load at scale-up. We will use an iterative testing approach to refine the integration of the text-mining pipelines until processing speed, memory use, and error reporting have reached acceptable levels.

Ethics Approval

This project was approved by the University of Florida Institutional Review Board on February 11, 2019 (IRB201900208).

Results

Work on this project will take place through March 2024. For this study, we will use data from approximately 332,230 encounters of 170,868 patients, including 6,980,470 narrative notes; these encounters took place from January 2012 to May 2021. We will create and validate a computable phenotype for hospital-induced delirium, develop prediction models for hospital-induced delirium using structured data and unstructured text data, and integrate text pipelines into the IDR. In addition, we will identify important nursing structured EHR data, curate data, and bring these data elements into the IDR to make them available for other future research projects.

Research findings will be disseminated through scientific conferences and peer-reviewed journals. Dissemination of the results and future studies (informed by this project) may expand practice-based evidence of hospital-induced delirium, which will improve clinical decision–making by clinicians and improve patient care in hospitals.

Discussion

In this study, we will use both structured and unstructured EHR data to develop computable phenotype and prognostic models for hospital-induced delirium. By leveraging nurse-generated data, including structured fields from flowsheets and text from notes, we will identify more robust and accurate predictor and outcome measures, resulting in a highly accurate prediction model with less risk of bias than those from prior studies [31,32].

Creating multiple models will allow us to assess which data and modeling techniques make an appreciable difference. There are challenges associated with using text data, and not all EHRs contain easily accessible clinical notes. In our study, by comparing our structured data model with our integrated text and structured data model, we will be able to determine whether the text data significantly helps to predict which medical-surgical patients are at high-risk of developing hospital-induced delirium. Since the model with both unstructured and structured data will include the structured data model, we can use nested model criteria to compare their performance on the test set.

In addition, we will be able to compare our expert-informed traditional logistic regression model with models developed

XSL•FO
RenderX

using machine learning methods. Even though models developed using machine learning techniques may be more accurate, they are also more difficult to interpret [44]. We will attempt to discern whether gain in performance is appreciable and if it outweighs the loss in interpretability.

Our study has some limitations; for instance, EHR data often has issues with completeness, accuracy, and complexity [11]. We will regularly consult with members of our IC task force so that we can better understand where and how clinicians usually document relevant data items in the EHR.

Findings from this study should allow us to develop and test a research-data infrastructure to support ongoing research on hospital-induced delirium, determine the scalability of our research-data infrastructure to OneFlorida, a state-wide PCORNet, and create synergistic relationships to test and translate our work in other health systems. This study will be a model for health care organizations to increase safe, effective care for the millions of older adults hospitalized every day.

Acknowledgments

This work was funded by the National Institutes of Health, National Institute on Aging (grant R33AG062884).

Abstract

Background: Diabetes is a costly epidemic in the United States associated with both health and economic consequences. These consequences can be mitigated by participation in structured lifestyle change programs such as the National Diabetes Prevention Program (DPP) led by the Centers for Disease Control and Prevention. Mississippi consistently has among the highest rates of diabetes and prediabetes nationally. Implementing the National DPP through large health care systems can increase reach and accessibility for populations at the highest risk for diabetes. Translational research on the National DPP in Mississippi has not been studied.

Objective: This study aims to evaluate the implementation and impact of the National DPP delivered using telehealth modalities at the University of Mississippi Medical Center in Jackson, Mississippi.

Methods: An effectiveness-implementation hybrid type III research design is proposed. The study design is guided by the Reach, Effectiveness, Adoption, Implementation, and Maintenance framework and the Practical, Robust Implementation and Sustainability Model. Participants are being recruited via provider referral, and the DPP is being delivered by trained lifestyle coaches. Study participants include adult (≥18 years) patients eligible for the DPP with at least 1 encounter at 1 of 3 ambulatory clinic specialties (lifestyle medicine, family medicine, and internal medicine) between January 2019 and December 2023. The National DPP eligibility criteria include a BMI ≥25 kg/m^2 and hemoglobin A_{1c} between 5.7% and 6.4%. The University of Mississippi Medical Center criteria include Medicare or Medicaid beneficiaries. The University of Mississippi Medical Center's a priori implementation plan was developed using the Consolidated Framework for Implementation Research and includes 23 discrete strategies. The primary aim will use an embedded mixed method process analysis to identify and mitigate challenges to implementation. The secondary aim will use a nonrandomized quasi-experimental design to assess the comparative effectiveness of the DPP on health care expenditures. A propensity score matching method will be implemented to compare case subjects to control subjects. The primary outcomes include patient referrals, participant enrollment, retention, engagement, the incidence of diabetes, and health care resource use and costs.

XSL•FO
RenderX

Results: At baseline, of the 26,151 patients across 3 ambulatory clinic specialties, 1010 (3.9%) had prediabetes and were eligible for the National DPP. Of the 1010 patients, more than half (n=562, 55.6%) were aged 65 years or older, 79.5% (n=803) were Medicare beneficiaries, 65.9% (n=666) were female, and 70.8% (n=715) were obese.

Conclusions: This is the first translational study of the National DPP in Mississippi. The findings will inform implementation strategies impacting the uptake and sustainability of the National DPP delivered in an academic medical setting using distance learning and telehealth modalities.

Introduction

Background

Type 2 diabetes mellitus (herein referred to as diabetes) is a costly epidemic in the United States responsible for significant morbidity and mortality. In 2019, over 37.1 million (14.7%) adults (≥18 years) were diagnosed with diabetes [1]. Diabetes is a metabolic derangement characterized by insulin insensitivity resulting from insulin resistance, reduced insulin production, and eventual pancreatic beta-cell failure, leading to hyperglycemia. Prediabetes is often a precursor to diabetes, a condition with plasma blood glucose levels higher than normal (hemoglobin A_{1c} [HbA_{1c}] 5.7%-6.4%) but not high enough to be characterized as diabetes (HbA_{1c} ≥6.5%) [2]. An estimated 96 million (38%) adults had prediabetes in 2019 [1].

In 2017, diabetes was estimated to impose a US $327 billion annual economic burden, including US $237 billion in direct medical costs [3]. A retrospective study of claims data from 2010 to 2014 among a commercially insured adult (18 to 64 years) population showed patients with newly diagnosed diabetes spent US $10,000 or more than their nondiabetic counterparts over the 5 years leading up to the diagnosis [4]. Annual medical expenditures are nearly one-third higher for those who subsequently develop diabetes relative to those who do not transition from prediabetes to diabetes, with an average difference of US $2671 per year [5]. At that cost differential, the 3-year return on investment (ROI) for diabetes prevention was estimated to be as high as 42% [5].

In 2010, the Centers for Disease Control and Prevention (CDC) introduced the National Diabetes Prevention Program (DPP) to mitigate the transition from prediabetes to diabetes [6-8]. In 2018, the Center for Medicare and Medicaid Services launched the Medicare DPP offering an unprecedented opportunity to reach the estimated 48.3% (25.9 million) of older adults with prediabetes [9]. Despite macrolevel policy support for disseminating lifestyle change programs (LCPs) such as the Medicare DPP, significant challenges hinder translation. There are gaps in program accessibility and population reach and challenges to community and organizational uptake and sustainability of LCPs [9-15]. A recent review by Ackermann and O'Brien [16] found that more than 1500 organizations had reached about 300,000 people with the DPP nationally, representing a mere 1% of the target population. In another review of Medicare DPP supplier organizations, Ritchie and Gritz [17] found 126 unique suppliers across 601 sites nationally (1 site per 100,000 beneficiaries), and the estimated reimbursement to cover program delivery was US $661 per beneficiary. The National DPP is less available to residents in rural locales [18], in counties with higher diabetes incidence, and among socioeconomically disadvantaged groups relative to their respective counterparts [19]. Furthermore, program attrition rates are the highest among racial and ethnic minority populations [14]. Efforts are needed to increase the overall detection, diagnosis, and referral of patients with prediabetes to an LCP such as the DPP, and tailored approaches for vulnerable populations are needed to ensure equity.

Hybrid implementation-effectiveness trials are particularly well suited to identify strategies to address these gaps. Blended designs study the translation of evidence-based interventions within a real-world context to foster more rapid translation over conducting these studies independently [20]. Curran et al [21] proposed 3 types of hybrid designs. Type I designs prioritize effectiveness testing and, secondarily, the gathering of contextual information for implementation. In type II designs, clinical and implementation aims are tested simultaneously, and type III designs prioritize implementation. Type III designs are specifically recommended when implementing an evidence-based practice or program such as the DPP in a new setting or population. Damschroder et al [10] used a type III design to study the implementation of LCPs to veterans through the Veterans Health Administration while comparing the effectiveness of the National DPP with the MOVE! weight management program [10]. The findings demonstrated that large health care systems have the potential to fill gaps in advancing equity in diabetes prevention through improved reach among priority populations and support for uptake in large health care systems. Critical implications included the need for buy-in among systems and local leaders, disseminating evidence-based findings to referring clinicians who may question the overall effectiveness of LCPs for diabetes prevention, and allocating sufficient time and resources for staff training. Conducting hybrid trials in regions with the highest rates of diabetes and disparities is a priority; however, in states such as Mississippi,

XSL•FO
RenderX

where diabetes rates are persistently among the highest, no translational studies of the National DPP have been conducted.

Aims

The primary aim of this study is to evaluate the implementation of the National DPP and Medicare DPP LCPs in 1 large health care system. The RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) framework [22] will guide a mixed methods process evaluation to understand how and why the DPP LCP worked, for whom, in what settings, and at what intensities. The secondary aim is to use a nonrandomized quasi-experimental design to assess the comparative effectiveness of the DPP on reducing diabetes risk, health care cost savings, and health care use. An overview of the study research questions is provided in Table 1.

Table 1. Research questions by measures of the Reach, Effectiveness, Adoption, Implementation, and Maintenance framework.

Measure	Research question
Reach	• What percent of potentially eligible patients were excluded and participated? • How representative were the participants of the target population?
Effectiveness	• What impact did the intervention have on all participants who began the program?
Adoption	• What percent of clinical sites and providers participated in the intervention?
Implementation	• To what extent were the intervention components delivered as intended?
Maintenance	
Organizational	• To what extent was the intervention continued? • How were the implementation strategies adapted? • To what extent was the intervention modified? • Can the institution maintain delivery of the LCP[a]? • What is the cost-benefit of delivering versus not delivering the LCP to patients with prediabetes?
Participant	• What was the attrition rate? • What was the representation of participants not completing the intervention? • How did attrition impact conclusions about effectiveness?

[a]LCP: Lifestyle Change Program.

Methods

Study Design

This study uses a hybrid type III research design [21] and follows the Standards for Reporting Implementation Studies (StaRI) [23]. StaRI guidelines were developed to promote the translation of implementation studies. The 27-item checklist ensures the transparent reporting of implementation strategies and the effectiveness of the intervention that is being implemented. The proposed study will be the first to comprehensively evaluate the translation of the National DPP and Medicare DPP in Mississippi.

Ethics Approval

This study was reviewed by the institutional review board at the University of Mississippi Medical Center (2020V0327). This trial is registered with ClinicalTrials.gov (NCT04822480).

Implementation Context

Setting

Mississippi is consistently ranked among the states with the highest rates of diabetes (n=326,420, 14.4%) and prediabetes (n=814,000, 35.6%) in the United States [24]. It is also the only state where every county is included in the Diabetes Belt, a cluster of counties in the Southeastern United States where obesity and physical inactivity account for one-third of all diagnosed diabetes cases [25]. Mississippi has the highest percentage of Black (n=1,111,340, 37.8%) populations of any state in the United States and persistently has higher rates of poverty (n=570,371, 19.4%) and a lower median household income (US $49,111) compared to national statistics (n=38,661,356, 11.6% and US $69,021, respectively) [26]. The exceedingly high rates of poverty contribute to Mississippi having the highest Federal Medical Assistance Percentage in the nation (77.27%) [27]. It is the nation's fourth most rural state [20], where 65 (79.3%) of the 82 counties are considered rural areas. According to the Health Resources and Services Administration [28], every one of Mississippi's 82 counties is designated a medically underserved area [28].

Implementation Site

The University of Mississippi Medical Center (UMMC) in Jackson, Mississippi, is the state's only academic medical center. Annually, UMMC physicians conduct over 535,000 clinical visits; 195,000 outpatient and 135,000 emergency room encounters; and 31,000 hospital admissions serving pediatric and adult patients statewide. The UMMC is a minority-serving and research-intensive health care organization with a state mandate to provide no less than 50% of its services to indigent persons (Miss. Code Ann. § 37-115-27; 2017).

The UMMC is also home to 1 of only 2 telehealth centers of excellence in the country funded by the Health Resources and Services Administration (6-U66RH31459-04-01). In partnership

XSL•FO
RenderX

with telehealth, the UMMC launched its DPP program in 2020. Implementing the National DPP LCP through health care systems, such as the UMMC, has the potential to increase program reach and accessibility for residents who are among those at the highest risk for diabetes in the most medically underserved communities; however, no studies of the translation of the DPP have been conducted in Mississippi. The proposed study will be the first to comprehensively evaluate the translation of the National DPP and Medicare DPP in Mississippi.

Implementation Strategy

The implementation plan was developed using the CFIR (Consolidated Framework for Implementation Research) [29]. The CFIR is a determinants framework for navigating the contextual factors that affect the uptake of innovations by health care institutions. The framework is comprised of 39 constructs across 5 complex interacting domains such as intervention characteristics, organizational inner setting context, outer setting context, characteristics of individuals involved with implementation, and implementation processes. The 4 interrelated processes include planning, engaging, executing and reflecting, and evaluating. The processes interact dynamically to achieve organizational (eg, UMMC health care system) and individual (eg, UMMC clinical providers) level use of an intervention as intended (eg, use of electronic health record system for screening and referral of patients at risk for diabetes). The UMMC's a priori implementation plan includes 23 [24] discrete strategies described in Table 2 [30]. One strategy is taking a phased approach to implementation. Thus, in phase 1 of implementation, 3 clinical specialties were targeted based on provider buy-in including family medicine (n=8 clinical sites), lifestyle medicine (n=1 clinical site), and internal medicine (n=5 clinical sites).

XSL•FO
RenderX

Table 2. Discrete implementation strategies according to the Consolidated Framework for Implementation Research domains and taxonomy.

Domain	Strategy
Implementation processes	
Evaluative and iterative strategies	1. Conduct a needs assessment to support the need for diabetes prevention LCP[a] 2. Develop a formal blueprint that defines goals and strategies 3. Access various organizational aspects to determine their degree of readiness to implement, barriers that may impede implementation, and strengths that can be used in the implementation effort 4. Stage implementation scale-up by starting with demonstration projects and gradually moving to a system-wide rollout 5. Collect and summarize clinical performance data to monitor, evaluate, and modify provider behavior 6. Obtain and use patient feedback on LCP to enhance program use and uptake
Adapt and tailor to context	1. Involve, hire, and consult experts to inform management on the use of data generated by implementation efforts 2. Tailor strategies to address barriers and leverage facilitators
Inner setting	
Financial strategies	1. Secure external funding to support implementation and dissemination 2. Explore innovative models of bundled payments
Change infrastructure	1. Change and adapt the location of clinical service sites to increase access 2. Change records systems to allow better assessment of implementation or clinical outcomes 3. Develop and implement tools for quality monitoring
Individuals	
Develop relationships	1. Identify early adopters to learn from their experiences 2. Inform providers identified as opinion leaders to serve as DPP[b] Champions, influence other providers, and contribute to an organizational climate that values prevention through lifestyle change
Provider engagement	1. Meet with providers in their practice settings to teach them about the DPP with the intent of increasing referrals to the DPP 2. Plan for and conduct continuous training 3. Develop and disseminate informational materials to educate about the DPP and how they can refer their patients
Support clinicians	1. Create a new clinical team by adding an operations manager and integrating trained lifestyle coaches into the clinical team 2. Develop reminder systems designed to help clinicians recall information and prompt them to use the clinical innovation
Outer setting	
Patient engagement	1. Develop strategies with patients to encourage adherence and problem-solving barriers 2. Prepare patients to be active participants in preventing diabetes
Develop multilevel and interdisciplinary partnerships	1. Identify and strengthen external partnerships and collaborations centered on diabetes prevention

[a]LCP: Lifestyle Change Program.

[b]DPP: Diabetes Prevention Program.

Intervention Characteristics

National DPP

The National DPP is a 12-month LCP delivered in a group setting by a trained lifestyle coach. The core 16 sessions are delivered weekly in the first 6 months of the program. In the maintenance phase, a minimum of 6 sessions are delivered monthly. The evidence-based program aims to develop behavior change skills leading to increased physical activity (150 minutes per week) and modest weight loss (7% reduction in total body weight), which are proven to prevent or delay diabetes in adults [7]. The DPP LCP is a clinical service of lifestyle medicine in the Department of Preventive Medicine in both the School of Medicine and John D. Bower School of Population Health at the UMMC. The LCP achieved full recognition from the CDC within the first year and, in 2020, became the third Medicare-approved DPP provider in Mississippi.

Interventionists

Lifestyle coaches are UMMC employees and include registered dietitians, project coordinators in population health, and community health workers. All interventionists completed a CDC-recognized lifestyle coach training, have a registered

XSL•FO
RenderX

National Provider Identifier, and completed continuing education units. Newly trained lifestyle coaches shadow an experienced coach prior to leading an independent cohort of patients.

Delivery

Group-based sessions are delivered using BigBlueButton, an open-source web-based classroom software [31]. This educational platform provides a unique link to connect participants using videoconferencing. Participants click a homeroom link, type their names, and enter the room. Weekly weight is tracked using digital body weight scales (developed by BodyTrace, Inc) equipped with cellular connectivity. Weekly physical activity minutes are reported to the lifestyle coach via phone call or email before or immediately following each session. Participant attendance, weight, physical activity, and billing (Medicare-eligible participants only) are tracked in patients' electronic medical records in Epic (Epic Systems Corporation).

Eligibility Criteria

UMMC adult patients (≥18 years) who are overweight (BMI≥25 to 29.9 kg/m^2) or obese (BMI≥30 kg/m^2), have an HbA_{1c} between 5.7% and 6.4%, and are Medicare or Medicaid beneficiaries are recruited for the LCP by physician electronic referral. Using the Healthy Planet coordinated care management tool in Epic [32], physicians are prompted at the patient encounter by Best Practice Alert to diagnose, inform, and refer patients with prediabetes to the LCP. Epic is a patient-centered, cloud-based electronic health record software program comprised of multiple systems to facilitate patient care. Patients with 1 or more of the following are excluded: <18 years; pregnant or planning to become pregnant within the next 12 months; a primary or secondary diagnosis of diabetes, including all International Classification of Diseases, Tenth Revision (ICD-10) codes with a prefix of E11; or end-stage renal disease (ICD-10 code N18.6). Patients with a diabetes diagnosis and an HbA_{1c} value above 6.4% will be excluded.

Given that the LCP is delivered in a telehealth setting, it is preferred that patients have their own computer, tablet, or smartphone equipped with a camera and connected to a reliable Wi-Fi network. However, in a largely rural and underresourced state, this is not a realistic expectation. Thus, participants are eligible to participate if they own or have access to a computer, tablet, or smartphone connected to a reliable Wi-Fi network, have a mobile or landline phone to call into group sessions, or agree to use a study-provided tablet equipped with Wi-Fi and cellular connectivity. Study-provided tablets have restricted use and are provided to participants for the duration of the LCP and must be returned to the study team at the end of the program.

Recruitment, Retention, and Engagement

Electronic referrals to the LCP were extracted from Epic monthly between 2019 and 2021. In 2022, a dedicated LCP staff person was hired, and referrals have since been extracted from Epic twice weekly. Prior to making contact, the coordinator confirms the patient's eligibility. Medical records of ineligible patients are updated, and they are referred to the Lifestyle Medicine clinic rather than being contacted. Among those eligible, up to 3 attempts are made to contact each patient including phone calls, voicemails, and emails. The date, time, type and outcome of contact, and the staff person's name are documented. At a failed third attempt to make contact, the contact attempt details are recorded in the patient's medical record and the referral is closed. Patients declining participation are also noted in their respective medical records and the referral is closed. Interested patients are added to a cohort and provided with information to attend session 0, an informational session.

Following session 0, interested participants are enrolled in the LCP and begin session 1 the following week. Scheduling cohorts consider patient preference and lifestyle coach availability. All session dates over the 12-month intervention period are determined prior to session 0, and participants receive the 12-month schedule at the start of the program. Makeup sessions are provided as needed but participants are encouraged to attend regularly scheduled group sessions. There is no limit to the number of participant makeup sessions. Up to 2 reminder contacts are made with each participant prior to each session. All participants with an email address are contacted via email, followed by a reminder phone call at which point participants are asked to report their weekly weight and physical activity minutes. For participants who do not have an email address, up to 2 phone call contacts are made. These procedures are consistent across participants and cohorts. In addition, when a participant misses 2 consecutive sessions, the project coordinator attempts to make contact to offer support in overcoming barriers and re-engaging them in the program. After 4 consecutive missed sessions and failed attempts to make contact, the participant is excluded from the program.

Implementation Outcomes

Overview

Implementation outcomes are mapped across the 5 domains of the RE-AIM framework (Table 2). The evaluation seeks to determine the intervention reach among patients at risk for diabetes, clinic and provider adoption, implementation fidelity, intervention effectiveness in preventing diabetes, and the organizational and patient uptake of the intervention. Implementation outcomes, research questions, measures, and methods are outlined in Table 3. Data sources will include electronic medical records, session notes provided by lifestyle coaches, intervention cohort and delivery details, meeting notes, and evaluation of DPP sessions conducted by an external reviewer.

XSL•FO
RenderX

Table 3. Implementation outcomes following the Reach, Effectiveness, Adoption, Implementation, and Maintenance framework.

Outcomes and measure	Methods
Reach	
Eligibility	• Number and proportion of patients eligible among the total number of patients in an ambulatory setting
Enrollment	• Number and proportion of patients enrolled among the total number of referred patients • Descriptive characteristics of patients enrolled
Exclusion	• Number and proportion of patients excluded among the total number of patients referred • Descriptive characteristics of patients excluded • Reasons why patients are excluded
Conversion rate	• Number and proportion of patients referred, eligible, and enrolled among those referred and eligible
Effectiveness	
Incidence of diabetes	• The ratio of the number of diabetes cases to the total time at risk among the LCP[a] participants compared with control-matched nonparticipants
Adoption	
Clinical sites	• Number and proportion of clinical sites making referrals among sites eligible to make referrals
Providers	• Number and proportion of providers making referrals among providers eligible to make referrals • The mean number of referrals made among the top 3 providers making referrals
Implementation	
Fidelity	• Organizational recognition status awarded by the CDC[b] • Barriers, solutions, and facilitators to program delivery • Observation of randomly selected DPP[c] sessions
Intervention costs	• Microcosting: time, training, and program materials
Maintenance	
Organizational	• Number of new clinical sites making referrals • Number of new providers making referrals
Participant engagement	• Number and proportion of sessions attended
Participant retention	• Duration of participation in days from first to last session within the 12-month program • Number of patients completing the 12-month LCP compared to the number of patients enrolled

[a]LCP: Lifestyle Change Program.

[b]CDC: Centers for Disease Control and Prevention.

[c]DPP: Diabetes Prevention Program.

Reach

The extent to which the target population is exposed to the intervention or population reach will be determined by the number of eligible patients referred to and enrolled in the LCP, yielding the appropriate referral to enrollment conversion rate. The a priori conversion rate goal is 50%. Reasons for exclusion and participant refusal to participate will be documented where possible. Descriptive characteristics such as age, sex, race, ethnicity, and BMI be explored and compared between patients eligible for the program who were referred and not referred.

Effectiveness

The LCP effectiveness will be determined by the differential incidence of diabetes. Diabetes will be defined by diagnosis code or HbA_{1c} values greater than 6.4%. Data will be extracted from patient medical records and reviewed biannually. The a priori reduction in diabetes diagnosis among the intervention compared with the control group is 50%.

Adoption

The adoption of the LCP will be defined as the number and proportion of clinical sites with referring providers making referrals to the LCP, and the number and proportion of eligible providers making referrals. Data will be extracted from medical records and reviewed quarterly. The a priori adoption clinical and provider addition rates are 70%.

XSL•FO
RenderX

Implementation

Implementation fidelity and costs will be evaluated. Fidelity will be based on the UMMC's recognition category by the CDC. The CDC standards consider participant recruitment, retention, attendance, the proportion of participants meeting the LCP 7% weight loss goal, the proportion of participants achieving 150 minutes or more of physical activity per week, and reductions in HbA_{1c}. Barriers, solutions, and facilitators will be documented by the project coordinator and lifestyle coaches in a weekly session log, during quarterly lifestyle coach meetings, and in strategic planning meetings with UMMC leadership and the American Medical Association Improving Health Outcomes team.

Maintenance

Ongoing organizational and participant engagement in the LCP will provide a robust measure of program maintenance. Longitudinal changes in the number of clinical sites and providers making referrals will be extracted from Epic quarterly, including data to monitor referral maintenance across sites and providers. Attendance and retention in the LCP will provide a measure of maintenance among participants. The a priori participant retention rate is 60%.

Economic Outcomes

The secondary aim of this study is to use a nonrandomized quasi-experimental design to assess the comparative effectiveness of the LCP on cost savings. The primary outcome will be health care expenditures (Table 4). For economic measures, trends in per capita medical expenditures will be tracked among a panel of case (LCP participant) and control (non-LCP participant) subjects. To compare variations in spending, the differences in the arithmetic mean, compound annual growth rates, and propensity score matching models will be implemented to compare case and control subjects. The investigators may also record data from those with prediabetes who are later diagnosed with diabetes and individuals with prediabetes who are not later diagnosed with the condition. These estimates of spending differentials and evidence of DPP participation and engagement rates will further enhance the estimates of potential cost savings and ROI if diabetes is prevented or delayed in the at-risk population who participate in the LCP.

Table 4. Economic outcomes.

Outcomes and measure	Method
Health care use	
Medical encounters	• Number and type of medical encounters extracted from electronic medical records • Types of CPT[a] codes at each medical encounter extracted from electronic medical records
Medical cost	
Medical expenditures	• Dollar amount billed per encounter
Condition or problem	• ICD-10[b] code or CPT codes per encounter

[a]CPT: Current Procedural Terminology.

[b]ICD-10: International Classification of Diseases, Tenth Revision.

Allocation

Overview

Study participants are identified in Epic using the eligibility criteria. Patients are placed in the intervention or comparison group based on natural selection. Each participant is assigned a study identification number that is matched to their medical record number. There is no interaction between study personnel and participants.

Intervention Group

The intervention group includes eligible patients referred to and enrolled in the LCP. Once a participant is enrolled in the study, they are assigned a study identification number.

Comparison Group

The comparison group includes patients meeting the inclusion criteria who are not enrolled in the LCP. Once a patient is enrolled in the DPP, they are no longer included in the control group. These participants include patients with and without a referral. Patients referred to the LCP, deemed ineligible based on insurance type, and referred to lifestyle medicine are excluded from the comparison group. Participants in the comparison group are matched to their intervention counterparts for final effectiveness and cost-benefit analyses. Participants enrolled in the comparison group are assigned a study identification number.

Study Period

The baseline period is January 2019 to December 2019. The study period is from September 2020 (the start of the first DPP patient cohort) through December 2023.

Statistical Analyses

Implementation Analysis

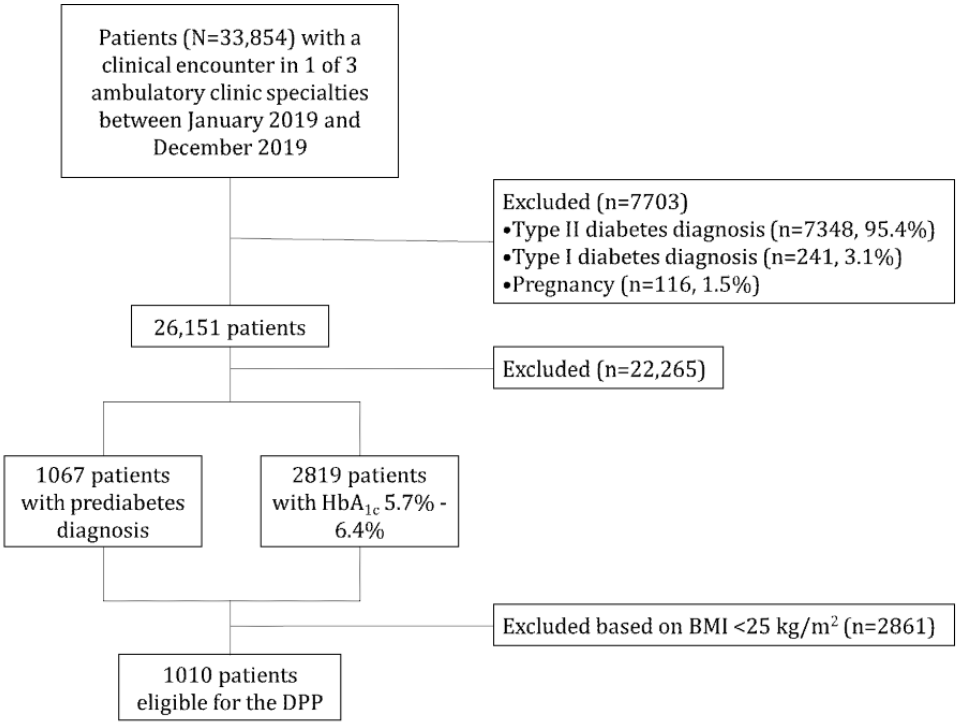
An embedded mixed method process analysis is being conducted to identify and mitigate challenges to implementation. Quantitative data are extracted from Epic and reviewed quarterly to inform reach and adoption. Quarterly data are used to adapt questions to further understand the quantitative data using qualitative methods. Qualitative data are subsequently analyzed using a narrative realist analytic approach. Meeting minutes,

XSL•FO
RenderX

observation notes, and lifestyle coach feedback are compiled and analyzed in Word (Microsoft Corp) documents twice annually. Solutions to challenges are framed in the context of what is acceptable and appropriate to patients and providers and what is feasible within the context of the health care system (inner setting) and outer setting conditions, policies, and funding [33]. Findings are used in the ongoing planning process to continuously adapt, implement, and evaluate. Similar complex mixed methods designs have been used for evaluating the implementation of lifestyle interventions within new populations and settings [34-38].

Economic Analysis

Arithmetic means will be calculated overall and for specific sectors of health care between the 2 groups. Compound annual growth rates in per capita expenditures will be calculated to track the geometric progression ratio and estimate the rate of growth in spending time. A propensity score matching method will be implemented to compare case subjects to control subjects. The model takes the form of $P(X)=Pr(D=1|X)$, where $D=1$ indicates DPP participation and matches on the probability of participation instead of attempting to create a match for each participant with the same value of X. This model aims to account for unobservables and obtain an unbiased and accurate measure of costs. Matched control subjects who do not participate in a DPP must be similar to the case subjects who did participate such that the only difference is attributed to the disease. The matching model in this analysis will control for the following: patient age; sex; race; ethnicity; zip code; and prevalence of other conditions such as but not limited to hypertension, chronic obstructive pulmonary disease, congestive heart failure, cancer, and metformin use in all years of the data. Differences in spending will be compared between individuals with prediabetes who participate in a DPP and those individuals who do not compute net savings and ROI (if any) of program participation. A similar methodology may be applied to compare individuals who progress to diabetes relative to those who do not progress for more in-depth cost savings and ROI analysis. Given this is the first time the DPP will be implemented at the UMMC, the sample size will be determined based on the convenience sample or the number of participants enrolled based on the proposed recruitment and retention strategies.



Data Security and Quality Assurance

Data will be exported from Epic and stored in password-protected computerized files. All data are deidentified at extraction. Data files are stored on the UMMC secure server and shared with the American Medical Association via a secure file transfer process and password protection.

Results

The baseline recruitment is depicted in a flow diagram in Figure 1. In 2019, a total of 33,854 adult patients had at least 1 clinic encounter at 1 of 3 UMMC specialty sites (lifestyle medicine, family medicine, or internal medicine). More than half (n=19,631, 58%) were non-Hispanic Black and 64.2% (n=21,744) were female. The mean HbA_{1c} was 6.4% (SD 1.69%), 49.7% (n=16,812) were obese, and 25.7% (n=8698) had a BMI between 25 and 30 kg/m^2. About 1 in 5 patients had diabetes (n=7348, 21.7%) and 467 (1.4%) had end-stage renal disease.

Figure 1. Baseline recruitment. DPP: Diabetes Prevention Program; HbA_{1c}: hemoglobin A_{1c}.

Of the 33,854 patients, 7703 (22.7%) patients were excluded based on diabetes diagnosis (7348/7703, 95.4%), type I diabetes mellitus diagnosis (241/7703, 3.1%), or pregnancy (116/7703, 1.5%).

XSL•FO
RenderX

Among the remaining 26,151 patients, 1067 (4.1%) patients had a prediabetes diagnosis (n=1067, 4.1%), and 2819 (10.8%) had an HbA_{1c} between 5.7% and 6.4%. After applying the BMI eligibility criterion, 1010 (3.9%) patients were eligible for the National DPP. Baseline characteristics for those patients are described in Table 5. Future outcomes will be published in peer-reviewed implementation science journals and presented at national, regional, and state professional meetings and conferences.

Table 5. Baseline characteristics of patients eligible for the National Diabetes Prevention Program.

Characteristics	Values (n=1010)
Age group (years), n (%)	
18-24	16 (1.6)
25-44	104 (10.3)
45-64	328 (32.5)
≥65	562 (55.6)
Sex, n (%)	
Female	666 (65.9)
Male	344 (34.1)
Race, n (%)	
Non-Hispanic Black	677 (67)
Non-Hispanic White	302 (29.9)
Other	31 (3.1)
Hemoglobin A_{1c}, mean (SD)	5.93 (0.31)
Weight status, n (%)	
Overweight	295 (29.2)
Obese	715 (70.8)
Insurance type, n (%)	
Medicare	803 (79.5)
Medicaid	207 (20.5)

Discussion

This is the first implementation study of the National DPP LCP in Mississippi. Iterative findings and adaptations will elucidate strategies to successfully improve access to the National DPP, improve awareness of prediabetes and LCPs, and meet physician and patient needs for diabetes prevention.

The hybrid study design is a strength of the proposed study. Limitations to the sample size as recruitment strategies are tested and refined may be a limitation of this study; however, outcomes from this study will be used to calculate a robust sample size for testing in phase 2 of implementation, which will include additional clinical sites and providers.

The implementation strategies from this study can be scaled and findings replicated to measure the impact of diabetes prevention efforts within other health care systems. In addition, given the relatively recent introduction of the Medicaid DPP and reimbursement models for Medicaid agencies, a longitudinal study, such as this, may be relevant to other large health systems seeking to quantify the impact of their diabetes prevention efforts in Medicare and Medicaid populations.

Abstract

Background: Physiological signals such as heart rate and electrodermal activity can provide insight into an individual's mental state, which are invaluable information for mental health care. Using recordings of physiological signals from wearable devices in the wild can facilitate objective monitoring of symptom severity and evaluation of treatment progress.

Objective: We designed a study to evaluate the feasibility of predicting obsessive-compulsive disorder (OCD) events from physiological signals recorded using wrist-worn devices in the wild. Here, we present an analysis plan for the study to document our a priori hypotheses and increase the robustness of the findings of our planned study.

Methods: In total, 18 children and adolescents aged between 8 and 16 years were included in this study. Nine outpatients with an OCD diagnosis were recruited from a child and adolescent mental health center. Nine youths without a psychiatric diagnosis were recruited from the catchment area. Patients completed a clinical interview to assess OCD severity, types of OCD, and number of OCD symptoms in the clinic. Participants wore a biosensor on their wrist for up to 8 weeks in their everyday lives. Patients were asked to press an event tag button on the biosensor when they were stressed by OCD symptoms. Participants without a psychiatric diagnosis were asked to press this button whenever they felt really scared. Before and after the 8-week observation period, participants wore the biosensor under controlled conditions of rest and stress in the clinic. Features are extracted from 4 different physiological signals within sliding windows to predict the distress event logged by participants during data collection. We will test the prediction models within participants across time and multiple participants. Model selection and estimation using 2-layer cross-validation are outlined for both scenarios.

Results: Participants were included between December 2021 and December 2022. Participants included 10 female and 8 male participants with an even sex distribution between groups. Patients were aged between 10 and 16 years, and adolescents without a psychiatric diagnosis were between the ages of 8 and 16 years. Most patients had moderate to moderate to severe OCD, except for 1 patient with mild OCD.

Conclusions: The strength of the planned study is the investigation of predictions of OCD events in the wild. Major challenges of the study are the inherent noise of in-the-wild data and the lack of contextual knowledge associated with the recorded signals. This preregistered analysis plan discusses in detail how we plan to address these challenges and may help reduce interpretation

XSL•FO
RenderX

bias of the upcoming results. If the obtained results from this study are promising, we will be closer to automated detection of OCD events outside of clinical experiments. This is an important tool for the assessment and treatment of OCD in youth.

Introduction

Increased heart rate and electrodermal activity (EDA) are associated with mental phenomena such as fear, anxiety, anger, contamination disgust, embarrassment but also happiness [1]. Decreased heart rate and increased EDA are associated with sadness and mutilation-related disgust [1]. These negative emotions are seen in obsessive-compulsive disorder (OCD). Several types of OCD symptoms are linked with specific emotional profiles (eg, fear of contamination and contamination disgust, fear of harming or violating others, and guilt and shame), which could be detected using affective computing. Thierfelder et al [2] showed that an increase in heart rate and a decrease in heart rate variability (HRV) are indicative of an increase in stress during OCD events. Heart rate and HRV show distinctive patterns of anxiety when patients are exposed to fearful situations and relief when performing compulsive behavior. These patterns were found to be highly different between individuals but useful for distinguishing between cognitive stress, exposure and response prevention (ERP) episodes, and physical activity.

OCD is a burdensome psychiatric disorder that affects up to 3% of youths (individuals younger than 18 years) [3-5]. Obsessions are repetitive and intrusive thoughts that cause negative emotions such as anxiety, disgust, embarrassment, shame, guilt, and feelings of incompleteness, that is, marked distress [6]. Compulsions are repetitive or ritualized behaviors or actions the patient feels compelled to perform, despite their sometimes nonsensical nature [7]. Distress can arise from performing compulsions and when prevented from performing compulsions.

First-line treatment for OCD is cognitive behavioral therapy with ERP [8,9]. In the context of OCD treatment, ERP refers to approaching OCD symptom–triggering stimuli (exposure) and refraining from performing rituals and compulsions (response prevention). During ERP, patients are asked to intermittently report their level of distress [10]. This information helps the therapist adjust the interventions. Awareness of distress trajectories within and across ERP sessions is also a tool used to increase therapeutic learning [11,12]. Therefore, monitoring distress levels during exposure is important for optimizing ERP and measuring the severity of symptoms in OCD. Similarly, when collected over time, distress can provide information about the progression and improvement of the condition [13].

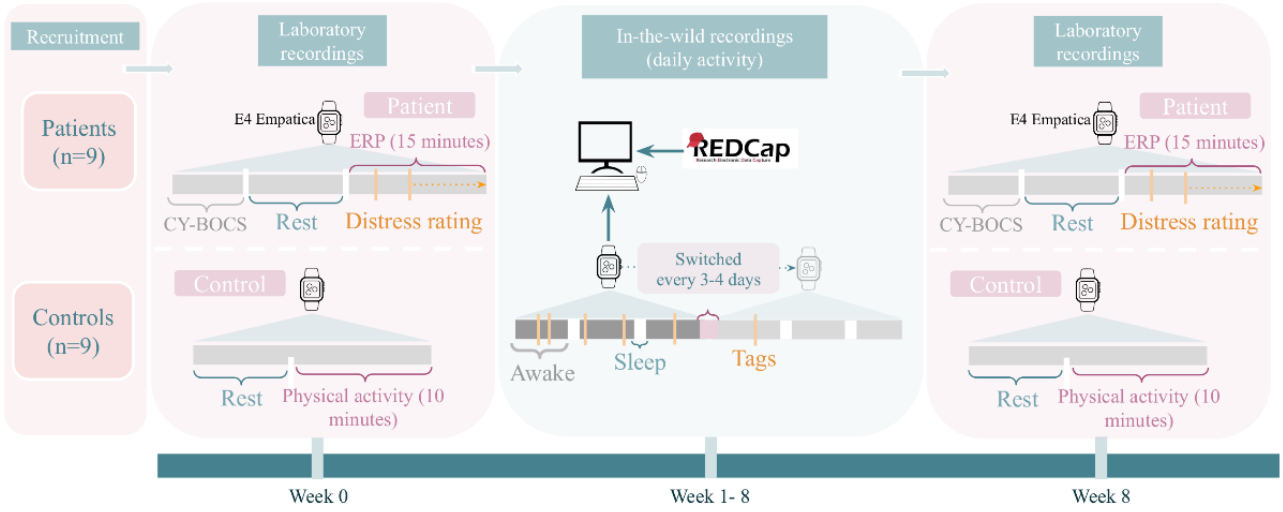
Many symptoms of OCD are directly related to specific objects or situations that cannot be realistically reproduced in clinical settings. Automatic, continuous detection of these OCD signals would facilitate close monitoring of patient treatment progress and allow for more targeted interventions and evaluation of treatment in the real world [14,15]. Ideally, distress would be objectively and affordably assessed in a noninvasive manner.

Recently, machine learning methods applied to data collected using smartwatches have demonstrated success in classifying stress levels [16,17], recognizing emotions [18,19], detecting panic attacks [20], and detecting hand washing—a common compulsion in individuals with OCD [15]. Thierfelder et al [2] demonstrated that recordings of heart rate and HRV using wearable devices may also be used to identify distress in patients with OCD caused by exposure during ERP sessions. Additionally, relief through compulsive behavior is reflected in the recorded heart rate and HRV, but the results also suggest that a change in the environment or simple distractions may reduce anxiety.

This paper aims to assess the possibility of using machine learning models for the detection of OCD events in the wild based on signals from wrist-worn devices. Automatic detection of OCD events will allow targeted interventions in the real world to improve OCD treatment. To the best of our knowledge, this is the first study of this kind. We aim to investigate the relationship between personalized and generalized predictive models by comparing the predictive performance of models trained on each participant individually and models trained on a sample of participants. In this paper, we also weigh our methodological decisions. Our research questions may be summarized as follows: (1) Is it feasible to collect enough data (physiological signals and tags) from individual participants to evaluate the feasibility of developing models? (2) To what extent do participants adhere to wearing the biosensor? (3) Is the number of event tags associated with OCD severity? (4) Do features extracted from physiological signals during OCD episodes in the wild resemble features during controlled ERP sessions in the clinic? (5) Can OCD episodes in the wild be predicted using physiological signals from a wearable biosensor? and (6) To what extent do predictive models generalize to newly recorded data from the same subjects or new subjects?

Methods

Overview



A complete description of the study design, recruitment, and data collection procedures are reported in the Wrist Angel study protocol, which was submitted for publication prior to the collection of data from the last participant [21].

XSL•FO
RenderX

Participants

A total of 18 youths aged 8 to 16 years and their parents were included in this study, and data were collected for 8 weeks. Nine participants had an OCD diagnosis (patients) and 9 youths presented without a psychiatric diagnosis (controls). Other studies have predicted aggressive behavior from wearables worn by 20 youths in 87 hours (10 consecutive days) or behavioral synchrony between father and their child with Down syndrome from wearables worn by 12 families in a 7-minute free play [22,23]. Although the number of participants is low, we followed each participant for 8 weeks, and we argue it will be enough for a feasibility study of prediction possibilities (as a minimum within individuals). Additionally, we are targeting a high emotional response, facilitating a stronger correlation between biosignals and emotional response. We present a brief description of the data acquisition illustrated in Figure 1 using the E4 wristband (Empatica) [24].

Figure 1. Design of the study and data collection procedure. Before and after an 8-week data collection period, all participants take part in a clinical recording session in the lab. Participants with an OCD diagnosis complete a clinical interview that assesses OCD severity and an ERP session. Participants with no psychiatric diagnosis engage in physical activity. During the in-the-wild recordings, participants wear the Empatica E4 biosensor daily during waking hours for 8 weeks and are asked to tag events of distress related to their OCD symptoms for patients, whereas nonclincal participants tag events of intense fear. Researchers meet with participants approximately every 3 days to switch wristbands. The collected biosignal data is then transferred to the hospital server. CY-BOCS: Children's Yale-Brown Obsessive Compulsive Scale; ERP: exposure and response prevention; OCD: obsessive-compulsive disorder; REDCap: Research Electronic Data Capture.

Ethical Considerations

This study was approved by the ethics committee of the Capital Region of Denmark on June 17, 2021 (H-18010607-79689). Participants received written and verbal information about the study and the plan for disseminating results before they or their legal guardians signed the consent forms. We were not aware of any major risks or benefits for participants associated with participation. Adverse reactions to the biosensor throughout the study were monitored.

Laboratory Recordings

Before (week 0) and after (week 8) data acquisition, each participant partook in laboratory experiments to obtain recordings of physiological signals in a controlled environment. Physiological signals were collected using the Empatica E4 wristband under rest and stressful conditions. During the rest period, participants were asked to sit still and quietly, without talking or touching each other, and to relax to the best of their ability. To simulate stressful conditions, control participants engaged in physical activity for approximately 10 minutes, while patients completed an ERP exercise. During the ERP task, patients approach OCD symptom–provoking stimuli and refrain from compulsions for up to 15 minutes led by a mental health professional in the presence of their participating parent. Patients provided subjective units of distress, that is, they rated their level of distress on a scale from 0 (no distress) to 10 (extreme distress), every few minutes.

In-the-Wild Recordings

The youth and 1 of their parents were asked to wear the Empatica E4 biosensor daily during waking hours for 8 weeks. Patients were asked to press the event tag button when they felt stressed by their OCD symptoms. Parents of patients were asked to tag every time they noticed their child was distressed by their OCD symptoms. Control youth were asked to push the button when they felt very scared, and control parents were asked to push the button when they noticed that their child felt very scared. Researchers met with participants up to twice a week during the 8 weeks to exchange biosensors full of data with empty fully charged biosensors.

Measures

Physiological Signals

The E4 wristband contains a photoplethysmographic (PPG) sensor, an EDA sensor, a 3-axis accelerometer, an optical thermometer, and an event tag button that records a point in time when pressed. PPG uses infrared light to measure changes in blood volume, that is, blood volume pulse (BVP). BVP is sampled 64 times per second and can be used to calculate the timings of the interbeat interval (IBI) and the heart rate [25]. Under conditions of slight movement (<30% of the time), it is

XSL•FO
RenderX

possible to use the IBI to compute HRV. However, this constraint is often too rigid and results in the removal of entire signals, making this approach impractical for robust data acquisition in the wild. The EDA sensor measures the skin conductance sampled 4 times per second. The accelerometer measures movement on 3 axes at a sampling rate of 32 times per second. The optical thermometer measures skin temperature at a sampling rate of 4 times per second.

Clinical Measures

Participants were assessed with the Children's Yale-Brown Obsessive Compulsive Scale (CY-BOCS) [26] before the start of the observation period. The CY-BOCS is the gold standard measure of OCD symptom severity [26]. Ten items (five items each for obsessions and compulsions) are summed to a total severity score [26]: (1) How much time is spent on obsessions and compulsions? (2) To what extent do obsessions and compulsions interfere with normal functioning? (3) How much distress do obsessions and compulsions (or not performing compulsions) cause? (4) To which extent are you able to resist obsessions and compulsions? and (5) To which extent do you have control over obsessions and compulsions? Five obsession or compulsion items can be summed to obtain obsession or compulsion severity scores, respectively. The CY-BOCS severity score has demonstrated high internal consistency and convergent and discriminant validity [10].

The CY-BOCS also includes a checklist for common symptoms, which are presented in 15 categories. These include seven obsession categories: (1) contamination, (2) aggressive, (3) sexual, (4) superstitious, (5) religious or moral, (6) hoarding, and (7) miscellaneous, and the eight categories for compulsions include (1) cleaning or washing, (2) checking, (3) repeating, (4) counting, (5) hoarding, (6) superstitious behaviors, (7) involving others in rituals, and (8) miscellaneous. Meta-analysis supports the existence of a 4-factor structure of OCD symptoms representing the following factors: symmetry, forbidden thoughts, cleaning, and hoarding [27]. Symmetry includes thoughts about symmetry and counting, ordering, and repeating compulsions. Forbidden thoughts include thoughts of an aggressive, sexual, and religious nature. The cleaning category covers contamination, somatic obsessions, and cleaning behaviors. Finally, the hoarding factor includes obsessions about losing or saving things and saving compulsions. We will accumulate the number of endorsed items belonging to each category to produce a category score as previously done in factor structure studies [28].

Analysis Plan

Overview

This work will focus on the in-the-wild recordings obtained from the youth participants only. We will treat marked OCD events as binary targets and design predictive models of these targets. We will limit the data to physiological signals and marked events from youth and only consider data recorded in-the-wild during the 8 weeks.

Assessing the Feasibility of In-The-Wild OCD Event Prediction

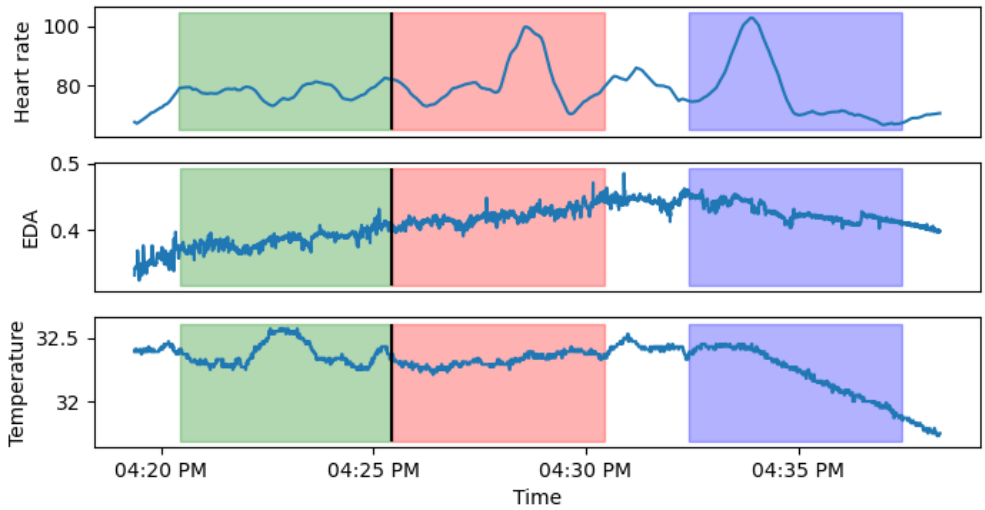
Continuous data acquisition as described previously presents several practical issues and barriers whose effects must be evaluated for wide-scale use. Even though the Empatica E4 wristband is generally considered a nonintrusive device, some patients might consider it a conspicuous piece of hardware and fear strangers might judge them on a potentially sensitive problem. Additionally, participants might need to adjust to wearing the bracelet and learn to tag events at the appropriate time, not forget to tag events, or even wear the wristband over time.

We qualitatively evaluate the potential issues and barriers based on feedback and comments from participants and their parents during data collection approximately every 3 days. We associate the number of days the wristband has been worn; the number of recorded hours and tagged events per day as a function of time to the CY-BOCS severity and type, number; and the severity of OCD symptoms from the preobservation period clinical interviews.

Preprocessing of Signals and Feature Extraction

We examine the length and end time of each recording session to verify that participants only wear the Empatica E4 wristband during waking hours. In the case where participants wear the wristband during sleep, we intend to manually exclude these recordings.

We extract features from the heart rate, skin temperature, EDA, and BVP signals recorded by the Empatica E4 wristband. The preprocessing of the signals is outlined as follows:



1. The skin temperature is processed using a sixth-order Butterworth low-pass filter with a cutoff frequency of 1 Hz.
2. The heart rate is extracted using the PPG sensor in the Empatica E4 wristband using a proprietary Empatica algorithm. The recordings of the heart rate are used as is and require no further preprocessing.
3. As discussed previously, the E4 wristband only provides the IBI signal in periods of low movement. Therefore, this signal is highly discontinuous and may not be useful for extracting the HRV during short time windows. Instead, the recorded BVP signal is segmented using a rolling window of 5 seconds with a time step of 1 second [29]. For each segment, we determine the noise level based on the skew and kurtosis [30]. If the kurtosis is less than εk=–0.5 and the magnitude of the skew is less than s=1, the segment is deemed a low-noise segment and included in the segmenting process. Features are extracted from each selected segment and then averaged to obtain the final features.
4. Features extracted from the EDA signal have previously been found to be good predictors of stress [31,32]. However, the EDA signal is also affected by physical activity and environmental factors, leading to expected participant and temporal variations unrelated to the stress level. The EDA signal is first processed using a sixth-order Butterworth low-pass filter with a cutoff frequency of 1 Hz. The signal

XSL•FO
RenderX

is then normalized to the interval [0,1] to reduce the effects of subject and temporal variations. The normalized signal was decomposed into its tonic and phasic parts using the *NeuroKit2* library [33] for Python (Python Software Foundation). The tonic part is a slowly varying baseline conductivity, and the phasic part is a series of event-related high-frequency peaks. The unnormalized EDA signal is retained for feature extraction as the normalization may inadvertently remove explanatory features related to the level of the signal.

For feature extraction, we apply a window strategy around each tagged OCD event, as shown in Figure 2. We use the 5-minute period before each tag as positive observations. The 5 minutes after each tag is removed is a buffer period to avoid event contamination in nonevent windows. Nonevent windows of equal temporal length are sampled randomly from the remaining time periods as negative observations. By increasing the number of randomly sampled negative observations, we investigate the performance differences between models trained on class-balanced data sets and models trained using more but imbalanced data.

Figure 2. Illustration of the windowing strategy around each tagged OCD event (black). Positive cases are sampled from the period leading up to the tagged event (green) and a buffer period of 5 minutes is applied after the event from which no observations can be sampled (red). Negative cases are sampled randomly from the remaining time periods (blue). EDA: electrodermal activity.

Within each extracted window, we compute the features tabulated in Table 1.

1. We compute the following time domain features of each used signal: mean (SD), minimum, maximum, and gradient of a least square regression. For the BVP signal, we also compute the minimum, maximum, and average of the slope fitted in each segment. For the heart rate and EDA signal where the level is expected to carry some explanative power, we also compute the quartiles and IQR.
2. From the BVP signal, we detect systolic peaks using the *NeuroKit2* library [33] within each low-noise segment. These peaks are used to calculate the interbeat interval and the successive differences of this interval. We then compute the final features as the average of the IBIs and the root mean square of the successive differences calculated in all low-noise segments.
3. For the phasic component of the EDA signal, we compute the number of peaks as well as the average peak amplitude and response time.
4. For the EDA signal, we compute the power of the frequency bands: ultralow frequency (0.01-0.04 Hz), low frequency (0.04-0.15 Hz), high frequency (0.15-0.4 Hz), and ultrahigh frequency (0.4-1.0 Hz). These frequency bands are computed for the unnormalized EDA signal and the phasic component.
5. For the BVP signal, we compute the mean (SD), median, IQR, minimum, maximum, and sum of the frequency content. These values are further separated into real and imaginary parts.

Table 1. Features extracted from each used signal.

Feature	Heart rate	Temperature	EDA[a]	BVP[b]
Mean and SD	μ_{HR}, σ_{HR}	μ_{TEMP}, σ_{TEMP}	μ_{sig}, σ_{sig} sig ∈ {EDA, Phasic}	μ_{BVP}, σ_{BVP}
Median	p^{50}_{HR}	—[c]	p^{50}_{sig} sig ∈ {EDA, Phasic}	p^{50}_{BVP}
25th and 75th quartiles	p^{25}_{HR}, p^{75}_{HR}	—	p^{25}_{sig}, p^{75}_{sig} sig ∈ {EDA, Phasic}	—
IQR	p^{75}_{HR}-p^{25}_{HR}	—	$p^{75}_{sig} - p^{25}_{sig}$ sig ∈ {EDA, Phasic}	—
Minimum and maximum	min_{HR}, max_{HR}	min_{TEMP}, max_{TEMP}	min_{sig}, max_{sig} sig ∈ {EDA, Phasic}	min_{BVP}, max_{BVP}
Slope	δ_{HR}	δ_{TEMP}	δ_{Tonic}	μ_{BVP}^{δ}, min_{BVP}^{δ}, max_{BVP}^{δ}
Average RR intervals	—	—	—	μ_{RR}
RMSSD[d] RR interval differences	—	—	—	$RMSSD_{RR}$
Number of peaks	—	—	$\#_{Phasic}$	—
Average peak amplitude and response time	—	—	μ_{Phasic}^{Amp}, μ_{Phasic}^{t}	—
Power in ULF[e], LF[f], HF[g], and UHF[h] components	—	—	f_{sig}^{x} x ∈ {ULF, LF, HF, UHF} sig ∈ {EDA, Phasic}	—
Mean (SD) of real and imaginary frequency component	—	—	—	RE (μ_{BVP}^{f}), RE (σ_{BVP}^{f}), IM (μ_{BVP}^{f}), IM (σ_{BVP}^{f})
Median of real and imaginary frequency component	—	—	—	RE ($p^{50}_{BVP,f}$), IM ($p^{50}_{BVP,f}$)
IQR of real and imaginary frequency component	—	—	—	RE ($p^{75}_{BVP,f}$-$p^{25}_{BVP,f}$), IM ($p^{75}_{BVP,f}$ -$p^{25}_{BVP,f}$)
Minimum and maximum of real and imaginary frequency component	—	—	—	RE (min_{BVP}^{f}), RE (max_{BVP}^{f}), IM (min_{BVP}^{f}), IM (max_{BVP}^{f})
Sum of real and imaginary frequencies	—	—	—	RE (Σ_{BVP}^{f}), IM (Σ_{BVP}^{f})

[a]EDA: electrodermal activity.

[b]BVP: blood volume pulse.

[c]Not applicable.

[d]RMSSD: root mean of successive square differences.

[e]ULF: ultralow frequency.

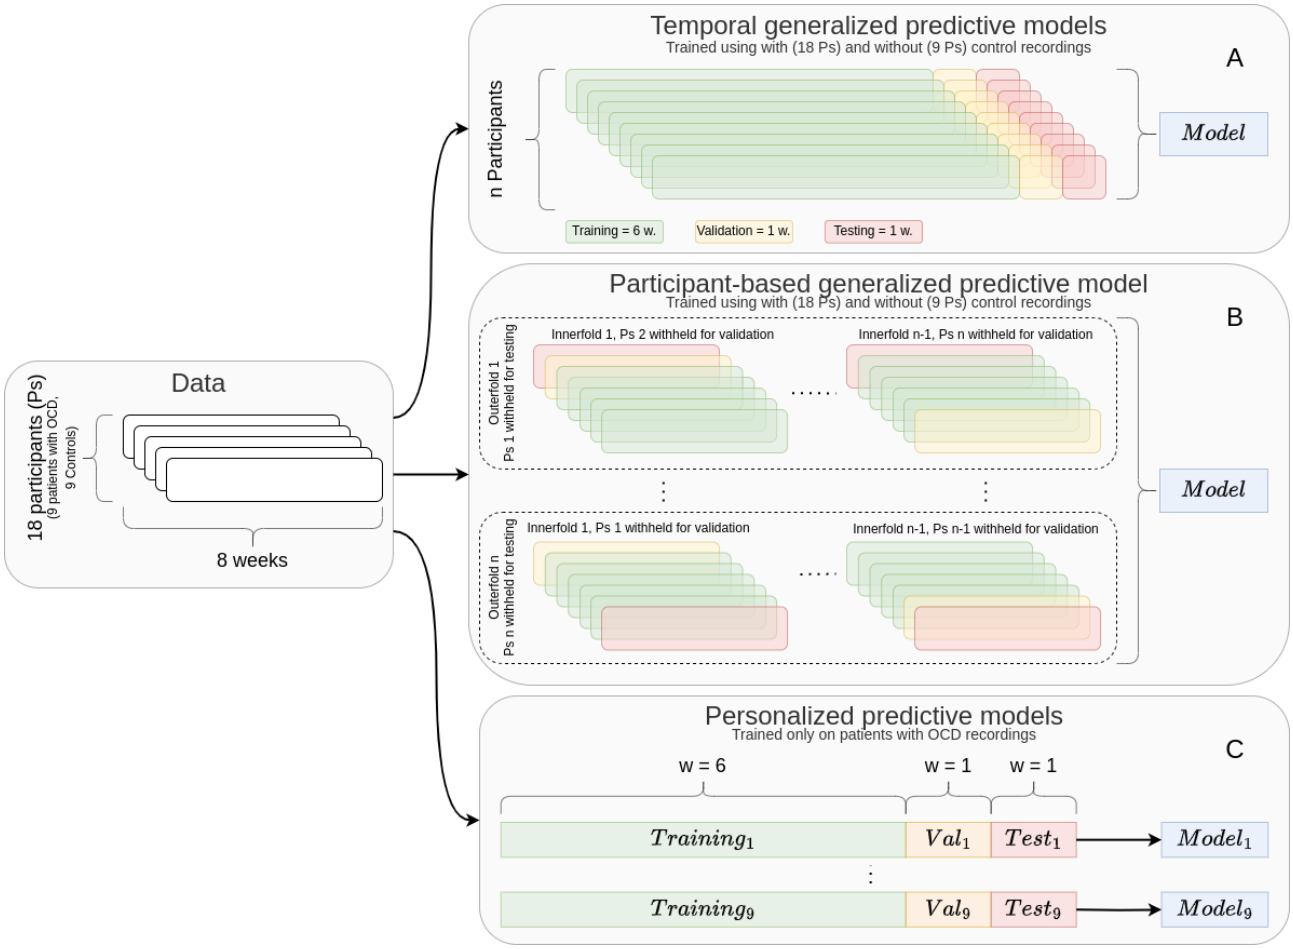
[f]LF: low frequency.

[g]HF: high frequency.

[h]UHF: ultrahigh frequency.

Machine Learning Modeling

To address the feasibility of predicting OCD events from in-the-wild recordings from a machine learning point of view, we make a principal component analysis decomposition of the extracted features from recordings obtained from different known settings. We compared recordings that precede tagged OCD events in the wild during clinical ERP sessions of patients with OCD, the resting phase of patients with OCD, and the physical activity of the control group.



We will consider the prediction of OCD events a binary classification problem. Each time window is considered an independent observation and will be labeled according to the window strategy outlined above. We apply a 2-layer

XSL•FO
RenderX

cross-validation strategy with each layer being a random 10-fold cross-validation.

We then consider 2 subproblems to study the generalization capabilities of OCD event prediction: generalized predictive models and personalized predictive models as shown in Figure 3. For each subproblem, we apply a 2-layer cross-validation strategy designed to evaluate the generalization across participants and time, respectively. The outer loop estimates model performance by the accuracy, F_1-score, and area under the receiver operating characteristic. The inner loop selects the model and hyperparameters that perform best according to accuracy among logistic regression, random forest, feed-forward neural networks (NNs), and mixed-effect random forest [34].

Figure 3. Design of the cross-validation strategies. Temporal generalized predictive models (A) and personalized predictive models (C) use a leave-last-week-out strategy, while participant-based generalized predictive model (B) uses a leave-one-subject-out strategy. OCD: obsessive-compulsive disorder.

Generalized Predictive Models

In generalized predictive models, we will train models to predict OCD events across patients and for new time periods. We compare the performance of models trained on data solely consisting of patients with OCD and models with data from both patients with OCD and controls.

In participant-based generalized models, we apply 2-layer cross-validation where both the inner and outer layers are leave-one-subject-out. That is, the models are trained on all available participants, except 1 participant who is withheld for testing purposes.

In temporal generalized models, the model is trained and tested on recordings from all participants. The recordings of each participant are divided into 3 data sets for training, validation, and testing. The test data consists of the last week of recording from all participants, and the validation set consists of the recordings from week 7 from all participants.

Personalized Predictive Models

Personalized predictive models are trained using the same schema as the temporal generalized models except a different model will be trained for each participant. That is, models are trained and tested on recordings from the same participant. For each participant, the type of model and hyperparameter values are selected using the training and validation data, and model performance is evaluated using the test set.

Exploring Deep Learning Models

Once a baseline model based on feature extraction within sampled windows is established, as described above, we will explore the feasibility of deep learning models as a secondary study. In particular, we will consider recurrent NNs [35] or 1D convolutional NNs [36,37]. Feng et al [35] use a combination of 1D convolutions and long short-term memory as feature

XSL•FO
RenderX

extractors for stress detection on the WESAD [17] data set, improving the performance over traditional machine learning methods. Chen et al [38] use 1D convolution of 3 physiological signals for automatic emotion recognition. Yu and Sano [37] propose an AutoEncoder-based semisupervised method for stress detection using physiological signals and self-reported stress tags. A benefit of long short-term memories and 1D convolutions is that they can be applied to the recorded time series with little need for preprocessing. We will use the same validation strategies as above. Considering data are limited, we consider this an exploratory proof-of-concept study, and we do not expect results from this study to directly generalize to other studies.

Results

Participants were included between December 2021 and December 2022. Participants included 10 female and 8 male participants with an even sex distribution between groups. Patients were between the ages of 10 and 16 years, and adolescents without a psychiatric diagnosis were between the ages of 8 and 16 years. Most patients (8/9, 89%) had moderate (CY-BOCS total score between 14 and 24 [39]) to moderate-severe OCD (CY-BOCS total score of 25-30 [39]), except for 1 patient with mild OCD (CY-BOCS total score below 14 [39]).

Discussion

Principal Findings

Here, we present a predefined plan for how data will be preprocessed, analyzed, and presented in the publication. If the artificial intelligence tools show promising results, this preregistered analysis plan helps reduce interpretation bias.

We will investigate the predictive generalization of models to newly recorded data and new individuals. Good generalization to new data is required for real-world applications where models are trained on historical data and then expected to perform well on new data recorded in real time. Similarly, if models are found to generalize well to new unseen individuals, they can be applied immediately to new patients without the need for recording data for fine-tuning. This would significantly expedite the application of models on new patients.

The relatively small number of participants In this study could raise issues regarding the generalization of the trained models, especially considering that the data distribution between participants is expected to be very imbalanced. To assess how much data are needed to train predictive models with acceptable performance, we will include a power analysis that compares models trained on different amounts of the available data and estimate the required number of observations to achieve a given performance level using the inverse power law.

As physiological signals may differ heavily from person to person, there is a risk that models trained using multiple people will perform worse than models trained using only 1 person. We assess this issue by comparing the predictive performance of models personalized for each participant and generalized models trained using multiple participants. If personalized models are found to be superior to generalized models, a natural following question is how much labeled data are needed to build such a personalized model and predict OCD cases. Ideally, the data collection period should be as short as possible. For this purpose, it could be interesting to study whether recordings from clinical sessions are sufficient to fine-tune models previously trained on data from a larger corpus.

Models trained solely on patients with OCD are prone to false positives and risk predicting OCD events in individuals without OCD. In future work, we will assess this risk by comparing predictive differences between models trained solely on data recorded from known patients with OCD and models trained using combined patient and control data.

Physiological signals recorded from in-the-wild wearable devices inherently contain high levels of noise and artifacts from the environment, motion, or reflection or absorption properties of different skin tones. This is discussed in van Lier et al [40], using a standardized assessment of the Empatica E4 EDA and BVP measurements compared with established clinical reference devices on multiple levels. Features extracted from the EDA signal using Empatica E4 are found to have significant nonsystematic differences from the same features using the reference device. However, they are still useful in detecting stressful events expected to substantially increase skin conductivity. Moreover, van Lier et al [40] speculate that the "cool-down" period following a stressful event is longer using the E4 than the reference device. This might be problematic for OCD detection as periods following an OCD event could have inflated feature values and be falsely classified as positives. This highlights the need for our proposed block of 5 minutes following each tagged event. For the BVP signal, van Lier et al [40] found a good agreement with the reference device for features related to the heart rate and root mean of successive square differences. However, they also conclude that the E4 has too much data loss due to noise to be useful for prediction of stressful events but argue that the events in their study might not induce enough stress or be of too short duration. The experiments of van Lier et al [40] were conducted in a stationary clinical setting. As such, the issues of data loss must be expected to only increase using in-the-wild data. To combat this issue, we apply the previously explained segmentation strategy to find low-noise segments in the BVP that are suitable for feature extraction.

In this initial study, we discard the parent recording and limit our data to the youth recordings. It is important to understand the relationship between the child tags and the child signals, and we wish to keep the analysis as simple as possible to assess the feasibility. However, in future work, we wish to incorporate data from the parents as well. Children often seek help or reassurance from their parents, which might increase the stress levels of the parent. Thus, we would expect some degree of synchrony between the physiological signals between child and parent. How well the patients cope with their stress levels is expected to be affected by the extent to which the parent accommodates or refuses to accommodate the patient's symptoms. Refusal to accommodate symptoms or overly accommodating behavior can both increase the stress of the parent at the expense of the patient's treatment. Additionally,

XSL•FO
RenderX

parents may notice stress triggers before the child and attempt to avoid the trigger. Such events can increase the stress of the parent but not the patient. Thus, physiological signals from the parent could be used for parent-focused interventions to ensure the proper supportive treatment. Additionally, the parent tags and signals may also provide insight into how their children's OCD affects the parents' peripheral autonomic nervous system responses. This is interesting independently of the children's signals.

Potential Clinical Implications

Automated detection of OCD events in the wild may help clinicians assess and monitor the clinical severity of patients waiting for or in treatment. Monitoring distress during ERP and in between sessions allows for data-informed therapy. Automatic feedback will help to increase the patient's awareness of physiological reactions and the connection between thoughts, feelings, sensations, and actions—a goal of cognitive behavioral therapy [41]. Furthermore, automated detection of OCD events during the build-up phase may serve as a tool for individually tailored ecological momentary interventions, which use upcoming stress events to prompt just-in-time interventions to prevent maladaptive behavior and promote adaptive coping strategies [42]. However, this poses significant requirements to the precision of the predictive models as this function itself could evolve into a source of stress for some patients. Additionally, if the signal characteristics indicating an OCD event are not unique to OCD, it could contribute to an overexaggeration of OCD symptoms if not implemented carefully. This would give clinicians a wrong assessment of the severity of patients and could result in wrong treatment plans. However, comparison with other conditions is outside the scope of this initial feasibility study and left for further research.

Limitations

In this initial study, we implement a simple windowing approach. We do not have knowledge of whether OCD events were tagged leading up to, during, or after a distress event. For this reason, we consider fairly large time windows to ensure a complete event is captured within each window. Larger time windows were found to increase performance in stress detection in a previous study [16]. The inherent risk associated with large windows is the reduction of the signal-to-noise ratio and the potential overlap of multiple events. Yet, others found that, overall, the window size had little effect on the task of detecting negative emotions using physiological signals in the wild [43]. However, window length was found to affect personalized predictive models differently. As OCD symptoms often differ from patient to patient, we similarly expect that window length will affect participants differently. Therefore, adaptive windowing based on each participant for personalized models might give some knowledge of whether this is an appropriate course to pursue. However, considering the small number of patients included in this initial study, we do not expect conclusive evidence regarding the generalizability of window size. Therefore, a detailed discussion of the relation between window length and symptom type is outside the scope of this study. In future work, we might consider comparing different window lengths for each patient, similar to Gjoreski et al [16].

Event tagging comes with inherent uncertainty. Patients might forget to tag events completely or tag events minutes later after remembering. Moreover, tags might happen by accident or the same event might be tagged multiple times. These issues might lead to falsely labeled positive and negative cases, thereby negatively impacting model training, evaluation, and quality. To circumvent this, Gjoreski et al [16] recommend also labeling windows adjacent to tagged events as positive cases. They argued that an anticipated stressful event might cause physiological arousal leading up to the event as well. However, as OCD events are entirely unplanned, this phenomenon is not expected in our data. On the contrary, falsely labeling windows earlier than the OCD event as positive cases would expectedly negatively impact model precision. In some cases, patients reported that they accidentally tagged events during data collection but could not report the exact time, allowing us to filter such wrong labels. However, these reports in combination with our practical feasibility study might give some insight into the extent of the false labels and allow us to gauge the impact on the model assessment. In the end, a ground truth is required for model training and the best source for internal private processes, such as obsessions or the discomfort caused by obsessions or compulsions, is the person experiencing them. Even if this is sensitive to the problem of human error.

The simple windowing approach ignores the temporal dependence between observations, which may cause false detection of windows in proximity to a labeled OCD event. Future work will investigate a time series–based approach to detect events in the biosignal time series. This could potentially be paired with some of the deep learning methods mentioned in the section "Exploring Deep Learning Models." A time-series approach may also be useful to address the issues related to the timing of the tags described above. Our current windowing approach treats each tag as an independent event. This may be a fair assumption for events separated by a longer period of time than the cool-down period of 5 minutes. However, for events less than 5 minutes apart, this assumption may not be valid. Patients were asked to tag events when they were bothered by their OCD, which can be interpreted in several ways. When an obsessive thought enters the patient's mind, the patient tags an event and the first obsessive thought triggers another obsessive thought. Should the patient tag a new event or is this still the same event? A potential prospective future work is to investigate how often tags appear and how dependent they are. Each tag could be used to define a new time series describing the probability of an OCD event currently taking place. At the time of a tag, this probability would be one and then slowly taper off during the period before the tag. This tapering would allow for more uncertainty than the binary tags.

Initially, we disregard recordings from the accelerometer built into the E4 wristband. Acceleration is not expected to be an explanatory signal for the prediction of OCD events. However, as previously discussed, explanatory signals such as EDA and BVP are expected to experience motion artifacts. In previous works, accelerometer data have been used to exclude periods of high movement (see Taylor et al [44], Sarker et al [45], and Hovsepian et al [46]). Initially, we were not interested in excluding periods of high movement as we wish to assess the

XSL•FO
RenderX

predictive performance of OCD events during periods of high movement. We intend to study this qualitatively using physical activity and ERP sessions in the clinical setting. Thierfelder et al [2] found that general movement energy increases with higher stress levels; however, that does not mean there is a causality. Thierfelder et al [2] also argue that some compulsive tasks may result in unique frequency spectra. However, this is not common to all compulsive tasks and requires the need for an accelerometer on both hands to look for asymmetric movements. If motion artifacts are found to resemble the changes in physiological signals due to OCD events, we suspect this will result in an increase in type 1 errors (false positives). Gjoreski et al [16] found that an activity context obtained from accelerometer data may reduce the number of false positives. In future work, we will use the laboratory recordings to obtain an understanding of how physiological signals (eg, EDA and BVP) are affected by physical motion compared to OCD events. If these studies find that motion artifacts resemble OCD events, we will aim for an end-to-end solution that explicitly includes the data from the accelerometer in the modeling to reduce the number of false positives.

Conclusions

In this work, we have discussed the data acquisition and planned analysis for a feasibility study of the prediction of OCD events in the wild using physiological signals recorded from smart wristbands. The current predefined analysis plan will help limit bias for reported results in future publications. We have discussed in detail the potential issues and sources of uncertainty as well as how we plan to address these issues, such as interparticipant and temporal differences, the window length used for feature extraction, event labeling, noisy recordings, and movement-based artifacts. Additionally, we discuss ideas for future work which will improve the understanding of how these limitations affect the problem of predicting OCD events in the wild. If the obtained results from this analysis plan are promising, we will be a step closer to automated detection of OCD events outside of clinical experiments. This is an important tool for the assessment and treatment of OCD in youth.

Abstract

Background: Chronic pain is a disabling symptom frequently reported in patients with breast cancer with a prevalence ranging from 25% to 60%, representing a major health issue. It has negative consequences on health status, causing psychological distress and affecting quality of life. Furthermore, the clinical management of chronic pain is often inadequate, and many patients do not benefit from the administration of pharmacological treatments. Alternative therapeutic options have been implemented to improve the psychophysical well-being of patients, including neuromodulation and complementary interventions.

Objective: We aimed to investigate the effectiveness of a home care strategy combining computerized rehabilitation, transcranial direct current stimulation (tDCS), and remote telemonitoring via a web-based platform in patients with breast cancer suffering for chronic pain.

Methods: A web-based structured survey aimed at monitoring chronic pain and its effect on psychological functions will be delivered to patients with breast cancer through social media and email. In total, 42 patients with breast cancer affected by chronic pain will be recruited during the medical screening visit. The patients will be randomly divided into 3 treatment groups that will carry out either tDCS only, exercise therapy only, or a combination of both over a 3-week period. All the treatments will be delivered at the patients' home through the use of a system including a tablet, wearable inertial sensors, and a tDCS programmable medical device. Using web-based questionnaires, the perception of pain (based on the pain self-efficacy questionnaire, visual analogue scale, pain catastrophizing scale, and brief pain inventory) and psychological variables (based on the hospital and anxiety depression scale and 12-item short form survey) will be assessed at the beginning of treatment, 1 week after the start of treatment, at the end of treatment, 1 month after the start of treatment, and 3 months after the start of treatment. The system's usability (based on the mobile app rating scale and system usability scale) and its involvement in the decision-making process (based on the 9-item shared decision-making questionnaire) will be also evaluated. Finally, at the end of the treatment, a digital focus group will be conducted with the 42 patients to explore their unexpressed needs and preferences concerning treatment.

Results: The study project is scheduled to start in June 2023, and it is expected to be completed by August 2025.

Conclusions: We expect that the combination of tDCS and telemedicine programs will reduce pain perceived by patients with breast cancer and improve their mental well-being more effectively than single interventions. Furthermore, we assume that this home-based approach will also improve patients' participation in routine clinical care, reducing disparities in accessing health care processes. This integrated home care strategy could be useful for patients with breast cancer who cannot find relief from

XSL•FO
RenderX

chronic pain with pharmacological treatments or for those who have limited access to care due to poor mobility or geographical barriers, thus increasing the patients' empowerment and reducing health care costs.

Introduction

Background

Chronic pain is related to a multitude of pathological conditions, with a prevalence of 20% to 30% in Europe, and it is considered one of the major health and social problems that our society is facing [1,2]. This disabling symptom is frequently reported in patients with cancer, who often have to deal with pain during their illness. For this reason, the term "chronic cancer-related pain" has recently been used to identify chronic pain caused by the primary cancer itself, metastases, or treatment [3].

In particular, chronic pain has been specifically investigated in patients with breast cancer, with a prevalence that varies from 25% to 60% of patients [4]. Chronic pain has a significant negative impact on the health status of patients with breast cancer that tend to experience higher levels of perceived stress and greater anxiety and depressive symptoms [5,6], thus compromising medical treatment adherence [7].

Moreover, chronic pain has a detrimental impact on daily activities by negatively affecting patients' quality of life and can cause high degrees of disability as well as the possible onset of psychiatric problems [2]. It can even compromise the ability to work, especially for the younger patients with breast cancer that face a constellation of complex responsibilities, such as family caregiving, professional duties, and financial uncertainty [4,8].

The clinical management of chronic pain is often inadequate since it is still frequently hidden by patients with breast cancer and often neglected by health care professionals [6]. In addition, many patients report several unmet clinical needs and are often referred to multiple specialists without being effectively taken care of by the health system [2,9-12]. Furthermore, it is important to highlight that in many cases, patients suffering from chronic pain do not benefit from the administration of pharmacological treatments. For this reason, alternative therapeutic options have been implemented, including neuromodulation and complementary interventions aimed at improving psychophysical well-being, such as cognitive-behavioral therapy, occupational therapy, physical treatment, and thermotherapy and cryotherapy [13-19]. Indeed, the implementation of complementary interventions can reduce pain intensity and psychological distress by improving the individual's ability to cope with and manage their pain [13-15,18].

The term "neuromodulation" refers to stimulation techniques that modify the activity of brain circuits [20]. Neuromodulation techniques are now considered an essential tool of precision medicine, and in recent years it has been greatly used in chronic pain management [21-25]. One of the most adopted approaches during clinical trials [26] is transcranial direct current stimulation (tDCS), a noninvasive neuromodulation procedure that uses a low-intensity current capable of modifying the excitability of the cerebral cortex [27].

The restrictions imposed by the COVID-19 pandemic and the mobility limitations that patients face due to chronic pain conditions have brought about awareness of the need to develop new health services based on digital technologies (ie, eHealth). To address these needs, the use of "telemedicine" has been implemented. Telemedicine is a subset of telehealth that uses communications networks for the delivery of health care services and medical education from one geographical location to another, primarily to address challenges like uneven distribution and shortage of infrastructural and human resources [28]. Among other advantages, it has allowed the provision of remote services directly in the homes of patients [29,30].

The development of computerized rehabilitation protocols at home in combination with noninvasive neuromodulation and monitoring by the clinical team could represent an innovative tool for improving the quality of life and life expectancy of patients at a relatively low cost [29]. It has been observed in patients with chronic pain that the improvement of monitoring through a telemedicine-oriented approach capable of guaranteeing continuous and effective communication with health care professionals [31] and an interaction with the patient community can lead to a significant increase in the effectiveness of treatments [32]. eHealth applications appear to be facilitators of the implementation of shared choice processes between doctor and patient, reducing decision-making conflicts and improving patient satisfaction with the treatment process [33].

The growing use of protocols combining neuromodulation techniques and cognitive behavioral interventions through telemedicine, and the possibility of using them in diversified clinical populations, has led to the search for technological ecosystems capable of guaranteeing more personalized treatment approaches [34,35]. Accordingly, a previous project developed an integrated platform, including customized applications and educational and telemonitoring tools for the management of patients with chronic pain [36,37].

Aims

This protocol is part of the Technopain project aimed at evaluating a new home care strategy combining computerized training rehabilitation, noninvasive neuromodulation, and remote telemonitoring via a web platform. In this study, the use of

XSL•FO
RenderX

telemedicine will allow the assessment of psychosocial and physical symptoms related to chronic pain in patients with breast cancer and the identification of its impact on patients' quality of life and on decision-making related to their own clinical care. In addition, this study aims to investigate the acceptance of the technological approach and the related ethical challenges in order to define a framework of reliability and trust for future therapeutic application.

Methods

Procedure

In a first stage, patients will be invited to participate in a mixed method study through social media and email. The delivery and self-administration of questionnaires will take place through a structured survey that can be filled in on a smartphone, tablet, or computer via a web-based platform (Qualtrics). After completing a web-based consent to data processing, participants will receive a link, which will allow them to access a web-based questionnaire aimed at monitoring the repercussions of chronic pain on psychological functions and on the performance of daily life activities. All data will be collected, anonymized, and stored in a password-protected electronic format.

Subsequently, patients who have previously completed the questionnaires will be identified at a screening visit by the doctor and selected according to the eligibility criteria shown in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Diagnosed with breast cancer (stage I, II or II)
- Aged ≥18 years
- Undergoing oncological treatments (postconservative or nonconservative surgery)
- Visual analogue scale score >4
- Completed and signed the informed consent form after a detailed explanation of the task and the tools used in the study
- Possess sufficient cognitive skills to support a rehabilitation process mediated by an electronic device
- Montreal cognitive assessment score >15.5 (adjusted for age and years of education) [38]

Exclusion criteria:

- Started new pharmacological treatments or changed current therapies that act on pain within the last month
- Have a bone marrow stimulator or intrathecal drug delivery pump
- Have respiratory, cardiac, metabolic, or other conditions incompatible with at least 30 minutes of light or moderate intensity exercise as assessed by a specialist
- Have severe cognitive impairment
- Have aphasia, dementia, or a psychiatric comorbidity interfering with communication or rehabilitation program compliance
- Have blindness or severe vision problems that may interfere with the use of the tablet
- Possess insufficient knowledge of the Italian language or inability to understand verbal and written instructions
- Concomitant participation in another study or clinical trial involving rehabilitation therapy or administration of an investigational drug

Questionnaires

Each patient enrolled in the study will be provided with a tablet on loan for use, which will allow the collection of some symptomatologic manifestations and behavioral characteristics relating to the presence of chronic pain. Table 1 describes the questionnaires that will be digitally administered to investigate the perception of pain, the psychological variables, and the patient's decision-making within the treatment path.

XSL•FO
RenderX

Table 1. List of questionnaires administered to each patient with chronic pain.

Questionnaires	Description
Pain	
PSEQ[a]	Measures the perception of self-efficacy in carrying out daily activities, despite the presence of pain [39,40]
VAS[b]	A 1-dimensional rating scale of pain intensity [41]
PCS[c]	Investigates catastrophic thinking resulting from the perception of chronic pain [42]
BPI[d]	Evaluates the severity of the patient's pain and its impact on daily functioning [43,44]
Anxiety and depression	
HADS[e]	Investigates the presence of anxious and depressive disorders and evaluates their severity [45]
Health status	
SF-12[f]	Measures the patient's perception of their health status [46]
Decision-making	
SDM-Q-9[g]	Measures the sharing of decisions between doctor and patient [47]
Usability tools	
MARS[h]	Investigates the quality of the app according to engagement, functionality, aesthetics, and information [48]
SUS[i]	Evaluates the usability of the pain monitoring system [49]

[a]PSEQ: pain self-efficacy questionnaire.
[b]VAS: visual analogue scale.
[c]PCS: pain catastrophizing scale.
[d]BPI: brief pain inventory.
[e]HADS: hospital and anxiety depression scale.
[f]SF-12: 12-item short form survey.
[g]SDM-Q-9: 9-item shared decision-making questionnaire.
[h]MARS: mobile application rating scale.
[i]SUS: system usability scale.

Randomization

All patients who have signed the informed consent form will be assigned an alphanumeric identification code through which they will be registered in a management software. Randomization is an integral part of the patient registration process and will take place automatically through an integrated randomization block with a 1:1 ratio, and each participant will be randomly assigned by the use of "RAND" formula in Excel (Microsoft Corp) to 1 of the 3 treatment groups described in Table 2.

Table 2. Description of the experimental groups.

Treatment group	Description
Group A (tDCS[a])	Patients will be treated with only tDCS 3 times a week for 3 consecutive weeks.
Group B (exercise therapy)	Patients will be treated exclusively with exercise therapy for 2 or 3 days a week for 3 consecutive weeks, depending on the patient's characteristics.
Group C (combined therapy)	Patients will be treated by combining tDCS with exercise therapy. They will be subjected to a cycle of tDCS 3 days a week for 3 consecutive weeks. On the days between 1 stimulation and another, the patients will carry out exercise therapy sessions.

[a]tDCS: transcranial direct current stimulation.

Treatment With tDCS

The delivery of tDCS will be administered through a programmable medical device called "HDCkit" (Newronica). This kit has been specifically designed for both research and clinical use and allows the administration of tDCS for use at home. The HDCkit comprises an "HCDstim" that delivers the tDCS treatment, a touch screen liquid crystal display "HDCprog" that is connected to the HDCStim and controls stimulation settings, and a "Mindcap" that guarantees the correct placement of the electrodes and the reproduction of the appropriate setup when the tDCS treatment is dispensed at home [50]. In the application, the tDCS consists of very low–intensity electric currents that are barely perceptible (1-2 mA) through

XSL•FO
RenderX

2 electrodes (an anode and a cathode) in electroconductive rubber with an area of about 25 cm^2 integrated inside sponges soaked in physiological solution to facilitate the flow of current.

Kari System

Patients who plan to undergo exercise therapy will be provided with the kari system (Euleria Health), a CE class 1/m medical device [51], on loan for use. The kari system comprises a tablet with its charger (supplied to all patients), a wearable inertial sensor (IMU) with its magnetic charging cable, a dedicated app that guides the patient through the exercise therapy program, and a kit of 7 elastic bands to facilitate easily positioning the inertial sensor on the body. The IMU is a noninvasive methodology used to collect motion data related to the body section where it is worn. It allows the clinical team to recognize the physical exercise and to verify the accuracy of the movements performed by the patients.

A member of the clinical team will educate each patient individually on the use of the kari system upon delivery of the same so that everyone acquires familiarity and independence in its safe use.

The tablets will also be used for the periodic compilation of questionnaires and rating scales by patients. The data will be saved locally on the device at the end of each training session and then transmitted to the web management system. Once transferred to the web management system, the data are immediately available for consultation by clinical staff.

The results of the clinical and functional evaluations will be collected anonymously on the patient data collection form.

Intervention

Patients in groups B and C will carry out exercise therapy sessions involving the use of the kari system at home for about 30 minutes a day under the remote supervision of the clinical staff via the web management system. This device allows researchers to remotely configure, customize, and quantitatively monitor an exercise therapy path for patients. A dedicated app guides the rehabilitation patient through the exercise therapy program configured by the professional. Monitoring is guaranteed by the integrated chat and video call functions, as well as by a web application accessible remotely by the therapist in which various quantitative factors related to the therapy can be monitored, such as adherence and program effectiveness.

Patients assigned to groups A and C will receive tDCS treatment, where stimulation parameters will be personalized on the basis of the patients' clinical characteristics, according to 1 of the methods described in Table 3.

Table 3. Description of transcranial direct current stimulation treatment typologies.

Type of stimulation	Description
Spinal stimulation	The active electrode will be placed on the spine in the median position in correspondence with the 10th thoracic vertebra with the reference on the right arm or in correspondence with the somatosensory area [52]. A stimulation intensity of 2.5 mA will be provided for 20 minutes.
Cerebellar stimulation	The active electrode will be placed in correspondence with the cerebellum with the reference on the right arm [53]. A stimulation intensity of 2.0 mA will be provided for 20 minutes.
Brain stimulation	The active electrode will be placed on the left motor cortex with the reference on the right arm or in correspondence with the contralateral supraorbital cortex [54]. A stimulation intensity of 2 mA will be provided for 20 minutes.
Dorsolateral prefrontal stimulation	The active electrode will be placed on the left dorsolateral prefrontal cortex with the reference on the contralateral area [55]. A stimulation intensity of 2 mA will be provided for 20 minutes.

To explore psychological variables and the individual impact of perceived pain, patients will be evaluated and receive a link with the questionnaires described in Table 1 at the following specific time points: before starting any treatments, 1 week after the start of the treatment, at the end of the 3 weeks of treatment, 1 month after the start of the treatment, and 3 months after the start of treatment. Furthermore, at the end of the treatment, each patient will be asked to answer questionnaires aimed at evaluating the usability of the system.

Finally, a focus group will be conducted with all the patients who took part in the study. The patients will be divided into groups of 14 participants based on the treatment group to which they were assigned. The aim of this investigation is to analyze the unexpressed needs, expectations, and preferences related to the home-based treatment. The focus groups will be conducted starting from a list of questions concerning the experience of the disease by the study participants, the relationship between the painful symptoms and the psychological significance, the expectations with respect to the treatment, and any difficulties encountered during the use of the technologies adopted during the rehabilitation program.

Focus Group Meetings

A telematic platform will be used to carry out the focus group meetings at the end of the treatment. The duration of the focus group meetings will be between 60 and 90 minutes, and breaks will be provided every 45 minutes to avoid tiring the patients. Audio and video will be recorded from every meeting and subsequently analyzed using T-Lab software, which comprises several linguistic and statistical tools [56].

Sample Size

At least 42 patients with breast cancer will be recruited for the study. The patients will be divided into 3 experimental groups, each consisting of 14 patients, based on the type of treatment performed (tDCS only, exercise therapy only, or combined treatment). In case of dropouts, the recruitment of patients will continue until 42 participants complete the treatment.

XSL•FO
RenderX

Since the present study is the first to evaluate the effects of tDCS in patients with different types of chronic pain over a 3-week period, to estimate the expected difference between the effect of tDCS and combined therapy (tDCS and exercise therapy), for the calculation of the sample size we relied on a recently published study [54] of 45 patients with fibromyalgia to calculate the sample size. The published study compared the effects of tDCS and exercise therapy if carried out individually or in combination for 1 week. The improvements observed in the 3 treatment groups are shown in the Table 4.

Table 4. Mean visual analogue scale (VAS) scores of the different treatment groups.

Treatment group	Baseline VAS	Improvement (%)	VAS at 1 week after treatment	ΔVAS (beginning of treatment vs 1 week after treatment)
tDCS[a]	7.2	18	5.904	1.296
Combined therapy	7.3	40	4.4019	2.8981
Exercise therapy	6.8	24	5.202	1.598

[a]tDCS: transcranial direct current stimulation.

The sample number for each individual clinical center was calculated to demonstrate the difference between the change in the visual analogue scale (VAS) value at the beginning of treatment and after 1 week of treatment between the group of patients receiving tDCS and that receiving combined therapy. A Wilcoxon-Mann-Whitney test was performed using G*Power V3 software [57] with an effect size of 1 and assuming the following parameters: a VAS change of 1.3 in the tDCS treatment group and 2.9 in the combined therapy group, as reported by Mendonca et al [54] in the evaluation after 1 week of treatment; an SD of 1.27 in both groups; a type 1 error of 0.05; and a power of 80%. A sample of the same size is adequate to demonstrate the difference in VAS between the exercise therapy group and the combined therapy group (based on data from Mendonca et al [54]).

Statistical Analysis

To evaluate the efficacy of the treatments, a statistical analysis will be conducted on the clinical scales, functional tests, and questionnaires using a dedicated software. Data distribution will be evaluated using Shapiro-Wilk tests. In the case of a normal distribution, statistical significance will be evaluated by applying parametric *t* tests and ANOVA for repeated measures. In case the assumption of a normal distribution is not supported, a nonparametric Wilcoxon-Mann-Whitney test will be used. Statistical analysis will be performed on all participants who complete the treatment required by the protocol. Participants who do not complete all phases of the study (ie, dropouts) will be excluded from the data analysis. Furthermore, as suggested by recent scientific literature, Bayesian statistics will also be applied using JASP open-source software in order to better estimate the possible absence of an effect of therapeutic strategy [58]. In particular, intragroup comparison analysis will be assessed using repeated measures ANOVAs (within subjects, time factors). Comparison of the subgroups (n=14 per group) will be performed using parametric or nonparametric hypothesis tests depending on the normality of the data distribution and corrections of type 1 errors. Finally, correlations will be performed between the VAS, patient demographics, and clinical data. All secondary outcomes will be evaluated by descriptive statistical analysis. Analysis will be carried out using SPSS Statistics (version 27; IBM).

Ethical Considerations

This protocol was approved by the ethical committee of the Istituti di Ricovero e Cura a Carattere Scientifico European Institute of Oncology (April 2023). Written and verbal information will be provided and informed consent will be obtained from all participants. Participation in the study is voluntary and free. No additional fees will be charged to the participants, and no payments will be made.

All the methodologies mentioned in the study protocol will be carried out according to the relevant guidelines and regulations.

Data Protection

Patient data will be treated as strictly confidential and subject to anonymity so that it cannot be associated in any way with the individual. For this purpose, at the beginning of the study, the study doctor will assign to the participants a code with which they will be identified during all subsequent phases of the study. The data relevant to the study, with the exception of patients' names, will be recorded, processed, and stored together with this code and all clinical data relating to the state of health. Only the physician and authorized parties will be able to link this code to the patients' names.

This information will be treated as strictly confidential in accordance with EU Regulation 679/2016, Legislative Decree 196/2003 as amended (Processing of Personal Data) and will only be used for research purposes in connection with this study.

Results

The project, Technopain, is scheduled to start in June 2023, and it is expected to be completed by August 2025. Results will be available following data analysis in the subsequent months.

This innovative approach will contribute to furthering our understanding of the neurophysiological mechanisms of chronic pain and the related psychosocial and physical symptoms. Additionally, the suitability of the telemedicine approach for patients and clinicians will favor the application of new technologies able to improve patients' well-being and access to care.

Discussion

Projected Impact

The present study protocol represents an innovative approach to the management of chronic pain in patients with breast cancer without the adoption of pharmacological treatments. Consistent with previous studies [15,59-62], we expect that the implementation of combined therapeutic interventions can directly produce a relevant improvement on pain relief.

Considering the beneficial effects of tDCS in increasing emotional well-being in psychiatric and neurological patients [63-65], we also assume that tDCS combined with telerehabilitation programs will reduce psychological distress and improve mental wellness in patients with breast cancer with chronic pain. Moreover, this interactive approach may motivate patients to increase treatment compliance, thus favoring better clinical outcomes.

Another key objective of this integrated home care strategy will focus on limiting the impact of physical and psychosocial symptoms associated with chronic pain on patients' daily lives [4,7]. They represent significant barriers that can affect the ease of travel to health facilities and cause difficulties in accessing care treatments, with consequent economic and organizational impacts [66]. We hypothesize that the introduction of a home-based approach directly and continuously monitoring patients at home will allow us to assess disease progression and improve patients' participation in routine clinical care, thus reducing disparities in accessing health care. Moreover, we expect to significantly optimize the rehabilitation session in terms of time and efficacy, thus reducing the direct and indirect health care and social costs.

Finally, the project aims to support patients affected by chronic pain through decision aids during critical moments of the therapeutic journey [67]. Telemonitoring of remote patients throughout the care process allows the evaluation of both clinical outcomes and patients' reported opinions. Furthermore, the focus groups will allow a greater exchange of the preferences and perceptions of the treatment received by patients with breast cancer, highlighting the strengths and barriers that could have influenced their psychoemotional well-being and their overall experience with chronic pain [68]. We expect that focus group sessions will also contribute to examine adherence, identifying patients who need more personalized pain management strategies, and contextualizing the problem of unrelieved pain.

Clinical Implications

It is possible to hypothesize several advantages following the application of this treatment. First, we expect a reduction in pain perceived by patients, since noninvasive brain stimulation methods and exercise therapy have been shown to have beneficial effects on the management and treatment of chronic pain in previous studies [15,17,18]. Furthermore, the information obtained may also be useful in the future for other people suffering from chronic pain, allowing us to determine which treatment among those investigated in the study will be more appropriate.

Additionally, we expect that the implementation of a home-based care system can facilitate patient adherence by reducing travel costs and establish a more direct and continuous exchange of information between patients and health care professionals.

Study Limitations

A main limitation of the present study could be the personal use of the home care strategy. Despite the many advantages of this technological approach, some patients may find it difficult to use the equipment without direct assistance from a health care professional. The self-management of the home care strategy could also have a negative influence on treatment adherence, causing possible dropouts during the study phases. For these reasons, it will be necessary to monitor patients' motivation during treatment to prevent patients from neglecting rehabilitation.

Patients should also be adequately informed of the possible risks linked to the administration of the treatments to reduce concerns about the occurrence of possible adverse effects of tDCS. In particular, adverse events could involve the appearance of local effects of the stimulation consisting of a slight burning sensation or skin redness. Nevertheless, it should be noted that participation in a trial involves strict control by the experimenter to limit any problems that may arise.

Furthermore, the initial recruitment via social media and email could orient the sample toward younger and technologically experienced patients. However, we adopted this instrument to promote the recruitment of patients throughout the country to overcome geographical barriers related to the access to health care. Additionally, due to the use of digital devices during the rehabilitation program proposed in this study protocol, the enrollment of technologically savvy patients with breast cancer could facilitate the use of the home-based treatment.

Finally, given the importance of subjective perception on the classification of pain, we chose to adopt several self-report tools to assess the personal experience of the patients with breast cancer. However, these instruments have limitations, as it is not possible to obtain objective information. When drawing conclusions, it will therefore be necessary to consider that the data may be influenced by various personal factors.

Conclusion

The Technopain protocol is a new home care strategy that combines computerized training rehabilitation, noninvasive neuromodulation, and remote telemonitoring via a web platform for the treatment of psychosocial and physical symptoms related to chronic pain in patients with breast cancer. In particular, this approach will evaluate the impact of chronic pain on patients' quality of life and will offer a rehabilitation program that can favor the treatment of the greatest number of patients through home delivery. This trial will primarily evaluate the fluctuation of perceived pain by patients during and after treatments, evaluating which of the different types of treatments is the most effective between the single treatments or their combination. In particular, we expect that this study will provide a useful treatment for all patients who cannot find relief from chronic pain with pharmacological treatments. Our ultimate aim is to

XSL•FO
RenderX

encourage the development of personalized telemedicine, which can provide daily clinical assistance to patients, eliminating the economic and geographical barriers related to the use of health services.

Acknowledgments

This work was supported by an “Unmet medical needs” grant from the Fondazione Regionale per la Ricerca Biomedica (grant 3440110). RF was supported by the Aldo Ravelli Research Center.

Data Availability

Data sharing is not applicable to this protocol as no data sets have yet been collected or analyzed.

Authors' Contributions

LC and CM wrote the protocol manuscript. LC, CM, RG, RF, AP, FM, and FR contributed to the design of the intervention. LC, CM, and RG drafted the original version of the manuscript. GP coordinated the study. All the authors have critically reviewed the entire manuscript and have read and approved the final version of the manuscript.

Conflicts of Interest

RF, AP, and FM are stakeholders for Newronika SPA.

Abstract

Background: Health anxiety (HA) by proxy is described as parents' obsessive worries that their child is severely ill although this is not medically confirmed. Research on HA by proxy suggests that it is highly distressing for the parent and that the child may be at risk of developing maladaptive symptom coping strategies. No targeted treatment for this group exists. We developed PROXY, an 8-week psychological internet-delivered treatment for parents with HA by proxy. The treatment components of PROXY are informed by cognitive behavioral therapy as well as acceptance and commitment therapy, and it was developed in collaboration with parents experiencing HA by proxy and clinical experts.

Objective: This paper describes the protocol for a study investigating the potential effects of PROXY on parents' worries about their children's health using a single-case experimental design (SCED).

Methods: Five parents clinically evaluated as experiencing HA by proxy will be included. A replicated randomized SCED study will be conducted in which each participant will be randomized to receive treatment after a baseline period of between 7 and 26 days (phase A). The treatment phase duration is 8 weeks for all participants (phase B), followed by a follow-up phase lasting between 14 and 33 days (phase C), ensuring that all participants remain in the study for 96 days. Participants will report daily anxiety level by SMS text message throughout the study. They will also answer self-report questionnaires, including questions on HA by proxy and own HA, 4 times during the study. Data will be submitted to structured visual analysis to inspect anxiety level, the variability of anxiety, trends, the overlap of data points among phases, when effects occur, and the consistency of data patterns across participants. Furthermore, randomization tests will be conducted for each participant to test the null hypothesis that PROXY will have no effect on participants' anxiety.

Results: The recruitment of parents began in June 2022. As of March 2, 2023, a total of 4 parents have been included in the study. Data collection was expected to cease in April 2023.

Conclusions: To the best of our knowledge, this protocol describes the only study of treatment for HA by proxy. As the prevalence of this condition is still unknown, a SCED was chosen because this method allows the inclusion of very few participants while still providing information on effects and treatment courses. Conducting the study with a replicated randomized phase design enables methodologically sound testing despite the inclusion of very few participants. The results will inform researchers on individual treatment courses and effects, which may direct future research in terms of the possible mechanisms of change, ideas for how to refine the treatment content, and how the treatment may be offered to patients in the future.

Introduction

Background

Health anxiety (HA) by proxy is defined as parents' excessive fear that their child is experiencing a serious illness although this is not confirmed by a medical professional [1]. It is characterized by obsessive rumination about the health of one's child and is often accompanied by control or avoidance behavior, such as facilitating repeated medical evaluations of the child or avoiding all information about child illnesses [2]. More severe cases may be observed in parents diagnosed with HA [3], but milder cases on the continuum are also likely to be recognized by health professionals working in pediatric settings.

A recent qualitative study investigating the lived experiences of parents with HA by proxy found that these parents experience significant distress as a result of their anxiety, and they struggle with finding the right balance in worrying about their child's health [4]. Furthermore, the parent's relationships with their child, other parent, and health professionals are affected [4].

HA by proxy may also have consequences for the child. Evidence suggests that HA symptoms in parents with health worries and increased focus on somatic concerns play a significant role in HA symptoms in children [5]. Furthermore, the parent's response to the child's health concerns [6] and how the parent copes with their own symptoms have been found to influence the health attitudes and behaviors of the child [7-10]. This risk may be especially high in HA by proxy because the child is exposed to a particular parental preoccupation with symptoms and fear of illness.

The members of the research team behind this study have previously investigated the assessment of HA by proxy by developing the Health Anxiety by Proxy Scale (HAPYS) with promising results [2]. Now that parents with excessive worries over their child's health can be identified, the next important step is to develop effective treatment. Existing treatments do not specifically address HA by proxy. A treatment program has already been developed to target parents with anxiety to prevent anxiety in their offspring [11], and effective psychological treatments for HA also exist in both face-to-face and internet-delivered formats [12-14]. Specifically, a recently developed treatment program for HA based on the principles of acceptance and commitment therapy (ACT) and delivered over the internet (iACT) [15] has shown promising results [14,16] and was usable as a template for the development of specialized treatment for parents with HA by proxy.

Developing an Internet-Delivered Treatment Program for HA by Proxy (PROXY)

PROXY is inspired by the existing iACT program for HA and uses the same web platform [17]. The treatment content for PROXY was developed de novo in several steps by 4 of the authors: 3 psychologists (KI, DHF, and LF) and a child and adolescent psychiatrist (CUR) with clinical and research experience with HA. Furthermore, 2 of these authors (LF and CUR) are also trained specialists in cognitive behavioral therapy (CBT). The development process included a number of steps. First, ideas for content, themes, exercises, videos, and audio files were brainstormed. These were presented as sketches to 3 parents diagnosed with HA and with worries about their children's health who subsequently provided group feedback.

Next, the treatment manual went through several rounds of feedback from the project group. Further written feedback on the text manual was provided by 2 (67%) of the aforementioned 3 parents with individual comments in Microsoft Word document format. These 2 parents also participated in patient videos about living with HA by proxy, how to involve relatives, and how to speak to their children about their anxiety. Finally, the content was programmed on a web platform with close collaboration between the project group and web developers.

Usability Test

The thinking-aloud method was used to test the usability of specific selected parts of PROXY. The method involved participants verbalizing their thoughts *while* using the web-based program [18,19]. A male layperson aged 25 years without prior knowledge about the treatment and a female patient aged 47 years with HA by proxy and prior ACT group treatment of HA explored how they experienced (1) navigating the treatment and (2) potential technical issues, as well as (3) how they understood the program. Generally, they navigated the platform easily. Minor adjustments to the instructions, navigation, the choice of wording, and models were made.

Final Version of PROXY

PROXY is an 8-week therapist-supported internet-delivered program containing written psychoeducation, audio files, behavioral exposure exercises, homework, and videos distributed in 8 modules (Textbox 1). The therapist answers questions and provides feedback every week using an embedded secure message system.

XSL•FO
RenderX

Textbox 1. Overview of module content.

Week 1

- Gain knowledge about health anxiety (HA) by proxy (module 1)
  - Helper: knowledge
  - Aim: for the parent to obtain knowledge about having HA on behalf of their child and explore how they can begin to understand their own anxiety
  - Exercises: (1) write own story of anxiety and (2) fill in the anxiety spiral
  - Videos and audio: (1) parent videos about having HA by proxy, (2) psychoeducation about HA by proxy, and (3) introduction video to the treatment
  - Homework: pay attention to when and where anxiety arises
- Learn about values (module 2)
  - Helper: values
  - Aim: to help the parent identify their own values as a parent and motivate them to start coping differently with their anxiety
  - Exercises: (1) consequences of the anxiety, (2) reflections on being a good parent, and (3) own values as a parent
  - Videos and audio: audio with focus on identifying values
  - Homework: practice putting off worries and set aside a specific time of day to worry

Week 2

- Look at the anxiety from the outside (module 3)
  - Helper: defusion
  - Aim: introduction to anxiety-related control and avoidance strategies, followed by exercise to investigate own behaviors; learning how to defuse from thoughts and feelings; the process of coping differently with the anxiety is initiated
  - Exercises: (1) “Don’t think about the ice cream,” (2) behavior analysis, and (3) defusion exercise
  - Videos and audio: audio with defusion exercise
  - Homework: practice putting off control and avoidance behavior

Week 3

- Practice acceptance (module 4)
  - Helper: acceptance
  - Aim: to practice accepting and holding the anxiety as a new way of coping
  - Exercises: (1) stop, breathe, observe inner states, and prioritize
  - Videos and audio: (1) audio with acceptance exercise and (2) audio with body scan
  - Homework: practice having more breaks during the day, and practice acceptance with mindfulness audio files

Week 4

- Challenge the anxiety (module 5)
  - Helper: exposure
  - Aim: to motivate parents to gradually expose themselves to their anxiety; focus on letting personal values direct choices instead of control and avoidance strategies
  - Exercises: (1) exposure exercise with pictures of sick children, (2) drafting their anxiety hierarchy, and (3) exposure work sheet
  - Videos and audio: none
  - Homework: practice exposure
  - Extra: a module for relatives is introduced with the aim of providing information on HA by proxy and how to be supportive during treatment, including exposure exercises

Week 5

XSL•FO
RenderX

- Practice self-compassion (module 6)
  - Helper: self-compassion
  - Aim: show the connection among one's expectations, stress, and anxiety, along with how one can be more kind to oneself and practice self-compassion
  - Exercises: (1) "How would you treat a friend?" (2) working with own conditional assumptions
  - Videos and audio: audio on self-compassion
  - Homework: do something nice for oneself and practice exposure

Week 6

- Use your network (module 7)
  - Helper: parents' network
  - Aim: to help parents use their close network for support and provide tools to talk about their anxiety with others, including their child
  - Exercises: (1) How is the anxiety affecting own close relations? (2) talk about the anxiety with a friend and partner, and (3) talk about the anxiety with child and or write a letter to child
  - Videos and audio: (1) parent videos about talking to their children about their anxiety and (2) parent video about family support
  - Homework: talk to child about anxiety and practice exposure

Weeks 7 and 8

- Your path further (module 8)
  - Aim: to recap the treatment content, emphasize why it is important to continue working with acceptance, values and exposure, and how to prevent relapse; furthermore, advice about how to handle future child symptoms and physician visits is provided
  - Exercises: (1) continued work and insights from the treatment and (2) strategies to apply in the event of setbacks
  - Videos and audio: none

The content framework is based on a combination of ACT [15] and CBT [20]. ACT aims to create greater psychological flexibility that allows (1) full awareness of here-and-now experiences, with an attitude of openness and curiosity; and (2) conscious and deliberate decisions inspired by core values, that is, deepest desires for who one wants to be and what one wants to stand for in life [15,21]. Thus, PROXY targets parents' maladaptive anxiety-driven behaviors toward their child with focus on their gradual exposure to the things or situations that trigger their anxiety. This means that the CBT concept of exposure is urged to be based on the patient's personal value. Furthermore, practicing acceptance helps to reduce the influence and impact of the painful thoughts and feelings that arise during the exposure.

Each of the first 7 modules in PROXY offers a *helper*, which is a treatment component (eg, awareness of values, acceptance, and self-compassion) that will help the patient move in a value-based direction in life instead of being trapped trying to control and avoid anxiety (Textbox 1).

Aims

In patient groups in which the prevalence of a health condition is low or unknown, as is the case with HA by proxy, randomized controlled trials are either not possible or unlikely to succeed [22]. Single-case experimental design (SCED) studies are used in clinical psychology to determine whether an effect of an intervention at an individual level has occurred [23-25]. Thus, a SCED study allows testing the effect of treatment for parents with HA by proxy in a small sample size while still controlling for external factors and upholding internal validity [26].

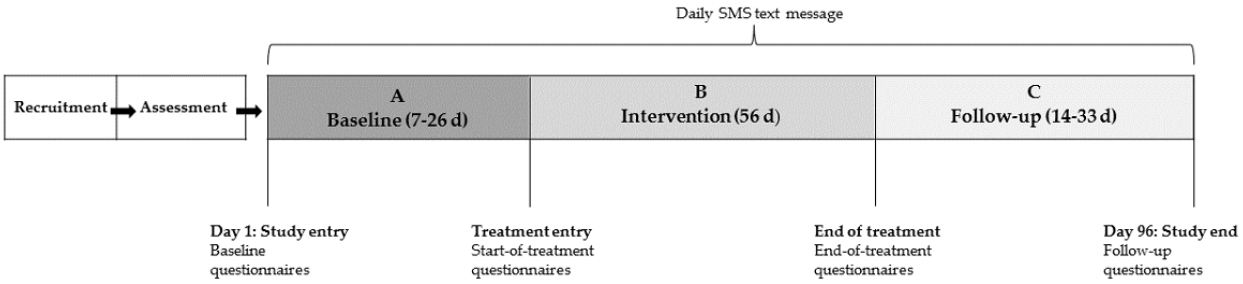
Consequently, this paper aims to describe the design for the first testing of PROXY using a SCED. The study investigates the potential effect of PROXY on parents' worries about their children's health. We hypothesize an initial increase in worries and anxiety, followed by a delayed and gradual reduction.

Methods

Study Design

A SCED study implies control of the independent variable (here, PROXY) while measuring the dependent variable (here, parental worries about their child's health) repetitively and often [24]. SCEDs should be distinguished from both case studies, which are not experimental but descriptive, and designs based on group comparisons where the experimental unit is the participant and where participants are assigned to different groups [27]. In a SCED, the experimental units are the repeated measures of a specific variable under investigation. Various types of SCEDs exist, but only the replicated randomized single-case AB phase design type will be elaborated here [23,27].

The project was registered on ClinicalTrials.gov on April 2, 2021 (NCT04830605).



XSL•FO
RenderX

A Replicated Randomized Single-Case ABC Phase Design

This study will apply a replicated randomized single-case AB phase design for testing the treatment effects. AB designs are particularly useful when testing a psychological treatment that cannot be subjected to withdrawal or to repeated reversal between treatment and baseline. By adding a randomization feature and a replication feature to this basic design, both the internal and external validity are strengthened [27-29]; for example, potential confounding variables related to time, such as natural changes in the participants' anxiety level or events that may affect anxiety, are statistically controlled for when the time point for the introduction of the intervention is randomized. In addition, replicating the design adds to the generalizability.

Specifically for this study, the intervention is randomly introduced after 7 to 26 days in the baseline phase (phase A). After the intervention (phase B), a follow-up phase (phase C) lasting between 14 and 33 days, depending on when the intervention was introduced, ensures that every participant has the same number of daily measurement points throughout the study (96 in total; Figure 1).

Figure 1. Study flowchart for the single-case experimental design (refer to Table 1 for specifics on questionnaires).

Participants

Five parents assessed with HA by proxy using the HAPYS [2] will be recruited for the study. No more than 3 participants may be allocated to a baseline duration of between 7 and 10 days to ensure that the participants will have different start times. The specific inclusion and exclusion criteria are presented in Textbox 2.

XSL•FO
RenderX

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Parents aged >18 y
- Assessed with health anxiety by proxy
- At least 1 child aged <18 y
- Read, write, and speak Danish

Exclusion criteria

- Comorbid diagnoses of substance abuse, bipolar disorder, psychotic disorders (International Classification of Diseases, Tenth Revision [ICD-10], codes: F20-29), or autism spectrum disorder
- Suicidal risk
- Recently started taking psychotropic drug therapy (within the last 2 mo)
- Child with severe health problems requiring care in hospital setting

Recruitment

Participants are recruited in two ways: (1) participants self-refer to the project through the secure email system at the Research Clinic for Functional Disorders and Psychosomatics (hereinafter the Research Clinic), Aarhus University Hospital, and complete the project questionnaire (Table 1) in Research Electronic Data Capture (REDCap; Vanderbilt University), which includes written consent to assessment [30,31], and, after a diagnostic interview, they are included in the project, if eligible; and (2) participants are recruited at their ordinary assessment for HA at the Research Clinic if they are also clinically assessed as experiencing excessive worries about their child's health.

Assessment

Participants are assessed using a short standardized diagnostic interview based on schedules for clinical assessment in neuropsychiatry (SCAN) [32,33] and supplemented with an assessment of HA by proxy using the HAPYS.

Ethical Considerations

All participants receive written and verbal information about the project before signing the consent to participate. The project has been approved by the Danish research ethics committee (1-10-72-296-20) and registered with the Danish data protection agency (1-16-02-921-17).

Outcome Measures

Primary Outcome

The primary outcome measures of HA by proxy are answered through a link in an SMS text message sent to the participants every day during the study period. The measures contain 3 items selected from the HAPYS [2] (1-3), 1 impact questionnaire (4), and 1 de novo formulated item on committed action (5). All items are answered on a scale ranging from 1 to 10 (Textbox 3; coded as 0-9 for analyses). A daily score is summed for items 1 to 3 (range 0-27), and items 4 and 5 are assessed individually (range 0-9). The 3 items from the HAPYS were selected by the project group based on the following considerations: items that have excellent face validity as evaluated by clinical experts (2 psychologists and 1 child and adolescent psychiatrist) and items indicative of high sensitivity to change as evaluated by looking at the sensitivity to change on similar items from the Whiteley-7 scale [34] using data from a randomized controlled trial of internet-delivered ACT for HA [14].

Textbox 3. Questions sent via SMS text message.

"On a scale ranging from 1 to 10, how well do the following statements describe your day? 1='does not describe it at all' and 10='describes it very well.'"

- "I have had persistent worries about my child's health."
- "I have been worried that my child suffers from a serious physical illness."
- "I have had the need to reassure myself by seeking a physician, examining my child, Googling symptoms, or something else."
- "My anxiety for my child's health has influenced my time together with my child."
- "I have done something in the past 24 hours that was important to me in spite of my anxiety."

Secondary Outcomes

The secondary outcome measures are full questionnaires answered 4 times during the study period. An overview of measures and data collection is presented in Table 1.

HAPYS Questionnaire

The HAPYS is a 26-item self-report questionnaire assessing HA by proxy, including an impact section with an additional 6 items [2]. The items are rated on a 5-point scale (0=not at all or never, 1=a little or rarely, 2=some or sometimes, 3=quite a lot or often, and 4=a lot or most of the time; range 0-104; higher

XSL•FO
RenderX

scores indicate more anxiety), except for the impact section, which is rated on a 4-point scale (0=no; 1=yes, a little bit; 2=yes, quite a bit; and 3=yes, a great deal; range 0-18; higher scores indicate more impact). The HAPYS has shown good psychometric properties [2].

Adult Response to Children's Symptoms–Protect and Monitor Subscales (Revised)

The Adult Response to Children's Symptoms scale measures parental behavior in relation to the child having abdominal pain and consists of 4 subscales: protect, monitor, minimize, and distract [35]. For this study, a revised Danish version of the protect (13 items) [36] and monitor (4 items) subscales are used, replacing *abdominal pain* with *feels unwell*. The monitor subscale was translated into Danish for this study following World Health Organization (WHO) guidelines [37]. Both scales are measured on a 5-point scale ranging from 0=never to 4=always, averaged to a total score of 0 to 4, with higher scores indicating more protective and monitoring parental behavior. The original scale and the subscales present with satisfactory psychometric properties [38-40].

Pain Catastrophizing Scale–Parent Version

The Pain Catastrophizing Scale–Parent version consists of 13 items assessing parents' thoughts and feelings when their child has pain symptoms (rated on a scale ranging from 0 to 4, with 0=not at all and 4=extremely; range 0-52; higher scores indicate more catastrophizing) [41]. Psychometric investigation has demonstrated a 3-factor model and good internal consistency [41]. The Danish version was translated following WHO guidelines [37] and showed good face validity after cultural adaption [42].

Whiteley Index-6 Revised

HA and illness worries are assessed using the Whiteley Index [34,43]. In this study, we use the Whiteley Index-6 Revised, where items concerning somatic symptoms were eliminated, and an item about obsessive illness rumination was included ("Recurrent thoughts about being ill that are difficult to put out of your mind"), resulting in strengthened psychometric properties [44]. The scale consists of 6 items with scores ranging from 0=not at all to 4=a great deal and a summed score of 0 to 24, with higher scores representing higher levels of illness worry.

Symptom Checklist

Parents' levels of distress, anxiety, and depression are screened by the Symptom Checklist-12, which are subscales from the Symptom Checklist-90-Revised [45] that have shown satisfactory sensitivity and specificity in detecting depression and anxiety and general distress in relation to emotional psychiatric disorders [46,47]. The scales are scored from 1=not at all to 5=extremely, and the summed scores are divided by the number of items to yield a mean score (range 1-5).

WHO-5 Well-Being Index

The WHO-5 Well-Being Index is a 5-item rating scale measuring subjective well-being on a scale ranging from 0 to 5. The raw score ranging from 0 to 25 is multiplied by 4, providing a final score ranging from 0 to 100, where a lower score represents worse well-being [48]. This scale has demonstrated high validity and is considered a good outcome measure for wanted and unwanted treatment effects [48].

Feasibility Outcomes

Experience of Service Questionnaire

The Experience of Service Questionnaire measures parents' experience with the treatment they have received [49,50]. In this study, a modified version will be used where all questions related to physical settings are removed, and 7 questions about impact on the parent, child, and their interaction are added from the Danish revised version developed and used by the Department of Psychology and Behavioral Sciences, Aarhus University [51]. The 14 statements are scored as 0=not true, 1=partly true, and 2=true (range 0-28).

Negative Effects Questionnaire-20

The Negative Effects Questionnaire-20 measures 6 factors related to the negative effects of psychological treatment: encompassing symptoms, hopelessness, failure, stigma, dependency, and quality [52]. Each negative effect is rated on a scale ranging from 0=not at all to 4=extremely and attributed to either "The treatment I received" or "Other circumstances." The 20-item version has demonstrated satisfactory psychometric properties [52].

Internet Evaluation and Utility Questionnaire

The Internet Evaluation and Utility Questionnaire will be used to evaluate the experience of receiving internet-delivered treatment. Using 15 items, this instrument measures the usability and utility of an internet-delivered treatment program with questions answered on a 5-point rating scale [53].

SMS Text Message Evaluation

Three questions evaluating SMS text message data collection will inquire about how the participants experienced answering an SMS text message every day, whether it had any influence on their daily life, and whether their answers were affected by the fact that they had to do this every day. The questions are answered in free writing and will inform the researchers about the experience of this type of self-monitoring.

Evaluation of Modules

After each module, the participants are asked about the content of the modules answered in free writing.

Analyses

Analysis of Primary Outcome Measure

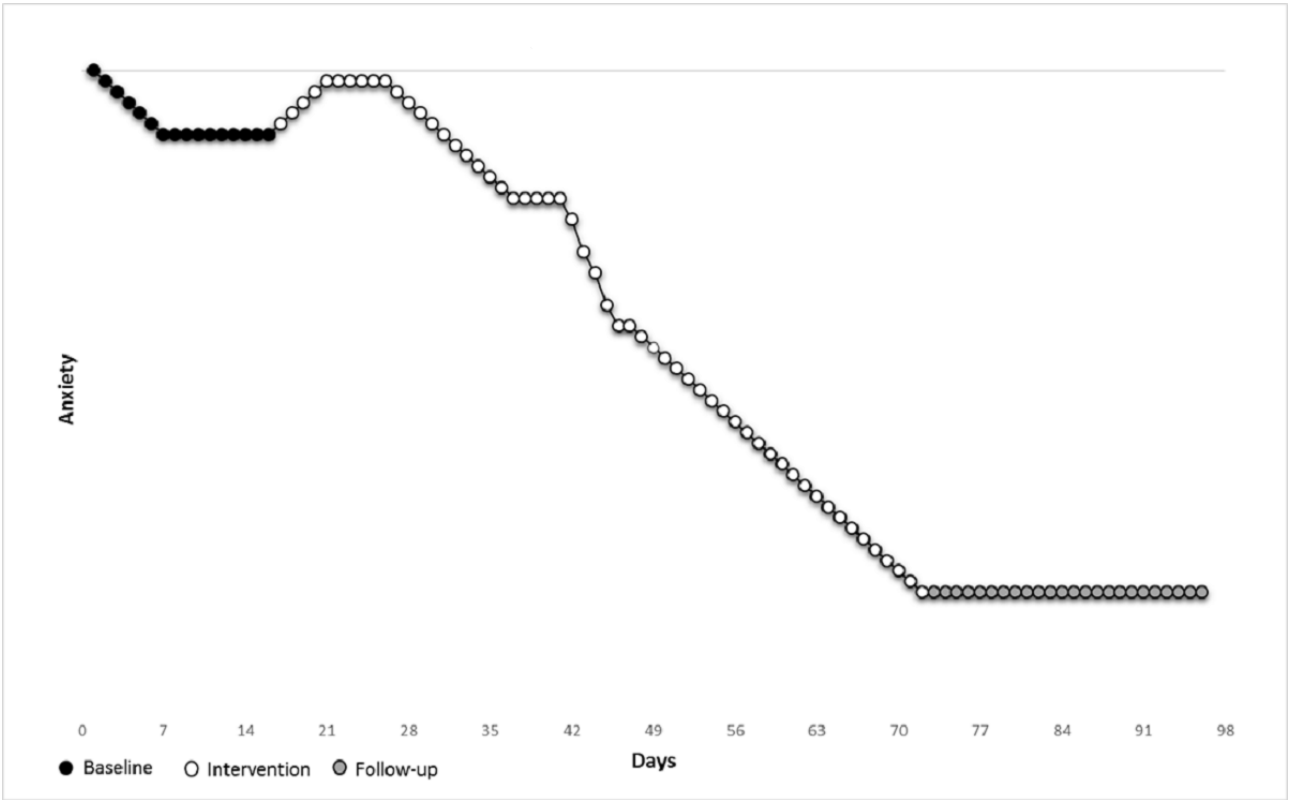
Visual Analysis

First, the data collected daily will be submitted to visual analysis, with the scores of the dependent variable on the y-axis and the measurement times on the x-axis. Six main features are visually examined using the guidelines provided in the study by Lane and Gast [54]: anxiety level in the phases, the variability of data points both within and among phases, trends in data, the immediacy of effect, the overlap of data points among phases, and the consistency of data patterns across participants [54,55]. As we have predicted a delayed treatment effect, we will explore the duration of the delay and whether this delayed effect is

XSL•FO
RenderX

consistent across participants, instead of testing immediate effects as proposed by Ledford et al [55]. Data patterns will be analyzed in detail in all 3 phases.

Randomization Tests



Randomization tests will be conducted for each participant to test the null hypothesis that PROXY will have no effect on the participants' anxiety [56-59]. A randomization test for a randomized single-case phase design uses the data in the order they were obtained and is based only on the randomly determined moment in time where the intervention is introduced. Two different test statistics will be used, as follows:

1. Primary test statistic: a mean comparison of phase A and BC will be carried out to investigate mean anxiety levels before and after treatment entry (mean A − mean BC = test statistic). As the starting point of phase B (intervention) is randomly determined and the follow-up phase does not include any new intervention methods, phases B and C are combined. As a mean comparison does not take into account the expected gradual and delayed effect of treatment, we also use a secondary test statistic.
2. Secondary test statistic: response functions [60] will be used to test the hypothesis of delayed and gradual reduction in anxiety (see the Aim section). Informed by previous research on internet-delivered treatment and exposure, we hypothesize that (1) assessment will have a positive effect on participants' anxiety level; (2) there will be an increase in anxiety at the beginning of treatment, followed by a gradual decrease that becomes steeper after exposure is introduced in module 5; and (3) the effect will be permanent throughout follow-up [14,61,62]. The response function predicted for participants in PROXY is illustrated in Figure 2. Importantly, this is not a prediction of exact anxiety scores but a predicted pattern. The absolute distance between the observed response pattern and the predicted response pattern is used as a test statistic.

As the exact course of treatment effect and the exact scores of anxiety are not known a priori, a multiverse approach will be followed exploring different response functions [60]. These different response functions will follow the same overall response pattern but with variations in the timing as well as the gradient of the response. The multiverse approach entails checking the degree to which the predicted response functions agree or converge with the collected data [63].

We will calculate the primary test statistic as well as the secondary test statistic for each possible randomization scenario of the treatment start using the obtained data. The proportion of test statistic values that are as extreme as, or more extreme than, the test statistic of the true treatment starting point is the *P* value of the randomization test [27,57-59]. This procedure is repeated with data from all 5 participants, and *P* values are combined using the additive method formulated by Onghena and Edgington [64].

Figure 2. Response function for participants in PROXY.

Effect Size Measure

In addition to the randomization tests, effect size measures will be calculated for each participant. An effect size measure is a standardized indicator that can be compared across studies and is not used as a test statistic in this study. Parker et al [65] recommend using the nonoverlap method Tau-*U* for SCED studies. Tau-*U* is particularly good if data show a baseline trend [65,66]. In addition, the effect sizes will be summarized across

XSL•FO
RenderX

all 5 participants by calculating common descriptive statistics (median and range).

Analysis of Secondary Outcome Measures

The secondary outcome measures will be analyzed using descriptive statistics because data from only 5 participants will be included.

Results

The recruitment of parents began in June 2022. As of March 2, 2023, a total of 4 parents have been included in the study. Data collection was expected to cease in April 2023. The project was funded in September 2019. Results are expected to be published in 2024.

Discussion

Summary

HA by proxy is a novel research area where much still remains to be investigated. Recent studies suggest that parents experiencing this type of anxiety struggle with how to cope with their health-related worries about their child [4]. When a parent directs special attention toward bodily symptoms and demonstrates health worries regarding their child, research suggests negative consequences for the child, such as negative illness perception and maladaptive symptom coping [5,6,67,68]. Together, this underlines the need for the development and testing of more specific treatment options. Therefore, we developed the first systematic treatment program for HA by proxy, named PROXY.

In this study protocol, we described the treatment components of PROXY and how these components were established in the web-based treatment program. It is a collaboratively developed treatment program that involved clinical experts, web developers, and users in the process. PROXY received positive feedback from patients during development, and it seems to be a usable treatment program. Conducting this first testing and having patients receive treatment in the program may shed light on how to further improve the treatment content of PROXY.

The SCED approach was chosen for the first testing of PROXY because it is particularly useful when testing novel treatments for smaller patient groups [22]. It enables us to measure potential effect with a limited number of participants and to investigate treatment courses for each participant.

Strengths and Limitations

The randomization and replication across participants are important methodological strengths of this SCED study. By using randomization and randomization tests, confounding factors that are time related are statistically controlled for [27-29]. The external validity is strengthened when this procedure is repeated for several participants [69]. This accommodates the criticism against the standard single-case AB phase design of having low internal validity and a lack of multiple phases without data collected concurrently [70,71].

The selected test statistics for the randomization test are mean comparison and predicted response functions. Using test statistics based on predicted response functions for SCED studies is a newly described framework with the purpose of offering statistical analysis for data with nonlinearity and delayed or gradual changes to the primary outcome measure, as is often seen in psychological treatment [60]. The advantage of response functions is the ability to test very specific developmental trajectories—this is central when testing therapeutic interventions where the introduction of therapeutic techniques can be hypothesized to cause sudden and temporary increase or decrease in symptoms (eg, exposing oneself to feared stimuli may initially increase one's anxiety symptoms). However, the great specificity of the trajectory described by a response function also means that there is a high risk of failing to reject the null hypothesis. Therefore, primary analyses include visual analysis. Furthermore, using the multiverse approach enables the testing of whether slight adaptations of the characteristics of the trajectory are more fitting.

Importance of This Study

As the treatment for patients with HA by proxy has not been previously examined, this study is particularly important in terms of describing the treatment development and content as well as the research protocol for using a SCED for the first testing of PROXY. Applying a SCED provides us with the opportunity to investigate the effect of the treatment in a small sample and explore individual treatment courses in detail. Furthermore, the detailed visual analysis provides implicit tests of treatment mechanisms. This has relevance in clinical practice and can potentially be used to inform larger studies on the mechanisms of change and when and how the treatment may be offered to patients in the future [22]. In addition, this study may help to further refine the treatment content of PROXY.

Acknowledgments

The project group would like to thank the participants and the team of web developers. Special thanks to Tobias Stenberg Christensen for programming the treatment. The project was funded by Aarhus University, Central Denmark Region (A2614); the AP Moller Foundation (18-L-0180); and the Aase and Ejnar Danielsen Foundation (19-10-0030).

Data Availability

Data sharing is not applicable as this is a protocol paper where no data sets were generated or analyzed.

Abstract

Background: Digital methods that enable early caries identification can streamline data collection in research and optimize dental examinations for young children. Intraoral scanners are devices used for creating 3D models of teeth in dentistry and are being rapidly adopted into clinical workflows. Integrating fluorescence technology into scanner hardware can support early caries detection. However, the performance of caries detection methods using 3D models featuring color and fluorescence in primary teeth is unknown.

Objective: This study aims to assess the diagnostic agreement between visual examination (VE), on-screen assessment of 3D models in approximate natural colors with and without fluorescence, and application of an automated caries scoring system to the 3D models with fluorescence for caries detection in primary teeth.

Methods: The study sample will be drawn from eligible participants in a randomized controlled trial at the Royal Children's Hospital, Melbourne, Australia, where a dental assessment was conducted, including VE using the International Caries Detection and Assessment System (ICDAS) and intraoral scan using the TRIOS 4 (3Shape TRIOS A/S). Participant clinical records will be collected, and all records meeting eligibility criteria will be subject to an on-screen assessment of 3D models by 4 dental practitioners. First, all primary tooth surfaces will be examined for caries based on 3D geometry and color, using a merged ICDAS index. Second, the on-screen assessment of 3D models will include fluorescence, where caries will be classified using a merged ICDAS index that has been modified to incorporate fluorescence criteria. After 4 weeks, all examiners will repeat the on-screen assessment for all 3D models. Finally, an automated caries scoring system will be used to classify caries on primary occlusal surfaces. The agreement in the total number of caries detected per person between methods will be assessed using a Bland-Altman analysis and intraclass correlation coefficients. At a tooth surface level, agreement between methods will be estimated using multilevel models to account for the clustering of dental data.

Results: Automated caries scoring of 3D models was completed as of October 2023, with the publication of results expected by July 2024. On-screen assessment has commenced, with the expected completion of scoring and data analysis by March 2024. Results will be disseminated by the end of 2024.

Conclusions: The study outcomes may inform new practices that use digital models to facilitate dental assessments. Novel approaches that enable remote dental examination without compromising the accuracy of VE have wide applications in the research environment, clinical practice, and the provision of teledentistry.

Introduction

Background

Dental caries is the most prevalent chronic disease in childhood [1]. It causes mineral loss within the dental hard tissue, which results in visual changes in the enamel in the initial stages [2]. With increasing severity, demineralization advances into the dentine-pulp complex, and a cavity can develop [2]. More severe caries can result in pain, difficulty eating, and infection, and its management is more invasive and costly from an individual and public health perspective. In contrast, managing early caries is noninvasive, and damage to the tooth surface is reversible [3]. Epidemiological research should use methods that enable early disease detection to better target caries prevention and timely intervention programs during the early years.

Dental Caries Detection in Epidemiological Research

In epidemiological research, visual examination (VE) is the standard method for detecting dental caries on visible tooth surfaces. VE can be subjective, particularly for early disease detection and monitoring. Validated indices, such as the International Caries Detection and Assessment System (ICDAS), improve the accuracy of VE for early caries detection [4-6]. ICDAS classifies caries based on severity, and a strong correlation exists between ICDAS and histological caries depth [7,8]. Studies using ICDAS report good inter- and intraexaminer reliability. Training and calibration improve examiner accuracy and reliability and are essential for standardizing examiners [9-11].

Epidemiological research, particularly multisite studies, requires the presence of multiple qualified dental examiners to undertake VE at the time of data collection, which is time and resource intensive. Digital photography has been suggested as an alternative to VE in these settings, where images are taken and assessed by trained and calibrated examiners. Boye et al [12] demonstrated high examiner agreement (weighted kappa, κ_w>0.9) between VE and remote assessment of 2D images. High accuracy for caries detection has been reported using 2D images compared to a gold standard examiner; however, the threshold used for disease detection in these studies is mostly tooth cavitation. Such thresholds cannot inform and drive early disease management strategies. Novel methods that facilitate the remote assessment of dentitions without compromising accuracy relative to VE for early disease detection would have broad applications in the research setting and beyond. Intraoral scanning technology provides such a method, yet its performance for caries detection in children's primary teeth has yet to be established.

Intraoral Scanners for Dental Caries Detection

Intraoral scanners (IOSs) are handheld devices that create 3D digital models of the teeth and surrounding structures [13]. Digital representation of the teeth is achieved using specialized hardware (to scan the teeth) and software (to combine the data received and create 3D models). Scanners shine light onto a tooth region, and the distance between the area of interest and the scanner sensor is calculated via optical triangulation, confocal imaging, or active wave front sampling [14,15]. Numerous data points regarding tissue geometry are generated and used to construct a 3D model [14]. Red, green, and blue signals received from the tissues are applied to the model as color texture. Recently, light-induced fluorescence technology has been incorporated into the hardware of a commercially available IOS to enhance early caries detection (TRIOS 4 and 5) [16].

Light fluorescence technology is suitable for detecting and quantifying early carious lesions [17]. Exposure to blue-violet wavelength light causes sound dental tissue to auto-fluoresce green and demineralized carious dental tissue to appear darker [17]. The diagnostic capability of light fluorescence is enhanced because porphyrins, a metabolite of bacteria associated with dental caries, emit red fluorescence when exposed to light at this wavelength [18].

The interpretation of light fluorescence can be subjective, as it depends on the skill and experience of the dental practitioner. A study investigating occlusal caries detection of permanent teeth with and without fluorescence found no difference in accuracy between on-screen assessment and VE, suggesting that on-screen assessment of 3D models could be used for early caries detection and as a potential alternative to VE [19]. To our knowledge, there are no studies that have investigated the validity of on-screen assessment of 3D models for caries detection in primary teeth.

Recent advances have seen the development of computational methods as a more objective measure to quantify dental caries and support clinical diagnosis. TRIOS has developed an automated caries scoring system for their software that can automatically classify caries on occlusal surfaces based on color and fluorescence changes (TRIOS Patient Monitoring [TPM]; version 2.3; 3Shape TRIOS A/S) [16]. When comparing the diagnostic performance as quantified by the area under the curve (AUC), early in vitro and in vivo validation studies suggest that the automated score is comparable to VE at the early (AUC VE

XSL•FO
RenderX

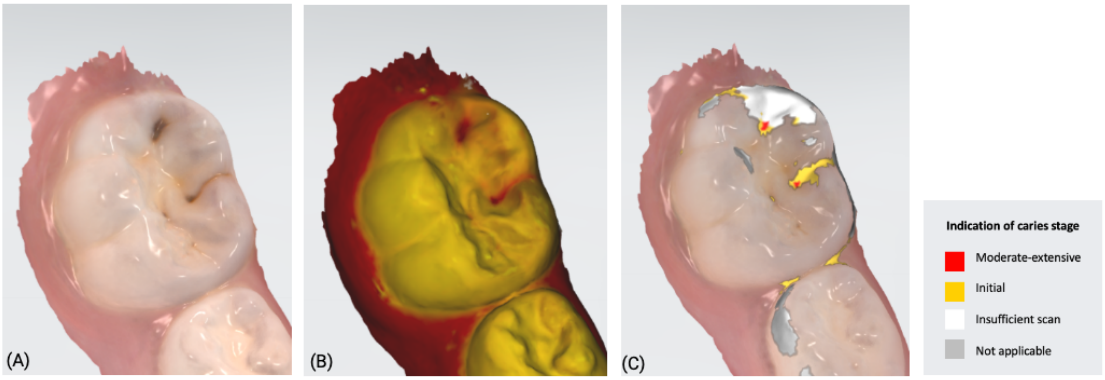
0.71 vs 0.76) and moderate disease thresholds (AUC VE 0.90 vs 0.90), based on a histological reference standard for permanent teeth [20]. A separate investigation into the validity of this algorithm in primary teeth concluded it had comparable performance (AUC 0.88) to VE (AUC 0.96) for caries detection of primary tooth occlusal surfaces [21]. The latter was a small in vitro feasibility study; consequently, results should be interpreted cautiously and not generalized to the clinical setting. The in vivo performance of automated assessment of 3D models for caries detection in primary teeth has yet to be established.

One of the problems with investigating early caries detection methods in realistic settings is the choice of a reference standard for method comparison, as histological or operative references are rarely feasible or ethical. It is argued that when VE alone is used as a gold standard, measures of diagnostic accuracy (sensitivity and specificity) may overestimate the true accuracy of the caries detection method under investigation [22,23]. Instead, reporting on the diagnostic agreement has been suggested to be more appropriate. Diagnostic agreement quantifies the similarity between methods in detecting the outcome of interest to be used interchangeably [24].

This study describes the protocol and statistical analysis plan for determining the diagnostic agreement between VE, on-screen, and automated caries detection methods using 3D models in children.

Methods

Aims and Objectives



The specific study objectives are to, first, determine and compare the diagnostic agreement between VE and on-screen visual assessment of 3D models in approximate natural colors with and without fluorescence to detect and classify carious lesions on visible tooth surfaces in primary teeth. The second objective is to determine the diagnostic agreement between VE and the automated caries scoring system for detecting and classifying occlusal carious lesions in primary teeth. Finally, the third objective is to explore the impact of caries threshold, tooth surface examined (smooth vs occlusal), and enamel defects' presence on the reported agreement estimates between caries detection methods.

Study Design

This is a diagnostic agreement study, as VE is not considered a gold standard in this setting [23]. Dental caries in this study is defined as primary coronal caries. Data sources (age at dental visit, sex, VE data, and 3D models) will be retrospectively sourced from a sample of children who underwent VE using the ICDAS and intraoral scanning with the TRIOS 4 to produce 3D digital models.

The 3D models for each eligible participant will be subject to an on-screen assessment by 4 qualified dental practitioners. Each practitioner will examine all 3D models at 2 separate time points. An on-screen assessment of 3D models based on tissue geometry and approximate natural colors (excitation to visible white light) will take place first (Figure 1A), followed by an on-screen assessment with the addition of fluorescence texture (excitation to light at 415 nm; Figure 1B). An interval of at least 4 weeks will follow to minimize recall bias before the on-screen assessment process is replicated. Occlusal surfaces of primary molars will be examined using the automated caries scoring system at a single time point only (Figure 1C). Examiners will be blinded to all clinical examination data and automated caries scores when scoring the 3D scans.

Figure 1. Caries detection methods based on 3D models obtained using an intraoral scanner.

Study Setting and Participants

The study sample will be drawn from eligible participants in an existing randomized controlled trial, the Melbourne Infant Study Bacille Calmette Guérin (BCG) for Allergy & Infection Reduction (MISBAIR; ClinicalTrials.gov NCT01906853; for a complete description of the trial, please refer to the MISBAIR study protocol) [25]. English-speaking immunocompetent pregnant women scheduled for birth at hospitals servicing Werribee, Ballarat, Geelong, and Melbourne in Victoria, Australia, from mid-2013 to mid- to late 2016 provided consent for their infants to participate in a longitudinal and randomized controlled trial to determine if BCG immunization within the first 10 days of life prevents the development of allergy and infection in early childhood. Infants were excluded if they had any conditions at birth that would contraindicate the use of live vaccines. The MISBAIR trial included a 5-year-old study visit where a clinical assessment (including dental assessment) was undertaken (219/536, 40.9% remaining MISBAIR participants). All study visits occurred between January 31, 2021, and March 31, 2022, at the Murdoch Children's Research Institute in Melbourne.

XSL•FO
RenderX

Participant Eligibility Criteria

MISBAIR participant data will be included for analysis in this study if participants meet the following criteria: (1) attended the 5-year-old study visit for MISBAIR (target age 4-6 years), (2) completed of a VE during the 5-year-old study visit, (3) acquired an intraoral scan at the same time as the VE, and (4) provided informed consent for the analysis of dental data and on-screen assessment of 3D models.

Tooth Surface Inclusion Criteria

For each participant, a tooth surface will be eligible for on-screen assessment if it (1) has been examined as part of the dental exam, (2) is from a primary tooth, and (3) is visible on the 3D model.

Tooth Surface Exclusion Criteria

Tooth surfaces will be excluded from on-screen assessment if (1) they have a sealant, direct or indirect restoration; (2) the tooth surface visibility on the 3D model is impeded by calculus, debris, or plaque; and (3) less than one-third of the surface is visible due to insufficient or missing scan data.

Tooth surfaces will be excluded from the application of the automated caries scoring system if they (1) have a sealant, direct or indirect restoration; (2) have an enamel defect; (3) are not a primary molar occlusal surface; and (4) less than one-third of the surface is visible due to insufficient or missing scan data.

Dental Examination Protocol at the 5-Year-Old Study Visit

VE Protocol

VEs occurred with participants in a semisupine position on an adjustable examination bed. The examiner stood to the side of, or behind, the participant. A portable LED light (220 lumens NÄVLINGE clamp spotlight IKEA) and a dental mirror were used and positioned to provide maximum illumination and visibility of the oral cavity without magnification. Cotton rolls and swabs were used to dry teeth and remove plaque. Compressed air was not used. Universal infection control standards and additional COVID-19 precautions were adhered to for all examinations.

Dental examinations were conducted by trained and calibrated registered dental practitioners (BJ and Jennifer Copley) with experience and prior training in using the ICDAS index in research settings. Examiner BJ is an oral health therapist with 13 years of clinical experience, and examiner Jennifer Copley is an oral health therapist with 5 years of clinical experience. Before commencing VEs, both examiners had participated in the web-based ICDAS and International Caries Classification and Management System (ICCMS) e-learning modules [26]. Additionally, a senior researcher and pediatric dentist (MS) with experience in conducting surveys using ICDAS and enamel defect indices facilitated a presentation on ICDAS using the ICDAS or ICCMS examiner training materials and training materials for the use of a modified molar incisor hypomineralization (MIH) index to assess for enamel defects (with permission from the author) [27]. A 2-hour calibration session on the application and interpretation of the indices, followed by a computer-based calibration exercise, took place. The computer-based calibration exercises were repeated until both examiners reached an intra- and interexaminer agreement of κ_w>0.8.

Dental caries experience was recorded for each tooth surface using the 2-digit ICDAS criteria [28]. Code 01 could not be scored for smooth surfaces due to a lack of compressed air. Enamel defects were recorded using a modified MIH index describing each surface's clinical presentation and the extent of the defect [29]. All tooth surfaces were examined using a systematic approach. The score given was the most severe of the 2 clinical presentations if multiple lesions were present on the same tooth's surface.

All dental examination data were collected and managed using Research Electronic Data Capture (REDCap; Vanderbilt University) tool hosted at Murdoch Children's Research Institute [30,31]. REDCap is a secure, web-based software platform designed to support data capture for research studies.

Intraoral Scanning

Immediately following the VE, intraoral scanning took place using the TRIOS 4 scanner. This generation scanner has a high accuracy and fast acquisition time relative to other scanners on the market for complete arch scanning [32]. It also has specialized fluorescence technology built into its hardware which exposes teeth to 415-nm light during scanning. Light emitted from the teeth passes through a filter in the scanner (which filters out blue light) to be received by the scanner sensor. The fluorescence signal overlays onto the 3D models as green fluorescence and red fluorescence texture, aided by commercial software (TPM; version 2.3, Dental Desktop and TRIOS; 3Shape TRIOS A/S).

The clinical examiners were trained to use the 3Shape TRIOS software interface and intraoral scanning protocols. Before scanning, the dental lamp was switched off, and the window blinds were closed to limit external light during the scanning process as per manufacturer instructions [33]. Teeth were dried with gauze or cotton rolls, and the manufacturer-recommended scanning strategy was followed. The scanning procedure was considered adequate when the software had obtained sufficient information about tooth color and fluorescence for the region of interest. If the scan was incomplete, the reasons why the scanning procedure was inadequate were documented. The reasons for insufficient scan data included the scanner tip being too big to accommodate, gag reflex, and behavioral or developmental issues that limited cooperation with the scanning procedure. Both complete and incomplete 3D models were saved with the participant's unique identifier in the dental desktop software.

Dental Examination Protocol for 3D Models Obtained From an IOS

On-Screen Assessment

3D models will be examined in postprocessed formats on a laptop with a 15-inch monitor (Alienware, DELL). On-screen assessment in approximate natural colors and featuring fluorescence will occur using a noncommercial software

XSL•FO
RenderX

(developed by 3Shape) that allows for visualization of the 3D models similar to the commercially available TPM software but permits faster examination of multiple models, making the viewing process more efficient for this study. 3D models will be viewed in rooms with natural lighting following a standard operating procedure. Examination periods will be at most 3 hours without breaks, and each 3D model will be viewed for less than 15 minutes to avoid examiner fatigue. The viewing time for each scan will be recorded.

Each model will be viewed first with color and then without color to inspect tissue geometry and possible surface cavitation. Dental caries experience for on-screen assessment of 3D models in color will be recorded using a merged ICDAS index. Codes 01 and 02 will be combined as "initial caries" because the 3D models cannot be dried, and codes 05 and 06 will be combined as "extensive caries" as discriminating between these latter categories is not of interest for this study (Table 1). These merged ICDAS categories still provide sufficient information about caries depth to support clinical decision-making [8,9,34].

Table 1. Caries classification criteria for on-screen assessment of 3D models obtained with TRIOS intraoral scanners.

Caries extent	Merged ICDAS index: on-screen assessment—color		Merged modified ICDAS index: on-screen assessment—fluorescence	
Sound (ICDAS 0)	Sound tooth surfaces which show no evidence of visible caries		Sound surfaces (yellow-green fluorescence) with no visible fluorescence change (no red fluorescence)	
Initial (ICDAS 1-2)	First or distinct visual changes in enamel seen as carious opacity or visible discoloration (white spot lesion and brown carious discoloration) not consistent with clinical appearance of sound enamel and which show no evidence of surface break down or underlying dentine shadowing		First or distinct visual changes in enamel seen with orange-red fluorescence and altered green fluorescence not consistent with the appearance of sound enamel and which show no evidence of surface breakdown or underlying red fluorescence from dentine	
Moderate (ICDAS 3)	A white or brown spot lesion with localized microcavitation of enamel without visible dentine exposure		Lesion with localized enamel breakdown with a distinct fluorescence change (usually intense red and reduced green), without visible dentine exposure. Usually, poorly delineated fluorescence change is seen	
Moderate (ICDAS 4)	Obviously discolored dentine or dark shadow visible through apparently intact or microcavitated enamel, which has originated on the surface being evaluated		Lesion with or without enamel breakdown and poorly delineated distinct fluorescence change (intense red fluorescence and significantly reduced green fluorescence which appears almost black), deriving from dentine	
Extensive (ICDAS 5-6)	A distinct cavity in opaque or discolored enamel with visible dentine		Distinct cavity with visible fluorescence changes and exposed dentine	

3D models will then be viewed with the addition of fluorescence texture and dental caries will be recorded using a merged ICDAS index previously described by Ferreira Zandoná et al [35], where each scoring criteria has been modified to incorporate fluorescence features (Table 1). This index enables a consistent approach to classifying carious lesions using fluorescence and has been previously validated for the on-screen assessment of 3D models [19]. If multiple lesions are present on the same tooth's surface, the caries classification will be the more severe of the 2 clinical presentations, per VE protocol. Data will be recorded using REDCap.

A total of 4 examiners will undertake on-screen assessment. Before commencing on-screen assessment, all examiners will undergo a 2-hour training workshop followed by calibration exercises. Training will focus on applying a merged and modified ICDAS criteria to a data set of 3D models with fluorescence. A dentist and expert in using modified ICDAS to interpret 3D models (SM) will facilitate training. To establish interrater agreement, each examiner will independently undertake an on-screen assessment of a training-calibration data set of 200 examination sites. This data set includes carious lesions and sound surfaces which have been validated histologically as part of a previous study [16,20]. Examiners

XSL•FO
RenderX

will repeat this calibration exercise 2 weeks after the initial assessment to establish an intrarater agreement. Examiners will repeat the calibration process until the agreement exceeds κ_w>0.7.

Automated Caries Scoring System

The automated caries scoring system will be applied to the occlusal surfaces of primary teeth and visualized using the commercially available software (TPM version 2.3; 3Shape TRIOS A/S) on a laptop with a 15-inch monitor (Alienware, DELL). Using a predefined logistic regression function, this software identifies a healthy reference standard per tooth and compares regions of interest to the healthy reference, to quantify fluorescence changes [16]. The automated system classifies a region of interest as caries based on the predefined cut offs which have been validated using permanent tooth histology as a reference standard, to indicate relative caries depth. The software classifies a surface as sound, initial caries (ICDAS 01/02) or moderate-extensive caries (ICDAS>03), and this is indicated on the 3D models as a yellow or red overlay respectively (Figure 1). The automated classification will be recorded using REDCap.

Sample Size

This is a retrospective study drawing all eligible participants from the MISBAIR trial who underwent the dental assessment at their 5-year-old study visit.

Outcome Measures

For agreement analyses, ICDAS and modified ICDAS codes will be collapsed for each surface into four categories labeled sound surface (0), initial caries (1), moderate (2), and extensive caries (3). A binary dental caries variable will be created for each surface, and the detection threshold will be initial caries (0 vs 1, 2, and 3).

Statistical Analysis

Data checking and cleaning will take place before analysis. Descriptive statistics for patient characteristics such as age, sex, caries prevalence, and the proportion of children with enamel defects will be reported. The total number of tooth sites included in the analysis will be reported.

Descriptive characteristics for the rater population will be reported, including qualification, clinical background, years of experience, and training results for each rater. Interrater and intrarater reliability for on-screen assessment of 3D models based on color and fluorescence using the intraclass correlation coefficient will be reported for all examiners. These estimates will be obtained from a multilevel model fitted to the surface-level data, accounting clustering (see below), and zero inflation.

To assess agreement among methods, we will undertake both surface-level and individual-level analyses. At the surface level, caries data naturally have 3 levels with surfaces clustered within a tooth, which are clustered within an individual. Therefore, for this analysis, we will use multilevel logistic regression to estimate method agreement while accounting for clustering for the tooth. Specifically, separate multilevel models will be fitted to compare VE with each of the alternative methods by including the variable method (VE vs on-screen assessment of 3D models in approximate natural colors, on-screen assessment of 3D models in approximate natural colors featuring fluorescence, and automated system) as the fixed effect. The coefficient estimates for the variable method will be used to indicate the level of agreement. The multilevel model will be fitted with a zero-inflated binomial distribution.

At the individual level, a numerical variable representing the number of lesions per individual will be generated and analyzed with 2 approaches. First, Bland-Altman method agreement analysis will be performed using a regression approach. Specifically, a model will be constructed to regress the difference between each pair of methods on their average [36]. The analysis will be repeated for each possible pair of methods. Second, for each possible pair of methods, an intraclass correlation coefficient will be estimated from a multilevel model fitted to the paired data consisting of the 2 measures for each individual obtained from the 2 methods, fitted with a zero-inflated Poisson distribution.

A sensitivity analysis will explore the impact of the diagnostic threshold used on agreement estimates. Analyses will be repeated with the caries data dichotomized at alternative thresholds: the moderate and extensive thresholds. In the analysis of the moderate threshold, sound and initial surfaces will be labeled caries absent (0) and all remaining categories (moderate-extensive) will be labeled caries present (1). In the analysis of the extensive threshold, sound, initial, and moderate caries will be combined and labeled as caries absent (0) and only teeth with extensive caries will be marked as caries present (1). To evaluate if the surface location and presence of enamel defects impact the diagnostic agreement estimates, these variables will be included as additional variables in the regression models for the surface-level analyses, including interaction terms with the method. The surface location variable will have 3 levels for each visible tooth surface (occlusal, smooth, and proximal). Enamel defects will be a binary variable, defined as present or absent per person. The sensitivity analysis to compare the agreement between on-screen assessment of 3D models in approximate natural colors and on-screen assessment of 3D models in approximate natural colors featuring fluorescence will include additional variables, rater and timing, as fixed effects.

Ethical Considerations

The MISBAIR trial has ethical and governance approval from Mercy Health Human Research Ethics Committee (HREC, No. R12-28) and Royal Children's Hospital (RCH) HREC (HREC No. 33025). Informed consent to participate in the study and to share dental data to validate and develop intraoral scanning technology for dental health assessment was obtained from participants' parents or guardians. Participant records sourced have a unique identifier and are not reidentifiable to the dental team. This diagnostic agreement study has ethical approval from the RCH HREC (RCH HREC No. 88321). It will be conducted according to the principles outlined in the Declaration of Helsinki. This protocol has registration with the Australian New

XSL•FO
RenderX

Zealand Clinical Trials Registry (ANZCTR; registration ACTRN12622001237774p).

Results

As of October 2023, automated caries scoring of primary molar occlusal surfaces on the 3D models for 213 eligible participants has been completed. Data are currently being analyzed, with expected results to be published within 6 months' time. On-screen assessment of 3D models based on color and fluorescence has commenced and is expected to be completed in March 2024, with results disseminated by December 2024.

The results of this study will be reported per the Guidelines for Reporting Reliability and Agreement Studies [37].

Discussion

This protocol aims to fill a knowledge gap by describing an approach for determining the diagnostic agreement between VE using ICDAS and on-screen assessment of 3D models featuring fluorescence obtained with an IOS.

Intraoral scanning is increasingly being adopted in dentistry as it offers improved clinical workflows for patient assessment and treatment planning, particularly in the disciplines of prosthodontics, orthodontics, and periodontics [13,38,39]. The role of scanning technology in supporting clinical diagnostics is an emerging research area [19,20,40-43]. There is paucity in the literature describing on-screen assessment of 3D models as a method for caries detection.

A strength of our study is the consideration of different approaches to analyze agreement. Our use of multilevel generalized linear regression models to analyze surface-level dental caries data has several strengths. First, caries from the same individual are more correlated than those between individuals. If this clustering is ignored, the estimated variance may be misleadingly small [44]. We will use multilevel models that account for clustering. Second, the multilevel regression approach allows for estimating method agreement while accounting for variability due to the influence of the rater and timing of assessment [45]. Finally, because all eligible primary teeth surfaces will be analyzed the high proportion of sound surfaces will result in zero-inflated outcome data. We will address this by fitting a generalized linear regression framework allowing the use of a zero-inflated binomial distribution; whereas traditional agreement methods, such as the κ statistic, are limited in this context [46]. A limitation of the statistical approach is that the coefficient estimates derived from the multilevel model do not quantify absolute agreement. As an alternative analysis, we will analyze the total caries at the individual level with a regression-based Bland-Altman agreement analysis [36]. The excess of zeros and, hence, the nonnormal distribution of the data precludes the calculation of the limit of agreement estimates that are clinically interpretable. Consequently, we will use the intraclass correlation coefficient derived from a multilevel model fitted with a zero-inflated Poisson distribution, acknowledging that this is influenced by the variability in the population.

Further limitations include the retrospective study design, as multiple raters did not undertake VE over multiple time points, so we cannot account for the effects of this in the analysis. The prospective design of the onscreen assessment is a strength, as it has been designed to capture these effects.

The study results will inform whether 3D models can be used interchangeably with VE for detecting and classifying dental caries. This work serves as a proof of concept for performing dental examinations digitally. Study outcomes may change existing practices for data collection in children for epidemiological research. The findings may also provide insight into how scanners can be used more broadly in the provision of teledentistry services and to improve the access of young children to comprehensive dental examinations.

Acknowledgments

We thank the Melbourne Infant Study Bacille Calmette Guérin for Allergy and Infection Reduction participants and their families for participating in the dental assessments. We thank examiner Jennifer Copley for her support with data collection. Figures were created with BioRender [47]. Images in Table 1 were adapted from 3Shape TRIOS A/S training materials with permission from 3Shape TRIOS A/S and coauthor SM, and the images in Figure 1 were obtained from the TRIOS Patient Monitoring Software. BJ's PhD stipend is funded by 3Shape TRIOS A/S fund according to an industrial PhD agreement with Murdoch Children's Research Institute. MS is funded by a Melbourne Children's Clinician-Scientist Fellowship. MMB is funded by the Australian Government NHMRC Investigator Grant (ID 2009572).

Data Availability

The data sets generated and analyzed during this study are not publicly available due to consent not obtained from participants for public sharing of data but are available from the corresponding author on reasonable request.

Authors' Contributions

BJ was responsible for conceptualizing the study, developing the research questions, study design, and protocol development. MS, CV, DB, NK, and SM contributed to supporting study conceptualization and development of the research questions, protocol, and study design as members of the research team. TC and MMB contributed to developing the statistical analysis plan. BJ was

Abstract

Background: Patients with hypertrophic cardiomyopathy (HCM) are at increased risk of sudden cardiac death (SCD) due to ventricular arrhythmias and other arrhythmias. Screening for arrhythmias is mandatory to assess the individual SCD risk, but long-term electrocardiography (ECG) is rarely performed in routine clinical practice. Intensified monitoring may increase the detection rate of ventricular arrhythmias and identify more patients with an increased SCD risk who are potential candidates for the primary prophylactic implantation of an implantable cardioverter-defibrillator. To date, reliable data on the clinical benefit of prolonged arrhythmia monitoring in patients with HCM are rare.

Objective: This prospective study aims to measure the prevalence of ventricular arrhythmias in patients with HCM observed by mobile health (mHealth)–based continuous rhythm monitoring over 14 days compared to standard practice (a 24- and 48-h long-term ECG). The frequency of ventricular arrhythmias in this 14-day period is compared with the frequency in the first 24 or 48 hours for the same patient (intraindividual comparison).

Methods: Following the sample size calculation, 34 patients with a low or intermediate risk for SCD, assessed by the HCM Risk–SCD calculator, will need to be recruited in this single-center cohort study between June 2023 and February 2024. All patients will receive an ECG patch that records their heart activity over 14 days. In addition, cardiac magnetic resonance imaging and genetic testing data will be integrated into risk stratification. All patients will be asked to complete questionnaires about their symptoms; previous therapy; family history; and, at the end of the study, their experience with the ECG patch-based monitoring.

Results: The Hypertrophic Cardiomyopathy: Clinical Impact of a Prolonged mHealth-Based Arrhythmia Monitoring by Single-Channel ECG (HCM-PATCH) study investigates the prevalence of nonsustained ventricular tachycardia (ie, ≥3 consecutive ventricular beats at a rate of 120 beats per minute, lasting for <30 seconds) in low- to intermediate-risk patients with HCM (according to the HCM Risk–SCD calculator) with additional mHealth-based prolonged rhythm monitoring. The study was funded by third-party funding from the Department of Cardiology and Intensive Care Medicine, University Hospital Ostwestfalen-Lippe of Bielefeld University in June 2023 and approved by the institutional review board in May 2023. Data collection began in June 2023, and we plan to end the study in February 2024. Of the 34 patients, 26 have been recruited. Data analysis has not yet taken place. Publication of the results is planned for the fall of 2024.

XSL•FO
RenderX

Conclusions: Prolonged mHealth-based rhythm monitoring could lead to differences in the prevalence of arrhythmias compared to 24- and 48-hour long-term ECGs. This may lead to improved identification of patients at high risk and trigger therapeutic interventions that may provide better protection from SCD or atrial fibrillation–related complications such as embolic stroke.

KEYWORDS

hypertrophic cardiomyopathy; nonsustained ventricular arrhythmia; sudden cardiac death; implantable cardioverter-defibrillator; long-term ECG; digital medicine; long-term electrocardiography

Introduction

Cardiac arrhythmias, especially nonsustained ventricular tachycardia (nsVT) and atrial fibrillation (AF), are important comorbidities of hypertrophic cardiomyopathy (HCM) [1,2]. In particular, nsVT is a predictor of sudden cardiac death (SCD) [3,4]. A well-established risk assessment is the HCM Risk–SCD calculator, which queries, among other parameters, the occurrence of nsVT. It is used for recommendations regarding the primary prophylactic implantation of an implantable cardioverter-defibrillator (ICD) [4].

Therefore, adequate screening for nsVT in patients with HCM is highly relevant. It must be assumed that more intensive monitoring can increase the detection rate of cardiac arrhythmias. For example, in one study, a 14-day long-term Holter electrocardiography (ECG) detected nsVT in up to 75% of intermediate-risk patients with HCM. In the same group, a 48-hour long-term ECG revealed nsVT in only 34% of patients [5,6]. In addition, a trial of 100 patients with HCM in Spain showed a 62% rate of nsVT during 30 days of monitoring compared to 8% in the first 24 hours [7]. In another study, 24- to 48-hour long-term Holter ECGs showed at least one AF episode in 23% of patients with HCM [8]. It can be speculated that prolonged ECG monitoring may increase AF detection, leading to the earlier introduction of oral anticoagulants to prevent embolic complications. Patients with HCM with AF have an exceptionally high risk of embolic complications [1].

The feasibility of mobile health (mHealth)–based screening for arrhythmias has not yet been thoroughly investigated in patients with HCM. Holter long-term ECGs and implantable loop recorders are established in everyday clinical practice. Whereas prolonged Holter monitoring is associated with patient discomfort, implantable devices are expensive, have some limitations concerning specificity in arrhythmia detection [9], and carry a risk of surgical intervention for implantation and explantation. More recently, mHealth ECG recorders have become increasingly available, and thus, it should be investigated to what extent mHealth-based prolonged ECG monitoring is feasible and accepted by patients.

In addition to the HCM Risk–SCD calculator, there is increasing evidence that the presence of late gadolinium enhancement and its extent is associated with an increased SCD risk in patients with HCM [10,11]. Furthermore, genotyping is recommended for patients with HCM by the current European Society of Cardiology guidelines since 60% of patients have mutations in cardiac sarcomere protein genes, which have been associated with an increased SCD risk [1,12]. Therefore, we aim to correlate the occurrence and frequency of nsVT associated with late gadolinium enhancement on cardiac magnetic resonance imaging (cMRI) or evidence of a pathogenic mutation. The extent of late gadolinium enhancement on cMRI will be graded as mild (<5%), moderate (5%-15%), or severe (>15%) using a semiquantitative score based on the standard left ventricular 17-segment model.

Prolonged monitoring for cardiac arrhythmias may have relevant implications for clinical decisions, such as primary prophylactic ICD implantation for nsVT and anticoagulation or rhythm-control measures for AF. The extent to which noninvasive prolonged rhythm monitoring through an mHealth ECG patch impacts the detection of cardiac arrhythmias and clinical decisions has not been investigated.

Methods

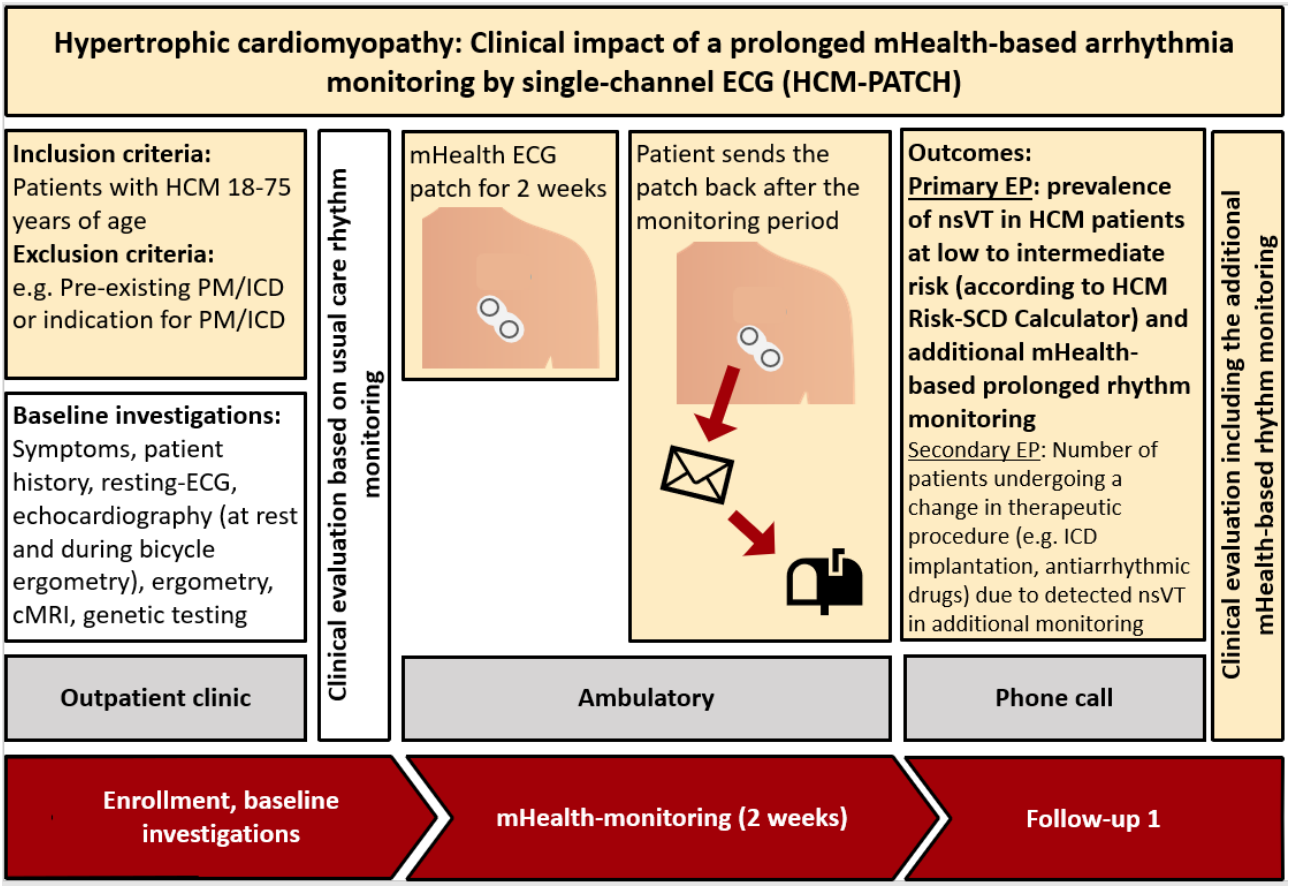
Study Design

The Hypertrophic Cardiomyopathy: Clinical Impact of a Prolonged mHealth-Based Arrhythmia Monitoring by Single-Channel ECG (HCM-PATCH) study aims to investigate the association between the occurrence of cardiac arrhythmias with detected gene mutations and the extent of late gadolinium enhancement in cMRIs. This single-center prospective cohort study will be conducted at the Department of Cardiology and Intensive Care Medicine at the University Hospital Ostwestfalen-Lippe (OWL), Campus Klinikum Bielefeld in Germany. The trial is registered under clinical trial number DRKS00032144 (DRKS-ID).

Recruitment

According to the sample size calculation (see Statistical Analysis section), recruiting 34 patients will be sufficient for the statistical analysis. Study participants will receive an echocardiography at rest and during exercise (bicycle ergometry) and a cMRI. In addition, their symptoms, family history, and premedication are collected, and their HCM Risk–SCD calculator score will be calculated. According to this score, patients are allocated to three risk groups: low risk (<4%), intermediate risk (4%-6%), and high risk (>6%) of SCD within 5 years. An ICD is generally recommended in the high-risk group, should be considered in the intermediate-risk group, and is not indicated for the low-risk group [1]. For this study, it is planned to recruit 17 patients with

XSL•FO
RenderX



low and 17 with intermediate risk scores. All these patients will receive the 14-day ECG patch.

Patients with HCM between the ages of 18 and 75 years will be included if they have not yet undergone implantable loop recorder, pacemaker, or ICD implantation and if their estimated 5-year SCD risk according to the HCM Risk–SCD calculator score is <6%. A maximum age of 75 years was set as the upper limit, as SCD in patients with HCM mainly occurs at a young age [13]. Patients with a pre-existing cardiac implant (pacemaker, ICD, or implantable loop recorder) or an already accepted indication for it; Morbus Parkinson disease with relevant tremor; a transcoronary ablation of septal hypertrophy procedure in the last 4 weeks; inability to give informed consent; and current symptoms or a history of skin cancer, rash from skin adhesive, or dermatoses (contraindication to wearing the patch) are excluded.

A therapeutic procedure is established for the patient based on the information available to date. Afterward, an ECG patch is applied to the chest to continuously monitor the heart rhythm over 14 days. After completing the 14-day wearing period, patients should return the ECG patch. Any arrhythmias recorded will then be documented, and the therapeutic procedure will be re-evaluated with a recalculation of the HCM Risk–SCD calculator score.

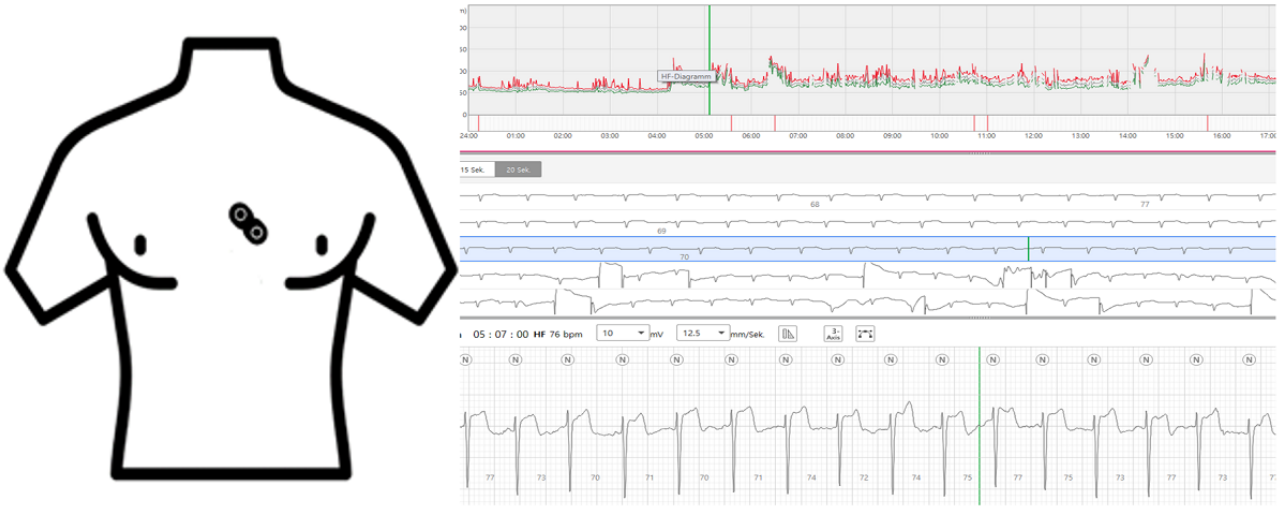
An overview of the study process can be seen in Figure 1.

Figure 1. Overview of the study process. cMRI: cardiac magnetic resonance imaging; ECG: electrocardiography; EP: endpoint; HCM: hypertrophic obstructive cardiomyopathy; ICD: implantable cardioverter-defibrillator; mHealth: mobile health; nsVT: nonsustained ventricular tachycardia; PM: pacemaker; SCD: sudden cardiac death.

Questionnaires

At the beginning of study recruitment, various data such as the patient's family history, previous syncope or rhythm abnormalities will be collected. In addition, secondary causes for left ventricular hypertrophy, such as arterial hypertension, will be queried. At the beginning and after monitoring completion, we will also ask patients if they have any questions, concerns, or requests they want to address with us. After completion of the 14-day monitoring period, the patient's perception of the mHealth measure will be evaluated through a questionnaire (Multimedia Appendix 1). This questionnaire is based on the System Usability Scale by Brooke [14], a standardized questionnaire for evaluating utensils.

Electrocardiogram Device



The ECG patch used is the AT-Patch from ATsens Co, Ltd (Seongnam-si, Republic of Korea), which is a single-channel ECG. The AT-Patch carries the CE mark as a registered medical device and is available for sale in the European Union. It can easily be attached to the chest and continuously records the heart rhythm for 14 days. During monitoring, patients can observe their ECG via an app (AT-Note) and may indicate symptoms (eg, dizziness or palpitations) via this app. Live tracking by the study physician is not possible. The ECG patch is light and compact and meets the grade of being showerproof (IP44/IP57). At the end of the monitoring period, the patient sends back the patch for rhythm evaluation. The detected

XSL•FO
RenderX

arrhythmias are documented and adjudicated by two independent physicians.

Figure 2 shows a schematic representation of the ECG patch on the chest and an example rhythm analysis of the accompanying app.

Figure 2. Single-channel electrocardiography system in situ and sample screen of the accompanying app.

Outcomes

The rate of nsVT detection in the first 24 and 48 hours of monitoring versus the whole 14-day monitoring period will be compared. In addition, the prevalence of AF and other arrhythmias will be examined. Moreover, the results of the cMRI and, if applicable, the results of the genetic examination will be considered. The HCM Risk–SCD calculator score will be recalculated if new findings have occurred.

nsVT is defined as ≥3 consecutive ventricular beats at a rate of 120 beats per minute, lasting for <30 seconds [1]. AF is defined as atrial tachyarrhythmia lasting for >30 seconds [15]. The diagnosis of HCM is based on echocardiography; septum hypertrophy ≥15 mm in the absence of other causes of myocardial hypertrophy or septal or posterior wall thickness ratio >1.3 is required.

At the patients' request, they will be informed about the rhythm-monitoring results and the resulting therapy changes after the ECG patch has been returned.

Statistical Analysis

The sample size has been planned in collaboration with the Department of Biostatistics and Medical Biometry at the Medical School OWL, Bielefeld University. Patients should be divided into low- or intermediate-risk groups according to their HCM Risk–SCD calculator score, and both groups should be of equal size. Based on the prevalence of nsVT, an assumption was made for the group of low-risk patients based on the publications of Magnusson and Mörner [16] and Sakhi et al [17], where the prevalence after a 24- to 48-hour long-term ECG ranged from 7% to 42%. For case-finding purposes, the assumption was made that a similar increase (ie, a doubling) would be expected after 14 days in the intermediate-risk group. Therefore, a prevalence of 25% after 14 days is assumed. In the intermediate-risk group, a prevalence of 75% is expected [6]. Using a χ^2 test, the total number of cases is 30, corresponding to 15 patients per group (α=0.05, power=0.8). In addition, a dropout probability of 10% was considered. This would result in 34 cases (17 per group).

After data collection, a statistical analysis will be conducted concerning the primary and secondary end points. Since this is a cohort study, all analyses will be adjusted for confounders, including, for example, age and sex. Potential confounders will be assessed from a clinical point of view before the statistical analysis is performed. A Poisson regression will be applied to analyze the primary end point (rate of nsVT detection). Furthermore, we will conduct a negative binomial regression as a sensitivity analysis. The same will be done for the secondary end points measured as the number of patients that experience specific events during the study period. Secondary end points regarding the prevalence of cardiac arrhythmias will be analyzed using logistic regression.

Data Protection of Study Participants

The single-lead ECGs generated by the device are stored in the hospital network without external access. A patient identification list is kept in the Department of Cardiology, in which patient identification numbers are linked to the full patient names of the participants. This list allows later identification of participating patients. It will be kept confidential and archived for at least 10 years after the end of the study. The patient identification list will be stored separately from the documentation records on a computer using appropriate rights management and access monitoring. Subsequently, all patient-related data will be pseudonymized so that it is no longer possible for outsiders to identify individual patients. Passing on the pseudonymized data to external parties is expressly prohibited.

Dropout

If the patient wishes to discontinue participation in the study during the 14 days of wearing the device, this is possible at any time and without any disadvantages for the patient. In addition, according to patients' preferences, they may not be informed about rhythm observations. The study physician should be

XSL•FO
RenderX

informed about this and discontinuation. If a patient does not return the patch after the 14 days, this will be counted as a dropout.

In addition, a minimum duration of 288 hours has been established. If the ECG patch is worn for less than this time, exclusion from the study will occur. How long the patch has been worn can easily be determined based on the duration that ECG data is available.

Ethical Considerations

Each patient is informed about the nature, relevance, objectives, potential risks, expected benefits, implications, and other aspects of the clinical trial through a discussion between the investigator and the patient. The patients receive written patient information. The investigator makes sure that the patient has understood the information. After the information session, each patient is given sufficient time and opportunity to clarify any unanswered questions and to decide on their participation.

The study will be conducted following the ethical principles originating in the Declaration of Helsinki and the recommendations of Good Clinical Practice and Good Scientific Practice. In addition, the study was approved by the ethics committee of the Ärztekammer Westfalen-Lippe (2023-262-f-S).

The devices were partially purchased by our department and partially sponsored by the company ATsens. None of the manufacturers were involved in the study design, and they will not participate in the data collection, statistical analysis, or manuscript writing. There are no other financial contributions. Participation in the study is free of charge for all study participants.

Results

The primary study objective and primary end point is the prevalence of nsVT in patients with HCM at low to intermediate risk (according to the HCM Risk–SCD calculator) and additional mHealth-based prolonged rhythm monitoring. We will also explore the following secondary end points:

- Number of patients undergoing a change in therapeutic procedure (ICD, antiarrhythmic drugs, etc) due to detected nsVT in additional monitoring
- Number of patients with detection of AF (duration >30 sec) by prolonged monitoring
- Number of patients who experience a change in therapeutic procedure (anticoagulation, antiarrhythmic drugs, catheter ablation, etc) due to detected AF
- Prevalence of cardiac arrhythmias in patients with positive cMRI findings (>5% late gadolinium enhancement)
- Prevalence of cardiac arrhythmias in patients with positive genetic diagnosis (detection of HCM-typical gene mutations)

Patient recruitment began in June 2023 and is expected to be completed in February 2024. Data analysis has not yet started. An example table listing patient characteristics and outcomes is provided in Multimedia Appendix 2.

Discussion

This prospective study aims to measure the prevalence of nsVT in 34 patients with HCM observed by mHealth-based continuous rhythm monitoring over 14 days compared to standard practice (a 24- and 48-h long-term ECG). Thereby, the frequency of ventricular arrhythmias in the 14 days is compared with the frequency in the first 24 or 48 hours for the same patient (intraindividual comparison). We will evaluate whether the prolonged rhythm monitoring detects nsVT and AF more often compared to conventional 48-hour monitoring and to what extent these findings can induce changes in therapeutic management. It may be speculated that, especially in patients with intermediate HCM Risk–SCD calculator scores, prolonged monitoring may identify patients at high risk, who may potentially benefit from a prophylactic ICD, with higher accuracy. If no rhythm abnormality is detected during the 14-day monitoring, this will not likely occur in everyday life and ICDs can be avoided due to a sufficiently low risk. In addition, a higher diagnostic yield for previously undetected AF may also improve decision-making regarding the need for early anticoagulant therapy.

We set an upper age limit of 75 years because it is known that especially young patients with HCM especially have a higher risk of SCD [13]. Nevertheless, a residual risk remains, so no upper limit for ICDs is defined in the European Society of Cardiology guidelines. Several years ago, the DANISH (The Danish Study to Assess the Efficacy of ICDs in Patients With Nonischemic Systolic Heart Failure on Mortality) study demonstrated no survival benefit from an ICD in patients older than 75 years in a sample of patients with systolic heart failure [18]. We have followed this age limit despite the different patient samples.

We hypothesize that prolonged rhythm monitoring will detect more arrhythmias than 24- or 48-hour monitoring. In a study with prolonged rhythm monitoring by Holter ECG over 14 days, 75% of patients with HCM had nsVT, compared with only 16.9% of patients in the first 24 hours [6]. However, it remains unclear if all these patients with nsVT should now receive an ICD. Previous studies have shown that patients who present with nsVT during 24-hour monitoring show it more frequently if monitoring is prolonged. Patients who showed nsVT later in the subsequent 14 days usually had only one episode [7]. Thus, it can be speculated that the detection of nsVT in a 24-hour monitoring period indicated more frequent spells of nsVT overall, with an associated higher SCD risk. Moreover, the rate and duration of nsVT vary, suggesting that longer and more rapid nsVT episodes indicate a higher SCD risk [6]. Prolonged monitoring may allow for the identification of patients with more frequent nsVT episodes, also taking into account the rate and duration of nsVT.

In addition, a correlation with late gadolinium enhancement load on cMRI will be investigated. If patients with high late gadolinium enhancement load show increased nsVT, these scar areas detected on cardiac MRIs could be identified as possibly pathogenic for the arrhythmias, and appropriate therapy (eg,

XSL•FO
RenderX

ICD fitting) should be performed. This has so far not been investigated, so the results are needed.

In addition, the mHealth ECG patch method used here offers opportunities for other diseases as well. For example, patients with a stroke of unclear origin can be screened for AF over an extended period. It is also possible to capture intermittent subjectively perceived cardiac arrhythmias with the help of such an ECG patch, as this is often not possible with normal long-term ECGs.

In summary, prolonged mHealth-based rhythm monitoring will be used to investigate arrhythmia burden in patients with HCM. Increased detection of arrhythmias compared with 24-hour long-term ECG monitoring can be expected. It is essential to individually consider the rhythm monitoring results and optimize therapy accordingly. Findings of prolonged rhythm monitoring might be helpful in cases of borderline risk. A thorough discussion of the findings and possibly individual reassessment using the risk calculator could be an approach.

Acknowledgments

This is an investigator-initiated study. Some of the devices were sponsored by the manufacturer, for which a contract was signed. There is no influence on the study results or their publication. The manufacturer provides no further financial support. The authors acknowledge support for the publication costs by the Open Access Publication Fund of the University of Bielefeld and the German Research Foundation.

There was no generative artificial intelligence used in any portion of the manuscript writing.

Data Availability

The data sets generated or analyzed during this study are not publicly available due to patient data protection but are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.
