The primary objective of this study is to determine how daily supportive email messages plus weekly mental health literacy information delivered via email would help improve mental health literacy and reduce the prevalence of moderate to high stress symptoms, burnout, moderate to high anxiety symptoms, moderate to high depression symptoms, and low resilience among schoolteachers in Zambia. The secondary objectives of this study are to map and determine the baseline prevalence and correlates of moderate to high stress, burnout, moderate to high anxiety, moderate to high depression, and low resilience among schoolteachers in Zambia. The specific objectives are as follows: (1) to determine the baseline prevalence and correlates of moderate to high stress, burnout, moderate to high anxiety, moderate to high depression, and low resilience among school teachers in Zambia. (2) To implement daily supportive email messages and weekly mental health literacy information delivered via email to improve mental health literacy. (3) To determine the effectiveness of implementing the Wellness4Teachers email messaging and mental health literacy program to reduce the prevalence of moderate to high stress symptoms, burnout, moderate to high anxiety symptoms, moderate to high depression symptoms, and low resilience among school teachers in Zambia.

Wellness4Teachers email messaging and mental health literacy program is anticipated to reduce the prevalence and severity of stress, burnout, anxiety, depression, and low resilience symptoms among Zambian teachers by at least 20%. Figure 1 is a conceptual framework illustrating the association between the various sociodemographic, personal, and work-related or organizational factors and stress, burnout, anxiety, and depression in teachers. The framework was based on empirical evidence, which showed a greater than 20% reduction in depression symptoms in 2 randomized controlled trials [56,57] and a greater than 20% reduction in anxiety symptom scores from baseline to 6 weeks and 3 months in subscribers of Text4Hope [51,52]. An increased number of predictors such as socioeconomic and demographic factors, workload, and poor organizational structure may correlate with the prevalence and severity of burnout and other psychological and mental health conditions experienced by teachers [3,16,19-23,49,58].

Figure 1. Conceptual framework.

Wellness4Teachers Email Messaging Program

The Wellness4Teachers email messaging program is one of the many suites of ResilienceNHope messaging programs, powered by the ResilienceNHope web-based application [53,59] and facilitated by the Global Psychological eHealth Foundation [60]. Wellness4Teachers email program is a daily supportive email messaging program designed to address stress, burnout, anxiety, and depression. The messages have been crafted by mental health therapists, psychiatrists, and psychologists based on the principles of cognitive behavioral therapy and have also been reviewed by the lead author, an education specialist. Teachers can personally subscribe to the Wellness4Teachers email program through the Lusaka Apex Medical University institutional account through collaboration between the Lusaka Apex Medical University and the local teachers' unions. Teachers will receive daily supportive messages designed to address stress, burnout, anxiety, and depression and weekly links to mental health literacy information for 1 year. The email messages will be noninteractive (one-way), and subscribers will be informed of the noninteractive nature of the email messaging program during the initial welcoming and introductory message. Different messages will be received daily by subscribers from a bank of messages. The mental health crisis services number in Livingstone, Lusaka, Kasama, and Solwezi will be included in the introductory message to subscribers, which they can call if they are in crisis. Examples of messages to be delivered to subscribers of the Wellness4Teachers email messaging program include:

- Even though thoughts are often seen as accurate, they are just guesses, not facts. Burnout and stress can make you experience negative emotions, making your thoughts overly negative. Take a moment to notice how you feel. Try to replace negative thoughts with positive thoughts and actions.
- Effective goals are "SMART": Specific, Measurable, Achievable, Realistic, and Timely. Think of one thing you want to accomplish. Break it down into smaller steps. Only focus on one small step, not the big overwhelming goal. General goals (eg, Getting fit) are not motivating. Making goals more specific (eg, Walk twice this week) are more achievable.
- We each have different signature strengths. It's not about competing with others but learning our unique strengths. Strengths come in many varieties: humor, curiosity, persistence, kindness, love, forgiveness, cooperativeness, and optimism. Share your strength with others. Help a struggling colleague.

Examples of the weekly mental health literacy information sent to subscribers can be found on the Global Psychological eHealth Foundation and the Mental Health Literacy for Educators websites [60,61].

XSL•FO
RenderX

ResilienceNHope messaging programs are evidence-based e-mental health programs designed to address mental health literacy and close the psychological treatment gap for individuals and communities globally [59]. The efficacy of the ResilienceNHope suite of programs has been evaluated and established through several randomized controlled clinical trials and evaluations of population-level programs. In a randomized controlled trial in Fort McMurray, Alberta, Canada, involving 73 patients diagnosed with major depressive disorder, the change in the mean difference in the Beck Depression Inventory scores between the intervention group (those who received twice-daily supportive SMS text messages for 3 months) and the control group (those who received a single thank-you message) was significant with an effect size (Cohen *d*) of 0.67 [62]. A similar trial was conducted in Ireland with similar results [63,64]. In addition, there were statistically significant reductions in the prevalence and mean scores on standardized measures for stress, anxiety, and depression at 6 weeks and 3 months for subscribers to the Text4Hope program [51,52].

Methods

Study Design

This will be an interventional study, specifically a quasi-experimental design, which will employ a quantitative longitudinal and cross-sectional survey methodology with data collected from subscribers of Wellness4Teachers email messaging service users.

Data Collection

Quantitative data will be collected using web-based questionnaires through the ResilienceNHope secure platform for managing web-based surveys and databases [57]. The web-based questionnaires will be designed to collect demographic and work-related variables and assess mental health literacy and clinical variables, including stress, burnout, anxiety, depression, and resilience [59]. The web-based surveys will be distributed to subscribers on enrollment at 6 weeks, 3 months, 6 months, and 12 months. The follow-up surveys will also include questions assessing subscriber experience and satisfaction with the Wellness4Teachers email messaging program.

Participants' Recruitment and Subscription

Subscription to the Wellness4Teachers email messaging program will be initiated by individual teachers accepting an invitation to subscribe from the Lusaka Apex Medical University's organizational account on the ResilienceNHope web-based application. The local principal investigator (CC) will work with the Zambian Ministry of Education, the Lusaka Teachers Association, district school boards, and heads of elementary and high schools to invite teachers to join the Wellness4Teachers email messaging program. Participants will be eligible for inclusion if they are school teachers and residents of Livingstone, Lusaka, Kasama, or Solwezi. Subscribers can unsubscribe from the program at any time by clicking the unsubscribe link associated with the messages. Based on the 10% dropout rate recorded for the Text4Hope program [51,52], the anticipated dropout rate for the email messaging program will be less than 15% [54].

Study Setting

The study will occur in Zambia. Zambia is an eastern, sub-Saharan African country with an estimated 2021 population of 18,920,657 and nearly half of the population under the age of 15 years, with almost equal proportions of males and females (49.5% and 50.5%, respectively) [65]. Zambia covers about 290,587 square miles (743,390 km^2), and the population's median age is only 16.8 years [65,66]. The country is prone to natural and man-made disasters such as floods, droughts, mine accidents, and deforestation [49]. War and other political uncertainty in surrounding states result in a refugee influx. The study will focus on 4 main cities in Zambia: Livingstone, Lusaka, Kasama, and Solwezi. Livingstone is a capital city in the southern part of the country, with a land area of 85,283 km^2 and a population of 1,799,885 in 2014. There were about 1241 basic schools in 2012 and 45 high schools in 2004. In 2014, there were 6158 teachers in school grades 1-9, and 1027 in high school [67].

Lusaka is the capital of Zambia and one of the 20 cities in Zambia, with a total land area of 375 km^2 with an approximate population of 3,042,000 in 2022, a 4.68% increase from 2021 [68]. There were 111 secondary schools and 758 primary schools in Lusaka in 2017 [66], and about 10,822 primary school teachers and 3383 secondary school teachers in Lusaka in 2016 [66]. There are several rural cities in Zambia, including Kasama (Northern Province) and Solwezi (North Western Province). Kasama had a land area of 77,650 km^2 and a population of 1,264,212 in 2014. There were 1208 basic schools and 26 high schools in 2004. In 2004, there were 5169 teachers in all schools, grades 1-9, and 656 teachers in high schools, grades 10-12 [67]. Solwezi has a land area of 125,826,656 km^2, and a total population of 811,706 was recorded in 2014. Basic schools in 2012 were 747 and 23 high schools in 2004. Teachers in all schools in grades 1-9 were 2837 in 2004, while teachers in high schools in grades 10-12 were 509 the same year [67].

Outcomes and Measures

Validated screening scales for self-reported symptoms will be used to assess clinical outcomes. These include the Mental Health Literacy Scale [69], the Generalized Anxiety Disorder 7-item (GAD-7) Scale (a GAD-7 score of ≥10 indicates moderate to high anxiety) [70], the Perceived Stress Scale (PSS-10) (a PSS-10 score of ≥10 indicates likely moderate to high stress) [71], the Brief Resilience Scale (BRS; BRS mean scores ranging from 1.00 to 2.99 indicate low resilience, scores from 3.00 to 4.30 suggest normal resilience, and mean scores from 4.31 to 5.00 suggest high resilience) [72,73], and the Patient Health Questionnaire-9 (PHQ-9; a score of ≥10 indicates moderate to high depression) [74]. Burnout will be assessed using the Maslach Burnout Inventory (MBI), specifically the MBI-Educators Survey, for use with educators [75,76]. An exploratory outcome will be to evaluate the acceptance of the Wellness4Teachers program by teachers in Zambia, which can be measured by the proportion of the target population (teachers in Livingstone, Lusaka, Kasama, and Solwezi) who subscribe

XSL•FO
RenderX

to the program. Primary outcomes for this study will be changes in mental health literacy and the prevalence of moderate to high stress, burnout, moderate to high anxiety, moderate to high depression, and low resilience from baseline to 6 weeks, 3 months, 6 months, and 12 months among the subscribers of the Wellness4Teachers Zambia program. Secondary outcomes include the mean score on the Mental Health Literacy Scale and the prevalence of moderate to high stress, burnout, moderate to high anxiety, moderate to high depression, and low resilience at baseline in subscribers of the Wellness4Teachers email messaging program. Other secondary outcome measures will include changes in mean scores on the PSS-10, MBI, GAD-7, PHQ-9, and BRS. In addition, sociodemographic factors, work-related factors, and mental health literacy correlate with moderate to high stress, burnout, moderate to high anxiety, moderate to high depression, and low resilience at baseline among subscribers of the Wellness4Teachers program.

Sample Size Estimation

With the total teacher population in Lusaka, Livingstone, Kasama, and Solwezi of about 30,561 [66], using a web-based script [77], it is projected that the sample size needed for our prevalence estimates with 95% confidence and a 3% margin of error for moderate to high stress, burnout, moderate to high anxiety, moderate to high depression, and low resilience among teachers in Livingstone, Lusaka, Kasama, and Solwezi will be 993. Based on the maximum survey completion rate attained for the Text4Hope and Text4Mood programs in Alberta of 20% [50,78,79], to achieve an estimated 993 completed surveys at baseline, it is planned to enroll at least 4965 teachers in the Wellness4Teachers email supportive and mental health literacy messaging program within 12 months.

Statistical Analysis

SPSS (version 25; IBM Corp) [80] will be used to analyze the quantitative data from the surveys. Surveys with more than 50% missing responses will not be included in the data analysis. There will be no missing data imputation, and the analysis of the included survey responses and results will be based on completed survey data. Descriptive statistics for demographic, mental health literacy, clinical, and burnout-related variables will be provided. A 2-tailed $P \leq .05$ will be used to determine statistical significance for all analyses, and descriptive characteristics will be presented as percentages and numbers. A chi-square test and logistic regression analysis will be used to separately identify demographic, clinical, and work-related correlates of anxiety, depression, stress, low resilience, and burnout for elementary and high school teachers. Significant and borderline significant variables from the chi-square analysis would be used to develop multivariable binary logistic regression models to predict the adjusted odds of outcomes for the exposure of interest and each potential correlate. The impact of the email supportive messaging program in reducing moderate to high anxiety, moderate to high depression, moderate to high stress, burnout, and improving resilience among subscribers will be evaluated by comparing the mean changes in these parameters from baseline to 6 weeks, 3 months to 6 months, and 12 months using the paired *t* test. To assess the effects of the intervention against a control group, we will choose a defined period of 3 months during the study period (for instance, the beginning of January 2023 to the end of March 2023) and compare the prevalence and mean scores on standardized scales for stress, anxiety, burnout, and depression at 6 weeks for subscribers who have received the daily supportive SMS text messages for 6 weeks (the intervention group) to the baseline prevalence and mean scores on the same scales for new subscribers during the period (the control group).

Data Quality Assurance

At each stage of data collection, we will implement checks to ensure that we collect high-quality data, enabling us to generate accurate insights. A 3-member data quality committee will be established, which will be responsible for checking quantitative data that is uploaded to the server. All data will be checked for consistency and accuracy. Any errors and inconsistencies will be immediately communicated to the data collection team for corrective action.

Ethics Approval and Informed Consent

The study has received ethics approval from the University of Alberta Ethics Review Board (Pro00117558), Dalhousie University Ethics Review Board 2022-6231, and Lusaka Apex Medical University, Zambia, Ethics Review Board IRB 00001131.00407-22. Participants' consent to participate will be implied when they complete and submit the web-based survey responses. Participants will be informed that participation is voluntary, they can opt out anytime they desire, and the information they share is confidential. Teachers will not receive reimbursement or incentives for participating in the Wellness4Teachers email messaging program.

Hypothesis

Based on the greater than 20% reduction in depression symptom scores in the intervention group compared to the control group in 2 randomized controlled trials in Ireland and Canada [56,57], and the greater than 20% reduction in anxiety symptom scores from baseline to 6 weeks and 3 months in subscribers of Text4Hope [51,52], we hypothesize that the Wellness4Teachers email messaging program will reduce the prevalence and severity of stress, burnout, anxiety, depression, and low resilience symptoms among Zambian teachers by at least 20%. We also hypothesize that the Wellness4Teachers email program will improve mental health literacy scores in the teachers subscribing to the program by at least 20%. In addition, we hypothesize that the prevalence of moderate to high stress, moderate to high anxiety, moderate to high depression, burnout, and low resilience would be comparable to the prevalence of these conditions reported in other jurisdictions [81,82]. Finally, we hypothesize that demographic factors, socioeconomic factors, organizational factors, and class size will be associated with burnout and other psychological disorders in teachers [16,19-23,49,58].

Results

The Wellness4Teachers email messaging program is anticipated to be launched in January 2023. Enrollment will continue for 12 months, and data collection will continue for another 12 months. Results of the study will be disseminated to stakeholders

XSL•FO
RenderX

in the education sector in Zambia, East African countries, and globally through workshops, conference presentations, and peer-reviewed publications.

Discussion

Principal Findings

Chronic stress can affect teachers, leading to burnout, anxiety, and depression. It can also indirectly affect students' academic achievement since teachers' performance is impacted by stress. In addition, this can also have a profound effect on teachers' general lifestyle, physical health, psychological safety, and well-being, leading to reduced professional fulfillment and a low level of resilience. Teachers require innovative, convenient, easily accessible, and cost-effective programs to improve their mental health literacy and support their mental health due to their busy schedules. This protocol outlines the use of supportive email messages and mental health literacy e-health tools for implementing a psychological intervention for teachers who may be experiencing stress, burnout, depression, and anxiety and improving their overall resilience. Teachers with low mental health literacy, prior mental health conditions, and those exposed to previous traumas or adverse childhood experiences are likely to benefit substantially from this program.

Results from this study will provide key information about mental health literacy levels and prevalence rates of stress, burnout, depression, anxiety, and low resilience and their correlates among teachers in Zambia (Livingstone, Lusaka, Kasama, and Solwezi). Findings will also provide valuable knowledge on eHealth approaches in the education sector. Evidence of the effectiveness of daily supportive email messaging programs to address stress, burnout, anxiety, depression, and low resilience among teachers will be ascertained. Evidence from this study will be both essential and crucial for shaping school policy and decision-making regarding psychological interventions for teachers in low- and middle-income countries. It is anticipated that the outcomes of this study will provide an impetus for integrating supportive email and mental health literacy messaging interventions into many organizations' occupational health programs.

Limitations

Like most studies, this one has some limitations. First, the supportive email messages will be delivered for 12 months, and the outcome measures will be evaluated at 6 weeks, 3 months, 6 months, and 12 months. It is not certain what the effects of the intervention would be if it were extended. It is also unclear if the benefits of the intervention would diminish with the cessation of daily email messages. Second, although standardized, the self-reported scales used to assess mental health variables, such as moderate to high anxiety, are not diagnostic. Third, it is possible that participants' demographics in the study may not reflect the demographics of the teacher population in Zambia; hence, the study findings may not be generalizable to all teachers in Zambia. In addition, web-based surveys with survey links delivered through SMS text messages usually achieve a response rate of less than 20% [54,78,79,83-86], so it is possible that we may not achieve our desired sample size with an email messaging program. Despite these limitations, this study is the first to assess the prevalence and correlates of stress, burnout, anxiety, and depression among teachers in Zambia using an email messaging program. To our knowledge, this study is also the first worldwide to assess if daily supportive email messages and mental health literacy information delivered by email would effectively reduce the prevalence and severity of psychological symptoms and improve mental health literacy among teachers.

Conclusions

This study will provide vital information about mental health literacy and the prevalence and correlates of psychological problems among teachers in Zambia. The study will also provide evidence of the effectiveness of the email messaging program, Wellness4Teachers, in reducing psychological symptoms and improving mental health literacy among teachers. The knowledge from this study will significantly impact the promotion of mental health literacy and the management of stress, burnout, anxiety, depression, and low resilience among teachers. The study outcome will help inform policy decision-making for health care resource allocation in support of the educational sector in Zambia.

Abstract

Background: The increasing emphasis to share patient data from clinical research has resulted in substantial investments in data repositories and infrastructure. However, it is unclear how shared data are used and whether anticipated benefits are being realized.

Objective: The purpose of our study is to examine the current utilization of shared clinical research data sets and assess the effects on both scientific research and public health outcomes. Additionally, the study seeks to identify the factors that hinder or facilitate the ethical and efficient use of existing data based on the perspectives of data users.

Methods: The study will utilize a mixed methods design, incorporating a cross-sectional survey and in-depth interviews. The survey will involve at least 400 clinical researchers, while the in-depth interviews will include 20 to 40 participants who have utilized data from repositories or institutional data access committees. The survey will target a global sample, while the in-depth interviews will focus on individuals who have used data collected from low- and middle-income countries. Quantitative data will be summarized by using descriptive statistics, while multivariable analyses will be used to assess the relationships between variables. Qualitative data will be analyzed through thematic analysis, and the findings will be reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines. The study received ethical approval from the Oxford Tropical Research Ethics Committee in 2020 (reference number: 568-20).

Results: The results of the analysis, including both quantitative data and qualitative data, will be available in 2023.

Conclusions: The outcomes of our study will offer crucial understanding into the current status of data reuse in clinical research, serving as a basis for guiding future endeavors to enhance the utilization of shared data for the betterment of public health outcomes and for scientific progress.

Introduction

The Value of Clinical Research Data

Although clinical research data are generated to answer specific questions, the data can be used for purposes other than those of the original planned analyses to increase medical understanding and improve the general health of the population [1,2].

Many recent advances in medicine are credited to the reuse of existing research data. During the outbreaks of H1N1; MERS (Middle East Respiratory Syndrome); Ebola; Zika; and, more recently, COVID-19, decision-making authorities such as the World Health Organization depended on the analysis of historical epidemiological and clinical data to understand disease progression patterns and associated risk factors. This knowledge was the basis of recommendations for nonpharmaceutical interventions to control the spread of the diseases [3-6]. Guidelines for treatment therapies and preventive medicines depend on findings from clinical trials. The design and interpretation of these clinical trials rely heavily on data from previous studies in, for instance, the calculation of sample sizes, definition of outcomes, selection of interventions and control treatments, and establishment of follow-up duration [7-10]. Existing clinical research data have also been used to answer completely new research questions for teaching purposes and to reproduce results of published research [11].

As the volume of research data continues to rise, there is greater potential for faster and innovative discoveries in diagnostics and the treatment and prevention of diseases through traditional analyses and machine learning technologies [12].

Recognizing the value of data reuse, funders, journals, and research bodies are establishing policies and making substantial resource investments in infrastructure to facilitate data sharing [13,14]. In 2003, the National Institutes of Health introduced the first funder-driven data sharing policy. By 2016, key health research funders required individual participant-level data that support findings of clinical trials to be made accessible at the time of the publication of study results [15-17]. Journals and publishers followed suit, with the majority of them mandating the inclusion of data availability statements in articles for publication [18]. These statements describe how and when data can be accessed and on which repository data are stored. Numerous repositories have been established by funders, pharmaceutical companies, academic research institutions, governments, and discipline-specific consortia [19]. In 2016, at the G20 Hangzhou Summit, the FAIR (Findable, Accessible, Interoperable, and Reusable) principles were endorsed. The FAIR principles aim to optimize the reuse of data sets by ensuring that data are findable; are accessible; are presented in a standardized, interoperable format; and exist on terms that allow reuse [20,21]. Groups such as the Clinical Data Interchange Standards Consortium have defined standard ways of describing data and metadata [22]. By standardizing data and metadata, researchers and algorithms can correctly interpret data without the need for intermediary translation or curation. Analytical tools, such as TwoRavens [23], now allow users to run statistical models and view summary statistics on data held in repositories. The implementation of this ecosystem requires staff with specialized skills; research institutions are investing in hiring and training data managers, programmers, and data scientists to develop interfaces and curate data and metadata.

It is expected that these investments in infrastructure will increase the usage of existing data and, consequently, generate a rich reference for evidence-based decision-making.

Rationale

Despite the efforts to facilitate data sharing, it is still unclear if and how shared data sets are used and whether the anticipated benefits are being realized. Previous studies described data usage trends based on data sets held in repositories and those from studies that are registered in clinical trial registries [24]. Negative results and studies terminated prematurely are often not published in repositories, yet data from these studies may hold useful insights for planning future research [25]. A substantial proportion of studies conducted in low- and middle-income countries (LMICs), especially noninterventional studies, are not registered [26]. Data sets generated in LMICs are particularly valuable, given the high disease burden in LMICs and the low volume of research being conducted in these areas [27-30]. To our knowledge, no recently published work has examined current barriers to and opportunities for maximizing data utility in LMICs.

Objectives

Against this background, our study aims to bridge the evidence gap by (1) characterizing how clinical research data sets are reused; (2) describing what impact, if any, data reuse has had on scientific research and general public health; and (3) defining barriers to and opportunities for promoting the ethical, efficient, and equitable reuse of data based on the perspectives of secondary data users.

As previous studies primarily focused on participants from high-income countries, we will target individuals working with data collected from LMICs for the interviews and aim to include respondents from both high-income countries and LMICs in the survey.

Methods

Overview

We will conduct a mixed methods study comprising an anonymous web-based survey and semistructured in-depth interviews. The survey will provide data from a large population, while the interviews will generate data on the detailed and contextualized perspectives of individual data users. We aim to include a wide spectrum of participants to reflect the diversity in research areas, career levels, and geographical locations.

Recruitment

Cross-sectional Survey

We will include at least 400 participants, of whom half will be individuals with a history of data reuse (data users), and the other half will be participants with no history of data reuse (nonusers). For the data user group, we will investigate what kinds of data sets were used, how the data were accessed, the purposes for requesting the data, and outcomes of the secondary

XSL•FO
RenderX

analyses. We will additionally probe for information on challenges faced in accessing and using the data. For the nonuser group, we will determine reasons for not using shared data sets and identify perceptions on data reuse.

The inclusion criteria are as follows: (1) individuals aged ≥18 years, (2) researchers and professionals working in clinical research or with clinical research data, and (3) those who provide written consent to participate in the study. Individuals with no access to a computer, a mobile device, or the internet will be excluded, as data collection will be mainly conducted via the internet.

Potential participants will be requested to provide consent by ticking a checkbox to confirm that they agree to participate in the study. Respondents who do not provide consent will not be able to access the survey.

Data users will be directed to a page for data users, while nonusers will be directed to a page for nonusers. It will take 3 to 7 minutes to complete the survey for data users and 1 to 2 minutes to complete the survey for nonusers.

The survey will be designed based on existing literature. A panel of experts will be involved in the survey design, including social scientists and ethicists (for informing how questions are framed), a statistician (for the sampling strategy and the development of measurement scales and scoring schemes), a data manager (for survey development and data extractions), and a group of researchers and data users (for piloting). We will use the cognitive debriefing method to pilot the survey among respondents who are similar to the target population. The pilot testing group will be selected purposively for practical reasons and will include individuals from diverse research areas, career levels, and geographical locations. During the pilot, we will check the comprehension of each question; the ability to recall answers; and whether questions are appropriate, are clear, and have sufficient response options. Feedback from the pilot phase will be incorporated in the final survey before deployment for data collection. To achieve demographic diversity, the survey will be translated into other languages, such as Spanish, French, and Portuguese. We will translate the survey by following the TRAPD (Translation, Review, Adjudication, Pretesting, and Documentation) model [31]. Professional translators will perform the initial translations before a review by bilingual individuals. To guarantee that the translated survey accurately represents the intended meaning, it will be pretested with native speakers who are comparable to the target audience.

The survey instrument focuses on the following four main areas: respondents' demographics, the nature of data use, challenges with data use, and interventions to enhance data use (Multimedia Appendices 1-5). Conditional logic will be applied to display nested questions that are dependent on the respondents' previous answers. For example, respondents who have published results that are based on secondary analyses will be asked to indicate the number of publications generated from those analyses. Similarly, questions on the history of data use will not be displayed for nonusers.

To reach the target population, the survey will be advertised on forums for researchers and secondary data users, such as the Global Health Network and the COVID-19 Clinical Research Coalition; in conferences; and through the collaborating institutions' social media platforms. Participants will also be encouraged to share the survey with their colleagues. The survey will be conducted globally. The data will be reviewed after the number of recruited participants reaches one-third (132/400, 33%) of the target sample size to monitor the distribution of respondents by geographical location, research area, and occupation. The results of the review will be used to strategize the advertisement and distribution of the survey to target specific groups.

Interviews

Semistructured in-depth interviews will be conducted with 20 to 40 data users or until a state of data saturation is reached. Data saturation occurs when further interviews no longer produce new insights or themes [32]. Considering limitations on travel and on holding meetings resulting from the COVID-19 pandemic, we will primarily use web-based or remote methods for data collection. In-person interviews may be conducted when it is safe to do so, in compliance with local regulations.

The inclusion criteria are as follows: (1) individuals aged ≥18 years, (2) researchers or professionals using clinical research data shared by other researchers for secondary purposes, and (3) those who provide consent to participate in the study.

Potential participants will be identified through a web-based search for publications that are based on secondary analyses, focusing on researchers and professionals who have used data from LMICs. The corresponding authors will be contacted by email and invited to participate in interviews. To reach data users who have not yet generated publications, we will invite individuals who have requested data sets from institutional data repositories. Individuals who are interested in participating in the study will be sent the participant information sheet and consent form by email. The information sheet will describe the nature of the study, what the interviews will entail, and details on how data will be stored and processed during and after the study. It will be clearly stated that the participants are free to withdraw from the study at any time, for any reason, and with no obligation to give the reason for withdrawal. The participants will be allowed as much time as they wish to consider the information, and they will be given the opportunity to raise questions with the investigator or other independent parties to decide whether they will participate in the study. Interviews will then be scheduled at mutually convenient times. Audio-recorded consent will be obtained prior to asking the interview questions. The interviewer will document that verbal consent was obtained on a consent form. The investigator will keep a copy of the signed form in the study file and send a copy to the participants by email. For interviews that are held in person, the participants will sign the consent form prior to start of the interview. The interviews are estimated to last 40 to 60 minutes. Multimedia Appendix 6 shows the interview guide.

It is likely that participants of the in-depth interviews may be included in the survey. However, as the survey is anonymous, it will not be possible to identify individuals who participate in both the survey and the interviews.

RenderX

Data Management

Quantitative data will be collected on the Jisc Online Surveys platform, which is managed through the University of Oxford [33]. Data will be exported from Jisc in CSV format for analysis and long-term preservation. The survey database will be retained for 6 months after the completion of data collection, after which all data will be exported from the survey platform and stored indefinitely in access-controlled servers at Mahidol Oxford Tropical Medicine Research Unit (MORU)—a collaboration between the University of Oxford and Mahidol University that carries out clinical and public health research [34]. Deidentified data may be uploaded on data repositories or shared with other researchers, in line with the data sharing policies of MORU and collaborating institutions, as applicable.

Qualitative data will include detailed summary notes and audio recordings of the interviews. Web-based interviews will be conducted in English via Microsoft Teams (Microsoft Corporation)—a secure access-restricted platform. Transcripts of the interviews will be generated by using the Microsoft Teams transcription feature. The draft transcripts will be manually checked for accuracy line by line. Using the Health Insurance Portability and Accountability Act safe harbor method, direct and indirect identifiers, such as references to names of individuals or institutions, will be removed from the transcripts [35]. The deidentified transcripts will be uploaded to the latest version of NVivo (QSR International) software for storage and organization. Audio recordings and email correspondence will be stored separately from deidentified transcripts to preserve the confidentiality and privacy of participants. After the completion of analyses and the reporting of study results, audio recordings and original transcripts will be deleted. Deidentified transcripts, summary notes, and coded data will be stored indefinitely in access-controlled servers at MORU.

Statistical Analysis

Sampling

Participants will be enrolled through nonprobability sampling, as no suitable sample frame exists for the population being studied. A minimum of 200 participants is adequate for estimating any prevalence of a response, assuming a 50% prevalence rate, with 95% confidence and a precision of around 7%. Considering a minimum of 200 data users and 200 nonusers, the minimum total sample size for the web-based survey is 400 participants. A sample size higher than 400 participants will increase the precision of the prevalence estimates.

The sample size for the qualitative study will depend on when data saturation is reached. We estimate that a purposive sample of between 20 and 40 participants will be adequate, following the rule of thumb for the estimation of sample sizes for in-depth interviews in mixed methods studies [36].

Analysis

Quantitative survey data will be analyzed by using Stata 15.0 (or later; StataCorp LLC) software. Frequency counts and percentages will be used to summarize categorical data. Associations between categorical variables will be assessed by using Pearson chi-square tests or Fisher exact tests, as appropriate. Data will be presented in tables, graphical displays, and summary statistics. Further analyses for determining the significance of relationships between variables will be performed when necessary. Tests of significance will be performed at the 5% significance level (α=.05) for quantitative data.

Qualitative data will be synthesized by using thematic analysis [37], and the findings will be reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines. Open coding will be performed by breaking data into discrete parts and assigning them codes. Through axial coding, related codes will be combined to form subthemes. Related subthemes will then be collated to form themes, and the relationships between themes will be presented using thematic maps. The themes will be described in detail within the study report, including verbatim quotes from participants as illustrations.

To ensure the validity and trustworthiness of the study results, data will be coded by 2 independent individuals. For codes that are contradictory, divergences will be outlined and discussed in the report.

Ethical Considerations

Ethical approval was obtained in December 2020, prior to initiating the study, from the University of Oxford's Tropical Research Ethics Committee (reference number: 568-20), which will provide overall oversight of the study. Institutional review board approvals may be obtained for collaborating institutions, as applicable.

Our study will pose minimal risk and harm to participants. Although there are no immediate benefits for study participants, participation in the study will afford them an opportunity to contribute to the generation of new knowledge that will potentially increase the reuse of data for public good.

The main ethical risks relate to privacy and confidentiality, particularly in the in-depth interviews. Care will be taken to maintain privacy during interviews and interactions with participants. Data containing person-identifying information will be stored securely and confidentially. Study documents and data will be accessible to study staff and authorized personnel only. The web-based survey is completely anonymous. Names, email addresses, IP addresses, or other person-identifying details will not be collected in the survey.

The study will comply with the European Union General Data Protection Regulation, as described in the participant information sheets for the survey (Multimedia Appendices 1-5) and the interviews (Multimedia Appendix 7). Personal data will be stored until the final analyses are completed, while anonymized data will be stored indefinitely.

Data Sharing

With participants' consent, anonymized data will be uploaded on data repositories and shared with other researchers, in line with the collaborating institutions' data sharing policies. We will share the information we collect in ways that do not reveal individual participants' identities.

XSL•FO
RenderX

Informed Consent

Participation in the study is voluntary. All participants must provide informed consent before involvement in the survey or in the interviews. Survey participants will only be able to access survey questions after providing consent. For in-depth interviews, verbal consent will be obtained at the start of the interview.

Dissemination

The results of our study will be primarily shared through the publication of results in peer-reviewed journals and through scientific presentations in webinars and seminars.

Results

The results of the analysis, including both quantitative data and qualitative data, will be available in 2023.

Discussion

Overview

Data sharing is widely regarded as a positive development for scientific and technological advancement. By making research data available beyond the primary research team, the data can be scrutinized, reused, and built upon, leading to greater insights, innovation, and collaboration. Research indicates that data sharing is becoming increasingly mandated, with funding agencies, academic institutions, and journals requiring researchers to make their data available. This is due to the belief that data sharing can lead to more reproducible and trustworthy results and an increase in the visibility of researchers in the scientific community. Despite these mandates, it is important to note that the uptake of data sharing practices among researchers is still relatively low. Although data sharing can bring significant benefits to scientific advancement and collaboration, it also requires significant investments in terms of time, resources, and technology. It remains unclear whether the benefits of data sharing are actually worth the costs. Furthermore, data sharing can also amplify challenges, such as the need for proper data curation and privacy protection. To date, there is sparse literature on the barriers and drivers of clinical research data reuse based on the perspectives of secondary data users [38-43]. Although some secondary data users cite the lack of access to quality and relevant data as a challenge, ironically, other researchers suggest that the clinical research data sets that exist in the public domain are grossly underutilized [1,44].

Expected Findings

Through our exploratory study, we aim to gain insights into how shared data sets are used, analyze the impact of secondary usage, and document barriers and facilitators of secondary data use based on the perspectives of data users.

Limitations

The survey participants will be selected by using nonrandom sampling, which means that the results may not accurately reflect the characteristics of the whole population and may be affected by bias in the selection process. Additionally, it is possible that the survey may only reach those who regularly use the web-based platforms where the survey is promoted, potentially resulting in an incomplete representation of the target population. Although it is acknowledged that the survey results may not be generalizable to a larger population, the data from our exploratory study will provide ideas and hypotheses that could guide future research. Additionally, the in-depth interviews are expected to provide valuable and contextualized information.

The study is limited to the description of the current state of data reuse, and it will not explore causal relationships. However, the findings from our study can be used as a foundation to design future studies that establish cause-and-effect relationships in secondary data use and explore perspectives of nonusers.

Conclusions

In conclusion, the findings from our work could offer insights into informing strategies for increasing the utilization of existing clinical research data sets in a manner that benefits researchers and populations, particularly in LMICs.

Acknowledgments

This project is funded through Trials Methodology Research Partnership Global Health Pump Priming Awards provided by National Institute for Health and Care Research, United Kingdom, and a Wellcome Trust Strategic Award (096527).

Data Availability

The data sets generated and analyzed during the study will be available from the Mahidol Oxford Research Tropical Medicine Research Unit Data Access Committee on reasonable request [45].

Abstract

Background: Suicide is a major public health problem, which affects people of all ages and ethnicities. Despite being preventable, the rates of suicide have steadily climbed (more than a third) over the past 2 decades.

Objective: Nurse practitioners (NPs) must be responsible for recognizing suicide risk and providing appropriate treatment referrals in addition to having an important role in suicide prevention. The reasons why NPs may not pursue suicide prevention training are their lack of suicide awareness and prevention, limited experiences with suicidal patients, and the stigma associated with mental illness. Before we begin to address the gaps within suicide awareness and prevention skills, we need to first examine NPs' knowledge of and attitudes (stigma) toward suicide prevention.

Methods: This study will comprise a mixed methods approach. First, quantitative data will be collected using the *Suicide Knowledge and Skills Questionnaireand the Suicide Stigma Scale (Brief version)* questionnaire. An email will be sent to the NPs explaining the purpose of the study. If they consent, they will click on a link to access the surveys on a secure site. In our previous research with this sample, email reminders to nonresponders after 2 and 4 weeks were sent. The quantitative component will be used to inform the qualitative interviews of this study. *The Suicide Knowledge and Skills Questionnaire* is a 13-item questionnaire comprising 2 subscales: suicide knowledge and suicide skills. All questions are rated on a 5-point Likert scale (1=completely disagree to 5=completely agree). The survey has been shown to differentiate between those with suicide training and those without and has a Cronbach α score of .84. *The Suicide Stigma Scale* (*Brief version*) is a 16-item survey that assesses stigma regarding suicide. The items are measured on a 5-point Likert scale (1: strongly disagree to 5: strongly agree) and have a Cronbach α of .98.

Results: This study was funded by the Faculty Research Grants program through the Office of the Vice Chancellor for Research and Economic Development at the University of North Carolina at Charlotte. Institutional review board approval was obtained in April 2022. Recruitment occurred between summer and winter 2022. Interview conduction began in December 2022 and will conclude in March 2023. Data will be analyzed during spring and summer 2023.

Conclusions: The study results will add to the literature on NPs' knowledge of and attitudes (stigma) toward suicide prevention. It represents a first step in addressing gaps within suicide awareness and prevention skills, among NPs in their respective practice settings.

Introduction

Background

Suicide is a major public health problem, which affects people of all ages and ethnicities [1-6]. It is a multifactorial phenomenon often influenced by events that destabilize some of the pillars of daily life, such as family bonds, job satisfaction, economic stability, recreational life, and well-being [7]. Suicide is a global public health concern costing the lives of over 800,000 people per year [8]. It is among the 3 leading causes of death in those aged 15-44 years and the second leading cause of death among children and young people aged 15-29 years [8]. Among the strongest risk factors for suicide are a history of suicide attempts, mental illness, and self-harm [8,9]. Despite being preventable, the rates of suicide have steadily climbed (more than a third) over the past 2 decades [1-6]. Between 2007 and 2017, past-year suicidal ideation among college students nearly doubled (from 5.8% to 10.8%). Based on the Household Pulse Survey by the Centers for Disease Control and Prevention conducted from February 17 to March 1, 2021, 42.2% of participants aged 18-29 years reported indicators of depression in the past week [10]. The number of people who think about or attempt suicide is even higher [1-6]. The impact of COVID-19 with social distancing and isolation has exacerbated the risk of "deaths by despair" (suicide and substance use) during the pandemic [11,12]. Studies show that the pandemic has further widened the mental health treatment gap, and outpatient mental health services have been particularly disrupted [13]. Since the COVID-19 pandemic, vulnerable people (eg, those with a history of preexisting psychiatric disorders, low-resilience people, individuals who reside in high COVID-19 areas, those who have a family member to die of COVID-19, and health care providers) have experienced more suicide ideations post pandemic than before the pandemic [14-16]. Among those who are vulnerable and at risk of suicide because of COVID-19 are also those who are more fragile to the COVID-19-related economic crisis, analogous to the 2008 economic crisis [17]. In addition, evidence suggest that various factors including stress-related disorders of depression, posttraumatic stress disorder, and sleep disorders are associated with suicidal ideation, suicide attempts, and death by suicide [18]. Several factors have been found to contribute to suicidal ideation and behavior, including the presence of economic stressors, increased consumption of addictive substances (drugs and alcohol), domestic violence, intense exposure to anecdotes of pessimism and helplessness, and persistent feelings of entrapment, isolation, and loneliness. These factors can interact and have a synergistic effect, thus creating a vicious circle [19,20].

Moreover, many recovering patients with COVID-19 or those in the postacute phase experience psychosocial difficulties and such as loss of employment and financial distress. They also experience physical symptoms for an extended period [18]. Studies have highlighted the role of physical illness, especially among the oldest patients. Physical illness exerted a stronger motivational effect for suicide in old-old (≥75 years) attempters compared to their young-old (65-74 years) and middle-aged (50-64 years) counterparts. One-third of those who are >70 years of age, who had attempted suicide, attributed their act to somatic distress. Among those who had died by suicide, a greater incidence of physical illness was reported in the old-old compared to the young-old and middle-aged adults [19,20]. Most people who died by suicide had contact with the health care system in the year before their death [19,20]. It is documented that among people who died by suicide and who attempted to commit suicide, 83% of them had visited a primary care clinician, like a medical doctor (MD), nurse practitioner (NP), or physician assistant (PA) in the prior year, whereas 50% had visited a primary care clinician rather than a psychiatrist within 30 days of their death [21]. Moreover, older individuals who attend the emergency department (ED) with a physical illness are vulnerable individuals. The ED visit often represents a "sentinel event" that may signal a medical or psychosocial fracture in their established equilibrium. In addition, the ED represents a clinical setting where the elderly with both physical illness and greater suicidality risk frequently converge [19,20]. These missed opportunities are considered significant since risk and prevention factors are being overlooked. NPs serve a vital role in today's health care system as primary care clinicians. In this role, NPs should be able to identify those at risk for suicide and intervene with prevention tactics and safety measures [22]. NPs of all specialties including family, pediatric, adult gerontology acute care, obstetrics/women's health, and psychiatry should possess effective suicide assessment skills; however, suicide prevention training in schools of nursing is inadequate and limited to a few lectures [22]. Smith et al [23] have identified that knowledge about suicidal behavior and its assessment and treatment among clinicians has lagged in research in the health care. They have identified that gaps between research and practice could be indicative to the lack of appropriate training [23]. These gaps within suicide prevention knowledge are reflective of the need to increase suicide knowledge and awareness among primary care clinicians like NPs [24]. Health care clinician training is a top research priority identified by the National Action Alliance for Suicide Prevention [24].

In North Carolina, suicide is the third leading cause of death for children and young adults aged 10-34 years, the fourth cause of death in adults aged 35 to 54 years, ninth leading cause of death for those aged 55-64 years, and 17th leading cause of death for those aged 65 years and older [25]. On average, 1 person dies by suicide every 6 hours in the state [25]. The 2012 North Carolina Suicide Prevention Plan *encourages* but does not *mandate* suicide prevention training for health care professionals [26]. NPs must be responsible for recognizing

XSL•FO
RenderX

suicide risk and providing appropriate treatment referrals, in addition to having an important role in suicide prevention [22]. One study suggests that NPs use more varied approaches in assessing, treating, and referring their geriatric patients with mental health problems [27]. This study also identified that NPs were more likely than their MD counterparts to express a lack of training and referral resources as barriers to treating symptoms such as depression among older adults [27]. The reasons why NPs may not pursue suicide prevention training is their lack of suicide awareness and prevention, limited experiences with suicidal patients, and stigma associated with mental illness [19,20,22]. Diamond et al [27] identified that even when funding is available to provide free training, behavioral change is gradual. Before we can begin to address gaps within suicide awareness and prevention skills, we need to first examine NPs' knowledge of and attitudes (stigma) toward suicide prevention.

Aims

Our long-term research goal is to increase suicide knowledge and awareness among NPs in the state of North Carolina. The purpose of this study is to use the Theory of Nursing Care of Patients at Risk of Suicide [28] as a guiding framework to identify NPs' suicide awareness, attitudes (confidence, stigma, facilitators, and barriers), knowledge, and prevention skills. Knowledge from this study is essential to inform the development of policy and a targeted intervention to increase NPs' knowledge of and improve their attitudes toward suicide awareness and prevention.

The aims of this study are to (1) explore NPs' knowledge of and attitudes toward suicide awareness and prevention; (2) examine the differences in NPs' suicide awareness and prevention skills based on practice specialty; (3) identify enablers and barriers to NPs' awareness and confidence of suicide prevention skills.

Theoretical and Conceptual Framework

Billings [29] identified that nurses should be prepared to recognize suicide risk factors and risk predictors so that they can make sensible and sound nursing decisions. Midence et al [30] used a questionnaire to investigate a sample of nurses' (n=27) views on the effects on them of patient suicides, and 45% (n=12) of the respondents said that suicide could be prevented if all patients were assessed for suicide risk. For this study, the Theory of Nursing Care of Patients at Risk for Suicide and the Theory of Planned Behavior were used in developing the study aims, design, measure selection, and qualitative inquiry and analysis. Specifically, the Theory of Nursing Care of Patients at Risk of Suicide was used as a guiding framework to identify NPs' suicide awareness, attitudes (confidence, stigma, facilitators, and barriers), knowledge, and prevention skills [28]. Based on a grounded theory approach, the Theory of Nursing Care of Patients at Risk of Suicide guides the nurses as they initiate and maintain therapeutic relationships with patients who are at risk for suicide [28]. The core category of this theory is the provision of safe and compassionate care via the therapeutic relationship. Additional categories linked to this core category include the following: providing holistic assessments, providing protection, providing basic care, and promoting healing through advanced care [28]. This theory has been identified as one that can advance the quality of care provided by nurses with their potential to instill hope in patients that have lost their ability to cope with life's events [28]. Moreover, the theory of planned behavior posits that human behavior is guided by three considerations leading to the formation of intention and then behavior: (1) beliefs about likely outcomes and evaluations of behaviors (*behavioral beliefs*), (2) beliefs about normative expectations of others and motivation to comply (*normative beliefs*), and (3) beliefs about the presence and power of factors that may facilitate or impede the performance of the behavior (*control beliefs*) [23,31]. Increasing awareness of suicide-related facts, risk factors, and prevention approaches may increase knowledge and, in turn, confidence in skills related to suicide prevention via influencing behavioral, normative, and control beliefs. Thus, increases in knowledge and confidence in skills may make it more likely that an individual will engage in suicide prevention behaviors such as suicide risk assessments and referrals [23].

Methods

Study Design

An observational mixed methods approach will be used for this study. Because the data collection questionnaires include forced choices and the prevention needs of NPs based on specialty practice have not been explored, the mixed method design is appropriate to address the objectives of the study. Descriptive statistics will be used to compute means and SDs for numerical variables and frequencies for categorical variables. Demographic and background information regarding age, gender, professional role, education, and previous suicide prevention training will be collected [32].

Qualitative Data

A cross-sectional survey design including a series of interviews for a small selection of nurses who have completed the survey will be used. Qualitative interviews will be audio recorded and fully transcribed removing any identifiable data to preserve participant anonymity [8]. Qualitative content analysis will be conducted on the open-ended questions [33]. We will use interpretative phenomenological analysis (IPA). IPA makes sense of the participant's experiences by seeking to understand the cognitive, affective, linguistic, and physical being while maintaining the researcher as an integral part of the sense-making process [34-38]. This methodology is best used in studies where the objective is to explore the meaning behind the experiences of participants. IPA is an especially fitting research approach when the researcher intends on asking complex, broad, and open-ended questions [34-38], as is the case in this research proposal. In keeping with the open-ended nature of qualitative research, this method allows the researcher to explore the research question in a flexible nonprescriptive manner, thus facilitating a more thorough exploration [34-38].

Quantitative Data

First, quantitative data will be collected using the *Suicide Knowledge and Skills Questionnaire* [39] *and the Suicide Stigma Scale (Brief version)* [40] questionnaire. An email will be sent

XSL•FO
RenderX

to the NPs explaining the purpose of the study. If they consent, they will click on a link to access the surveys on a secure site. In our previous research with this sample, email reminders to nonresponders after 2 and 4 weeks were sent [41]. The quantitative component will be used to inform the qualitative interviews of this study.

Quantitative Component-Measures

The Suicide Knowledge and Skills Questionnaire [39] is a 13-item questionnaire comprising 2 subscales: suicide knowledge and suicide skills. The items in this survey were based on the 100-item Suicide Opinions Questionnaire (SOQ) [23,39]. The SOQ consists of 8 subscales derived using expert consensus and empirical tests for internal consistency. The Suicide Knowledge and Skills Questionnaire has 9 items that parallel the items on the SOQ, and it will assess participants' knowledge about suicidal behavior and comfort dealing with suicidal clients [39]. The Suicide Knowledge subscale included 9 items that will reflect either truth or falsehood about suicide. Moreover, the Suicide Skills subscale has 4 items that assess the respondents' comfort dealing with suicidal clients in terms of their confidence in their training, skills, and supervision received [23,39]. All questions are rated on a 5-point Likert scale (1 completely disagree, 2 disagree, 3 don't know, 4 agree, and 5 completely agree). An example item is as follows: "I am comfortable asking direct and open questions about suicide," "I have received the training I need to engage and assist those with suicidal desire and/or intent [23,39]." The questionnaire takes 10 minutes to complete. The survey has been shown to differentiate between those with suicide training and those without and has a Cronbach α score of .84 [23,39]. *The Suicide Stigma Scale (Brief version)* [40] is a 16-item survey that assesses stigma regarding suicide. The items are measured on a 5-point Likert scale (1, strongly disagree to 5, strongly agree), has a Cronbach α of .98 and takes 10 minutes to complete [40].

Demographic Survey

Participants will report demographic data such as age, gender, specialty, education level, years of NP experience, previous suicide prevention training, and experience with suicidal patients.

Recruitment and Participants

Sampling Strategy and Power Analysis

The researchers will use the North Carolina Board of Nursing database for NPs registered to practice in the state. Inclusion criteria are as follows: (1) a licensed NP in the state of North Carolina and (2) able to give consent. Exclusion criteria include not being able to provide consent and not being a NP in the state of North Carolina. Our study is powered to detect the primary outcome of suicide knowledge subscale differences among nursing specialties and controlling for other demographic characteristics. Smith et al [23] used an analysis of covariance model (ANCOVA) design and reported between-group differences of approximately 0.2 and an interrespondent SD of 1.53, which leads to an implied effect size of f=0.13. However, since their study involves comparisons among other health professionals as well, we account for effect size uncertainty by using a mid-point between this informative choice and an uninformative small effect size of f=0.10, leading to f=0.115 [23]. We assume an attrition level in line with a recent study in which we used the same recruitment strategy and population [41]. We anticipate sufficient respondents from (or grouping respondents into) 5 core specialties (family, pediatric, adult gerontology acute care, obstetrics/women's health, and psychiatry). With an 80% power and a 5% alpha, the required sample size before attrition to detect group differences of f=0.115 among 5 specialties, with a conservative upper bound of 0.25 for the multiple correlation from demographic confounders, is 5,535 [42]. This is smaller than the population accessible by the researchers via email (N=10,916). In our previous study, we were able to obtain over 2000 responses without incentives; in this study, we will give US $10 gift cards (first 150 participants) [41].

Study Setting

First, quantitative data will be collected using survey data via a questionnaire. An email will be sent to the NPs, and upon consent, they will have to access the surveys on a secure site. The quantitative component will utilize semistructured interviews via Zoom (Zoom Video Communications, Inc). An interview guide will be developed guided by the Theory of Nursing Care of Patients at Risk of Suicide [28] and quantitative data responses (Multimedia Appendix 1). Consistent with qualitative interviewing methods, we will begin the interview with an introductory statement: "Tell me about your previous experiences with suicide." The process will continue addressing questions focused on suicide knowledge (providing protection and basic care and promoting healing) and awareness (confidence, facilitators and barriers, and experiences). Participants will receive a US $50 gift card for completing the interview process.

Data Collection, Management, and Analysis

Demographic data will be analyzed using descriptive statistics. Differences in questionnaire responses across specialists while controlling for other demographic characteristics will be analyzed with ANCOVA. These data will be analyzed using Statistics for Macintosh (version 28, IBM Corp).

Our qualitative data sampling strategy will use NPs who complete the quantitative surveys. NPs will be able to indicate if they are interested in participating in a virtual interview lasting about 50 minutes to identify facilitators and barriers to suicide knowledge and awareness. A representative sample of NPs based age, gender, ethnicity, specialty practice, and location (rural vs urban) using an address to identity (N=15 or until saturation) will be interviewed for part two of the study.

The semistructured interviews will be recorded and transcribed verbatim. The data will be managed using NVivo software (QSR International) for content analysis and analyzed for points of convergence and divergence.

Confidentiality

Participants will be informed that safeguards have been put in place to protect confidentiality and anonymity. All study-related information and spreadsheets will be stored in a locked office and file cabinet. All participant information will be coded by

XSL•FO
RenderX

identification number to maintain confidentiality. We will protect confidentiality by removing all identifiers. Only members of the research team will have access to the data, and only aggregate data will be presented for publication.

Ethics Approval

Approval from the University of North Carolina at Charlotte institutional review board (IRB-22-0925) was required since the protocol is categorized as a research study [43]. The study's protocol, surveys, and informed consent forms were reviewed to ensure respect, fairness, and safety in human subjects research [44]. The protocol was followed in accordance with the standards for human subjects research. The study participants will be given the opportunity to opt out and will be informed of their right to privacy. Each member of the research team has completed the required training on proper methods of conducting research in compliance with federal and state requirements [44].

Instruments

The instruments and the reliability and validity values to be used in our pilot study are shown in Table 1.

Table 1. Instruments and reliability values of this study.

Study outcome	Instrument	Reliability values
Demographic survey: participants will report demographic data such as age, gender, specialty, education level, years of nurse practitioner experience, previous suicide prevention training, and experience with suicidal patients.	Demographic survey	N/A[a]
Nurse practitioner knowledge and skills-Suicide	Suicide Knowledge and Skills Questionnaire [39]	Cronbach α score of .84
Nurse practitioner stigma-suicide	Suicide Stigma Scale (Brief version) [40]	Cronbach α score of .98

[a]N/A: not available.

Timeframe

The project can be completed within 12 months. We anticipate no problems in recruiting subjects for the proposed study. The timeline for this study is shown in Table 2.

Table 2. Research tasks timeline.

Research tasks	Jan-Apr 2022	May-Dec 2022	Dec-Feb 2023	Feb-May 2023
Obtain institutional review board approval, send surveys, and email reminders	✓	—[a]	—	—
Recruit for qualitative interviews and analyze quantitative data	—	✓	—	—
Conduct interviews and analyze data	—	—	✓	—

[a]Not applicable.

Strengths and Limitations

In this pilot feasibility study, we will have a sample of convenience, which may result in response bias. We are recruiting participants who are NPs in the state of North Carolina. Hence, the findings may be different from those who are MDs or PAs. For future research, we may consider the inclusion of additional clinicians like MDs or PAs. The strengths include the capacity to reach all registered NPs in the state of North Carolina.

Results

Overview

The institutional review board's approval was obtained in April 2022. Recruitment occurred between summer and winter 2022. Data analysis is to be completed by the second quarter of 2023. Our study is expected to conclude in the second quarter of 2023. We will submit a manuscript for publication consideration by the third quarter of 2023.

Anticipated Findings

We hypothesize that NPs will endorse self-efficacy working with suicidal clients, familiarity using evidence-based assessment procedures, and identifying best practices for suicide prevention [45].

Discussion

Principal Findings

In this study, we describe a protocol for examining NPs' knowledge of and attitudes (stigma) toward suicide prevention. This represents a first step in addressing gaps within suicide awareness and prevention skills, among NPs in their respective practice settings or sites. Telepsychiatry interventions and digital tools (eg, mobile apps, internet chatbots, and videoconferencing)

XSL•FO
RenderX

have proliferated rapidly in response to the COVID-19 emergency [10]. It is important for NPs to be aware of the various resources to help them with their assessment of patients. One of the most effective ways to combat serious public health problems, like suicide, is to increase knowledge about risk factors, assessment procedures, and treatment options [23]. Gold-standard evidence-based training approaches aim to improve both knowledge and skills about suicide and how to intervene and include some form of didactic training (in-person or web-based) with a demonstration or modeling of suicide prevention skills, opportunities to practice these skills, and expert coaching and feedback on practicing these skills [21]. Many also target attitudes for increasing willingness and motivation to engage in suicide prevention activities given that stigma, anxiety, and unhelpful myths about suicide are common among the general population and professionals [21]. Lastly, we hope this protocol paper will provide a roadmap and resources for other researchers who would like to implement a similar approach in their studies [45]. It has been suggested that when screening programs and training programs have been implemented in different medical care settings patients at risk for suicide who would otherwise have gone unnoticed have been identified [21].

Future Directions

We have developed a strategic dissemination plan. The research process and our findings will be shared with university colleagues and clinical providers, in a peer-reviewed journal, and at a research conference.

Conclusions

This study will close the gap in identifying NPs' knowledge of and attitudes toward suicide awareness and prevention. In addition, the results with help to examine differences in NPs' suicide awareness and prevention skills based on practice specialty. Finally, we expect our results to identify enablers and barriers to NPs' awareness and confidence in suicide prevention skills. The study's findings will add to the current literature on NPs' knowledge of and attitudes (stigma) toward suicide prevention. Our study results may inform practice, policy, further research, and training. The results may shape how members of the health care system respond to people who are at risk of suicide and their families [36]. It represents a first step in addressing gaps within suicide awareness and prevention skills, among NPs in their respective practice settings.

Acknowledgments

This project is funded by the Faculty Research Grants program through the Office of the Vice Chancellor for Research and Economic Development at the University of North Carolina at Charlotte.

Data Availability

The data sets generated during or analyzed during this study are not publicly available but are available from the corresponding author on reasonable request.

Abstract

Background: Dry eye disease (DED) is one of the most common ocular surface diseases. Numerous patients with DED remain undiagnosed and inadequately treated, experiencing various subjective symptoms and a decrease in quality of life and work productivity. A mobile health smartphone app, namely, the DEA01, has been developed as a noninvasive, noncontact, and remote screening device, in the context of an ongoing paradigm shift in the health care system, to facilitate a diagnosis of DED.

Objective: This study aimed to evaluate the capabilities of the DEA01 smartphone app to facilitate a DED diagnosis.

Methods: In this multicenter, open-label, prospective, and cross-sectional study, the *test method* will involve using the DEA01 smartphone app to collect and evaluate DED symptoms, based on the Japanese version of the Ocular Surface Disease Index (J-OSDI), and to measure the maximum blink interval (MBI). The *standard method* will then involve a paper-based J-OSDI evaluation of subjective symptoms of DED and tear film breakup time (TFBUT) measurement in an in-person encounter. We will allocate 220 patients to DED and non-DED groups, based on the *standard method*. The primary outcome will be the sensitivity and specificity of the DED diagnosis according to the *test method*. Secondary outcomes will be the validity and reliability of the

XSL•FO
RenderX

test method. The concordance rate, positive and negative predictive values, and the likelihood ratio between the *test* and *standard methods* will be assessed. The area under the curve of the *test method* will be evaluated using a receiver operating characteristic curve. The internal consistency of the app-based J-OSDI and the correlation between the app-based J-OSDI and paper-based J-OSDI will be assessed. A DED diagnosis cutoff value for the app-based MBI will be determined using a receiver operating characteristic curve. The app-based MBI will be assessed to determine a correlation between a slit lamp–based MBI and TFBUT. Adverse events and DEA01 failure data will be collected. Operability and usability will be assessed using a 5-point Likert scale questionnaire.

Results: Patient enrollment will start in February 2023 and end in July 2023. The findings will be analyzed in August 2023, and the results will be reported from March 2024 onward.

Conclusions: This study may have implications in identifying a noninvasive, noncontact route to facilitate a diagnosis of DED. The DEA01 may enable a comprehensive diagnostic evaluation within a telemedicine setting and facilitate early intervention for undiagnosed patients with DED confronting health care access barriers.

Introduction

Dry eye disease (DED) is one of the most frequently encountered ocular surface diseases, with a prevalence ranging from 5% to 50% [1,2], which is projected to increase, likely due to the worldwide trend toward an aging population and lifestyle changes associated with a digitalized society [1-4]. DED-related symptoms are detrimental to quality of life (QoL) and work productivity, leading to society-wide economic loss [5,6]. Subjective DED-related symptoms are highly variable and include ocular dryness, eye discomfort, eye strain, decreased visual acuity, and photophobia [7-11]. Additionally, DED is highly heterogeneous, with patients presenting with seemingly unpredictable combinations of the abovementioned symptoms. Therefore, patients with DED are prone to having their nonspecific presentations overlooked, and many are left undiagnosed without appropriate management [3,9,12-14]. There is no definitive cure for DED, and current standards of care comprise ex post facto symptom management, highlighting the importance of early diagnosis and intervention to prevent disease progression and longstanding damage [15-19].

Concerning DED diagnosis, Tear Film & Ocular Surface Society and Asian Dry Eye Society criteria recommend evaluating a patient's subjective symptoms and tear film breakup time (TFBUT) [20,21]. However, TFBUT measurement is inherently invasive owing to the need for sodium fluorescein application, and measurements under light microscopy are required [20-23]. The ongoing COVID-19 pandemic has also increased the demand for a noninvasive alternative that could be used in remote settings [24,25]. One major obstacle to DED diagnosis in the context of telemedicine is the inability to evaluate the ocular surface and the use of slit-lamp microscopy in TFBUT, and clinicians may be solely reliant on subjective symptoms for diagnosis. Therefore, identification of a novel proxy for existing invasive examinations is needed for a reliable, noninvasive DED diagnosis.

Recent studies have suggested the maximum blink interval (MBI) measurement as a noninvasive alternative to TFBUT, with the MBI defined as the maximum length of time a patient is able to keep their eyes open between 2 blinks [26]. A positive correlation has been reported between the MBI and TFBUT, likely owing to the MBI's capability to reflect ocular surface integrity [26-30]. The simplicity and noninvasive nature of MBI measurements underscores its candidacy as an alternative to TFBUT for screening purposes. Our earlier studies have indicated that the concomitant use of the MBI and the Ocular Surface Disease Index (OSDI) questionnaire can determine DED with similar accuracy to standard diagnostic methods using TFBUT and the OSDI [31,32].

Mobile health (mHealth) is defined by the World Health Organization as "medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices" [33]. The capability of mHealth to digitally perform therapeutic activities has raised the interest of clinicians and providers due to its potential use in disease prevention, diagnosis, and treatment through commonplace smart devices [32,34-39]. Previous studies concerning the validity and reliability of smartphone-based administration of MBI examinations and OSDI questionnaires yielded a satisfactory result [3,32,40]. Reported findings suggest that noninvasive and nonintrusive DED screening during activities of daily living may be possible, enabling an earlier DED diagnosis and interventions in remote settings [40,41]. More importantly, this possibility may have implications in accurately identifying undiagnosed patients with DED, allowing for timely intervention, preventing a further decrease in QoL, and reducing societal economic loss.

In this clinical study, we intend to use an in-house smartphone app, namely, the DEA01, which has been designed as an investigational device to facilitate a DED diagnosis. This study

XSL•FO
RenderX

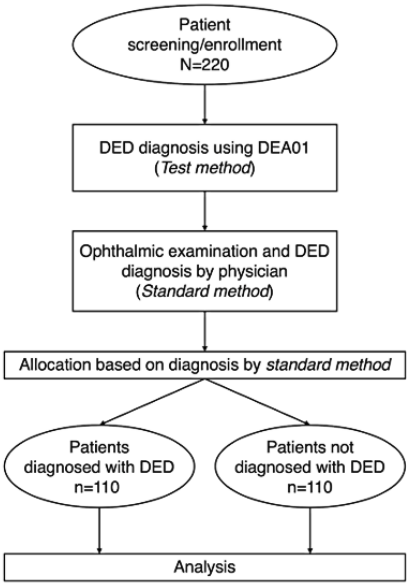
will aim to evaluate the capabilities of the DEA01 in facilitating a diagnosis of DED.

Methods

The DEA01 Smartphone App

The DEA01 smartphone app for DED diagnostic assistance was developed by InnoJin, Inc. It will be available on Apple's App Store and the Google Play Store. As of December 2022, it has not yet been approved as software for a medical device in Japan. The DEA01 collects dry eye symptoms using the OSDI and MBI to facilitate a DED diagnosis [32]. Blinking is measured using the smartphone camera and the *CIFaceFeature* function in the iOS interface for facial detection. DEA01 version 1.0 will be installed on an iPhone 13 Pro (Apple Inc). The app will be modified should minor issues arise during the study. Screenshots of the current version of the DEA01 (December 2022) are shown Figure 1.

Figure 1. Screenshots of DEA01: screenshots of the (A) welcome screen, (B) Ocular Surface Disease Index (OSDI) questionnaire, (C) measurement of the maximum blink interval, and (D) examination result screen for dry eye diagnostic assistance.



Objective

This study's primary objective is to evaluate DED diagnostic accuracy using the DEA01 smartphone app compared with standard DED diagnostic methods.

Study Design

In this multicenter, open-label, prospective, and cross-sectional study, patients will be evaluated for DED using the DEA01 (*test method*). A physician will then provide a DED diagnosis based on 2016 Asia Dry Eye Society criteria [20] (*standard method*). To ensure that the *test method* will not affect a patient's treatment plan, the physician will make a diagnosis using only *standard method* results without reviewing *test method* results. A minimum number of 220 patients will be enrolled, with patients allocated into a DED group or a non-DED group based on the diagnosis obtained using the *standard method*. The study design is shown in Figure 2.

Figure 2. Study flowchart. DED: dry eye disease.

XSL•FO

Ethics Approval

This study has been approved by the Juntendo University Certified Review Board, Tokyo, Japan (approved protocol V.1.1.1, dated December 19, 2022; approval number: J22-003). Patients will have the option to voluntarily provide written informed consent to participate in the study. Written consent will be obtained from a patient's parent or legal guardian for patients aged <20 years. All involved parties will make every effort to protect study patients' personal information and privacy. Patient-related data will be anonymized, and research-related data and the smartphones used in this study will be stored in locked lockers at each collaborating institution, with access strictly controlled by the research staff. All patients will receive a 1000-yen (US $7.77) voucher.

Study Setting

This study will be conducted between February 1, 2023, and November 30, 2023. Patients will be recruited from the Departments of Ophthalmology at 3 medical institutions, namely, Juntendo University Hospital, Tokyo, Japan [42]; Toho University Omori Medical Center, Tokyo, Japan; and Tokyo Dental College Ichikawa General Hospital, Chiba, Japan.

Patient Selection

Outpatients who visit the Ophthalmology Departments of the cooperating hospitals will be recruited for the study. Enrolled patients will include those with DED and other concomitant ocular diseases. Inclusion and exclusion criteria are shown in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

1. Patients with dry eye disease (DED) or suspected DED
2. Patients aged ≥16 years at the time of providing informed consent
3. Patients able to use smartphones
4. Patients/guardians who, after receiving a full explanation concerning participation in the study and with a full understanding of the study, voluntarily provide written consent to participate

Exclusion criteria

1. Patients with eyelid closure disorder, ptosis, psychiatric disorders, and Parkinson disease
2. Patients who wear contact lenses
3. Patients who are unable to comply with the study protocol for physical or mental reasons
4. Patients whom the principal investigator deems unsuitable to participate in this study

Patient Withdrawal

Patients will be withdrawn from the study if, due to the occurrence of other diseases, it is deemed difficult to continue the research; if patients or their parents/guardians request to terminate their participation in the research; if the research study is discontinued; or if the principal investigator and subinvestigators determine that it is appropriate to discontinue the research.

Study Procedures

After enrollment in the study, patients will be evaluated for DED by clinical research coordinators using the DEA01. A physician will diagnose DED using the *standard method* without checking *test method* results. Details regarding the *test method* and *standard method* are shown in Textbox 2.

Textbox 2. Test and standard method.

Test method

- Dry eye disease (DED) diagnosis based on the app-based Japanese version of the Ocular Surface Disease Index (J-OSDI) and maximum blink interval (MBI), using the DEA01
- Patients will respond to the app-based J-OSDI questionnaire and be measured using the app-based MBI on the DEA01. The J-OSDI questionnaire is used to evaluate the subjective symptoms of DED on a 100-point scale [43,44]. The MBI will be defined as the length of time that a patient can keep their eyes open before blinking [26]. The app-based MBI will be measured using the smartphone's camera on the DEA01 and a visually confirmed MBI will be measured using a stopwatch.

Standard method

- DED diagnosis using a paper-based J-OSDI and tear film breakup time (TFBUT)
- Patients will respond to the paper-based J-OSDI questionnaire and be measured using TFBUT [20]. The diagnosis of DED using the *standard method* will be based on 2016 Asian Dry Eye Society criteria, with positive subjective symptoms (J-OSDI total score ≥13) and decreased TFBUT (≤5.0 s) being used to diagnose DED [20]. Based on the diagnosis using the *standard method*, patients will be allocated to DED and non-DED groups.

XSL•FO
RenderX

Data Collection and Outcome Assessments

The data collection items are shown in Textbox 3. The assessments will be done according to a predetermined sequence. First, the assessment of subjective symptoms of DED using the app-based J-OSDI and MBI on the DEA01 will be conducted as the *test method* by trained clinical research coordinators. The physician will not be informed of the *test method* results. The physician will then perform clinical examinations for DED, using the *standard method* and ophthalmic examinations. Clinical examinations for DED will include an evaluation of subjective symptoms of DED using the paper-based J-OSDI questionnaire, slit lamp–based MBI, TFBUT, corneal fluorescein staining (CFS), and tear secretion volume using Schirmer test I. The ophthalmic examinations will include measurement of visual acuity, intraocular pressure, and slit-lamp microscopic photography. All examinations will be performed within one day.

Textbox 3. Data collection.

Patients' characteristics

- Age, sex, medical history, and medication

Test method

- Subjective symptoms of dry eye disease (DED) evaluated using the app-based the Japanese version of the Ocular Surface Disease Index (J-OSDI) on the DEA01
- Visually confirmed maximum blink interval (MBI)
- App-based MBI

Standard method

- Subjective symptoms of DED evaluated using the paper-based J-OSDI
- Tear film breakup time

Other DED examinations

- Corneal fluorescein staining
- Slit lamp–based MBI
- Tear secretion volume using Schirmer test I

Ophthalmic examinations

- Visual acuity
- Intraocular pressure
- Slit-lamp microscopy

Other outcomes

- DEA01 failure
- DEA01 operability and usability
- Adverse events

The Japanese Version of the OSDI

The Japanese version of the OSDI (J-OSDI) is a questionnaire comprising 12 questions to evaluate subjective symptoms of DED and has been validated in Japan as an OSDI-equivalent questionnaire for DED diagnosis [43-45]. Patients will answer each question on a scale ranging from 0 to 4, with 0 indicating "none of the time" and 4 indicating "all of the time." For questions 6 through 12, if a question is not applicable to a patient, they can select "not applicable." The J-OSDI results are reported on a 100-point scale to determine the severity of DED symptoms. The J-OSDI total score is calculated according to the following formula [43,44]:

(1)

TFBUT

TFBUT will be measured using sodium fluorescein to assess tear film stability [20]. To minimize the effect of a test strip on tear volume and TFBUT, a small amount of dye will be administered using wet fluorescein strips. After the dye is instilled, the patients will be instructed to blink 3 times to ensure that the dye is uniformly incorporated into the tear film. The time interval between the last blink and the appearance of the first dark spot on the cornea will be measured, and the average value from 3 measurements will be used as the test outcome. A cutoff TFBUT value of ≤5.0 seconds will be used to diagnose DED [20].

XSL•FO
RenderX

MBI

The MBI is defined as the length of time that a patient is able to keep their eyes open before blinking during each trial [26]. In the *test method*, the app-based MBI will be measured using the smartphone's camera on the DEA01, and visually confirmed MBI will be measured using a stopwatch by a trained clinical research coordinator. In the *standard method*, the MBI will be measured by a physician using a slit-lamp microscope. In both methods, the MBI will be measured twice for each patient and the average value will be adopted as the result. An MBI exceeding 30 seconds will be recorded as 30 seconds. The MBI cutoff value will be calculated using receiver operating characteristic (ROC) curve analysis [31].

CFS

CFS will be assessed under a slit-lamp microscope with blue light and a yellow band–pass filer according to the van Bijsterveld grading system, in which the ocular surface will be divided into 3 zones: the nasal bulbar conjunctiva, temporal bulbar conjunctiva, and cornea [46]. Each zone will be evaluated on a scale from 0 to 3, with 0 indicating no staining and 3 indicating confluent staining. The maximum potential score is 9.

Schirmer Test I for Tear Secretion Volume

Schirmer test I will be performed without topical anesthesia after all other examinations. A Schirmer test strip will be placed on the outer one-third of the temporal lower conjunctival fornix for 5 minutes. The length of the moisture stain on the filter paper (in mm) will be recorded [47].

Environmental Conditions

The temperature of the examination room will be set at 26 °C in summer and at 24 °C in winter, with a constant relative humidity of 50%, following *Guidelines for Design and Operation of Hospital HVAC Systems*, established by the Healthcare Engineering Association of Japan [48].

Primary Outcome

The primary outcome will be the sensitivity and specificity of the *test method* for DED diagnosis, compared with the *standard method*. Sensitivity and specificity will be calculated based on the diagnostic results of the 2 methods. In the *test method*, an app-based J-OSDI total score ≥13 measured using the DEA01 and an MBI score greater than the cutoff value based on the secondary outcome (5) will be considered DED positive. In the *standard method*, a paper-based J-OSDI total score ≥13 and TFBUT ≤5.0 seconds will be considered DED positive.

Secondary Outcomes

Secondary outcomes are as follows:

1. An overall concordance rate between the *test method* and *standard method*
2. A positive/negative predictive value between the *test method* and *standard method*
3. A positive/negative likelihood ratio between the *test method* and *standard method*
4. An area under the ROC curve of the *test method* for DED diagnosis using the *standard method*
5. An MBI cutoff value of the *test method* for DED diagnosis using the *standard method*
6. An area under the ROC curve of the *test method* for TFBUT ≤5.0 seconds
7. An MBI cutoff value of the *test method* for TFBUT ≤5.0 seconds
8. Internal consistency of the app-based J-OSDI
9. Correlation, agreement, and comparison between the app-based J-OSDI and paper- based J-OSDI
10. Correlation, agreement, and comparison between the app-based MBI and slit lamp– based MBI
11. Correlation and comparison between TFBUT and the app-based MBI
12. Correlation and comparison between TFBUT and slit lamp–based MBI
13. DEA01 operability and usability
14. DEA01 failure
15. Adverse events

Secondary outcomes 1 to 4 were set to evaluate the DED diagnosis accuracy of the *test method* compared with that of the *standard method*. Secondary outcome 5 was included to determine the cutoff value for the app-based MBI using ROC analysis for DED diagnosis. Secondary outcomes 6 and 7 were included to determine if MBI measurements could be used as a substitute for TFBUT measurements. Secondary outcomes 8 and 9 were set to evaluate the reliability and validity of the app-based J-OSDI. Secondary outcomes 10 to 12 were set to evaluate the validity of app-based and slit lamp–based MBIs. In secondary outcome 13, patients will answer the following questions: "I think it's easy to operate this smartphone app," "I can use this smartphone app by myself," "I want to be tested using this smartphone app rather than being tested at a medical institution," and "I will continue to use this smartphone app" [49,50]. Patients will answer these questions on a 5-point Likert scale (1, strongly disagree; 2, disagree; 3, neutral; 4, agree; and 5, strongly agree) [51]. Secondary outcomes 14 and 15 were set to evaluate the safety and stability of the DEA01. DEA01 failure is defined as something not working as expected. Adverse events comprise unexpected signs, symptoms, or diseases encountered during the clinical trial, regardless of whether they are related to treatment. If serious adverse events or failure occur, these will be referred to the Juntendo Hospital Certified Review Board, and appropriate treatments will be provided as needed.

Sample Size and Statistical Analyses

In total, the enrollment of a minimum number of 220 study patients will be required. The CI for the sensitivity and specificity of the *test method* is set at ±10%. It is possible to calculate a sample size and a CI (a margin of error) using the following formula [52]:

(2)

Therefore, the minimum sample size will be 100 patients in each group. To meet the minimum required number of patients in each group, the target total number of patients will be set at

XSL•FO
RenderX

110 for each group, assuming a 10% exclusion rate due to missing data.

For the primary end points, the sensitivity and specificity of DED diagnosis using the DEA01 will be calculated using ROC curve analysis with the cutoff value for the app-based MBI in the *test method*. This cutoff value will be calculated using ROC curve analysis [31]. The ROC curve will show sensitivity (positive rate) on the vertical axis and 1-specificity (false positive rate) on the horizontal axis, and the plots will be connected using straight lines. The point at which the sensitivity and specificity for DED diagnosis using the app-based MBI will be maximized and will be set as the cutoff value for MBI [31].

The secondary outcomes of the overall concordance rate, positive/negative predictive value, and positive/negative likelihood ratio will be calculated by comparing the DED diagnosis results from the *test method* with the results from *standard method* in a mixed matrix. The diagnostic performance of DEA01 will be evaluated through calculating the area under the ROC curve plotted from the sensitivity and specificity of the *test method*. The substitutability of MBI measurement for TFBUT measurement in DED diagnosis will be assessed using ROC curve analysis and through calculating the area under the ROC curve, using the cutoff value of the app-based MBI for TFBUT ≤5 seconds. The internal consistency of the app-based J-OSDI will be evaluated using factor analysis and Cronbach α coefficient, with $\alpha>0.70$ considered an acceptable range [53]. Correlation and consistency will be evaluated using Pearson or Spearman correlation coefficients, an intraclass correlation coefficient, and Bland-Altman analysis. In each patient group, study patients' backgrounds will be analyzed using a 2-tailed unpaired *t* test for continuous variables and a chi-square test for categorical variables. If a continuous variable does not clearly follow a normal distribution, it will be appropriately transformed to a logarithm and aggregated with the mean and SD or the median and IQR will be used as descriptive statistics. The operability and usability of the DEA01 will be evaluated in each group using the average score of the 5-point Likert scale responses to the operability and usability questions and the number of patients who answered better or worse than neutral using 2-tailed unpaired *t* and chi-square tests. For safety assessment, the frequency and rate of adverse events will be calculated for each group, and between-group comparisons will be performed using Fisher exact probability or chi-square tests.

A 2-sided level of significance will be set at 5%, and the confidence coefficient will be set at 95%, unless otherwise specified. Missing value completion will not be performed.

Data Management

Data management will be conducted at an off-campus data center designated by the Juntendo University Certified Review Board in accordance with a preprepared data management plan. Data will be collected and linked at several points in time. Following database locking, locked data will be transferred to the person responsible for statistical analysis.

Results

This study will start on February 1, 2023, at 3 medical institutions in Japan. Patient enrollment is expected to begin on February 1, 2023, and will end on July 31, 2023. Data will be analyzed in August 2023, and the results will be reported from December 2023 onward.

Discussion

A recent report suggested that a significant portion of patients with DED might currently be left undiagnosed and experiencing a preventable decrease in QoL [13]. For those who are appropriately diagnosed, barriers to receiving care remain, including limitations related to employment, education, and the ongoing COVID-19 pandemic. Hence, there is a need for a nonintrusive, telehealth-based alternative to current in-person evaluations. In this study, the capabilities of a smartphone app-based diagnostic assistive device will be investigated in a multicenter, open-label, prospective, and cross-sectional study. The results are intended to demonstrate the reliability and validity of the DEA01 as a noninvasive tool to facilitate a diagnosis of DED, through determining the appropriate MBI cutoff value. Confirmation of the value of the DEA01 is likely to facilitate early intervention and greater outreach to undiagnosed populations with DED.

The health care paradigm is rapidly shifting to promote remote and online care given societal changes implemented during the ongoing COVID-19 pandemic [32]. Notably, for glaucoma- and diabetes-related retinopathy management, a new approach has been sought to monitor disease progression at home through the use of portable devices and to offer visits for ocular anomalies of concern [54]. This study aims to establish a new means to facilitate DED diagnosis in a nonintrusive, noninvasive manner using the DEA01 smartphone app, which can yield an objective metric for clinicians to evaluate remotely. This may lead to a global shift toward endorsing telehealth and thus, increasing accessibility and helping to remove barriers to health care. The potential to promote early diagnosis and intervention can dramatically affect disease prognosis on a global scale. Additionally, such apps are well aligned with the current paradigm shift away from standard facility-oriented care and toward a daily life–oriented longitudinal, human-centered health care approach [40,55,56].

The DEA01 is used to help assess subjective symptoms and collect objective findings through OSDI administration and MBI measurements, respectively. The reliability and validity of the MBI and OSDI in a remote setting to facilitate DED diagnosis have been previously shown through a previous DEA01 app designed for DED research, namely, DryEyeRhythm [31,32]. Additionally, discrepancies between results obtained from the standard paper-based OSDI and app-based OSDI have been previously shown to be acceptable [32]. Our prior study utilized the MBI cutoff derived from a slit-lamp microscopy–based MBI study [26]. This study aims to establish an MBI cutoff for smartphone app-based diagnosis assistance for DED. The establishment of an optimal MBI cutoff value

XSL•FO
RenderX

will enable more robust and reliable app-based remote DED diagnosis assistance through the use of the DEA01.

In this study, the diagnostic performance utilizing the app-based MBI as a proxy for the standard TFBUT will be evaluated using the DEA01. TFBUT reflects tear film stability and homeostasis, acting as a critical component of DED diagnosis. However, it requires specialized tools and materials, including fluorescein dye and slit-lamp microscopy. Moreover, the invasive nature of the examination disrupts the in vivo status of the tear film and the ocular surface [20-23]. Some studies have shown that fluorescein dye results are not consistently reproducible and that the dye may negatively affect the stability of the tear film [57-59]. The MBI has been shown to have a positive correlation with TFBUT [26], suggesting that the MBI can be used as a noninvasive, nonintrusive metric to substitute for TFBUT. An online screening test, based on a patient's self-measurement of the time from stopping blinking to feeling discomfort, has shown the utility of screening for DED detection [26,60]. However, the DEA01 may be more objective as it automatically measures the MBI using the sensors of a smartphone camera and allows for the evaluation of DED symptoms using the J-OSDI questionnaire. This study seeks to assess the viability of replacing TFBUT with app-based MBI measurements, which may enable remote, noninvasive, and nonintrusive diagnosis assistance concerning DED.

This study may have some limitations. First, this study may be affected by selection bias, as study patients are limited to those who have been evaluated in a highly specialized university hospital and those who are able to use the smartphone app [32]. Second, the study will be performed in a specific order. Patients will be required to first use the app, after which there will be a clinical evaluation for DED. This study sequence may be a confounder and might affect the results; therefore, assessing the effects of the examination order in a randomized study may be necessary [61]. Lastly, the DEA01 is designed to be an ancillary tool for initial DED diagnosis assistance, and specialized tests such as corneal staining and Schirmer test may be required to further assess disease severity and progression.

In conclusion, this study will evaluate the capability of the DEA01 in assisting a DED diagnosis. The study findings may potentially help to establish a noncontact, noninvasive, and remote consultation method for app-based DED diagnostic assistance using the mHealth DEA01 smartphone app. It is hoped that the DEA01 will provide effective diagnostic evaluation for DED in telemedicine and allow for early intervention in patients who have not been diagnosed with DED due to limited access to medical care.

Acknowledgments

The authors would like to thank the collaborators of Juntendo University Hospital, Toho University Omori Medical Center, Tokyo Dental College Ichikawa General Hospital, and Juntendo Clinical Research and Trial Center for their research support.

Abstract

Background: The Canadian 24-Hour Movement Guidelines for adults provide specific recommendations for levels of physical activity, sedentary behavior, and sleep (ie, the movement behaviors) required for optimal health. Performance of the movement behaviors is associated with improved mental well-being. However, most postsecondary students do not meet the movement behavior recommendations within the Canadian 24-Hour Movement Guidelines and experience increased stress and declining well-being, suggesting the need for an intervention targeting students' movement behaviors.

Objective: We aimed to develop and implement a theory-informed intervention intended to improve the movement behaviors and mental well-being of first-year postsecondary students.

Methods: The Intervention Mapping protocol was applied in the development and implementation of the intervention. Intervention Mapping entailed performing a needs assessment, determining the intervention outcomes, selecting theory- and evidence-based change methods and applications, preparing and producing intervention plans and materials, developing the implementation plan, and finally developing an evaluation plan. The Theoretical Domains Framework and the Behavior Change Wheel were also used in conjunction with the Intervention Mapping protocol to ensure a solid theoretical basis for the intervention. This protocol led to the development and implementation of a 6-week, theory-informed ParticipACTION app–based intervention aimed at helping first-year postsecondary students improve their movement behaviors and mental well-being. The developed app content provided students with information on each of the movement behaviors and behavioral strategies (ie, goal setting, action planning, monitoring,

XSL•FO
RenderX

and coping planning). The use of Intervention Mapping allowed for the continuous involvement of various multidisciplinary partners and end users, ensuring that the intervention design and implementation was appropriate for the target audience. The feasibility, acceptability, and potential impact of the intervention will be examined in a subsequent proof-of-concept study at 2 Canadian university campuses.

Results: Participant recruitment occurred during September 2021, and the intervention was conducted from October to December 2021. The deadline for completion of the postintervention questionnaire by participants was mid-December 2021. The analysis of data examining the feasibility, acceptability, and potential impact of the intervention began in January 2022, with the publication of the proof-of-concept evaluation expected in 2023.

Conclusions: Intervention Mapping with the Theoretical Domains Framework and Behavior Change Wheel was a useful approach to combine evidence and theoretical concepts to guide the design and implementation of a ParticipACTION app–based intervention targeting postsecondary students' movement behaviors and mental well-being. This process may serve as an example for other researchers developing multiple behavior change app–based interventions. Should the forthcoming evaluation demonstrate the intervention's acceptability, feasibility, and potential impact, the intervention may provide a scalable method of improving postsecondary students' movement behaviors and mental well-being.

Introduction

The Canadian 24-Hour Movement Guidelines (24HMG) for adults aged 18 to 64 years and adults aged 65 years or older [1] provide specific recommendations for ideal levels of physical activity, sedentary behavior, and sleep required for optimal health. Despite the established physical and mental health benefits of increasing physical activity, decreasing sedentary behavior, and ensuring sufficient sleep [1], population-level engagement in these behaviors is suboptimal [2]. Indeed, although a guideline can signal the recommended action, it alone does not guarantee use [3]. As a result, purposefully chosen and implemented evidence-informed efforts to increase the uptake and use (ie, implementation) [4] of the 24HMG among target populations are required.

To address this gap and using an integrated knowledge translation approach [5,6] and the Knowledge-to-Action Framework [6] as an organizing model, the developers of the 24HMG established a knowledge translation team [7] comprising partners (eg, representatives from the Canadian Health Promoting Campuses Network, Canadian Sleep Society, Canadian Medical Association, and Canadian Public Health Association) and researchers who together designed, implemented, and evaluated a strategy to promote adoption of the 24HMG.

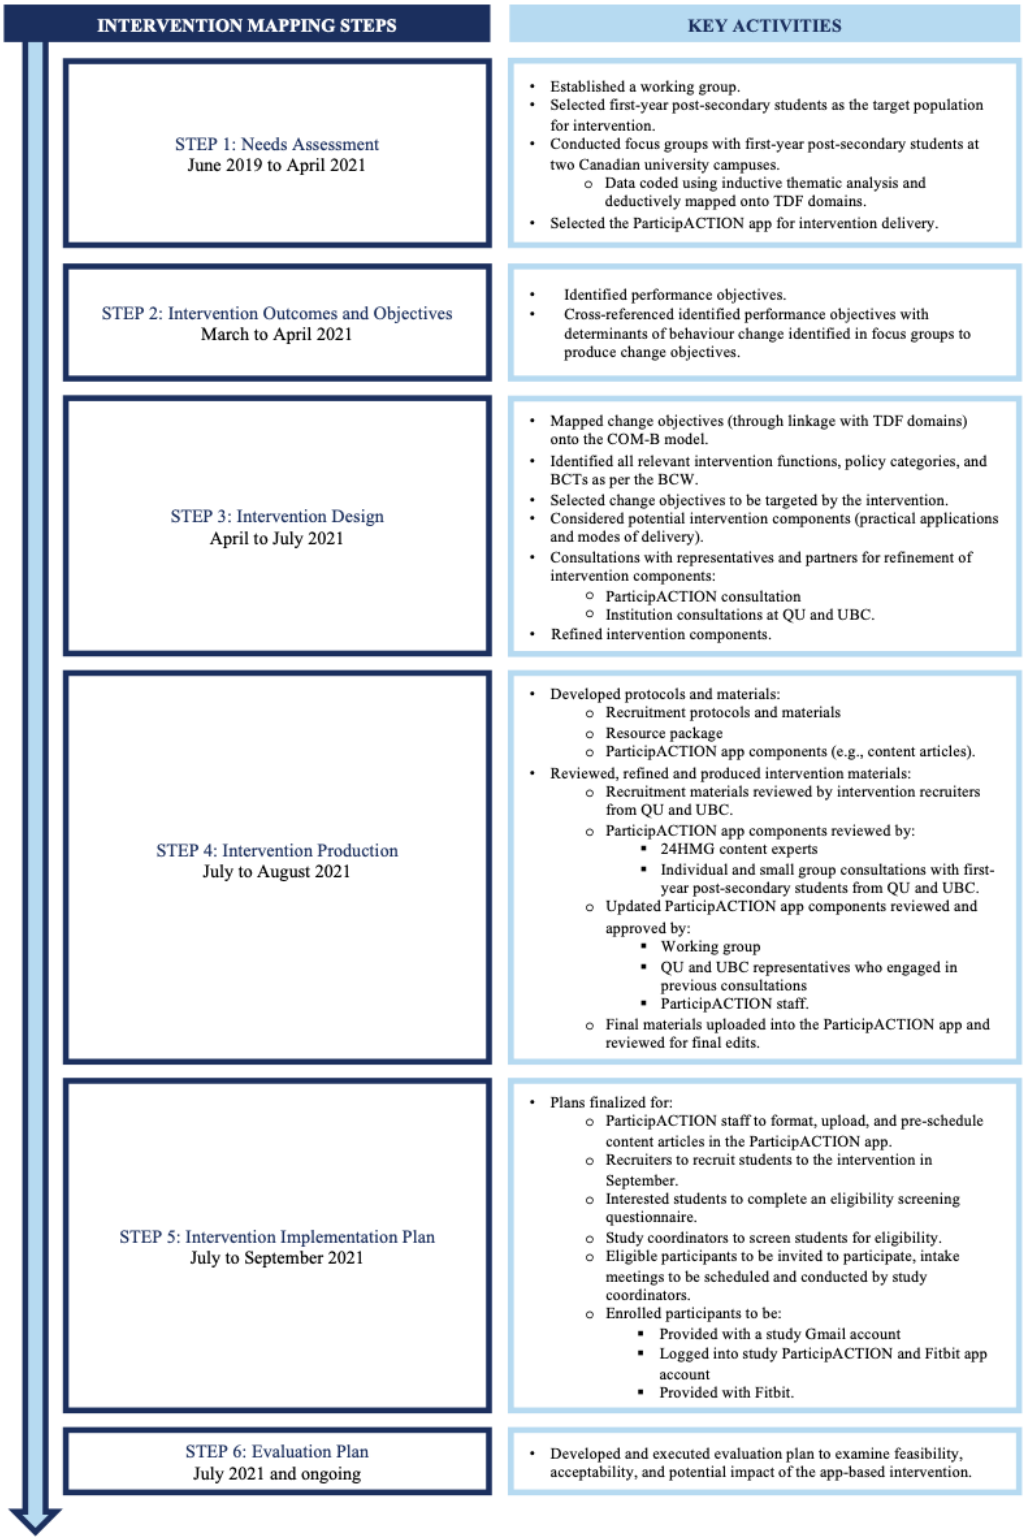
The knowledge translation team identified postsecondary students (ie, students entering or attending college or university, also known as *tertiary education institutions* internationally) as the target audience for guideline implementation (see the study by Tomasone et al [7]). Despite the evidence supporting the link between movement behaviors and impacts on their mental health and well-being [8,9] and academic performance [10], most postsecondary students engage in suboptimal levels of the movement behaviors [9]. Moreover, the COVID-19 pandemic exacerbated students' suboptimal movement levels with stay-at-home orders and widespread remote learning [11-14]. Short-term negative consequences of this change included increased stress and declining mental health and well-being (eg, higher rates of severe anxiety) [15,16]. The long-term impact on students' physical and mental health remains unknown. Thus, an intervention targeting the movement behaviors and mental well-being of postsecondary students was timely and necessary.

Interventions developed using theory may be more effective than those based on little or no use of theory [17]. To inform intervention design and implementation, we applied Intervention Mapping—a rigorous and systematic protocol for developing theory- and evidence-based behavior change interventions [18,19]. Although Intervention Mapping offers an iterative protocol for developing and tailoring an implementation intervention, it was necessary to use other frameworks in conjunction with Intervention Mapping to fully inform design and implementation. The Theoretical Domains Framework (TDF) and Behavior Change Wheel (BCW) were used to help inform the Intervention Mapping protocol. The TDF is a theoretical framework that provides a way to view the cognitive, affective, social, and environmental influences on behavior [20] and maps onto the capability, opportunity, motivation, behavior (COM-B) model within the BCW. At its core, the BCW has the model of behavior known as COM-B, referring to "capability," "opportunity," "motivation," and "behavior," which recognizes that behavior is part of an interacting system involving all these components [21,22]. The BCW identifies different intervention options that can be applied to change each of the components and policies that can be adopted to deliver those intervention options [21,22]. Finally, the BCW involves identifying content and implementation options (ie, identifying behavior change techniques [BCTs] and modes of delivery) [21,22]. Given the complexity of applying these 2 frameworks in conjunction with the Intervention Mapping protocol, this paper provides a systematic description of the process used to design and implement an intervention aimed at improving the movement

XSL•FO
RenderX

behaviors and well-being of first-year postsecondary students (ie, students who have just graduated high school or took a single gap year before entering an undergraduate program and turning 18 years or older).

Methods



Overview

The Intervention Mapping protocol specifies 6 steps for the development of theory and evidence-based interventions [18,19]. Step 1 (the needs assessment) involves establishing a planning or working group, defining the context of the intervention in terms of the health problem and population (ie, intervention target group), establishing the determinants of behavior change (ie, the barriers and facilitators), and finally describing the intervention setting. In step 2, the intervention outcomes are determined, which include performance objectives (ie, behavioral changes necessary to achieve intervention outcomes) and change objectives (ie, specific behaviors that will lead to changes in the behavioral determinants, which are needed to achieve performance objectives). Step 3 involves choosing theory- and evidence-based change methods, selecting or designing practical applications to deliver change methods, and finally refinement of the selected intervention components. Step 4 focuses on intervention production by preparing intervention plans and drafting protocols and materials followed by the pretesting, refinement, and production of intervention materials. In step 5, the development of an intervention implementation plan occurs and includes identifying intervention program users (ie, adopters and implementers). Step 6 comprises specifying an evaluation design and developing the indicators and measures of assessment.

We implemented the first 5 steps in the development and implementation of the intervention. Step 6 (evaluation plan) will be published in detail in a forthcoming proof-of-concept evaluation paper; however, a brief synopsis of the evaluation plan is described in subsequent sections. Figure 1 outlines the 6 Intervention Mapping steps, the period over which each step was performed, and the key activities within each step.

Step 1: Needs Assessment (June 2019-April 2021)

Establish a Working Group

We formed a multidisciplinary team of partners and researchers to create a new working group (see Multimedia Appendix 1 for the working group constituency and roles). Several working group members were members of the original 24HMG Knowledge Translation Advisory Committee [7], and additional members were added to ensure comprehensive expertise for intervention development, implementation, and evaluation. The working group collectively possessed expertise in the 24HMG behaviors, tailored intervention development and delivery, postsecondary student health and well-being, and knowledge translation and behavior change research and evaluation.

XSL•FO
RenderX

Working group members were engaged at various steps of the Intervention Mapping approach.

Description of Health Problem and Intervention Target Group

Three factors contributed to defining the health problem and intervention target group: (1) established, suboptimal performance of the movement behaviors (ie, not meeting 24HMG recommendations); (2) suitability of the intervention target group for receiving a targeted intervention; and (3) adoption of a health-promoting charter directing action at postsecondary institutions.

Postsecondary students are at risk of negative physical and mental health impacts associated with suboptimal performance of the movement behaviors. In the first deployment of the Canadian Campus Wellbeing Survey in early 2020, Weatherson et al [9] reported that only 9.9% of postsecondary students achieved 4 components of the 24HMG (moderate to vigorous physical activity, total sitting time, recreational screen time, and sleep). Large decreases in physical activity levels, sleep quantity, and sleep quality as well as increases in students' sedentary behavior are observed as students (adults aged 18-19 years) adjust to the transition from high school to postsecondary education [23-28]. This life transition, compounded with the negative impact of the COVID-19 pandemic on students' movement behaviors [11-14], may further negatively impact students' short- and long-term physical and mental health.

Fortunately, postsecondary students are malleable learners and an intervention that provides an opportunity for students to learn and develop healthy movement behaviors, especially in their first year, can facilitate the development of habits that they can continue to use in their adult years ahead [29]. In addition, physical activity and sleep have been found to be positively associated with postsecondary students' positive affect and mental health [30,31], suggesting further benefit of postsecondary students receiving this intervention.

Several Canadian postsecondary institutions have adopted the Okanagan Charter for Health Promoting Universities and Colleges [32]. The Okanagan Charter calls on institutions to embed health in all aspects of campus culture and to lead health promotion action and collaboration. The working group anticipated that campuses that have adopted the charter would be supportive in helping to develop, implement, and evaluate an intervention aimed at improving students' movement behaviors and mental well-being. Two Canadian campuses—Queen's University (QU) and the University of British Columbia (UBC)—were selected as sites for implementation of a fall 2021 intervention, as both institutions have adopted the charter and had 24HMG knowledge translation team member representation on these campuses (ie, team members GF and MD are located at UBC, while JRT, AELC, and SMF are located at QU).

Determinants of Behavior Change

Given the novelty of the 24HMG in Canada, there was a paucity of published data on the determinants (ie, barriers and facilitators) of postsecondary student-integrated movement behaviors; thus, we collected our own. Focus groups were conducted with 74 first-year undergraduate postsecondary students at QU and UBC [33]. Focus group data were coded using inductive thematic analysis before codes were deductively mapped onto TDF domains [34,35]. The TDF was used to more thoroughly understand the individual-level factors that may act as barriers or facilitators to behavior change; within Intervention Mapping, the TDF domains represent the determinants of behavior change. In total, 13 of the 14 TDF domains were identified as influencing students' movement behaviors, with the unidentified TDF domain being *optimism*. For each code within every TDF domain, a belief statement was generated to provide details about the perceived role of the domain in influencing the behavior [36], helping to exemplify the barriers and facilitators experienced by students when attempting to engage in the movement behaviors [33]. Multimedia Appendix 2 [21,22,33] provides a full list of barrier and facilitator belief statements and change objectives.

Beliefs within the *Knowledge* and *Behavioural Regulation* domains were cited as facilitators and those within the *Social/Professional Role* and *Identity* domains were cited as barriers to engaging in guideline-level movement behavior. Beliefs within 10 domains (*Skills; Beliefs about Capabilities; Beliefs about Consequences; Reinforcement; Intentions; Goals; Memory, Attention and Decision Processes; Environmental Context and Resources; Social Influences;* and *Emotions*) were cited as both facilitators and barriers to students performing the movement behaviors. Interestingly, many of the determinants operate at an individual level (eg, within the students' control, such as developing and maintaining a schedule), whereas other determinants operate beyond the students' immediate control (eg, the university's provision of standing desks and desk cycles for student use). See Multimedia Appendix 2 for more details.

Intervention Setting

Intervention development occurred during the COVID-19 pandemic; consequently, there was uncertainty about the timing of a return to campus. To minimize in-person intervention components, using an app was appealing as an intervention delivery mechanism. An app is a useful vehicle for intervention delivery for this population, as students tend to report high use of health-related apps [37,38]. Although an app-based intervention is restricted to only being able to target individual-level determinants of behavior change, given the unpredictability of the COVID-19 pandemic, opting for an app-based delivery was a pragmatic decision. Not only are app-based interventions a viable means of intervention in the target population, but previous empirical evidence has also demonstrated that apps can be effective in changing health-related cognitions and behavior [39-41].

ParticipACTION, a physical activity nonprofit organization and one of the main partners of the 24HMG, already possessed an evidence-informed app that was leveraged by the working group to help support and expedite the implementation of the intervention within a short timeframe. The ParticipACTION app was developed using the BCW framework [21,22] as its theoretical basis [42].

The free ParticipACTION app serves as both a self-monitoring device (tracking users' steps, "move minutes" and "active

XSL•FO
RenderX

minutes" by linking the app with a fitness tracker [eg, Fitbit or Apple Watch] or having users manually add their activity) as well as a content hub (where evidence-informed articles are provided to help educate users on the 24HMG, goal setting, barrier identification and action planning)—these components work together to provide a tailored experience for users. App users are also eligible to win rewards (eg, weekly draw for a CAD $10 [US $7.4] Amazon gift card funded by ParticipACTION and its funders: the Public Health Agency of Canada and Sports Canada) by earning daily badges (ie, extrinsic motivation), where each badge releases entries in the next draw for rewards automatically. The app user earns additional badges by tracking their activity and hitting their active minute goals, engaging in challenges, reading articles, and watching videos within the app. ParticipACTION also offers "ParticipACTION+," a premium for-a-fee version that includes all standard app features as well as additional features such as in-app team challenges and leaderboards (eg, to compare step counts against other organization or team members), member engagement reporting, and customizable content and notification delivery. Fees for ParticipACTION+ are paid for by the intervention delivery team and not by app users. As the ParticipACTION app was theoretically informed and would allow for us to address many of the identified determinants of behavior change without in-person contact, it was deemed an appropriate vehicle for intervention delivery.

Step 2: Intervention Outcomes and Objectives (March 2021-April 2021)

The primary intervention outcome was to improve first-year undergraduate postsecondary students' movement behaviors, whereas the secondary outcome was to improve students' mental well-being. The performance objectives for students' movement behaviors are listed in Multimedia Appendix 2 and were drawn from each of the main 24HMG recommendations (ie, physical activity, sedentary behavior, sleep, and integration of the behaviors). Performance objectives were cross-referenced with the belief statements (ie, determinants) generated in step 1 (section *Determinants of Behaviour Change*) to produce the change objectives in Multimedia Appendix 2. The change objectives state what needed to change about a specific behavioral determinant (eg, intentions) for students to achieve a specific performance objective. In some instances, multiple belief statements were collapsed together as they represented a common change objective. Multimedia Appendix 2 includes all the performance objectives and corresponding potential change objectives identified from the focus group data.

In line with the secondary outcome of improving students' mental well-being, a final performance objective was identified: "student has positive feeling and functional aspects of mental well-being (eg, feeling optimistic, having energy to spare)." Given that following the 24HMG is associated with a lower risk of anxiety and depression and improved quality of life [1], the working group interpreted the change objectives for this final performance objective as students' performance of the movement behaviors themselves.

Step 3: Intervention Design (April 2021-July 2021)

Theoretical Methods

To move forward with intervention design and selecting change methods for step 3, we examined the theoretical links between the generated belief statements (see the section Step 1: Needs Assessment [June 2019 to April 2021]) organized by TDF domain and the antecedents of behavior, which can be selectively targeted in an intervention. Through their linkage with the TDF domains, change objectives were mapped onto the COM-B model, and accordingly, all relevant intervention functions and policy categories were identified following the process described in the BCW guide [22] (Multimedia Appendix 2). The next step was to identify intervention content in terms of which BCTs best serve the intervention functions. BCTs are considered the "active ingredients" of an intervention designed to change behavior and are the proposed mechanism of change to be used alone or in combination with other BCTs [43]. To assist in selecting candidate BCTs for the intervention, we used the Theory and Techniques Tool [44] to specify the links between TDF domains and BCTs [44-46].

Members of the working group reviewed Multimedia Appendix 2 (ie, the complete list of formulated change objectives mapped onto the TDF and BCW) and considered which change objectives could and should be addressed within the app-based intervention. The discussion included reflecting on the identified TDF domains, COM-B sources of behavior, intervention functions, policy categories, and BCTs. Selected change objectives are set in bold in Multimedia Appendix 2. Working group members believed that all 6 sources of behavior change (psychological and physical capabilities, social and physical opportunities, and automatic and reflective motivation) and 13 of the 14 TDF domains should be targeted within the intervention.

Notably, all selected change objectives focus on individual-level changes, with organizational- and community-level changes lying outside the scope of an app-based intervention. However, Multimedia Appendix 2 outlines all the identified change objectives, where some change objectives address organizational-level changes. One example is "encouraging residences to enforce quiet hours and promote an atmosphere that encourage healthy sleep habits."

Intervention Components: Practical Applications and Mode of Delivery

Overview

Multimedia Appendix 3 presents the intervention components described in this section as well as a description of the evidence and rationale that guided the formation of each component. In total, 7 out of the 9 possible BCW intervention functions were selected: education, persuasion, incentivization, training, enablement, modeling, and environmental restructuring. To support implementation of the intervention functions, 2 BCW policy categories were selected: communication and marketing and environment and social planning.

The working group considered the potential intervention components (ie, practical applications and modes of delivery)

XSL•FO
RenderX

to facilitate the identified change methods. The BCW intervention functions and policy categories guided the selection of the intervention components. In addition, the BCW presents the affordability, practicality, effectiveness, acceptability, safety, and equity criteria, which should be applied when engaging in the process of developing, selecting, and implementing interventions [22]; the working group reflected on these criteria during the component selection process. Five intervention components, described in subsequent sections, were considered to facilitate change objectives: ParticipACTION app content articles, notifications, badges, and competition as well as a resource package outside of the ParticipACTION app.

ParticipACTION App: Content Articles

A series of content articles specific to the 24HMG would be created, tailored for first-year postsecondary students, and uploaded into the ParticipACTION app. These articles would take student participants on a "content journey," providing information about each of the individual movement behaviors and how the movement behaviors are connected, while also addressing related barriers and facilitators identified in the needs assessment. For example, content would include information about the benefits of performing the movement behaviors pertinent to postsecondary students. Articles would also persuade and enable participants to perform the movement behaviors by focusing on select BCTs (eg, action planning). Articles would provide suggestions on how to restructure physical and social environments to encourage performance of the movement behaviors (eg, improvising a standing desk and how to be active with roommates). Students would be able to visit articles multiple times if desired, and through ParticipACTION+, articles could appear on students' app home page. Although students would have the flexibility to explore the ParticipACTION app, they would be presented with the developed content articles sequentially over the intervention period.

ParticipACTION App: Notifications

The use of the ParticipACTION+ service would enable the development and delivery of both push notifications and movement behavior reminder notifications. Push notifications would inform participants of the release of new content article in the app and would link to the new article. Movement behavior reminder notifications would encourage participants to engage in a specific movement behavior. These reminder notifications would serve as a prompt for the behavior, which was identified as an important BCT.

ParticipACTION App: Content Article Engagement Badges

The development of a weekly content article engagement badge was proposed because ParticipACTION app users can already earn badges for the number of articles read and their physical activity (eg, number of steps). Participants would earn a badge for engaging with the intervention content articles each week. The allocation of badges to participants would provide general encouragement to participants, reinforcing their behavior of engaging with the content articles.

ParticipACTION App: Competition

Competition was identified within the needs assessment as a facilitator for movement behavior engagement and would offer students a form of social comparison. The working group proposed 2 types of competition: within-campus and between-campus competitions. For within-campus competition, participants attending the same institution would be placed on teams that would compete to see which team has the highest step count or the most move minutes using the ParticipACTION+ challenge app feature. Participants would be able to view scores on a leaderboard to determine how other teams were performing. A reward would be offered where participants on the winning team would each win a material reward (eg, e-gift card) at the end of the intervention. Between-campus competition would involve participants at each institution competing to see which institution can collectively accumulate more move minutes by the end of the intervention. A weekly notification would be used to inform participants of their institution's progress. Similar to the within-campus competition, participants at the winning institution would each receive a material reward (eg, e-gift card) at the end of the intervention.

Resource Package

Formative work identified that participants needed access to resources on their campus or within the city to assist with meeting the behaviors, including free and low-cost options. Rather than providing tailored resources for each institution (ie, QU and UBC) and its respective city (ie, Kingston, Ontario, and Vancouver, British Columbia) within the app content, the working group proposed developing a tailored resource package that would be shared with participants via participant email. This decision allowed for the developed app content to be applicable to both campuses rather than requiring 2 sets of app content tailored to each institution's campus and city, supporting future scalability of the intervention.

Nonintervention Components

The working group acknowledged that by giving students access to the ParticipACTION app, they would have access to the additional ParticipACTION app components (eg, "Take 10" prompts, exercise videos, and rewards). Students would not be instructed to explicitly use these additional components as part of the intervention, but they might be of benefit to those students who engaged with these additional ParticipACTION app components. In addition, the working group decided a commercial wearable device (ie, the Fitbit Inspire 2) would be provided to participants as a device-assessed measure of their movement behaviors. Fitbit was chosen instead of researcher-grade devices (eg, accelerometer) for several reasons. First, the physical activity data from Fitbit would be synced into the ParticipACTION app. Accordingly, all participants would have equal access to the full app functionality (ie, monitoring steps and active minutes directly within the ParticipACTION app). Second, because our interest was in all movement behaviors reported over a 24-hour period, we determined that using a device-assessed measure of movement behaviors would decrease participant burden and increase the accuracy of movement behaviors compared with self-report

XSL•FO
RenderX

measures [47,48]. Finally, wrist-worn consumer-grade wearable devices increase consumer appeal and wear compliance compared with waist-worn research-grade accelerometers [47,49]; thus, we hoped that this would translate into increased compliance among our target population.

It is conceivable that Fitbit alone could have provided participants self-monitoring and feedback. However, though Fitbits (and other consumer wearables) have been linked with multiple theoretically relevant strategies associated with increased adherence and maintenance of movement behaviors such as physical activity [50], when wearable technology alone has been given to participants, without any intervention component, minimal changes in physical activity behavior are observed [51]. Consequently, Fitbit itself would not be considered an intervention component.

Considering all the above components, the working group proposed an intervention length of 6 weeks during the second half of postsecondary students' 12-week fall 2021 term, allowing sufficient time for intervention recruitment and intake while ensuring the completion of the intervention before end-of-term examinations. The working group proposed that limiting content articles to 2 succinct articles per week for the 6-week intervention for a total of 12 articles would prevent overwhelming students and may help to potentially circumvent intervention attrition. On the basis of the formative work conducted, the format of the proposed content journey would be such that the first article each week would be "informational" in nature, providing necessary knowledge with tips and benefits pertinent to participants, and the second article for each would focus on a particular behavior change strategy, describing how to perform the behavior change strategy in the context of one specific movement behavior.

Refining Intervention Components

Consultations with the broader ParticipACTION team and partners at both institutions were held to obtain further insight on the affordability, practicality, effectiveness, acceptability, safety, and equity of the proposed intervention. Engaging these additional partners allowed for the selection and further refinement of the proposed intervention components.

ParticipACTION Review

Although ParticipACTION representatives sit on the working group (Multimedia Appendix 1), broader feedback was sought from additional ParticipACTION representatives on the feasibility of the proposed intervention components. A written draft of the components was reviewed by ParticipACTION staff with knowledge in the following areas: behavior and insights, knowledge translation, marketing and communications, product marketing, strategy and insights, and health promotion. ParticipACTION staff supported the inclusion of all the proposed components with the exclusion of the content article engagement badges. Reasoning for exclusion of this component was owing to feasibility related to the creation of this app badge within the intervention development timeframe and budget. Accordingly, the working group agreed to exclude this intervention component.

Institution Representative Consultations

Consultations were held with representatives (ie, campus staff and students) from each institution using Zoom (Zoom Video Communications). The consultation at QU was held with 9 representatives from Student Wellness Services, Residence Life, Q Success (ie, a first-year peer mentorship program), the International Centre (ie, cross-cultural advisory), and first-year postsecondary students attending QU. The UBC consultation was held with 14 members of the campus Physical Activity Committee, which included individuals from Athletics and Recreation, the Office of Wellbeing Strategy, the University Neighbourhoods Association, the Student Wellness Centre, Kinesiology Undergraduate Society, and the Graduate Student Society.

Before the consultations, representatives were provided with a description of the intervention and potential evaluation components, including participant eligibility and recruitment, intervention components (eg, proposed content for the articles), and proposed evaluation components. During group-based, 60-minute consultations via Zoom, facilitated by SMF and JRT, representatives were presented with the findings of the formative research conducted as part of the needs assessment. Group discussion focused on obtaining representatives' insight on the "content journey" articles (eg, order of movement behavior content, behavior change strategies, and frequency of content) and inclusion of the competition feature of the app. Representatives were then asked to provide feedback on the proposed participant eligibility (ie, inclusion and exclusion criteria) to suggest potential avenues and strategies for intervention recruitment and to comment on proposed evaluation components. Representatives' suggestions from both consultations were summarized and brought forward to the working group for discussion.

Representatives agreed with the proposed intervention length of 6 weeks, to limiting content to 2 articles per week, and to the format of the content journey. However, the main topic of discussion during the consultations was about the order of presentation of the movement behaviors within the content journey articles. Originally, the working group proposed focusing on behaviors in the order presented in the 24HMG tag line of "Move More, Reduce Sedentary Time, Sleep Well" (ie, physical activity, sedentary behavior, and sleep). However, representatives reported that many students are aware that they are not obtaining sufficient physical activity; rather than immediately focusing on a behavior that individuals often perceive as being difficult to perform, it may be more motivating to start with a behavior they may perceive as being easier to achieve. With this feedback, the working group altered the content journey to begin by introducing the 24HMG, then present content focused on the movement behaviors in sequence from sleep, sedentary behavior, light physical activity, to moderate to vigorous physical activity, and finally revisiting the integrated nature of the movement behaviors at the end of the intervention.

Finally, representatives advocated for the removal of the competition component of the intervention. The ParticipACTION app does not offer team communication as

XSL•FO
RenderX

part of its functionality; given that social connection and support would be important for successful between- and within-campus competition and maintaining participant engagement in competition, the working group agreed to remove this intervention component. See Multimedia Appendix 3 for detailed descriptions of the intervention components (both included and excluded, following representative consultation).

Step 4: Intervention Production (July 2021-August 2021)

Prepare Plans and Draft Protocols and Materials

With the input of our working group and the application of feedback from the consultations conducted in step 3, we moved forward with outlining the participant recruitment protocols and materials for each institution, the resource package, app content articles, and app notifications.

Recruitment Protocol and Materials

Participant recruitment serves as the vehicle of entry for participants into the intervention; thus, recruitment protocol and materials were carefully considered. It was determined that participant recruitment would involve student self-referral to the intervention to limit the burden on recruiters (ie, campus representatives who would be asked to assist with recruitment). At QU and UBC, recruitment avenues included residence advisors or counselors, Student Wellness Services, and undergraduate societies and programs. Recruiters were provided with a 2-page study description as well as posters and preprepared social media posts. Recruiters were asked to place study posters in areas that students were likely to view (eg, student spaces in residences, wellness services, or office bulletin boards) and use preprepared social media posts on their institutional office, service, or society social media accounts (ie, Facebook, Instagram, and Twitter). In addition, instructors of first-year courses at each institution were contacted and provided with a Microsoft PowerPoint slide to add to the beginning of their lecture presentations as well as brief intervention descriptions they could post on their course pages on their institutional course platforms. All developed recruitment materials included links and QR codes for the intervention eligibility screening questionnaire for interested students to complete.

Resource Package

The resource package, a PDF document that would be emailed to participants, was developed by the 24HMG project coordinator (SMF) and research assistant (BT) to include the public facing 24HMG; infographics (ie, tips to "move more, reduce sedentary time, sleep well," benefits of following the 24HMG); and physical activity, sedentary behavior, sleep, and mental well-being resources for campus, community, and web. The resource packages were tailored for each campus and institution city with input from QU Student Wellness Services and UBC Wellbeing.

ParticipACTION App Components

ParticipACTION shared existing app content (ie, evidence-based articles created by ParticipACTION and partners) on the topics of instruction, lifestyle, and behavior change. A research assistant (BT)—a fourth-year undergraduate kinesiology student at QU trained in behavior change theory and practice—reviewed the existing ParticipACTION app content, selected intervention functions, and BCTs (Multimedia Appendix 3) to draft the 12 content journey articles. In total, 12 accompanying push notifications (ie, to notify participants about each new piece of content in the app) and 12 behavior reminder notifications (ie, to remind participants to engage in movement behaviors) were simultaneously drafted to ensure consistent messaging with the content articles.

The developed content articles followed the order of behaviors and behavior strategies defined and selected in step 3 (see Multimedia Appendix 3 for the description of the content articles). Notifications addressing the same movement behavior were scheduled to be staggered across the 6-week period to emphasize the integrated nature of the behaviors. An iterative content review process with the 24HMG project coordinator (SMF) and knowledge translation lead (JRT) was undertaken.

Pretest, Refine, and Produce Materials

Recruitment Materials

The developed recruitment materials were shared with recruiters from QU (Student Wellness Services and Residence Life) and UBC (UBC Wellbeing) for feedback. Minor feedback was provided on the social media posts, suggesting that the amount of text be reduced.

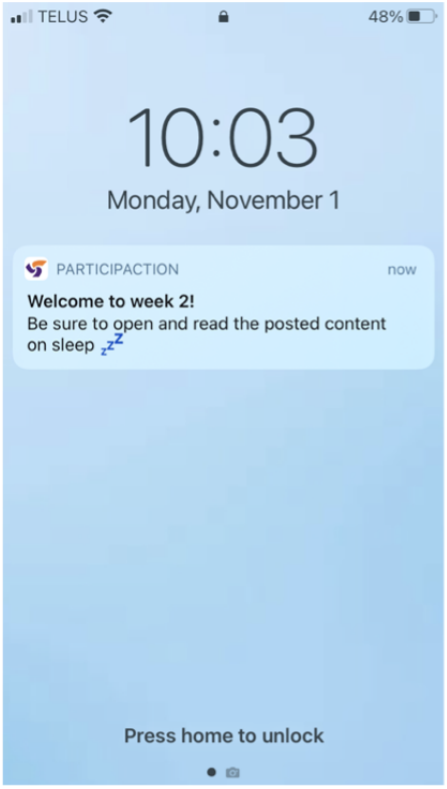
Resource Package

The resource package was sent to QU and UBC campus representatives on the working group who collaborated with colleagues on their end to provide additional suggestions on the developed resources. The final version was reviewed by a subset of the working group and approved for distribution.

ParticipACTION App Components

The developed content journey articles and notifications were reviewed by the 24HMG content experts (ie, researchers involved in the development of the 24HMG recommendations). Incorporated feedback from content experts included (1) making the language less formal, (2) distinguishing more clearly between sedentary time and screen time, (3) hyperlinking to existing ParticipACTION app content (ie, exercise videos) within the content articles, and (4) adding calls to action (eg, "What is your SMART goal?") within the content articles.

Individual and small group consultations were subsequently held with 9 first-year postsecondary students across both institutions, facilitated by the 24HMG research assistant (BT). Students were sent Microsoft Word document drafts of the content articles and notifications in advance of the consultations. During consultations held via Zoom, students were asked to consider whether first-year students would find the content engaging, motivating, exciting, appropriate, and interesting and whether the content was too long or too short. Students were also encouraged to provide feedback on phrasing and whether additional tips or strategies should be included. Feedback from students that was used to refine content included (1) breaking down bigger paragraphs to bullet points for visual appeal, (2) making the content articles read as conversational with the use



XSL•FO
RenderX

of rhetorical questions, (3) adding definitions for terms that are less known (eg, sedentary behavior and screen time), (4) adding yoga to the coping planning behavior change strategy article (a popular activity), and (5) breaking down the 150 minutes of moderate to vigorous physical activity into more "manageable" chunks (eg, five 30-minute segments).

Students were also queried about which days of the week and time of day they would prefer to receive app notifications; they reported a preference for push notifications (for content articles) in the mornings and movement behavior reminder notifications in the afternoons. Students agreed with the proposed suggestion of receiving content articles and push notifications on Monday and Wednesday mornings and the movement behavior reminder notifications on Tuesday and Thursday afternoons. These suggested timings were adopted as part of the intervention delivery.

The updated ParticipACTION app content was then reviewed and approved by the entire working group and campus representatives (including first-year students) by email. The content was sent to ParticipACTION staff with expertise in health promotion, knowledge translation, and marketing. The content was reviewed to ensure that ParticipACTION standards, tone, and voice were maintained. Staff edited and formatted the content and returned the content to the knowledge translation lead (JRT), 24HMG project coordinator (SMF), and research assistant (BT), who made the final edits and returned the content to ParticipACTION. Finally, ParticipACTION staff uploaded the content into the ParticipACTION app and prescheduled the delivery of the content articles, push notifications, and movement behavior reminder notifications. Once in the app, the content articles were reviewed by 4 of the working group members (SMF, BT, LMV, and JRT) who suggested final edits relating to formatting and image placement. The final ParticipACTION app content text and images for intervention week 1 can be viewed in Multimedia Appendix 4. Figures 2-5 present examples of students' views in the ParticipACTION app, including examples of notifications, the app home page, and a content article.

Step 5: Intervention Implementation Plan (July 2021-September 2021)

To implement and deliver the intervention at the 2 institutions, ParticipACTION staff, recruiters, and study coordinators were required to act as implementers. For this intervention, the adopters were the first-year postsecondary students for whom the intervention was developed.

Implementers

ParticipACTION staff were responsible for formatting and uploading the content articles into the ParticipACTION app and for scheduling the release or delivery of the content and notifications. Recruiters (eg, campus staff and lecturers at UBC and QU) at each institution acted as gatekeepers for the intervention. Their support and recruitment efforts were critical for recruiting students to the intervention. The study coordinators (SMF and JM) were responsible for determining student eligibility for participation in the developed intervention and for participant intake processes.

Adopters

The intervention adopters included first-year undergraduate postsecondary students from QU and UBC. To participate in the intervention, students had to meet the eligibility criteria determined a priori by the working group and refined during consultations with campus representatives (see the section Step 3: Intervention Design [April 2021-July 2021]). Interested students completed an eligibility screening questionnaire via Qualtrics.

The inclusion criteria for eligibility stipulated that students must (1) be first year, full-time, postsecondary students enrolled in an undergraduate program who have just graduated high school or students who graduated high school and took a gap year before enrolling in their current undergraduate degree and have not attended another college or university in the interim; (2) be born in 2003 or earlier (ie, students who will be turning 18 years or older in 2021, as the behavioral recommendations in the 24HMG for adults are applicable to ages 18-64 years); (3) want to make a change in their physical activity, sedentary behavior, or sleep (ie, are contemplators, intenders, or actors); and (4) not be accumulating 150 minutes per week of aerobic moderate to vigorous intensity physical activity (ie, getting <150 minutes per week of moderate to vigorous intensity physical activity); (5) score between 20 and 60 out of 70 on the Warwick-Edinburgh Mental Wellbeing Scale [34], indicating average or low mental well-being; (6) have a smartphone; (7) feel comfortable navigating technology (ie, students were asked if they felt comfortable navigating the ParticipACTION app via their smartphone and were provided with the ParticipACTION app accessibility specifications); and (8) be able to read, speak, and understand English.

The exclusion criteria stipulated that students would be ineligible if they (1) have a physical impairment, as the intervention content focuses on the 24HMG, which was not designed for persons with a physical disability or impairment and therefore may not be appropriate for these individuals; (2) have an acute concussion or symptoms of postconcussion syndrome, as the intervention content was delivered via smartphone and these individuals should avoid screens; or (3) are a QU student

XSL•FO
RenderX

enrolled in the kinesiology undergraduate degree program or are a UBC student enrolled in any of the following courses: HEAL 100, KIN 300, NURS 180, or NURS 290, as these degrees or courses are confounders for the evaluation (ie, students learn intervention content in these courses).

Screening and Intake Processes

The 24HMG project coordinator (SMF) reviewed the completed eligibility screening questionnaires to determine student eligibility to participate in the intervention. Students were contacted by QU and UBC study coordinators (SMF and JM, respectively) informing them of whether they were eligible to participate in the intervention. Eligible participants were invited to participate in intake meetings conducted by the coordinators (SMF and JM). To ensure anonymity, all participants were given a new Gmail (Google Inc) account, which was used to create ParticipACTION and Fitbit app accounts during their intake meeting. Once logged into the ParticipACTION app, participants were given the ParticipACTION+ code by the study coordinator, enabling intervention content and notification delivery. Both coordinators were provided with the ParticipACTION+ code as well, allowing them to receive intervention content and notifications to confirm intervention fidelity. During intake, participants were provided with their Inspire 2 Fitbit, asked to log into the Fitbit app using their new Gmail account, and showed how to synchronize their Fitbit to both the Fitbit and ParticipACTION apps. Finally, coordinators also provided a clear, verbal outline of the intervention ParticipACTION content journey and walked through what was included in the PDF resource package and emailed participants the PDF document.

Step 6: Evaluation Plan (July 2021-Ongoing)

To complete the iterative Intervention Mapping protocol, a plan for the evaluation of the intervention was developed. A nonrandomized proof-of-concept study was conducted to examine the feasibility, acceptability, and potential impact of the app-based intervention. Note that no a priori criteria were set to assess feasibility and acceptability. Data analysis is ongoing. Full details of the evaluation plan will be published in a forthcoming paper; however, a brief summary of the evaluation plan is described here.

Feasibility will be examined by reviewing the recruitment of students to the intervention (eg, the number of students screened and number of students eligible for participation and enrolled in the intervention), and participant attrition over the course of the intervention. Characteristics of participants (ie, demographics including gender, age, ethnicity, etc) were also collected and will be used to describe who participated in the intervention. The feasibility of evaluation measures will be assessed through the evaluation response rates.

Acceptability of the intervention will be assessed by using the data on ParticipACTION app engagement (eg, percentage of participants clicking and engaging with intervention content articles). Satisfaction with the intervention will be evaluated through analysis of a postintervention questionnaire with items measuring participant agreement on whether the intervention was interesting, useful, easy to participate in, credible, and personally important to them.

The evaluation plan also attempted to establish the potential of the intervention for changes in outcomes between baseline and after the intervention. Outcomes of interest included participants' (1) capability, opportunity, and motivation for the movement behaviors; (2) movement behavior levels; (3) mental well-being; and (4) awareness and knowledge of the 24HMG. Surveys were administered at baseline and after the intervention to assess outcomes 1, 3, and 4. Means and SDs of questionnaire items at each time point and effect sizes between time points will be reported. To assess outcome 2, means and SDs of time spent in each of the movement behaviors before, during, and after the intervention as well as trends in movement behaviors over time will be examined and reported.

Ethics Approval, Informed Consent, and Participation

Ethics approval for the focus groups conducted with first-year postsecondary students was granted by the QU General Research Ethics Board (GSKHS-329-19). Written informed consent was obtained by all focus group participants. Separate ethics approval was sought and granted by the QU General Research Ethics Board (GSKHS-394-21) and UBC Behavioral Research Ethics Board (H21-02741) for the app-based intervention development, recruitment, data collection, analysis, and reporting activities, including all ParticipACTION and Fitbit app–related components. All participants provided written informed consent for the collection, analysis, and storing of their self-reported (ie, survey) data and ParticipACTION and Fitbit app data. All data were deidentified with identifying information stored in separate, password-protected databases on secure, locked servers and not attached to participants' study data. Participants who completed the baseline and postquestionnaire survey were compensated with a CAD $5 (US $3.7) e-gift card for each questionnaire. Participants who participated in the intervention were able to keep the provided Fitbit following the intervention period.

Results

Participant recruitment occurred during September 2021, and the intervention was conducted from October to December 2021. The deadline for completion of the postintervention questionnaire survey by participants was mid-December 2021. We began analyzing the survey, ParticipACTION, and Fitbit data in January 2022, and the publication of the proof-of-concept evaluation is expected in 2023.

Discussion

Summary

Given postsecondary students' suboptimal engagement in the 24HMG behaviors [9], this population is at risk of negative impacts on their physical and mental well-being. In this paper, we describe the application of the Intervention Mapping framework to design and implement an app-based intervention intended to improve first-year postsecondary students' movement behavior and mental well-being.

XSL•FO
RenderX

Strengths and Limitations

The design and implementation of the intervention followed an iterative process using several frameworks: the Knowledge-to-Action Framework [6], Intervention Mapping [18,19], the TDF [34,35], and the BCW [21,22]. The steps of Intervention Mapping aligned well with the Knowledge-to Action framework, which has been used to guide the overall 24HMG knowledge translation process [7]. Although Intervention Mapping was used to guide a stepwise intervention design and implementation process, the TDF and BCW enabled the working group to categorize barriers and facilitators and to choose intervention functions and BCTs most likely to overcome barriers and leverage facilitators. When used together, these frameworks were well suited to designing an intervention addressing 3 separate movement behaviors, each of which are complex (ie, not a "single incidence" behavior) and occur in multiple contexts and at various times and frequencies. The involvement of a multidisciplinary team helped ensure that the intervention was designed appropriately for the target population [5,52]. Indeed, meticulous efforts were taken to design the intervention content with multiple layers of consultations.

This intervention has several limitations. First, content articles delivered to students in the ParticipACTION app are in a written format; some students may have benefited from the opportunity to view content in alternative formats such as video, which may also increase engagement with the content. In addition, the selected intervention components lacked the elements of social support. Social support can help to facilitate students' performance of the movement behaviors and to improve mental well-being—students identified social support as being an important facilitator for movement behavior change within the needs assessment (Multimedia Appendix 2). However, given the context of the COVID-19 pandemic and the uncertainty of the return of on-campus programing, we chose to not engage interventionist support at the onset of intervention design. This consideration also informed the pragmatic decision to implement individual-level strategies to address behavioral change, even though data from the needs assessment in step 1 suggested that institutional-level strategies (eg, encouraging residences to enforce quiet hours) may also promote performance of the movement behaviors in line with the 24HMG recommendations. Institutional-level strategies need to be explored in future research. Despite these limitations, we developed an intervention that could be scalable to other postsecondary campuses in the future. Finally, prompts and push notifications delivered through the ParticipACTION app may have implications for students' recreational screen time, either through minutes spent on the ParticipACTION app or other unintended app use (eg, students viewing other apps on their phone after being prompted by the ParticipACTION app). However, it is important to consider whether said screen time is considered "productive" or "purposeful" (eg, time spent on the ParticipACTION app may be considered educational as opposed to minutes spent absentmindedly scrolling through a social media app). Although beyond the scope of this study, future work should examine unintended effects of app-based health interventions and recreational screen time and, more broadly, sedentary behavior.

Conclusions

Intervention Mapping, with the use of the TDF and BCW, was a useful approach to combine evidence and theoretical concepts to guide the design and implementation of a ParticipACTION app–based intervention targeting postsecondary students' movement behaviors and mental well-being. This study may be used as an example for other researchers developing multiple behavior change app–based interventions, and should the forthcoming proof-of-concept intervention evaluation demonstrate the intervention's acceptability, feasibility, and potential impact, the intervention may provide a scalable method for improving students' movement behaviors and mental well-being and future behavior change interventions.

Acknowledgments

This work was made possible through funding from the Public Health Agency of Canada, Canadian Society for Exercise Physiology, Queen's University, and ParticipACTION. The views of the funding agencies had no influence on the content or conduct of this work. The authors would like to thank the following individuals for their contributions to this work: *ParticipACTION Consultations and Staff*—Natalie Toman, Stacey McNabb, Michael Moses, Brad Gerard, Rebecca Jones, and Shauna Pichosky. *Queen's University Consultations*—Jason Summers, Arunima Khanna, Julia Krpan, Madeline Mayers, and Audrey Wong. *University of British Columbia Consultations*—Alyssa Reyes, Emily Jarvis, and Crystal Westgate, Josie Chow, Annika Szarka, Amanda Unruh, Sam Kenston, Chris Rumary, Steve McGinley, Emma Jepsen Chartrand, and Dylan Brown. *24-Hour Movement Guidelines (24HMG) Content Experts*—Robert Ross, Jean-Philippe Chaput, Lora M Giangregorio, Ian Janssen, and Travis J Saunders. *Undergraduate Student Consultations*—Abbey Rehaut, Annika Szarza, Jacob Lawler, Arissa Derakhshan, Jonah Anzescarcha, Madeline Mayers, Julia Krpan, Audrey Wong, Will Davidson, Xinye Lu, and Margarita Liubetskaya. *Queen's University Recruitment*—Erin Burns, Jason Summers, Rebecca Shillington, and Nathan Aniekan Utioh. *University of British Columbia Recruitment*—Alyssa Reyes, Emily Jarvis, and Freeman Woolnough.

Data Availability

Multimedia Appendix 2 includes the complete list of performance and change objectives, with mapping of the combined links between Theoretical Domains Framework domains (ie, determinants of movement behaviors) and Behavior Change Wheel components. After analysis of the data examining the feasibility, acceptability, and potential impact of the intervention (eg, the survey, ParticipACTION, and Fitbit data) is complete, the data sets will be available from the corresponding author upon reasonable request.

Abstract

Background: Motivational interviewing (MI) is an evidence-based, patient-centered communication method shown to be effective in helping persons with serious mental illness (SMI) to improve health behaviors. In clinical trials where study staff conducted lifestyle interventions incorporating an MI approach, cardiovascular disease (CVD) risk profiles of participants with SMI showed improvement. Given the disproportionate burden of CVD in this population, practitioners who provide somatic and mental health care to persons with SMI are ideally positioned to deliver patient-centered CVD risk reduction interventions. However, the time for MI training (traditionally 16-24 hours), follow-up feedback, and the coaching required to develop and maintain patient-centered skills are significant barriers to incorporating MI when scaling up these evidence-based practices.

Objective: We describe the design and development of the following 2 scalable MI training approaches for community mental health practitioners: real-time brief workshops and follow-up asynchronous avatar training. These approaches are being used in 3 different pilot implementation research projects that address weight loss, smoking cessation, and CVD risk reduction in people with SMI who are a part of ALACRITY Center, a research-to-practice translation center funded by the National Institute of Mental Health.

Methods: Clinicians and staff in community mental health clinics across Maryland were trained to deliver 3 distinct evidence-based physical health lifestyle interventions using an MI approach to persons with SMI. The real-time brief MI workshop training for ACHIEVE-D weight loss coaches was 4 hours; IMPACT smoking cessation counselors received 2-hour workshops and prescribers received 1-hour workshops; and RHYTHM CVD risk reduction program staff received 4 hours of MI. All workshop trainings occurred over videoconference. The asynchronous avatar training includes 1 common didactic instructional module for the 3 projects and 1 conversation simulation unique to each study's target behavior. Avatar training is accessible on a commercial website. We plan to assess practitioners' attitudes and beliefs about MI and evaluate the impact of the 2 MI training approaches

XSL•FO
RenderX

on their MI skills 3, 6, and 12 months after training using the MI Treatment Integrity 4.2.1 coding tool and the data generated by the avatar-automated scoring system.

Results: The ALACRITY Center was funded in August 2018. We have implemented the MI training for 126 practitioners who are currently delivering the 3 implementation projects. We expect the studies to be complete in May 2023.

Conclusions: This study will contribute to knowledge about the effect of brief real-time training augmented with avatar skills practice on clinician MI skills. If MI Treatment Integrity scoring shows it to be effective, brief videoconference trainings supplemented with avatar skills practice could be used to train busy community mental health practitioners to use an MI approach when implementing physical health interventions.

motivational interviewing; training; cardiovascular disease; lifestyle interventions; community mental health

Introduction

Background

Addressing inequities in cardiovascular health is a critical public health objective, particularly for persons with serious mental illness (SMI) who experience alarmingly high rates of cardiovascular disease (CVD) risk factors (obesity, hypertension, dyslipidemia, and diabetes mellitus) and risk behaviors (tobacco smoking, physical inactivity, and unhealthy diet) [1-4]. Lifestyle interventions, especially those that adopt a patient-centered approach, have been shown to be effective in helping persons with SMI to improve a wide range of health behaviors, including weight loss management, smoking cessation, and diabetes management [5,6]. A foundational approach for many of these lifestyle interventions is motivational interviewing (MI), which is an evidence-based, patient-centered communication method aimed at evoking patients' motivations for change [7]. MI practitioners adopt a collaborative and empathic attitude, empower patients to act as an equal partner in their disease management, and use specific and core patient-centered communication skills to guide them toward change.

Patients' CVD risk profiles improved significantly in clinical trials in which the study staff incorporated an MI approach to conduct lifestyle interventions among participants with SMI [8-12]. To lessen the disparity of CVD risk experienced by this population on a wider scale, evidence-based programs to improve cardiovascular health need to be implemented in community mental health settings where patients routinely receive their care [13]. Real-world practitioners in these settings need the training not only to deliver the CVD health intervention itself (the requirements of which will likely differ based on education and prior experience) but also for the specific preparation necessary to incorporate an MI approach. Although some mental health practitioners may have had previous exposure to MI, the method involves a complex skill set such that attending a seminar or a traditional 2- to 3-day in-person workshop alone is usually insufficient to build competency [14-16]. A meta-analysis of MI training studies suggested that for learners to gain and sustain MI skills after a workshop training, an average of 3 to 4 coaching sessions with performance feedback from practice sessions over several months were needed [17]. Yet, when scaling up evidence-based practices (EBP) for implementation research, the stated amount of training to deliver patient-centered behavior change lifestyle interventions may be harder to accomplish among practitioners in community mental health settings who have demanding caseloads and limited time for additional training activities [18]. Furthermore, because of the diverse occupational backgrounds of the health care team in these real-world community settings (which often include physicians, nurses, therapists, and frontline day program staff) [19], it is essential to develop MI training that is both tailored and acceptable to a variety of practitioners.

There are a few promising formats to efficiently train busy mental health care practitioners in MI [20]. Synchronous or real-time trainings over videoconferencing can be used to provide learners with a basic introduction to MI. Live videoconferencing, although still requiring coordinating schedules of learners and trainers, can simulate an in-person event. Videoconference trainings may be shorter than standard multiday trainings and can be broken into smaller chunks of time; this may be more appealing to managers and allows learners time to meet their other work demands. This format also allows practitioners the opportunity to reflect on and integrate the concepts they are learning between training sessions.

Web-based self-study programs that include video and workbook activities can be entirely asynchronous or may integrate a *live component* in which learners meet with trainers during scheduled times [21-23]. Both real-time synchronous and web-based training options have the advantage of being able to reach a wider audience of practitioners, including those working in rural settings or where skilled trainers of MI are not available, than in-person events. Both approaches reduce the travel time and cost for trainers and limit the need for learners' transportation, workshop space, and other expenses associated with in-person workshops. When implementing the intervention at multiple locations, videoconference training provides a practical way to reach several sites simultaneously. Constraints around social distancing imposed during the COVID-19 pandemic have created the need for effective options other than traditional in-person trainings for teaching different counseling approaches. Although these modalities have been used more frequently in the past few years, research on the impact of web-based [22] and video trainings in MI remains limited [24].

XSL•FO
RenderX

Another scalable remote training format for MI involves the use of computer simulations [20,25,26]. SIMmersion [27] offers video-interface trainings; videotaped role-play conversations with human actors give learners the ability to practice and receive coaching and feedback on their recorded responses [20,28]. Avatar-interface programs, by contrast, provide learners with a virtual reality training experience to learn and practice their skills with simulated avatar patients [29,30]. Avatar trainings may involve a human trainer [31] or consist of fully automated, preprogrammed simulations; some platforms also offer coaching and feedback features to learners. Kognito [32] offers several avatar simulations in which the users enter an interactive virtual environment and engage in role-play conversations with emotionally responsive virtual humans on a variety of topics in health care, mental health, and patient-provider communication. Their approach combines the science of learning, the art of conversation, and the power of gaming technology. Avatar-interface programs can be used as stand-alone or as follow-up MI practice opportunities; they have the advantage of allowing learners to practice their skills in a convenient and private environment.

Objective

Despite the many different approaches to training and the demonstrated effectiveness of MI [6], the amount and type of training necessary for real-world practitioners to develop and sustain proficiency in the method is uncertain [24]. In the context of 3 pilot implementation research projects that address weight loss, smoking cessation, and CVD risk reduction among persons with SMI, we aimed to develop scalable training in MI. This paper will provide a brief description of the 3 pilot projects; their corresponding setting and intervention; the design and development of the 2 MI training approaches, real-time brief workshops and follow-up asynchronous avatar training used to implement the EBP; and how we propose to evaluate the impact of the training on practitioners' skills, attitudes, and beliefs about MI.

Methods

Implementation Pilot Studies Overview

The Johns Hopkins ALACRITY Center for Health and Longevity in Mental Illness is a research-to-practice translation center funded by the National Institute of Mental Health that aims to reduce premature mortality from CVD in people with SMI [33,34]. There is an untapped opportunity to develop scalable and generalizable solutions that integrate physical health care into mental health service sectors, which have not historically provided such services. Through the ALACRITY Center, we are conducting 3 pilot implementation projects in community mental health settings to study strategies for the adoption and integration of evidence-based CVD risk reduction interventions related to (1) weight loss; (2) tobacco smoking cessation treatment; and (3) hypertension, dyslipidemia, and diabetes care for people with SMI. This study is a substudy within the ALACRITY Center methods core and focuses on the 2 types of innovative MI training: real-time brief workshop training over videoconferencing and asynchronous avatar training, which span the 3 projects described in the following paragraphs.

ACHIEVE-D (Adapting an Evidenced-based Weight Management Intervention and Testing Strategies to Increase Implementation in Community Mental Health Programs) is a 6-month, 2-arm, weight loss pilot cluster randomized controlled trial (RCT), which is designed to assess the degree to which the implementation strategy, that is, performance coaching, impacts psychiatric rehabilitation program (PRP) coaches' knowledge, self-efficacy, and fidelity to the delivery of the adapted ACHIEVE-D weight loss program curriculum when compared with a standard control group. ACHIEVE-D is a behavioral weight loss program designed for persons with SMI that provides basic weight loss health education using an MI approach, which was adapted from an intervention tested in a previous RCT [10,12,35]. Coaches in PRPs will be provided with the materials, trained on all aspects of the ACHIEVE-D weight loss curriculum, and encouraged to use MI skills in their interactions with the participants.

IMPACT (Promoting Evidenced-Based Tobacco Smoking Cessation Treatment in Community Mental Health Clinics) is a pretest-posttest design–based 12-month observational study that aims to examine the effects of an implementation intervention on mental health providers' delivery of four EBP related to smoking cessation treatment for clients with SMI: (1) assessment of smoking status, (2) assessment of willingness to quit, (3) behavioral counseling, and (4) pharmacotherapy prescribing. Psychiatrists and mental health counselors at 5 community mental health clinics will receive training to implement smoking cessation practices, incorporating an MI style in their interactions with the patients. Counselors and prescribers will be encouraged to use MI to understand their patients' smoking behavior and engage them in smoking cessation treatment.

RHYTHM (A Quality Improvement Process to Support Delivery of Cardiovascular Care in Community Mental Health Organizations) is a pretest-posttest design–based 12-month pilot study examining the effects of an adapted 5-step Comprehensive Unit–Based Safety Program implemented during care coordination aimed at reducing CVD risk for patients participating in behavioral health home programs [36]. Behavioral health home staff will receive the training necessary to implement the program, which will include the use of MI as a way of interacting with patients as they discuss various aspects of their patients' CVD care.

Participants Receiving MI Training

In these pilot implementation projects, we are assessing the use of MI among clinician and staff participants who have been trained to deliver the lifestyle interventions to mental health clients. Practitioners recruited from community mental health settings across Maryland will implement the 3 projects. Only English-speaking adults (aged ≥18 years) who provide informed consent are enrolled. Additional inclusion criteria include willingness to provide baseline data, attend training, implement the study intervention, and participate in follow-up data collection. Exclusion criteria across the 3 projects are minimal and exclude any staff who express an intention to leave the

XSL•FO
RenderX

facility before project completion. ACHIEVE-D enrolled interested residential staff and employees at the PRP program as coaches. IMPACT participants include community mental health clinic staff (eg, licensed counselors, psychologists, and social workers) and prescribers (eg, nurse practitioners and psychiatrists). RHYTHM participants include PRP staff and health home nurses who are currently employed at the study sites.

Ethics Approval

Approval to conduct the studies and the associated MI trainings was granted by the Johns Hopkins Institutional Review Board (IRB) protocols. ACHIEVE-D study received IRB approval in March 2021 (IRB00247344). IMPACT study received IRB approval in January 2021 (IRB00231836), and RHYTHM study received IRB approval in December 2020 (IRB00269855).

MI Training

MI Training for the ALACRITY Center studies consists of 2 distinct approaches: real-time brief workshop training over videoconferencing and asynchronous avatar training.

Real-time Brief Workshop Training

Overview

Traditional introductory MI training is typically in person and is 16 to 24 hours long. However, based on the preferences expressed by stakeholders at study sites before initiating the projects, we present brief, real-time, and standard introductions to MI over videoconferencing uniquely tailored for each project. The MI trainer (ATD) is an MI practitioner, is a member of the Motivational Interviewing Network of Trainers (MINT), and has extensive experience in training practitioners who treat patients with SMI in the context of health services research. Following the guidelines recommended by MINT members [37], each training session invites the learners to consider why MI is useful in conversations around health behavior change and includes a definition of the method; a discussion of the MI spirit (ie, the accepting, compassionate, collaborative, and empowering style used in MI); an introduction to patient language related to change (change talk and sustain talk); and a brief overview of the following core MI skills: open-ended questions, affirmations, reflections, summaries, and collaborative information exchange [7]. Table 1 presents the real-time training content.

The amount of time devoted to each topic and opportunities for interaction vary by study. To increase the feasibility and acceptability of the workshops, the length of training for each project was negotiated in advance with the site leadership. ACHIEVE-D weight loss coaches will receive 4 hours of MI training. Psychiatrists prescribing smoking cessation pharmacotherapy in IMPACT will receive 1 hour of MI training; mental health counselors who provide the smoking cessation counseling will receive 2 hours of MI training. RHYTHM health home staff who implement the CVD risk reduction program will receive 4 hours of MI training.

[e]OARS: Open-ended questions, Affirmations, Reflections, Summaries

Development

Owing to the advent of the COVID-19 pandemic, all MI trainings were modified from an in-person format to delivery over videoconferencing. Although there is not much known about how best to adapt the content of in-person experiential training workshops for this purpose, MINT members communicated ideas for the transition on the e-forum of their listserve [38]. Additional ideas for modifying training activities were offered during workshops, and a monthly virtual trainers meeting for sharing activities, ideas, and successes is ongoing for any interested MINT member. As a result of participation in these various collaborative conversations, the first author (ATD) modified several training activities for the videoconferencing format. One key consideration was how best to engage participants and encourage them to try different components of the MI method while being observed by others on screen rather than in the privacy of small groups. The trainer incorporates multiple activities, alternating training techniques to keep learners interested, including the use of written transcripts with change talk and sustain talk indicated in different colored fonts and small breakout rooms for practice exercises [39,40]. Efforts are made to switch styles every 20 minutes to best engage learners. Anonymous polling provides low-stakes opportunities for learners to select the most MI-consistent practitioner strategy in response to a vignette (eg, choose an evocative question, select the reflective listening statement, or identify the best example of a collaborative information exchange); the chat function allows the trainees, who may be less comfortable or quick to respond, opportunities to pose questions or respond to trainer requests.

All synchronous, real-time trainings will be held over videoconference and scheduled at a time that accommodates most practitioners at each site. As it is challenging to synchronize participants from multiple sites where the research is being conducted, for anyone unable to attend the real-time meeting, recorded Zoom sessions (Zoom Video Communications) will be made available for viewing. The first author developed a tailored handout resource packet with specific examples of how to use MI when discussing each project's target behavior change; this material will be provided to practitioners to further support their MI skill acquisition during and after training.

Asynchronous Avatar Training

Overview

The ALACRITY Center partnered with a web-based experiential learning company, Kognito [32], to develop the asynchronous avatar training. This development process with Kognito took approximately 14 months and resulted in the products described in the following sections. After the completion of their real-time MI training, the practitioners are given access to the web platform and are encouraged to register for an account that houses their study-specific avatar training and simulation. The first component is a 12-minute didactic module, "Motivational Interviewing Techniques," which uses an avatar coach to provide an overview of the method. This module is identical for each of the 3 projects and must be completed before the learners move on to the second part of the training, the conversation simulation. The participants are asked to complete their first conversation simulation as soon as possible after the real-time MI training and are prompted to use the platform throughout the study period.

Each study has 1 distinct conversation simulation that addresses the project's respective behavioral target. All conversation simulations involve 3 characters (Figure 1). The avatar practitioner character is played by the study MI learner and discusses weight loss (ACHIEVE-D), smoking cessation (IMPACT), or cholesterol reduction (RHYTHM) with an avatar patient. The avatar patient has speech that is coded to be generated automatically; when the character stops speaking, there are 3 to 4 choices presented to the learner representing options that are more or less effective when using the guiding style of MI. Table 2 shows the learner response choices for the avatar weight loss simulation.

The avatar patient, the character that is not playable or maneuverable by the practitioner, is modeled after an atypical patient with SMI in a community mental health setting. Depending on the study, the avatar patient is obese, smokes tobacco, or has high cholesterol. The avatar patient responds to the practitioner in the way a typical client might respond as the practitioner selects one of the previous MI-consistent or non-MI directive choices. The third avatar character functions as a virtual coach who both narrates the didactic module and, when a response choice is selected by the practitioner, provides on-screen text guidance that either affirms the learner's use of MI or, as needed, provides corrective suggestions to the learner as they engage in the respective conversations about weight loss, smoking cessation, or cholesterol reduction. Learners have the opportunity to undo their selection and pick a different option to see how such a change impacts the conversation flow.

The avatar platform includes several feedback features to assist learners in improving their MI skills. An on-screen meter registers and reinforces practitioners' ability to cultivate change talk, a core skill that is essential in an MI interaction [7]. For example, if the practitioner says, "You're aware of the health effects of smoking and they worry you enough to consider quitting" and the client responds, "Yea, I think about it...I used to smoke right after a shower but now I try to go longer...," then the meter would indicate movement toward cultivating change talk. The simulations also include occasional thought bubbles; that is, a text appears above the avatar patient's head and allows the learners to read the patient's unspoken thoughts from the most recent exchange. This feature is most useful when the patient responds with silence, one-word answers, or if they appear hesitant to voice confusion over what is being discussed. As the learners move through the simulation, the platform keeps a tally of each practitioner's choice; after completing the full simulation, there is a performance dashboard available to the learner on their use of MI spirit and skills. Learners are able to see their scores on the relational components of the MI spirit (partnership and empathy); adherence to the technical aspects of the approach (cultivating change talk and softening sustain talk); and their use of specific core MI skills, questions, and reflections (Figure 2). The participants are encouraged to practice their MI skills with the avatar at least monthly throughout the study.

Figure 2. The performance dashboard.

Development: The Avatar Characters

Early in the development process, members of the ALACRITY team who were the most familiar with the community mental health program environment provided Kognito with pictures of the study sites and descriptions of practitioners and patients seen at the sites. After a few iterations (eg, adjusting characters' skin tone, patient affect, and voice speed), the project's 3 avatar characters were created. The virtual characters were brought to life with animation, lip-synced speech, and the use of facial and hand gestures to demonstrate their nonverbal emotional responses. The images of the players are the same for each of the studies. The topics of conversation and the names and mannerisms of the virtual patient characters vary by study behavioral focus. The patient avatars were modeled after clients with well-controlled depression (ACHIEVE-D), schizophrenia (smoking cessation), and bipolar disorder (CVD risk reduction) who were seen at the community mental health programs.

Development: The Didactic Module

Kognito's existing MI Techniques module formed the foundation for the product's final didactic training; the first author modified the content to reflect the most current constructs in MI [7]. Clinician and client language tailored to each study's target behavior was incorporated so that the practitioners would find the learning module more relatable. For example, to indicate that the patient was referring to changing their smoking- or weight-related behaviors, we included examples of the patient's change talk statements such as "I need to cut back" or "I'd like to be able to move around more easily."

Development: The Conversation Simulations

To inform the script for each conversation, subject matter experts from the ALACRITY team met with Kognito. Coders then created branching scripts for how the conversations would progress as learners made choices that demonstrated both their use of MI and their options not being aligned with the patient-centered method. Practitioner choices that demonstrated the use of non-MI–adherent strategies, for example, confronting

XSL•FO
RenderX

the patient's behavior of soda drinking when their weight goes up, were carefully crafted; the MINT member authors (ATD and SM) revised the scripts designed to demonstrate MI skills (eg, asking an open-ended question to learn what the patient knows about lowering cholesterol before giving information) to more closely model effective practitioner responses. Finally, based on our experience during previous clinical trials focused on these CVD risk behaviors [8-11,41], the same authors modified the avatar patient language to better align with more predictable patient responses to each of the practitioner's choices.

The Feedback Mechanisms: On-Screen Coaching

Kognito's platform includes several feedback mechanisms for which ATD and SM provided content expertise. On-screen coaching tips from the virtual coach are available to practitioners as they move through each simulation. For example, if the learner selects the best conversation or target choice, such as, "Well...cutting down smoking, even a little, shows that you're really serious about making changes for your health," the coaching text affirms their effort and identifies the specific MI skill used: "You affirmed specific efforts Danny has made to quit smoking and he told you that in addition to his health, he values spending time with family." If an ineffective choice is selected, such as "So, you know how difficult it is to quit," the coach names the non-MI–adherent tactic and suggests the better or target choice: "By bringing up challenges, you missed an opportunity to affirm the efforts he's already been making. You might have said, 'You were able to cut out your morning cigarette even though you live with people who smoke.'"

The Feedback Mechanisms: The Performance Dashboard

The performance dashboard was designed to help learners know how well they use MI in their simulations. Study MI experts worked with Kognito to modify their existing automated scoring system so that it was better aligned with up-to-date MI training and feedback guidance. This was a multistep and iterative process. First, a careful review of the conversation scripts allowed the study team and Kognito to identify learner pitfalls. A pitfall by definition is when a practitioner selects a conversation strategy that is not likely to be effective when guiding the patient toward the desired behavior change (eg, if a practitioner chooses to ask an information-gathering question when a better response would be to provide a reflection). MI-nonadherent behaviors, such as persuading a patient to take a medication or confronting their lack of willingness to make a change, as well as reflecting on patient sustain talk, missing an opportunity to reflect on change talk, or failing to empathize with the patient, are coded as pitfalls. The team also identified examples of conversation targets for the learner. The targets are defined as the practitioner's conversation choices that are the most consistent with MI in guiding the patient avatar toward the desired behavior change (eg, asking evocative questions, affirming the patient's effort, and seeking collaboration before offering advice).

The study team was interested in having the automated performance feedback align with what is measured by the Motivational Interviewing Treatment Integrity Tool (MITI; version 4.2.1) [42]. MITI is a validated coding system that is used to assess MI skills and provide feedback to learners and is widely accepted as a treatment integrity measure for clinical trials involving MI. The tool has the following 2 components: global scores and behavior counts. Global scores capture the rater's global impression or "gestalt" of the entire interview on 5-point Likert scales for the following 4 dimensions: Cultivating Change Talk, Softening Sustain Talk, Partnership, and Empathy. Because Artificial Intelligence is unable to characterize the "gestalt of a conversation," the study team worked with Kognito to create separate matrices to classify the scoring for each of the MITI global domains. On the basis of the number of targets and pitfalls possible in each conversation type, we determined what combination of pitfalls and targets would comprise the grading criteria for each of the Likert scale scores (1-5). We decided to weight equally hitting the target and avoiding a pitfall. For example, if the domain of Partnership had a total possibility of 4 targets and 5 pitfalls during the weight loss conversation simulation, a *1* on the Likert scale would be assigned if the practitioner missed all the targets and hit every pitfall. A *5* on the Likert scale would be assigned if the practitioner avoided all the pitfalls and hit every target. We used this same mapping process to identify Likert score categories for each global domain for all the 3 conversation types.

MITI behavior counts are tallied instances of 10 specific practitioner behaviors including those that are categorized as MI-adherent (eg, emphasize autonomy, seek collaboration, and affirm) and MI-nonadherent (eg, confront and persuade). The human coder's task is to simply count each instance of the clinician's behavior during the segment being reviewed. The final step in the development of the automated scoring system for this study was to label each practitioner's conversation choice as one of the 5 learner behaviors measured (eg, question, reflection, affirm, persuade, and confront); the automated system as currently developed was not built to provide counts for the 5 additional behaviors measured by MITI (ie, providing complex reflections, persuading with permission, giving information, seeking collaboration, and emphasizing autonomy).

Evaluation of Training Components

Data Collection

Data on the measures as described in the *Measures* section will be obtained from the study practitioners before their MI training and will be collected via telephone, videoconference, or through REDCap (Research Electronic Data Capture; Vanderbilt University) or paper questionnaires. The participants will be compensated for their time to complete all data collection measures; no other financial compensation for participating in the training or implementing the study will be provided. We will use the web-based REDCap survey system or deliver paper questionnaires upon request. We will collect follow-up measures at 3 months and the end of study (at 6 months for ACHIEVE-D) and at 3 months, 6 months, and end of the study (12 months for IMPACT and RHYTHM). Continuing medical education credits will be provided to IMPACT practitioners upon the completion of 3 avatar simulations. Table 3 summarizes data collection items.

[c]Applicable to ACHIEVE-D study only.

Measures

We adapted the *Beliefs about Motivational Interviewing* questionnaire [43] to assess participants' beliefs about MI. The original scale asks participants to react to 7 statements about MI on a 5-point Likert scale from "Strongly Disagree" to "Strongly Agree." We included the following two statements in our modified version: (1) "There is strong empirical support for motivational interviewing" and (2) "I am effectively implementing motivational interviewing."

We created a 12-item questionnaire, *Importance and Confidence to Use MI*. The participants are asked about their perspectives on the importance of, and their self-reported confidence to use, MI skills. Example questions include, "Please rate how important is it for you to use motivational interviewing" and "Please rate how confident you are in your ability to use motivational interviewing to elicit behavior change in your patient." Responses are chosen on a 5-point Likert scale from "Not at all" to "Extremely."

We will use the MITI tool to measure clinician fidelity to MI from audiotaped standardized patient (SP) interviews [44-46]. Correlations between practitioners' adherence to MI with real patients and SPs are moderate to large on most indexes of performance [47]. Practitioners will conduct interviews with SP actors playing the role of patients with SMI. SP actors will talk as if they are interested in either weight loss, smoking cessation, or CVD management according to the pilot project their practitioner interviewer is implementing. MITI scores will be determined by blinded, independent coders who were trained by the tool's creators.

XSL•FO
RenderX

A study staff member blinded to other survey measures will extract data on practitioners' automated scores from the performance dashboard at each data collection time point as another measure of adherence to MI.

Given the novelty of the avatar training, we will also assess participants' perceived usefulness of the avatar platform. Perceived usefulness is a key construct in the literature on technology adoption and use and refers to the extent to which a person believes that using the technology system will enhance their job performance. We adapted the Technology Acceptance Model questionnaire [48,49] to include 6 questions about the perceived usefulness of the avatar on participants' role in the study. Responses are on a 5-point Likert scale presented as 1 ("Strongly Disagree") to 5 ("Strongly Agree"). Example items include "I found the avatar to be useful in my role..." and "Using the avatar enhanced my effectiveness..."

We will track adherence to the following 2 training modalities: attendance at real-time training and frequency of asynchronous avatar use.

At the end of each project, we will collect qualitative data from the interviews and focus groups using a standard protocol to elicit participants' perceptions of both the real-time and avatar MI training.

Analytic Plan

We will examine changes in the MITI from baseline to each subsequent time point to assess the change in practitioners' skills in implementing MI. All SP interviews will be coded. A difference of 1 on a 5-point scale between pre- and posttraining scores for MITI global scores will be considered a clinically significant change in MI skills proficiency and will be used for statistical testing as the relevant effect size [42].

We will use a random 20-minute segment from the audiotaped SP interviews for coding as recommended by the creators of the MITI tool [42]. We will use a random calculator to ensure that the sampling of interviews that are >20 minutes is truly random so that proper inferences about the use of MI can be drawn.

We will examine changes in practitioners' automated scores from completed avatar simulations from baseline to each follow-up time point.

We will also compare the associations of the MITI scores from the SP interviews with the Kognito-automated performance feedback metrics from a conversation simulation completed during the same time as the data collection window.

We will examine changes in participants' beliefs about and the importance of using MI and their confidence to use its components with their patients.

Qualitative data from interviews and focus groups will be audio recorded and transcribed. Using thematic analysis [50], 2 research team members will identify meaningful segments within the responses and assign codes. We will then group these codes into themes, which will be examined by the research team.

Results

The ALACRITY Center was funded in August 2018. Recruitment for the studies started in February 2021. We have enrolled 127 participants. We anticipate the projects will be completed in Spring 2023 and anticipate that the results will be reported in late 2023 or 2024.

Discussion

Overview

The treatment of CVD risk factors is a public health priority for persons with SMI who experience symptoms disproportionally owing to these chronic health conditions. In community mental health practices where patients regularly receive their care, providing physical health interventions using an MI approach has untapped potential [4]. However, practitioners in these facilities already have excessive demands on their time, a challenge exacerbated by staff shortages and turnover, and they may not have the time, energy, or organizational support to learn how to implement patient-centered CVD risk reduction interventions [18,19]. To overcome some of the barriers to wide-scale adoption of MI in these contexts, we have adapted the traditional MI training format and created brief videoconference workshops supplemented by postworkshop avatar-based practice simulations to prepare the practitioners to deliver 3 evidence-based health interventions in community mental health settings. We hope that these formats will be acceptable and lead to an uptake and improvement of practitioners' patient-centered skills.

Strengths

There are several strengths in this study. We created a tailored training that has shorter duration than traditional training as a way to expose busy practitioners to MI. Brief trainings (<8 hours) are more time efficient and have been shown to make some difference in physician consultation behavior [51]. We adapted the real-time training to be delivered remotely in shorter bouts of time. We aim to identify whether the brief trainings provided are adequate to prepare real-world clinicians to perform the EBP and subsequently assess their skill acquisition with a validated measure.

Although technology-based virtual reality training methods have been used in medical and other health professionals' education, the use of avatars and other computer programs that provide interactive learning opportunities is not as common in behavioral health skills training [25,26,30,52-54]. Virtual platforms are a relatively new, potentially promising mode for training in MI and allow busy practitioners to learn the patient-centered counseling approach from expert trainers without having to travel to an off-site location. We incorporated 3 novel avatar conversation simulations tailored for practitioners to practice and receive feedback on their use of MI in simulated discussions about weight loss, smoking cessation, and cholesterol management. We will assess their acceptability to a wide range of practitioners at the end of each project.

We describe the study's training content and development of the avatar simulations as well as 2 methods of measuring

XSL•FO
RenderX

adherence to MI and assessing change in practice that results from the trainings provided. Research has shown that the immediate skill gains from a workshop training diminish within a few months and that postworkshop follow-up performance feedback with coaching is needed for practitioners to sustain or further improve MI skills [14,16,17,55]. Although our initial training is brief, the automated coaching and feedback offered during the avatar simulations should mirror the role of coaching as a way of providing follow-up training to improve learners' skills. Simulation technology offers the capability to move beyond traditional in-person training and provide skill training through repeated practice and feedback [56].

Limitations

One limitation of the study is that none of the training methods have a comparator condition. The pretest-posttest outcomes are used here to assess the acceptability, feasibility, and effectiveness of the 2 training methods for improving practitioners' MI skills.

Avatar practice requires practitioners to set aside time during their busy workdays. The extra workload and responsibilities of staff during the COVID-19 pandemic may leave little time or motivation for avatar skills practice after their initial exposure to MI, thus potentially decreasing the impact of this component of the training.

Another limitation is that because of the nature of the avatar platform and how the 3 conversations simulations are built, there are limited choice options. Therefore, after a learner has used the platform a few times, they might find it redundant and be less willing to practice. The didactic module and the conversation simulations may be a great opportunity for novice learners to practice their skills; practitioners with more experience in patient-centered counseling may be less interested in using a platform that offers few multiple-choice conversation options.

To overcome the challenges of assessing MI skills in implementation settings, we are using multiple measures, namely, MITI and the automated feedback scores from the avatar simulations. The feedback feature of the avatar simulations was originally designed to assist learners in improving MI skills. The mapping approach we used to create the automated scoring system for each of the global scores may limit the precision of the measure to capture how well the clinician is using MI. In addition, because participants complete the same simulations for training and assessment purposes, scoring from the simulations may not be a valid outcome measure of their MI skills.

This study design was in the context of implementation research and does not allow us to examine the effect of the MI workshop training component alone. However, examining MI in real-world settings is an innovative aspect of the study. Although there are limitations to asking about experiences of the training over a 6- or 12-month period, our qualitative interviews at the end of the study will add detail to the quantitative results.

Although the development of our avatar conversation simulations included multiple iterations between our study experts and the developers of the platform, further advances in virtual training have become available since the study was first conceptualized. Other programs that allow for additional branching conversation scripts could be integrated into future versions of this training to better support virtual learning [57]. Virtual reality programs that create endless iterations of interactive experiences such as those offered by SIMmersion are another option to promote learning. Platforms that use natural language processing with actual recorded patient encounters also have the potential to offer feedback to learners on their MI skills and could be an addition to MI training for busy mental health practitioners [56,58].

Conclusions

This study will help us understand the effectiveness of 2 scalable training strategies on practitioners' use of MI and how these approaches impact practitioners' beliefs about, the importance of, and their confidence to use MI when delivering 3 interventions focused on CVD risk reduction to patients with SMI. The degree of tailoring to specific lifestyle change targets and the amount of real-time interaction needed to garner training effects in MI are not known; this research will contribute to knowledge about the effectiveness of brief videoconferences for training community mental health practitioners in MI. Testing MI skill uptake from videoconference training sessions has not been documented in the literature; this project will be a step forward in filling this gap. The study will also provide information about the perceived usefulness of the avatar as a modality for learning MI. On the basis of our results of this study, a logical next step to determine the most effective scalable training approach would be an RCT that compares different MI training modalities and includes a comparator condition.

Data Availability

The data sets generated during and analyzed during this study are not publicly available because the study is ongoing but are available from the corresponding author upon reasonable request after the study is completed. Data would be deidentified and provided to researchers whose proposed use of the data has been approved, along with a signed data access agreement and appropriate international review board approval.

Authors' Contributions

ATD and GLD conceived the design of the study. ATD drafted the original version of the manuscript with assistance from GJJ, SM, and CTY. ATD developed the training. SG and SM contributed to the training materials. NYW developed the analytic plan. JG, EM, and TF participated in the recruitment and data collection. All authors read, reviewed, and approved the final manuscript.

Conflicts of Interest

KAG serves as the medical director for the American Board of Obesity Medicine, has a research grant from Novo Nordisk, and is a paid consultant to Eli Lilly.

Abstract

Background: No evidence-based support has been offered to young people (YP) who have experienced technology-assisted sexual abuse (TASA). Interventions aimed at improving mentalization (the ability to understand the mental states of oneself and others) are increasingly being applied to treat YP with various clinical issues. Digital technology use among YP is now common. A digital intervention aimed at improving mentalization in YP who have experienced TASA may reduce the risk of revictimization and future harm and make YP more resilient and able to manage distress that might result from TASA experiences.

Objective: In this paper, we describe a protocol for determining the feasibility of the i-Minds trial and the acceptability, safety, and usability of the digital intervention (the *i-Minds* app) and explore how to best integrate i-Minds into existing routine care pathways.

Methods: This is a mixed methods nonrandomized study aimed to determine the feasibility, acceptability, safety, and usability of the intervention. Participants aged between 12 and 18 years who report distress associated with TASA exposure will be recruited from the United Kingdom from the National Health Service (NHS) Trust Child and Adolescent Mental Health Services, sexual assault referral centers, and a web-based e-therapy provider. All participants will receive the i-Minds app for 6 weeks. Coproduced with YP and a range of stakeholders, the i-Minds app focuses on 4 main topics: mentalization, TASA and its impact, emotional and mental health, and trauma. A daily prompt will encourage YP to use the app, which is designed to be used in a stand-alone

XSL•FO
RenderX

manner alongside routine care. We will follow participants up after the intervention and conduct interviews with stakeholders to explore the acceptability of the app and trial procedures and identify areas for improvement. Informed by the normalization process theory, we will examine barriers and enablers relevant to the future integration of the intervention into existing care pathways, including traditional clinic-based NHS and NHS e-therapy providers.

Results: This study was approved by the Research Ethics Board of Scotland. We expect data to be collected from up to 60 YP. We expect to conduct approximately 20 qualitative interviews with participants and 20 health care professionals who referred YP to the study. The results of this study have been submitted for publication.

Conclusions: This study will provide preliminary evidence on the feasibility of recruiting YP to a trial of this nature and on the acceptability, safety, and usability of the i-Minds app, including how to best integrate it into existing routine care. The findings will inform the decision to proceed with a powered efficacy trial.

Introduction

Background

Child sexual abuse (CSA) is a major risk factor for many health risk behaviors as well as physical and mental health problems. CSA negatively impacts developmental trajectories, educational attainment, occupational prospects, and communities more broadly, at huge societal and economic costs [1,2]. For young people (YP), using the internet is a routine part of daily life, but it can place them at risk for various forms of CSA. Technology-assisted sexual abuse (TASA) can occur through any device connected to the internet and across multiple platforms and apps. YP can be coerced into sharing sexual images of themselves, taking part in sexual activities via a webcam or smartphone, or having sexual conversations by text ("sexting"). Web-based grooming, abuse, and exploitation may also lead to contact abuse; contact abuse cases increasingly involve web-based elements (eg, the production and distribution of images). Offline and web-based sexual abuse is not mutually exclusive in terms of risk behaviors or harm, but there is evidence of additional risks of TASA afforded by the internet and unique social and psychological harms associated with TASA [3,4].

COVID-19 has led child protection organizations to urge governments, tech companies, educators, and parents to be alert, take urgent measures to mitigate potential risks, and ensure that YP engage in web-based interactions in a safe and positive way. In the United Kingdom, an Online Safety Bill has been published and further consultation will be brought into law in 2022. The bill acknowledged the need for new legislation to make the internet a safer place for everyone, especially children, while protecting their right to freedom of expression on the web. The sharp increase in TASA, even before COVID-19, had already caused increased pressure on health care services, education, and government systems. Recent data show an increase of 34% in the demand for mental health support from YP during the pandemic [5]. The distinctive nature of TASA relative to other forms of abuse is recognized in the current National Institute for Clinical Excellence (NICE) guidelines for responding to child abuse and neglect [1]. The NICE found no evidence-based interventions for improving the mental health and well-being of YP who have experienced TASA (YP-TASA) and recommended further research on the efficacy of interventions aimed at improving well-being and relationships and preventing further harm following internet-facilitated abuse. The efficacy of interventions that could improve well-being and prevent further harm in YP-TASA remains an unmet research need.

Theoretical Framework

Multiple factors are likely involved in vulnerability to being exposed to TASA. A relevant risk factor is a young person's ability to accurately estimate others' intentions and motivations when engaging in a web-based environment. This ability to understand what is going on in our own minds as well as in other people's minds (in terms of thoughts, intentions, desires, and beliefs) is known as mentalization [6]. Mentalization is the ability to attend to and reflect on the mental states in ourselves and in others and consequently understand our own actions and those of others on the basis of intentional mental states. An inverse relationship exists between emotional arousal and mentalization [7]. YP who are distressed or have difficulties with regulation because of being victimized, abused, or exploited on the web may be at the greatest risk of developing difficulties in mentalizing, increasing the likelihood of repeated victimization and harm [8]. Furthermore, social anxiety (often experienced by YP who are groomed on the web) has been found to be associated with mentalization difficulties [9]. People's assumptions about the intentions and motives of others are usually based on the verbal and nonverbal cues of real-life interactions. When we communicate in a web-based environment, signals of empathy and understanding are transmitted more opaquely [10-12], and mentalizing, which is already compromised in vulnerable YP, can be even further affected. Difficulty mentalizing can compromise the evaluation of risk and assumed trust in web-based communications [13] and might therefore represent a valuable target for interventions aimed at reducing risk in YP who have already been exposed

XSL•FO
RenderX

to TASA. Indeed, difficulties in mentalizing processes have been linked to greater vulnerability to a range of mental health problems that are common among TASA survivors, including depression, anxiety, eating disorders, and shame [14,15].

A recent systematic review [14] has highlighted mentalization-based therapy (MBT), a therapeutic approach that specifically aims to improve mentalizing capacity and consequently affect regulation and psychological distress, as a promising treatment approach across a wide range of clinical presentations, including groups that have previously shown a limited response to psychological therapy (eg, adolescents who self-harm). The efficacy of MBT has been more extensively trialed in adult mental health; however, a growing evidence base is emerging for the efficacy of MBT in YP. For example, in a randomized controlled trial with adolescents who self-harmed, Rossouw and Fonagy [16] found that MBT for adolescents was more effective than treatment as usual, with a recovery rate of 44% in comparison with 17%. A pilot randomized controlled trial conducted by Griffiths et al [17] found that a brief (12 weeks) mentalization-based intervention was acceptable in YP enrolled in Child and Adolescent Mental Health Services (CAMHS) and was associated with significant treatment effects across a range of outcomes, including anxiety, self-harm behaviors, and the ability to regulate distressing emotions. Therefore, improved mentalization capacity following a mentalization-based psychological intervention might result in improvements in two key intervention targets for YP-TASA: (1) reducing the risk of revictimization and future harm and (2) improving the emotional and mental well-being of users who might experience current distress due to TASA experiences.

The Role of Digital Interventions

Although psychological interventions for YP can be delivered across multiple modalities, digitally mediated interventions represent an acceptable way to support YP and overcome some central limitations of traditional clinic-based services. Recent systematic reviews and meta-analyses have demonstrated that digitally mediated psychological interventions represent effective treatment options for improving the mental health and well-being of YP across a range of problems [18], including computerized cognitive behavior therapy targeting depression and anxiety, which have been most commonly examined. Existing feasibility, acceptability, and efficacy studies of digital interventions indicate that they are acceptable across genders [19], impact behavior as well as mood [20], and are safe for vulnerable YP [21]. Long waiting times in CAMHS indicate that there are significant delays in help being offered, preventing timely access to support, potential exacerbation of problems brought about by TASA exposure, and increased risk for repeated victimization in the interim. When effectively integrated within existing care pathways for YP, a digital intervention for YP-TASA has the potential to (1) scale-up access to support and tackle the overwhelming demand for services to provide timely therapeutic input and (2) ensure support can be implemented "in the flow of daily life" and in a format that is both familiar to YP and unconstrained by location and time, allowing access to therapeutic strategies even when traditional means of support are not available.

This Study

The aim of our National Institute for Health and Care Research (NIHR)–funded i-Minds clinical feasibility trial was to assess the feasibility, acceptability, safety, and usability of a theory-driven, coproduced, mentalization-based digital health intervention (the "i-Minds" app) for YP-TASA. This trial represents the third phase in the development and testing of the i-Minds app. In phase 1, we interviewed health care professionals (HCPs) across both Northwest England and Edinburgh, Scotland, to inform them of the content of the i-Minds app and the protocol design of the trial. We explored the following issues: (1) HCPs experiences of adapting face-to-face interventions to a web-based environment, (2) their understanding of TASA and current service approaches to supporting YP-TASA, (3) specific issues HCPs face when working with YP-TASA, (4) previous experience of mentalization approaches in clinical work, (5) advantages and disadvantages of delivering psychological approaches using digital tools, (6) perceived barriers or facilitators to implement digital tools in clinical practice, and (7) uptake of a digital health intervention of this nature with this client group and our proposed trial procedures (results currently being prepared for publication). We also held monthly to bimonthly participatory workshops with a range of stakeholders, including those with lived experience, YP, parents and professionals, and nationally representative stakeholders, to inform the design and functionality of the digital health intervention and our proposed trial procedures. In phase 2, the University of Manchester Digital Health Software (DHS) team built the i-Minds app over an 8-month period of agile development and testing alongside qualitative and participatory design work. In the third phase, using a nonrandomized open trial design, we will test whether the i-Minds app is feasible, acceptable, and safe for YP-TASA.

Regarding consent, where prospective participants expressed an interest in taking part in the study, their clinician obtained the individual's written or verbal consent to pass on their name and contact details to the research team. Once it has been established that a prospective participant is interested in taking part in the study and has given permission to be contacted by the research team, the researcher will contact the prospective participant to explain the study to them in detail and give them the opportunity to ask questions. The researcher will explain that participation is voluntary and that they can withdraw consent at any point during the study without giving a reason, which will not impact them continuing to access standard care within the referring service (as the i-Minds app is designed to be used in addition to, not in place of, standard care) or other sources of support they might access simultaneously.

Personally identifiable data are collected by the local recruitment site, separate from the research database. The research data were deidentified.

YP-TASA participants will be remunerated £40 (US $50) for their time to complete the baseline assessment (£20 [US $25]) and the follow-up (postintervention) assessment (£20 [US $25]). Participants who also participated in the nested qualitative interview study will receive a further £20 (US $25) for their time. This amount was based on NIHR INVOLVE guidelines.

XSL•FO
RenderX

YP who do not have access to a smartphone will be provided with one, and their data network charges will be covered for the 6-week intervention period. HCPs who participated in the nested qualitative interview study will not receive payment for their participation.

Objectives

The primary study objectives were to determine (1) whether it is feasible to deliver the i-Minds app for YP-TASA, including recruitment and retention to the trial, and identifying primary and secondary outcome measures; (2) whether the i-Minds app is acceptable to users; (3) whether the i-Minds app is usable and safe; and (4) how best to integrate the app into existing National Health Service (NHS) and web-based mental health and sexual abuse service care pathways.

Methods

Study Setting

The trial is funded by the NIHR Health and Social Care Delivery Research program. The study took place across the CAMHS and sexual assault referral centers in Greater Manchester (England) and Edinburgh (Scotland). We also aimed to recruit participants from an NHS-commissioned national (England) e-therapy provider (Kooth).

Ethics Approval

The study was approved by the National Research Ethics Committee (REC) of West Scotland REC 4 (approval number 22/WS/0083).

Study Design

Overview

This was a multicenter mixed methods study comprising two components: (1) a nonrandomized feasibility clinical trial with the aim of recruiting a target sample of 60 YP-TASA across recruitment sites. This sample size was shown to be sufficient to pilot test the feasibility and acceptability of an intervention of this nature. All participants will have access to the app and will be included in all analyses for the feasibility clinical trial. To evaluate who might benefit from using the i-Minds app, we will recruit participants with varied characteristics wherever possible (eg, ethnicity, sexual orientation, gender, TASA experiences); (2) a combination of quantitative data on adoption, uptake and use (aligned with the AMUsED framework [22]), and qualitative data from semistructured interviews guided by the Normalization Process Theory (NPT) with participants (n=approximately 20) and HCPs who referred YP-TASA to the trial (n=approximately 20) and service managers from the referring service provider (n=approximately 10) who referred to the trial will explore the acceptability and usability of the i-Minds app.

Eligibility

The participant inclusion and exclusion criteria are presented in Textboxes 1 and 2, respectively.

Textbox 1. Inclusion criteria.

- Young people (YP) who have experienced technology-assisted sexual abuse (TASA) participants
  - Aged 12 to 18 years
  - Have been exposed to (TASA) and report associated distress
  - Are receiving support from National Health Service Child and Adolescent Mental Health Services, sexual assault referral centers or e-therapy provider (Kooth) and will continue to be actively supported by the provider over the duration of the trial
  - Willing to use an app designed to support YP who have experienced TASA
  - Proficient in speaking and writing in English
  - Capacity to consent
  - Consent to providing their username to the research team (Kooth participants only)
- Health care providers or service manager participants (qualitative interviews)
  - The member of the young person's direct care team who referred the young person to the feasibility clinical trial
  - The manager at the service that referred the YP to the feasibility clinical trial
  - Able to understand and speak English

XSL•FO
RenderX

Textbox 2. Exclusion criteria.

- Young people who have experienced technology-assisted sexual abuse people participants
  - Insufficient verbal and written command of English
  - Moderate learning difficulties (as assessed by their direct care team)
  - Are at risk of current or recent suicidality
- Health care professional participants
  - None (other than not meeting the inclusion criteria)

Recruitment

Feasibility Clinical Trial

The research team will liaise with the CAMHS and sexual assault referral centers teams and the e-therapy provider Kooth to provide information about the study via presentations at team meetings and study information leaflets, referral and consent to contact forms, and copies of the relevant participant information sheet. Clinical staff will be encouraged to identify potentially eligible participants from their caseload. Participants may also be identified by placing poster advertisements in waiting rooms or via digital spaces (via the digital magazine used by the e-therapy provider Kooth). The advertisement will invite interested prospective participants to ask for information about the study from a member of their clinical team.

After obtaining informed consent, potential participants will be provided with a participant information sheet for reading. Prospective participants aged 12-15 years recruited from the English NHS recruitment site will be provided with a bespoke participant information sheet to give to at least 1 of their parents or caregivers. The parent or caregiver will have the ability to opt their child out of taking part in the study (by contacting the research team or the child's clinical team or by completing an opt-out form), should they not wish their child to take part. Prospective participants aged 12-15 years recruited from the Scottish site will be asked if they would like their parents to be given a participant information sheet.

Nested Qualitative Study: YP-TASA Process

Participants who participated in the feasibility clinical trial and who consented to participate in the qualitative study will be eligible to participate in qualitative interviews, which aim to understand how participants experienced the i-Minds app and its acceptability. Participants will be invited to the qualitative interview study when information is provided, and consent will be obtained for the feasibility clinical trial. Participants will be approached directly by the research team to participate in the interview upon discontinuation from accessing and using the app or completion of using it. Therefore, participants who do and do not complete the feasibility clinical trial in its entirety will be asked to participate in the interview. Participants will be selected according to a sampling framework to capture varied demographics, experiences of TASA, and levels of engagement with the i-Minds app.

Nested Qualitative Study: HCPs or Service Managers

As trial participants start completing postintervention assessments, a research worker will contact and invite a target sample of approximately 20 HCPs who referred YP-TASA to the feasibility clinical trial and 10 service managers from the referring service provider to participate in a semistructured interview (postintervention). A list of referring clinicians or managers will be kept separate from the research data.

Consent

Trained members of the research team will receive consent. In both the quantitative feasibility clinical trial and nested qualitative interview study, fully informed consent will be sought from YP and HCPs or service managers and obtained before data collection and when participants access and use the app. Health Research Authority (HRA)– or REC-approved copies of age-appropriate participant information sheets and consent forms will be used for prospective YP, including those aged 12-15 years and 16-18 years. Prospective participants aged 12-15 years who are recruited in England will be provided with a participant information sheet to give to at least 1 of their parents or caregivers, who will be given the opportunity to opt for their child to not wish their child to take part in the study. Parents or caregivers of 12-15 year olds recruited from our Scottish site will be given a copy of the participant information sheet if the young person wishes. Parents or caregivers of prospective participants aged 12-15 years in Scotland will not be able to opt out of the study if the prospective participant is Gillick competent.

YP are provided with information about both the feasibility clinical trial and the qualitative study in one age-appropriate participant information sheet given to them before taking part in the feasibility clinical trial. They were asked to consent to participate in the qualitative study as part of the consent process for the feasibility clinical trial, but continued consent was checked if they were invited to participate in the interview.

The researcher will explain to all potential participants that participation is voluntary and that they can withdraw their consent at any point during the study without providing a reason. It will be made clear to YP that, as the intervention is not in place of standard care (it is in addition to standard care), withdrawal from the intervention will not impact their ability to continue to access standard care within the referring service or other sources of support they might access contemporaneously. Prospective participants in both the feasibility clinical trial and qualitative study will be given

XSL•FO
RenderX

multiple options for documenting their informed consent, including (1) a signed hard copy of the consent form by standard mail, (2) returning a digitally signed copy of the consent form by email (encrypted), and (3) recording their consent on an encrypted audio file that will be stored separately from any research data collected from them. The participant's general practitioner or care team will be provided with a letter to inform them that a young person is taking part in the study.

Participants will be given at least 48 hours to decide whether to participate. If a participant who has provided informed consent loses the capacity to consent during the study, the participant will be withdrawn from the study. Identifiable data already collected with consent will be retained and used in the study. No further data will be collected or any other research procedures will be carried out on or in relation to the participant. The withdrawn participants will be referred to their service provider so that appropriate follow-up care and action can take place.

Data Collection and Management

Quantitative and qualitative data were collected through psychometric measures and interviews. The initial interview will involve the completion of self-reported sociodemographic questions, technology use, and clinical or service details. A range of validated self-report scales will measure key intervention targets and outcomes of the intervention both before (week 1) and after using the app (weeks 7-9 post baseline), including reflective function (mentalization), problematic internet use, emotional distress, internet abuse-related distress, emotion regulation, interpersonal sensitivity, attitudes and views toward close interpersonal relationships, and resilience. Multimedia Appendix 1 describes the schedule of the assessments at the 2 assessment time points.

Measures will be completed via the web-based Qualtrics survey system, capturing all the measures in the case record form, or, where this is not possible, a paper or hard-copy version of the case record form will be used. Demographics, clinical, and web-based abuse-related distress measures will be completed with support from the research worker (participants will be given the choice to complete the remaining self-report measures either on their own or with continued support from the researcher). The assessments of reflective function and emotion regulation will be administered next, with the remaining measures completed in a randomized order. All data (ie, demographic data, clinical data, self-report questionnaires, data related to trial administration, and procedures) will be entered and managed on the REDCap (Research Electronic Data Capture; Vanderbilt University) platform [23], a secure clinical trial management system. Data will be stripped of any identifying information and each participant will be assigned a unique participant ID. All information obtained is confidential. Research workers at each participating site will input data collected via Qualtrics (Qualtrics International Inc) into the REDCap database. In the case of paper or hard copy–completed questionnaires, research assistants will (1) scan paper copies for digital preservation of all research completed as part of the study and (2) enter questionnaire scores on the REDCap database.

Qualitative interviews will be audio-recorded for transcription and analytic purposes, using recording devices that enable encryption at the point of data collection. All interviews were anonymized at the time of transcription, and all identifying details were removed. Audio-recorded consent (including participants' names) will be recorded on a separate audio file so that this information cannot be directly linked with the interview transcripts or audio recordings.

Outcomes

Primary Outcome

The primary objective of the trial was to determine the feasibility and acceptability of delivering the i-Minds app for YP-TASA. No formal attempt has been made to test the effectiveness of the intervention which will be conducted.

Feasibility

We will collect detailed recruitment and retention data congruent with all relevant fields of the CONSORT (Consolidated Standards of Reporting Trials) statement for feasibility studies [24], including (1) the number of eligible participants consenting; (2) the total number recruited, including information about recruitment setting to inform the sampling strategy of a future definitive trial; (3) completeness of outcome measures; (4) the number lost to follow-up; and (5) number of services offered the intervention. To evaluate the extent to which YP-TASA engaged with i-Minds, we collected data on the (1) proportion of participants completing the intervention, (2) dropout rates and reason for withdrawal, and (3) platform use and engagement data using Matomo click analytics software [25] with use analysis guided by the AMUsED framework [22].

Acceptability

To understand how the intervention is experienced and how acceptable the app and trial procedures are, we will conduct in-depth qualitative interviews with a proportion of YP-TASA who will be selected according to a sampling framework to capture varied demographics, experiences of TASA, and levels of engagement with the i-Minds app. Interviews will be conducted in rounds of approximately 5 participants to allow for iterative analysis and inform further sampling. Topic guides developed with input from our advisory groups will be used to examine (1) whether i-Minds met expectations; (2) what level of support is needed to facilitate engagement with i-Minds; (3) overall impressions of i-Minds (enjoyable, usability, and satisfaction); (4) what participants liked and did not like about the intervention in terms of content and usability of the platform; (5) how it helped and did not help; (6) what changes they would make; (7) barriers to participation or engagement, including the perceived burden of the research assessment procedures; and (8) acceptability of trial procedures.

To examine barriers and enablers (and unintended consequences) to integration and uptake of the intervention into existing care pathways, we conducted qualitative interviews with a target sample of 20 HCPS who referred to the trial and 10 service managers to examine specific questions around (1) ways in which we can maximize uptake, utility, user experience, acceptability, satisfaction, and reach of the platform; (2) how the platform can be locally adapted and translated into practice;

XSL•FO
RenderX

(3) HCPs' views on referral routes to a digital intervention within existing care pathways; and (4) strategic perceptions about the relative advantage of the digital platform and its wider transactability (whether it can be scaled up). Before taking part in the interview, HCPs will be asked to complete some brief demographic questions (eg, age, profession, and years of professional experience).

Topic guides were developed in collaboration with our lived experience, parents or caregivers, and professional advisory groups. We anticipate all qualitative interviews to take approximately 1 hour, depending on the extent to which the participant requires breaks or further support or guidance and includes full debriefing.

Secondary Outcomes

The secondary objectives of this trial were to explore whether the i-Minds app brings about clinically meaningful changes in outcomes (described in Multimedia Appendix 1), differences in engagement and attrition, and potential clinical benefits across key demographic groups (eg, lesbian, gay, bisexual, transgender, queer, and others [LGBTQ+] and Black, Asian, and minority ethnic [BAME]), demographics and service differences across recruitment sites (Manchester, Edinburgh, or Kooth), and barriers and enablers to integration and uptake into existing mental health care provider pathways. We will also explore the safety and usability of the app and our trial procedures.

Safety

We will collect detailed adverse event reports using standardized operating procedures in line with our study sponsor and HRA safety reporting procedures.

Any adverse event observed over the course of the research will be documented and reported according to a bespoke standard operating procedure that will fully comply with appropriate HRA safety reporting procedures, sponsor requirements, and local research and development policies of participating NHS organizations. All adverse events will be monitored by an independent Data Monitoring and Ethics Committee (DMEC) that aims to meet on 3 occasions (and more frequently if needed) over the course of the trial period. An adverse event log file will be created to systematically record occurrences with reference to an a priori defined list of anticipated and unanticipated adverse events.

Usability

As this was a feasibility clinical trial, we had no a priori hypotheses or intentions regarding the level of compliance with the app. Rather, we sought to explore and understand how participants used the app and how they used it. Platform use and engagement data collected using secure software analytics while participants use the app will be guided by the AMUsED framework [22]. All interactions with the app are date and time stamped and collected via Matomo click analytics software [25] to help us understand how a participant uses the app; it is open source and is General Data Protection Regulation compliant. All the analytical data were stored securely. The data were stored on a secure server hosted by the University of Manchester. Analytics can be viewed by the researcher using a secure web interface dashboard. Multimedia Appendix 2 provides an overview of the study objectives and time points for the evaluation of each outcome.

The Intervention: i-Minds App

The i-Minds app was developed in phase 2 of the broader program of our work on TASA. It is a modular intervention, underpinned by mentalization principles, and designed to be used as a standalone platform without restrictions. Following the overall structure and content of a mentalization-based manual developed by members of our team in a previous trial [17], the i-Minds app involves several tasks that not only provide psychoeducation about mentalization but also encourage the application of mentalization principles to a range of scenarios presented to YP. For example, we present the story of a young person with lived experience of TASA (called *Mel*) and, in vignette style, invite users to put themselves in *Mel's* shoes and consider a range of questions, such as *How do you think Mel feels at school, at home and in other situations that might remind her of what she went through?* We extend the vignette further throughout the app and invite users to pick out situations that could bring about negative feelings for *Mel* in a range of contexts (school, home, and peer relationships), which we further extended using video material and other interactive exercises.

The aim of the intervention is to help YP-TASA understand the motives of adults and peers more clearly, help protect them from future abuse, and help them feel more confident in ambiguous and challenging interpersonal interactions. The app includes content that aims to introduce the concept of mentalization and relate it to scenarios that YP-TASA might identify with, encourage emotional and cognitive literacy in interpersonal interactions, encourage reflection on interpersonal relationship patterns and their development, and explore how these concepts affect emotional expression, behavior, mental health (eg, anxiety, mood, trauma responses, self-esteem, self-harm behavior), and perspective taking. The content is organized into four modules or topic areas: (1) mentalization, (2) psychoeducation of TASA, (3) emotional and mental health, and (4) trauma. There are links to other areas of the app within each core topic area to maximize interactivity and user experience. In addition to the core topic areas, there is a multimedia repository of available resources that can be accessed from the home screen (Multimedia Appendix 3).

The app can either be downloaded onto a participant's own smartphone or a participant will be loaned a smartphone with the i-Minds app preloaded. The participant can configure certain features of the app themselves during the app "onboarding" session with the researcher, which will either take place in person or remotely, depending on the participant's choice. Participants were required to work through the mentalization module, which is core to the theoretical orientation of the intervention, before all other features of the app can be accessed. There were no limits to how often or when a participant could use the app. That is, we did not restrict how users interacted with the app over the 6-week intervention period.

Consultation with our advisory group indicated that YP would like the app built around a tree metaphor (see Multimedia Appendix 4 for screenshots of the i-Minds app). Topic areas

XSL•FO
RenderX

are represented by branches of a tree, and subtopics are represented by smaller tree branches. As a user works through a subtopic, a leaf is added to the tree, which begins to flourish as the user works through the content (the branches are bare to start with). As suggested by both our young persons' and professionals' advisory groups, we also included a "progress ring" around each topic area, which shows the user how far they have progressed through each topic. Tapping on a particular topic area opens an introduction screen that includes introductory text on the topic area. Informed by our advisory group, the flow of each topic area thereafter includes text, video material, and interactive exercises exploring the topic areas, as shown in Multimedia Appendix 3.

Daily Prompt

A daily prompt in the form of a standard app notification (similar to a Facebook or Twitter notification) will request the participant to check in with the app. The daily notification is designed to prompt engagement with the app and has been included in response to advisory group feedback and our prior experience with app studies [26]. If a participant could not interact with the app at the time of the prompt, they received a reminder notification 3 hours later. This daily prompt was not sent if the participant had already used the app on that day. Participants can also self-initiate use of the app at any time of the day, as many times as they chose. At midday after each 7-day period, an additional weekly prompt invites the user to reflect on app use in the previous week. A research worker will also call the participant 1 week after the onboarding session to troubleshoot the potential technical difficulties. We include the 1-week phone call, as we know that if any technical issues arise, they will most likely be apparent at this time point.

Onboarding Session

A research worker will meet the participant (either remotely or in person) for a single onboarding session. Here, the research worker will take the participant by configuring the app (eg, including contact details of trusted others), explaining the terms of use in young person friendly terms, demonstrating the features of the app, and demonstrating how to use a smartphone.

Postintervention

At the end of the 6-week intervention period, if the participant had received a loaned phone, the researcher collected the handset at the follow-up assessment. If the app is downloaded onto a participant's own handset, the researcher will either delete the app from the participant's phone so that they can no longer interact with it or the app will automatically stop working no later than 3 weeks after the intervention window. Data network charges will be covered by vouchers and topped up by a member of the research team (if required). Participants will be encouraged to continue receiving support from their health care providers. As participating in this trial does not replace usual care and as all participants will be involved with a clinical service throughout the duration of the trial, participants' posttrial will continue to be supported by the referring health care provider. Participants will be given an information sheet, signposting them for further support if required.

Feature Implementation

We followed an agile development process that supports close collaboration between software engineers, clinical academics, and advisory groups that developed and shaped the content of the intervention, enabling the incorporation of changing requirements throughout app development. In line with this process, the working software was delivered on a regular basis and reviewed by the clinical team and advisory groups who provided interim feedback on the user interface developed, software performance, and usability. Any required changes were then incorporated into the next iteration of platform development and continued until the app was fully functional.

i-Minds was written as a hybrid app (HTML, Cascading Style Sheets, JavaScript) using the ionic or capacitor platform [27]. Phone interactions, such as notifications and alarms, are implemented using the capacitor plug-in framework, which facilitates interactions between JavaScript code and platform-specific phone capabilities. The app uses a secure connection (http secure or SSL) to send data to a server. The only data sent were to indicate progress through each module. Before release, the app is unit, integration and system tested, and then reviewed internally at the University of Manchester before submission to the Google Play and Apple App stores.

The i-Minds app is made available on Apple iPhone Operating System and Android devices and implements best practice guidelines offered by the platform providers (Android App Accessibility Guidelines [28] and Apple Human Interface Guidelines [29]). The app is offered as an app to both Google Play and Apple App stores. This software was developed by the University of Manchester DHS.

The app is not a medical device as it has not been designed to be used for diagnosis, prevention, monitoring, treatment, or alleviation of disease, injury, or handicap.

Accessibility Statement

Accessibility needs of the target audience have been considered when developing accessibility provisions within the i-Minds app, and every effort has been made to ensure that the provision meets the needs of these users. Accessibility needs have been developed in accordance with Public Sector Bodies (web sites and mobile apps) (No 2) Accessibility Regulations 2018 ("Accessibility Regulations" [30]). When using the app on Apple iPhone Operating System and Android devices, users can use the built-in accessibility settings to adjust font sizes, use high contrast settings, zoom in up to 300% with the text staying visible on screen, navigate using only a keyboard or speech recognition software, and use the screen reader. In line with user input, we have made the text in the app as simple as possible to understand to increase its suitability for learners with a wide range of educational backgrounds. Users and research workers can report problems directly to the University of Manchester DHS team email address, which is monitored during the usual working hours. All participants had to accept the end-user license agreement, which is based on a standard template, before they could use the app. A lay version of the end-user license agreement was developed by the research team and was shared and discussed during the onboarding session to

XSL•FO
RenderX

ensure that participants were making an informed choice about how their data were used.

Testing

We followed a strict user-acceptance testing procedure before the first public test release of the app. This procedure includes a section that specifically encourages researchers to test all accessibility features of their devices and determine which aspects of the app support these features. This procedure highlights any content that is not compliant with the Web Content Accessibility Guidelines 2.1-AA standard. Any noncompliant content that is considered the core functionality of the app or essential to the user experience was addressed at this stage.

Privacy, Security, and Risk

Security measures are robust and fully comply with national policies and relevant data management and information governance policies and procedures of the participating Universities and NHS organizations. All trial investigators and site staff comply with the requirements of the Data Protection Act 2018 or General Data Protection Regulation and the NHS Confidentiality Code with regards to the collection, storage, processing, and disclosure of personal information and will uphold these acts' core principles. The i-Minds app uses the University of Manchester Privacy Notice for Research Participants (available upon request). Once the user has installed it, they are given a unique code. The app will only become functional after the unique code has been given to the researcher, and the researcher will add it to the participant record via the web interface.

The following security features are used: (1) app: Use of the app requires a PIN code on the user's phone, which will be checked and enforced when the app starts. Data collected within the app are sent to the server over http secure using secure ciphers; (2) server: the server is part of the University of Manchester's research virtual machine infrastructure and is secured inside the University's network. Operating system and related security patches are applied on a regular basis to these servers by the University's infrastructure team; and (3) web-based interface: members of the research team are each allocated their own username and password to access the web-based interface. The DHS team has administrative access to the web-based interface to enable it to maintain the system and manage accounts for researchers. All members of this team received their current data protection training.

To minimize security risks, no part of the system will collect identifiable information. A pseudonymized identifier was used to identify each participant. Only the research team knows the link between this identifier and the actual participant. This link will not be stored anywhere in the system, and the software team will only have access to pseudonymized identifiers.

Regarding participant safety and risk, at the point of referral, we will collect the contact details of the participant's general practitioner and key worker from the referring service, who will be our primary point of contact for subsequent liaison with the clinical team or key worker to manage any significant risk. If a participant discloses something that raises serious concerns (eg, historical abuse, current abuse) about their safety or the safety of others or if a research worker becomes distressed themselves, given the topic and nature of the work, we will follow the safeguarding and distress management procedures described in our coproduced and ethically approved detailed standard operating procedure. As a general rule, we signed participants to the appropriate sources of support in their locality.

Withdrawal

A participant will be withdrawn if they express either to a member of the research team or to their key clinical worker that they wish to withdraw from the intervention, the trial, or both. If a participant withdraws from the study, we will complete a withdrawal form, suspend data collection activities, and retain and analyze the anonymized data collected up to the point of withdrawal. If a participant withdraws from the intervention, we will cease their use of the app but still invite them to complete follow-up measures and a qualitative interview to understand their reasons for withdrawal from the intervention (but only if the participant consents to this).

Independent Oversight

Independent oversight of the trial is provided by a project steering committee (PSC) and a DMEC who are independent from the sponsors and investigators and approved by the funder. The PSC comprises an independent chair, statistician, academic, clinician, and patient and public involvement representative and will meet every 6 months over the duration of the project. The PSC is responsible for the independent oversight of the project on behalf of the sponsor and funder and will ensure that the project is conducted according to the rigorous standards set out in the Department of Health's Research Governance Framework for Health and Social Care and the Guidelines for Good Clinical Practice. The DMEC comprises an independent chair, statistician, and digital health expert and is responsible for monitoring ethical issues of consent and confidentiality, data quality and completeness, incidence of adverse events, compliance with the protocol by participants and investigators, and any other issues relevant to the transparent and ethical delivery of the trial. The DMEC aims to meet on 3 occasions over the course of a feasibility clinical trial.

Patient and Public Involvement and Engagement

Our aim was to develop a digital intervention as opposed to an "offline" one that was directly influenced by the views and preferences of YP-TASA. Before our application for funding, we conducted extensive consultations with YP-TASA and a range of stakeholders. In line with NICE [1] research recommendations for developing interventions to improve well-being following TASA, we have continued to seek extensive feedback from YP-TASA, parents, and practitioners via 3 advisory groups, who we will work with for the lifetime of feasibility and nested qualitative studies. The active involvement of YP-TASA, their parents or caregivers, and relevant professionals ensures active input into the development of the intervention, including its content, format, and structure, and linked procedures to ensure participant safety, as well as to

XSL•FO
RenderX

deliver its evaluation and dissemination of the findings to maximize impact.

Three advisory groups were established. A national stakeholders advisory committee meets every 6 months and comprises professionals from national law enforcement and child protection or safeguarding organizations, academic institutions, TASA support services, and social media organizations. A professional advisory committee meets every 6 months and comprises clinicians from relevant services that provide mental health and web-based sexual abuse or safeguarding support to YP in our recruiting sites. Our lived experience advisory group comprises up to 10 people with TASA experiences who meet monthly to bimonthly over the course of the project. Input was received both through web-based meetings and through individual written feedback on participant-facing documents and app content itself. The lived experience advisory group has already influenced the participant information sheet, for example, explaining that not all sexual experiences on the web are unwanted and some may be wanted but in fact go wrong; as such, we have reflected this important point in our participant-facing documents. Our advisory groups reviewed and entered key trial documents, including our risk management and distress protocols.

In line with the United Kingdom Government User Research guidelines [31], app development was supported by a series of participatory consultations, which enabled end users to influence the design and functionality of the app, leading to the development of an intervention that we hope is more likely to be acceptable, have better uptake, and be effective. By working together, developers and users can learn and optimize platform functionality, with developers being responsible for pointing out technical options and users providing information about their needs, practices, and how they will use the system.

Statistical Analysis Plan

Because hypothesis testing is not the objective of this study, formal power calculations are not appropriate. The proposed sample size is sufficient to establish feasibility and to report response rates, follow-up rates, safety information, and attrition, as well as the clinical characteristics of our study population at the beginning of the study and follow-up.

Appropriate descriptive statistics (mean and SDs for continuous data; counts and percentages for categorical data) will be used to summarize (1) recruitment and retention data in line with CONSORT statement standards and the extent to which services refer to trial, (2) data use patterns (frequencies; data visualization) using secure software analytics in line with the AMUsED framework for analyzing and measuring use and engagement data in digital interventions [22], (3) completeness of study measures, and (4) the number and nature of adverse events observed over the course of the trial. Pre- and postintervention questionnaire data will be analyzed using the Leeds Reliable Change Indicator [32] or other approaches for the evaluation of reliable or clinically significant changes in secondary outcome measures (eg, when conditions for the application of the Leeds Reliable Change Index are not met) to determine the number and proportion of participants who achieved significant improvement on clinical measures and who achieved no significant worsening of clinical measures at posttreatment. To explore how different participants engage with the app, attrition, and clinical benefit across key demographic groups (eg, LGBTQ+ and BAME) and potential service differences across recruitment sites, we will use descriptive analysis to inform future work; we will not test for differences, as the study is not powered for this.

When a participant has completed a questionnaire but has not completed all elements of that questionnaire, we will use validated instruments and will follow the established procedures for calculating overall scores in the presence of partially missing data.

When data are completely missing for a whole questionnaire, we will record the occurrence of this and, if the prevalence of such missing data permits, use multiple imputations assuming these data are missing at random. We may also, if we think these data may be informatively missing, ie, missing not at random, investigate appropriate sensitivity type analyses to see whether our findings are robust to these missing data.

For qualitative data, we used a qualitative framework approach. Analysis of qualitative interviews will occur alongside transcription and data collection so that we can iterate our topic guide. We initially use the framework method to adopt an inductive approach to theme generation. Subsequent theme refinement will be deductive and guided by the NPT. NPT is a widely used [33,34] theory to explain the processes by which an intervention becomes, or fails to become, normalized into routine practice, and offers a framework for assessing the conditions in which interventions become practically workable in health care. NPT comprises 4 constructs (coherence, cognitive participation, collective action, and reflexive monitoring), which are a set of propositions that we will use to explore perceptions, expectations, attitudes, challenges, and unintended consequences of integrating a digital intervention for YP-TASA in existing NHS service and e-therapy provider pathways. This approach enables us to answer our research questions while allowing important insights to be iteratively produced. The coding framework is then applied to the analysis of subsequent transcripts, with ongoing adaptations as new themes emerge. Data will then be charted into a matrix with illustrative extracts and interpretive themes refined through discussions at regular analysis meetings. We will engage a wider research team, our advisory groups, and stakeholders in the analysis process (member checking or participant verification). This peer verification process (together with member checking) is a recognized method for ensuring the trustworthiness of the data and subsequent findings [35]. Records of field notes will be maintained and reflections providing adjunctive data will be used to illuminate and justify interpretative decisions.

Dissemination

We plan to present our findings at academic conferences and publish them in peer-reviewed academic journals. We also developed a project website [36] which we will keep up to date with study progress. Our social media account will also be used to promote the study, update progress, and disseminate high-level findings. The findings will also be disseminated with support from our advisory groups in a multimedia format at, for example, practitioner and public forums, events (eg,

XSL•FO
RenderX

conferences, meetings, seminars), and via government and policy events. Feedback to participants and clinical services will be provided through coproduced written summaries.

Results

We aimed to collect data from up to 60 YP. This study was registered as a clinical trial (ISRCTN43130832). Recruitment was initiated in May 2022. We expect to report results for feasibility on (but not necessarily limited to) (1) the number of eligible participants consenting; (2) the total number recruited, including information about recruitment setting to inform sampling strategy of a future definitive trial; (3) completeness of outcome measures; (4) the number lost to follow-up; (5) the number of services offered the intervention; (6) the proportion of participants completing the intervention; (7) dropout rates and reason for withdrawal; (8) platform use and engagement data; and (9) safety of the app and our trial procedures. We also expect to report on differences in engagement and attrition and potential clinical benefits across key demographic groups (eg, LGBTQ+ and BAME), the demographics and service differences across recruitment sites, and the barriers and enablers to integration and uptake into existing mental health care provider pathways. We expect the results to be available at the end of 2023 (subject to recruitment targets and funding requirements).

Discussion

Expected Findings

The aim of our NIHR-funded i-Minds trial was to assess the feasibility, acceptability, safety, and usability of the theory-driven, coproduced, mentalization-based i-Minds app for YP-TASA. Specifically, our primary objectives were to determine (1) whether it is feasible to deliver the i-Minds app for YP-TASA, including recruitment and retention to the trial and identifying primary and secondary outcome measures; (2) whether the i-Minds app is acceptable to users; (3) whether the i-Minds app is usable and safe; and (4) how best to integrate the app into the existing NHS and web-based mental health and sexual abuse service care pathways. To the best of our knowledge, this is the first clinical trial of this type in this population worldwide, which is why we chose to conduct a feasibility clinical trial rather than a powered efficacy trial.

To date, we have carried out a series of qualitative interviews and focus groups with HCPs working with YP in secondary care mental health settings, held regular advisory group meetings with our 3 advisory groups, incorporated input and feedback from this work into the development of the app content and user interface, built and tested the app and met all the security standards required for deployment, and commenced recruitment to the clinical feasibility trial. The user-driven design approach we have adopted in this trial is intended to ensure that the intervention is engaging and relevant and reflects the experiences of YP-TASA. For example, Vichta et al [37] used interactive workshops and a web-based survey to gather YP's perspectives on platform integration into mental health care. Venning et al [38] conducted semistructured interviews and focus groups to explore the acceptability of a low-intensity digital computer-based training platform incorporating a virtual coach with university students and HCPs.

If feasibility for the current approach in this population is found, we will use the results from the nested qualitative study about how our approach can be integrated into a model of care (eg, hybrid, stepped, or blended) to inform the design of the next phase trial, should one be indicated.

Limitations

This study targeted young help-seeking individuals accessing clinical services. It is hoped that these findings could also be useful in YP experiencing distress but not necessarily seeking help or support from clinical services. As this was a pilot study, we were unable to conclude whether the intervention brought about a clinically significant change. However, this study design, with its focus on feasibility, acceptability, safety, and usability, will provide valuable insights that will inform parameters for a future definitive trial, should this be indicated. Moreover, feedback from all stakeholders will allow for improvements in the app, trial procedures, and plans for implementation.

Conclusions

This feasibility clinical trial stands to advance the support for YP-TASA, a nascent area for both research and clinical delivery. Exploring the feasibility, acceptability, usability, and safety of the intervention is the first step in creating a more definitive intervention that may be further tested in future studies and implemented to support YP-TASA across a range of settings.

Acknowledgments

This study was funded by the National Institute for Health and Care Research (NIHR) and Health Services and Delivery Research Program (NIHR 131848). The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care. This study was supported by the National Institute of Health Clinical Research Network. The authors would like to thank lived experience and professionals' advisory groups in developing the trial procedures, as well as the members of our project steering committee and Data Monitoring and Ethics Committee for their independent monitoring and advice.

Data Availability

The data set generated in this study is not publicly available owing to ethical restrictions for personal health information; however, limited, deidentified data may be made available from the corresponding author on reasonable request.

Authors' Contributions

SB, FV, MS, and EQ conceived the study and, along with KC who secured funding and MM, led the development of the i-Minds app. MM is responsible for engineering the i-Minds app. KC and SB drafted the trial protocols. PW led the participatory design work. KC led the Patient and Public Involvement and Engagement work. SB, MS, FV, and EQ led to the development of the app content. JN provided an overview of the trial design. SB and FV reviewed the clinical aspects of Manchester's study. MS and EQ oversaw the clinical aspects of Edinburgh's study. PC and CR oversaw the clinical management of recruiting sites in Greater Manchester and Edinburgh, respectively. VG provides a Patient and Public Involvement and Engagement overview of the study. SB drafted the manuscript. All authors critically revised the manuscript for intellectual content and approved the final version of this protocol.

Conflicts of Interest

Unrelated to this project, SB and PW are directors and shareholders of CareLoop Health Ltd, which develops and markets digital therapeutics for schizophrenia and a digital screening app for postnatal depression. SB also reports research funding from the National Institute for Health and Care Research and Wellcome Trust. PW is also a Director of Prism Life Ltd, a small research and consultancy company, unrelated to this project.

Abstract

Background: In the health care setting, electronic health records (EHRs) are one of the primary modes of communication about patients, but most of this information is clinician centered. There is a need to consider the patient as a person and integrate their perspectives into their health record. Incorporating a patient's narrative into the EHR provides an opportunity to communicate patients' cultural values and beliefs to the health care team and has the potential to improve patient-clinician communication. This paper describes the protocol to evaluate the integration of an adapted person-centered narrative intervention (PCNI). This adaptation builds on our previous research centered on the implementation of PCNIs. The adaptation for this study includes an all-electronic delivery of a PCNI in an outpatient clinical setting.

Objective: This research protocol aims to evaluate the feasibility, usability, and effects of the all-electronic delivery of a PCNI in an outpatient setting on patient-reported outcomes. The first objective of this study is to identify the barriers and facilitators of an internet-based–delivered PCNI from the perspectives of persons living with serious illness and their clinicians. The second objective is to conduct acceptability, usability, and intervention fidelity testing to determine the essential requirements for the EHR integration of an internet-based–delivered PCNI. The third objective is to test the feasibility of the PCNI in an outpatient clinic setting.

Methods: Using a mixed method design, this single-arm intervention feasibility study was delivered over approximately 3 to 4 weeks. Patient participant recruitment was conducted via screening outpatient palliative care clinic schedules weekly for upcoming new palliative care patient visits and then emailing potential patient participants to notify them about the study. The PCNI was delivered via email and Zoom app. Patient-reported outcome measures were completed by patient participants at baseline, 24 to 48 hours after PCNI, and after the initial palliative care clinic visit, approximately 1 month after baseline. Inclusion criteria included having the capacity to give consent and having an upcoming initial outpatient palliative care clinic visit.

Results: The recruitment of participants began in April 2021. A total of 189 potential patient participants were approached via email, and 20 patient participants were enrolled, with data having been collected from May 2021 to September 2022. A total of 7 clinician participants were enrolled, with a total of 3 clinician exit interviews and 1 focus group (n=5), which was conducted in October 2022. Data analysis is expected to be completed by the end of June 2023.

XSL•FO
RenderX

Conclusions: The findings from this study, combined with those from other PCNI studies conducted in acute care settings, have the potential to influence clinical practices and policies and provide innovative avenues to integrate more person-centered care delivery.

KEYWORDS

electronic health record; mixed methods; narrative; person-centered care; palliative care

Introduction

Background and Rationale

Health care advances have extended the life span and cured many diseases; however, advanced health care treatments are sometimes discordant with patient preferences, values, and beliefs, which can lead to insufficient symptom control, difficult patient-clinician interactions, and poor psychosocial and spiritual support [1-3]. Furthermore, poor patient-clinician communication contributes to continued unwanted care. A comprehensive palliative care approach improves communication, leading to better quality of life (QoL) for patients [4-6]; however, discordant care continues in part because of knowledge gaps about patients' psychological, social, and spiritual needs [7-10]. Person-centered narrative interventions (PCNIs) can fill these knowledge gaps [11-20], yielding an increased understanding of patients' psychological, social, and spiritual needs, which will help clinicians develop tailored palliative care interventions.

Storytelling (narrative) is an effective way for patients to communicate their cultural values and beliefs. As early as 1542, when Joannes Fernel coined the term physiology, the discussion at that time described the person as a structure of physiological, pathological, and clinical stories [21]. However, in the health care system, patients do not always have the opportunity to share their clinical stories with their clinicians [3,22-26]. Furthermore, even if patients have the opportunity to discuss values, beliefs, and preferences for care, some research has described treatment errors that may occur when clinicians overlook contextual information in a clinic visit. These treatment errors are known as contextual errors [27-29] and are defined as a "decision making error that occurs because of inattention to patient context" [29].

In the health care setting, the electronic health record (EHR) is one of the primary ways of communicating the status of patients; however, most of this EHR information is clinician centered. There is a need to consider the patient as a person and integrate their perspectives into their health record. Incorporating a patient's narrative into the EHR provides an opportunity to communicate patients' cultural values and beliefs to the health care team and has the potential to improve patient-clinician communication [30,31]. However, research on the effective integration of a patient's narrative into the EHR is limited. PCNIs that incorporate cultural values and beliefs are important components of person-centered care [14,31]. Person-centered care includes implementing shared decision-making, providing holistic patient care with respect for patients' preferences and goals, paying attention to nonmedical aspects of care, facilitating communication, knowing the patient as a person, and understanding culture, which influences health behaviors and the meaning of illness [3,14,22-26]. Quality communication is a critical element of person-centered care [3,32,33]. Story theory can be applied to person-centered care because of its foundation in "meaning making" built on promoting intentional dialogue, creating ease, and connecting with self-in-relation [34]. Using the foundation of story theory, patient narratives about illness experiences offer clinicians a view of patients' cultural attitudes about their illness and their psychological, social, and spiritual beliefs and values [14,31]. When a clinician knows more of the patient's narrative, improved quality of communication may occur, which can create opportunities for culturally congruent care with the potential to improve QoL for persons living with serious illnesses [3,32,33]. The PCNI is an example of how story theory might be applied to the fragmented health care system. However, in the current health care environment, limitations on a clinician's time prevent these opportunities to better understand what may or may not improve QoL for persons living with serious illness. A narrative intervention implemented with persons living with serious illnesses can draw together the complexities and varied cultural meanings of illness experiences, and this can improve QoL [3,14,32,33]. Patient participation in narrative interventions has been linked to reduced pain, stress, anxiety, and fatigue and improved psychosocial and QoL outcome measures [15-20].

The integration of the PCNI into the EHR could benefit patients and clinicians interacting in technology-rich environments. Because the EHR is one of the primary modes of communicating health care information about the patient, the integration of patients' narratives into the EHR has the potential to (1) improve person-centered care by incorporating patients' values and beliefs, (2) provide opportunities to enhance patient-clinician communication, and (3) positively impact patients' psychosocial and spiritual well-being. Minimal research has integrated narrative interventions into the EHR in a meaningful and efficient way to test whether the narrative intervention could improve communication between patients and clinicians and impact patients' overall well-being. Our research program investigates innovative ways to integrate patient values, beliefs, and preferences into EHR through PCNIs [14,31]. A *central hypothesis* that guides our research is that the implementation of a PCNI will result in improved patient-clinician communication and care delivery and improve patients' psychological and social well-being. We have conducted prior studies of PCNI in an acute care setting where the intervention was conducted in a face-to-face interaction [14,31]. However,

XSL•FO
RenderX

owing to the COVID-19 pandemic, there is an urgent need to investigate innovative internet-based–delivered ways to incorporate the patient's narrative into their health care record. In our fragmented health care systems, the lack of personhood in delivery of care has been linked to decreased QoL for persons living with serious illness [32,34-38].

Study Context

We developed a PCNI to address existing gaps in the delivery of person-centered palliative care**.** Our first study on this PCNI used a narrative analysis methodology to elicit illness narratives to aid in understanding patients' psychological, social, and spiritual experiences [37]. This led to a crucial clinical question: how might these person-centered narratives be shared efficiently and effectively with the health care team? Although the use of narratives is an effective way for people to communicate cultural values and beliefs [3,32,33], patients rarely have the opportunity to share such information with their clinicians [4,7,39,40]. Within the health care system, EHR is the primary mode of communicating patient information [30,31]. Thus, incorporating a person-centered narrative into the EHR is an opportunity to share patients' values, beliefs, and preferences, with the potential to improve patient-clinician communication and well-being [14,31,37]. Our second study, a feasibility study, used the Consolidated Framework for Implementation Research (CFIR) [41] to define and refine the integration of the in-person delivery of PCNI into the EHR for persons with serious illness in the inpatient acute care setting [14]. Findings from the second study showed that the PCNI was (1) feasible and acceptable for all 20 hospitalized persons and (2) usable by acute care nurses [14]. Implementation data from our initial feasibility study revealed the ways in which PCNI is valuable and usable for clinicians. The PCNI's added value in nursing care is when the nurse manager of one of the clinical units began reading the person-centered narratives aloud to her entire staff at shift handoffs. We also found value added for the entire health care team when 1 of the person-centered narratives was read during an ethics consultation. The ethics consultation was initiated owing to patient noncompliance and stated the desire to leave treatment against medical advice. Once they heard the person-centered narrative read during the consultation, the health care team realized why the patient was trying to leave before the proposed surgery—he needed to see his 2 daughters, who lived in another state, beforehand. We are currently conducting a third study, a 3-year mixed methods pilot study in the acute care setting [31]. Our long-term goal is to optimize the use of PCNIs by investigating how and in what context they are effective in improving patients' overall well-being and quality of communication with their clinician. A challenge for any biobehavioral intervention is translation across complex health care contexts [42]. Because our in-person–delivered PCNI has been shown to be feasible and to demonstrate preliminary efficacy in the acute care setting, we aim to purposefully enroll participants in the outpatient setting and use an all-internet-based delivery of the PCNI to further evaluate implementation in a new setting and use an all-internet-based delivery—from email recruitment, electronic consent, and Zoom narrative interview to electronically delivered outcome measures.

Objectives

In this protocol, we aim to further develop the continued testing of the feasibility and efficacy of the EHR integration of PCNI in an outpatient setting using an all-internet-based–delivered platform. The first objective of this study is to identify barriers and facilitators of an internet-based–delivered PCNI from the perspectives of persons living with serious illness and their clinicians. The second objective is to conduct acceptability, usability, and intervention fidelity testing to determine the essential requirements for the EHR integration of an internet-based–delivered PCNI. The third objective is to test the feasibility of the PCNI in an outpatient clinic setting.

Methods

Study Design

This study will use a mixed methods design [41,43-45] and collect data from both patient and clinician participants. Our study relies on the CFIR [41,45] to inform the implementation of this single-arm trial across the 2 years of the study. This is a novel approach that documents what affects implementation in a new context of outpatient clinical care with a protocol that is all delivered electronically. The CFIR is a conceptual framework developed to guide multilevel assessment of factors that may influence an intervention's implementation and effectiveness [41,45]. The core CFIR domains are (1) intervention characteristics, (2) inner setting (ie, implementing organization), (3) outer setting (ie, external environment), (4) individual characteristics (ie, knowledge and beliefs of the individuals involved in the implementation), and (5) processes (ie, strategies and tactics used in the implementation [41,45]). Within each domain, specific constructs may influence the implementation. Constructs in the proposed taxonomy of implementation outcomes have the potential to capture clinician attitudes (acceptability) and behaviors (adoption and uptake) as well as contextual factors (system penetration, appropriateness, and implementation).

In this phase of our biobehavioral interventional development, both quantitative and qualitative data give necessary information about acceptability, feasibility, and usability for the optimization of the narrative intervention. Quantitative data include longitudinally measured patient-reported outcomes, and qualitative data include (1) patient and clinician exit interviews for triangulation of the quantitative findings and (2) patients' illness narratives. All data collection and study procedures will be conducted electronically, using secure videoconference, phone, REDCap (Vanderbilt University) [46] surveys, and electronic consent forms. Evaluating the barriers to and facilitators of the implementation of the adapted internet-based delivery of PCNIs is essential for effective translation to practice. Such a design is particularly salient when conducting studies with a palliative care population [47-49] to collect a broad range of data. For example, our qualitative data will provide a deeper understanding of the barriers to and facilitators of the intervention from participants' perspectives not captured through the traditional quantitative measures [50-52]. We will analyze key implementation facilitators and challenges and link these to the outcomes [51]. This work will result in an

XSL•FO
RenderX

evidence-based set of core functions and forms of this complex intervention into complex health care systems by providing recommendations to guide future PCNI implementation across different health care settings [53-55].

Participants

Purposeful sampling strategies will be used to recruit and enroll 20 patients. The small sample size was chosen to be consistent with both qualitative data analysis techniques [50] and usability data analysis techniques [56,57]. Patient participants (N=20) who are aged ≥18 years (no upper limit), able to read and speak English, and capable of providing informed consent will be enrolled in the study. Owing to the feasibility of this study, we allowed participants to enroll at any stage of illness or symptom acuity. These participants will be newly establishing care at one of the University of Colorado Hospital (UCHealth) outpatient palliative care clinics (Outpatient Palliative Care Clinic and Supportive and Neuro-Palliative Medicine Clinic). The clinician participants (N=10) will be members of the outpatient palliative care interprofessional team, which includes physicians, advanced practice clinicians, registered clinicians, social workers, and a spiritual care clinician. These clinician participants will be included if they are able to confirm verbally that they were involved in the outpatient palliative care of a patient participant.

For the patient participants, the research team will review the outpatient palliative care clinic schedules weekly via the EHR (Epic) to identify persons with upcoming initial new patient visits (NPVs) in the palliative care clinics. These identified persons will receive an initial recruitment email with an institutional review board–approved language and a follow-up email with the initial language approximately 1 week later for those who have not responded. For those who respond to the recruitment email with interest, the research team will arrange a secure videoconference or phone call to discuss the study, review the consent form, and answer questions. When a person opts to participate, the research team will send an email with a link to the electronic consent form (in REDCap) [46] and instructions for completing the consent. It should be noted that persons are contacted approximately 4 weeks before their NPV to facilitate ample time for pre-NPV study activities.

For the clinician participants, the research team will identify the assigned clinician of the enrolled patient participant, once the patient's narrative is uploaded to the EHR. In the same electronic delivery, the research team will contact these clinicians via email to (1) alert them that a narrative was available for one of their newly establishing patients and (2) inquire about their interest in participating in the study using institutional review board–approved language. Because of the nature of the feasibility and usability study, we targeted recruitment efforts to capture the entire interprofessional perspectives of the palliative care clinical team members. For those who respond to the recruitment email with interest, a research team member will arrange a secure videoconference or phone call to discuss the study, review the consent form, and answer questions. When a clinician opts to participate, the research team will send an email with a link to the electronic consent form (in REDCap) [46] and instructions for completing it.

Procedures

Ethics Approval and Data Privacy

All procedures were approved by The University of Colorado Institutional Review Board (Colorado Multiple Institutional Review Board 21-2887), and the approval has been maintained in good standing. REDCap is available as a Health Insurance Portability and Accountability Act–compliant secure research data interface [46]. Web servers routinely use secure socket layer encryption technology and certification authority to ensure the secure transmission of data over the internet. To facilitate secure file sharing between research team members, we will establish internet-based private networks and create sponsored user accounts for all study personnel. All research data files are stored on dedicated, password-protected, access-controlled, and shared drives. Safeguards for protecting participants' anonymity will include creating a master list of names with corresponding numbers assigned to participants at the time of the enrollment. Once assigned, the corresponding numbers will then be used to deidentify the remainder of the participants' personal information and each participant's data. Electronic consent forms, participant identity, and participant data will be securely stored on a password-protected network server. Participants will only be identifiable by an ID number on the server, and only anonymized data will be provided to the data analysis team members. The potential for breach of confidentiality is being addressed through the maintenance of a secure "log-on" system on the secure computer server dedicated to this protocol.

All participants will be compensated for their time. Patient participants will be provided a US $25 electronic gift card after the completion of PCNI and time point 2 and a second US $25 gift card after the completion of time point 3 for a total of US $50 in remuneration. Clinician participants will be provided one US $25 electronic gift card after the completion of the exit interview. In addition to the confidentiality of patient data, there are some minimal physical, social, or psychological risks to the patient participants. Participants could become fatigued during the 60-to-90–minute narrative interview process, the 30-minute exit interview process, outcome measure data collection procedures. In the event of fatigue, the research team members will encourage rest periods or, if necessary, schedule an additional study visit to complete the interview. For the patient participants, there is a minor, moderate, or severe risk of psychological distress because of the sensitive topics of serious illness. Because of the feasibility of the design, we will ensure that the patient participants understand both orally and in writing that they are free to decline participation in any or all study activities at any time based on their own level of distress [58,59]. This could include declining to answer specific questions, refusing participation in the intervention, requesting to speak off the record, or requiring complete withdrawal from the study. We did not apply a specific tool for distress screening; rather, we will give frequent reminders to the participants about the voluntary and autonomous nature of the study, for the participants to determine if the study activities are too distressing for them at any level (mild, moderate, or severe). If any of the interview or psychometric assessment data reveal increased participant distress, dissatisfaction, or any adverse event, the data collection will cease. If the participant exhibits any verbal

XSL•FO
RenderX

or nonverbal distress, the research team member will allow the participant to stop the interview, reschedule for a return visit to complete the interview, or allow participants to withdraw consent. If moderate distress is exhibited, the research team member will assist in referring participants to emotional support through family, friends, or the health care team for the follow-up related to the participant's distress. If distress is severe, such as suicidal ideation, the research team member will immediately refer the patient for further work-up and care. The research team members will carry a list of contact phone numbers for such referrals. If any moderate or severe distress is noted, it will be reported immediately to the principal investigator to help determine if the event meets the criteria for a reportable adverse event. If deemed a serious adverse event, the institutional review board will be notified, and the participant's involvement in the research study will be discontinued. In a previous study using this methodology, none of the adverse events occurred. Therefore, we anticipate these risks to be rare events, given the nature of the data collection procedures.

The PCNI Procedure

The enrolled patient participants will participate in a narrative interview. These audio-recorded interviews will be conducted by a research team member using an open-ended interview guide. During the interview, patients will be prompted to share their narrative through probing questions or statements such as: tell me about your illness; tell me how your illness has affected your emotions, your relationships, and your spirituality (Textbox 1 lists the interview questions). These probing questions have been field tested in 3 previous studies. As the patient responds, the research team member will take field notes and ask for follow-up or clarification questions as necessary. Using the audio recording and field notes, the research team member will then create a 1-to-3–page metanarrative. Each narrative must meet the following criteria: it must (1) be written in the patient's first-person voice, (2) be nonjudgmental, (3) capture the patient's voice, (4) accurately reflect the content of the interview, and (5) nondiagnostic (not labeling). The patient narrative is then returned to the patient within 48 hours for member checking, the cocreation phase of the PCNI. In this electronically delivered protocol, at the time of member checking, the patient will make any desired changes to the narrative on their own or during a follow-up session with the research team member. These sessions will facilitate the cocreation of the narrative. Once the narrative is approved by the patient, the research team will upload it to the patient's EHR and alert the patient's assigned clinician via email that their patient's narrative is available in the patient's health record. The workflow diagram is depicted in Figure 1.

Textbox 1. Interview guides for narrative and exit interviews.

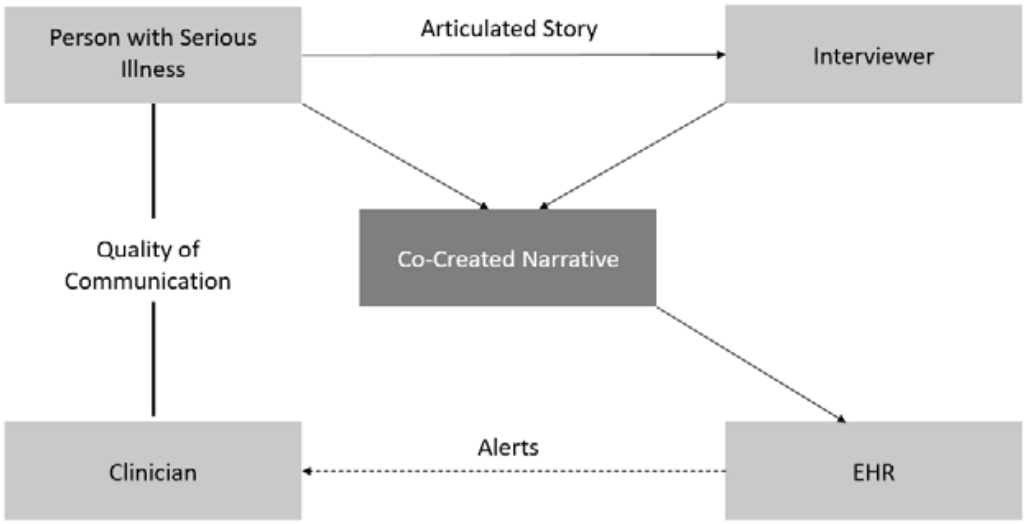
Narrative intervention interview guide

- Conversational questions
  - May I call you?
  - What is your illness?
- Conversational probes throughout intervention
  - For example
  - Tell me more about that
  - Anything else?
- Open-ended questions
  - Tell me what it has been like to have _____ (illness).
  - Tell me how your illness has impacted you emotionally, your feelings?
  - Tell me how your illness has impacted your relationships with family, friends, and others?
  - Tell me how your illness has impacted your spirituality? Your faith, beliefs, your values, or your thoughts about a higher power?
- Closing question
  - Is there anything else we have not talked about that you would like to tell me?

Exit interview guide: patient participants

- Describe what you liked about participating in this study.
- Describe what you did not like about participating in this study.
- Did you have the opportunity to discuss your story with anyone other than the research team?
  - *If yes, follow-up questions*
    - Who did you discuss it with?
    - Did you initiate the conversation, or did they?
    - Describe which parts of the story you discussed.
    - How did this discussion make you feel?
  - *If no, follow-up questions*
    - Why do you think others did not discuss it with you?
    - Why did not you discuss it with others?
- Is there anything you would have changed about the study?
- What would you think about participating in a similar intervention in the future?
- Is there anything else you would like us to know?

Exit interview guide: clinician participants



- What did you think about the intervention?
- Were you able to read the patient's story?
- Do you think the study was beneficial to the patients?
- Did you notice any particular patient reactions to the intervention?
- Was the study beneficial to you in any way?
  - *If yes, follow-up questions*
    - Describe what was beneficial to you.
  - If no, follow-up questions

XSL•FO
RenderX

- Describe what was not beneficial to you.
- What changes could we make to the study for it to be more beneficial to you?

- Do you feel like having the patient's story changed how you delivered care to your patient?
  - *If yes, follow-up questions*
    - Can you provide an example?
  - *If no, follow-up questions*
    - Are there changes we could make that would help with this?
- Did the notification system of the story in the medical record work for you?
  - *If no, follow-up questions*
    - How could the notification system be improved?
- Were there any other study difficulties that you encountered that I have not asked you about?
- Are there improvements to the intervention that you would suggest that we have not already discussed?
- Is there anything else you would like us to know?

Figure 1. Person-centered narrative intervention (PCNI) workflow figure. EHR: electronic health record.

Outcome Evaluations of the PCNI

Usability Testing

Using a human, organization, and technology–fit factor [53] evaluation framework for health information systems, we will collect data across several usability factors. Usability is defined as the relationship between humans and computers [53]. Usability testing [53,56,57,60] focuses on evaluating process measures based on 4 major components: user (clinician), task (use of metanarrative), system (metanarrative in EHR), and environment (outpatient setting). This user-task-system-environment framework of process measures [61] will be incorporated into our usability testing to determine barriers and facilitators from the clinician's perspective, and to help determine the essential requirements for integrating the narrative intervention into the EHR by evaluating information flow, use of information, and system functionality. The process measures collected to determine usability will include (1) chart review and log analysis of the clinical use of the patient's story; (2) time and cost analyses of collecting the story, writing and cocreating the metanarrative, and uploading the final metanarrative into the EHR; and (3) exit surveys and interviews with both patient and clinician participants.

Intervention Uptake and Attrition

We will also analyze the intervention uptake and attrition between baseline and follow-up data collection points [47-49]. Uptake (acceptability) will be assessed using descriptive summaries examining acceptors among people approached for recruitment. The number of dropouts, reasons given, and the

XSL•FO
RenderX

timing of withdrawals from the study will also be reported. When possible, patient participants who drop out will be provided with a 1-page query about why they left the study. Feasibility will be examined by examining operational issues, namely, staff time spent or issues with recruitment, EHR use, or training. Identified issues will be noted in project logs to guide future studies. These are critical steps for evaluating scalability for the successful implementation of PCNIs in other complex systems. This approach incorporates the human, organization, and technology–fit [53] factors for the successful implementation of PCNIs.

Patient-Reported Outcomes

The primary patient-reported outcome measures for this protocol are the PROMIS (patient-reported outcomes measurement information system)-29 Profile v2.0 form [62] and PROMIS Psychosocial Illness Impact [63]. The PROMIS-29 profile v2.0 form consists of 29 items that assess physiological, social, and psychological outcomes. These biopsychosocial domains include physical function, anxiety, depression, fatigue, sleep, the ability to participate in social roles or activities, and pain interference and intensity. The PROMIS Psychosocial Illness Impact measure consists of 16 items that assess the negative and positive aspects of the illness experience. The PROMIS positive item bank measure (8 items) assesses the positive psychosocial outcomes of illness. Positive psychosocial illness impacts refer to outcomes, such as greater life appreciation, interpersonal relationships, and personal resources, that can occur because of confrontation with one's mortality. The PROMIS negative item bank measure (8 items) assesses the direct negative psychosocial effect of illness, distinct from general emotional distress. All PROMIS measures have established reliability and validity. At baseline, demographic information will also be collected from patient participants, including age, biological sex, gender, race and ethnicity, perceived illness severity, years of education, income, marital status, religion or spirituality preference, and clinical details (to identify comorbidities and severity of illness).

The primary outcome measures for the patient participants will be collected across 3 time points. After enrollment, the research team will generate participant-specific survey links in REDCap [46] and email them to the participants to complete the demographic survey and the baseline (time point 1) outcome measures (Table 1). Outcome measures could also be collected by phone, if preferred by the participant. At a mutually scheduled time, the participant and a research team member will meet on a secure videoconference to conduct and audio record the PCNI interview, as described previously in *The PCNI Procedure*. Within 48 hours after the narrative is uploaded into the EHR, participants will complete time point 2 outcome measures using the same process described for time point 1. Time point 3 will be completed 1 month after the narrative upload and the NPV. Finally, after time point 3, the research team will conduct exit interviews with patient participants at the end of their study participation to collect information about their experience, including suggestions for improvement (Textbox 1 lists the interview questions).

For the clinician participants, the research team will conduct exit interviews with clinician participants within 2 to 4 weeks of their initial appointment with a patient participant to collect information about their experience of having and using the patient narrative before the initial consult. At the end of study enrollment, 1 to 2 audio-recorded focus groups (based on scheduling needs) will be cofacilitated by research team members with all the clinician participants to collect additional information and feedback about their experience and facilitate and record group discussion about their use of the patient narratives in their clinical practice. Interviews will be conducted via a secure videoconference or a phone call and audio recorded. See Table 1 for participant study activities.

Table 1. Participant study activities.

Participant	Outcome	T1: baseline (prenarrative upload)	T2: 24-48 hours after T1 (postnarrative upload to EHR[a])	T3: 1 month after T1
Patient	Biopsychosocial and spiritual well-being	• PROMIS[b]-29-Profile • PROMIS Psychosocial Illness Impact; positive and negative effects	• PROMIS-29-Profile • PROMIS Psychosocial Illness Impact; positive and negative effects	• PROMIS-29-Profile • PROMIS Psychosocial Illness Impact; positive and negative effects

[c]N/A: not applicable.

Data Analysis

Quantitative Analysis

Analyses will be performed using SAS software (version 9.4; SAS Institute Inc) [64]. Analyses will be primarily descriptive to determine the feasibility of collecting patient-reported outcome data in this setting (ie, data completeness) and summary statistics and distributional characteristics of those outcomes. Data will be inspected for errors and outliers. Data completeness will be summarized in terms of missing responses across the 3 data collection time points (ie, percent attrition at each follow-up) as well as missing item responses within each measurement period (ie, inspection of item-level missing data patterns). A high level of retention (>90%) across follow-up waves is expected based on previous research in an inpatient setting [14]; however, this will be empirically investigated. Missing responses at the item level are similarly expected to be low, but if present, they will provide information on potential

XSL•FO
RenderX

response fatigue or problematic items. Baseline demographics and outcome measures at all 3 waves will be summarized using standard descriptive statistics (eg, mean, SD, and range). Preliminary testing of the outcome measures for change from baseline, T2, and T3 will be analyzed in a repeated measures framework (time effect in mixed effect model) to evaluate the effects of the intervention on the individual patient participant's patient-reported outcomes of the PROMIS 29 Profile and PROMIS Psychosocial Illness Impact. This single-arm study is not powered to evaluate the statistical significance of changes in patient-reported outcomes over time; however, distributional characteristics of outcomes and effect size estimates of mean change will be useful for informing a larger-scale randomized trial.

Qualitative Analysis

Qualitative data management software will be used to organize narrative and exit interview data and coding by team members. Notes and transcripts will be collated to provide summaries of patient flow, use of equipment and supplies, perspectives on the PCNI, and ideas about its integration into current practice. A conventional content analysis approach [50-52] will be used to analyze the observations and interviews, and a category system will be created based on the CFIR domains to create a codebook [41,45] (with new codes added if needed). Obtaining data from a variety of interviewees allows for triangulation of data sources to support qualitative rigor. Triangulation of data will also occur between narrative interview data and exit interview surveys to better understand PCNI implementation fidelity and to identify any potential or needed modifications. The research team expects that the outcomes of this analysis will inform the next steps of PCNI integration as we move to implementation at future sites and for future studies. The information gained through this analysis will be used to provide a greater empathetic view of what is currently offered and what matters most to patients and clinicians, as they offer and integrate new evidence-based practices or interventions. We will extract contextual factors (events or statements) from observations (study notes) and interviews to document what facilitates or acts as a barrier to implementation (eg, challenges, resolutions, and the impacts of champions and naysayers). Quantitative data, from patient logs of session completion and the tracking database, will be integrated with qualitative data from observations and transcripts of semistructured interviews with patient participants and nurse participants. Triangulating our data sources will allow us to corroborate the evidence, prevent researcher bias in interpretation, and increase the confirmability of our qualitative data. The first round of coding will be guided by the CFIR domains and constructs [41,45], which include (1) intervention characteristics, (2) inner setting (ie, implementing organization), (3) outer setting (ie, external environment), (4) individual characteristics (ie, knowledge and beliefs of the individuals involved in the implementation), and (5) process (ie, strategies and tactics used in the implementation). Within each domain, specific constructs may influence the implementation. We will also capture emergent themes in the data (the inductive component) [43], which will allow for the discovery of themes not included in a priori CFIR codes. We will follow an iterative process, whereby the analysis will begin at the time of the first observation and will inform the direction and content of future data collection. Research team members will code the data independently and discuss it with other team members. To maximize convergence in coding [43], the team will meet regularly during data collection and analysis to review emerging themes, reconcile differences in coding, and determine whether modifications to the interview guide are needed for the remaining interviews. Discrepant interpretations [43] of the interview data during the coding phase will be resolved by consensus during team meetings. We will maintain an audit trail [50] to document all coding and analytic decisions made during the study. We will conduct between-case analysis to compare cases to look for similarities in processes promoting implementation among similar cases and differences in processes promoting sustainment among different cases [43]. We will analyze coded data by constructing causal diagrams that link the coded elements, logically minimizing the diagrams to produce a parsimonious set of pathways, and using explicit decision rules to guide the analysis [43,55].

Results

The study received funding in January 2021, and ethics approval was received on March 21, 2021. The recruitment of participants began in April 2021. Patient participant recruitment was conducted via weekly screening of the outpatient palliative care clinic schedules for upcoming new palliative care patient visits, and emails were sent to potential patient participants. At this time, some data have been collected and analyzed. A total of 189 potential patient participants were approached via email, and 20 patient participants were enrolled, with data having been collected from May 2021 to September 2022. A total of 7 clinician participants were enrolled, with a total of 3 clinician exit interviews conducted in 2021 and 2022 and 1 focus group (n=5) conducted in October of 2022. Data analysis has been ongoing from the end of data collection in October 2022 to June 2023. Overall, for this feasibility study, we were able to recruit a total of 20 patient participants and 7 clinician participants for data collection. In the initial findings, the electronically delivered person-centered narrative was feasible, acceptable, and usable for both patient and clinician participants. The overall findings are expected to be submitted for publication by the end of June 2023.

Discussion

Overview

Although PCNI is not new [14,31], it has never been studied in an outpatient setting and completed via an all-electronic, internet-based–delivered protocol, a necessity to implement in our postpandemic world. Keeping the safety of all at the forefront in the setting of a continued global pandemic, it was necessary for the PCNI to be evaluated on an electronically and internet-based–delivered platform. In comparison with our previous studies on PCNI [14], the all-internet-based–delivered platform to conduct the study activities and collect person-centered narratives did have some challenges.

Using the CFIR as our framework [41,45], we encountered some implementation challenges. In the CFIR domain of the

XSL•FO
RenderX

intervention, we did not change any components of the institutional review board–approved person-centered narrative interview conducted in the Zoom app (Zoom Video Communications Inc). We did not change anything from the domain of the inner setting. The entire study was conducted in the outpatient clinic population of persons with serious illnesses who were having an initial palliative care visit. It was feasible to cocreate the PCNI and upload the PCNI before all the initial palliative care visits of patients, with the exception of 1 patient participant. For future studies, there needs to be ample time between narrative interviews and a person's initial visit to the palliative care team. Alternatively, narrative interviews could be conducted at any time of a person's clinical care without the need for the narrative to be uploaded before a patient's initial visit.

In contrast to our acute care studies [14], we did not realize the longer time required to complete the member checking of the cocreated narrative. This process took an average of 5 days versus an average of 48 hours in our acute care studies. This increased time links to the CFIR domain of the outer setting. Persons were not as acutely ill as in the acute care studies of the PCNI. The outpatient participants spent more personal time changing, adding, or adjusting their cocreated narratives. Therefore, the individual characteristics of this outpatient population were distinctly different from those of other patients who are hospitalized in our previous studies. Because these patient participants were also active in their home environments and not hospitalized, additional time was required to obtain the second Zoom app–facilitated session scheduled for the member-checking step of the PCNI review and the approval of their narrative before the narrative was uploaded into the EHR for the clinical team.

In the last CFIR domain of process, we implemented several strategies and tactics for the successful implementation. As we began email recruitment and electronic consenting, we chose not to enroll any patient participant who was noted to have a medical diagnosis of Alzheimer disease or dementia, or terms of cognitive impairment, confusion, or delirium on their problem lists. For this study, this screening excluded 20% of persons with a new patient palliative care visit. At this stage of data analysis, we would suggest that future PCNI programs should consider cognitive impairment. In future studies, the need for a mental capacity screening can be an important consideration. Alternatively, in future studies, the PCNI would need to consider the cognitive capacity of persons who have a serious illness and include a person's support individuals to be a part of a dyadic PCNI. It should be noted that the integration of the PCNI into an outpatient palliative care clinic provides systematically more time for palliative care clinicians to engage with the narrative based on the allowed new palliative care patient visit time allotment of 1 hour. In future studies in other clinical settings that are nonpalliative, the acceptability and usability of the person's narrative will require clinical workflow evaluations of the best strategies for allowing the nonpalliative clinician adequate time to engage with the person's narrative. As in our other PCNI studies, once a patient participant is enrolled, there are limited withdrawals. Only 1 participant reported mild distress with the narrative interview questions that were being asked and made a choice to withdraw from the study.

Finally, although the overall goal of the PCNI is to consider the improvement of the quality of communication in clinical care, for this protocol, the quality of communication is being analyzed by exit interviews with both patient and clinician participants. In our other PCNI study [14], the quality of communication measure has been used [65]. However, in this study, the patient participants were enrolled before NPVs with the palliative clinical team. Therefore, we were unable to quantitatively measure any changes in the quality of communication between the patients and palliative care clinicians. For future studies of PCNIs, the consideration of not timing the PCNI before an NPV should be considered.

Limitations

There are known limitations to our mixed methods single-intervention feasibility study. First, it was conducted in 1 geographic location in 1 health care system. This is an important consideration when considering the contextual complexities of health care systems, their EHRs, and the clinical workflows of clinicians. Second, owing to the nature of the internet-based delivery in this study, this study excluded participants who did not have access to email and technology with an internet connection. During the screening for this study, 11 patients did not have email addresses. Therefore, email should not be the only recruitment method. One would need to add an in-person recruitment approach to capture potential participants who do not have an EHR-listed email. During this in-person session in the clinical setting, one could also verify a person's technology needs and preferences. If the preference or need for technology was identified, the opportunity to conduct the PCNI in person in the outpatient clinical setting could also be used. In this study, participants who expressed less agility with technology were offered more detailed instructions ("click-by-click") or additional phone calls during which the research team member could help them navigate the required systems.

Conclusions

This 2-year feasibility study will provide a site-specific understanding of barriers to and facilitators of the usability and acceptability of the PCNI from the perspectives of both patient and clinician participants. These barriers and facilitators in the setting of a CFIR framework will provide important knowledge about the scalability of the intervention, process-oriented insights, successful implementation strategies, and modifications that are necessary to improve the integration of a person's narrative into the clinical workflow for clinicians. The overall long-term research goal is the creation of a PCNI that could be broadly applicable and sustainable outside of the research setting, with implementation in a variety of health care settings in multiple health systems. The knowledge gained will provide necessary information to evaluate future ways to scale PCNIs, with the goal of implementation across health systems, and will continue to inform the integration of person-centered narratives into the patient's EHR. This feasibility study will provide important information to fully understand the mechanisms of the effects and concurrently contribute to additional knowledge

XSL•FO
RenderX

of the key factors of implementation. The knowledge gained from this mixed methods study will contribute to key data for the continued development and refinement of PCNIs.

Acknowledgments

The authors wish to acknowledge the following individuals for their recruitment support in the implementation of the study: Jonathan Treem, MD, and Christina Vaughn, MD. The research reported in this study was supported by the Cambia Health Foundation Sojourns Scholar Award (principal investigator, HC) and K24 AT011995 (principal investigator, AZD). The content is solely the responsibility of the authors and does not necessarily represent the official views of the Cambia Health Foundation or National Institutes of Health.

Data Availability

The data sets generated and analyzed during this study are not publicly available owing to patient participant confidentiality but are available from the corresponding author upon reasonable request.

Authors' Contributions

All authors made substantial contributions to the design of the work, participated in revising this document critically, provided final approval of the version to be published, and agreed to be accountable for the work.

Conflicts of Interest

None declared.

Abstract

Background: Sexual dysfunction represents a critical aspect of quality of life for adolescent and young adult cancer survivors. Studies have consistently documented that adolescents and young adults report greater psychological and physical morbidity than older survivors and healthy peers, including elevated rates of sexual dysfunction, often accompanied by lower satisfaction with sex life and delays in meeting sexual milestones. Moreover, sexual dysfunction, body image concerns, and fertility status affect their confidence in being both physically and emotionally intimate. Despite this evidence, limited research has investigated the influence of psychosocial and interpersonal factors on sexual health outcomes reported by this group. This constitutes a significant gap in the provision of comprehensive sexual health care for adolescent- and young adult–onset cancer survivors, especially since greater emphasis has been recently placed on the biopsychosocial model of sexuality and dyadic approaches to intervention and treatment. In comparison to other cancer types, the incidence of colorectal cancer (CRC) has been increasing at an alarming rate for the adolescent and young adult group. Patients with early-onset CRC experience elevated rates of sexual dysfunction, psychological distress, and social and physical burden, often resulting from issues with bowel control, incontinence, and body image.

Objective: This study uses an explanatory sequential mixed methods approach to (1) characterize sexual function, sexual distress, dyadic coping, infertility-related distress, relationship and mental health outcomes of adolescent and young adult CRC survivors within the first 5 years post diagnosis and their partners; (2) examine the reciprocal influence of sexual function and dyadic coping behaviors on sexual distress; and (3) identify interpersonal or couple characteristics associated with coping with sexual dysfunction and its associated distress.

Methods: Participating couples (n=60) will complete a quantitative web-based survey investigating sexual function, sexual distress, dyadic coping, infertility-related distress, emotional functioning, relationship satisfaction, and body image (cancer survivors only). A subset of 20 couples will participate in an in-depth dyadic interview with 2 members of the research team to further explore couple-based strategies implemented to cope with cancer-related sexual dysfunction and distress.

Results: The study received institutional review board approval. Recruitment and enrollment of couples began in July 2022.

Conclusions: Results will provide a deeper understanding of the challenges couples experience as they navigate sexual intimacy after CRC treatment by highlighting the role of interpersonal processes. These findings will inform a dyadic intervention for young couples at risk of greater sexual distress in the aftermath of CRC.

Introduction

Background

Cancer-related sexual dysfunction is one of the most common and distressing consequences of the illness, which, if untreated, persists or worsens over time [1-4]. Among adolescents and young adults—individuals aged between 15 and 39 years at diagnosis—a considerable body of research has unveiled unique challenges [5,6] including disruption of normative physical, psychosocial, and emotional development, which can lead to sexual dysfunction [7-13]. Studies have consistently documented that adolescents and young adults report greater psychological [14,15] and physical morbidity [5,6,16] than older survivors and healthy peers, including elevated rates of sexual dysfunction [11,13,17-21] often accompanied by lower satisfaction with sex life [22-26], delays in meeting sexual milestones [21,27,28], and reduced frequency of sexual activity [21,27]. Between 42% and 52% of adolescent and young adult survivors experience 1 or more sexual problems [12,13,29], with one-third of them reporting worse sexual function up to 2 years post diagnosis [13]. Differences exist by sex, with females reporting higher dysfunction scores [30-32]. Young female survivors experience greater problems with pain, lubrication, desire, and sexual satisfaction than healthy peers [22-26,28]. Qualitative studies document that women report pain, lack of desire, and reduced sexual enjoyment, while males experience erectile dysfunction, ejaculation, and arousal problems [12]. While aggregate data from large studies report that the majority of adolescents and young adult survivors were involved in a relationship [12,21], cancer and treatment-related side effects proved to be detrimental to masculinity and perceived closeness with partners [21-27]. Sexual dysfunction, body image concerns, and fertility status may limit the confidence in being both physically and emotionally intimate [29,31,33,34] and contribute to more negative outcomes [29,31,33-35]**.**

In comparison with other cancer types, the incidence of colorectal cancer (CRC) has been increasing at an alarming rate [36-41] for the adolescent and young adult group. Recent reports have projected that by 2030, the largest increase in the incidence of colon (90%) and rectal (125%) cancer will occur for the 20-34–year-old group [36-39,42-45]. Treatments include a combination of chemotherapy, pelvic radiation, and abdominoperineal resection—often with a temporary or permanent ostomy—which negatively impact psychological, sexual, and reproductive health outcomes [46-49]. Patients with early-onset CRC experience elevated psychological distress and social and physical burden, often resulting from issues with bowel control or incontinence and body image [50,51]. Rates of sexual dysfunction are higher than those of other cancer types [51]. Additionally, approximately 48% of young patients with CRC reported that sexual health issues have negatively affected the relationship with their partner [52,53]. Despite the burden associated with the long-term symptoms that accompany this cancer type and elevated rates of impaired functioning, sexual health has been mostly addressed as an individual experience without exploring how young patients with and survivors of CRC cope with sexual distress in the context of their relationship with a partner [10,14,35,54,55].

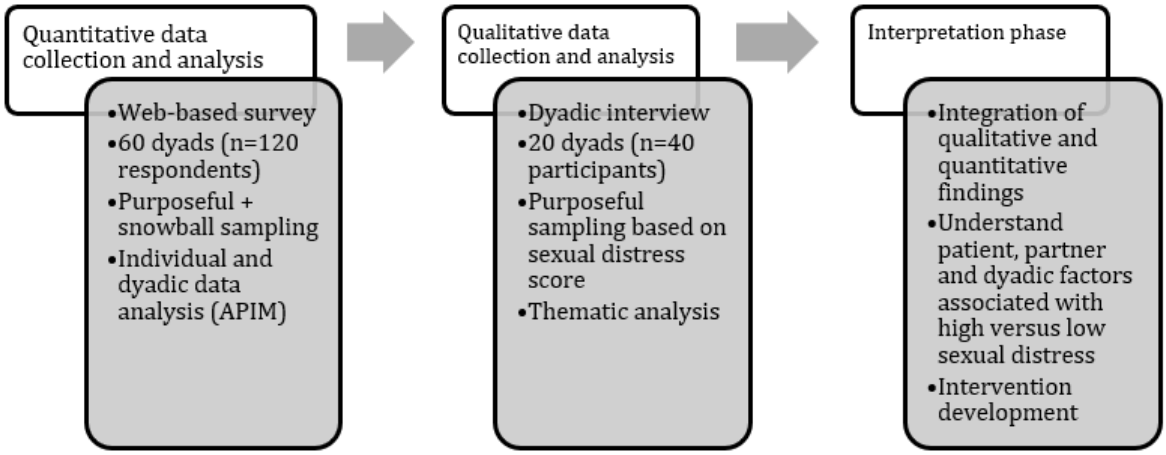
It is well recognized that the multidimensional distress of cancer affects both patients and partners [3,56-59]. Yet, only a few studies have investigated sexual health outcomes from a couple perspective among adolescents and young adults despite 3 important considerations. First, partners play a critical role in providing emotional, physical, and practical support [56,57,59,60]. Intimate partners also contribute to patients' adjustment to the illness: distress experienced by either partner has been found to directly affect distress levels in the other, with negative outcomes in quality of life, relationship functioning, and mental health for discordant couples [61-64]. Second, integrative models of sexuality place greater emphasis on psychosocial and interpersonal factors [65,66]. This finding supports the notion that greater attention should be placed on the psychosocial experience of both members of the dyad, in terms of shared loss and coordinated strategies to cope with cancer-related sexual dysfunction [3,60,67,68]. Finally, recent findings indicate that interventions addressing both partners' experiences in the context of sexual recovery and treatment are feasible and acceptable and they improve outcomes for both [58,69-76]. Hence, there is a critical need to investigate interpersonal characteristics that influence adolescent and young adult cancer survivors and their partners' experience with sexual dysfunction. This knowledge gap affects the provision of comprehensive sexual health care for adolescent and young adult cancer survivors [12,19,20,35] and the development of interventions tailored to the needs of individuals and couples at higher risk of sexual distress during survivorship.

This paper describes the protocol of the AYA CRC SHARE (ie, Sexual Health And REproductive concerns) project, which investigates sexual and reproductive issues of young adult CRC survivors and their partners within the first 5 years after diagnosis. This study will fill a significant gap in the current body of evidence assessing the long-term consequences of treatments for CRC on sexual health and wellbeing–related outcomes. In addition, this investigation will inform a subsequent intervention to enhance couples' coping and communication skills critical to sexual intimacy.

Theoretical Model

This study is underpinned by a theoretical model that integrates the Biopsychosocial Model of Sexuality after Cancer developed by Bober and Varela [65], with Wittmann's Sexual Recovery Model [67,77,78]. Bober and Varela [65] have outlined an

XSL•FO
RenderX



integrative biopsychosocial model, where cancer-related sexual problems exist at the intersection of biological (ie, body image change, fatigue, pain, and loss of sensation), psychological (ie, depression and anxiety), sociocultural (ie, social and cultural norms), and interpersonal factors such as relationship quality, intimacy, and communication [65]. Wittman [74,78] has extended this work, illustrating how changes in sexual functioning after cancer represent a loss for both patients and partners. Their model conceptualizes sexual recovery as a process that shares similarities with the grief experience [67,74,77-79]. Finally, if we consider cancer and the resulting sexual loss as a dyadic stressor, it is possible to postulate that dyadic coping strategies are needed to adjust to this transition. According to the Systemic-Transactional Model [80], dyadic coping includes both partners' strategies to manage their own and their partners' distress as well as coordinated coping behaviors implemented by the dyad in response to stressful situations that may affect the quality of the relationship. Therefore, our work investigates whether dyadic coping behaviors that characterize the exchange within young partners may alleviate the burden associated with sexual distress experienced after cancer.

Methods

Study Design

This study will use an explanatory sequential mixed methods approach [81] to (1) characterize sexual function, sexual distress, body image, fertility concerns, and dyadic coping among adolescent and young adult CRC survivors and their partners using validated measures (n=60 couples); (2) examine the reciprocal influence of each partner's sexual function (model 1) and dyadic coping style (model 2) on self-reported sexual distress; (3) identify interpersonal or couple characteristics associated with their ability to cope with sexual dysfunction; and (4) integrate quantitative and qualitative findings to expand the current understanding of dyadic adjustment to sexual distress (Figure 1).

Figure 1. Overview of the mixed methods explanatory sequential design of the study. APIM: Actor-Partner Interdependence Model.

Inclusion and Exclusion Criteria

The target sample includes 60 dyads composed of young adult CRC survivors and their romantic partners (n=120). A subset of 20 couples (n=40) will complete an in-depth dyadic interview with 2 members of the research team to further explore couple-based strategies implemented to cope with cancer-related sexual dysfunction. Couples will be selected for the qualitative component of the study based on their score on the sexual distress measure (see *Quantitative Web-Based Survey Study Component*). Couples scoring in the highest and lowest 10th percentile will be invited to complete qualitative interviews. Inclusion criteria for cancer survivors consist of (1) having received a diagnosis of CRC (stages I-IV) within 5 years prior to study enrollment; (2) being in a romantic relationship with a partner; (3) being older than 18 and younger than 39 years at the time of diagnosis; and (4) speaking English. Intimate partners are included in the study if they are (1) older than 18 years and (2) able to speak in English. Exclusion criteria are (1) cognitive impairment or severe mental illness that would impede the completion of self-report instruments; (2) attending couples therapy at the time of survey completion; (3) currently receiving end-of-life care; and (4) the partner is not present or unwilling to participate. No exclusions will be made on the basis of gender identity, sexual orientation, ethnicity, or cultural background.

Participant Recruitment and Study Procedure

Multiple recruitment strategies will be implemented to reach the expected sample size of adolescent and young adult couples inclusive of CRC survivors and their partners. Informational flyers and social media scripts will be distributed among advocacy and community-based organizations for individuals with CRC, adolescents and young adults with cancer, and sexual or reproductive health with the help of a CRC survivor and advocate who is a member of the research team (AR). Investigators will also recruit participants at CRC events and conferences. We will work closely with the University of Texas MD Anderson Cancer Center Adolescent and Young Adult Program to promote study recruitment through existing listerves and private social media groups. In addition to active recruitment, study investigators (CA, DW, and MR) will share the study with psychosocial oncology providers and pediatric or medical oncologists to encourage them to refer participants to the study.

Potential participants can self-refer to the study in two ways: (1) by clicking on the URL and QR code, which will link them

XSL•FO
RenderX

to a web-based study information form and screening questions or (2) by contacting the research team directly via email or telephone. The study information form includes a list of exclusionary criteria, and potential participants can opt out of the study if they present any of the characteristics that would interfere with their ability to qualify for the study activities. To preserve the integrity of the data, a brief telephone screening ascertaining age, cancer diagnosis, and relationship status will be implemented. Upon successful recruitment, participants will receive an individualized link to complete the web-based survey. They will be asked for their permission for the study team to contact their romantic partners, and couple completion of the survey will be monitored through individual and dyadic identifiers. Inclusion in the study is based on both partners' provision of informed consent and completion of study questionnaires. If only one partner completes the study questionnaire or if less than 50% of the survey questions are answered, they will be excluded from the final sample. Two reminders will be sent to the participants and their partners. Additionally, among couples who express interest in participating in the qualitative component of the study while completing the survey, dyadic interviews will be conducted, with 10 couples reporting elevated sexual distress and 10 couples reporting low sexual distress (based on our sample distribution of scores) to appraise strategies implemented to cope with cancer-related sexual dysfunction.

Ethical Considerations

This study will be performed in accordance with the tenets of the Declaration of Helsinki. The University of Houston's institutional review board has reviewed and approved the study protocol (reference number STUDY00003538). Informed consent will be obtained from each participant before commencement of study research activities.

Recruitment and consenting of study participants will occur mostly through web- and internet-based approaches. A cover letter precedes the web-based survey explaining the study aims and procedures. Written information describing the research will be provided to survey participants, and this information will reference the optional interview procedures for a portion of the sample. Upon survey completion, a US $30 Amazon gift card (US $60 per couple) will be distributed via email. Additionally, a US $60 electronic gift card will be provided to each partner after participating in the dyadic interview (US $120 per couple).

Although this is considered a low-risk study, it is possible that answering questions about cancer diagnosis, sexual and reproductive health, as well as cancer-related impact on the couple's relationship may cause participants to experience distress, sadness, or anxiety. The study team will provide participants with resources for cancer-related support in the follow-up thank you message used to disseminate the incentive. Participants can also contact the investigators or let the study team members know about their interest in being referred to community-based organizations. For partners who will participate in the qualitative interview, potential aspects of distress include cancer-related distress, sexual, fertility, and negative relational outcomes. In addition, mental health and suicide risk may emerge in the exchange with the investigators. Both participants (survivor and healthy partner) will receive a copy of the resource list created ad hoc from the research team, which includes the National Suicide Prevention Lifeline link and a 24/7 phone number. Being in an electronic format, the resource list will be attached to the thank you email for the participants, and it can also be shown directly to them upon conclusion of the interview. Other risks include breach of confidentiality or privacy. Efforts will be made to limit the potential for privacy to be threatened by a data breach: first, we made the decision of not pairing data from the web-based survey and the interview with identifying information. When data are downloaded, they will be stored in a password-protected encrypted computer. Each subject's name will be paired with a code number, which will appear on written study material. The list pairing the subject's name to the assigned code number will be kept separate from these materials, and only the study principal investigator will have access to this information.

Participant Safety

Participant safety will be addressed through the implementation of the following strategies. First, survey instruments and study procedures will be reviewed and tested by expert e-patients and young CRC advocates [82] until consensus is achieved. Second, investigators will closely monitor responses to instruments assessing emotional functioning. An ad hoc list of resources in the areas of sexual health, mental health, caregiving, financial toxicity, and oncofertility has been compiled in collaboration with content experts or patient advocates, and it will be distributed to all participants at the end of the study activities. Third, 2 facilitators with expertise in research on sensitive health topics will conduct the interviews to reduce potential harm to participants because of the distress that may be elicited by the topics discussed [83], while affirming the cathartic and empowering aspect of using one's experience to improve quality of care for adolescent and young adult couples. Additionally, to protect the individuals' well-being and couples' functioning, participants may opt to conduct the interview separately.

Study Measures

Quantitative Web-Based Survey Study Component

Survivors and partners will be asked to complete questions about sociodemographic information including current age, sex, gender identity, sexual orientation, race and ethnicity, education, occupational status, insurance status, and income. Relationship characteristics include marital status, length of relationship, cohabitation, and presence of children. Clinical information for adolescent and young adult survivors will include cancer diagnosis, stage of the disease, age at diagnosis, time since diagnosis, and treatment type. Table 1 provides an overview of the sexual and psychosocial measures administered to participants.

Sexual function and satisfaction will be assessed with the Patient-Reported Outcomes Measurement Information System (PROMIS) Sexual Function and Satisfaction Measure version 2.0 Brief Profile (female version: 14 items, and male version: 10 items) [84,85]. The following domains will be answered by females: vaginal lubrication, vaginal pain, vulvar discomfort,

XSL•FO
RenderX

and clitoral discomfort. The erectile function domain will be completed by male partners and survivors. The brief measure also includes 4 gender-neutral domains: interest in sexual activity, satisfaction with sex life, orgasm ability, and orgasm pleasure. All respondents are invited to complete items related to interest in sexual activity, whereas the remaining domains are to be completed only by respondents who had been sexually active. Per PROMIS network instructions, domain scores will be transformed to a *t* score distribution, where 50 represents the mean for the general US population [24,86]. A cutoff of 1 SD from the mean *t* score distribution of each domain will be used to define sexual dysfunction. The Sexual Function and Satisfaction Measure has shown adequate construct, content, known-groups validity, and test-retest reliability in adults and in groups of adolescents and young adults with cancer [84,85,87]. Because of the focus on young CRC survivors, 2 additional items will explore discomfort in the anus and rectum areas. Participants who do not identify as male or female in their sexual relationships are given the option to complete the General Measure of Sexual Satisfaction [88]. The instrument contains 5 semantic differential items rated on a 7-point scale. The total score, calculated as the sum of each item, ranges from 5 to 35 and higher values indicate greater sexual satisfaction. The instrument has demonstrated strong reliability and validity [88].

Table 1. Overview of the sexual and psychosocial measures included in the web-based survey.

Instruments	Items, n	Psychometrics
Sexual function and satisfaction		
Patient-Reported Outcomes Measurement Information System Sexual Function and Satisfaction Measure Brief Profile	10 for males and 14 for females	Females: α=.89-.95; males: α=.71-.87

Emotional functioning		
Patient Health Questionnaire-8	8	Cronbach α=.82
Emotion Thermometers	5	Cronbach α=.90
Relationship satisfaction		
General Measure of Relationship Satisfaction	5	Cronbach α=.96
Body image		
Body Image Scale[a]	10	Cronbach α=.93

[a]Only for colorectal cancer survivors. This scale is not administered to partners.

Sexual distress will be measured with the Sexual and Relationship Distress Scale [89], which consists of 30 items assessing multidimensional (14-factor) individual and relationship distress experienced in the context of sexual difficulties. Each subscale score is calculated by combining the scores on each item, which ultimately determines the resulting total score. The instrument has demonstrated high internal consistency and high convergent and discriminant validity [89], and it has been administered in the context of breast and gynecological cancer survivorship in young adults [90].

Dyadic coping will be assessed using the Dyadic Coping Inventory [71,91-95], a 37-item questionnaire evaluating dyadic coping strategies implemented to cope with the stress of cancer on a 5-point Likert scale from 1="very rarely" to 5="very often." Dyadic coping describes partners' strategies implemented to manage their own and their partners' distress as well as shared coping behaviors enacted by the dyad in response to stressful situations that affect the relationship. Items are organized in multiple subscales: stress communication, supportive, delegate, negative, and common dyadic coping. In addition, respondents are invited to rate their satisfaction with and the effectiveness of the dyadic coping behaviors implemented. Satisfactory psychometrics have been previously reported both for the original version of the instrument [94,95] and the English validated questionnaire [91,96].

Perceived infertility-related distress in cancer survivorship will be measured by administering the Relationship Concern and Need for Parenthood subscales (10 items each) from the Fertility Problem Inventory [97]. Each subscale and the instrument's total score have demonstrated appropriate internal consistency and convergent and discriminant validity, with scores on the selected subscales being associated with marital adjustment.

XSL•FO
RenderX

Current treatment protocols for CRC have long-term implications for fertility status [98-102], which can represent an additional source of distress for patients and their partners. Participants can opt out of these questions if they have completed their family-building or if the questions are considered not applicable.

Emotional functioning will be assessed with the Patient Health Questionnaire-8 [103,104] and the Emotions Thermometer [105,106]. The Patient Health Questionnaire-8 is a brief measure of depression validated both for the general population and for individuals with cancer [103,104]. Participants rate on a 4-point Likert scale that ranges from 0 to 3 (0="not at all," 1="several days," 2="more than half of the days," and 3="nearly every day") symptoms of depression experienced over the past 2 weeks; for example, feeling tired or having little energy, poor appetite, or overeating. The total score, obtained as a sum of each item, ranges from 0 to 24, with higher scores representing mild, moderate, and severe levels of depression. Excellent psychometric characteristics have been recorded across age and racial and ethnic groups, supporting its application in the context of psychosocial oncology [107-110]. The Emotions Thermometer is a self-report visual analogue tool including 5 domains (distress, anxiety, depression, anger, and need for help) on a scale ranging from 0 to 10. Excellent reliability (Cronbach α=.90), sensitivity (82.4%), and specificity (68.6%) of the instrument have been confirmed in multiple samples [105,106].

Relationship satisfaction will be measured using the General Measure of Relationship Satisfaction to examine the quality of the couple's relationship. This 5-item scale contains five 7-point semantic differentials—"good-bad," "pleasant-unpleasant," "positive-negative," "satisfying-unsatisfying," and "valuable-worthless"—in response to the question, "How would you describe your relationship with your partner?" The scale has shown strong reliability and validity [88] in men (Cronbach α=.96) and women (Cronbach α=.96).

Body image concerns of CRC survivors will be assessed with the Body Image Scale [111,112]. Items assess how patients feel about their appearance and any changes that may have resulted from their disease or treatment ("Have you felt less physically attractive as a result of your disease or treatment?" and "Did you find it difficult to look at yourself naked?"). The 10 items are rated on 4-point response option consisting of "not at all," "a little," "quite a bit," and "very much." Higher scores are indicative of lower body image perception. The scale has demonstrated high reliability (Cronbach α=.93), discriminant validity, and sensitivity to change [111].

Qualitative Study Component

A subset of 20 couples (n=40) will complete an in-depth dyadic interview with 2 members of the research team to further explore strategies implemented by the 2 partners to cope with cancer-related sexual dysfunction and its associated distress. Dyads will be selected for the qualitative section of the study based on their sexual distress score (Sexual and Relationship Distress Scale [83]). Ten couples scoring in the highest and lowest 10th percentile of sexual distress will complete the qualitative interviews. Questions will address participants' experience with sexual dysfunction, sources of sexual distress or concerns; perceived changes and consequences on couples' relationships; and preferences for interventions addressing sexual health issues for patients with CRC and their partners. Couples will be contacted by the research team via email or telephone. Members of the research team will share information about the topics covered in the interviews, how interviews will be conducted, and how data will be collected, stored, and analyzed. Interested participants will be verbally consented at the beginning of the interview, which will be conducted either via telephone or via a Health Insurance Portability and Accountability Act–compliant web-based videoconferencing platform.

Statistical Analysis

Univariate descriptive statistics and graphs will be analyzed to assess variables' distributions. A missing data analysis will be conducted to determine whether list-wise deletion or multiple imputation will be appropriate; this will consider the amount of missingness and viability of the missing at random assumption necessary for multiple imputation [113]. Pearson *r* correlation coefficients will be used to assess the linear relationship among sociodemographic, clinical, and sexual or psychosocial measures, with specific attention to the variables of interest for the study. Comparisons of demographic characteristics between adolescent and young adult CRC survivors and their partners will be conducted using paired samples *t* tests for continuous variables and chi-square tests of association for nominal variables. Correction for multiple tests will be applied to control type I errors.

Then, the Actor-Partner Interdependence Model will be used to examine actor and partner effects of sexual function (model 1) and dyadic coping styles (model 2) on sexual distress of each member of the dyad [114-117]. A patient's score on the predictor variable is expected to affect their own criterion variable scores (actor effect) and those of their partner (partner effect), and vice versa. Thus, it will be possible to determine whether sexual distress results from the score of the patients, partners, or both on the dyadic coping and sexual functioning measure [114,117,118]. Given the small sample size (60 dyads), the pooled regression approach will be used [114,117]. Stata (version 17; StataCorp) [119] will be used for the analysis, as the pooled regression approach is straightforwardly implemented using the *mvreg* command. The reasonableness of regression assumptions will be assessed using diagnostic statistics and plots [120]. Departures from assumptions will be handled using contemporary approaches such as the use of heteroscedasticity-consistent SEs. Power estimates were favorable: with a sample size of 60 dyads, assuming an α level of .05, the power of the regression *F* test to detect a significant model of each partner's sexual function (model 1) and dyadic coping style (model 2) for sexual distress is approximately 0.86 in the presence of a medium effect size [115].

The qualitative phase of the study is designed to further explain quantitative results via purposive sampling of a subset of dyads. Interview recordings (n=20 dyadic interviews) will be transcribed verbatim and analyzed using thematic content analysis [121]. Transcripts will be reviewed for concordance, and discrepancies will be resolved through discussion among

investigators. Qualitative data will be reviewed iteratively to reach saturation; that is, when no new information emerges during coding [122,123]. Atlas.ti software (ATLAS.ti Scientific Software Development GmbH) will be used to manage and organize qualitative data [124].

Mixed Methods Integration

This study adopts an explanatory sequential mixed methods design, which incorporates quantitative and qualitative approaches as part of 2 consecutive phases [81]. Explanatory designs use qualitative data to explain and achieve greater understanding of the results emerging from the quantitative data [81,125]. In this design, the qualitative component builds on the survey and couples participating in the dyadic interview are selected from the sample that had previously completed the quantitative component. Integration of the 2 strands of data will be presented in a joint display table [126], thus yielding a more comprehensive view of participants' experiences and illustrating interpersonal processes that inform couples' coping with impaired sexual functioning.

Results

Recruitment and data collection started in July 2022, and data collection is expected to be concluded in September 2024. No results are available as of manuscript preparation.

Discussion

This mixed methods study, to the best of our knowledge, will be among the first to apply a relational perspective to the investigation of sexual health outcomes among adolescent and young adult CRC survivors. Conducting research with dyads presents numerous challenges in research design, measurement, and data analysis [96,109-111]. Approaches to recruitment and data collection have been selected on the basis of previous acceptability in similar studies conducted by members of the investigative team (CA and DW) and the existing literature on couple-based research [111-115]. In addition, age-tailored web-based data collection efforts will contribute to the study's feasibility. We consider it a strength of the proposed study that we will integrate survey and qualitative feedback from both partners and from diverse typologies of dyads.

Addressing changes in sexual function and their implications for psychosocial and clinical outcomes is essential to quality cancer care; yet, it is often challenging to translate this knowledge into routine practices inclusive of cosurvivors [20,57]. The expected outcomes of this investigation are to (1) characterize sexual function, sexual distress, and dyadic coping of adolescent and young adult CRC survivors and partners through validated measures; (2) provide a deeper understanding of the challenges couples experience as they navigate sexual intimacy after CRC treatment by highlighting the role of interpersonal processes; and (3) use the findings to develop and test interventions supporting the recovery of sexual intimacy of young couples coping with CRC. Sexual dysfunction and altered intimacy with a partner are salient factors impairing long-term quality of life and emotional well-being [20,69,116]. Through the identification of individual, partner, and relationship-level factors that shape how couples negotiate the loss elicited by the illness and redefine their sexual experience or repertoire, this work will inform the development of a couple-based intervention that promotes intimacy by enhancing coping and communication skills. The results from this study will also contribute to identifying couples who are more vulnerable to poor emotional and relationship functioning, either because of clinical, sociodemographic, or interaction effects. This information can be used to alert the multidisciplinary team and offer timely referral to services.

While the cross-sectional design and the small sample size are limitations of this protocol, this work can lead to further interesting areas of inquiry. Future research will be needed to evaluate sexual health outcomes over time and elicit information about preferred timing, format, and contents of sexual health programs. In addition, investigators can consider integrating momentary ecological assessment approaches and dyadic diaries to better capture antecedents and patterns associated with differential trajectories. Finally, future studies should investigate whether delivering sexual health interventions results in improved quality of life and other psychosocial health outcomes among adolescents and young adults.

In conclusion, sexual health problems are among the most distressing consequences of the disease for young patients with CRC, with recent literature documenting the lack of evidence-based approaches tailored to their experience, preferences, and needs [12,20,55,127]. This study seeks to fill this gap by involving survivors and their partners to generate a dyadic model of sexual functioning and intimacy. In addition, while the literature has often linked addressing sexual health concerns with a higher quality of life, emotional well-being, and relationship functioning [67], these relationships have been minimally examined in this group. This lack of knowledge impairs the range and quality of services, especially considering the impact of sexual dysfunction, body image concerns, and fertility status on physical and emotional intimacy. As growing evidence has documented how the complexity of sexual health issues may hinder providers' capacity and confidence to discuss this topic [127-130], results from this work will provide important recommendations for timely and patient-centered care delivery.

Acknowledgments

The authors would like to express their gratitude to all the patients' advocates and caregivers who have provided critical feedback and suggestions in the development of the study. This research was funded by the Sexual Medicine Society of North America (SMSNA) through a SMSNA Foundation Research Grant awarded to CA, PhD, LMSW.

Data Availability

The data that support the findings of this study will be available from the corresponding author (CA) upon reasonable request. The data are not publicly available due to information that could compromise the privacy of research participants.

Authors' Contributions

CA, DW, and MR conceptualized the study and designed the methodology. CA, DW, MR, and ZG carried out the investigation. CA, DW, MR, and AR procured the resources for the study. CA, LCC, and ZG curated the data. CA drafted the manuscript, and CA, DW, MR, AR, LCC, ZG, and EI reviewed and edited the manuscript. CA and ZG were responsible for the study's administration. CA acquired the funding for the study. All authors have read and agreed to the current version of the manuscript for publication.

Conflicts of Interest

None declared.

Abstract

Background: In Australia, aged care and disability service providers are legally required to maintain comprehensive and accurate clinical documentation to meet regulatory and funding requirements and support safe and high-quality care provision. However, evidence suggests that poor-quality clinical data and documentation are widespread across the sector and can substantially affect clinical decision-making and care delivery and increase business costs.

Objective: In the Optimizing the Quality of Clinical Data in an Australian Aged Care and Disability Service to Improve Care Delivery and Clinical Outcomes (OPTIMISE) study, we aim to use an Agile *Lean Six Sigma* framework to identify opportunities for the optimization of clinical documentation processes and clinical information systems, implement and test optimization solutions, and evaluate postoptimization outcomes in a large postacute community-based health service providing aged care and disability services in Western Australia.

Methods: A 3-stage prospective optimization study will be conducted. Stage 1 (baseline [T_0]) will measure existing clinical data quality, identify root causes of data quality issues across services, and generate optimization solutions. Stage 2 (optimization) will implement and test changes to clinical documentation processes and information systems using incremental Agile sprints. Stage 3 (evaluation) will evaluate changes in primary and secondary outcomes from T_0 to 12 months after optimization. The primary outcome is the data quality measured in terms of defects per unit, defects per million opportunities, and Sigma level. The secondary outcomes are care delivery (direct care time), clinical incidents, business outcomes (cost of quality and workforce productivity), and user satisfaction. Case studies will be analyzed to understand the impact of optimization on clinical outcomes and business processes.

Results: As of June 1, 2022, stage 1 commenced with T_0 data quality audits conducted to measure current data quality. T_0 data quality audits will be followed by user consultations to identify root causes of data quality issues. Optimization solutions will be developed by May 2023 to inform optimization (stage 2) and evaluation (stage 3). Results are expected to be published in June 2023.

Conclusions: The study findings will be of interest to individuals and organizations in the health care sector seeking novel solutions to improve the quality of clinical data, support high-quality care delivery, and reduce business costs.

Introduction

Background

In Australia, aged care and disability service providers are legally required to maintain comprehensive and accurate documentation of the care provided to each client [1,2]. This clinical documentation is crucial to support safe and high-quality care delivery, maintain professional accreditation, and acquire government funding [3-5]. However, widespread clinical documentation and data quality issues have been identified across the sector, with evidence suggesting that most existing clinical data in the aged care and disability services sector are of substandard quality and lack consistency within and across individual organizations [3,6,7].

This problem has been partly because of the absence of national data standards and minimum requirements to guide information collection and documentation processes [3,7]. Therefore, service providers are challenged to collect extensive clinical information to meet multiple funding and regulatory reporting requirements across different and often segregated information systems [3,7]. Existing clinical information systems have also largely used "shrink-wrapped" or off-the-shelf systems owned by external vendors that are modeled on designs from other health care environments, with limited customization to account for the specific environment, workflows, and information requirements of aged care and disability services [8-10].

Investigations of workflow in Australian residential aged care facilities (RACFs) have shown that clinical documentation and information processing are major time-intensive staff activities [9,11]. A study involving 6 RACF sites in New South Wales and Victoria estimated that registered nurses spent a median of 60 minutes on documentation per shift, whereas service managers spent a median of 360 minutes on documentation activities, including filling forms, progress notes, incident reporting, and medication management [9]. Similarly, a second study estimated that RACF support workers spent a mean 14.5% of the total working time per shift on documentation tasks, which is equivalent to approximately 60 minutes for a standard 7.5-hour shift [11].

Although documentation is an essential activity of health care provision, excess time spent on documentation directly reduces the amount of care time spent with residents, which can compromise the quality of care delivery [12]. A survey in the United Kingdom found that 81% of the nurses believed they spent a disproportionate amount of time on record keeping and documentation tasks, which prevented them from providing direct care [13]. Other research has shown that the clinical documentation burden is a major driver of burnout among clinical and care staff [14,15], who believe that time could be better spent attending to residents [16-18], and can negatively impact job satisfaction [17].

Health IT (HIT) has a great capacity to support efficient information processing in aged care and disability services and facilitate high-quality person-centered clinical decision-making at the point of care [19,20]. Research has shown that the overall workforce and management perception of the use of electronic health records (EHRs) in aged care is positive, with widespread agreement that EHRs are beneficial for improving workforce efficiency [21]. However, there is a need to optimize HIT systems based on a detailed understanding of the workflow and requirements specific to aged care and disability services [9]. Several pre-post implementation studies in Australian RACFs have shown that the implementation of electronic systems alone does not automatically lead to greater efficiency [11,12,19] or data quality improvement [22] compared with paper-based systems. Instead, the implementation of suboptimal HIT systems can lead to unintended adverse consequences, including increased documentation time, difficulty in data entry and information retrieval, increased complexity of information management, and increased documentation burden and business costs [23].

Several common issues with EHR systems used in aged care and disability services have been described in the literature. End users have reported that existing systems lack clarity and contain inconsistent data fields, definitions, and terminology that do not match the specific information requirements for aged care and disability services [3,19]. When relevant input fields are unavailable, information is either omitted or recorded elsewhere, meaning that the EHR is often incomplete and does not contain all essential information necessary for the delivery of safe care [24]. Systems have also been reported to be difficult to navigate [25] and lack the structure and organization to guide the workforce to record the required clinical information efficiently [7,20]. A clinical documentation audit study in 7 Australian RACFs showed that although EHRs contained a greater *quantity* of information than paper-based records, information recorded in EHRs had a lower total mean *quality* score [22].

Other research has shown that end users can become reluctant to use EHR systems if they do not easily integrate into their workflow and often revert to using paper-based documentation [3]. This creates further inefficiency with respect to double documentation and the duplication of effort, contributing to a "vicious cycle" [19] of increased documentation burden and poorer data quality [3,9]. One study found that RACF nurses reported an excessive amount of time spent entering the same information across multiple incompatible systems and that double documentation resulted in the omission of important information, inaccuracy, and potential safety concerns [24].

In addition to EHR system–related issues, other complex process-related issues have been described that can contribute to missing, incomplete, inaccurate, or not up-to-date clinical data. In the primary care setting, for example, workload and time constraints [26], workforce attitudes toward documentation tasks, and prioritization of direct care tasks [27] have all been shown to affect the quality of nursing documentation. Well-designed EHR systems can support higher-quality clinical data by guiding the workforce to input the required information more efficiently but may not address all process-related barriers related to clinical documentation.

Ultimately, as organizations become more data mature, important business decisions are increasingly reliant on analytics using administrative, clinical, and other service data [28]. Poor data quality can result in flawed business decisions and increased

XSL•FO
RenderX

business costs [29]. Therefore, there is a clear need to optimize clinical documentation processes and clinical information systems to support efficient, safe, and quality care delivery and effective business decision-making in aged care and disability services [9].

However, any form of organizational change in systems or processes represents a major cost for service providers, which can be a major barrier to implementation. Therefore, it is important to be able to clearly demonstrate the added value and cost benefits of transformation initiatives to organizational leadership [19]. Currently, few aged care and disability service providers collect benchmarks to routinely evaluate and monitor data quality or its impact on care delivery and organizational efficiency [30]. Implementation without routine evaluation or a control plan can substantially increase business costs, while adding little value to care delivery or operational efficiency.

The Optimizing the Quality of Clinical Data in an Australian Aged Care and Disability Service to Improve Care Delivery and Clinical Outcomes Study

The overarching goal of the Optimizing the Quality of Clinical Data in an Australian Aged Care and Disability Service to Improve Care Delivery and Clinical Outcomes (OPTIMISE) study is to use an integrated Agile *Lean Six Sigma* (LSS) framework [31,32] to (1) identify opportunities for the optimization of clinical documentation processes and clinical information systems, (2) implement and test optimization solutions, and (3) evaluate postoptimization outcomes in a large postacute community-based health service providing aged care and disability services in Western Australia.

Objectives

Specifically, the 3-stage study will include the following:

1. Stage 1 (*baseline*): measure existing clinical data quality, identify the root causes of data quality issues, and generate optimization solutions
2. Stage 2 (*optimization*): implement and test changes to clinical information systems and clinical documentation processes
3. Stage 3 (*evaluation*): evaluate changes in clinical data quality, care delivery, clinical outcomes, and business costs following optimization

Table 1 presents the specific study objectives mapped to the Agile LSS phases (see the *Study Design and Framework section*).

Table 1. Objectives of the Optimizing the Quality of Clinical Data in an Australian Aged Care and Disability Service to Improve Care Delivery and Clinical Outcomes study.

Stage and phase	Objective
Stage 1: baseline	
1.1. Define	Define study goals, scope, outputs, and methodology
1.2. Measure	Measure clinical data quality across aged care and disability services
1.3. Analyze	Identify root causes of data quality issues
1.4. Improve (part 1)	Generate solutions to support optimization of clinical documentation processes and clinical information systems
Stage 2: optimization	
2.1. Improve (part 2)	Implement and test changes to clinical documentation processes and clinical information systems specific for aged care and disability services
2.2. Control	Establish policies and procedures for clinical data governance, collection, and input across care services
2.2. Control	Establish a control plan for routine audit of clinical data quality across care services
Stage 3: evaluation	
3.1. Evaluation	Measure change in primary outcomes (clinical data quality)
3.1. Evaluation	Measure change in secondary outcomes (care delivery, clinical outcomes, business costs, and workforce satisfaction)

Methods

Study Design and Framework

The OPTIMISE study will be a prospective optimization study using an integrated Agile LSS Define, Measure, Analyze, Improve, Control (DMAIC) framework.

Six Sigma is a statistical measurement-based method for process optimization and quality improvement that aims to reduce the number of *defects* in a process to <3.4 defects per 1 million opportunities [33]. *Lean* methodology is focused on reducing *waste* in a process, which is defined as any unnecessary or suboptimal items, actions, tasks, components, materials, systems, or human resources that increase costs and time spent on a process [34]. Therefore, the *Lean Six Sigma* framework aims to reduce both *defects* and *waste* to improve the quality of products and services, improve efficiency, and reduce business costs [35,36]. Originally conceptualized in the manufacturing industry, LSS has been increasingly applied in health care to control rising costs and improve the quality of care delivery [30,36-38].

The strength of LSS is its rigorously structured framework for quality improvement based on statistical measurement. However, this structure can lack flexibility to accommodate changes across the project cycle [32]. *Agile* methodology can complement LSS to increase flexibility and adaptability [39].

XSL•FO
RenderX

Agile is a popular methodology used in software development that involves the iterative development of a product over short-term incremental cycles called sprints [31]. It is a highly flexible and responsive methodology that allows for product changes during development based on customer feedback. However, this method neglects decision-making based on objective and measurable data, which can compromise quality and efficiency. Therefore, the integration of Agile and LSS frameworks provides a structured methodology for product development, evaluation, and improvement that is simultaneously flexible and responsive to changes over iterative cycles. Hybrid Agile LSS frameworks have been increasingly used in the literature as a more powerful method for quality improvement than single frameworks [39-42].

Study Setting

The study will be undertaken at Brightwater Care Group ("Brightwater"), a large postacute, residential, and community-based aged care and disability service in Perth, Western Australia. Brightwater provides residential and home-based care for approximately 1882 aged care and 522 disability services clients across 10 different programs (Table 2).

Table 2. Overview of aged care and disability services.

Service type and program name	Sites, n	Clients, n	Description
Aged care			
RAC[a]	11	750	Long-term or permanent high care accommodation for people aged >65 years
SDCP[b]	1	31	Long-term or permanent high care accommodation for people with dementia
TCP[c]	2	101	Short-term, posthospital support and active management for older people aged >65 years
AH[d]	—[e]	1000	Home-based support for people aged >65 years
Disability			
TRP[f]	1	53	Specialist neurorehabilitation service for people aged 18-65 years with acquired brain injury
TAP[g]	1	23	Short-term, posthospital support and active management for people aged 18-65 years with disability
SIL[h]	8	71	Long-term and permanent high care accommodation for people aged 18-65 years with disability
CAPB[i]	—	375	Home-based support for people aged 18-65 years with disability and NDIS[j] funding

[a]RAC: residential aged care.

[b]SDCP: Specialist Dementia Care Program.

[c]TCP: Transitional Care Program.

[d]AH: at home.

[e]AH and CAPB services are at-home and community-based care sites.

[f]TRP: Transitional Rehabilitation Program.

[g]TAP: Transitional Accommodation Program.

[h]SIL: Supported Independent Living.

[i]CAPB: capacity building.

[j]NDIS: National Disability Insurance Scheme.

Patient and Public Involvement

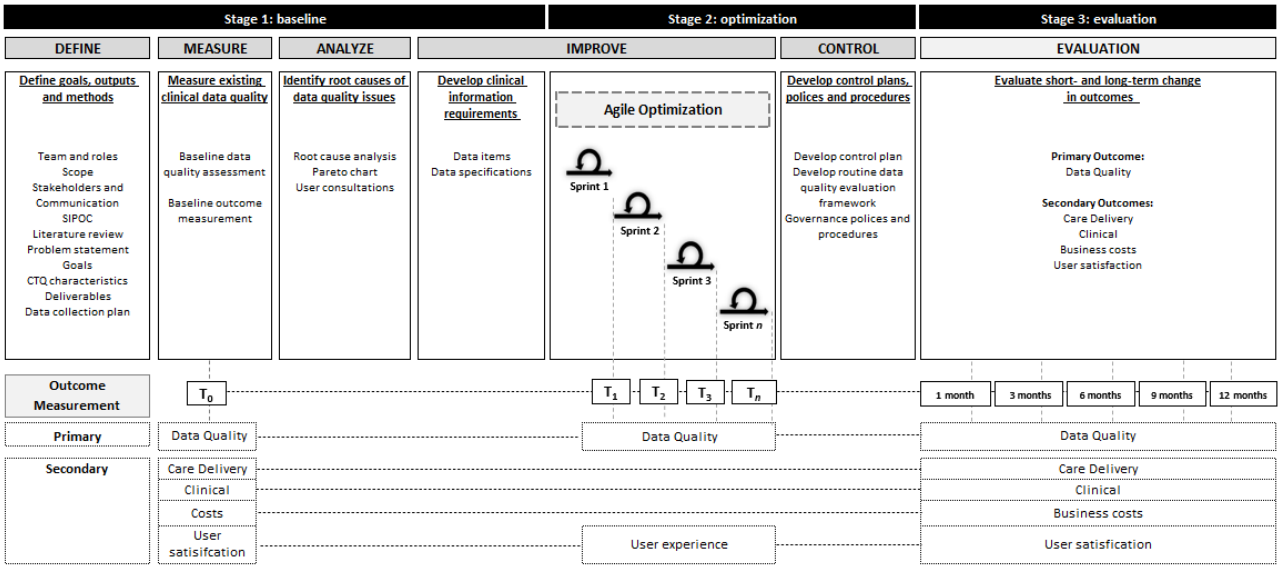
Patients or the public were not involved in the design, conduct, reporting, or dissemination plans of our research, as the end product (clinical information system) is not directly used by patients or the public.

Ethics Approval

The study protocol was approved by Brightwater Care Group as a Level 2: Low Risk Study (reference: 2021/BCG2110). This study is classified as an internal service evaluation and does not require ethics approval for research in Australia.

Consent and Participation

Client EHR data will be deidentified before the analysis. Clients provided written consent for their deidentified clinical data to be used for research and service evaluation as part of the conditions of entry into the service. Staff member participation in user surveys and interviews will be voluntary, and nonparticipation will not impact their usual role. All participant data will be deidentified by assigning a randomized numbered code. Participant names will be changed to pseudonyms when referring to qualitative data. When transcribing interviews verbatim, words or statements that could be used to identify participants will be removed to ensure privacy. Audio recordings will be deleted once the transcriptions are complete.



XSL•FO

Study Phases

Overview

Figure 1 outlines DMAIC phases of the study. Stage 1 (*baseline*) will measure existing clinical data quality across services, identify root causes of data quality issues, and generate solutions to directly inform optimization. Stage 2 (*optimization*) will implement and test changes to clinical documentation processes and information systems specific to aged care and disability services. Stage 3 (*evaluation*) will measure the short-term (1-3 months) and long-term (4-12 months) changes in data quality and clinical and business outcomes following optimization.

Figure 1. The Optimizing the Quality of Clinical Data in an Australian Aged Care and Disability Service to Improve Care Delivery and Clinical Outcomes study design. CTQ: critical-to-quality; SIPOC: Suppliers, inputs, process, outputs, customers.

Stage 1: Baseline

Phase 1.1: Define

To execute the study, a multidisciplinary *Six Sigma* project team [43] was formed, consisting of 5 *regular* team members—a project champion (director of research), process owner and expert (technology services manager), project leader (data scientist), project manager and analyst (information systems analyst), and process user (clinical expert). The project leader has >8 years of experience in leading evaluation projects using complex clinical data including hospital, emergency department, general practice, pharmaceutical, Medicare, mortality, aged care, and disability data, whereas the project manager and analyst holds >6 years of experience in project management, policy analysis, and information systems analysis, and both have Black Belt certifications in LSS. The process user is a research-trained occupational therapist with 3 years of experience providing clinical care for residents at 1 of the residential aged care sites involved in the study and was included as a regular team member to provide clinical oversight and expertise as a direct user of clinical information systems.

In addition, 5 executive and senior managers were included as *resource* and ad hoc team members to provide high-level information and process expertise, as needed.

Several different LSS techniques including Voice of Customer; 5 Whys; Specific, Measurable, Achievable, Realistic, and Timely goals; stakeholder analysis; and a Suppliers, Inputs, Process, Outputs, and Customer diagram were used to define study goals, scope, outputs, critical-to-quality (CTQ) characteristics, and methodology [43]. In addition, a Failure Modes and Effects Analysis [44] was conducted to identify the potential risks and failures. Multimedia Appendix 1 provides a brief description of the LSS techniques that appear in this manuscript for readers who are unfamiliar with the LSS framework.

The main component of the define phase was to define the CTQ metrics to be used to measure data quality in the study. CTQ metrics are key factors or attributes determined to be important by an organization and are used to measure the performance of a process [45]. The CTQ metrics for the clinical data were determined using the Delphi consensus method [46]. First, a literature review was conducted to identify data quality metrics commonly used in data quality assessments [47-49]. After review by the project team, a shortlist of the 15 most relevant metrics was circulated to an expert group consisting of 68 key stakeholders in the organization across executives, care services, clinical excellence, quality, technology, business analytics, and research departments, who independently ranked metrics in order of those most critical to clinical data quality in their role. The final CTQ metrics represented the 6 metrics with the highest rankings among the expert group (Table 3).

The define phase was completed in January 2022. The subsequent sections outline the planned protocol for the remaining phases.

XSL•FO
RenderX

Table 3. Critical-to-quality metrics used to measure clinical data quality.

Rank	Metric	Definition of metric	Measurement method	Defect definition
1	Accuracy	The degree to which EHR[a] data correctly represent a client's personal, medical, clinical, and psychosocial circumstances and care needs	Manual audit of random sample of EHRs compared with original documents (eg, admission documents or medical reports)	Data that do not match the original source of truth
2	Completeness	The degree to which all required data in the EHR are present	Data warehouse audit of all EHRs	Missing data (ie, null or blank fields)
4	Currentness	The degree to which EHR data are up to date and reflect the client's current condition and changes in circumstances and care needs	Data warehouse audit of all EHRs	Data fields not updated within required timeframes as per clinical guidelines
3	Clarity	The degree to which data are presented in a clear format and enable the user to understand a client's care needs without ambiguity	Manual assessment of a random sample of EHRs	Data fields with unclear presentation
5	Compliance	The degree to which EHRs capture all the required information to meet legal, funding, and regulatory requirements and in accordance with best practice clinical guidelines	Manual review of data fields captured in existing systems	Missing mandatory data (ie, null or blank fields)
6	Usability	The degree to which data are presented in a format that allows the information to be directly and efficiently used for primary (eg, care provision) and secondary purposes (eg, reporting, analytics, and evaluation)	Data warehouse audit of all EHRs	Data with limited primary and secondary usability

[a]EHR: electronic health record.

Phase 1.2: Measure

The measure phase will focus on measuring the baseline (T_0) quality of clinical data across services and identifying key data quality issues. T_0 data quality will be measured through an audit of client EHRs using a 6-month lookback period. Data quality will be measured in terms of the *number of defects* present in EHRs, measured using the CTQ metrics identified by the expert group.

Specifically, T_0 data quality will be measured by the number of defects per unit (DPU), defects per opportunity (DPO), defects per million opportunities (DPMO), and the Sigma level (Table 4). T_0 data quality will be measured for each of the 8 programs to allow the identification of any systematic variation between sites and service-specific data quality issues. In addition, the assessment will identify the most common types of defects across services to inform system optimization.

Table 4. *Six Sigma* metrics for measuring defects.

Metric	Formula	Description
DPU[a]		Measures the average number of defects present in a unit (ie, the average number of defects in each client EHR[b])
DPO[c]		Measures the number of defects as a proportion of the total number of data fields (ie, opportunities) present in each client EHR
DPMO[d]		Measures the number of DPO expressed per million
Sigma level	Determined from conversion tables using calculated DPMO	Measures the amount of variability in a process. *Six Sigma* quality performance is defined as 3.4 DPMO.

[a]DPU: defects per unit.

[b]EHR: electronic health record.

[c]DPO: defects per opportunity.

[d]DPMO: defects per million opportunities.

Phase 1.3: Analyze

Following the identification of key data quality issues across services, the analyze phase will focus on understanding the *root causes* of data quality issues. A qualitative research approach will be used to understand the workforce experiences of clinical documentation processes using existing clinical information systems and to identify the root causes of poor data quality.

A purposive sample of the workforce across all 8 programs will be selected to participate in user consultations using either semistructured interviews or web-based surveys (Multimedia Appendix 2). Different functional user groups will be purposively sampled at each site (care staff and clinical, administrative, and service managers) to provide whole-of-organization insight into existing processes, strengths, and gaps. At least 1 site from each program will be selected (a

XSL•FO
RenderX

minimum of 8 sites). For programs with multiple sites, the sites with the highest, median, and lowest data quality based on the findings mentioned in *Phase 1.2: Measure* will be selected for consultation. In addition, users from the corporate workforce who routinely use clinical data or clinical information systems for reporting and analytics will also be consulted to provide insight into the back-end quality of clinical data.

Data collected through user consultations will be used to generate initial subthemes and themes using an inductive thematic analysis approach [50]. Generated themes and subthemes will then be assembled into a fishbone diagram [51], which is an LSS visualization technique to identify the root causes of poor data quality across services.

Phase 1.4: Improve (Part 1)

In the final phase of stage 1, information collected in the measure and analyze phases will be used to generate solutions to optimize clinical data quality across services. Solutions will address identified process-related issues (eg, deprioritization of documentation tasks and workforce roles and responsibilities) and system-related issues (ie, system design, performance, and usability).

Program-specific *data requirements* and *priorities* will be established to meet funding and regulatory requirements, best practice clinical guidelines, and the specific workflows of each service. In addition, data specifications will be developed to enable efficient and accurate information capture to enable high-quality primary (eg, care delivery) and secondary (eg, reporting, research, and evaluation) uses of data. A solutions selection matrix [43] will be used to propose and rank solutions according to perceived cost benefits and to prioritize recommendations for implementation based on the most urgent needs of the organization.

Stage 2: Optimization

Phase 2.1: Improve (Part 2)

Stage 2 will use Agile methodology to test and implement changes to clinical documentation processes and clinical information systems over a 12-month period.

Program-specific data optimization will be conducted to meet the specific workflows and funding, regulatory, and clinical requirements of each service. *Data requirements* and *priorities* established in stage 1 will determine the order of the Agile sprints (ie, incremental cycles of changes). At the end of each sprint, data quality will be evaluated by calculating DPU, DPO, DPMO, and the Sigma level statistics as mentioned in the *Phase 1.2: Measure* section. User acceptance, experience, and satisfaction will be evaluated through user surveys, and user feedback from each sprint will be directly incorporated into the next Agile sprint. This iterative optimization method ensures a flexible approach that incorporates both user feedback and statistical measurement.

Phase 2.2: Control

At the end of stage 2, governance policies and procedures and a control plan will be developed to allow the process owner to routinely monitor and evaluate the quality of clinical data across the service after implementation.

The control phase is the final phase and a critical part of the LSS DMAIC framework, which ensures that a new or improved process continues to work successfully after its implementation as a regular business process. A *Clinical Data Quality Audit Tool* will be designed to allow the routine evaluation of data quality across services as part of ongoing business practice. Internal policy and procedure documents will be developed, and training will be provided to the relevant departments.

Stage 3: Evaluation

The final stage of the study will evaluate changes in the primary and secondary outcomes in the 12 months following the full optimization (Table 5). Outcomes will be measured at T_0 and at 1, 3, 6, 9, and 12 months after full optimization. Previous studies in Australian RACFs have shown that the time spent on documentation tasks generally increases in the period after the implementation of new or changed systems as users learn the new technology and adjust their workflows [11,12]. Therefore, long-term evaluation is critical for reliably quantifying changes in outcomes and their impact on organizational processes.

[a]DPU: defects per unit.

[b]EHR: electronic health record.

[c]DPO: defects per opportunity.

[d]DPMO: defects per million opportunities.

[e]National Quality Indicator Program (NQIP) outcome.

Primary Outcome

The primary study outcome is data quality measured using DPU, DPO, DPMO and Sigma level. Improvement in data quality from T_0 to 12 months after optimization will be determined by a reduction in DPU, DPO, and DPMO and an increase in Sigma level. A well-performing process should operate at a Sigma level of 6 and have ≤3.4 DPMO [43].

Secondary Outcomes

Care Delivery

Care delivery will be measured by the proportion of weekly direct care time spent with residents using a self-report version of the Work Measurement Tool developed by Munyisia et al [52], which measures 8 categories of care activities in Australian RACFs, including *direct care*, *medication management*, *communication*, *documentation*, *indirect care*, *personal*, *in-transit*, and *other*. Clinical and care staff will be invited to complete self-report surveys from T_0 to 12 months after optimization to provide a measure of workflow before and after optimization. Self-reported activities will be validated against observer-rated activities for a random staff subsample.

Clinical Outcomes

Under the National Quality Indicator Program, Australian aged care providers are required to undertake mandatory reporting of 5 National Quality Indicator Program indicators as a measure of the quality of clinical services and care provision [53]. These include *pressure injuries*, *physical restraints*, *falls*, *unplanned weight loss*, and *medication management*. In addition, Brightwater routinely measures 5 internal clinical indicators of quality across both aged care and disability services (behaviors of concern, choking, infection, unplanned hospital admission, wounds; Table 5). This study will measure changes in clinical outcomes from T_0 to 12 months after optimization.

Business Outcomes

A cost of quality (CoQ) analysis [54] will be undertaken to compare the operational costs before and after optimization. The CoQ analysis is a critical part of the LSS framework to estimate the ongoing operational costs of optimizing the data or information system and to ensure that the expenses associated with achieving higher data quality are balanced against the costs of poor quality, which is defined as expenses incurred on resources and non–value-added activities to fix poor-quality data. CoQ costs include costs incurred on the optimization, ongoing operation, and maintenance of the data or information system, whereas poor-quality costs include costs incurred on activities such as data cleaning, data quality inspection, and meetings to rectify data inconsistencies. A health economist will be employed to undertake the CoQ analysis.

In addition, workforce productivity will be evaluated before and after optimization in relation to regulatory reporting. Corporate staff will be invited to complete self-report surveys from T_0 to 12 months after optimization to provide an estimate of the number of hours worked to complete regulatory reporting activities before and after optimization.

User Satisfaction

Finally, self-report surveys and qualitative interviews will be used to measure changes in user satisfaction with clinical data systems before and after optimization. Prior research has shown that clinical documentation burden is a major driver of burnout among care staff [14,15] and can negatively impact job

XSL•FO
RenderX

satisfaction [17]. Therefore, user satisfaction is an important outcome of this study.

Quantitative Analysis

Quantitative analyses will be conducted using STATA (version 16.0; StataCorp LLC) [55]. Multilevel mixed effects regression models will be used to evaluate any change in primary and secondary outcomes from T_0 to 12 months after optimization. For clustered longitudinal data, multilevel modeling recognizes that a change in outcome is affected by a fixed effect (ie, implemented changes) and random effects at both individual and group levels and can explicitly account for this multilevel random variation [56].

An a priori power calculation was performed to determine the minimum number of EHRs required to be evaluated to detect a significant change in our primary outcome (ie, data quality measured using DPU, DPO, DPMO, and Sigma level) from T_0 to 12 months after optimization. First, we used G*Power [57] to compute the required sample size to detect a medium difference (f=0.15) at a Cronbach α level of .05 and a power level of .80 using a linear multiple regression analysis with k=3 fixed predictors (time, program, and the time × program interaction), which returned a required sample size of 77.

This was multiplied by the anticipated *design effect* [58], which is an adjustment factor for clustering in multilevel models. The design effect is calculated as:

$$1 + [(n - 1) \times \text{ICC}] \quad \textbf{(1)}$$

where n is the expected number of subjects per cluster and "ICC" is the intracluster coefficient or the expected correlation within clusters [58]. We defined a cluster as a facility (ie, site) with a median cluster size of 30 clients per facility. With an anticipated moderate intracluster coefficient of 0.10, the design effect is equal to 3.9, giving a required sample size of 77 × 3.9 = 300. On the basis of the occupancy rates and client population size (n=2200) as of January 2022, our primary outcome analysis will have sufficient statistical power.

Qualitative Analysis

Qualitative data from user interviews and surveys will be coded and analyzed using NVivo 12 (QSR International) [59]. An inductive thematic analysis approach will be used to identify and understand key themes, specifically to classify, order, and reassemble data to identify converging and diverging perspectives. A total of 50 interviews are anticipated to reach saturation.

Results

As of June 1, 2022, stage 1 commenced with T_0 data quality audits conducted to identify the current data quality and system strengths and limitations. T_0 data quality audits will be followed by user consultations to identify root causes of data quality issues. Clinical information requirements will be developed by May 2023 to inform optimization (stage 2) and evaluation (stage 3). Results are expected to be published in June 2023.

Discussion

It is anticipated that the study findings will show that optimization of clinical data and documentation will, in turn, have a major impact on care delivery and clinical outcomes and reduce business costs. Although the aim of the OPTIMISE study is to build internal organizational capacity for continuous improvement of clinical data quality, the findings will also be important to individuals and organizations across the aged care and disability service sector, as well as the wider health care sector, which is seeking novel technology solutions to improve the quality of clinical data to support high-quality care delivery and operational efficiency. In addition, the findings will be relevant to researchers and organizations interested in learning the opportunities and limitations of engaging an Agile LSS framework for quality improvement in a health care setting. These findings can stimulate organization-level research to support the development of evidence-based care. The findings will also be disseminated nationally and internationally through industry presentations, scientific conference presentations, and peer-reviewed journal publications.

Data Availability

Data sharing is not applicable for this paper as no data sets were generated or analyzed during this study.

Authors' Contributions

LT designed and leads the study; developed the study framework, methodology, and analysis plan; and leads the evaluation. GT designed the study, developed the study framework and methodology, and performs data collection and analysis. RW performs data collection and analysis. AM designed and leads the study and provides study oversight. MR developed the technology strategy and leads the technology optimization.

Abstract

Background: Surgery remains the standard curative treatment for early-stage colorectal and upper gastrointestinal cancer. Reduced preoperative functional capacity, nutritional status, and psychological well-being are associated with poor postoperative outcomes. Prehabilitation aims to improve preoperative functional reserves through physical, nutritional, and psychological interventions. Yet, how it transitions from a trial setting to being integrated into a real-world health setting is unknown.

Objective: The primary aim is to evaluate the implementation of a multimodal (supervised exercise, nutrition, and nursing support) prehabilitation program into standard care for patients with gastrointestinal cancer (colorectal and upper gastrointestinal cancer) scheduled for curative intent surgery. The secondary aim is to determine the impact of a multimodal prehabilitation program on functional capacity, nutritional and psychological status, and surgical outcomes.

Methods: This is an implementation study that will investigate a multimodal prehabilitation intervention, in a nonblinded, nonrandomized, single-group, pre-post design. Patients diagnosed with colorectal and upper gastrointestinal cancer scheduled for potentially curative intent surgery at Concord Repatriation General Hospital, with ≥14 intervention days prior to surgery and are medically cleared to exercise will be eligible. The study will be evaluated using the Reach, Effectiveness, Adoption, Implementation, and Maintenance Evaluation Framework.

Results: The protocol was approved in December 2019 by the Concord Repatriation General Hospital Human Research Ethics Committee (reference number 2019/PID13679). Recruitment commenced in January 2020. In response to the COVID-19 pandemic, recruitment was paused in March 2020 and reopened in August 2020 with remote or telehealth intervention adaptations. Recruitment ended on December 31, 2021. Over the 16-month recruitment period, a total of 77 participants were recruited.

Conclusions: Prehabilitation represents an opportunity to maximize functional capacity and improve surgical outcomes. The study will provide guidance and contribute to the evidence on the integration of prehabilitation into standard care using adaptive models of health care delivery including telehealth.

Introduction

Gastrointestinal cancer is a common type of cancer, with around 28,600 Australians diagnosed each year [1], and incidence rates are expected to increase with our aging population. In Australia alone, colorectal cancer (CRC) is the fourth most diagnosed cancer and the second most common cause of death, with 15,540 new cases and 5295 deaths estimated per year [1]. Upper gastrointestinal (UGI) cancers including esophageal, gastric, hepatic, pancreatic, and biliary represent approximately 12,434 new cancer cases [2] and more than 17% of cancer-associated deaths [1]. Despite improvements in surgical and oncological treatments, morbidity rates remain high, particularly among those with UGI cancer [3].

Surgery remains the best chance of cure for patients with colorectal cancer and upper gastrointestinal cancer. However, even with advances in surgery, anesthesia, and perioperative care, including the application of enhanced recovery after surgery protocols to mitigate the surgical stress response [4,5], postoperative complications still occur in 30%-50% of patients and are associated with higher morbidity and mortality rates, increased health care costs, and reduced quality of life [6-8]. Even in the absence of complications, major gastrointestinal surgery can still result in a 20%-40% reduction in physical and functional capacity, nutritional decline, and delayed recovery [9,10] particularly in the elderly or those with comorbidities, with many not returning to their baseline function or proceeding to their intended oncological treatment.

In the past decade, the focus of optimizing patients in the preoperative period to withstand the upcoming surgical stressor has emerged in a concept known as prehabilitation. Prehabilitation aims to improve preoperative functional reserves through physical, nutritional, and psychological interventions to mitigate the predictable detrimental effects of surgery [11,12]. While early prehabilitation studies focused on the feasibility of singular interventions [12], a multimodal (exercise, nutrition intervention, and psychological support) approach is increasingly favored [13-17]. We previously reported a pilot feasibility study of a short-term multimodal (exercise, healthy eating, and nursing support) prehabilitation program in CRC surgery [18]. In total, 22 participants completed the program, and the median length of the intervention was 14 (range 7-29) days. We found that attendance was excellent (78.5%, mean 3.5 sessions), moderate-intensity aerobic exercise increased from 17 to 73 minutes per week, and functional capacity measured using the 6-minute walk test (6MWT) [19,20] had a clinically significant increase of 48 (from 435 to 483) m. Participant satisfaction was excellent, with all participants strongly recommending prehabilitation.

While the evidence surrounding prehabilitation grows, how it transitions from a trial setting to being integrated into a real-world health setting is less clear. Implementation science frameworks aim to help understand the barriers and facilitators to support the uptake of research findings into routine clinical care [21]. The “RE-AIM” (Reach, Effectiveness, Adoption, Implementation, Maintenance) evaluation framework [22,23] is a theoretical implementation framework that can guide and assess the translation from research into practice at both the individual and organizational levels. The primary aim of this study is to evaluate the implementation of a multimodal (supervised exercise, nutrition intervention, and nursing support) prehabilitation program into standard care for patients with gastrointestinal cancer (CRC and UGI cancer) scheduled for curative intent surgery using the RE-AIM framework. The secondary aim is to determine the impact of a multimodal prehabilitation program on functional capacity, nutritional and psychological status, quality of life (QOL), length of stay at the hospital, and postsurgical outcomes including complications and recovery. We hypothesize that prehabilitation (1) will be feasible, with good participant adherence; (2) will decrease the length of stay at the hospital and postsurgery complications; and (3) improve functional and nutritional status, recovery, and QOL. Here, we outline the trial protocol, including adaptations made to accommodate the COVID-19 pandemic.

Methods

Study Design and Setting

This protocol describes a translational, implementation study that will investigate a multimodal prehabilitation intervention, in a nonblinded, nonrandomized, single-group, pre-post design, in patients with colorectal cancer and upper gastrointestinal cancer undergoing potentially curative intent surgery at Concord Repatriation General Hospital, a tertiary teaching hospital in Sydney, Australia. The study will be evaluated using the RE-AIM Evaluation framework [22,23] (Table 1). Exploratory comparisons of some secondary end points will be made with historical colorectal cancer and upper gastrointestinal patient data obtained from the hospital’s surgical database. The minimum recruitment period will be 12 months. Recruitment commenced in January 2020.

Table 1. Reach, Effectiveness, Adoption, Implementation, and Maintenance evaluation framework adapted to prehabilitation before gastrointestinal cancer surgery study.

Domain	Description	Data collection instrument
Reach	• The number (and proportion) of eligible patients having gastrointestinal cancer surgery who participated (numerator) and how representative they are of the target population (denominator) of participants and eligible patients who did not consent • Participant characteristics and comparison to nonparticipants	• Patient screening logs • Prehabilitation before gastrointestinal cancer surgery study Research Electronic Data Capture (Vanderbilt University) database including demographics
Effectiveness	• Changes in functionality, nutrition, and well-being from pre- to post intervention	• Participant-reported outcomes (psychological status, and quality of life) and functional assessments (6-minute walk test and 2-minute step test), nutritional status, and body composition, at baseline, before surgery, and 30 days after surgery assessments
Adoption	• For the single site, the number of surgeons who participated versus invited surgeons, characteristics of participating surgeons versus non-participating surgeons, the number of referrals received, referral sources, and barriers to referrals • Clinician and surgeon perceptions	• Number of referring surgeons (numerator) versus total number of surgeons at the site treating colorectal cancer or upper gastrointestinal cancer patients (denominator) • In-house clinician satisfaction surveys
Implementation	• Fidelity of intervention in the real world: consistency of the intervention delivery described in the protocol and adaptations made • Intervention completion rates, defined as the proportion of participants that completed the intervention with reasons for withdrawal described • Participant adherence to the intervention and completion of program evaluation	• Intervention session notes compared with the protocol • Prehabilitation before gastrointestinal cancer surgery study database regarding adherence, completion, and withdrawals • Exercise attendance and support phone call logs • Self-reported exercise and protein diary • Satisfaction surveys and exit interviews
Maintenance	• Setting level: extent of program delivery as part of standard care 12 months after study completion • Standard care program adaptations	• Participant enrolment in the standard care prehabilitation program and delivery as recorded in the medical notes • Multimodal program intervention

Ethics Approval

Ethics approval was granted by Concord Repatriation General Hospital Human Research Ethics Committee under reference number 2019/PID13679, and the study was registered on the Australian and New Zealand Clinical Trials Registry (ACTR 12620000409976). The study will be performed in accordance with the National Health and Medical Research Council National Statement on Ethical Conduct in Human Research (Commonwealth of Australia, 2007 and updates) and the World Medical Assembly (Helsinki 2017 and updates).

Study Population

Patients will be considered eligible if they are 18 years or older, undergoing elective colorectal cancer or upper gastrointestinal cancer resection with curative intent at the Concord Repatriation General Hospital with a minimum of 14 days prior to surgery for the intervention. All participants must be medically fit to exercise as determined by their treating physician, willing to attend supervised exercise sessions at the Sydney Cancer Survivorship Gym Concord Repatriation General Hospital 1-2 times per week, take prescribed high protein oral nutritional supplements, and have Eastern Co-operative Oncology Group performance status of 0-2 [24]. Patients treated with neoadjuvant chemotherapy or radiotherapy are eligible to participate after completion of neoadjuvant chemotherapy or radiotherapy provided there is a 14-day intervention time available before surgery. Patients who do not speak English are eligible and will be provided with a professional health interpreter. Inclusion and exclusion criteria are further outlined in Textbox 1.

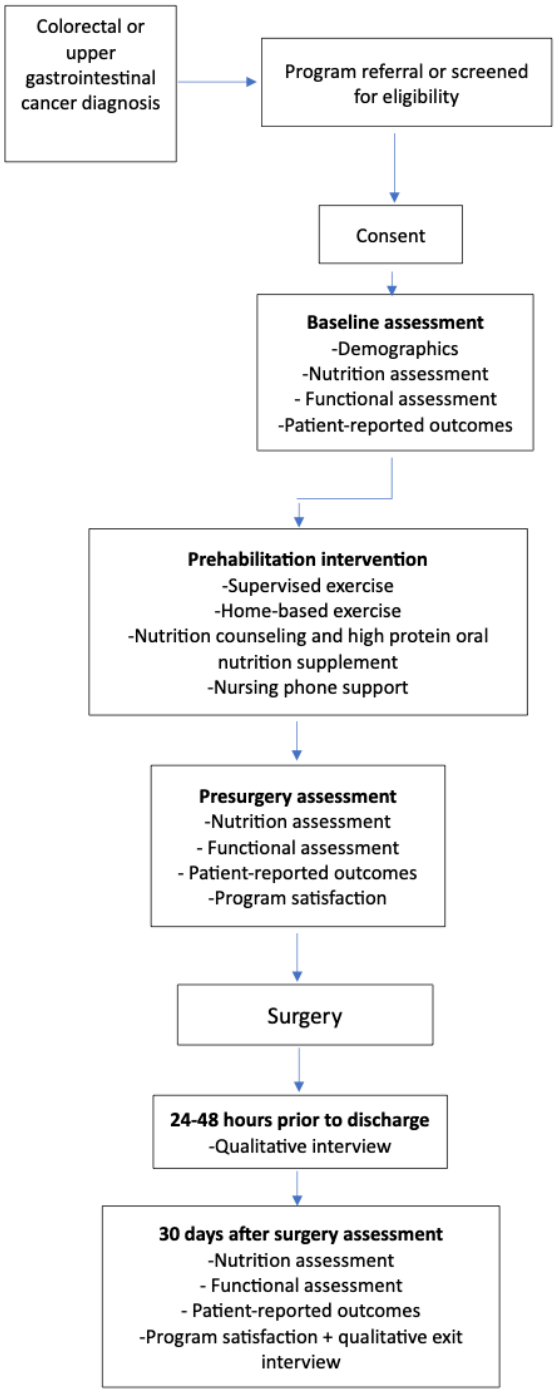
XSL•FO
RenderX

Textbox 1. Study inclusion and exclusion criteria.

Inclusion criteria

- Aged at least 18 years
- Give written informed consent
- Confirmed stage I-III colorectal or upper gastrointestinal cancer or limited stage IV (eg, limited liver metastases planned for curative resection) cancer that is potentially curable with surgery
- Elective surgery scheduled ≥14 days after the time of referral
- Medically cleared to exercise, as determined by the treating physician or Adult Pre-exercise Screening System page 1 V2 (2019) [25]
- Willing to attend supervised exercise sessions at the Concord Repatriation General Hospital Sydney Cancer Survivorship Gym 1-2 times per week until surgery
- Willing to take daily high protein study oral nutritional supplement until surgery
- Eastern Co-operative Oncology Group [24] performance status of 0-2
- Willing to complete patient-reported outcome questionnaires and exercise or dietary logs
- Agreeable to follow-up for 30 days after surgery

Exclusion criteria



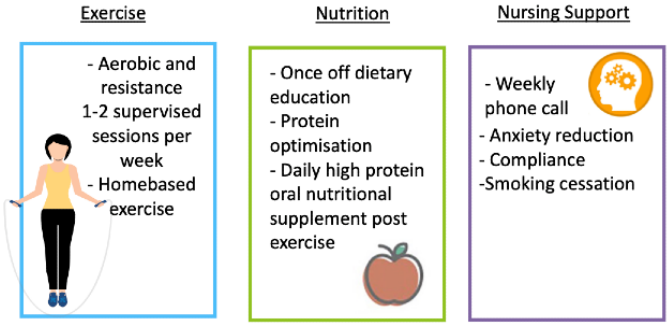
- Unable to exercise or take high protein oral nutritional supplements for physical or medical reasons
- Taking immunonutrition supplements (eg, oral nutritional supplements with immunomodulating ingredients) during the intervention
- Unable to give informed consent or follow instructions due to cognitive difficulties
- Currently receiving chemotherapy or radiotherapy (patients will be eligible providing ≥14 days is still available after completion of neoadjuvant chemotherapy and radiotherapy and before surgery)

Study Procedure

Patients will be referred directly by their surgeon or oncologist or screened in a preadmission clinic for eligibility. Patient flow throughout the study is presented in Figure 1. The study coordinator or cancer nurse specialist will screen and contact eligible patients to explain the study. After consent, a baseline assessment will be conducted in eligible participants within 1-2 days of referral from the surgeon or preadmission clinic visit. Day 1 of the intervention period will be the day of the baseline assessment.

XSL•FO
RenderX

Figure 1. Study flowchart.



Intervention

The duration of the intervention will vary depending on the scheduled surgery date but will run over 2-4 weeks (minimum of 14 days). The intervention is outlined in Figure 2.

XSL•FO
RenderX

Figure 2. Multimodal prehabilitation intervention.

Exercise

An accredited exercise physiologist will assess the participant's mobility and exercise capacity during the baseline assessment. Participants must commit to a minimum of one 60-minute weekly supervised session but will be encouraged to attend two 60-minute supervised exercise sessions per week.

Exercise sessions will include both aerobic and resistance exercise training. These sessions will be individually prescribed, facilitated, and monitored by an accredited exercise physiologist at the Sydney Cancer Survivorship Gym, Concord Cancer Centre. Exercise sessions will be delivered either individually or in a small group-based format with other cancer survivors. All participants will complete a warm-up routine consisting of dynamic stretching and a range of motion exercises. Participants will complete 20 minutes of aerobic exercise per 60-minute session with a target intensity of 60%-75% of heart rate reserve. Aerobic exercise may include the use of a cycle ergometer, treadmill, rowing ergometer, elliptical trainer, boxing due to equipment availability, and will be selected depending on participants' preference and capability. The remainder of each session will focus on resistance exercises targeting large muscle groups through multijoint movements and use body weight, hand weights, resistance bands, or cable machine exercises. Participants are assisted in completing 2 sets of 8-12 repetitions for each movement with a target rating of perceived exertion of 13-15, measured using Borg's Rating of Perceived Exertion 6-20 scale [26]. Heart rate and rating of perceived exertion will be recorded throughout each session for safety monitoring and exercise prescription purposes. The exercise volume and intensity will be adjusted by the exercise physiologist in a stepwise fashion.

Participants will be advised to participate in a nonhospital–based aerobic exercise (eg, walk, jog, cycle, swim, and step) program tailored to their baseline ability on at least 5 days per 7-day period. The target duration is a minimum of 30 minutes (continuous or broken into shorter bouts) per day at a self-rated perceived exertion of moderate intensity (13-15). An exercise diary and instructions will be provided to capture the frequency, intensity, time, and type of exercise. During the supervised exercise sessions, the exercise physiologist will provide support to promote program compliance, progression, and adherence.

Nutrition

Nutritional assessments will be completed by an Accredited Dietitian at baseline, before surgery, and 30 days after surgery, using The Patient-Generated Subjective Global Assessment [27]. Other assessments include body composition measured using bioelectrical impedance analysis (The Seca mBCA 515 Analyser) and a diet assessment (calories and protein) using a 24-hour diet recall.

Participants will receive a 200 mL bottle high protein oral nutritional supplement (Fresubin Protein Energy Drink, Fresenius Kabi) containing 20 g protein and 300 kcal per 200-mL bottle to be consumed daily within 60 minutes after exercise to support muscle synthesis [28-30]. Fresubin Protein Energy Drink is taken in addition to normal food and protein intake. Oral nutritional supplement tolerance will be assessed and recorded by the study dietitian. Dietary advice and written material will be provided with the aim of assisting the participant to achieve a protein intake (spread across meals) of 1.2-1.5 g per kg per body weight (or adjusted body weight in participants with obesity) as per the European Society for Clinical Nutrition and Metabolism guidelines [28]. Participants who have additional nutritional support needs (ie, malnutrition or nutrition-impact symptoms: early satiety, altered bowels, nausea, and loss of appetite), will have further individualized nutrition support and have education as a standard of care as determined by the dietitian and their clinical team. Nutrition support after surgery will be determined by the clinical team as per standard practice.

Nursing Support

Participants will be contacted weekly by phone or in person, associated with gym visits, by a cancer nurse specialist to provide support promoting adherence to the exercise and nutritional interventions, reassurance, and to enable participants to discuss any concerns about their upcoming surgery. Participants who are smokers will be strongly encouraged to stop smoking. Sessions are based on semistructured questions developed in association with an experienced oncology clinical psychologist. See Multimedia Appendix 1 for further details. Participants could be referred to a clinical psychologist according to the standard of care if the cancer nurse specialist believed it was required.

Program Satisfaction

Participants will complete an investigator-developed satisfaction survey at completion of the intervention prior to surgery (1-4 days before hospital admission or surgery) and 30 days after surgery (±7 days). A qualitative semistructured exit interview will be conducted 24-48 hours prior to hospital discharge and

XSL•FO
RenderX

at 30 days after surgery, by an independent researcher face-to-face or over the phone in a subset of participants.

Surgical ward nurses will be requested to complete a survey before the prehabilitation intervention begins and after the completion of the study. Clinical specialists (surgeons and anesthetists) will be requested to complete a web-based evaluation survey after completion of the study.

Study Outcomes

Data will be collected at 3 assessment times: baseline, before surgery (1-4 days before hospital admission or surgery), and 30 days (±7 days) after surgery assessment. Additional data will be collected during the participant's hospital stay. Table 2 gives an overview of all assessments and measurements. The primary end point is related to implementation based on the RE-AIM evaluation framework (Table 1) and will be reported using the following dimensions:

- Reach: number (and proportion) of eligible patients having gastrointestinal cancer surgery who participated among eligible participants and patients who did not consent, and participant characteristics.
- Effectiveness: change in participant outcomes (functionality, nutrition, and well-being) before and after the intervention.
- Adoption: number (and proportion) of surgeons who referred and surgeon characteristics. Total number of referrals, referral sources, barriers to referrals, and clinician and surgeon perceptions.
- Implementation: delivery of the intervention as per the protocol and adaptations made. Overall completion rates, withdrawals and reasons, adherence to exercise sessions, nutrition intervention, and nurse support, and completion of program evaluations.
- Maintenance: status of the program 12 months after study completion and adaptions made.

The secondary end points collected are outlined in Table 2.

Other exploratory end points include the following:

- Participant satisfaction/experience: measured using an investigator-developed questionnaire and qualitative exit interviews.
- Compliance/adherence: measured through attendance logs (exercise and nursing support) and a participant self-reported diary (exercise and high protein oral nutritional supplement consumption).

XSL•FO

Table 2. Assessments and outcomes.

Variables	Timeline
Demographics/history	
• Age • Sex • Smoking history • Background, language spoken, with or without an interpreter • Medical history • Concomitant medications • Cancer diagnosis • Comorbidity index [31,32] • Eastern Co-operative Oncology Group performance status [33]	Baseline, before surgery, and 30 days after surgery
Functional assessment	
• Handgrip strength • 30-second chair stand [34] • 2-minute step test [34] • 3-m timed up and go [35] • 6-minute walk test [19,20] • Activities of daily living [36]	Baseline, before surgery, and 30 days after surgery
Anthropometry	
• Height (cm) (baseline only) • Weight (kg) • Body mass index (BMI) (kg/m^2) • Body composition: fat mass, fat-free mass, skeletal muscle mass, and visceral adipose tissue • Waist circumference (cm)	Baseline, before surgery, and 30 days after surgery
Nutritional assessment	
• Nutritional status using PG-SGA[a] [27] • Total protein intake (diet and oral nutritional supplement): 24-hour diet recall • Patient high protein supplement diary (during intervention)	Baseline, before surgery, and 30 days after surgery
Patient-reported outcomes	
• Exercise behavior—modified Godin's Leisure Time Exercise Questionnaire [37] and Exercise Log/Diary • QoL: EORTC QLQ-C30[b] [33] • FACIT-F[c] subscale [38] • Symptoms of anxiety and depression—HADS[d] [39] • Nutrition/Sarcopenia—PG-SGA. Short form [27] and sarcopenia screening using SARC-F[e] [40] • Distress—National Comprehensive Cancer Network Distress Thermometer (single item) [41]	Baseline, before surgery, and 30 days after surgery
Adverse events	
• Adverse events will be recorded and graded using National Cancer Institute Common Terminology Criteria for Adverse Events Version 5.0 (NCI CTCAE v5.0) [42]	Baseline and before surgery
Hospital stay information	
• Surgical complications: intra- and postoperative including Clavien Dindo Grading (I-V) [43] • Length of hospital stay (days) • Discharge information including medically cleared for discharge date, social services required on discharge, discharge destination, and so forth • Length of physiotherapy intervention (days) • Readmission within 30 days of surgery	30 days after surgery
Compliance/adherence	
• Attendance at exercise sessions • Home-based exercise/protein diary (self-reported) • Adherence to nurse calls • Adherence to protein supplement drinks (self-reported)	Before surgery

XSL•FO
RenderX

Variables	Timeline
Program evaluation	
• Investigator-developed program satisfaction survey • Exit interview	Baseline and before surgery

[a]PG-SGA: Patient-Generated Subjective Global Assessment.

[b]EORTC QLQ-C30: European Organization for the Research and Treatment of Cancer Quality of Life Questionnaire.

[c]FACIT-F: Functional Assessment of Chronic Illness Therapy—Fatigue.

[d]HADS: Hospital Anxiety and Depression Scale.

[e]SARC-F: Strength, assistance with walking, rising from a chair, climbing stairs, and falls.

COVID-19 Adaptations

Assessments and interventions were initially designed to be conducted face-to-face. In response to the COVID-19 pandemic, local lockdowns, reduction in nonurgent face-to-face health care, and cancellation of nonurgent elective surgery with decreased surgery activity, face-to-face recruitment, and intervention delivery were paused in March 2020. The study protocol was adapted to use digital technologies and telehealth methods, and recruitment was recommenced in August 2020. Textbox 2 highlights the key changes.

Textbox 2. Protocol telehealth adaptations to accommodate the COVID-19 pandemic.

- Inclusion criteria
  - Access to internet-based videoconferencing platforms including email address and internet (family members to assist if required)
- Consent
  - Electronically completed consent forms
- Baseline, before surgery, and 30 days after surgery assessments
  - Assessments conducted remotely over videoconferencing or zoom appointments with links emailed to participants
- Nutrition assessment
  - Anthropometric variables self-measured: weight, height, and girths (waist, hip, and midarm; standardized tape measure provided)
  - Body composition analysis omitted
- Exercise assessment
  - Remote functional capacity assessment
    - 6-minute walk test and hand grip test omitted
    - Continuation of 30-second chair stand, 2-minute step test, 3-m timed up and go (to measure cardiovascular fitness)
- Supervised exercise intervention
  - Home-based individualized supervised exercise sessions conducted remotely via videoconferencing or zoom
  - Principles of the original protocol were followed in terms of frequency, intensity, time, and types of exercise
- Nutrition intervention
  - Education material and high protein oral nutritional supplements mailed to participants
- Patient-reported outcome questionnaires
  - Completed by hard copy (mailed out) or web-based or electronically using Research Electronic Data Capture

Statistical Analysis

Sample Size

The sample size is pragmatic, which is based on 2018/2019 surgical and oncology site numbers. We estimate that 50% (n=85) of eligible participants will agree to participate in the prehabilitation program. The study anticipates recruiting 100 participants over a 12-month period. Based on our pilot study adherence and the short-term nature of the intervention, we anticipate attrition will be less than 20% (n=20) of those who complete the baseline assessment, but higher in those who have already undergone neoadjuvant chemotherapy. This gives us sufficient statistical power at the 5% significance level to detect

XSL•FO
RenderX

an increase of 20 m in the distance walked in the 6MWT from baseline to postintervention based on our pilot study.

Statistical Analyses

The primary outcome based on the RE-AIM evaluation framework will be reported descriptively, with a focus on referral, recruitment, and retention targets.

Secondary end points including baseline characteristics, functional, and nutritional status, will be reported using descriptive statistics, mean (SD) for normally distributed data, or median and IQR for nonnormally distributed data. Counts and percentages will also be used as appropriate. Reported changes in outcome variables from baseline to postintervention (presurgery) and 30 days after surgery will be measured using mixed models and will include all participants with baseline data including those with missing data at follow-up, with adjustment for predictors of dropouts to minimize selection bias. Postsurgery outcome variables will be evaluated using mixed models. Outcomes for UGI cancer and CRC participants will be evaluated separately and combined. Length of hospital stay and postsurgical complications will be compared to historical data from the hospital's surgical 2019 database.

Responses to the investigator-developed questionnaire (participants and clinician) will be presented descriptively using means (SDs) or medians (IQR) and counts and percentages as appropriate. Free text responses will be summarized. The statistical package SPSS (version 24 or the newest release) will be used for quantitative data analysis.

Semistructured interviews regarding participant satisfaction will be transcribed verbatim and undergo qualitative content analysis. Initial transcript sample readings will be carried out. Themes and content will be analyzed descriptively. Coding, linking, and retrieving the qualitative data will be conducted using NVivo software (QSR International).

Data Collection and Management

Participants will be given a unique study number. Deidentified information will be entered into a password-protected project specific Research Electronic Data Capture Database (Vanderbilt University) at Concord Cancer Centre, Concord Repatriation General Hospital. Identifiable information will be stored in a standalone instrument within the Research Electronic Data Capture database and access restricted to a limited number of the research team. In addition, deidentified raw body composition data will be stored on a copy of the manufacturer's secure password-protected computer software (Seca) at the Concord Cancer Centre, Concord Repatriation General Hospital.

Results

The study recruitment commenced in January 2020. Recruitment was paused in March 2020, due to the COVID-19 pandemic, and the protocol was adapted to include a remote or telehealth intervention. Recruitment restarted with the telehealth adaptations in August 2020. Due to ongoing COVID-19 disruptions (restrictions and cancellation of elective surgeries at the hospital), recruitment was extended until December 31, 2021. During the 16-month active recruitment period, a total of 198 (133 CRC and 65 UGI) patients were screened, of which 102 were ineligible. The most common reasons for ineligibility were less than a 14-day intervention time period between screening or referral and scheduled surgery date (n=64), not for surgical intervention (n=12), and not medically cleared to exercise (n=6). In total, 96 patients met the eligibility criteria, and 77 were recruited (64 patients with colorectal cancer and 13 patients with upper gastrointestinal cancer). The results from the study will be analyzed and published in a peer-reviewed journal.

Discussion

Principal Findings

Surgery remains the standard curative treatment for early-stage CRC and UGI cancers. Despite advancements in surgical practices and postoperative care pathways, morbidity and mortality rates remain high [6,7,10]. A reduction in postoperative complications is important. It is well established that the number and severity of postoperative complications are associated with preoperative health status, functional capacity, nutritional status, and muscle strength [44]. While traditional approaches have focused on lifestyle modifications in the postoperative period, recent evidence shows that the preoperative period may be the more appropriate time to intervene [45].

Positive lifestyle practices, including exercise and nutrition, are associated with many health benefits and have been shown to decrease the risk of several common cancers, including CRC and some UGI cancers, and possibly to decrease the risk of cancer recurrence [46,47]. However, only approximately 20% of people diagnosed with cancer are meeting the current exercise guidelines [48-50], and only 37% of patients with gastrointestinal cancer undergo nutrition screening and are offered preoperative nutrition support [51,52]. Recent reviews indicate that optimizing functional capacity with exercise, nutrition interventions, and psychological support strategies in a gastrointestinal surgical population resulted in reduced complications, length of hospital stay, and improved QOL [13-17]. However, few studies have evaluated the integration of prehabilitation practices into standard of care.

This pragmatic prehabilitation program will deliver integrated care, increasing patients' self-management skills to support healthy living during and after a cancer diagnosis. It has the potential to change standard care with a simple, safe, relatively inexpensive coordinated intervention that confers multiple physical and psychological health benefits. This study will determine whether a multimodal (exercise, nutrition intervention, and nursing support) prehabilitation program can be integrated into routine standard care and whether it improves outcomes by reducing postoperative complication rates and length of stay at the hospital. Unique data will be collected on physical activity, nutritional status, dietary intake, and psychological well-being and their influence on surgical outcomes to inform the current evidence base in gastrointestinal surgical oncology preoperative care.

XSL•FO
RenderX

Prehabilitation adapted to include a telehealth model of care represents a strategy to combat pandemic-related patient and health system challenges. Telehealth initiatives provide an opportunity to minimize health inequalities [53] and improve patient outcomes and access to health care services [54] by offering an alternative delivery method that is not bound by location, especially for those living remotely, or those who have travel difficulties, caregiver or work commitments, or conflicting medical appointments. While telehealth interventions can vary from live consults, electronic monitoring, questionnaires, and support using multimedia platforms, the benefits of education sessions conducted by telehealth have shown to improve the patient's knowledge and satisfaction during cancer treatment [55]. While the evidence in the preoperative setting is limited [56,57], preliminary findings indicate that home-based prehabilitation programs delivered by telehealth are positively received by patients and clinicians.

The hospital system is complex. Engagement from clinicians, administrative personnel, and participants is crucial to the successful implementation of a multimodal intervention. Importantly, the results of this study will identify priority areas regarding the value and feasibility of integrating prehabilitation into routine quality cancer care for patients undergoing major cancer surgery. It has the potential to improve the outcomes of patients undergoing resection for CRC and UGI cancer and deliver better health at a low cost to the Australian and wider communities.

Conclusions

Prehabilitation represents an opportunity to intervene, treat, and prevent physiological and nutritional decline before major gastrointestinal cancer surgery by combining physical, nutritional, and psychological interventions in a multimodal approach. The study will provide new evidence on the integration of prehabilitation into standard care using adaptive models of health care delivery including telehealth, with the secondary aim of improving postoperative outcomes. The intervention could be generalizable to other types of cancer, emphasizing the importance of preoperative optimization to mitigate the surgical stress response and improve patient outcomes. The study outcomes have the potential to change standard care, with a relatively inexpensive intervention delivered either face-to-face or by telehealth especially for those living remotely or with travel or social difficulties, which can improve health-related quality of life and reduce health care costs.

Acknowledgments

Fresenius Kabi supplied the high protein oral nutritional supplements and provided 1-year part-time funding for the study dietitian position. Additional funding was provided by Concord Cancer Centre through a seed research grant to support the part-time exercise physiologist position. Fresenius Kabi and Concord Cancer Centre did not contribute to the study design, data collection, and will not be involved in results analysis, interpretation, or dissemination.

Data Availability

Data will be available from the corresponding author upon reasonable request.

Authors' Contributions

JV is the coordinating investigator and devised the study concept and design. All authors contributed to the study protocol with KLR and JV as the first author and principal investigator, respectively. KLR, SYT, SE, and JV wrote the initial manuscript. All authors read and approved the final manuscript. SE provided statistical analysis support.

Conflicts of Interest

The Concord Repatriation General Hospital Dietetics department and KLR discloses that funding was received for a part-time wage for 1 year from Fresenius Kabi to support the study.

Protocol

An Interactive Communication Model for Self-Care—Regardless of Health Literacy: Protocol for a Quasi-Experimental Study

Abstract

Background: Clear dialogue-based (interactive) communication that ensures comprehension and recall becomes more important in patient-provider interactions, especially in relation to patients with chronic diseases, where self-management education and counseling are cornerstones in managing these diseases. If patients with chronic disease experience challenges in obtaining, understanding, and applying health-related information (necessary to make informed health decisions and sufficiently manage their health), clear communication and ensuring comprehension become even more critical in the patient-provider interactions. Furthermore, patient-provider communication has been proposed as a potential pathway through which health literacy might influence health outcomes, especially in individuals with chronic diseases. Hence, adjusting communication to the individual level of health literacy might have a positive influence on health outcomes. On this basis, the authors have developed a web-based interactive communication model that both seeks to accommodate health literacy by allowing tailored communication and ensure comprehension and recall between nurses and patients.

Objective: This study seeks to examine the use of an IT solution that comprises an interactive communication model that seeks to accommodate health literacy in communication and ensure comprehension and recall between nurses and patients.

Methods: A quasi-experimental control group study including full economic evaluation with 6-month follow-up. Based on power calculation, a total of 82 participants will be included. Participants are assigned either the interactive communication model (intervention) or usual nursing care. It will be assessed if the model influences the level of health literacy and participants experience a higher health-related quality of life. Further, cost-effectiveness will be evaluated. Overall, the statistical methods will follow an intention-to-treat principle. Results will be presented in accordance with the Transparent Reporting of Evaluations with Non-randomized Designs guidelines for nonrandomized designs as well as the Consolidated Health Economic Evaluation Reporting Standards.

Results: This paper describes a protocol for a clustered quasi-experimental control study that seeks to evaluate the effectiveness of the interactive communicative model. Most studies in the field of health literacy are epidemiological studies that seek to address the effects of poor health literacy in populations and its potential impact on health inequity. A total of 82 participants, who receive community nursing will be included. The final trial day is May 1, 2022, with the first report of results in the final quarter of 2022.

Conclusions: The results of the trial can create the base for conducting a large-scale study and inspire the conduction of more studies that seeks to create and evaluate interventions aimed at enhancing the level of health literacy and reducing the usage of health resources.

Introduction

Background

The demographic profile is changing all over the world with a longer life expectancy that yields an increase in the number of people living with chronic diseases [1]. The challenge of meeting the needs of this growing number of people will fall upon already overwhelmed health care services that are struggling to cope with the current demands of changing health care systems [2]. As a result, the role of modern patients is changing from paternalistic models of health care that placed the patient as a passive recipient to more active involvement of patients in their own care [3]. This change in the role of modern patients, however, sets some requirements to their level of patient empowerment and self-management; two concepts wherein health literacy (HL) plays an important role [4]. HL is a relatively new area of research that focuses on the ability to make sensible health choices that promote and maintain good health, based on the individual ability to access, evaluate, and use health-related information [5]. The World Health Organization has defined HL as "the cognitive and social skills which determine the motivation and ability of individuals to gain access to, understand and use information in ways which promote and maintain good health" [6].

The concept of HL includes multiple levels with different requirements to personal skills in relation to health care, making it a very broad and complex concept. In a widely used approach, Nutbeam [7] frames the different levels of HL as follows:

- *A functional level of HL* comprises the basic skills of numeracy, reading and writing that allow an individual to function effectively in a health care setting (eg, by being able to navigate the health care system, take the right dose of medication, and provide an accurate presentation of symptoms).
- *An interactive level of HL* refers to a more advanced level of literacy, that is, social and cognitive skills that allow an individual the capability to understand and retrieve health information. At this level, individuals are also able to engage actively in a dialog about their disease and course of treatment with health care professionals.
- *The critical level of HL* comprises an advanced set of skills that allow the capability to critically analyze health-related information retrieved from the health care system or independently and the ability to act on this information.

According to a Danish study [8], 10%-20% of the Danish population experience difficulties with the ability to understand health-related information sufficiently to act on it and the ability to interact with health care professionals (2 important dimensions of HL). Hence, they do not have the necessary HL competencies to manage their health sufficiently, which incur a higher risk of adverse health effects, including improper use of health care services and medications, poor self-management, and poor health outcomes [9]. On this basis, clear communication and ensuring comprehension and recall become more important in patient-provider interactions, especially in relation to patients with chronic diseases, where self-management education and counseling are cornerstones in managing these diseases. If patients with chronic disease also experience challenges in obtaining, understanding, and applying health-related information (necessary to make informed health decisions and sufficiently manage their health), clear communication and ensuring comprehension become even more critical in the patient-provider interactions [10]. Furthermore, patient-provider communication has been proposed as a potential pathway through which HL might influence health outcomes, especially in individuals with chronic diseases. Hence, adjusting communication to the individual level of HL might have a positive influence on health outcomes [11,12]. Nurses play an essential role in providing education and counseling for patients with a chronic disease through communication—it is considered a core competency in their nursing practice [13]. However, nurses rarely use communication that focuses on comprehension and recall in their interaction with patients [14]. On this basis, this study examines the use of an interactive communication model (ICM) that seeks to accommodate HL in communication and ensure comprehension and recall between nurses and patients.

Objectives

The main objective of this study is to conduct a broad evaluation of a web-based ICM (refers to the interaction between the user [the community nurses in this study] and the recipients [the citizens receiving community nursing in this study]) that both seek to identify knowledge and skills (HL) by enhancing tailored communication and ensure recall and comprehension between patients and nurses. Specific research questions concern whether the ICM improves HL among participants, who receive community nursing care, and whether they experience a higher health-related quality of life. Secondary outcomes include evaluating the cost-effectiveness of the ICM and assessing if it improves the quality of community nursing care, which includes the evaluation of citizens' adherence to care and treatment as well as the community nurses' satisfaction with using the ICM in their care. Finally, how participants, who receive community nursing care from the nurses in the intervention group, experience nursing care prior and after the intervention was assessed.

Methods

Study Design

This trial is conducted as a clustered quasi-experimental control group study with 6-month follow-up. The trial runs from November 2021 to May 2022. This study was originally designed as a 2-armed cluster-randomized controlled trial. However, the randomization protocol was abandoned after several months of unsuccessful recruitment efforts, and the study was redesigned as a quasi-experimental control group

XSL•FO
RenderX

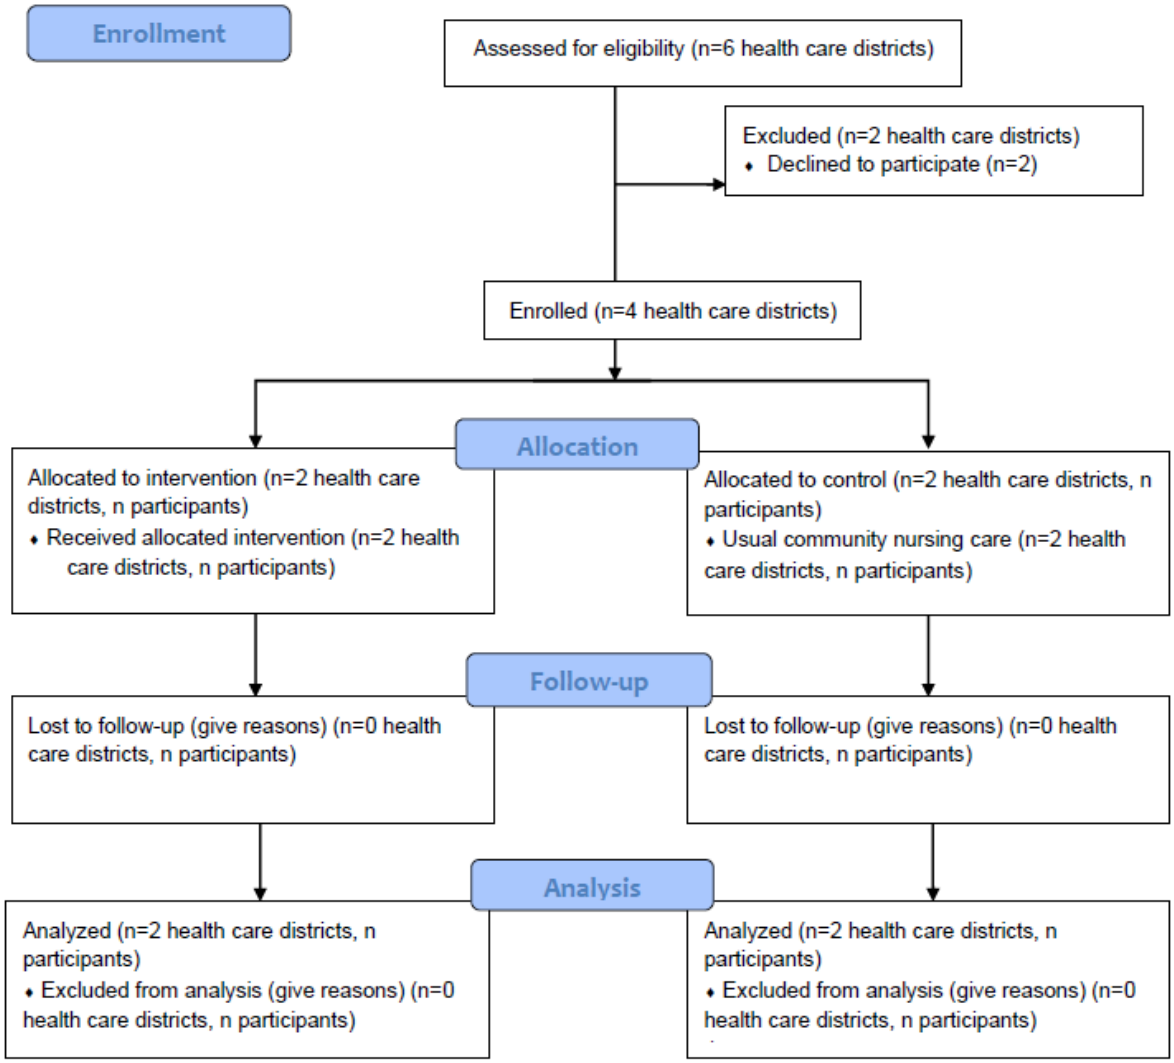
study. The primary reason for abandoning the randomized controlled trial design was challenges related to recruiting all districts making it difficult to conduct a meaningful randomization. The trial is registered at ClinicalTrials.gov (NCT04929314).

Ethical Considerations

The trial has been presented to the Regional Ethical Committee for Medical Research in North Denmark. The committee determined that no ethical approval was necessary (number 2020-000992-45). The trial has been approved by the Danish Data Protection Agency. Data will be anonymized and stored in accordance with the Danish Data Protection Rules [15].

The investigation conforms with the principles outlined in the Declaration of Helsinki. Potential participants were informed of the content and aims of the study and required to give written, informed consent before enrollment. All participants were informed that the data collected can be used for research purposes, and they were asked to sign an informed written consent form if they wished to participate after thoroughly reviewing the material regarding the study. The informed written consent includes consent for publication. All participants were informed that participation is voluntary, and they can withdraw from the study at any time. The participants did not receive any compensation for their participation in the study.

The Target Sample



The trial population consists of citizens in 4 districts in the municipality of Aalborg who receive health care services. Participants are eligible for inclusion if they receive home health care (community nursing at least every 2 weeks) in Aalborg Municipality and are older than 18 years at the point of enrollment. Further, participants must receive community health care services for a period of more than 3 months prior to enrollment and be able to speak, read, and write Danish. The participants must also have a fixed residence in Aalborg Municipality. Participants will be excluded from the study if they do not meet the inclusion criteria and if they are terminal or diagnosed with a psychiatric disease, dementia, or other severe cognitive impairments. Participants are also excluded if they are unable to understand and speak Danish (unable to complete study questionnaires).

Recruitment

Recruitment has been ongoing since April 2021 in 4 out of 6 care districts in Aalborg Municipality. The community nurses identify eligible participants (Figure 1) and create a list of potential participants, who have given permission for the researcher to contact them by telephone. The researcher provides further information about the trial, answers questions, and guides them regarding the questionnaires and the written consent form. Subsequently, written information about the study, questionnaires, and a written consent form are sent to eligible participants after receiving oral consent over the telephone. If the participants still wish to participate after thoroughly reviewing the material received, they will return the written consent form and the questionnaires to the community nurse before the date specified in the material. The researcher's contact information is highlighted in the written information, allowing the participants an opportunity to receive support in filling out the questionnaires. Due to the COVID-19 situation, it is attempted to reduce physical contact between the researcher and the participants, and that is why all communication is preferred over the telephone.

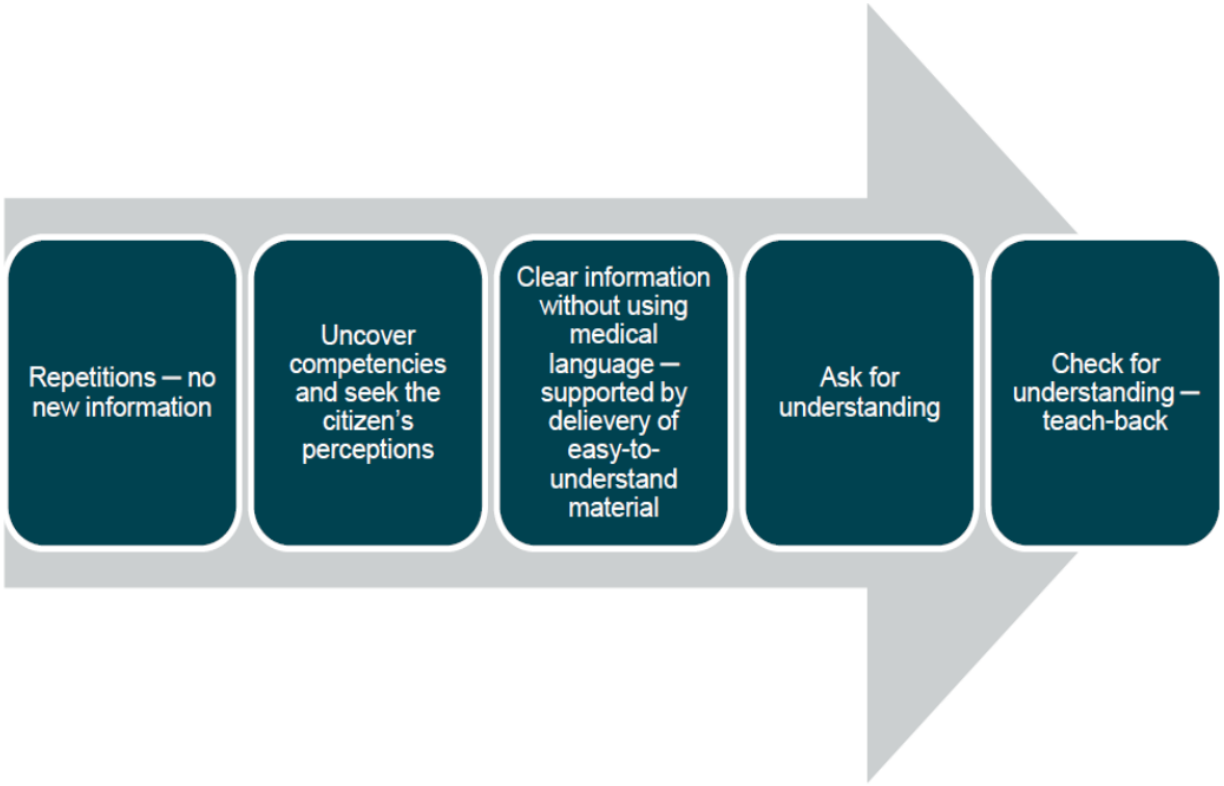
Figure 1. Flowchart diagram representing the design of the study.

The Intervention

Overview



The intervention is based on the research-based knowledge about HL and focuses on interactive communication between community nurses and citizens who receive community nursing care. It seeks to ensure uniform interactive communication from the community nurses to ensure that citizens understand and adapt the information given by nurses, regardless of the level of HL. The intervention is not based on research alone but has been developed in close collaboration with practice (Aalborg Municipality). Almost all community nurses in Aalborg Municipality have participated in a workshop on rehabilitation, self-rehabilitation, and HL. In total, 14 workshops were conducted (a total of 335 community nurses from Aalborg Municipality participated) in the autumn of 2019 as part of a pilot project prior to this research project. A central point of these workshops was to identify challenges related to the more active involvement of citizens (receiving community nursing care) in their own health and disease. Aalborg Municipality puts great emphasis on "self-rehabilitation," where the ambition is to transfer as many health-related tasks (eg, medication administration and dispensing) as possible to the citizens receiving community nursing care and, thus, placing more responsibility on the citizens themselves. The development of the intervention is based on a best-practice approach from the literature combined with solid experience from nursing practice. The involvement of the community nurses in the development of the intervention has also contributed to a sense of ownership among the users (the community nurses in Aalborg Municipality). It should be noted that the community nurses have never seen or used the intervention during the workshops; the workshops contributed to the development of the intervention, as it was identified what community nurses saw as challenges in strengthening self-care among their citizens.

The material from the workshops, in conjunction with relevant research literature, has formed the basis for the development of an intervention containing the following components: (1) a development of competences is related to HL among community nurses in Aalborg Municipality (only those who are responsible for citizens who receive the intervention). The community nurses will receive general education about HL and how to screen for it with the Danish European Health Literacy Survey Questionnaire (HLS-EU-Q-16) [16]. It should be noted that assessing each citizen's level of HL is only being done as part of the study and not as part of standard protocol. (2) The

XSL•FO
RenderX

community nurses will also receive practical training in systematic and integrative communication using the ICM with integrated teach-back, see Figure 2 for detailed description. The systematic and integrative communication is supplemented by the delivery of easy-to-understand material to the citizen. The material has been developed and evaluated in advance. (3) The community nurses will be introduced to a guide that describes how to document the use of the ICM. This guide seeks to ensure consistency and uniformity in the documentation of nursing care.

Figure 2. Illustration of the elements in the interactive communication model (ICM). The model is inspired by Schillinger et al [17].

Repetitions

The model starts with a repetition of key points (very few sentences) from the last visit or learning session. The community nurse simply repeats key points and provides no new information at this stage. By the first visit, the community nurse cannot perform repetitions, but instead, the citizen is presented with the plan to enhance knowledge and self-care.

Uncover Competencies and Seek the Citizen's Perceptions

This allows the community nurse and citizen to reach a common understanding. Moreover, it helps the community nurse assess how to tailor information and instructions for the citizen.

Clear Information Without Using Medical Language

The community nurse provides information and instructions at a very easy-to-understand level without using medical language. The information and instructions are provided based on predefined material made available to the community nurse on a web page accessible from her working tablet. The information and instructions are supplemented by the delivery of easy-to-understand material to the citizen.

Ask for Understanding

The community nurse asks the citizen directly if they have understood the given information and what has been discussed.

Check for Understanding—Teach-Back

The community nurse uses the teach-back technique to ensure that the citizen understands the information or instructions and what has been discussed. The community nurse asks the citizen to retell (in their own words) the information and instructions provided. This stage may also involve the citizen having to demonstrate the performance of a "task," for example, the community nurse asks the citizen, with chronic obstructive pulmonary disease, to demonstrate their inhalation technique.

The ICM must be an easily accessible and efficient tool for community nurses, and it is therefore created as a web-based IT solution. The IT solution is entitled "personalized support for self-care" and can be accessed from the community nurses' working tablet—direct link on the start page.

The content of the IT solution is selected based on the most prominent diseases and reasons for receiving community nursing in Northern Jutland. People receiving community nursing often have multiple health-related challenges and comorbidities and have a high level of vulnerability, which sets high requirements to their level of HL. The concept is that the ICM (made available in the web-based IT solution) can support community nurses in accommodating citizens' broad range of information and communication preferences. The ICM uncovers what people know about their own health and situation instead of a subjective assumption of what they know; thus, it can be considered a

XSL•FO
RenderX

more objective approach to accessing knowledge and skills. The IT solution includes a general description of the ICM and how to conduct each individual communicative step in the model. The general description is supported by a graphical illustration of the different steps in the model. There are thorough instructions on how to incorporate the different communicative steps into practice; a "correct" use can promote more interactive communication.

The IT solution also describes how to use the ICM in relation to the most prominent diseases such as chronic obstructive pulmonary disease, diabetes, and cardiovascular diseases. It is thoroughly described how to carry out each individual step in the ICM related to the disease in question—all the way down to how questions should be formulated and asked to uncover citizens' knowledge and level of skills (step 2—ask for understanding) and how information is provided in a concise easy-to-understand manner without medical language (step 3—clear information without using medical language). The idea is that users of the IT solution, containing the ICM, do not have to decide for themselves what easy-to-understand language is because it is provided by the web-based system. The instructions and information formulated in the IT solution, containing the ICM, have been developed in the following manner: information and content about the specific diseases are inspired by an acknowledged national patient–centered web page (sundhed.dk) and use of pedagogical tools that focus on increasing and ensuring the understanding with the recipient [18,19]. The material in the IT solution, containing the ICM, is kept on a readability of sixth- to seventh-grade level and, thus, users provide information and guidance on this level when using the ICM. The material was read thoroughly by independent reviewers to ensure easy-to-understand and concise language not exceeding sixth- to seventh-grade level. It should be noted that the IT solution also provides different links and video material (easy-to-understand that can be used in *step 3—clear information without medical language*) relevant to the specific diseases.

Even though the instructions and information in the IT solution, containing the ICM, serve as a guide to learn the ICM technique, the goal is that users adapt the communication technique into their everyday practice. The IT solution, containing the ICM, is intended to facilitate the use of a very easy-to-understand language and check the understanding of information by the recipient. The community nurses in this study, who are responsible for citizens who receive the intervention, will be instructed to use the IT solution, containing the ICM, at each visit. The web-based IT solution, containing the ICM, has been tested in a small pilot study [20].

The Control: Usual Community Nursing Care

Danish community nursing care combines nursing practice and primary health care in the Danish community setting. Denmark comprises 98 municipalities, which have a specialized role in community nursing care that requires nursing and practical help in the citizens' own homes. Danish community nursing care varies across the municipalities. Community nurses primarily deliver health services, health education, preventive care, rehabilitation, etc, to Danish citizens. Community care nurses in the control group will not receive the special training described earlier, and the participants in this group will receive their usual care and treatment throughout the study period of 6 months.

Allocation

Aalborg Municipality is comprised of 6 health care districts. However, due to practical reasons, a total of 2 districts declined to participate in this study. The remaining 4 districts are matched 1:1 in terms of geographical area (2 rural districts are matched and so are 2 urban), and each pair is then allocated so that one district is in the intervention and the other is in the control group. Coincidently, each pair also matches with the estimated level of social classes (judged by the municipality). Before allocation, all participants must have signed informed consent and conducted baseline measurements.

Outcome Measurements

Primary and Secondary Outcomes

The primary outcome of this study is the change in the level of HL assessed by the HLS-EU-Q-16 questionnaire [16] from baseline to follow-up at 6 months. The HLS-EU-Q-16 measures self-perceived HL and reflects the conformity between individual competencies needed to navigate the health care system and situational complexities. Hence, the HLS-EU-Q-16 reflects the self-perceived level of HL, and this should be taken into consideration when interpreting the survey results. This study hypothesizes that adding the ICM and continuity in documentation to usual community care will lead to a significantly higher level of self-perceived HL for the included participants.

Two secondary outcomes will be reported: first, the between-group difference in health-related quality of life measured by the EQ-5D-3L questionnaire [21] at follow-up after 6 months, and second, the incremental cost-effectiveness ratio representing the total cost per additional HLS-EU-Q-16 point accrued from baseline to follow-up at 6 months. This trial adopts a health- and social sector perspective with the following cost categories: intervention costs, costs associated with all hospital contacts, primary sector costs (ie, general practitioners and other primary care visits), costs associated with home nurse visits, and home care costs due to individual care and practical help as well as individual or group rehabilitation costs. Service cost components will be based on register data, that is, from the Danish National Patient Register (all hospital contacts) [22], the National Health Insurance Service Register (all primary care contacts) [23], and the electronic care register in Aalborg Municipality. All data can be unambiguously linked with the help of a 10-digit social security number that all Danish citizens have.

Additional Outcomes

The quality of nursing care is assessed using a self-constructed questionnaire, which has been used in a previous pilot study by our research group. The quality of nursing care will be evaluated by the community nurses in Aalborg Municipality.

Another additional outcome is to assess how the citizens, who receive community nursing care from the nurses in the

XSL•FO
RenderX

intervention group, experience nursing care prior to the intervention and after the intervention. Hence, the citizens will be interviewed twice during the study: prior to the intervention and after the intervention. As per the study by Kvale and Brinkmann [24], semistructured qualitative individual face-to-face interviews will be conducted with the citizens in the intervention group in the comfort of the own homes. The interviews will be conducted before the community nurses in the intervention group receive any special training and start using the intervention (prior) and again at follow-up (after). The interviews will be recorded and transcribed by researchers.

It is hypothesized that the ICM will be associated with a larger gain in HL in the intervention group, as the model is expected to increase citizens' control of their own lives as it establishes a more solid knowledge and empowerment of their disease and health [25-27].

Sample Size and Power Calculation

Sample size calculation for the primary outcome was performed in Stata (version 16; StataCorp). The intention is to detect a standardized mean difference in favor of the intervention based on Cohen d>0.8 [28]. Requiring a power of 80% and a significance level (1-sided) of 0.05, with 4 clusters given (2 in each alternative) and assuming a coefficient of variation in cluster size of 0.25 and intracluster correlation equal to 0.05, the required sample size is 37 participants in each arm (or an average of 18.5 participants in each cluster). With an expected loss-to-follow-up of 10%, the total required sample size is 41 in each arm (or an average of 20.5 in each cluster).

Analyses

Overall, the statistical methods will follow an intention-to-treat principle [29]. Results from the trial will be presented in accordance with the Transparent Reporting of Evaluations with Non-randomized Designs guidelines for nonrandomized designs [30] as well as the Consolidated Health Economic Evaluation Reporting Standards [31]. Missing data will be subject to multiple imputations [32]. Data will be analyzed with Stata 16 software.

Between-group differences for both the primary and secondary outcomes of health-related quality of life and cost-effectiveness will be calculated by applying multilevel generalized linear models, and both an unadjusted and adjusted estimate controlling for meaningful baseline differences will be reported. To allow for evaluation of the impact of variability and parameter uncertainty, the economic evaluation will also report the results of one-way and probabilistic sensitivity analysis [33]. The probabilistic sensitivity analysis will be carried out using Excel (Microsoft Inc).

All data from the interviews will be analyzed using NVivo R1 (version 13.0; Lumivero). Inspired by Kvale and Brinkmann [24], the analysis will be conducted according to the following steps: (1) identification of key themes and definitions from theoretical framework, inspired by Braun and Clarke [34]. (2) Review of all data from the interviews to obtain an overall impression of the themes on how the citizens experience their level of HL and self-management, both prior to the intervention and after the intervention. (3) Design of code tree based on key definitions and concepts derived from the theoretical framework and interviews. (4) The researchers will discuss and revise the code tree to ensure intersubjectivity. (5) The first step of the coding process will be centered on gaining an overall understanding of the citizens' perception of their level of HL and self-management, both prior to the intervention and after the intervention. (6) The next step will focus on widening the understanding beyond the citizens' perception. What presents a challenge to their level of HL and self-management and what strengthens it? (7) The final step will be an analysis centered on the citizens' perception of their level of HL and self-management and if this is altered when community nurses use the intervention in their nursing care. (8) Data will be condensed and presented as key themes and findings.

Results

A total of 82 participants, who receive community nursing will be included. The final trial day is May 1, 2022, with the first report of results in the final quarter of 2022.

Discussion

This paper describes a protocol for a clustered quasi-experimental control study that seeks to evaluate the effectiveness of an IT solution that comprises the ICM seeking to enhance more dialogue-based and tailored communication. Most studies in the field of HL are epidemiological studies that seek to address the effects of poor HL in populations and its potential impact on health inequity [35]. There is, however, a call for studies centered on developing interventions aimed at strengthening HL; strengthening HL in populations and making health services more accessible to people with a low level of HL may be a practical strategy to reduce disparities and promote greater equity in health [9,36]. To our knowledge, this is one of the first studies to assess the effectiveness of an intervention that seeks to enhance the level of HL. The strength of this study is that it attempts to illuminate the effects of an intervention centered on interactive communication using a control group design. Another strength is that the study has characteristics like an effectiveness trial, as it evaluates the effects of enhancing knowledge of HL among community care nurses and integrating the use of the ICM in their nursing care.

A limitation of this study is the design as a quasi-experimental and abandoning the original randomization protocol. This means that this study may be subjected to selection bias, as between-group baseline characteristics may differentiate. Another limitation is the relatively short follow-up time, as between-group comparisons can only be made at the 6-month follow-up. This might be problematic since changes in particularly costs and health-related quality of life require behavior change that might take time to occur. However, recent guidance for developing and evaluating complex interventions recommends that broad-ranging evaluations are conducted in the early phases and that they also include economic evaluation. The aim is to identify the scope of cost and different effects that can help decision makers understand the potential of the intervention and decide whether proceeding to a large-scale evaluation is worthwhile [37]. In making this judgment, it is a

XSL•FO
RenderX

standard health economic practice also to model the joint decision uncertainty surrounding particularly health-related quality of life outcomes and costs [38,39]. Reporting cost-effectiveness (including health-related quality of life, costs, or quality-adjusted life years) with 6-month follow-up specific to the domain of HL has also previously been reported [40,41] and to other interventions aimed at changing behavior [42,43]. The expectation is that the results of the trial therefore can create the base for deciding to conduct a large-scale study and inspire the conduction of more studies that seeks to create and evaluate interventions aimed at enhancing the level of HL and reducing the usage of health resources.

Acknowledgments

This research did not receive any specific grants or funding. Aalborg Municipality (responsible for community care nursing) has contributed significantly to the project in terms of hosting the workshops that has created the basis for the development of the intervention. Aalborg Municipality has further contributed with extensive community nursing hours; the community nurses have helped in the recruitment of citizens and handling clinical practical challenges.

Data Availability

All data will be stored in a secure drive (UCNemDok). Only researchers from the University College of Northern Denmark and Aalborg University will have access to the trial data set.

Authors' Contributions

LKEH conceived, designed, and coordinated the study and drafted the manuscript. OKH contributed to the design of the study and methodological considerations. FWU contributed to the statistical analysis and methodological considerations of the study. All authors read, critically revised, and approved the final manuscript.

Conflicts of Interest

None declared.

Protocol

Behind the Scenes of a Technologically Enhanced Intervention for Caregivers of People With Dementia: Protocol for a Feasibility and Acceptability Study

Abstract

Background: Alzheimer's disease affects 55 million people worldwide. As the disease progresses, these individuals require a devoted caregiver, often a family member, who provides evolving complex care. Caregivers can experience a variety of ongoing stressors, resulting in reductions in caregiver emotional well-being (and other quality-of-life indicators). Information and communication technologies provide an excellent opportunity to train caregivers remotely and help them to manage these stressors and related distress.

Objective: This protocol describes the theoretical rationale, study design, and methods of a new, technologically enhanced psychoeducational skill-building intervention for caregivers of people with dementia that includes a virtual reality component.

Methods: *Through Alzheimer's Eyes* is a 4-week, single-arm, pre-post test pilot study consisting of 4 sessions of 90 minutes each that are delivered by videoconferencing. These sessions include a weekly virtual reality experience characterizing the journey of an older Latina with Alzheimer's disease from her perspective to help caregivers see through the eyes of a person with dementia. The 4 sessions cover the skill-training topics of communication, managing challenging behaviors and unhelpful thoughts, the importance of self-care, and mindfulness—all of which are key components designed to reduce stress and distress in family caregivers. Individual interviews conducted before and after the intervention gather participant insights into the intervention, evaluate its feasibility and acceptability, and assess its impact on key outcomes.

Results: Data collection for the study started in January 2022, and the results are expected to be submitted for publication in the second half of 2023. Twenty caregivers from the United States have completed the workshop to date. Preliminary data gathered from these participants support the intervention's feasibility and acceptability.

Conclusions: *Through Alzheimer's Eyes* leverages existing technology combined with psychoeducational skill building to help caregivers manage their stress, regardless of their location.

Introduction

Background

Alzheimer's disease and related dementias (ADRD) are progressive diseases that primarily affect individuals aged ≥65 years. Worldwide, these diseases affect approximately 55 million people [1]; in the United States, 6.5 million people currently live with ADRD. Given the nature of ADRD, devoted family caregivers provide evolving complex care during the disease trajectory, which can amount to as much as 80% to 100% of the care [2]. This constant care translates into ongoing stressors

XSL•FO
RenderX

for caregivers because they must ensure their loved one's well-being and quality of life. Caregiver tasks include, but are not limited to, aiding the loved one in activities of daily living and instrumental activities of daily living such as bathing, dressing, eating, managing medications, managing problematic behaviors, handling finances, attending physician appointments, and shopping [3]. Caring for people with ADRD can be further complicated by the caregiver's own physical health limitations, mental health concerns, and other stressors (eg, from being housebound to functional impairments, history of depression or anxiety, financial concerns, and employment-related challenges) [3,4]. In addition, the stress associated with family caregiving for loved ones with dementia often translates into deterioration of caregivers' physical and mental health [3,5-8], whether or not caregivers face substantive vulnerabilities or life challenges beyond their caregiver role.

Numerous in-person interventions for caregivers of people with ADRD are available that promote aging in place, caregiver self-care, caregiver burden, and skills training while improving quality of life, relationships, and stress and distress management skills [4,5,9]. A growing number of these interventions have shown effectiveness for decreasing burden, depression, and stress, as well as improving quality of life and one's sense of competence [10,11]. However, in-person interventions present many limitations, especially for caregivers who have scheduling conflicts, work full-time or part-time, live in remote locations, have limited access to transportation, or have a limiting illness [12,13].

Caregiving interventions delivered through information and communication technologies (ICTs) can overcome many of the constraints of in-person intervention delivery and can play a crucial role in reaching out to caregivers of people with ADRD. ICTs are tools and procedures used to acquire and distribute information and enhance communication via technologies such as hardware, software, or the internet. ICTs enable the collection, capture, processing, production, treatment, registry, storing, exchanging, and presentation of information [14,15]. Regardless of their age, many caregivers are willing and eager to incorporate new technological tools into their daily lives [16,17]. However, there are limited studies in the literature that have used ICTs to deliver caregiving interventions to caregivers of people with ADRD. Among the few interventions that have done so, delivery channels have included virtual reality (VR), assistive devices, and internet-based interventions, and all have met with high acceptance [18,19]. Of note, VR is a computer-created interaction-enabled simulation that allows the user to engage in a realistic environment through a specific VR headset [19].

ICT interventions have been successful in training formal (ie, paid professionals and staff) and informal caregivers. Examples of studies include qualitative projects with formal and informal caregivers. One study indicated that the dementia simulation program helped participants to have more empathy for people with dementia as well as enhanced understanding of dementia and risks of developing dementia, to increase their awareness of any changes in the attention and affection they give to people with dementia, and to acquire and reinforce new care strategies and change other strategies such as communication techniques [20]. Another qualitative study with health care providers also highlights that simulation of what it is to have dementia is an insightful, evocative, and convincing immersive experience that takes dementia awareness training to the next level [21]. When the general population interacts with the VR simulation of a person with dementia, results indicate that after the experience, the participants' sense of community is increased. The subscales of the Sense of Community Scale—solidarity and proactiveness as well as reliance on others—also showed a statistically significant positive shift. In addition, participants changed their attitudes toward dementia after the educational program [22].

Two studies are important to highlight when considering projects that use VR to train informal caregivers of people with dementia:

1. The program *Into D'mentia* consists of a 20-minute simulated experience for caregiver participants that focuses on the beginning stages of dementia (primarily of the Alzheimer's disease type). The program helps caregivers to feel the confusion that a person with ADRD might experience when their routine activities cannot be completed as desired. The simulation was followed by a one-on-one conversation with the trainer and a half-day group meeting with other participants. No statistically significant differences were found on key outcomes (eg, empathy, sense of competence, quality of relationship with care recipient, depression, anxiety, and caregiver burden). However, caregivers did report a heightened understanding of dementia and that, after the program, they changed the way they cared for their loved ones. Study limitations delineated by the researchers include the minimal number of simulation and group sessions and a lack of applicability to caregivers whose loved ones have progressed beyond the early stages of dementia [11,23].
2. The *Through the D'mentia Lens 360º* program is a VR adaptation of *Through the D'mentia Lens* scenarios. The experience consists of a 360-degree simulation movie and a self-paced e-course covering topics about dementia and communication. The results indicate that the simulation intervention was user friendly and improved understanding of dementia. Furthermore, the project contributed to improved caregiver empathy on the subscales perspective taking (Interpersonal Reactivity Index questionnaire), proactive competence when caring for a person with dementia as well as resilience (Trust in Own Abilities questionnaire), and more positive interactions with the person with dementia (Dyadic Relationship Scale). Study limitations included the lack of a control group as well as a small sample size and personal circumstances that might have affected the outcome of the study (eg, involvement of professional caregivers or deterioration of the person with dementia), testing effects, sampling bias owing to selection of particular informal caregivers recruited by case managers, using nonvalidated questionaries, and having a large proportion of female participants; in addition, the impact of each component of the intervention was not evaluated individually (rather, the intervention as a whole was evaluated) [24].

Thus, although there are new interventions using ICTs, including simulation or VR for training formal and informal caregivers of people with dementia, there is still a gap in how to implement

XSL•FO
RenderX

and use new technologies to help educate caregivers about dementia and provide them with different skills to manage behavior challenges and reduce their own stress.

Objectives

To address the paucity of ICT-delivered ADRD caregiving interventions and known limitations, such as the lack of more VR sessions and group meetings, we designed a user-friendly multicomponent ICT-delivered intervention entitled *Through Alzheimer's Eyes*. This intervention is guided by social cognitive theory (SCT), owing to its relevance when learning in a social environment, and cognitive behavioral therapy (CBT) as a model to help caregivers develop and master appropriate skills. Several of the intervention's components are drawn from prior caregiver intervention studies grounded in these theories conducted by Gallagher-Thompson et al [25], Coon et al [26], Belle [27], and Coon [28]. The intervention leverages effective design considerations of previous in-person ADRD caregiving interventions (group format, educational modules and handouts, discussions with participants, home assignments, and individual weekly sessions) to support the participant learning process and promote behavior change. Furthermore, the intervention is designed to prepare caregivers of people with ADRD for their role as caregivers in alleviating stress and distress while improving communication, behavioral management skills, and management of unhelpful thoughts, as well as well-being, with the support of VR. *Through Alzheimer's Eyes* is delivered through the Zoom videoconferencing platform (Zoom Video Communications, Inc) and augmented with VR. In this paper, we describe the theoretical rationale, study design, and methods of a 4-week pilot study designed to evaluate the acceptability and feasibility of the intervention. The aims of the study were to (1) evaluate the feasibility and acceptability of our new ICT-delivered program for caregivers of people with ADRD focusing on VR, educational, and skill-building components; (2) examine patterns of change among key outcomes targeted by the intervention, including communication skills, management of behavioral issues, and management of unhelpful thoughts; and (3) learn about the benefits of the sessions from the participants' perspective. Feasibility and acceptability will be assessed by examining recruitment strategies, participant retention, adherence to the intervention, and participant feedback provided through a postintervention satisfaction survey and one-on-one qualitative interviews. Pre-post intervention changes in key caregiving outcomes will be assessed using validated surveys.

Methods

Study Design and Participants

The study is a 4-week, single-arm, pre-post test pilot study designed to examine the feasibility and acceptability of a technologically enhanced skill-building intervention. The study is ongoing and to date has enrolled 20 adults who are caregivers of people with ADRD. The inclusion criteria are as follows: (1) self-report of being an unpaid primary caregiver of a person with ADRD for at least 6 months, (2) the caregiver and the person with ADRD must live together, (3) the caregiver must be aged ≥18 years, (4) they must be able to speak and read English, and (5) they must have access to a computer or similar device with a camera, speaker, microphone, and reliable bandwidth. Caregivers are not considered for the study if they have (1) vision or hearing impairment that impedes full participation over Zoom or (2) serious memory problems themselves. The research staff consults the principal investigator before determining eligibility if (1) the care recipient has been diagnosed with a severe mental illness before the age of 45 years (as reported by the caregiver), (2) the caregiver reports having memory loss, (3) the caregiver has frequent difficulty comprehending the questions during the screening, or (4) the caregiver is currently participating in a program, study, or workshop for caregivers designed to reduce stress and distress.

Setting

As this is an ICT-delivered intervention, participants can join from any location in the United States. Every participant selects a private location that best meets their needs to connect to the intervention via videoconference. Researchers connect from their preferred location while ensuring privacy and confidentiality.

Ethics Approval

The study protocol for *Through Alzheimer's Eyes* was approved by the Arizona State University institutional review board (STUDY00014856).

Informed Consent

Written informed consent was obtained after initial eligibility screening and before intervention delivery. The consent form contained detailed information about the purpose of the research; intervention details such as assessments to be performed, program schedule, time invested in the intervention, risks, privacy and confidentiality protection, what happens to the information collected for research, funding, cost, and payment (a total of US $25 in the form of eGift cards) for completion of the study's interviews; whom to talk to should the participants have any questions; and a question asking participants whether they are willing to be contacted about participating in future studies (participants did not have to agree to participate in this study).

Privacy and Confidentiality Protection

To ensure privacy and confidentiality, all the records are kept confidential and saved in password-protected secure servers, and any written documentation is kept in locked file cabinets in a secured access research office.

Through Alzheimer's Eyes Intervention

The 4-week intervention includes dementia education and skill-training components on techniques for communicating effectively, managing challenging behavior, controlling unhelpful thoughts, and caring for oneself, which are vital when providing person-centered care [18]. Participants engage with one another and their group leaders through activities facilitated by the group leaders, including mini-lectures, VR experiences, discussions, mindfulness exercises, and other relevant intervention activities, to master the skills. The facilitator has access to the VR set and plays the VR experience for the participants. Participants are divided into two groups: (1)

XSL•FO
RenderX

immersive VR users and (2) semi-immersive VR users (those who are unable to use the VR headset owing to experiencing cybersickness while using the headset). Semi-immersive VR users will experience what life is like for a person with Alzheimer's disease through visualization on the user's computer via screen sharing.

The semi-immersive VR experience facilitated by Embodied Labs [29] consists of visualizing the journey of "Beatriz," an older Latina with Alzheimer's disease. Participants see through Beatriz's eyes and experience what it is like to have memory challenges, hearing impairments, confusion, and hallucinations, among other limitations associated with the disease.

Intervention Content

The selected topics for the psychoeducational skill-training components of the intervention sessions include not only increasing dementia knowledge but also improving the following skills: (1) communication with the loved one, family, friends, and health care providers; (2) managing challenging behavior; (3) controlling unhelpful thoughts; and (4) mindfulness and other relaxation skills. The goal is to help caregivers manage their most pressing concerns and sources of their stress successfully and understand the changes in the brain associated with Alzheimer's disease and the symptoms their loved one displays [9,30]. The topics were chosen based on existing literature about caregiving's most pressing concerns and sources of stress, as well as past successful psychoeducational interventions such as *Coping with Caregiving* [25,26,31]. Communication, problem-solving, and combativeness (behavioral issues) are topics where caregivers perceive they need the most help. Focusing on skill-building activities with education about the disease helps caregivers manage and decrease their stress. In addition, caregivers often need assistance and reminders about maintaining a healthy lifestyle and relaxation [26,30-32].

Communication skills have been chosen because caregivers need to learn how to communicate effectively with a person with dementia. As the cognition of the person with dementia deteriorates, new ways of communication are encouraged to be implemented to ensure that the caregiver communicates effectively, and the care recipient understands the message. Communication education and skill-training was divided into (1) how to communicate assertively with family and others, as well as the differences between passive and aggressive communication; and (2) how to communicate with the loved one, including verbal and nonverbal tips to deliver messages to their loved ones as the disease progresses. Effective communication helps to increase caregiver and care recipient satisfaction [33,34], and participants from previous interventions considered communication an excellent coping skill [33].

Increasing caregiving skills in managing challenging behavior or combativeness helps the caregiver to provide better and more effective care. Helping the caregiver to find the root or trigger of the challenging behavior decreases their stress [25]. During the intervention, the caregiver learns about the triggers and how to resolve them by helping the care recipient to be calm and helping to decrease the frequency of challenging behavior. Managing these challenges can have a positive impact by improving the quality of the relationship between caregiver and care recipient [5,26].

Learning to control unhelpful thoughts has been chosen as a key skill to help the caregiver change these unhelpful thoughts into productive ones to improve their own well-being [5,25,26]. During the session, participants identify unhelpful thoughts and learn different ways to replace them with more helpful ways of thinking about their loved ones, themselves, and their caregiving situations. Finally, mindfulness skills help the caregiver to be aware of the present moment, such as being aware of unhelpful thoughts when they occur, and offer the opportunity to learn different relaxation techniques to help decrease stress [5,26,27]. The techniques include mindful breathing, mindful eating, and body scan, as well as access to the Calm app for more resources.

Interventionists

A master's prepared social worker and a Doctor of Philosophy candidate in nursing were trained to deliver the intervention under the supervision of the second author, an experienced caregiver intervention researcher and geropsychologist. The main role of the interventionists is to deliver the weekly intervention sessions, guide the weekly individual sessions with the participants, provide extra resources when needed, provide feedback related to the home exercises, and guide the discussions during the sessions.

Intervention Sessions

The intervention will consist of 4 sessions delivered via videoconference (Zoom) over 4 weeks to a group of 5 to 9 family caregivers. Each group session lasts 90 minutes and consists of a new topic, a discussion that includes a review of the previous week's topic, a VR experience, home practice, and mindfulness exercises. The participants join the interventionist individually for a 30-minute discussion to revisit content and work on personalized goals between group sessions. Textbox 1 illustrates the content of both group and individual sessions. Mini-lectures, VR experiences, discussions, mindfulness activities (including options for mindfulness apps), and home exercises or home practice provide excellent opportunities to reinforce the knowledge acquired during the group sessions and facilitate different discussions about the topics covered during these sessions.

XSL•FO
RenderX

Textbox 1. The intervention's weekly modules, activities, and content.

Week 1

- Weekly topic: learning about Alzheimer's disease, how it affects the brain and symptoms, and communication skills (to decrease challenging behavior)
- Virtual reality (VR) experience 1: focus on early stages of the disease
- Mindfulness: mindful breathing; introduction to mindfulness resources

Week 2

- Weekly topic: problem-solving, managing disruptive and challenging behavior, and applying communication skills
- VR experience 2: focus on middle stages of the disease
- Mindfulness: mindful eating

Week 3

- Weekly topic: controlling unhelpful thoughts; emphasis on actions that can lead the caregiver to have unhelpful thoughts, especially those related to quality of care and future options
- VR experience 3: focus on late stages of the disease
- Mindfulness: mindful walking

Week 4

- Weekly topic: importance of self-care and revision of the covered topics
- VR: experience all 3 VR experiences covering early, middle, and late stages of the disease
- Mindfulness: body scan
- Between sessions
- A 30-minute one-on-one Zoom session with an interventionist
- Review of the materials and work on individual stressors and goals

VR Experience

Participants watch a different VR experience every week. The VR experience facilitated by Embodied Labs consists of 3 modules targeting 3 different stages of the disease: early, middle, and late. The experience portrays the story of Beatriz, an older Latina with Alzheimer's disease, and her journey from the early stages to the late stages of the disease, emphasizing her struggles with communication as visual and hearing impairments affect her activities of daily living and her family. The participant watches the video through the eyes of Beatriz (Figure 1).

Figure 1. Screenshot of a virtual reality scene created by Embodied Labs (reproduced with permission). In this scene, the participant sees the bathroom through Beatriz's eyes and perspective; Beatriz is in the middle stages of Alzheimer's disease. This scene corresponds to when she takes a bath. The participant is experiencing Beatriz's ability to complete daily tasks.

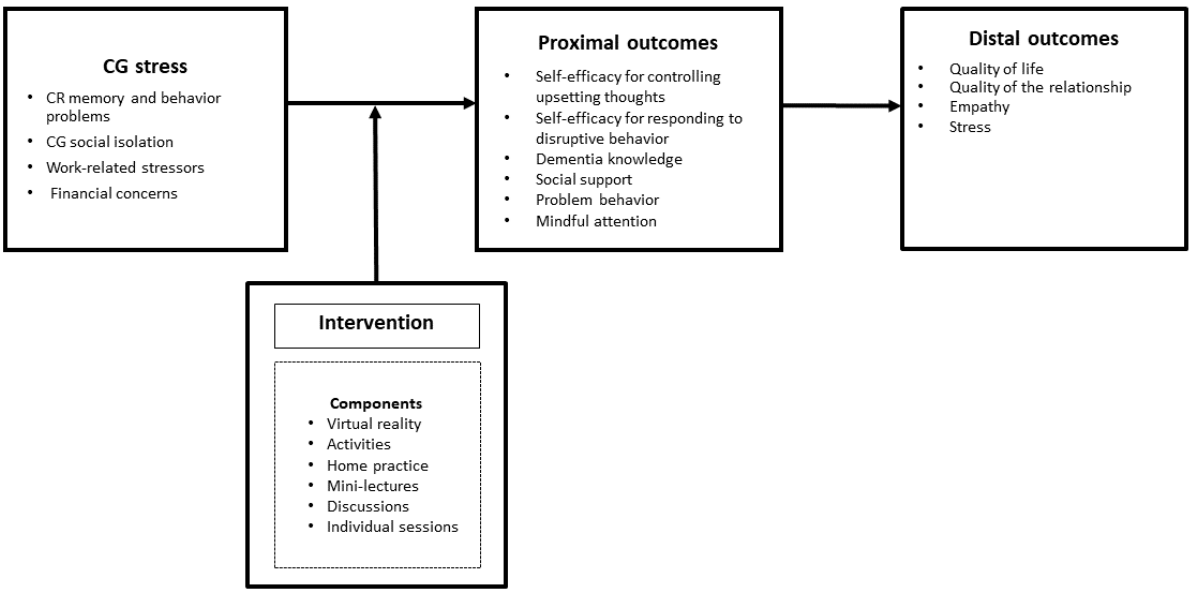
XSL•FO
RenderX

VR Equipment

The VR equipment includes materials for the instructor as well as for the participants. The instructor VR headset (Figure 2) consists of a laptop computer with the software and a headset connected to the laptop computer. The equipment and software were purchased from Embodied Labs, whose representative provided one-on-one training on the VR software and use of the equipment before its implementation in the intervention. Both the equipment and the software are very user friendly.

The participants have a VR headset adapted for their mobile phones to visualize the experience from their homes. The mobile phone–adapted headset for the participants was bought from a web-based vendor, and the brands used included BNext and Viotek, depending on market availability.

Figure 2. Set-up of the virtual reality equipment (reproduced with permission from Embodied Labs).



Theoretical Framework

The overall intervention is guided by two main frameworks: (1) SCT, which focuses on behavior change; and (2) CBT to help guide participant training in cognitive and behavioral skills (Figure 3).

SCT is a dynamic, interpersonal behavioral theory. SCT posits that the interaction among the beliefs and attitudes of the person, their behavior, and their social and physical environment influence each other reciprocally and dynamically. SCT explains that acquiring and maintaining new behavior is best achieved when people learn in a social environment while drawing on past experiences [35]. SCT constructs emphasize that learning comes from four sources: (1) mastery experience: acquiring knowledge through obtaining information, (2) vicarious experience: watching others perform an activity, (3) verbal persuasion: learning from feedback, and (4) emotional arousal: learning from past experiences [35,36]. SCT and CBT concepts and intervention components, definitions, relationships among the constructs, outcomes, and scales used to measure the outcomes are described and summarized in Multimedia Appendix 1.

Figure 3. Theoretical framework. CG: caregiver; CR: care recipient.

XSL•FO
RenderX

The cognitive behavioral skill-building model (based on CBT) is a counseling approach focusing on thoughts and behavior that affect mood. One of the main applications of CBT concerns helping with mental health problems such as anxiety or depressive symptoms, where thoughts and behavior get in the way of a person's mood and functioning [36-38]. CBT is a fundamental component in this intervention, guiding the interventionist to help the caregiver develop cognitive (thought monitoring and restructuring) and behavioral (problem-solving, behavior management, communication, and relaxation) skills [36,37,39].

Feasibility and Acceptability Evaluation

Feasibility and acceptability will be evaluated by examining the different recruitment strategies, adherence to the intervention, and treatment implementation. In addition, individual postintervention Zoom interviews will provide further insight into the benefits and usefulness of the intervention.

Adherence Strategies

To encourage participation over the 4 weeks, strategies include weekly reminders from one session to another, calendar invitations, reminders during the one-on-one videoconference calls, and reminders in emails exchanged during the week. At the end of the study, adherence will be examined by comparing completers with dropouts.

Treatment Implementation

We have chosen the treatment implementation model developed by Burgio et al [40] to evaluate the feasibility and acceptability of the intervention. The treatment implementation model focuses on the 3 components of treatment delivery, receipt, and enactment to monitor activities in the different groups, minimize intervention efficacy bias, and evaluate treatment. The goal is to present the intervention as intended.

Treatment delivery focuses on the interventionists and the consistency of the intervention as delivered in the different groups [40,41]. Strategies to ensure consistency include manuals for the interventionists with a timeline to ensure that the same amount of time is devoted to the intervention activities across the different groups. In addition, a script is available to guide the individual Zoom calls. Weekly monitoring and feedback ensure that the interventionists deliver the sessions consistently.

Treatment receipt records whether the participant has received the intervention and understands the concepts as intended [40,41]. Strategies to evaluate the participant's knowledge include interventionists asking the caregiver about using the different concepts during the individual weekly Zoom calls and whether the caregiver has any questions about the content covered. In addition, during the sessions, the interventionist asks the participants for examples and requests them to share some of the home practices. This measure ensures that participants understand the concepts discussed during the session. The postassessment survey and an individual postintervention Zoom interview also include questions about the caregiver's perspectives of the intervention and their experiences.

Treatment enactment allows us to record and assess the use of skills and knowledge acquired during the different sessions in the participants' daily activities [40,41]. Strategies include recording in the enactment form after each session whether participants completed some written home practice, participated in the discussions, displayed understanding of the content through the question-and-answer sessions, and demonstrated the use of skills in the session, as well as whether they talked about using the skills outside of the intervention sessions.

Perception of Benefit

A 16-item postinterview survey asks participants about the perceived benefits derived from their involvement in the intervention. The survey is drawn from previous research [27,40] with family caregivers, with ratings ranging from *not at all* and *a little* to *a lot*. The survey questions include "Overall, how much do you think you benefited from participating in the program?" "How much did participation in the project help enhance your ability to care for your loved one?" "How much did participation in the program help to control upsetting thoughts?" The findings are expected to help inform whether the intervention meets caregiver needs.

Perceived Changes

The survey on perception of change includes 8 questions [27,40] indicating self-perceived changes in several key areas, including mood, communication, confidence, level of preparation for future care, and physical health. The ratings range from *declined substantially*, *declined minimally*, and *stayed the same* to *improved minimally* and *improved substantially*. The survey questions include "Do you think the communication with others, besides your loved one, has improved, declined, or stayed the same?" "Do you feel your overall confidence that you can provide care for CR has improved, declined or stayed the same?" [27,40].

Pre- and Postintervention Web-Based Surveys

To provide preliminary data on the impact of the intervention, the caregiver participants complete pre-post surveys to assess potential changes in proximal (eg, self-efficacy in responding to disruptive behavior and dementia knowledge) and distal (eg, quality of life and empathy) outcomes. The study's intervention outcomes are assessed with the following scales: Revised Scale for Caregiving Self-Efficacy, Preparedness for Caregiving Scale, Problem-Solving Self-Efficacy Scale, Alzheimer's Disease Knowledge Scale, Negative Interaction and Satisfaction with Social Support, Revised Memory and Behavior Problems Checklist, Mindful Attention Awareness Scale, Quality of Life–Alzheimer's Disease, Kingstone Caregiver Stress Scale, Interpersonal Reactivity Index, and Dyadic Relationship Scale. Table 1 describes each measure used. Sociodemographic information is collected at the screening.

XSL•FO
RenderX

Table 1. Description of the assessments used to assess changes in key outcomes.

Questionnaire[a]	Subdomain	Cronbach α	*R*	Description
Sociodemographics (specific to study)	N/A[b]	N/A	N/A	Data collected include age, level of education, race and ethnicity, marital status, occupation, and years providing care [42]
Proximal (secondary) outcomes				
Revised Scale for Caregiving Self-Efficacy	Controlling unhelpful thoughts	.800 to .850	0.790	Assesses the confidence of caregivers of chronic individuals to cope with the care recipient's demands and challenges. Selected subdomains focus on efficacy for managing distressful thoughts and managing disruptive behavior [43]
Revised Scale for Caregiving Self-Efficacy	Disruptive behavior	.800 to .850	0.700	Assesses the confidence of caregivers of chronic individuals to cope with the care recipient's demands and challenges. Selected subdomains focus on efficacy for managing distressful thoughts and managing disruptive behavior [43]
Preparedness for Caregiving Scale	N/A	.700 to .800	—[c]	Gauges the ability to perform as a caregiver [44]
Problem-Solving Self-Efficacy Scale	N/A	.830	0.683	Evaluates the caregiver's confidence to perform a skill and solve a problem [45]
Alzheimer's Disease Knowledge Scale	N/A	.710	0.810	Tests knowledge of Alzheimer's disease among the general population and health providers [46]
Negative Interaction and Satisfaction with Social Support	Negative interaction	.873	—	Assesses social support by using 10 items to measure 3 domains of support: received support, satisfaction with support, and negative interactions of support [25,47,48]
Negative Interaction and Satisfaction with Social Support	Satisfaction with support	.878	—	Assesses social support by using 10 items to measure 3 domains of support: received support, satisfaction with support, and negative interactions of support [25,47,48]
Revised Memory and Behavior Problems Checklist	N/A	.840 to .900	—	Evaluates differences in problem behaviors of care recipient and how much it bothered the caregiver [49]
Mindful Attention Awareness Scale	N/A	.800 to .900	—	Assesses mindfulness awareness though a 15-item questionnaire: how attention and sensitive awareness happens while observing the surroundings [50]
Distal (primary) outcomes				
Quality of Life–Alzheimer's Disease	N/A	.860	0.100 to 0.650	Measures physical health, mental health, social and financial domains, and overall quality of life [51,52]
Kingstone Caregiver Stress Scale	N/A	.880	0.880	Monitors stress over time in 3 domains: caregiving, family, and financial issues [53]
Interpersonal Reactivity Index	N/A	.710 to .770	0.610 to 0.710	Evaluates on 4 subscales how the person reacts when observing others' experiences [54,55]
Dyadic Relationship Scale	N/A	.740 to .770	—	Assesses positive and negative aspects of the family relationship [56]

[a]All scales are evaluated before and after the intervention, except for demographics (data gathered during the screening and before the assessment).

[b]N/A: not applicable.

[c]Not available.

Postintervention Qualitative Interviews

After the 4-week intervention and postintervention assessment are completed, an individual postintervention Zoom interview with a research team member (other than the interventionist) gathers additional insight into the usefulness of the intervention and its materials, such as the VR experience, mindfulness activities and apps, and content of the sessions. Examples of questions include "What are your thoughts on the VR experience?" "How did the experience make you feel?" "How useful do you think the communication component is?" "How useful do you think the mindfulness component is?" "How often did you use it?" "How interesting is it for you?"

Study Protocol

Recruitment and Retention

Nonprobability purposive and snowball sampling is used to recruit the maximum number of participants. Purposive sampling allows for selecting caregivers of people with dementia who meet the aforementioned selection criteria [57]. In addition,

XSL•FO
RenderX

participants are asked to refer other people they know who are in the same situation to participate in the study [58].

The recruitment strategy consists of advertising the intervention via social media platforms such as Facebook, Twitter, Instagram, and TikTok. In addition, flyers and related project information are shared with close professional contacts and other providers at community-based organizations such as the local branch of the Alzheimer's Association and local area agencies on aging, including through invitations to participate sent via email.

To encourage participants to join and complete the workshop, we focus on the following strategies: (1) once a participant contacts the team inquiring about the program, the research team texts, emails, or calls the participants via telephone or videoconference to establish a relationship and offer the opportunity to ask questions before enrolling; (2) provide incentives (eGift cards) after the completion of the pre-post assessments; (3) offer different options of mindfulness and relaxation apps for participants to use; and (4) provide a VR headset compatible with the participant's mobile phone.

Screening

Trained research staff screen participants to determine eligibility via telephone call or Zoom videoconference. Eligible and interested participants complete a second short survey about their fitness to use the VR headset compatible with their mobile phone. This short questionnaire helps to determine whether the participant can safely use VR without physical side effects during the intervention sessions. The questions include "Do you experience motion or car sickness?" "Do you have any conditions where flashing or intense light might affect you, such as epilepsy, migraines, unexplained seizures, recent concussions, or light sensitivity?" If participants answer positively to even one of the questions, they will be deemed noneligible for VR use and asked to visualize the experience through their laptop computers (semi-immersive VR) instead of using the VR headset to avoid potential side effects during the intervention sessions. The questionnaire was determined in coordination with the university institutional review board.

Study Enrollment and Consent

To enroll in the program, eligible participants sign the consent form via REDCap (Research Electronic Data Capture; Vanderbilt University), a Health Insurance Portability and Accountability Act–compliant web-based secure tool to capture and manage research data [56]. The consent form is sent to the participant's preferred email address. In addition, a telephone number is provided to participants in case they need further information or assistance while signing the consent form.

Follow-up Assessment Procedures

Enrolled participants fill in the web-based preassessment survey within 2 weeks before the first day of the intervention sessions via REDCap. Once this survey is completed, participants receive a VR headset compatible with their mobile phone if they are eligible for a VR headset based on the screening about VR tolerance, a binder with the materials, and options for mindfulness apps. As part of the screening process, we identified those who were unable to use the headset because of cybersickness. During the intervention, participants are split into 2 groups: VR and semi-immersive VR (ie, unable to use the headset). However, there is no difference in what the 2 subgroups of participants observe during the VR experience, and the VR experience lasts exactly the same amount of time for both groups during the intervention. Thus, the only difference is during the visualization mode of the VR experience to avoid cybersickness symptoms. As this is a feasibility and acceptability study, we gather feedback about each participant's experience and will be able to comment on differences between the groups as a result. We will explore differences in outcomes across the groups, but as an acceptability and feasibility trial, the study may not have the power to detect differences.

After the intervention, participants fill in the postassessment survey and meet with trained research staff (other than the interventionists) for the individual Zoom interview within 2 weeks after the last web-based check-in. eGift cards are electronically sent to participants who complete each assessment.

Data Analysis

Data analysis will follow the embedded design approach, a type of mixed methods approach, also known as intervention mixed methods framework [59,60]. The study blends elements of quantitative and qualitative research approaches to gain a deeper understanding of a phenomenon—in this case, the experimental intervention. Equal weight will be given to both components because the qualitative results will help to interpret the quantitative results, describe the participants' experiences with the intervention, and refine the intervention for future implementation based on the data gathered [59,61].

Sample Size Considerations

The study objective was to evaluate the feasibility and acceptability of an ICT-delivered intervention for caregivers using a VR component, and 20 caregivers were recruited to date to provide feedback on the VR experience as well as the usefulness of the intervention content. Although the focus is on feasibility and acceptability, the sample will provide us with the opportunity to gather feedback on the project's pre- and postintervention assessments as well as gather preliminary data on changes in key outcomes. The findings will guide the implementation of lessons learned from the project for adaptation of this intervention or the development of new technologically enhanced interventions in the future.

Quantitative Data Analysis Strategies

Variable-oriented data will be entered and analyzed using SPSS software (version 23.0; IBM Corp). Descriptive statistics will help to identify distributions (means and frequencies) for sociodemographic information and feasibility outcomes (perception of benefits and satisfaction survey). Paired 2-tailed *t* tests will be used to explore changes between the pre- and postintervention assessments. Given the focus on feasibility and acceptability, the *P* value for statistical significance will be established at $\alpha<.05$ and 95% CI. Cohen *d*will also be computed to describe the magnitude of each mean change to estimate power for future interventions [61].

Qualitative Data Analysis

Directed content analysis, which allows for the combining of multiple techniques, will be used to analyze data regarding participant perspectives [62]. Individual postintervention Zoom interviews will gather participants' perceptions of the intervention's critical components, such as the usefulness of including VR or the amount of time devoted to each session. Participants' viewpoints will be audio recorded and transcribed using the Zoom transcription function.

The qualitative analysis will consist of (1) information complementing the quantitative data and (2) thematic analysis to unveil and elaborate on components of the intervention such as participants' views of the VR experience. For data analysis and interpretation, the analytic approach will be based on the indications for coding provided by Miles et al [63], consisting of a first and second cycle of analysis of the transcriptions.

Data Analysis Steps

Overview

The first step of data analysis will be the creation of a codebook with codes and definitions. A list of provisional initial codes will be derived from the research questions and other variables, such as inquiries about the different psychoeducational skill-building components. All the codes will have clear operational definitions.

The anticipated approach for the first cycle of coding will correspond to descriptive coding (1-word summaries), in vivo coding (words used by participants), emotion coding (feelings), evaluation coding (judgments about programs), and theming the data (a phrase that identifies a unit of data). The goal is to create a level 1 code with meaningful units. The first coding cycle will help to identify expected deductive codes (eg, *VR views, communication, challenging behavior, understanding dementia*, and *areas for improvement*). In addition, after a thorough and careful analysis of the data, inductive codes could potentially be identified; therefore, pattern codes will be extracted from the first cycle.

The second cycle of coding will consist of summarizing segments of data using pattern coding, grouping those summaries into a small number of themes (*focused coding*). Codes will be organized in an Excel spreadsheet (Microsoft Corp) using the following format: label used for each code or category, description of the concept or theme the code refers to, samples in the text, notes on how the code relates to others, and quotes. Once data saturation is reached, and the table is populated with all the codes obtained from the interviews, the next step will be to create a tree diagram. The tree diagram will include the main code, subcodes, a second level of subcodes when needed, and quotes that refer to the specific code or subcode. The tree diagram will help to organize and visualize the data, collapsing codes, and explain the relationships among the identified codes. This approach will facilitate interpreting and capturing the main essence of the caregivers' experiences with the intervention, the different components, what they like, suggestions, and other themes [62]. Two team members will revise the downloaded transcriptions to verify the transcription and data analysis accuracy. In case of discordance, a third researcher will intervene. Excel will be a supporting tool to help organize and display the data.

Issues of Trustworthiness

The selected theoretical framework will guide the data analysis process and enable us to draw conclusions. Credibility, dependability, confirmability, transferability, and application will be assessed to ensure trustworthiness. This process will ensure that potential biases affecting the study's design, implementation, and analysis are diminished and affirm that the conclusions are of high quality [58,63,64].

Credibility

To ensure methodological validity (credibility) of the study, we will (1) involve different researchers during the research process, including data analysis, synthesis, and interpretation of the results; (2) revise and discuss the findings with colleagues; and (3) build a logical chain of evidence and present data using illustrations plotting tentative relationships when needed [58,63,64].

Dependability

All the procedures will be documented to demonstrate the consistent use of codes and categories to ensure dependability. The involved colleagues will maintain a diary with their data analysis memos and steps to enhance transparency. Finally, a monitoring plan, including a moderator guide, will be created to help junior researchers interpret data [63,65,66].

Confirmability

To assess confirmability, memos and transcripts can offer a unique opportunity for the reader to evaluate the findings. In this case, a transcript segment will be facilitated in the form of a figure with the coding process to offer visible evidence of the process followed [58,65].

Transferability

The findings will be presented with a rich description of the sample and context, a consistent summary of the findings, and suggestions for new environments to broaden the perspective to ensure transferability [58,59,63].

Application

The data obtained will reach consumers via scientific publications, poster presentations, and oral communications. The findings can bring awareness to policy makers and promote further research [66].

Results

Recruitment began in January 2022, with 20 caregivers across the United States recruited to date. However, recruitment and data collection are still ongoing, and the results are expected to be submitted for publication in the second half of 2023. Preliminary data and feedback from participants support the feasibility and acceptability of the project. All the participants enrolled to date have completed the workshop as well as the pre- and postintervention assessments, including the individual Zoom interview.

Discussion

Strengths and Limitations

Through Alzheimer's Eyes is a 4-week multicomponent intervention that includes a VR experience in every session. The intervention is designed to decrease the stress and distress of family caregivers of people with memory challenges by improving communication, behavioral management skills, management of unhelpful thoughts, and mindfulness.

A strength of *Through Alzheimer's Eyes* is that it combines VR experiences with different skills-driven components to help caregivers of people with ADRD. VR provides a valuable eye-opening opportunity to experience what it is like to have Alzheimer's disease. The intervention is guided by 2 robust theories: SCT and CBT; this increases the possibility of having a positive impact on participants' behaviors. In addition, the intervention is delivered via Zoom, enhancing the acceptability and feasibility of the intervention because participants can connect from their preferred private location via mobile phone or laptop computer with an internet connection. Connecting from home helps to resolve stressors that arise from in-person interventions (eg, finding respite, transportation, parking fees, and work schedules). This ICT-delivered intervention presents the advantage of reaching individuals living far from the intervention location and allowing caregivers to participate while remaining close to their care recipient, avoiding the hassle of looking for paid caregivers [67-69]. Potential limitations include technical difficulties that can be encountered while using the VR headsets and Zoom, which could affect the timing and flow of the session.

The intervention's novelty includes using VR and connecting remotely to help caregivers cope with stressful situations and better understand ADRD, as well as improve communication skills, manage unhelpful thinking, and increase confidence when providing care. The analysis and synthesis of the results will guide future research by providing information about VR use for learning purposes and promoting behavior change among caregivers of people with dementia.

Conclusions

This innovative study merged technology with psychoeducational and skill-building interventions, addressing a gap in the existing research literature. Interventions using ICTs such as VR present unique advantages [70]. In particular, VR brings the user to a quasi-naturalistic real-life situation where, in a safe environment, they can experience having Alzheimer's disease to help them better understand their loved one and provide holistic care. In addition, ICT-delivered interventions can provide cost savings and be more affordable than traditional in-person interventions [69,71]. By including VR and promoting an ICT-delivered intervention, we aim to reduce the number of caregivers who experience diminished well-being and provide the opportunity for caregivers to better care for their loved ones and themselves while ensuring that their own needs are met [72].

Implications for public health research and health care professionals' education and practice include the opportunity to use technology combined with skill building to (1) broaden awareness of the need to care for the caregiver, (2) advance actions in health care practice that move toward treating the caregiver and care recipient dyad and not focus only on the care recipient's treatment and health care goals, (3) create new training and related resources to promote healthy aging in place at a lower cost to people with ADRD and their family caregivers, (4) offer VR experiences about having Alzheimer's disease to foster understanding for students and professionals serving the older population, (5) reinforce interdisciplinary education and practice to help caregivers better navigate systems when seeking resources, and (6) enhance partnerships among researchers, health systems, and not-for-profit organizations to embed evidence-based technologically enhanced caregiver interventions across providers to fill gaps and more widely distribute resources for caregiving training. If the results are beneficial, they will provide a basis for a future intervention on a larger scale, including a comparison group. A comparison group will help to draw more robust conclusions regarding changes in key outcomes of interest. Improved intervention content based on participant feedback and translation of the lessons learned through piloting this technologically enhanced intervention will also assist in adapting interventions that help caregivers of patients with other chronic conditions to stay healthier and more interpersonally connected. Future studies will offer the sessions in other languages, such as Spanish, to reach the growing Hispanic and Latino communities and bridge health care inequalities. Technologically enhanced interventions hold promise as a tool for training caregivers that can be expanded in the future to serve a wider community.

Acknowledgments

This study is funded by the Arizona State University Graduate and Professional Student Association Research Grant, Edson College of Nursing and Health Innovation's PhD seed grant, and Arizona State University's Edson Initiative for Dementia Care and Solutions (from the Edson New Idea Fund). Special thanks to Dr A Mulchandani and the team—Allison Glinka, Phil Carll, Sidney Perez, Socorro Gonzalez, and Zenya Weatherall, as well as Emily Smith (Director of Customer Success at Embodied Labs)—for their help and support.

Data Availability

The data sets generated and analyzed during this study are not publicly available because of ongoing enrollment and future data analyses. However, data generated and analyzed as part of this study will be published in a peer-reviewed journal.

Abstract

Background: Cigarette smoking is the leading preventable cause of disease and death in the United States. Despite the availability of a plethora of evidence-based smoking cessation resources, less than one-third of individuals who smoke seek cessation services, and individuals using these services are often those who are actively contemplating quitting smoking. There is a distinct dearth of low-cost, scalable interventions to support smokers not ready to quit (ambivalent smokers). Such interventions can assist in gradually promoting smoking behavior changes in this target population until motivation to quit arises, at which time they can be navigated to existing evidence-based smoking cessation interventions. Conversational agents or chatbots could provide cessation education and support to ambivalent smokers to build motivation and navigate them to evidence-based resources when ready to quit.

Objective: The goal of our study is to test the proof-of-concept of the development and preliminary feasibility and acceptability of a smoking cessation support chatbot.

Methods: We will accomplish our study aims in 2 phases. In phase 1, we will survey 300 ambivalent smokers to determine their preferences and priorities for a smoking cessation support chatbot. A “forced-choice experiment” will be administered to understand participants’ preferred characteristics (attributes) of the proposed chatbot prototype. The data gathered will be used to program the prototype. In phase 2, we will invite 25 individuals who smoke to use the developed prototype. For this phase, participants will receive an overview of the chatbot and be encouraged to use the chatbot and engage and interact with the programmed attributes and components for a 2-week period.

Results: At the end of phase 1, we anticipate identifying key attributes that ambivalent smokers prefer in a smoking cessation support chatbot. At the end of phase 2, chatbot acceptability and feasibility will be assessed. The study was funded in June 2022, and data collection for both phases of the study is currently ongoing. We expect study results to be published by December 2023.

Conclusions: Study results will yield a smoking behavior change chatbot prototype developed for ambivalent smokers that will be ready for efficacy testing in a larger study.

Introduction

Cigarette smoking continues to be the leading preventable cause of disease and death globally and in the United States [1]. Cigarette smoking kills more than 480,000 Americans each year and results in more than US $240 billion in health care spending and nearly US $372 billion in lost productivity [2]. Thus, promoting smoking behavior change with the long-term goal of achieving successful cessation is critical to reducing the public health impact caused by tobacco use. Within the United States, the past few decades have seen a groundswell of evidence-based interventions to quit smoking. These have included a wide range of strategies such as mobile health (mHealth) apps [3,4], availability and increased access to effective pharmacotherapy for cessation [5], SMS text messaging support [6,7], evidence-based behavioral counseling [8], and comprehensive state-based programs, such as tobacco quitlines [9,10]. However, despite their widespread availability, less than one-third of people who smoke cigarettes actively avail themselves to cessation strategies [11]. For example, tobacco quitlines—free evidence-based smoking cessation programs providing telephone-based behavioral counseling combined with cessation pharmacotherapy available in all 50 US states—are used by less than 3% of people who smoke [12]. One potential reason for the low uptake of existing services for cessation may be that strategies to promote cessation differ according to an individual's readiness and motivation to quit [13]. Although smokers actively committed to quitting respond positively and engage with cessation services, ambivalent smokers (ie, those not actively seeking treatment) may benefit from approaches that promote modest changes or "behavioral *nudges*" toward smoking behavior change (but not cessation) [14,15]. Most cessation research is focused on those expressing an intention to quit, and research on promoting behavior change in ambivalent smokers (not actively thinking about quitting) is scant.

A conversational agent or "chatbot" is an inexpensive and scalable approach to deliver personalized health information in a human-like manner. Common in the consumer-service sector, chatbots are increasingly being deployed in the health sector to provide education, support, service navigation, and interventions for a range of health issues, from COVID-19 to asthma [16,17]. Human-delivered interventions for smoking behavior change are effective but are resource-intensive, lack scalability, and can be expensive to implement. Chatbots have the intuitive appeal of being low-cost automated interventions that can widely reach ambivalent smokers. Moreover, chatbots can provide "virtual accompaniment" at the frequency and duration preferred by the smoker until the motivation to quit arises, at which time they can be swiftly connected to an existing evidence-based cessation intervention. A few studies on chatbots for smoking behavior change target participants actively intending to quit smoking [18-20] and, while important, only address the tip of the iceberg in terms of reaching the smoking population. Since motivation to quit smoking is dynamic and occurs along a continuum [21], strategies to engage ambivalent smokers may be most helpful if they are tailored to accommodate smokers' changing preferences and are responsive to rapid changes in motivation (eg, connecting smokers to quitlines when ready to quit), while focusing on evidence-based strategies that have been effective for smoking reduction leading to cessation (eg, quit tips, self-monitoring, and tracking savings). Since interventions to assist smokers ambivalent about quitting are in their infancy, little is known about key elements of a chatbot-based smoking behavior change intervention tailored for this target population.

To overcome these gaps in the field, the goal of our study is to test a proof-of-concept of a novel chatbot to support and engage smokers who are not actively engaged in a quit attempt (ambivalent smokers). We propose accomplishing our aims in 2 phases. In phase 1, we will identify the key attributes that will guide the development of the chatbot prototype. We will survey ambivalent smokers to determine their preferences and priorities for a smoking cessation support chatbot. Using conjoint analysis, we will systematically elicit participant preferences for the proposed chatbot prototype (see details below). Grounded in macroeconomic principles [22], conjoint analysis is a quasi-experimental approach that decomposes a product or service into its key attributes, then poses the attributes to patients to understand patient-determined values for each attribute [23,24]. These preferences will be programmed into the chatbot prototype. In phase 2, we will invite participants to use the prototype over a 2-week period to assess the feasibility and acceptability of the developed chatbot prototype.

Methods

Study Overview

To develop the chatbot prototype (phase 1), we will recruit 300 participants who identify as current cigarette smokers to complete a web-based survey. The survey will collect demographics, smoking behavior history, and e-cigarette use, and solicit preferences for the most important features of the proposed chatbot. The top 5 preferred attributes will be used to design and develop the chatbot prototype. In phase 2, 25 participants will be recruited to engage with the developed prototype for a 2-week period. Preliminary acceptability and feasibility data will be collected via validated questionnaires at the end of 2 weeks. For both study phases, participants will be recruited using an established survey panel (Prolific). Study eligibility criteria are as follows: older than 18 years, self-report any smoking in the last 7 days, and no current intention to quit smoking in the next 30 days (score of ≥5 on a 10-point Likert scale assessing likelihood to quit smoking).

Ethics Approval

All study procedures have been approved by the University of South Florida's Institutional Review Board (IRB # 004183). For phase 1, the data are deidentified with participants only providing a prolific ID. For phase 2, participant names and phone numbers will be stored on a password-protected computer only accessible to the study staff. All participants will be identified by a study ID and any identifying information will be removed from interview transcripts prior to beginning qualitative data analysis. Participants will be compensated for both phases of the study. Participants will receive US $6 for completing phase 1 and US $70 for completing phase 2.

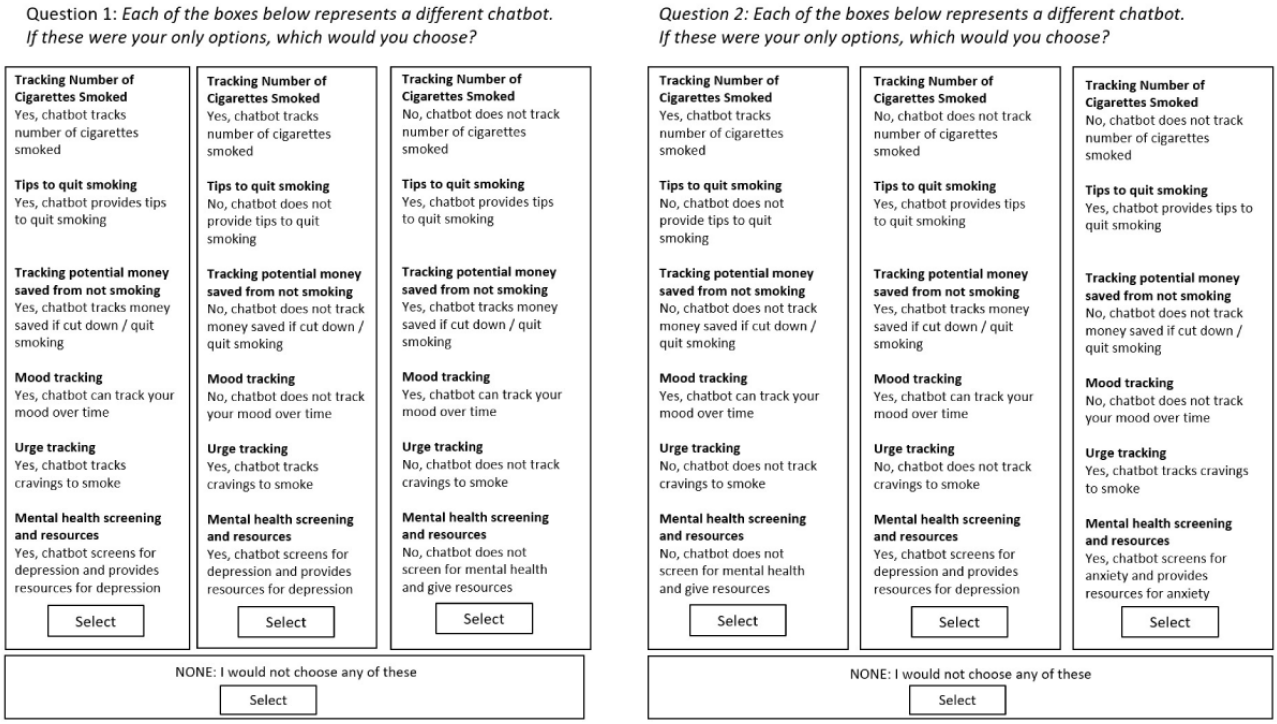
RenderX



Phase 1: Development of Chatbot Prototype

Overview

This phase is designed as a cross-sectional survey to develop a prototype of the proposed chatbot by assessing preferred attributes in a sample of individuals ambivalent about quitting smoking. To do so, 300 participants have been identified who will be invited to complete a web-based survey. Participants will be recruited using the internet and an established study panel (Prolific). After completing a web-based informed consent, participants will provide information on demographics and smoking history, after which they will be provided with a brief explanation of chatbots (what they are and how they work). They will also be asked about their previous and current experience with chatbots and interest in a chatbot designed to support people who may decide to quit smoking in the future.

Next, we will administer a choice-based conjoint (CBC) analysis experiment to understand participants' preferences for a smoking cessation chatbot. Using Sawtooth Software's web-based choice analytics survey platform, we will construct hypothetical smoking cessation chatbot "scenarios" comprising the following six attributes (ie, potential chatbot features) with varying levels: (1) number of cigarettes smoked per day tracked (yes or no), (2) smoking quit-tips provided (yes or no), (3) money saved by reducing smoking tracked (yes or no), (4) mood tracking (yes or no), (5) smoking cravings tracked (yes or no), and (6) mental health screening and resource provision (only depression screening, only anxiety screening, or no mental health screening). These attributes were chosen a priori based on published smoking cessation literature identifying evidence-based strategies to promote and support smoking behavior change. The sixth attribute, mental health screening, was added given the comorbidity between smoking and mental health [25,26]. In the CBC experiment, participants will be presented with a series of tasks; each task will display 3 different chatbot configurations composed of identical attributes but differing combinations of attribute levels. A total of 10 tasks will be presented to participants. Each question will contain 3 panels that present a combination of the attributes and associated scenarios, and participants will be asked to choose the chatbot configuration they would most prefer (ie, the chatbot that contains the combination of chatbot attribute levels most desired). Participants may also choose "none" if no chatbot configuration presented is desirable. Figure 1 displays examples of the CBC tasks. Finally, the desired frequency of chatbot messages will be assessed, and at the end of the survey, interest in participating in phase 2 will be elicited.

Figure 1. Examples of a conjoint analysis task.

Measures

For phase 1, assessments will include demographics (eg, age, sex, gender identity, and education) and smoking history (age of smoking initiation and number of previous quit attempts in the past year) [27]. Nicotine dependence will be measured by the Fagerstrom Test of Nicotine Dependence [28], which is a validated and ubiquitous instrument assessing dependence on nicotine. Smoking cessation self-efficacy will be measured using the validated Smoking Abstinence Self-Efficacy Questionnaire [29]. This 12-item questionnaire measures an individual's self-reported confidence in resisting the urge to smoke in various settings and conditions. Given the high prevalence of e-cigarette use among individuals who smoke [30], current e-cigarette use will also be assessed [31]. In addition to these measures, we will also collect information on current use and frequency of marijuana or cannabis [32] and alcohol use [33].

XSL•FO
RenderX

Data Analysis

Summary statistics (mean [SD] or frequency [%]) will be calculated for demographic and smoking characteristics. For the CBC data analysis, also completed using Sawtooth Software [34], utility scores will first be computed to determine the relative desirability of each level within each attribute. These data will inform which of the chatbot feature levels were most desired (eg, whether a cigarette tracking feature is desired). Next, the relative attribute importance scores (ie, the relative impact of each attribute in respondent choices) will be computed; these data will indicate the order of importance of each of the 6 chatbot features (most important to least important). We will also compute the 95% CIs for each of the attribute scores. Finally, CBC data will be examined for variance by select sociodemographic variables (eg, sex, gender, education, and number of quit attempts) to determine possible chatbot preference differences by population segments. The combined data will inform the prioritization of chatbot features programmed into the prototype chatbot tested in phase 2.

Phase 2: Acceptability and Feasibility Testing of the Chatbot Prototype

Overview

For phase 2, 25 eligible individuals expressing interest to participate at the end of phase 1 will be recruited to engage with the developed chatbot prototype. Participants will be contacted by the study staff to explain study procedures and complete informed consent, following which the participant will receive a link to complete a baseline survey. Following completion of the survey, they will be scheduled for an appointment to participate in a 45- to 60-minute interview conducted via secure videoconferencing. During this time, study staff will share a link with the participants to activate the chatbot prototype. An overview of the chatbot will be provided, following which participants will verbalize their thoughts and reactions while interacting with the chatbot, based on the think-aloud usability testing technique [32], and provide initial feedback while interacting with the chatbot. The interview will be audio and video recorded and participant interactions with the chatbot will be observed. At the end of this session, participants will be encouraged to use the chatbot over a 2-week period, engaging and interacting with the programmed attributes and components. To increase retention during this period, data entry and chatbot engagement will be monitored on a frequent basis, and all participants will receive daily reminders to engage with the chatbot. At the end of the 2-week period, participants will complete acceptability and feasibility assessments, provide feedback to open-ended questions to identify any aspect of the chatbot that was confusing, what they liked or disliked, perceived helpfulness of the chatbot, feedback on features they would like included, and aspects that would help keep them engaged with the chatbot. Participants will receive a total of US $70 for phase 2 (US $20 for the interview and US $50 after completion of the follow-up surveys).

Measures

In addition to the measures used in phase 1, phase 2 measures will include intervention acceptability using the Acceptability of Intervention Measure, Intervention Appropriateness Measure, and Feasibility of Intervention Measure [33], as well as intervention usability using Health Information Technology Usability Evaluation Scale [35].

Data Analysis

Quantitative data will be cleaned and analyzed to generate summary tables. We will limit analysis to only include descriptives due to the small sample size, which prevents tests of association. Qualitative data (ie, recorded transcripts from the videos during which participants interact with the chatbot and the qualitative interviews after interacting with the chatbot) will first be transcribed verbatim, resulting in text transcripts. Next, the transcripts will be loaded into the qualitative software, Dedoose [36], and analyzed using a framework analysis approach [37]. Transcripts will be read in their entirety and coded using a preliminary codebook derived from the interview guide, adding de novo codes as new themes are detected. Reports will be generated for all codes and related text extracted into tables for deeper analysis, during which cross-cutting themes will be identified and reported. The COREQ (Consolidated Criteria for Reporting Qualitative Data) checklist [38] will be completed to enhance data rigor and methodological transparency [28-31].

Results

The study was funded in June 2022, and regulatory processes and approval were completed by August 2022. Data collection for the study is currently ongoing, and we anticipate publication of expected outcomes by December of 2023. In phase 1, the methodology described above will result in the identification of key attributes that participants report a preference for in a smoking cessation support chatbot. These data will be used to program a chatbot prototype. Using SmartBot360 [39], a "point-and-click" chatbot development software, a prototype smoking cessation support chatbot will be programmed that contains the top preferences and features as expressed by the participants in phase 1. In addition to the attributes, information on existing evidence-based smoking cessation resources will also be programed to gauge participant preferences for existing evidence-based cessation resources. These will include, but not be limited to, links to sign up for free SMS text messaging services (eg, smokefree TXT) or mHealth quit apps (eg, QuitGuide), connecting to smoking cessation experts (eg, National Cancer Institute's LiveHelp or a state quitline), and information on pharmacotherapy.

At the end of phase 2, we will obtain participant data on chatbot acceptability and feasibility.

Discussion

The goal of our study is to develop and pilot-test for feasibility and acceptability of a novel chatbot prototype to support and engage smokers who are not actively engaged in a quit attempt (ambivalent smokers). The study will test a proof-of-concept of the chatbot, and the anticipated main result of our project is a pilot-tested conversational agent ready to be tested for efficacy in a larger study. To our knowledge, this is the first study to

XSL•FO
RenderX

develop a conversational agent (chatbot) for ambivalent smokers using a novel methodology.

Interventions to engage individuals ambivalent about quitting smoking are an unexplored area in smoking cessation research [11]. This study will begin an innovative line of research on strategies to optimize and personalize smoking behavior change services for individuals ambivalent about quitting smoking. Of specific mention is the use of conjoint analysis as an innovative strategy to assess and incorporate user preferences in the development of an mHealth intervention. Methodologies to systematically assess and incorporate individual preferences in the delivery of health care services are in their infancy [40], and little is known about the preferences of ambivalent smokers for chatbots as they navigate the motivation to quit continuum. While conjoint analysis has been increasingly used in the health sector, including in the smoking cessation field [41,42], to our knowledge, no mHealth interventions for smoking behavior change have used this methodology for design and implementation. Our investigative team has successfully used conjoint analysis for other health issues, including determining consumer preferences for oral and topical HIV chemoprophylaxis [43,44]. If acceptable in this pilot study, our chatbot could be a low-cost and low-resource intervention that fills a much-needed gap in the field.

The study has a few limitations. First, the study design does not lend itself to testing the effects of the chatbot on smoking behavior change outcomes. However, given the dearth of research in this area, the development of the chatbot and acceptability and feasibility testing are the first steps. At the end of the study, we will have a developed chatbot that will be ready for efficacy testing in a larger randomized controlled trial. Next, our participant recruitment methodology uses a web-based survey panel, which may reduce generalizability. While such survey panels use purposive sampling to gain a representative sample of participants [45], we anticipate using a combination of social media, community-based recruitment efforts, and web-based recruitment panels for larger efficacy trials, which will increase the generalizability of our results.

Our intervention that uses a chatbot to promote smoking behavior change in a sample of ambivalent smokers fills a distinct gap in the field. Our model is a scalable and pragmatic model that can be adopted by cessation services (quitlines) and is designed for easy accessibility to the broader population of individuals who are not actively contemplating quitting smoking. It could additionally serve as a tool for health care providers as they recommend quitting smoking resources to their patients. In the long run, our study design and methodology can be used to develop chatbots that can increase access to other evidence-based interventions within the context of substance use disorders (eg, cannabis and opioids) or compulsive behaviors (eg, eating disorders and gambling).

Abstract

Background: Despite effective treatment options, chronic kidney disease (CKD) has become a major cause of mortality worldwide due to the ever-increasing number of patients with type 2 diabetes mellitus (T2DM). Guideline-compliant, at least, annual screening of patients with T2DM is crucial to prevent renal disease progression. However, data on the prevalence of CKD in patients with T2DM and on screening frequency are limited. SMART-Finder is the first study to exclusively use data provided directly by patients via an adherence app to collect information on the prevalence of CKD, risk factors, disease management, and quality of life of patients with T2DM in Germany.

Objective: The primary objective of this study is to determine the proportion of patients with T2DM and an elevated urine albumin-to-creatinine ratio (UACR; albumin-to-creatinine ratio stage A2 and A3) at baseline and after 12 (±3) months. Secondary objectives include the proportion of patients who remain in or switch to another albumin-to-creatinine ratio classification category after 12 months, information on quality of life, disease awareness, and adherence rates, as well as the proportion of patients without any UACR-screening data. Recruitment occurs via push notification among MyTherapy app users with T2DM.

Methods: This is a single-arm, retrospective/prospective, observational, digital, patient-centered cohort study, with recruitment and data documentation via a health app. Required routine laboratory data are provided by treating physicians to their patients for data entry. The study population includes adult patients with T2DM documenting their data in the MyTherapy app using their own smartphone or tablet. Study participants are provided with a specifically developed electronic case report form containing questions on demographic and general data, quality of life, disease awareness, and laboratory values including estimated glomerular filtration rate, UACR, hemoglobin 1Ac, and blood pressure. Apart from demographic and general data, all data are collected at baseline and 12 months after the last UACR assessment. An automatically generated push notification reminds participants of the second data entry. The extracted and pseudonymized data are analyzed descriptively.

Results: The enrollment period for this study started in February 2023 and shall end after 12 months or after the enrollment of 5000 patients. An interim analysis is planned 3 months after the inclusion of the first patient and the final analysis after 12 months of follow-up.

Conclusions: Overall, the study will contribute to minimizing the existing data gap on the prevalence of CKD in patients with T2DM in Germany, provide important insights into the current disease management of patients with T2DM in everyday clinical practice in Germany, and support guideline-based care for the participating patients.

KEYWORDS

app-based documentation; chronic kidney disease; prevalence; MyTherapy; type 2 diabetes mellitus; urine albumin-to-creatinine ratio screening

Introduction

Chronic kidney disease (CKD), a common comorbidity of the ever-increasing number of patients with type 2 diabetes mellitus (T2DM), is a leading cause of death worldwide [1-9]. It is usually characterized by persistently decreased estimated glomerular filtration rate (eGFR) or persistently elevated urine albumin excretion, is often progressive and may finally lead to end-stage renal disease [10-13].

At the same time, effective therapeutic approaches are available, which, if applied early and consistently, can favorably influence or delay the development or progression of kidney damage [9]. According to current recommendations of the Kidney Disease: Improving Global Outcomes Work Group, the treatment of patients with T2DM includes lifestyle measures as an important basic therapy, followed by renin-angiotensin system inhibitors, sodium glucose transport protein 2 inhibitors (SGLT-2i), statins, and metformin as first-line drug therapies. Glucagon-like peptide-1 receptor agonists are recommended if SGLT-2i and metformin do not achieve sufficient glycemic control. For patients at high risk of progression to CKD and cardiovascular events despite standard therapies, a nonsteroidal mineralocorticoid receptor antagonist is recommended in addition to baseline therapy.

In order to effectively implement these therapeutic measures to delay progression, early identification of patients with diabetes at increased risk for renal disease is crucial. National and international guidelines recommend to determine the eGFR on the basis of serum creatinine determination and albuminuria using the urine albumin-to-creatinine ratio (UACR) at least once a year in patients with T2DM [8,9,14-18]. In patients diagnosed with CKD, these parameters should be determined up to 4 times a year, depending on the severity and progression risk [9].

However, data on the prevalence of CKD in patients with T2DM in Germany are sparse. Similarly, data on longitudinally eGRF and UACR measurements are limited, as there are only few studies of patients with T2DM and CKD in a real-world clinical setting [19-21].

A major aim of the study presented here is to minimize the data gap on the prevalence of CKD in patients with T2DM as well as to assess risk factors, satisfaction with treatment management, and quality of life of patients with T2DM over 12 months. SMART-Finder is the first study exclusively using data provided directly by patients via an adherence-supporting app for this purpose.

Methods and Objectives

Objectives

The primary objective of this study is to investigate the proportion of patients with T2DM with elevated UACR levels (albumin-to-creatinine ratio [ACR] stadium A2 and A3) at baseline and after 12 (±3) months. Secondary objectives include investigating the proportion of patients who remain in or switch to another ACR classification category after 12 months as well as the proportion of patients without UACR-screening data, the description of patient characteristics stratified by hypertension and nephrotoxic comedication status, and information on quality of life for patients with T2DM and relevant subgroups. Further secondary endpoints include the description of disease awareness and medication adherence rates among patients with regard to blood pressure control and antidiabetes drugs. Medication adherence is defined as the number of patients who are compliant and persistent during the observation period, that is, who document at least 80% of their planned medication in the MyTherapy app (compliance) and do not stop taking their planned medication during the observation period (persistence).

Study Design

This is a single-arm, retrospective/prospective, observational, digital, patient-centered cohort study in Germany. Both recruitment for this study and documentation of the data are carried out without the assistance of a health care professional (HCP), but as part of the routine use of the MyTherapy app (smartpatient GmbH) by patients with T2DM who document their data in the MyTherapy app using their own smartphone or tablet.

This study is neither intended nor designed to record safety-related data regarding the treatment with T2DM drugs or the use of the MyTherapy app. However, the Diabetes Treatment Satisfaction Questionnaire (DTSQ) questionnaire, which is part of the study electronic case report form (eCRF), captures hypo- and hyperglycemia. Adverse events (AEs) indicative of hypo- or hyperglycemia that may be recorded there, as well as Bayer drug-related AEs recorded in the context of this study, are forwarded from smartpatient, the owner of the MyTherapy app, to the sponsor as a cumulative listing after the end of the study. Furthermore, patients are asked in the patient information of this study to contact HCPs in case of any AEs. For direct reporting, patients are referred to specific web pages [22,23], which is also accessible via an in-app link from the MyTherapy app.

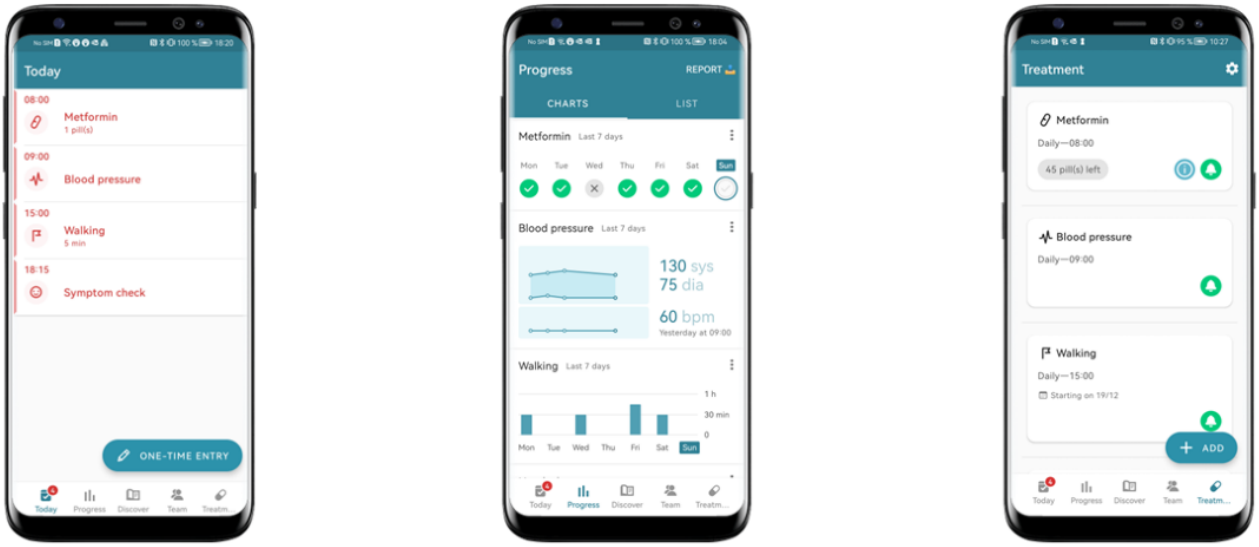
Ethics Approval

Ethics approval for this study was granted by the Ethics Committee of the North Rhine Medical Association (Ärztekammer Nordrhein) on October 13, 2022 (approval number 2022263).

Patient consent for the use of personal data is required for participation in the study. The patient information form explains in detail which data will be used for the study and obtains consent for the use of pseudonymized data.

XSL•FO
RenderX

Once the eCRF, including questions on UACR, is completed, patients will receive two €10 (US $10.8) vouchers for Shop Apotheke as compensation for their time spent on data documentation, 1 for completed questionnaires at baseline and 1 after follow-up.



Study Population

The study population consists of adult patients with T2DM in Germany using the MyTherapy app to document their medication intake and monitor adherence. Patients with a self-reported diagnosis of type 1 diabetes mellitus and patients who are treating their diabetes with an insulin pump are not eligible.

MyTherapy App

The MyTherapy app is a widely used medication management app (over 8 Mio Downloads, available in more than 30 languages) that helps patients manage their treatment-related tasks and other health topics, including comorbidities. The application allows the user to track medication intakes and activities and to review them over time. For this purpose, the application translates both simple and complex therapies into a daily list of "To do's," which are either related to "Medication," "Measurement," "Activity," or "Symptom check" (Figure 1). The app then supports the user, by reminding them of their health-related tasks; each user is asked to clear their daily list of "To do's" and is rewarded with a picture of the day afterward. App users can access all tracked events over time in the "Progress" section or request a printable report to be sent to their email address, which can be printed and brought to the next doctor's visit. Studies have already shown that the app strengthens adherence to medication and the doctor-patient relationship in patients with T2DM [24,25].

Figure 1. English version of the MyTherapy app sections "Today," "Progress," and "Treatment.".

The app can also, as in the context of this study, be extended by additional functionalities, such as educational content or surveys. In this case, the user benefits from all features of the basic MyTherapy app, while additionally having access to the extension. For this study, specific content (ie, video, patient information on the study) is provided, users are enabled to give informed consent to participate in the study, and a standardized eCRF is shared with and can be completed by MyTherapy app users who participate in the study.

As the MyTherapy app is routinely used by about 13,000 patients with T2DM in Germany to document their medication adherence and to monitor adherence to self-determined goals [24], it provides a cohort of patients suitable for this study. Therefore, usage of the MyTherapy app enables efficient recruitment of eligible patients and collection of relevant retrospective and prospective data with low operational effort.

Patient Journey and Study Procedure

Recruitment and Study Inclusion

Recruitment for this study is exclusively conducted via the MyTherapy app. All users of the MyTherapy app who have set up reminders for a diabetes medication automatically receive an invitation to participate in this study via push notification during their routine app use as well as a reminder 2 weeks later. An initial question further helps to identify the users with T2DM. In this context, the following medications or medical devices are considered for the initial selection of the target group: metformin, acarbose, dipeptidylpeptidase-4 inhibitor, glucagon-like peptide-1 receptor antagonist, renin-angiotensin system inhibitor, SGLT-2i, basal insulin, nonsteroidal mineralocorticoid receptor antagonist, sulfonylurea, and blood glucose test strips. Interested patients can find a video in German about the etiology of CKD and the importance of regular screening, as well as key information about the SMART-Finder study within the "Discover" section (available as Multimedia Appendix 1). After clicking on the push notification, users access information in German about the background and scope of this study and are able to access, read, and agree to the consent form for participation in this study.

Self-reporting of Data

All data will be entered by the patients themselves via the MyTherapy app, both as part of routine use and on a specifically developed eCRF in German. After completing the patient informed consent, an eCRF including 4 questionnaires is

XSL•FO
RenderX

provided and can be completed directly within the app: One questionnaire on demographic and general data, 1 on laboratory values, and 2 on quality-of-life aspects. The 2 quality-of-life questionnaires are standardized and validated (EuroQol Five Dimensions Questionnaire [EQ-5D] and DTSQ), both implemented for digital use. Table 1 summarizes variables collected within these 4 questionnaires of the eCRF. Multimedia Appendix 2 provides a detailed description of all variables, including their possible response options and ranges, collected in this study.

Table 1. Listing of variables collected in the electronic case report form.

Questionnaire/topic	Variables
General data	Name, zip code, year of birth, age, gender, weight (kg), height (cm), smoking habit; last systolic blood pressure, and last diastolic blood pressure
Laboratory values	UACR[a], eGFR[b], HbA_{1c}[c], and serum fasting glucose level
QoL I (DTSQ[d])	Satisfaction with current treatment; signs of hypoglycemia, signs of hyperglycemia; feasibility of treatment; satisfaction with the flexibility of actual treatment; satisfaction with own knowledge about the disease; recommendation of own treatment to others; and satisfaction with the continuation of current treatment
QoL II (EQ-5D-5L)	Mobility, self-care, usual activities, pain/discomfort, and anxiety/depression

[a]UACR: urine-albumin-creatinine-ratio.

[b]eGFR: estimated glomerular filtration rate.

[c]HbA_{1c}: hemoglobin A_{1c}.

[d]DTSQ: Diabetes Treatment Satisfaction Questionnaire.

Apart from demographic and general data, all questionnaires should be filled in twice by patients: first at baseline documentation and then 12 (±3) months after the initial UACR measurement ("end-of-observation documentation"). To remind participants of this second data entry, users receive an automatically generated push message.

During the first data entry (baseline documentation), patients are asked to document their most recent available lab values of the last 12 months in the eCRF for UACR, eGFR, HbA_{1c} (hemoglobin 1Ac), and blood pressure. If patients do not know these lab values, they are encouraged to request them from their treating physician. For this purpose, a document is provided via the "Discover" section in the app, which can be shared via email or can be printed to inform the treating physicians about lab values that are required and may still need to be collected.

Overall, laboratory values for baseline documentation can be recorded retrospectively for up to 12 months and prospectively for 3 months after giving informed consent for this study. In addition, patients also have to document fasting blood glucose values, smoking status, and aspects of their quality of life and disease awareness within the other questionnaires of the eCRF as part of this baseline documentation.

The "end of observation documentation" takes place 12 (±3) months after the first documented UACR measurement. Accordingly, the observation period (the period between the 2 UACR screenings) for each patient is 12 (±3) months; however, the period between providing informed consent and the end of observation may be less than 12 months due to the possibility of retrospectively collected UACR baseline data.

Each patient may withdraw from the study at any time and without giving a reason. In this case, no further study data will be collected.

Statistical Considerations

Sample Size

Based on approximately 13,000 MyTherapy app users with T2DM in Germany and recruitment rates from a comparable study focusing on patient adherence and physician-patient relations, participation of up to 5000 patients is expected [24].

Statistical Analysis

All variables are analyzed descriptively with appropriate statistical methods: categorical variables by (absolute and relative) frequency tables, frequencies, and continuous variables by sample statistics (ie, mean, standard deviation, minimum, median, quartiles, and maximum). Continuous variables are described by absolute value and as a change from baseline per analysis time point, if applicable. All analyses are performed for the total study population (overall analysis) and stratified by subgroups (eg, age, gender, and blood pressure), whenever reasonable.

Data Management and Quality

Data sources are limited to the MyTherapy app database including data that have been received from the health records of the treating physicians and documented in the eCRF by the patients. MyTherapy users only participate in the study after having signed study-related informed consent. Data are documented by the participating patients themselves. Data are not queried after data entry, but a check for multiple documented patients is performed.

To avoid free-text entries and queries, and to ensure convenient and accurate data entry, the eCRF is designed with all but 2 fields being checkboxes with suggested response options. Furthermore, incomplete questionnaires cannot be saved but must first be completed. While this may result in a higher dropout rate, it contributes considerably to the completeness of the data sets of study completers.

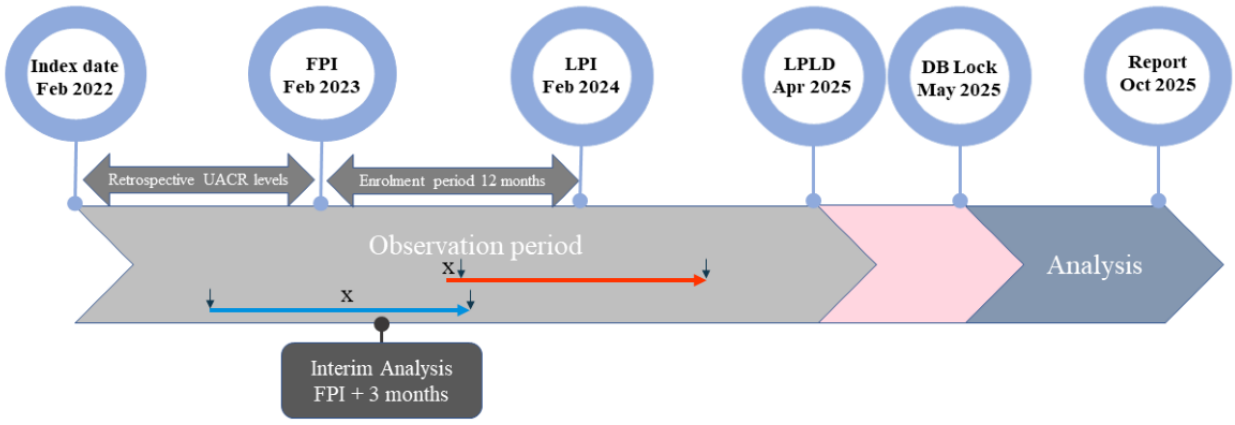
XSL•FO
RenderX

With regard to lab values, data entry is only allowed within certain ranges to minimize errors when transferring data (see Multimedia Appendix 2 for detailed information on acceptable ranges per variable). In addition, as described, patients are encouraged to request missing laboratory values from their treating physician and are supported with a document (Multimedia Appendix 2).

Moreover, with regard to the UACR values, patients are given the opportunity to request missing data over a certain period of time: Patients who state "UACR value not yet measured, but have made a doctor's appointment to have my UACR value measured" are informed twice at intervals of 2 weeks via push message that the UACR values are still missing. Subsequently, they must enter a UACR value or select "UACR value not measured." Otherwise, the questionnaire is considered as not answered, and the participant drops out of the study.

The category "value not measured" can only be selected for the lab values UACR, eGFR as well as HbA_{1c} and provides important information on how the guideline-compliant assessment of these lab values is implemented in routine clinical practice.

Smartpatient is assigned with the development of eCRFs and their integration into the MyTherapy app, the quality control of data collection, and the transfer of the pseudonymized study database to the clinical research organization Institute Dr Schauerte, Munich, Germany, which performs data analyses and data transfer to Bayer. Digital implementation of the 2 validated and standardized quality of life questionnaires in MyTherapy was reviewed and approved by their respective providers, that is, EuroQoL Research Association, Rotterdam, The Netherlands (for EQ-5D) and Prof Clare Bradley, Health Psychology Research, University of London, Egham, Surrey, UK (for DTSQ).



Trial Organization and Regulatory Authorization

This study is sponsored by Bayer Vital GmbH, Leverkusen, Germany. It is performed in collaboration with smartpatient GmbH, Munich, Germany, the provider of the MyTherapy app, a subsidiary of Shop-Apotheke, one of the largest internet-based pharmacies in Germany.

Results

The enrollment period of this study is planned from February 2023 (first patient in) until February 2024 (last patient in). During this period, patients accepting the invitation to participate in the study within the MyTherapy app are consecutively enrolled. Enrollment is stopped, after the target sample size of 5000 patients is reached or at the end of the planned enrollment period. Patients dropping out (eg, withdrawal, lost to follow-up) after the end of enrollment are not replaced. The observation period of each individual patient is 12 (±3) months (last patient last documentation: April 2025). An interim analysis is planned 3 months after the inclusion of the first patient and a final analysis after the study end. Figure 2 illustrates the study time frame.

Figure 2. Study time frame illustrating examples for patients with a retrospectively (blue arrow) and a prospectively (orange arrow) measured first UACR level. FPI: first patient in; LPI: last patient in; LPLD: last patient last documentation: DB, database; x = informed consent; ↓: UACR measurement.

Discussion

The study design presented here is novel, as it uses data exclusively documented by the patients in an app for the first time to collect information on the prevalence of CKD, risk factors, disease management, and quality of life of patients with T2DM. Since recruitment and data entry for this study are carried out via the MyTherapy app, which is routinely used by approximately 13,000 patients with T2DM in Germany, participation of about 5000 patients is expected. This provides a solid database to answer several scientific questions. This study is the first to estimate the proportion of patients with CKD or at high risk of developing CKD among patients with T2DM using UACR data documented exclusively by patients in the app. Also, any change in disease severity over the course of 12 months is identified in this way. In this context, it is a strength of the cohort study design presented here that the required laboratory values and especially UACR values are collected by HCPs and provided to their patients for entry into the app. It is expected that the study will make an important contribution to minimize the existing data gap in Germany regarding the prevalence of CKD in T2DM patients and contribute to a better understanding of its occurrence, severity, and risk of progression.

In addition, this study will also provide key data on the disease management and health care situation of patients with T2DM

XSL•FO
RenderX

in routine clinical practice in Germany. For example, adherence data of (co-)medications reported by patients in the MyTherapy app as well as the identification of treatment despite contraindication (taking nephrotoxic drugs) will provide important insights into therapy implementation in clinical routine.

Another key aspect is that the proportion of patients with T2DM who receive regular, guideline-compliant UACR and eGFR measurements at least once a year will be determined. To date, only limited data are available in this regard, which suggest a certain discrepancy with recommended annual screening and at least hesitant implementation of guideline-based diagnostics with some potential for improvement. A recent study on adherence to treatment guidelines in Germany, based on combined data from the *Diabetes Patienten Verlaufsdokumentation* and *Diabetes Versorgungsevaluation* databases, showed that only 49.1% of 116,747 patients with T2DM received annual CKD screening measurements [19]. Studies from Finland and Australia indicate similar results [20,21].

Considering that CKD screening in patients with T2DM is not yet universally implemented in clinical practice [19-21], another crucial aspect of this app-based study is the fact that it raises awareness of CKD risk in patients with T2DM and also fosters their self-responsibility and health literacy by pointing out the guideline-recommended UACR and eGRF screening of at least once a year. Furthermore, by providing study participants with a printable document for discussion with their treating physician in case of missing lab values, patients are empowered to take care of their disease themselves to a certain extent. For the future, this study also offers the possibility to establish a systematic, app-based early screening for CKD or other fields or indications.

Overall, the study aims to raise awareness of guideline-based management of patients with T2DM, both among physicians and patients and may help to improve early detection of kidney disease in patients with T2DM—a fundamental prerequisite for timely, guideline-based therapy that can prevent or delay disease progression and help to avoid end-stage renal disease.

Limitations of this study include, first, the fact that UACR values cannot be self-assessed by the patients, as the test strips are only approved for use by a health care professional. Even if a printable document is accessible to support medical consultation, it may still pose a barrier for some patients with T2DM to arrange a medical appointment and ask the doctor to collect this value. Therefore, missing UACR values might be a concern. On the other hand, the number of missing UACR values provides important insights into disease management and guideline adherence in Germany. Second, with a follow-up of 12 months, “digital” attrition, that is, a decreasing adherence to the app, is also to be expected, as its regular use may be challenging and may cause dropouts. Third, potential errors in data transmission are also a limitation as patients document values themselves without the possibility of querying them. However, efforts are undertaken to minimize transmission errors by permitting data entry only within a certain range (see Multimedia Appendix 2 for detailed information on the permitted ranges per variable). Fourth, the study population consists of patients with T2DM routinely using the MyTherapy app to review self-defined health goals and to support their medication adherence—and thus represents a biased subpopulation of health-conscious and technology-savvy patients with T2DM. Accordingly, it may be expected that the UACR screening rate determined in this study may rather represent an overestimation. Nevertheless, it can be assumed that, due to the recruitment and consecutive enrollment among health app users with only very limited exclusion criteria, the study population covered in this study is considerably more “heterogeneous” in terms of health than that in controlled, randomized clinical trials and can therefore provide a more realistic picture of the disease and management situation of T2DM patients in Germany.

In conclusion, it can be assumed that the study will provide important insights into the current disease management of patients with T2DM in everyday clinical practice in Germany as well as into the prevalence of patients with elevated UACR values in this T2DM cohort and will support guideline-based care of the participating patients.

Abstract

Background: Digital health technologies using mobile apps and wearable devices are a promising approach to the investigation of substance use in the real world and for the analysis of predictive factors or harms from substance use. Moreover, consecutive repeated data collection enables the development of predictive algorithms for substance use by machine learning methods.

Objective: We developed a new self-monitoring mobile app to record daily substance use, triggers, and cravings. Additionally, a wearable activity tracker (Fitbit) was used to collect objective biological and behavioral data before, during, and after substance use. This study aims to describe a model using machine learning methods to determine substance use.

Methods: This study is an ongoing observational study using a Fitbit and a self-monitoring app. Participants of this study were people with health risks due to alcohol or methamphetamine use. They were required to record their daily substance use and related factors on the self-monitoring app and to always wear a Fitbit for 8 weeks, which collected the following data: (1) heart rate per minute, (2) sleep duration per day, (3) sleep stages per day, (4) the number of steps per day, and (5) the amount of physical activity per day. Fitbit data will first be visualized for data analysis to confirm typical Fitbit data patterns for individual users. Next, machine learning and statistical analysis methods will be performed to create a detection model for substance use based on the combined Fitbit and self-monitoring data. The model will be tested based on 5-fold cross-validation, and further preprocessing and machine learning methods will be conducted based on the preliminary results. The usability and feasibility of this approach will also be evaluated.

Results: Enrollment for the trial began in September 2020, and the data collection finished in April 2021. In total, 13 people with methamphetamine use disorder and 36 with alcohol problems participated in this study. The severity of methamphetamine or alcohol use disorder assessed by the Drug Abuse Screening Test-10 or the Alcohol Use Disorders Identification Test-10 was moderate to severe. The anticipated results of this study include understanding the physiological and behavioral data before, during, and after alcohol or methamphetamine use and identifying individual patterns of behavior.

Conclusions: Real-time data on daily life among people with substance use problems were collected in this study. This new approach to data collection might be helpful because of its high confidentiality and convenience. The findings of this study will provide data to support the development of interventions to reduce alcohol and methamphetamine use and associated negative consequences.

Introduction

Background

Substance use disorder (SUD) is a major public health concern worldwide. The harmful use of alcohol is responsible for 5.1% of the global burden of disease (7.1% for males and 2.2% for females) [1]. The prevalence of heavy episodic drinking, defined as ≥60 g of pure alcohol on at least one occasion at least once per month, was 18.2% in 2016 among the total population [2]. Alcohol use disorders are more prevalent in high-income countries [2]. About 5.5% of the global population aged 15-64 years had used psychoactive drugs in the previous year, and about 35 million people are estimated to be affected by drug use disorders [3]. However, treatment access has been limited because of the increasing costs of the health care system, patient time demands, and concerns about stigma [4-7]. Additionally, alcohol and other substance use increased during the COVID-19 pandemic [8-10]. The need for accessible and effective health care services has increased.

Ecological Momentary Assessment

Advances in technology have the potential to reduce barriers to treatment services in this field. Broadly known as digital health or mobile health (mHealth), research in these areas uses mobile and computer software apps and wearable biosensor devices to understand and treat health conditions better [11-15]. In the field of SUD, various mobile apps have been developed to provide information on substance use and preventive health care services to continuously track specific health data such as substance use or support chronic condition management. Additionally, mHealth programs can help bridge treatment gaps by allowing patients to communicate with their physician or health care team without meeting face-to-face. One of the typical approaches of mHealth in this area is the ecological momentary assessment (EMA) method. The EMA approach has been developed to explore real-time substance use and motives, cravings, or triggers of substance use in daily life [12,16-19]. EMA has more benefits in capturing data on situations of substance use in the real world than cross-sectional or laboratory setting assessment because substance use is an episodic behavior influenced by immediate environmental factors (eg, external triggers) and internal factors such as stress and craving, which can be difficult to practically and ethically duplicate in an experiment environment [15-17]. Moreover, self-reported substance use can be biased by retrospective recall [20]. In a typical EMA, signaled prompts are sent to participants on a portable device (eg, smartphone) several times per day. The timing of the prompts depends on each study. There are generally the following 3 patterns: random time, fixed time, and event contingent. When participants receive these prompts, they are required to record their current thoughts, behaviors, and feelings on their devices.

Although EMA has advantages in assessing substance use accurately and repeatedly, compliance and missing data are still challenges [18,21]. Participants are likely to be unwilling to complete assessments during work, while studying, or when spending time with friends [22]. In people who use substances, noncompliance may occur because of an unstable life, comorbid psychopathology, and social pathology [17,23]. Missing data, especially systematically missing data (not at random), can lead to low statistical power and biased findings [18,24]. Uncomplicated EMA methods to minimize a participant's engagement with a collection tool are needed to increase compliance with the EMA protocol. Moreover, it is difficult to confirm the validity of the data collected by self-reported assessment [25], even when using EMA methods, because social desirability bias influences subjective judgment when people report situations regarding substance use, especially illicit drug use [26,27].

Wearable Activity Trackers

One of the solutions to the challenges of EMA might be the use of a wearable activity tracker (eg, Fitbit and Apple Watch), which can automatically collect participants' data. Although these products are not specifically made for the data collection on substance use, researchers can repeatedly gather various objective data, such as behavioral data (eg, steps and sleep) and biological data (eg, heart rate, blood pressure, and degree of stress). These devices have been used in observational studies to collect accurate real-time data [28-30], as well as in intervention studies to promote healthy behavior and improve health-related outcomes [31-33]. Also, numerous data collected repeatedly over minutes, hours, or days for a certain period enable the prediction of health outcomes using machine learning methods. For example, acute exacerbation of chronic obstructive pulmonary disease [34], depression [35], movement types [36], sleep stage [37], and COVID-19 symptom exacerbation [38] were detected by analyzing data collected using wearable devices.

If a wearable activity tracker and a self-monitoring tool that records variables related to substance use are combined in a study, researchers can collect behavioral and biological data with minimal reliance on participant input. Moreover, researchers can analyze the data collected by a wearable activity tracker in many ways because these data could be potential predictive factors of substance use or subsequent outcomes following substance use. Daily self-monitored behavioral data along with momentary biological data collected by wearable activity trackers have the potential to bridge important data gaps.

Purpose of This Study

This paper aims to introduce a procedure for implementing wearable tracker technologies as a method of EMA. We describe the methods to analyze data on substance use and psychological

XSL•FO
RenderX

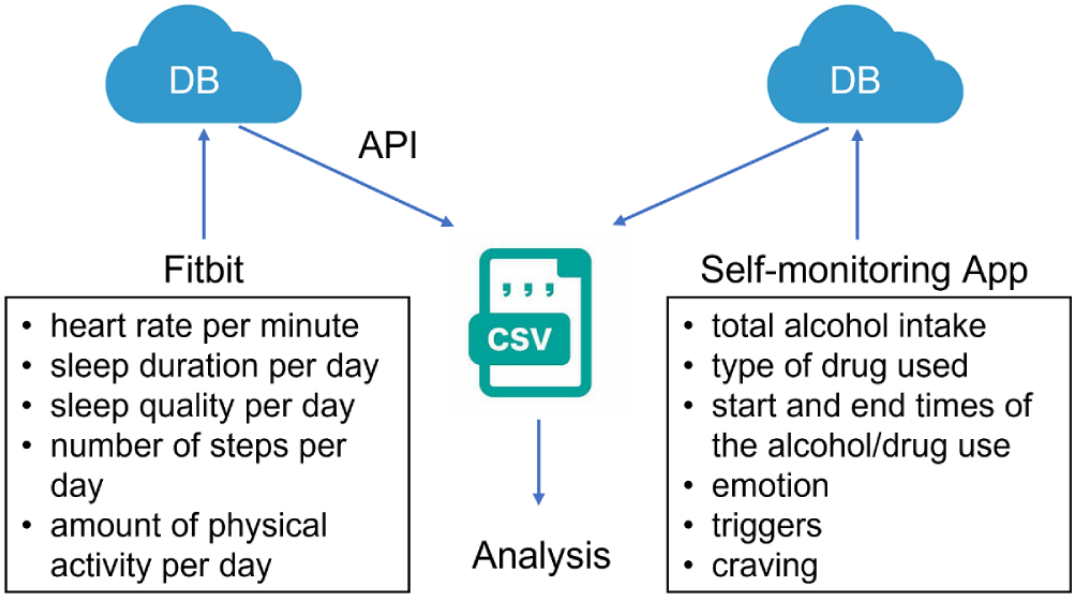
data using a self-monitoring app and objective behavioral and biological data using a wearable activity tracker (Fitbit). We will develop a predictive model of substance use by analyzing combined data using machine learning methods.

Methods

Materials and Equipment

Wearable Activity Tracker (Fitbit)

Fitbit (a registered trademark of Fitbit LLC) provides devices that offer a range of wearable activity trackers that can automatically track and display a users' daily activity, exercise, and sleep data in real time. Fitbit is designed for use on both Android and iOS smartphones. Its popularity has grown consistently over the years, selling approximately 16 million devices in over 100+ countries in 2019, with an active user community of over 29 million users [39]. The device used in this study was the Fitbit Inspire 2 which uses a combination of a 3-axis accelerometer and optical heart rate monitor in order to track daily steps, calories burned, distance traveled, active minutes, floors climbed, sleep duration and quality, heart rate, and GPS-based information [40].



Self-monitoring Apps

Two self-monitoring mobile apps were newly developed for use in this study, depending on whether the participant had mainly alcohol or drug-related problems. Self-monitoring is a widespread approach in mHealth apps in the field of substance use [41]. Moreover, self-monitoring is low-intensive, feasible, and effective for reducing substance use [42]. App content in this study were developed based on previous studies that implemented a web-based relapse prevention program in which treatment effectiveness was already validated [43]. The newly developed self-monitoring apps used validated content and user interfaces from the previous study.

Study Design

This study is an ongoing observational study using a Fitbit and a self-monitoring app (Figure 1). Participants were required to wear the Fitbit for 8 weeks as well as open the Fitbit app every day in order to sync the Fitbit data with their smartphones. Participants were also required to record daily entries in a self-monitoring app for 8 weeks and answer an in-app survey at the time of participation, 1-month, and 2-month follow-up. After the study was finished, participants received the Fitbit along with a gift card as compensation for participating in the study.

Figure 1. Content included in the self-monitoring apps. API: application programming interface; DB: database.

Participants and Recruitment

Participants were outpatients with alcohol or methamphetamine use disorders from 2 psychiatric hospitals in Japan. A psychiatrist specializing in SUD screened potential participants based on inclusion and exclusion criteria, and patients were referred to the study if applicable. General residents with alcohol problems were recruited through a research company. Considering realistic circumstances at each facility and the approximate number of participants required to adequately perform preliminary model testing using machine learning, 20 people with methamphetamine use problems and 40 people with alcohol problems were recruited for this feasibility study. Inclusion criteria were as follows: (1) alcohol consumption with health risks in the past year (Alcohol Use Disorders Identification Test [AUDIT]: 8-19 points) [44,45], or methamphetamine use with health risks in the past year (Drug Abuse Screening Test [DAST]-10: 1-8 points) [46,47]; (2) owning a smartphone (iOS14 or Android 7.0 or later); (3) being able to wear the Fitbit constantly for approximately 8 weeks and record the self-monitoring app daily; and (4) being 20 years of age or older. Exclusion criteria were as follows: (1) not being able to speak or write in Japanese; (2) not being able to access the internet or complete the web-based survey; (3) not being able to participate for the entire 8-week research period, and (4) attending an outpatient clinic and having been deemed unsuitable to participate in the study by their attending physician.

XSL•FO
RenderX

Measurements

Fitbit Data

The following data were measured while wearing the Fitbit for 8 weeks: (1) heart rate per minute, (2) sleep duration per day, (3) sleep stages per day, (4) the number of steps per day, and (5) the amount of physical activity per day. Data were synced from Fitbit to the Fitbit app every time it was connected to the participant's smartphone. These data were retrieved from the Fitbit servers daily through an application programming interface and stored per user in a secure database created for this study. If there were no records for over 3 days in the past week, an email reminder was sent to the participant by the researcher.

Self-monitoring Data

The following data were measured daily through the self-monitoring app for 8 weeks (Figure 2): (1) total alcohol intake in pure ethanol equivalent format or the presence and type of drug used (depending on whether the participants' main problem was alcohol or drug use), (2) general emotion of the day selected from 4 typical emotion symbols, (3) presence of alcohol or drug use triggers set by the participant, (4) degree of craving selected from a slider scale of 0-10 points, and (5) start and end times of the alcohol or drug use event. Data were retrieved from the self-monitoring app daily and stored per user in a secure database created for this study. Participants were advised to complete the daily entries at the end of each day, but were able to record entries the next day if it was difficult to record an entry before the end of the day.

Figure 2. Framework for data collection using Fitbit and self-monitoring app.

Survey Data

Overview

Surveys were conducted at baseline, 4 weeks, and 8 weeks from the start of participation (Table 1). Alcohol- and drug-related measurements and demographics, as well as treatment history information were collected at the baseline survey. The 4-week survey consisted of the alcohol- and drug-related measurements as well as the usability and satisfaction measures, and the 8-week survey included alcohol- and drug-related measurements. A reminder was sent to the users' registered email addresses when it was time to complete a survey, and a reminder email was sent after 3 days if the survey was not completed.

Primary substance (alcohol or drug)	✓		
Severity of substance use disorder (AUDIT[a] or DAST[b]-10)	✓		
Treatment history	✓		

[a]AUDIT: Alcohol Use Disorders Identification Test.

[b]DAST: Drug Abuse Screening Test.

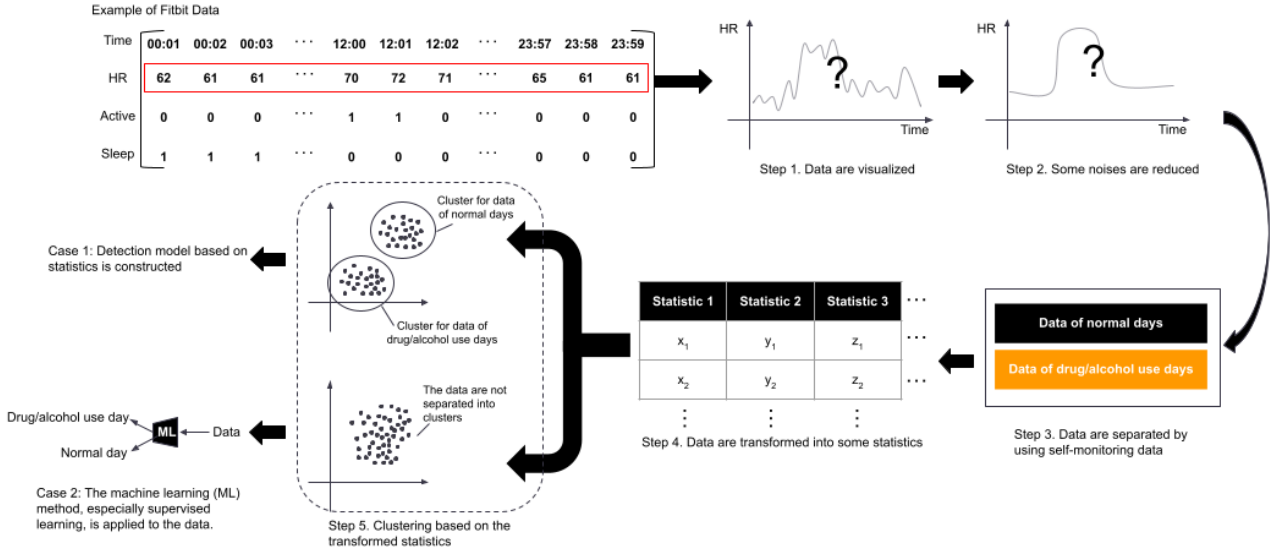
Alcohol- and Drug-Related Measurements

The amount of alcohol or drug consumed per day (grams of pure alcohol or drug equivalent) in the past 7 days and the number of drinking or drug-use days during the observational period were assessed in this section. Mental health was measured by the General Health Questionnaire abbreviated version with a range of 0-30 points, validated in a Japanese population sample with a cutoff of over 6 points indicating mental distress [48,49]. Health-related quality of life measures were assessed by the Short Form-8, with higher scores indicating higher quality of life, validated in Japanese by previous studies [50,51]. Finally, the degree of behavioral changes was measured by the University of Rhode Island Change Assessment Scale (URICA) [52]. A higher URICA score indicates further progress in behavioral change. URICA was translated into Japanese, and equivalence between the English and Japanese versions was partially confirmed with back translation.

Usability and Satisfaction

The System Usability Scale (SUS), which consists of a total of 10 items, was used to assess the ease of use of the app [53,54]. A higher SUS score means good usability for the self-monitoring app. User satisfaction was measured using the Japanese version of the Client Satisfaction Questionnaire (CSQ) [55,56]. A higher score for the CSQ shows better satisfaction while using the self-monitoring app. Any adverse events concerning physical problems or discomfort using the app were asked in an open-ended question. The validity and reliability of SUS and CSQ have been confirmed in previous studies [54,56].

Demographics and Treatment History



Gender, age, last education, employment status, and marital status were asked as general demographic data. The following were also asked concerning the participants' treatment history: the substance primarily responsible for the problem (alcohol, methamphetamine, marijuana, dangerous drugs, prescription drugs, over-the-counter drugs, organic solvents, or other drugs); the severity of SUD (AUDIT or DAST-10); the frequency of primary substance use in the past year; frequency of primary substance use in the past month (in days); the age of first alcohol or drug use; the age when first recognized an alcohol or drug use problem; the age when first sought medical care for an alcohol or drug use problem; social resources (medical institutions, mental health welfare centers, public health centers, or private addiction rehabilitation facilities); and the presence of comorbid psychiatric disorders and diagnosis.

Data Analysis

Fitbit's application programming interfaces capture data for heart rate per minute, sleep duration per day, sleep stages per day, the number of steps per day, and the amount of activity per day (hereafter referred to as "Fitbit data"). We finished collecting the data in April 2021 and are preparing to conduct data analysis. In order to determine substance use based on the Fitbit data, 3 steps were applied, as shown in Figure 3, and are described in further detail as follows:

XSL•FO
RenderX

Figure 3. Planned future data analysis. HR: heart rate.

First, the Fitbit data will be visualized to confirm typical Fitbit data patterns for individual users. There are many patterns to detect drug or alcohol use; for example, the heart rate may remain high while drinking alcohol. Accordingly, data visualization is beneficial for confirming such patterns. If, for example, we can detect a typical pattern as mentioned above, signals other than that pattern may be considered noise for this analysis. Subsequently, noise removal methods will be applied to the Fitbit data. For example, average heart rate or heart rate variability may also be influenced by exercise or walking rather than drug or alcohol use. Therefore, we will use step counts or activity amounts on Fitbit data to specifically filter out such movement or workout periods. Other possible methods for noise removal, in terms of signal processing, may include signal smoothing methods, for example, moving average and Gaussian filter. Methods will be chosen to retain typical patterns but remove the other signals.

Second, the Fitbit data will be analyzed by using statistical analysis methods in order to predict drug or alcohol use on a relatively long-term basis, such as within a day or a week. By using self-monitoring data, we can separate the Fitbit data into data reflecting substance use and data from normal activity. Some descriptive statistical methods, for example, averaging, variance, self-correlation, or frequency-domain analysis, will be applied to each parameter in the separated data sets to determine features that include the days a user has declared drug or alcohol use. In this analysis, survey data containing the participants' relation to drug or alcohol use, along with psychological and behavioral data points, may also be added as complements through the descriptive statistics. After transforming the data into its statistics, we would like to apply clustering methods to provide a quantitative evaluation of typical patterns reflecting drug or alcohol use.

There are 2 approaches to determining an optimal detection method for drug or alcohol use. If we can successfully obtain distinctive features by using the above statistical analysis, we will accordingly construct a detection model based on it. However, constructing such a model may be insufficient to isolate use with high accuracy and precision. Therefore, data analysis using both machine learning and statistical analysis methods will be performed in order to create a model that solves the problem as indicated above, based on the combined Fitbit and self-monitoring data. The primary candidate for machine learning methods will be Long Short-Term Memory. Long Short-Term Memory is considered one of the most suitable methods for analyzing time series data, which applies to this study. Meanwhile, other deep learning methods will also be considered to fit the data. The deep learning model will be carefully selected after we perform the statistical analyses, and then this model will be tested based on 5-fold cross-validation. Partitioning data depends on the degree of temporal precision with which drugs and alcohol consumption is estimated. Further preprocessing and machine learning methods will be conducted based on the preliminary results of the validation.

Ethical Considerations

This study was approved by the Ethics Committee of the Faculty of Medicine and Graduate School of Medicine of Tokyo Medical and Dental University (M2020-189) and the Institutional Review Boards of each recruiting hospital. Data collected from the self-monitoring app were automatically stored in a protected database. Fitbit data were archived from the Fitbit server and preprocessed on a cloud-based, protected database without personal information attached. These data were managed by Humanome Lab, Inc. Both self-monitoring data and Fitbit data were then matched using participants' ID numbers. Patients or participants provided their written informed consent in person before participating in this study.

Results

Enrollment for the trial began in September 2020, and the data collection was completed in April 2021. In total, 13 people with methamphetamine use disorder and 36 with alcohol problems participated in this study. Table 2 shows participants' demographics and days of methamphetamine use or drinking. The mean age of the participants was approximately 46 years. In the methamphetamine group, most participants were male, and 5 (38%) were unemployed. In the alcohol group, half of

XSL•FO
RenderX

them were male, and 26 (72.2%) were employed. The severity of methamphetamine or alcohol use disorder assessed on the DAST-10 or AUDIT-10 was moderate to severe. The resting heart rate measured by Fitbit was 72 in the methamphetamine group and 65 in the alcohol group, whereas the sleep duration per day was 408 minutes in the methamphetamine group and 386 minutes in the alcohol group.

There are 2 main anticipated results in this study. The first is to gain a better understanding of physiological and behavioral data before, during, and after alcohol or methamphetamine use. For example, an extended period of sleep deprivation may lead to a heightened sense of craving, and alcohol or methamphetamine use may increase. On the other hand, sleep quality may decrease due to several days of drinking.

The second anticipated result is to develop more personalized predictive models for alcohol or methamphetamine use. Data gathered through Fitbit are valuable in that it provides longitudinal and sequential data compared to periodic visits to hospitals. Although Fitbit is not a medical device, these data offer a new perspective into the daily life of participants with alcohol or methamphetamine problems. For example, individual participants may drink at night on workdays when stressed, and their heart rate increases to 110 beats per minute during the day.

In the future, understanding physiological and behavioral data and identifying individual patterns of behavior may lead to more effective personalized interventions that support preventive behaviors such as promoting eating or sleeping as a method of harm reduction when there is the detection of continuous levels of high stress and accelerated heart rate. Limitations of previous EMA and wearable tracker studies are still prevalent in this study, as compliance and missing data are still predictable risks. However, along with traditional deterrence methods such as data visualization, rewards, and reminders, this study uses consecutive biological data collected through Fitbit and an extended study period of 8 weeks to supplement missing data.

Discussion

In this study, we collected data related to substance use and consecutive biological and behavioral information simultaneously using Fitbit and a smartphone app. To the best of our knowledge, this study is the first to collect and analyze real-time data on daily life among people with substance use problems in Japan. Similar to other Asian countries, drug policies in Japan are strict, and there is severe stigmatization against people with substance use problems. The new approach to data collection in this study might be helpful because of its high confidentiality and convenience. We will analyze the data in 2023 and then recruit additional participants based on the results for a more robust analysis.

The use of digital health technologies will be increasingly necessary in the future. In fact, during the COVID-19 pandemic, innovations in cost-effective and user-friendly drug prevention and treatment services, such as internet-based or mobile phone-based services, accelerated to increase accessibility and coverage of services [10]. Accordingly, in future research, based on the findings of this study, we will develop an ecological momentary intervention program to encourage participants to reduce substance use and negative consequences.

Acknowledgments

We wish to thank Dr Kanae Myoenzono for helping us to prepare for the acquisition of Fitbit data. We also thank Mr Junichiro Matsuda and Mr Gen Kikuchi from KANAME Co, Ltd. for the development of the self-monitoring app and for helping us prepare the data analysis. This work was supported by JSPS KAKENHI grant JP20H03977. This study was also partially funded by Revi Co, Ltd. The funders were not involved in the study design, collection, analysis, interpretation of data, writing of this paper, or decision to submit it for publication.

Data Availability

The data sets in this study are not available because we have not obtained the agreement of participants to disclose raw data or the approval of the ethics committee in each institution for data sharing.

Authors' Contributions

AT, MS, MO, and JS were involved in the study design and protocol. AT, KO, KN, YY, and TM were involved in participant recruitment and management of the study. AT, KO, MS, MO, and JS were involved in the preliminary data consideration and analysis, and drafted the manuscript. All authors critically revised the manuscript and approved the final version.

Abstract

Background: Paroxysmal atrial fibrillation (AF) is a probable cause of cryptogenic stroke (CS), and its detection and treatment are important for the secondary prevention of stroke. Insertable cardiac monitors (ICMs) are clinically effective in screening for AF and are superior to conventional short-term cardiac monitoring. Japanese guidelines for determining clinical indications for ICMs in CS are stricter than those in Western countries. Differences between Japanese and Western guidelines may impact the detection rate and prediction of AF via ICMs in patients with CS. Available data on Japanese patients are limited to small retrospective studies. Furthermore, additional information about AF detection, including the number of episodes, cumulative episode duration, anticoagulation initiation (type and dose of regimen and time of initiation), rate of catheter ablation, role of atrial cardiomyopathy, and stroke recurrence (time of recurrence and cause of the recurrent event), was not provided in the vast majority of previously published studies.

Objective: In this study, we aim to identify the proportion and timing of AF detection and risk stratification criteria in patients with CS in real-world settings in Japan.

Methods: This is a multicenter, prospective, observational study that aims to use ICMs to evaluate the proportion, timing, and characteristics of AF detection in patients diagnosed with CS. We will investigate the first detection of AF within the initial 6, 12, and 24 months of follow-up after ICM implantation. Patient characteristics, laboratory data, atrial cardiomyopathy markers, serial magnetic resonance imaging findings at baseline, 6, 12, and 24 months after ICM implantation, electrocardiogram readings, transesophageal echocardiography findings, cognitive status, stroke recurrence, and functional outcomes will be compared between patients with AF and patients without AF. Furthermore, we will obtain additional information regarding the number of AF episodes, duration of cumulative AF episodes, and time of anticoagulation initiation.

Results: Study recruitment began in February 2020, and thus far, 213 patients have provided written informed consent and are currently in the follow-up phase. The last recruited participant (May 2021) will have completed the 24-month follow-up in May 2023. The main results are expected to be submitted for publication in 2023.

Conclusions: The findings of this study will help identify AF markers and generate a risk scoring system with a novel and superior screening algorithm for occult AF detection while identifying candidates for ICM implantation and aiding the development of diagnostic criteria for CS in Japan.

KEYWORDS

atrial cardiomyopathy; atrial fibrillation; biomarker; cryptogenic stroke; insertable cardiac monitor

Introduction

Stroke is a leading cause of mortality and disability worldwide. A primary goal of stroke management is to clarify the stroke etiology to optimize secondary prevention. Despite standard extensive diagnostic workups, approximately 15%-40% of all ischemic stroke cases are of unknown etiologies and are classified as cryptogenic [1]. Cryptogenic stroke (CS) is heterogeneous in origin, but most cases involve embolic mechanisms. Paroxysmal atrial fibrillation (AF) is suspected to be a major cause of CS, and patients are likely to develop severe cerebral infarction in the absence of anticoagulation therapy. Current guidelines recommend a secondary prevention regimen of antiplatelet agents to prevent stroke recurrence in patients diagnosed with CS and for whom the AF status is unknown. Long-term cardiac rhythm monitoring can reveal occult AF that may otherwise be missed by conventional short-term monitoring [2]. Since September 2016, insertable cardiac monitors (ICMs) for patients with CS have been covered by insurance in Japan.

The term “embolic stroke of undetermined source” (ESUS) has been proposed to describe CS that is not lacunar and is not associated with proximal arterial stenosis or a recognizable cardioembolic source [1]. Two international ESUS trials demonstrated that oral anticoagulants (rivaroxaban and dabigatran) were not superior to aspirin for the prevention of recurrent stroke after ESUS [3,4], although a secondary analysis in the RE-SPECT ESUS (Randomized, Double-Blind Evaluation in Secondary Stroke Prevention Comparing the Efficacy and Safety of the Oral Thrombin Inhibitor Dabigatran Etexilate Versus Acetylsalicylic Acid in Patients With Embolic Stroke of Undetermined Source) study demonstrated that, compared with aspirin, dabigatran was associated with a lower risk of recurrent stroke among Japanese patients with ESUS [5]. In Japan, magnetic resonance imaging (MRI) is widely used in the diagnosis of stroke. The Japanese guidelines indicate that MRI is essential in the selection of candidates with CS eligible for ICM implantation [6]. Branch atheromatous disease (BAD) is a single subcortical infarction larger than lacunar stroke in the territories of deep perforators without relevant arterial stenosis [7]. The Japanese guidelines on the clinical indications for ICMs recommend that BAD should not be considered as an indication because it results from a nonembolic mechanism [6]. These procedural differences between Japan and Western countries may impact the detection rate and predictors of AF in patients with CS. However, available data on Japanese patients are limited to small retrospective studies. Furthermore, additional

XSL•FO
RenderX

information about AF detection, including the number of episodes, cumulative episode duration, anticoagulation initiation (type and dose of regimen and time of initiation), rate of catheter ablation, role of atrial cardiomyopathy, and stroke recurrence (time of recurrence and cause of the recurrent event), was not provided in the vast majority of previously published studies [8,9].

This study aims to clarify the proportion and timing of AF detection via ICMs in patients diagnosed with CS in Japan. Additionally, we aim to identify risk stratification criteria using real-world data, which could then be used in clinical practice to predict occult AF, identify optimal candidates for ICM implantation, and inform the development of diagnostic criteria.

Methods

Study Design

The LOOK (a multicenter observational study on the detection of AF using insertabLe cardiac mOnitors in patients with cryptOgenic stroKe) registry is an observational, multicenter, prospective registry of patients who have been diagnosed with CS and implanted with an ICM. The Medtronic CareLink Network is being used to remotely transmit the device data.

Ethics Approval

Ethical approval for this study was obtained from the ethics review committee of Nippon Medical School (B-2019-043) and from the relevant ethics committees of all participating centers. Written informed consent is required from all patients or their family members before study participation. This study is registered with the University hospital Medical Information Network (UMIN) Clinical Trial Registry (UMIN000039809).

Patient Population

Patient enrollment for this ongoing study started in February 2020 in 24 medical institutions throughout Japan. The inclusion criteria for this study are as follows: (1) patients who have been diagnosed with CS according to the Japanese diagnostic criteria and have been implanted with an ICM (Reveal LINQ), and (2) patients aged 40-90 years. The main exclusion criterion is the presence of contraindications for MRI. A full description of the inclusion and exclusion criteria is presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Patients of either sex, between 40 and 90 years of age
- Patients diagnosed with cryptogenic stroke and implanted with an insertable cardiac monitor
- Patients (or their legal representatives) who have given written consent

Exclusion criteria

- Patients with a history of atrial fibrillation and atrial flutter
- Patients with permanent contraindications or indications for oral anticoagulants
- Applicable patients with pacemaker or implantable defibrillator implantation
- Magnetic resonance imaging–contraindicated patients
- Patients diagnosed with life expectancy within 2 years due to some disease
- An inappropriate decision made by the investigator

Data Collection

The study data, such as patient background, laboratory data, coagulation test, B-type natriuretic peptide, physiological examination (electrocardiogram [ECG], transthoracic echocardiography, transesophageal echocardiography [TEE], and carotid echocardiography), neuroimaging examination, Mini-Mental State Examination (MMSE), modified Rankin Scale (mRS), and presence of cardiovascular events, gastrointestinal bleeding, and other adverse events, or death (Table 1 and Textbox 2), will be stored on an encrypted website and will be accessible only to study researchers with appropriate training and ethics review board approval. Data monitoring will be performed independently by the study steering committee.

[c]TTE: transthoracic echocardiography.

[d]TEE: transesophageal echocardiography.

[e]MRI: magnetic resonance imaging.

[f]MMSE: Mini-Mental State Examination.

[g]mRS: modified Rankin Scale.

Textbox 2. Detailed survey items in this study.

Patient characteristics

- Age, sex, body mass index, prestroke modified Rankin Scale (mRS) score, antithrombotic therapy before the index case, previous stroke, hypertension, dyslipidemia, diabetes mellitus, alcohol intake, smoking, peripheral artery disease, history of cancer, education level, and CHA_2DS_2-VASc (Congestive Heart Failure, Hypertension, Age [≥75 years], Diabetes, Stroke/Transient Ischemic Attack, Vascular Disease, Age [65-74 years], Sex [Female]) score

Neuroimaging

- Distribution of infarct lesions, infarct size, number of infarcts, major vessel occlusion, intra-arterial signal signs, susceptibility vessel signs, Diffusion-Weighted Imaging—Alberta Stroke Program Early Computed Tomography Scores, natural recanalization, hemorrhagic transformation, number and location of cerebral microbleeds, old cortical lesions, and recurrence of stroke after magnetic resonance imaging

Electrocardiogram (ECG) and Holter ECG

- Deep terminal negativity of the P-wave V1, P-wave terminal force in lead V1, P axis, PR interval, heart rate–corrected QT interval, and the number and percentage of atrial premature contractions and ventricular premature contractions

Blood examination

- Routine blood biochemistry examinations, including creatinine clearance and measurements of D-dimers, C-reactive protein, brain natriuretic peptide (BNP), and N-terminal prohormones of the BNP

Transthoracic echocardiography and transesophageal echocardiography

- Left atrium diameter, left atrial volume index, valvular disease, right to left shunt, aortic plaque thickness and morphology, spontaneous echo contrast, left atrial appendage filling and emptying velocity, left ventricular ejection fraction, atrial septal aneurysm, and strand readings

Carotid ultrasound

- Max intima-media thickness, plaque morphology, internal carotid artery stenosis as assessed by the European Carotid Surgery Trial method, peak systolic velocity, and end diastolic velocity

Incidence of recurrent stroke or transient ischemic attack

Use and type of oral antithrombotic therapy and antiarrhythmic drugs

Stroke severity assessed using the mRS and the National Institutes of Health Stroke Scale

Cognitive status evaluated through the Mini-Mental State Examination

Cardiovascular events, gastrointestinal bleeding, cancer, other adverse events, or death

XSL•FO
RenderX

Sample Size

Recent retrospective observational ICM studies have demonstrated that major vessel occlusion (n=84) and frequent premature atrial contractions (n=66) were associated with AF detection after adjustment for risk factors and comorbidities, respectively [8,9]. A subanalysis of the CRYSTAL AF (Cryptogenic Stroke and Underlying AF) study (including 221 patients with a 30% AF detection rate) demonstrated that older age and longer PR interval were associated with an increased likelihood of detecting AF [10]. On the basis of the results of these previous studies, we decided to enroll 200 patients in this observational study to perform statistical analyses, including multivariate regression analysis, with sufficient statistical power.

Data Analysis Plan

Table 1 presents an overview of the protocol schedule for this study. Categorical variables will be expressed as frequencies and percentages, whereas continuous variables will be expressed as mean with SD or median with IQR, as appropriate. Patient characteristics, medical history, vital signs, laboratory data, the CHA_2DS_2-VASc (Congestive Heart Failure, Hypertension, Age [≥75 years], Diabetes, Stroke/Transient Ischemic Attack, Vascular Disease, Age [65-74 years], Sex [Female]) score, neuroimaging characteristics, ECG characteristics, TEE characteristics, MMSE score, mRS score, and stroke recurrence will be compared between patients with AF and patients without AF (Textbox 2). Intergroup differences will be assessed using the chi-square test or the Wilcoxon rank-sum test, as appropriate. The Yates correction or the Fisher exact test will be used if the validity conditions for the chi-square test are not met (theoretical number <5). Furthermore, we will obtain additional information regarding the number of AF episodes, duration of cumulative AF episodes, and time of anticoagulation initiation. We will investigate the rate of initial AF detection within the initial 6, 12, and 24 months after ICM implantation using Kaplan-Meier survival estimates. Cox proportional hazards regression models will be fitted to various baseline characteristics for the prediction of AF. Receiver operating characteristic curve analysis will be performed to assess the predictive accuracy of a variable in AF detection. All analyses will be performed via JMP version 13 (SAS Institute Inc), with $P<.05$ indicating statistical significance.

Study Organization

The LOOK study has been organized by a central coordinating center at the Department of Neurology, Nippon Medical School, and is being conducted at 24 medical centers throughout Japan. A steering committee is managing the trial.

Results

Study recruitment started in February 2020, and thus far, 213 patients have provided written informed consent in May 2021 and are currently in the follow-up phase. The last recruited participant will have completed the 24-month follow-up in May 2023. Data cleanup and analyses are projected to be completed by September 2023, and the results are expected to be submitted for peer-reviewed publication in 2023.

Discussion

Principal Findings

Recent meta-analyses demonstrate that, compared with short-term monitoring, prolonged cardiac rhythm monitoring is associated with higher rates of AF detection, a higher incidence of anticoagulation initiation, and reduced stroke recurrence in patients with CS [11]. However, these studies were mainly conducted in Western countries, and the generalizability of these findings to Asian populations is unclear. We are therefore conducting this study, in which we will recruit patients prospectively and identify the proportion of patients with AF to effectively compare the characteristics and outcomes with respect to the presence and absence of AF in patients with CS in Japan.

Some testing biases are affected by geographic location; for example, brain MRI is used less frequently in European patients with ESUS [12]. However, there is better access to MRI in Japan, and it is often implemented upon hospital admission as well as during follow-ups. Furthermore, MRI is necessary for the selection of candidates for ICMs according to Japanese guidelines [6]. This study is thus investigating detailed MRI findings, such as the presence of lesion patterns, susceptibility vessel signs, hemorrhagic transformation, old cortical lesions, and new asymptomatic lesions, during follow-up.

Recent evidence indicates that atrial cardiomyopathy, diagnosed by the presence of serum or electrocardiographic biomarkers, leads to AF and may result in thromboembolism even before AF manifests [13,14]. In this study, we are investigating not only the left atrial diameter but also the left atrial volume index and P-wave parameters in ECG, including P-wave terminal force in V1. Atrial cardiomyopathy may explain a proportion of ESUS cases, although AF is currently the sole diagnostic criterion for atrial thrombogenic potential. ARCADIA (AtRial Cardiopathy and Antithrombotic Drugs In Prevention After Cryptogenic Stroke) is an ongoing trial investigating whether anticoagulant therapy reduces the occurrence of stroke in patients with atrial cardiomyopathy without known AF [15]. This study will clarify the association among atrial cardiomyopathy markers, AF, and stroke recurrence in patients with CS.

A previous retrospective study reported that plasma brain natriuretic peptide (BNP) levels were elevated in the acute phase of stroke but were substantially reduced in patients with cardioembolic stroke [16]. This suggests that fluctuating levels of BNP or N-terminal prohormone of BNP (NT-proBNP) may be associated with occult paroxysmal AF. However, serial changes in plasma BNP or NT-proBNP levels in patients with CS and ICMs have not been fully investigated. In this study, we will be conducting serial measurements of BNP or NT-proBNP levels.

Conclusions

By conducting this prospective LOOK multicenter study, the characteristics of patients with occult AF detected by ICMs will be clarified in more detail than previously reported by analyzing imaging studies on admission and during follow-up, serial

XSL•FO
RenderX

measurements of blood markers, and various physiological findings. We hope that our findings will contribute to the identification of markers and enable the development of a risk scoring system with a new and better screening algorithm, which could inform future guidelines for stroke screening in patients with CS as well as the development of comprehensive clinical trials.

Acknowledgments

We would like to thank all collaborators and LOOK investigators for their help with participant recruitment. The LOOK study received funding support from Medtronic Japan Co, Ltd.

Data Availability

Deidentified participant data will be shared on request. Researchers who make the request should include a methodologically sound proposal on how the data will be used. They will also need to sign a data access agreement. The corresponding author can be contacted directly to request data sharing.

Abstract

Background: The COVID-19 pandemic and the halt to in-person research activities beginning in March 2020 brought new challenges to protocol development and implementation. Due to the pandemic, we had to revise our protocol for the Brain Relationships Among Information, Neuroprocessing, and Self-Management (BRAINS) study, which was designed to examine health information behavior, brain activity, diabetes status, and self-management behavior among Black women with hypertension.

Objective: This report outlines 7 steps describing how our research team (1) revised the BRAINS study protocol, (2) implemented a remote method of data collection, and (3) mitigated the challenges we faced.

Methods: Prior to March 2020, Black women with hypertension were invited to participate in the BRAINS study to undergo a functional magnetic resonance imaging scan, complete surveys, have their blood pressure measured, and have their blood drawn. After these measures were collected, participants would receive phone calls from a dietician to complete two 24-hour dietary recalls using the Nutrition Data System for Research. Our revised protocol relied on a web-based, interactive approach. Participants received a study kit that included an Omron automatic home blood pressure monitor and a hemoglobin A_{1c} kit from the DTIL laboratory. In a Zoom meeting with each participant, our team played an introductory video, administered surveys (via Qualtrics), and guided participants through measuring their blood pressure and performing a finger stick to collect a blood sample for hemoglobin A_{1c} testing. We examined cognitive function using the TestMyBrain Digital Neuropsychology Toolkit, as we were unable to access the functional magnetic resonance imaging laboratory to assess brain activity. The 7 steps in revising our protocol were as follows: conceptualizing the move from in-person to remote study activities (step 1); contacting the funders (step 2); submitting changes for Institutional Review Board approval (step 3); preparing to implement the revised protocol (step 4); implementing the study changes (step 5); mitigating challenges (step 6); and evaluating protocol implementation (step 7).

Results: Approximately 1700 individuals responded to web-based advertisements about the BRAINS study. A total of 131 individuals completed our eligibility screener. We conducted our first Zoom appointment in July 2020 and our last Zoom appointment in September 2020. Using our revised strategies, a total of 99 participants completed all study measures within a 3-month period.

Conclusions: In this report, we discuss successes and challenges in revising our protocol and reaching our population of interest remotely, safely, and effectively. The information we have outlined can help researchers create similar protocols to reach and conduct research remotely with diverse populations, such as individuals who are unable to participate in studies in person.

Introduction

The COVID-19 pandemic complicated the delivery of medical care and the implementation of research studies [1]. While health assessments typically occur in person and include blood pressure readings and other tests conducted by a trained professional, these standards of care were not feasible given the "Stay at Home" orders and imminent dangers of being in-person for routine health care appointments. During the beginning of the pandemic, there was a significant decrease in the "usual care" of preventative screening and monitoring of chronic illnesses [2,3].

Consequently, a shift to self-reported data emerged after March 2020. Although self-reported data has the benefit of being easier to obtain at a smaller expense, there are some considerable drawbacks. These include some participants' inability and willingness to recall and report their measurements [4]. Factors such as age, formal education level, and regular access to health care professionals impact the accuracy of self-reporting, especially self-reporting of hypertension status [5]. Given barriers to accessing health care services at the beginning of the COVID-19 pandemic, the discrepancies related to self-reported data were even more concerning, particularly among vulnerable groups like Black women with hypertension.

Hypertension affects approximately 57.6% of Black women in the United States [6]. Black women who have hypertension are also more likely to have higher blood pressure levels, which increases the risk for other chronic illnesses, such as end-stage renal disease and type 2 diabetes [7]. While hypertension and type 2 diabetes frequently co-occur among all racial and ethnic groups, Black women's odds of this comorbidity are 6 times higher than the odds for White women [8]. Additionally, Black women are the most likely of any racial group to have undiagnosed diabetes [9].

The decrease in usual care at the beginning of the pandemic was even more concerning for individuals who were already part of vulnerable groups, such as Black women with hypertension. Previously, some health care professionals reported difficulty in reaching diverse populations, and this was magnified during the pandemic [10-12]. Prior to the pandemic, previous studies highlighted the barriers to reaching Black individuals with chronic illnesses [10,11]. Not only were Black individuals more severely affected by COVID-19 [12-14], those with chronic illnesses were more likely to have increased difficulty in managing them [15,16]. Previous studies highlight the viability of videoconferencing platforms as tools to meet with patients, but state that additional studies are needed to further assess their utility [17,18].

Prior to the COVID-19 pandemic, we developed an in-person protocol (Brain Relationships Among Information, Neuroprocessing, and Self-Management [BRAINS]) to assess the relationships among health information behavior, brain activity and executive function, diabetes status, and health outcomes among Black women with hypertension. However, to ensure the safety of our participants and our research team, we had to move to remote data collection during the COVID-19 pandemic. In this report, we outline the following seven steps we completed in modifying the BRAINS study: (1) conceptualizing how to move from in-person to remote, (2) contacting funders, (3) submitting Institutional Review Board (IRB) changes, (4) preparing to implement our revised protocol, (5) implementing our protocol, (6) mitigating the challenges we faced, and (7) evaluating our implementation. This study was novel not only because we were able to quickly pivot to remote data collection, but we also were able to reach our diverse population of interest (Black women with hypertension), which is traditionally regarded as a "difficult to reach" group [19]. Future studies can use these guidelines to develop thoughtful, informed, evidence-based, and carefully crafted protocols to reach other diverse or underrepresented populations.

Methods

Study Overview

The BRAINS study aimed to examine relationships among health information behavior, brain activity, diabetes status, and self-management behavior among Black women with hypertension. The study design was descriptive, cross-sectional, and measured concepts using surveys, blood pressure readings, serum testing, and functional magnetic resonance imaging (fMRI) scans (see Textbox 1 for a list of measures). After receiving IRB approval, study recruitment began in June 2020. We used a Facebook campaign to seek individuals who self-identified as Black women. Additional inclusion criteria were being 21-64 years of age, being diagnosed with hypertension by a health care professional, having access to a computer or tablet, and living in the metro Detroit area (determined by zip code).

Textbox 1. Brain Relationships Among Information, Neuroprocessing, and Self-Management study measures.

Measures:

- Health information behavior [20]
- Neuroprocessing using functional magnetic resonance imaging [21]
- Self-efficacy [22]
- Self-regulation [23]
- Patient activation [24]
- Self-management diet behaviors (Nutrition Data System for Research) [25-27]
- Blood pressure [28,29]
- hemoglobin A_{1c}(HbA_{1c}) [30]
- Quality of life (Patient-Reported Outcomes Measurement Information System) [31]
- Basic cognitive assessment—Montreal Cognitive Assessment [32]

Ethical Considerations

This study was reviewed and approved by the University of Michigan IRB (HUM00138174). Women who were interested in participating in the study reviewed the BRAINS study consent form, then provided informed consent by clicking "Yes, I consent," prior to completing study measures in Qualtrics [33]. Each participant was assigned a study ID number. All study data were deidentified and stored according to study ID. After participants completed all study measures, they received US $75 gift card to compensate them for their time.

In this report, we outline the 7 steps that we completed to revise our BRAINS study from an in-person protocol to a fully remote study.

Steps in Revising the Protocol

Step 1: Conceptualizing the Move From In-Person to Remote Study Activities

The COVID-19 pandemic brought all in-person study activities to a complete halt. We had to decide if we were going to suspend our study activities or pivot to a fully web-based format. We asked the following questions:

(1) *How can we meet safely with our participants?* The first decision we made was to use Zoom, a videoconferencing platform, to meet with our participants [17]. We felt that Zoom would be the best web-based platform where we could send links to surveys and assist participants as needed. We were already using Qualtrics as a platform for our surveys, so we were sure that we could continue to use it remotely by sending participants a link.

(2) *Of the remaining measures, which can be collected remotely and which cannot?* In addition to the surveys we planned to deliver via Qualtrics, we still needed to determine how to collect blood pressure readings, serum testing, and fMRI scans, or find alternative measures. See Table 1 for an overview of the original protocol compared to the protocol changes and revisions.

(i) *Blood pressure measurement*. To obtain participants' blood pressure readings, we selected the Omron 10 series automatic home blood pressure monitor (HBPM). We selected this HBPM for 2 reasons. First, the Omron 10 Series HBPM received satisfactory results during validation testing [34,35]. Second, this HBPM contains a cuff that can accurately obtain blood pressure readings on an arm with a circumference of 9 inches to 17 inches, which is a larger cuff than others included with most HBPM [36]. This allowed for accurate blood pressure readings from a wide variety of participants, and less concern about the diameter of the participant's arm.

(ii) *Blood glucose measurement*. Our team had a previously established relationship with DTIL, a company that packaged and processed at-home hemoglobin HbA_{1c} tests. Therefore, we send their kits to participants to assess their blood glucose levels [30].

(iii) *Measures we were unable to capture*. We did not find at-home alternative measures for high-sensitivity C-reactive protein collection or the fMRI scans. The cost of doing an at-home high-sensitivity C-reactive protein test was not feasible for this study, and there is no replacement for the brain activity data that can be gathered from an fMRI scan. However, we were able to gather data on cognitive function pathways using Harvard University's TestMyBrain, which is a web-based battery of neurocognitive tests [37].

(3) *How will we get the new required supplies to our participants?* We decided to mail participants a study welcome kit that included a welcome letter, a HBPM, and a HbA_{1c} test. We chose to use United Parcel Service to mail the kits because their shipping time estimates were the fastest, and we did not want any delays in getting our supplies to our participants. Our university also had an account preregistered with United Parcel Service that would bill directly to our study's shortcode. All supplies were inventoried before being sent out, and the HbA_{1c} kits were labeled with our study participant ID numbers to make sure that each sample and result would be matched to their other study results.

(4) *How will we obtain informed consent?* We met with our institution's IRB staff to understand how to prepare for and obtain consent remotely. We were advised that we needed to present the consent form to participants in the same format as we usually would, and they would need to read the consent

XSL•FO
RenderX

themselves. Contact information for the study was given in multiple places, in case potential participants had questions about their participation. At the bottom of the consent page, we asked if participants had thoroughly read and agreed to participate in all study activities. They could either check yes or no. If they checked yes, they were able to complete screening questions to confirm their eligibility for the study. If they checked no, they were routed to a screen that thanked them for their time.

Table 1. The Brain Relationships Among Information, Neuroprocessing, and Self-management (BRAINS) study protocol—original, revised, and additions.

Measure	BRAINS in-person (original protocol)	BRAINS remote (revised protocol)	Additions to revised protocol
Qualtrics surveys	Completed on an iPad, sitting next to a study team member	Completed during a Zoom appointment, with a study team member	Added 7 questions about changes required to blood pressure self-management routine
fMRI[a] scan	Completed in the fMRI laboratory	Unable to conduct	None
Cognitive assessment	MoCA[b]	MoCA	TestMyBrain
Blood pressure	Measured by a study team member	Measured by the participant, with guidance from a study team member	None
HbA_{1c}[c]	Collected by a research nurse	Collected by the participant, with guidance from a study team member	None
High-sensitivity C-reactive protein	Collected by a research nurse	Unable to collect	None
24-hour dietary recall	Collected by a dietician via telephone	Collected by a dietician via telephone	None

[a]fMRI: functional magnetic resonance imaging.

[b]MoCA: Montreal Cognitive Assessment.

[c]HbA_{1c}: hemoglobin A_{1c}.

Step 2: Contacting the Funders

After we conceptualized the changes required and had evidence to support each change, we were able to reach out to the lead investigators who obtained the funds for this study. There were 2 funding sources to support this study; both sources of funding were National Institute of Health center pilot grants (P20 and P30). We wrote a letter to both center directors, briefly describing the challenges we were facing and requesting a meeting to discuss the changes we wanted to implement. During both meetings (Zoom), we displayed PowerPoint slides with our revised study aims and goals for the safety of both participants and members of our team. After meeting with both center directors, we received feedback that our changes were thoughtful and reasonable; therefore, approval to revise the protocol was granted.

Given that we could not access the fMRI lab and complete the fMRI scans, we had an excess of funds to spend. Included in our letter to the center directors was a request to increase the sample size from 50 to 100 participants. We were also able to increase our study incentive to further encourage participation. Both directors agreed that this request made sense and approved it, so we created an IRB amendment to receive their approval as well.

Step 3: Submitting Changes for IRB Approval

We met with a representative from the University's IRB team to receive guidance on revising our protocol. We wanted to make sure that we were aware of all the new requirements related to the COVID-19 pandemic. We asked questions about remote consent, how other studies implemented revisions to their protocols, and how long we could expect before being notified that our revised amendment was approved. This meeting was critical to our success, as we relied on their expertise to complete the revisions in a timely fashion, and we required IRB approval to move forward with the study. We prepared and submitted our IRB amendment, then waited for approval.

Step 4: Preparing to Implement the Revised Protocol

Overview

After receiving IRB approval for our revised protocol, there were several tasks to complete to prepare for the implementation of the study. We had to buy supplies, prepare materials to be mailed, establish a contract with the shipping company, and develop a tracking system to make sure that the correct box got to its intended participant. We purchased boxes and sealable plastic shipping bags. This would keep the study materials protected from physical and water damage during the shipping process. To prepare the materials to be mailed to the participants, all study supplies were inventoried, assigned, and labeled with participant study ID numbers to ensure that the correct supplies went to the correct participant. This was particularly important for the HbA_{1c} kits, as the participant would need to send their prelabeled sample back to the DTIL laboratory.

Each participant's HBPM and HbA_{1c} kit was placed and sealed in a plastic shipping bag and tied with a ribbon to look like a gift. The shipping bags were then placed inside a shipping box that was also labeled with the participant ID number. As participants were enrolled and assigned a study ID number, the assigned box was labeled with a shipping label and the tracking

XSL•FO
RenderX

number was recorded. We developed a Zoom training protocol for our team to prepare them to meet with participants.

Zoom Meeting Preparation

It was important that the research staff were familiar with and comfortable with Zoom and interacting with participants remotely. Each staff member was sent a HBPM, a HbA_{1c} kit, and a standardized script to follow for the Zoom meetings. Staff meetings were held (via Zoom) to practice instructing participants on how to complete the blood glucose and blood pressure measurements. Each staff member practiced how to instruct participants at least 3 times before they were ready for participant interaction, and everyone received feedback on how to improve their technique and the clarity of their instructions.

After being trained, "mock" Zoom calls were scheduled where staff would guide a participant (another team member) through all of the steps of a study visit. During the mock call, the staff could ask questions and had the option to complete a second mock call if needed. All staff felt comfortable after completing 1 mock call.

Step 5: Implementing the Protocol Changes

While the staff prepared to complete the Zoom calls, we launched our Facebook campaign. Advertisements for the study were displayed on our lab's Facebook page. After viewing the advertisements, individuals who were interested in learning more and potentially participating clicked a link that directed them to a web-based eligibility survey on the Qualtrics platform [33]. The Qualtrics survey contained a study overview, consent document, and eligibility screening questions.

Individuals who provided informed consent to participate in the study and met eligibility criteria were asked to submit their contact information and were contacted by a member of the research team. During a phone call with each potential study participant, the team member verified the information from the Qualtrics screener and administered the Montreal Cognitive Assessment (MoCA) [32]. Given that the test would be administered by phone, the researchers used the blind version of the test that did not incorporate any of the written parts of the traditional MoCA. Participants had to score an 18 or above on the MoCA to be eligible to continue study participation.

Step 6: Mitigating Challenges

There were some issues (technical and shipping) that arose during the implementation of the revised BRAINS protocol.

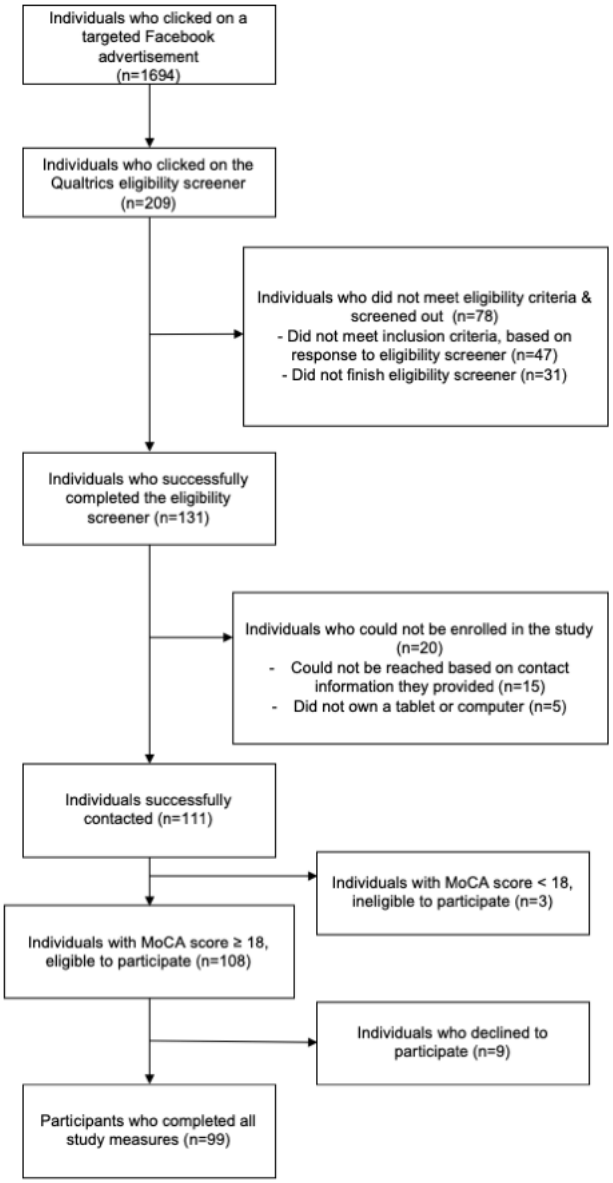
Technical Difficulties

Participants experienced some technical difficulties participating in the study remotely. Some participants had some difficulty with Zoom, perhaps because of different levels of experience with the platform. Some participants required more assistance than others, but all were able to measure their blood pressure. The TestMyBrain assessment could not be completed with a smartphone, as the participants' reaction time information could not be properly collected. This prevented 5 individuals from participating in the study, as we could only enroll those who could complete the study on a tablet or a computer. Even so, during the study, we also found that the "Amazon Fire tablet" was not compatible with the TestMyBrain website.

Shipping Issues

There were also some issues with mailing the study kits to participants. Occasionally, a participant's study materials would not reach the participant's home in time for their Zoom appointment, which required a research staff member to drive the kit out to the participant and leave it outside to maintain social distancing. The HbA_{1c} tests were sent directly to the DTIL laboratory in Georgia by the participant via the US Postal Service. When the DTIL laboratory contacted our team and stated that a HbA_{1c} test did not arrive, we had to contact participants and ask if they would be willing to retake the test.

Step 7: Evaluating Protocol Implementation



After completing the BRAINS study, we reflected on its implementation to evaluate our processes. There were several successes in this revised protocol. Since we were unable to access the fMRI laboratory, we used the additional funds to increase our sample size. Given that the study was conducted remotely, we were able to reach more women in our population of interest, including those who were potentially unable to come in person to participate in our study. Using Zoom, we were able to meet with our participants in their homes, where they were most comfortable, which gave the study a less "clinical feel." In fact, the principal investigator prepared a 3-minute video thanking participants for joining the study and reminding them how important their participation was. Many of the participants stated that they enjoyed the video and felt at ease after watching it.

Results

In response to our Facebook campaign, 1694 individuals clicked on the link that directed them to an eligibility screener. Of those who clicked, 131 individuals completed the screener and were eligible to participate in the BRAINS study. Figure 1 illustrates participant enrollment. We conducted our first Zoom appointment in July 2020 and completed our last Zoom appointment in September 2020. Despite the challenges that we faced, we were able to obtain all study measures from 99 participants in a 3-month period. A total of 14 of the HbA_{1c} tests were not received by the DTIL laboratory. When we contacted participants to ask if they would retake the HbA_{1c} test, only 8 participants agreed. Therefore, 6 HbA_{1c} results are missing; this is the only measure that is missing from our data set.

RenderX

Figure 1. Participant Flow Diagram.

Discussion

Overview

Due to the COVID-19 pandemic, we revised our BRAINS protocol from a study designed to be conducted in person to complete remote data collection. We increased our sample size from 50 to 100 participants and were successful in collecting all study measures from 99 Black women with hypertension. In this report, we highlighted the revisions we completed, described how we moved from in-person data collection to remote data collection, and outlined the challenges that needed to be mitigated to reach our goals.

Most importantly, we were able to safely conduct our study, despite the pandemic and associated challenges of in-person, health-related interactions [1]. We reviewed previous studies that had been conducted remotely with videoconferencing as we revised our protocol [17,18]. We designed the revised study so that we could still meet the study aims while ensuring that there were no in-person interactions between the members of our research team and our participants.

An important part of our protocol was to assess the diabetes status among our participants. Although hypertension and diabetes frequently co-occur [8], there is a gap in the literature regarding when Black women with hypertension are most likely to be diagnosed with type 2 diabetes and possible ways to prevent the transition to a diabetes diagnosis. Our protocol is one of the first that outlines steps to assess diabetes status among Black women with hypertension remotely.

Given concerns about self-reported measures [4,5], it was a top priority for our team to determine how to obtain accurate blood pressure measurements. Previous studies have validated HBPM for use outside of the clinic and patient use [35]. Each member of our research team received a HBPM and training on how to use it correctly to measure their blood pressure. After completing the training successfully, our staff was able to guide our participants in applying the blood pressure cuff and measuring their blood pressure. Additionally, while completing the screener

XSL•FO
RenderX

to determine eligibility to participate, potential participants had the opportunity to self-report their blood pressure. In our data analysis, we will be able to compare self-reported blood pressure to actual blood pressure measurements.

Some of the measures outlined in the original protocol were unable to be collected remotely. For example, there was no proxy for conducting an fMRI scan, an important part of the original BRAINS protocol. As of this writing, we are inviting participants to undergo an fMRI scan and to repeat some of the original study measures, including the TestMyBrain cognitive assessment, allowing us to examine relationships between the fMRI scan and the neurocognitive battery of tests.

Limitations

As with any research protocol, there were limitations to implementing our protocol that are worth discussing. Some of the measures that we collected required that participants complete them on a tablet or computer rather than a cell phone. This means that participants who did not own the necessary equipment were automatically excluded from participating in the study, creating bias. During 1 Zoom study visit, we learned that the Amazon Fire tablets were not able to load the TestMyBrain software. Additionally, this study was conducted during the COVID-19 pandemic, so participants' habits might have been patterned differently than their usual habits. Despite these limitations, this revised protocol was a unique opportunity to safely reach our population of interest during the pandemic.

Conclusions

The COVID-19 pandemic required revisions of many research protocols for the safety of participants and research staff alike. The pandemic provided a unique opportunity for researchers to gain knowledge about alternate ways of engaging with participants during a "Stay at Home" order. Before the COVID-19 pandemic, the BRAINS protocol was designed so that participants came in person to complete study activities (eg, surveys, serum sample collection, and fMRI). During the COVID-19 pandemic, we pivoted to a completely web-based format to collect survey data, an at-home HbA_{1c} test, and blood pressure measurement. Since we were unable to conduct the fMRI scans, the cost of our research activities dropped drastically, so we were able to enroll additional participants in our study. In addition, working remotely allowed our team to be more flexible with scheduling participants and offer evening and weekend appointments, as we were not subject to the fMRI laboratory's hours. In the future, researchers can use this study as a guide to develop protocols to reach diverse groups, such as individuals who are unable to participate in research activities due to distance, time, or travel constraints.

Acknowledgments

Research reported in this publication was supported by the National Institutes of Health—National Heart, Lung, and Blood Institute (K01HL145366), National Institute of Nursing Research (P20NR015331), National Institute of Aging (P30AG015281), and the Gordon and Betty Moore Foundation through the Betty Irene Moore Fellowship for Nurse Leaders and Innovators (GBMF9048). LMJ contributed to all aspects of the study, assisted with data collection, and led manuscript preparation. KK and KM assisted with data collection, basic data analyses, and manuscript preparation. KEM conducted literature review and assisted with manuscript preparation and formatting.

Abstract

Background: Anxiety and depression are leading causes of disease worldwide, requiring timely access to evidence-based treatment. Digital mental health (dMH) interventions increase accessibility to evidence-based psychological services delivered in a variety of web-based formats (eg, self-help and therapist-assisted interventions). Robust and rigorous studies of adaptive web-based intervention designs are scarce. No identified randomized clinical trial has investigated the efficacy of a 2-stage adaptive design, whereby the program-only condition or *no support* dMH treatment program is augmented by either low or high therapist assistance, if a participant does not improve or engage in the program-only condition.

Objective: The primary objective is to assess whether low or high therapist-assisted support delivered via video chat is more effective in reducing anxiety and depressive symptoms compared with a dMH program–only condition. The secondary objective is to evaluate the role of motivation; self-efficacy; and preferences in participant engagement, adherence, and clinical outcomes (anxiety and depression symptoms) among the 3 treatment conditions (program only, low-intensity therapist assistance, and high-intensity therapist assistance). A mixed methods analysis of factors affecting participant attrition, participant reasons for nonengagement and withdrawal, and therapist training and implementation of dMH interventions will be completed. Qualitative data regarding participant and therapist experiences and satisfaction with video chat assessment and treatment will also be analyzed.

Methods: Australian adults (N=137) with symptoms or a diagnosis of anxiety or depression will be screened for eligibility and given access to the 8-module Life Flex dMH treatment program. On day 15, participants who meet the augmentation criteria will be *stepped up* via block randomization to receive therapist assistance delivered via video chat for either 10 minutes (low intensity) or 50 minutes (high intensity) per week. This adaptive trial will implement a mixed methods design, with outcomes assessed before the intervention (week 0), during the intervention (weeks 3 and 6), after the intervention (week 9), and at the 3-month follow-up (week 21).

Results: The primary outcome measures are for anxiety (Generalized Anxiety Disorder–7) and depression severity (Patient Health Questionnaire–9). Measures of working alliance, health status, health resources, preferences, self-efficacy, and motivation will be used for secondary outcomes. Qualitative methods will be used to explore participant and therapist experiences of video chat assessment and treatment, participant reasons for withdrawal and nonengagement, and therapist training and implementation experiences. Data collection commenced in November 2020 and was completed at the end of March 2022.

XSL•FO
RenderX

Conclusions: This is the first mixed methods adaptive trial to explore the comparative efficacy of different intensity levels of self-help and a therapist-assisted dMH intervention program delivered via video chat for adults with anxiety or depression. Anticipated results may have implications for the implementation of dMH interventions.

Introduction

Background

The Global Burden of Diseases, Injuries, and Risk Factors Study 2019 identified depression and anxiety disorders as the 2 most debilitating mental disorders worldwide [1]. A recent study by Collaborators Cochrane Mental Disorders [2] quantified the global impact of COVID-19 on the prevalence of depression and anxiety disorders. That study estimated, for depression, an international prevalence of 246 million people (increase from 193 million people before the pandemic) and, for anxiety disorders, a prevalence of 374 million people internationally (increase from 298 million people before the pandemic). Such statistics demonstrate that anxiety and depressive disorders are leading diseases on a global scale that become more prevalent during global events such as the COVID-19 pandemic.

Rates of help seeking for a mental health–related service have also increased in light of the COVID-19 pandemic [3]. There has been increased use of digital mental health (dMH) interventions and telehealth services, attributable first to their ability to disseminate and scale quickly and, second, to their utility as an adjunct to existing face-to-face mental health services [4]. However, long wait lists to access psychological treatment via telehealth are reported [5,6], as are substantial costs associated with the delivery of psychological services via telehealth [3].

To ensure access to evidence-based treatment for the wider community, empirical research conducted over the past 20 years has investigated different methods of delivering psychological treatment. As an alternative to the standard in-person, face-to-face model, dMH interventions now have a well-established evidence base for the provision of psychological treatment for anxiety and depression delivered via the internet, in a variety of formats (eg, self-help and therapist-assisted interventions), mitigating the increasing demands for mental health services.

The dMH interventions serve to increase accessibility to evidence-based services within a high-volume, low-intensity treatment model [7]. Low-intensity treatment models have been developed to assist individuals experiencing mild to moderate psychological difficulties and propose that more intensive treatment regimens could then be provided to individuals who do not benefit from less intensive forms of psychological treatment [8]. The dMH interventions can address the evolving needs of consumers by adapting the implementation of treatment such that individuals can be *stepped up* to receive high-intensity treatment if required.

Adaptive intervention treatment designs use decision rules to determine whether and how the delivery of a course of treatment is altered [9]. Stepped care models are identified as a type of adaptive intervention design. Stepped care models incorporate a low-intensity intervention that is increased if certain criteria are fulfilled and can often include augmenting, switching, or maintaining a course of treatment based on some type of consumer characteristic (ie, low engagement levels) or response (ie, symptom severity) [9]. Within a stepped care model, dMH interventions are offered as part of the first step of self-management (eg, self-help web-based program), and if required, an individual's treatment can be increased, whereby a therapist is added to support the dMH intervention.

Previous empirical studies investigating the effectiveness of therapist-assisted dMH interventions for anxiety and depression have largely used telephone, instant messaging, and email assistance. Recent advances in dMH include the use of video chat technology, in which face-to-face synchronous digital communication most closely aligns with the traditional in-person, gold-standard service delivery model in psychology. Empirical investigation into the efficacy of video chat, compared with that of other dMH care models for treating anxiety and depression, is lacking. Most of the research studies completed so far have investigated posttraumatic stress disorder and have compared psychiatric treatment delivered via video chat with that delivered in-person, with comparable outcomes reported [10,11].

Currently, there is a paucity of robust and rigorous studies on the use of video chat methods in dMH interventions. No identified clinical trial has investigated the efficacy of a 2-stage adaptive design offering the *no therapist support* dMH program and augmenting a participant's program with either low or high therapist assistance if they do not improve or engage in the *no therapist support* program-only condition. Within the field of psychology, the literature about dMH is also largely biased toward quantitative research methodology that minimizes the opportunity to more closely investigate factors contributing to the efficacy of various intensities of a dMH treatment program (eg, participant attrition and engagement factors). Therefore, the testing of an adaptive, mixed methods randomized clinical trial design will provide great insight into participant characteristics of engagement; efficacy of video chat as a mode of therapist assistance in dMH interventions; and, overall, improvement of future services delivered via dMH.

XSL•FO
RenderX

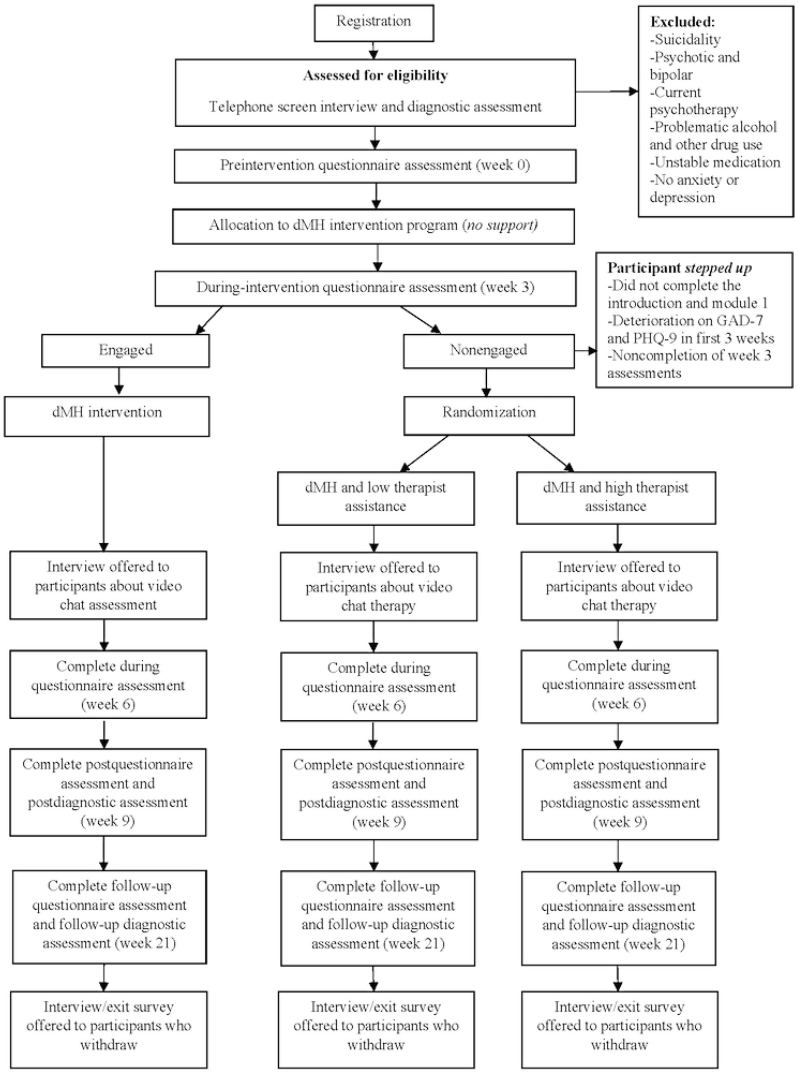
Objectives

The purpose of this study is to present a protocol designed to evaluate various support intensities of a dMH treatment program for anxiety and depression within a mixed methods design. Therefore, the study has the following primary objectives:

1. To compare the efficacy of clinical outcomes (anxiety [Generalized Anxiety Disorder–7; GAD-7] and depression [Patient Health Questionnaire–9; PHQ-9] symptoms) among the 3 treatment conditions (dMH program only, low-intensity therapist assistance, and high-intensity therapist assistance), with particular focus on whether therapist-assisted support produces greater reductions in anxiety and depression severity compared with those produced by dMH program–only support.
2. To examine the role of motivation and self-efficacy on engagement, adherence, and clinical outcomes (anxiety [GAD-7] and depression [PHQ-9] symptoms) among the 3 treatment conditions (dMH program only, low-intensity therapist assistance, and high-intensity therapist assistance) at postintervention (week 9) and follow-up (week 21) assessments, compared with those at preintervention (week 0) assessment.
3. To explore participant and therapist experiences and satisfaction with assessment and therapist assistance delivered via video chat technology, using semistructured interviews; specific areas of focus will include the ability to develop and maintain therapeutic relationships, implementation barriers and facilitators, and identified strengths and limitations of video chat technology for conducting assessments and delivering dMH treatment.
4. To explore therapist training and implementation experiences in the delivery of dMH interventions.
5. To use a mixed methods analysis to examine factors affecting participant attrition in each of the treatment intensities; quantitative examination of preferences, treatment condition allocation (dMH program only, low-intensity therapist assistance, and high-intensity therapist assistance), and attrition rates will be explored; qualitative exploration of participant reasons for withdrawal and nonengagement with therapist support will also be conducted using semistructured interviews.
6. To explore the outcomes of working alliance, health resources, and health status among the 3 treatment conditions (dMH program only, low-intensity therapist assistance, and high-intensity therapist assistance).

Methods

Trial Design



This trial will follow the International CONSORT (Consolidated Standards of Reporting Trials) guidelines and evaluate the conditions using an adaptive randomized clinical trial design [12]. The clinical trial also adheres to SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials; Multimedia Appendix 1). All information will be strictly confidential, yet subject to legal limitations (eg, legal subpoena), and only accessed by the investigators. Data are stored securely using 256-bit encryption Secure Sockets Layer and Transport Layer Security software when information is transmitted. Any hard copy data will be stored securely in lockable filing cabinets at the Federation Community Psychology Services at Federation University.

Eligible participants will be given access to a self-help dMH treatment program (Life Flex) and have their symptoms of anxiety or depression evaluated at day 15 to assess whether they meet the criteria to have their treatment program augmented with therapist assistance. Participants will be considered as eligible to be *stepped up* to a therapist-assisted condition if they meet any of the following criteria: they have not read the introduction module or module 1 of the Life Flex program; have symptoms of anxiety or depression that have deteriorated by >5 points (as assessed by comparison of their baseline depression [PHQ-9] and anxiety [GAD-7] scores against their week-3 scores); show symptom improvement, but their scores remain in a severe range; and are yet to complete the week-3 questionnaire assessment.

Outcomes will be assessed before the intervention (week 0), during the intervention (weeks 3 and 6), after the intervention (week 9), and at the 3-month follow-up (week 21). Results will be disseminated via publication. Figure 1 illustrates the study's design and expected participant flowchart.

Participant Recruitment

Eligibility

Participants will be recruited from the Australian community and will be eligible for the trial if they meet the following criteria: aged ≥18 years, are Australian residents, have access to the internet, able to register their interest via the web using an email address, able to read and write in English, and have symptoms or a diagnosis of anxiety or depression (as assessed by the Mini International Neuropsychiatric Interview [MINI] 7.0.2 [13]).

Participants will be excluded if they are currently receiving psychological treatment for their mental health, have moderate to severe levels of alcohol or substance use, have active psychosis or active suicidal intent or plan, have unstable bipolar disorder (as assessed by MINI 7.0.2 [13]), or take unstable doses of medication (ie, eligible participants will need to be on the same doses of their prescribed medications for at least one month before commencing the intervention).

Screening Procedures

Potential participants will register their interest to participate in the study via the completion of a screening contact form on the study's website. Interested participants will be presented with the Plain Language Information Statement before completing the contact form. Consent will be obtained at 2 intervals (upon initial completion of the contact form and again when entered into the trial), whereby participants will be required to click a button, *I agree*, indicating that they consent to the study. After consent is obtained, participants will be invited to participate in a brief telephone screening interview that corresponds with the *Diagnostic and Statistical Manual for Mental Disorders, Fifth Edition* (DSM-5) [14] criteria for generalized anxiety disorder, social phobia, panic disorder, agoraphobia, and major depressive disorder. During the telephone interview, the participants' ability to attend a video chat assessment will be determined. The interview will conclude with exploration of their motivation to improve their symptoms of anxiety or depression.

Eligible participants will be scheduled for a diagnostic assessment. That is, administration of MINI 7.0.2 [13] via video chat technology accessed through the My Digital Health platform of Federation University. This clinical assessment will determine the presence of mental health symptoms (allowing for assessment of the inclusion and exclusion criteria of the study) and assignment of clinical severity ratings for any

XSL•FO
RenderX

identified disorders. MINI is a short, structured interviewing tool designed to aid DSM-5 diagnosis and monitor the clinical outcomes of the 17 most common mental disorders. It has a mean administration time of 15 minutes, with questions requiring a "yes" or "no" response (eg, "In the past two weeks, were you much less interested in most things or much less able to enjoy the things you used to enjoy, most of the time?"). MINI has been validated against the long Structured Clinical Interview for Diagnostic and Statistical Manual for Mental Disorders diagnoses and has been identified as a more time-efficient diagnostic tool, demonstrating excellent interrater reliability (k=0.88-1) [13]. MINI will be administered before the intervention (week 0); after the intervention (week 9); and 3 months after the treatment, at follow-up (week 21).

Participant Measures

Overview

Eligible participants will be given access to the preintervention (week 0) self-report questionnaire assessment comprising a demographic questionnaire (including age, sex, relationship status, education level, alcohol and other drug use, medication use, and current and past access to mental health services). Participants will also be asked to complete a short questionnaire package at weeks 3 and 6 and outcome measures after the intervention (week 9) and at the 3-month follow-up (week 21). At week 3, participants' questionnaire data for anxiety (GAD-7) and depression (PHQ-9) will be compared against the preintervention outcome data to assess whether the stepped care rules of the trial have been met and whether a therapist is required to be assigned to a participant. Table 1 shows the schedule and frequency of the assessments during the trial for participants.

Table 1. Schedule of enrollment and assessments.

XSL•FO
RenderX

Anxiety

The GAD-7 [15] is a self-report measure that assesses anxiety symptoms over the past 2-week period. Total scores range from 0 to 21, with high scores suggestive of more severe anxiety symptoms. Each item is rated on a 4-point scale, with scores >8 indicative of clinically significant anxiety symptoms, warranting further evaluation. Scores of 5, 10, and 15 represent the cutoff points for mild, moderate, and severe anxiety symptoms, respectively. The GAD-7 is sensitive to changes in generalized anxiety disorder, social phobia, panic disorder, and posttraumatic stress disorder, with a score of >5 points indicative of clinically meaningful change over time [15]. The GAD-7 has strong psychometric properties [15].

Depression

The PHQ-9 [16] is a self-report measure designed to assess symptoms of major depressive disorder over the past 2-week period. Total scores range from 0 to 27, with high scores indicative of great depressive symptoms. Each item is rated on a 4-point scale, with scores >10 used as cutoff to indicate the presence of clinically significant depressive symptoms. Scores of 5, 10, 15, and 20 represent the cutoff points for mild, moderate, moderately severe, and severe depressive symptoms, respectively. The PHQ-9 has strong psychometric properties [16].

Working Alliance

The Working Alliance Inventory–Short (WAI-S) [17] is an abbreviated version of the Working Alliance Inventory based on the theory by Bordin [18] and comprises the following subscales: goal agreement, task agreement, and bond. In this study, the WAI-S is available in a therapist version (10-item scale) and a participant version (12-item scale), with both versions to be used to capture the strength of the therapeutic alliance from both perspectives. Total scores range from 12 to 60, with high scores suggestive of strong therapeutic alliance. Each item is rated on a 5-point scale, and the measure has strong psychometric properties [17]. To assess participants' technological alliance with the self-help dMH program, the wording of the items of the WAI-S have been slightly modified for this study, to capture participant ratings for a dMH program without therapist assistance.

Health Status

The Assessment of Quality of Life (AQol) [19] is a 12-item, self-report measure designed to assess ratings of health-related quality of life in a variety of life areas such as independent living, illness, social relationships, psychological well-being, and physical senses. The AQol can be scored in 2 ways—as a psychometric measure and as a utility measure. As a psychometric measure, scores are used to derive a simple psychometric score for health-related quality of life and provide profile scores on each of the 5 dimensions. When the AQol is scored as a utility measure, it can provide dimension scores and an overall index of the health state, which can be used in economic evaluation and cost analysis. The AQol has been validated across several countries, has been shown to have high degree of internal consistency (Cronbach α=.81), and is deemed an acceptable measure of health-related quality of life.

Health Resources

A Health Care Resource Usage questionnaire for cost-effectiveness has been specifically designed for the study to evaluate participants' primary and secondary health care consultations and admissions, use of antidepressant and antianxiolytic medication, and resource use associated with treatment received in the trial. The treatment received in the trial will encompass the amount of therapist time required, supervisor's time, internet access, and computer use.

Motivation

The Client Motivation for Therapy Scale (CMOTS) [20] is a self-report measure designed to assess the degree to which an individual is motivated for therapy and the impact of a person's motivation on treatment effectiveness and mental health symptoms. The 24 items assess 6 dimensions of the self-determination continuum of motivation proposed by Deci and Ryan [21]: intrinsic motivation, 4 forms of extrinsic motivation (integration, identification, introjection, and external regulation), and amotivation for therapy. The CMOTS obtains subscale scores for each type of motivation, with high scores reflecting high levels of each type of motivation. Each item is rated on a 7-point scale. The CMOTS has strong psychometric properties [20].

Self-efficacy

The Bipolar Self-efficacy Scale (BPSES)–Modified [22] has been slightly modified for use in this study to measure the self-efficacy of participants with anxiety and depressive symptoms opposed to bipolar disorder symptoms. The 17 items of the modified self-report measure of self-efficacy assess how confident an individual feels in performing a range of activities related to their mental health such as taking their medication as prescribed, maintaining regular hours of sleep, and identifying early warning signs of anxiety and depression (as opposed to bipolar symptoms). Each item is rated on a 10-point scale, with high scores indicative of high levels of self-efficacy. The BPSES has strong psychometric properties, with sensitivity to detect change over the course of treatment [22].

Usability

The System Usability Scale [23] is a 10-item measure designed to assess participant perceptions of the usability of a program. The System Usability Scale will be used in this study to assess participants' ease and perceptions about the dMH program's usability (eg, "I thought the program was easy to use"). Each item is rated on a 5-point scale, with high scores reflective of increased system usability.

Preferences

A bespoke preferences questionnaire has been purposively developed to assess participants' preferences for treatment before commencing the trial. Participants are presented with brief information about each of the 3 treatment conditions (dMH program only, low intensity therapist assistance, and high intensity therapist assistance), which they are then asked to rank in order of their preference.

XSL•FO
RenderX

Satisfaction

A purposively designed 10-item satisfaction questionnaire has also been developed to assess participants' level of satisfaction with the treatment received. Overall, 8 of the 10 items are rated on a 4-point scale. For the other 2 questions, participants are asked to qualitatively share what they believe were the best and worst parts of the dMH treatment program.

Primary Outcomes

The primary outcomes will be participants' level of anxiety (GAD-7 [15]) and depression (PHQ-9 [16]).

Secondary Outcomes

The secondary outcomes being assessed are working alliance (WAI-S [17]), health status (AQol [19]), health resources, self-efficacy (BPSES [22]), and motivation (CMOTS [20]).

Treatment Conditions

Life Flex Program

The primary dMH intervention in each of the 3 treatment conditions is Life Flex, which is one of the dMH programs housed and offered via the My Digital Health platform. Life Flex is a third-wave transdiagnostic biopsychosocial treatment approach that aims to increase psychological flexibility, through cognitive behavior therapy, emotion regulation, and positive psychology principles, for anxiety and depression. The Life Flex program is suitable for individuals with or those without a DSM-5 diagnosis of anxiety or depression.

Life Flex teaches participants biopsychosocial *life skills*. It comprises 6 core modules, along with an introductory module and a booster module. The introductory module provides a rationale for the program, discusses brain plasticity and change processes, includes information about anxiety and depression, and explores factors contributing to motivation for change. Each of the 6 core modules focuses on increasing flexibility within a particular domain, such as biological (eg, breathing, nutrition, and sleep), emotional (eg, increasing emotional awareness), thinking (eg, identifying and challenging unhelpful cognitions), behavioral (eg, increasing pleasurable activities), wellness (eg, loving kindness), and life flexibility (eg, consolidating the life skills learned and goal setting). The booster session focuses on consolidation and reinforcement of learning. Further information about the Life Flex program can be accessed via a forthcoming paper that has recently been accepted for publication in JMIR Formative Research [24].

Each module of the Life Flex program will take approximately 25 minutes to complete. In addition, to reinforce the module-based information, there are 20 to 30 minutes of offline activities each week. Offline activities include applying the concepts and techniques discussed in the modules (eg, self-monitoring depressive and anxiety symptoms), undertaking one of the biological and wellness flexibility intervention strategies, monitoring emotions and thoughts, and undertaking the gradual exposure or behavioral activation activity. Participants will also receive automated emails (eg, to remind them to log in or to complete the questionnaires) and will be asked several questions at the beginning of each module to help gauge their progress. Module features include text, graphics, audio, video, editable forms, interactive games (eg, brain training), and downloads. Modules can be accessed via web, mobile phones, or tablet devices.

Life Flex Program–Only Condition

The treatment in step 1 of the trial will comprise the *program-only* Life Flex treatment program, whereby participants complete the fully automated, self-help program without therapist assistance. If participants do not improve in the *program-only* condition within the first 3 weeks (ie, no change in anxiety or depression symptoms, symptoms remain in the severe range, or noncompletion of the preintervention or week 3 questionnaire) or do not engage with the program (ie, noncompletion of the introduction module or module 1), they will be randomized to augment their program with either *low* therapist assistance (ie, one 10-minute support session per week) or *high* therapist assistance (ie, one 50-minute therapy session per week), delivered via video chat technology by provisionally or generally registered psychologists. Participants who improve or engage with the Life Flex program (program only) within the first 3 weeks maintain their no therapist assistance program. Participants who remain in the *program-only* treatment condition will complete the Life Flex program on a scheduled release design, with a new module being released every week, with the exception of module 4 (participants are given 2 weeks to work through and practice module-4 content).

Life Flex Program and Low-Intensity Therapist Assistance

Participants who are *stepped up* to the low-intensity therapist-assisted treatment condition will complete the same dMH treatment program (Life Flex), with the addition of a 10-minute weekly video chat session with a therapist for support and progress check-in of program content. The role of the therapist in the low-intensity treatment condition is to support the participant's engagement with the Life Flex program by specifically checking participant progress with modules, task reinforcement, providing clarification where required, encouraging reading and skill practice, and ensuring that participants are clear about their between-session module tasks assigned for completion.

Life Flex Program and High-Intensity Therapist Assistance

Participants who are *stepped up* to the high-intensity therapist-assisted treatment condition will complete the same dMH treatment program (Life Flex), with the addition of a 50-minute weekly video chat therapy session with a therapist for individualized tailoring of the program content. Participants in the high-intensity treatment condition will have the opportunity to receive therapist guidance, tailored program content, questionnaire feedback, and support for generalizing skills to daily life and to engage in problem-solving where required.

Therapist assistance in both low-intensity and high-intensity conditions will be offered to participants for a period of up to 7 sessions. To ensure treatment fidelity and standardized treatment, the therapists will be provided with a treatment manual, with random checks of their recorded video chat

XSL•FO
RenderX

sessions (eg, 20% of the total) by independent raters to determine adherence to the study protocol and treatment fidelity.

Assessors and Therapists

Therapist Training Program

Before commencement of the trial, provisionally and generally registered psychologists will be required to complete and obtain competency in a purposively developed 14-hour, 5-module web-based training program covering an introduction to dMH interventions (specifically video chat technology), diagnostic assessments (covering MINI, anxiety, depressive disorders, and suicidality), qualitative interviewing techniques, and transdiagnostic cognitive behavior therapy principles that underpin the Life Flex dMH treatment program. The training program comprises a 40-item multiple-choice competency assessment, for which therapists are required to obtain a minimum score of 80%. The training program also contains a pre-evaluation and postevaluation survey designed to assess therapists' knowledge about and confidence in the use of dMH interventions before and upon completion of the program and to obtain their satisfaction ratings of the training program.

Outcome Assessors and Trial Therapists

The assessors who complete the diagnostic clinical assessments and the therapists who deliver the low-intensity and high-intensity treatment assistance will be provisionally and generally registered psychologists who are on clinical placement at the Federation Community Psychology Services at Federation University in Ballarat, Victoria, Australia. A new assessor will be assigned for all 3 assessment time points and will differ from any therapist assigned to participants in both the low-intensity and high-intensity therapist-assisted conditions. The assessors will complete and be required to demonstrate competency in diagnostic assessments before administration, and both assessors and therapists will receive training and supervision from an experienced clinical psychologist throughout the trial.

Both assessment and therapist sessions will be audio or video recorded (with participants' permission), so that random checking (eg, 20% of the total) can be completed to ensure adherence to administration, to enable agreement and interrater reliability of diagnoses, and to ensure that adherence to the therapist's role (low or high intensity) is maintained. Adapted versions of the Internet-Delivered Cognitive Behavior Therapy–Therapist Rating Scale [25] and Cognitive Therapy Rating Scale (Multimedia Appendix 2) will be used by supervisors in the review process to ensure treatment fidelity in both treatment conditions. Each therapist will also be required to undertake regular supervision, where any remedial strategies to improve fidelity will be implemented. Remedial strategies will include the provision of constructive feedback, review of the components of treatment in sequence, further practice of skills where drift may have occurred, additional training (if necessary), review of initial fidelity training materials, and extra coaching or supervision.

Participant Interviews

Within the study, there will be 4 different types of interviews offered to participants depending on what is relevant to them: exploration of experiences of assessment via video chat technology, exploration of experiences of therapist assistance delivered via video chat technology, exploration of reasons for nonengagement with therapist assistance, and exploration of reasons for disengagement and withdrawal. Participants will be offered an interview at a suitable time and via their preferred mode: instant message, telephone, video chat, or email. Participants will also have the option to complete a brief exit survey instead of an interview if they withdraw from the study or choose not to engage with the offer of therapist assistance.

Participants who complete a diagnostic assessment or receive at least two therapist-assisted sessions via video chat will be invited to participate in a semistructured interview to reflect upon and share their experiences with the video chat interaction. They will be asked a series of questions focusing on their ability to develop a therapeutic alliance with their assessor and therapist, their views on video chat technology, exploration of any technological issues experienced, and overall strengths and limitations of video chat. The interviews will be conducted by the first author, focusing on asking questions in an open, curious, and reflective manner. If the interview is completed via telephone or video chat, it will be audio recorded (with participants' permission) for qualitative analysis.

Assessor and Therapist Interviews

The provisionally and generally registered psychologists of the study will also be invited for interview to share their experiences with administering diagnostic assessments and delivering treatment via video chat technology and explore their training experiences. Assessors and therapists will be offered an interview at a suitable time and via their preferred mode: instant message, telephone, video chat, or email. They will be asked a series of questions focusing on their ability to develop a therapeutic alliance with their participants; their views about video chat technology; exploration of any technological issues experienced; exploration of implementation barriers and facilitators; and overall reflections about how a service delivered via video chat compares with an in-person, face-to-face service. The interviews will be conducted by the first author, and if completed via telephone or video chat, the interview will be audio recorded (with permission) for qualitative analysis.

Randomization

The process of randomly allocating participants to either the low-intensity or high-intensity treatment groups will comply with CONSORT guidelines. A block randomization design will be used to randomly allocate each participant to either the low-intensity or high-intensity therapist assistance condition throughout the trial. Random allocation will occur when a participant has met the criteria to be *stepped up* to have their Life Flex program augmented with therapist assistance. Participants will be aware of the group they have been randomly allocated to but will remain unaware of the study's objectives. The provisional or general psychologists will not be blinded to the treatment conditions, as they will need to adhere to either the support or the therapist role.

XSL•FO
RenderX

Sample Size Calculation

Only aggregate data will be used for the main analysis. Assuming a conservative medium effect (ie, GPower f[v] test=0.25), significance set at 5% (P=.05), and power at 80%, 98 cases are required to demonstrate statistical significance in the primary outcome measures. However, allowing for a 30% attrition rate [26], a total target sample size of 137 participants will be required.

Ethics Approval

The trial will be conducted in accordance with the ethical guidelines in the National Statement on Ethical Conduct in Human Research (National Statement on Human Research 2007; updated in 2018). Ethics approval for this project has been granted by the Federation University Australia Human Research Ethics Committee (A19-095), and this clinical trial is registered with the Australian and New Zealand Clinical Trials Registry (12620000422921).

Results

Recruitment began in November 2020 and was completed at the end of March 2022. In total, 240 individuals registered for the clinical trial, of which 113 (47.1%) were assessed as eligible to commence the dMH intervention. At week 3, of the 113 participants, 73 (64.6%) met the stepped care criteria to have the dMH intervention augmented with therapist assistance, whereas 40 (35.4%) remained in the program-only condition. The results of the clinical trial are forthcoming as they have recently been accepted for publication in JMIR Publications [27].

Data will be entered, screened, and analyzed using statistical software. Intention-to-treat analysis will be used for primary outcomes, controlling for baseline differences where appropriate. The primary analysis will be conducted using 2 planned contrasts comparing a change in anxiety (GAD-7) and depression (PHQ-9) scores from preintervention assessment with those of the postintervention (week 9) and follow-up (week 21) assessments, using a mixed model repeated-measure analysis. A mixed model repeated-measure analysis is preferred owing to its ability to include participants with missing data. The study will also investigate whether reliable and clinically significant change has been achieved for participants following the recommendations of Jacobson and Traux [28]. Moderation analyses will be used to determine the role of self-efficacy and motivation in engagement and adherence and their effects on anxiety and depression outcomes in the 3 treatment conditions, and a t test will be used to determine the impact of preferences and treatment allocations on attrition rates.

Data obtained from open-ended questions about intervention satisfaction questionnaires and from interview questions will be transcribed verbatim from audio recordings into text and then analyzed using protocols of thematic analysis to identify common themes. Text transcripts will be read several times to identify emerging themes. Thematic analysis allows for the identification of themes that are driven by the data, using an experiential, bottom-up approach [29]. Close analysis of the data will suggest names for the themes, which are likely to represent something of meaning to participants and therapists, with direct quotes used to further illustrate meaning. Researchers will meet throughout the analysis process to review and discuss the data.

Discussion

Principal Findings

This study protocol presents an outline of the first adaptive intervention trial designed to determine the efficacy of various support intensities (ie, none, low, and high) of a dMH treatment program for anxiety and depression. The primary objective is to compare the efficacy of clinical outcomes (anxiety and depression) among the 3 treatment conditions. Specifically, it is predicted that therapist assistance delivered via video chat will be more effective in reducing anxiety and depression symptoms compared with program-only support. If this hypothesis is supported by the study findings, it will demonstrate that augmenting a dMH intervention with therapist assistance offered via video chat is beneficial for enhancing mental health outcomes within a community mental health treatment setting. The difference between low and high therapist assistance will also be evaluated. If the results indicate that the outcomes of these treatment conditions are similar, support will be provided for the implementation of low-intensity dMH interventions within the community, thus increasing timely community access to evidence-based interventions.

The study also has several secondary objectives that will be assessed. Examination of the role of motivation; self-efficacy; and participant preferences in engagement, adherence, and clinical outcomes among the 3 treatment conditions will be beneficial in improving our understanding of factors affecting participant attrition and engagement within dMH interventions. Qualitative evaluation of participant and therapist experiences and satisfaction with video chat technology is expected to provide further knowledge about the use of video chat for the assessment and treatment of anxiety and depression, specifically, the development of therapeutic relationships, implementation barriers and facilitators, and strengths and limitations of video chat technology. Furthermore, qualitative exploration of therapist training and implementation experiences in the delivery of dMH interventions is likely to improve the future adoption of dMH interventions incorporating video chat technology.

The findings of the trial have the potential to contribute toward the evidence base of adaptive treatment designs for anxiety and depression, with considerable implications for the implementation of stepped care models in dMH. As the study will evaluate outcomes of health resources and health status among the 3 treatment conditions, it is anticipated that the study results will enhance our understanding of participant needs and resources required at the self-help (dMH program only; step 1) and therapist-assisted (low and high therapist assistance; step 2) levels in the context of an adaptive intervention design.

Limitations

Although the current trial is believed to contribute significantly to advancing the field of dMH interventions, the study is likely to have some limitations. Given the widely known high attrition

XSL•FO
RenderX

rates in dMH treatment and the difficulties that people with depression and anxiety can face, such as avoidance and lack of motivation, participant recruitment and overall engagement may present a challenge. The study protocol has been designed with these considerations in mind, with the overall aim of reducing the impact of these challenges and furthering our knowledge about various support intensities of dMH treatment for anxiety and depression.

Conclusions

This protocol outlines the first adaptive mixed methods clinical trial design investigating the efficacy of a 2-stage adaptive dMH intervention program incorporating both low-intensity and high-intensity therapist assistance delivered via video chat technology, compared with program-only support. This trial adds to the existing studies on dMH interventions and provides further understanding of participant and therapist experiences and satisfaction with video chat assessment and therapist assistance, along with therapist training and implementation experiences. Outcomes are expected to have implications for stepped care models and wide dissemination of dMH interventions for anxiety and depression.

Acknowledgments

The authors thank and acknowledge the Australian Government Research Training Program for supporting BA. The authors want to thank the provisionally and generally registered psychologists who have greatly assisted with this trial and the participants who participated. The authors would also like to acknowledge those who have assisted in the development of the My Digital Health Life Flex program, including Retsim, Rubber Duck, Gasoline Media, Eammon Jones, Jodie Parkinson, Gemma Munro, Rachelle Bridges, and Brett James.

Data Availability

Deidentified aggregate data sets generated or analyzed during this trial may be made available from the corresponding author upon reasonable request and if data sharing is in accordance with the study's ethics approval and general data protection regulations.

Conflicts of Interest

BK was one of the primary creators of the Life Flex digital mental health program. BK receives no personal income from the Life Flex program.

Abstract

Background: Duchenne muscular dystrophy (DMD) is a rare progressive muscular disease that primarily affects boys. A lack of comprehensive care for patients living with DMD is directly associated with a compromised quality of life (QoL) for those affected and their caregivers. This disease also has a huge economic impact on families as its treatment requires substantial direct, indirect, and informal care costs.

Objective: This study presents a protocol developed to evaluate the feasibility and efficacy of a patient-centered care (PCC) model for children with DMD. The care model was designed with the aim to empower families, improve QoL, and reduce economic burden on their families.

Methods: This study is planned as a quasi-experimental study that will enroll 70 consecutive families with boys (aged 5-15 years) with DMD visiting a tertiary care center. The study is being conducted in 2 phases (preintervention and postintervention phases, referred to as phase 1 and phase 2, respectively). During phase 1, the patients received routine care. The study is now in phase 2, with the intervention currently being administered. The intervention is based on the PCC model individualized by the intervention team. The model has a comprehensive DMD telecare component that includes teleconsultation as one of its key components to reduce in-person physician visits at the health facility. Teleconsultation is especially beneficial for late-ambulatory and nonambulatory patients. Data on economic burden are being collected for out-of-pocket expenses for both phases during in-person visits via telephone or messaging apps on a monthly basis. QoL data for patients and their primary caregivers are being collected at 3 time points (ie, time of enrollment, end of phase 1, and end of phase 2). Outcome measures are being assessed as changes in economic burden on families and changes in QoL scores.

Results: Participant recruitment began in July 2021. The study is ongoing and expected to be completed by March 2023. The findings based on baseline data are expected to be submitted for publication in 2023.

Conclusions: This paper outlines a research proposal developed to study the impact of a PCC model for patients with DMD in low- and middle-income countries (LMICs). This study is expected to provide evidence of whether a multicomponent, patient-centric intervention could reduce economic burdens on families and improve their QoL. The results of this study could guide policy makers and health professionals in India and other LMICs to facilitate a comprehensive care program for patients living with

DMD. The economic impact of a rare disease is an important consideration to formulate or evaluate any health policy or intervention related to new treatments and financial support schemes.

Introduction

Background

Duchenne muscular dystrophy (DMD) is an X-linked recessive disease with an incidence of 1 in 3500 to 6000 live male births [1]. It progresses from an ambulatory to a nonambulatory stage, with the child usually becoming wheelchair-bound between 11 and 13 years and death occurring in the late teens or early twenties [2-4]. Even with this short span of life, children with DMD face many challenges, as their progression through various transitional phases impacts not only them but also their families and society at large [5].

The progressive and irreversible damage to the muscles results in weakness, loss of ambulation, breathing issues, and cardiomyopathy. Currently, there is no definitive treatment to halt the disease's progression. Disease management mostly revolves around symptom management and involves a multidisciplinary approach to address various systemic complications [6].

Course of Disease

Boys with DMD usually remain asymptomatic up to 2 years of age and get diagnosed between 4 to 6 years of age. Most of the boys with DMD are limited to assisted ambulation with the help of long leg braces by the age of 10 years. Age of loss of ambulation globally is between 13 and 14 years, whereas in resource-limited settings, it is between 9 and 11 years [4]. There is no study on the prevalence or incidence of DMD in India. However, a study from southern India [7] on 275 genetically confirmed patients with DMD was conducted to study the natural course of motor milestones. Authors reported the mean age of onset of symptoms was 3.7 years, and the mean age at presentation was 8.1 years. During the follow-up period of 15 years, 155 out of 275 (56.4%) children had either become wheelchair-bound or bed-bound or died. The affected children were wheelchairs bound by a mean age of 10.4 years and bed-bound by 11.8 years. Seven boys (2.6%) died during the follow-up period at a mean age of 15.2 years.

DMD requires a multidisciplinary team approach for holistic management. This includes diagnostic services, physical therapy, orthotics, respiratory therapy, corrective orthopedic surgery, ventilation, feeding support, and speech therapy. Muscle degeneration can be slowed down with the use of corticosteroids, while antibiotics may be needed for respiratory infections [8-11]. Occupational therapy, assistive devices, and a wheelchair are also beneficial to the children. Some patients may need a pacemaker for cardiac abnormalities and assisted ventilation for respiratory muscle weakness. Patients diagnosed with DMD should expect to make a successful transition to adulthood, which includes education, health care, and social support to transition smoothly from adolescence to adulthood [12,13].

The DMD Care Considerations Working Group identified eleven components of care: (1) diagnosis, (2) neuromuscular management, (3) rehabilitation management, (4) gastrointestinal and nutritional management, (5) respiratory management, (6) cardiac management, (7) orthopedic and surgical management, (8) psychosocial management, (9) primary care and emergency management, (10) endocrine management (including growth, puberty, adrenal insufficiency, and bone health), and (11) transitions of care across the life span. The mainstay of management is still limited to physiotherapy and glucocorticoids therapy, which help in delaying loss of ambulation, an important milestone of the disease [6,14]. Treatment modalities also have changed, especially with the advent of exon-skipping therapy and gene editing tools. However, these new modalities of treatment have not made a significant clinical impact yet [15].

Empowering Patients and Caregivers

Globally, we are witnessing a new paradigm shift to resolve problems from a mechanistic or Newtonian worldview to a holistic view. This approach involves human values, creativity, and evolution, and it has affected the approach toward understanding human health. Nevertheless, the reductionistic approach dominates the imagination of the scientific fraternity [16]. The biomedical or reductionistic approach sees patients as an isolated problem, whereas we need to understand that a holistic approach (ie, social, economic, sanitary, environmental, and political commitment) is needed to manage a disease.

An inclusive paradigm has two major components: (1) self-empowerment of the patient and (2) holism. Empowering patients involves developing skills, control over resources, ensuring autonomy in decision-making, and taking ownership of their health [17,18].

Empowering patients through an effective health care delivery model has the potential to improve the cost-effectiveness of care, especially for people affected by long-term conditions [19]. Patient-centered care (PCC) increases adherence to disease management, reduces loss to follow-up in the health care system, and, in turn, reduces morbidity and improves quality of life (QoL) for patients [17].

XSL•FO
RenderX

QoL of Children Living With DMD

With the advancement in medical management, patients with DMD are reported to live longer up to the third decade of life. These require more years to live with functional disability and more years of caregiving. Past studies have reported variable QoL among patients with DMD, with some studies showing poor QoL and others showing no difference between healthy children and those with DMD. Being able to participate in various activities of daily living, like personal care, mobility, social relationships, education, recreation and leisure, spirituality, and community life, are outcomes of health. Physical disability substantially decreases participation and consequently impairs QoL [18]. Studies have reported that only physical participation levels were much lower in patients with DMD, and other participation levels were almost the same.

Bendixen et al [20] compared participation in life activities and perceived QoL between younger and adolescent boys with DMD and age-matched controls. No differences in perceived QoL were observed between the participants with DMD and the healthy controls, but the older adolescent participants with DMD had significantly lower QoL subscales of physical, social, and total composite scores. de Moura and colleagues [21] studied the relationship between physical dependence and QoL of patients with DMD and the QoL and burden of caregivers. Lower QoL was observed in caregivers with increased age and the burden of caregiving. In a review, Landfeldt et al found [22] the informal care of patients with DMD was associated with a substantial burden, and they recommended further research to better understand the relationship between clinical implications and progression of disease and caregiver burden. A cross-sectional study by Jackson et al [23] examined mothers' demographic characteristics and their sons' QoL-related factors to identify which ones contribute to poorer health-related QoL and greater emotional distress. Mothers' perception of their sons' health-related QoL is a significant predictor of their own health-related QoL and emotional distress. In turn, mothers' physical and emotional health influences their social activities. Social activities are important to manage stress among caregiving parents. QoL is a measure used to obtain additional information on the effectiveness of clinical measures, the quality of services they need for health care, the effectiveness of the interventions, and cost-utility analyses. Change in QoL reflects how much a patient is satisfied with his or her treatment or the system of health care delivery [20,24,25].

Economic Burden of Disease

Previous studies have revealed that DMD also has a substantial economic burden on families. Studies have shown that this burden increases markedly with disease progression; however, no such study has been conducted in the Southeast Asian region [22,26].

Health care delivery systems frequently use patient engagement to reduce expenditure and improve health outcomes. When analyzing the health care delivery system in the state of Minnesota, Hibbard et al [27] concluded that patients who were less actively engaged in their treatment had 8 times higher health care costs in the first year, and this was significantly different from patients who were actively engaged in their treatment. Another review by Hibbard and Green [28] on patient engagement concluded that various tailor-made interventions to increase patient involvement in their disease significantly improved health outcomes. Nevertheless, very few studies comment on costs related to disease. Proper allocation of resources is most important for any institution to have sustainable development, and this applies to the health care system as well. Cost-of-illness studies can provide important information to policy makers at both the micro (eg, cost-effectiveness of new interventions) and macro level (eg, fund allocation for further research and prioritization of disease for preventive interventions) [13,29-31].

The Indian Ministry of Health and Family Welfare has begun to address this issue related to rare diseases, as reflected in its 2017 National Health Policy. The Indian government approved the separate National Rare Disease Policy in 2021. This policy recommends a focusing on indigenous research and local production of medicines, searching for low-cost treatments for rare diseases, and screening and early detection. Financial support is sought to be given to the rare diseases classified as Group 1 in the policy under the umbrella of Rashtriya Arogya Nidhi or Pradhan Mantri Jan Arogya Yojana. However, DMD is classified under Group 3, described as "diseases for which definitive treatment is available but challenges are to make optimal patient selection for benefit, very high cost and lifelong therapy" [32]. The policy identified 8 tertiary care centers as Centers of Excellence for managing rare diseases. The hospital-based National Registry of Rare Diseases was created in these centers to ascertain the exact burden of rare diseases.

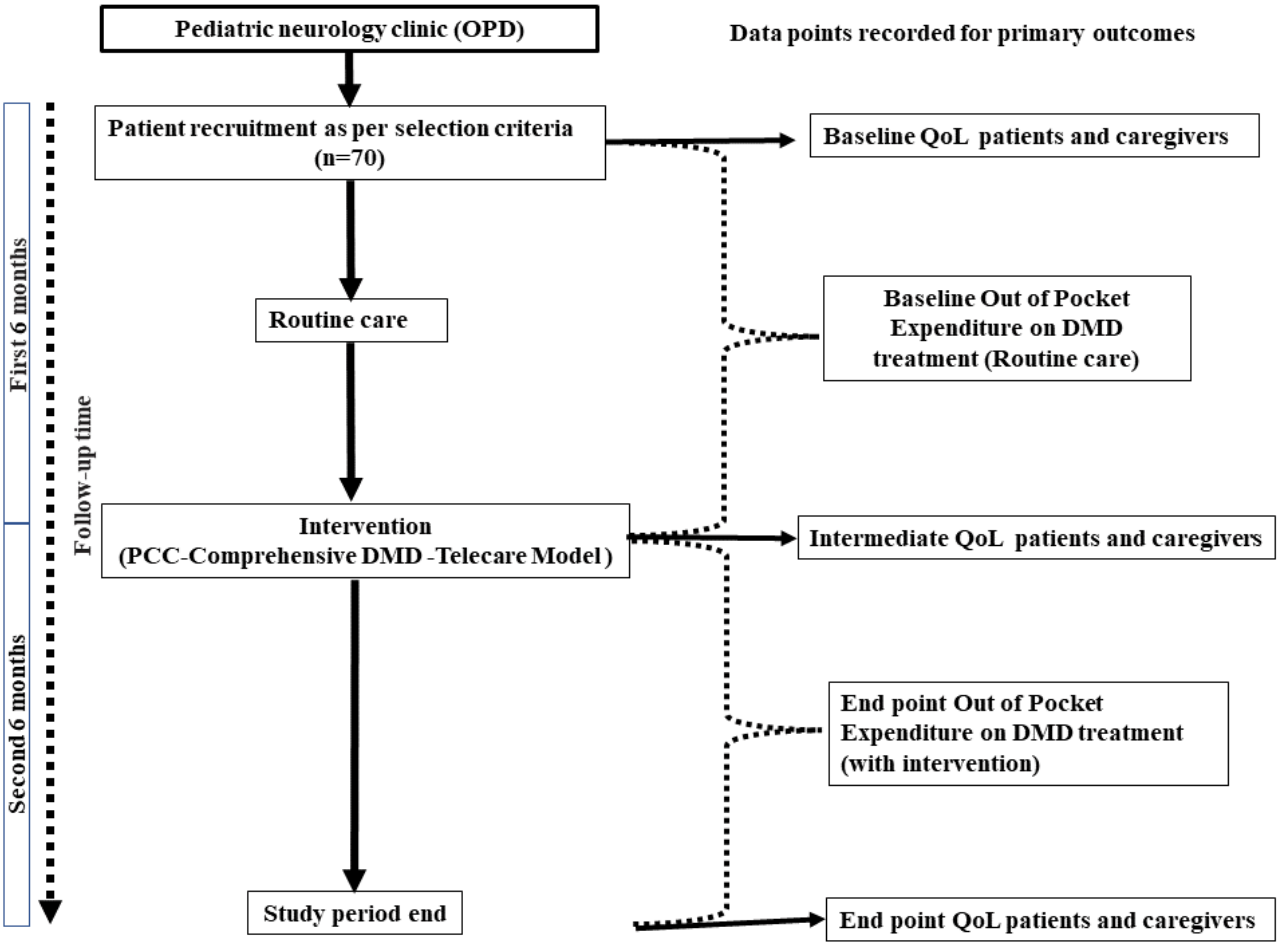
Accordingly, this study aims to estimate the economic burden incurred by the families of children with DMD seeking care at a government hospital. Next, we aim to develop a PCC model (intervention) to build the capacity of affected families to cope with DMD, thus reducing the financial burden on families. Finally, we aim to compare the impact of intervention with routine care on QoL (caregiver and patient) and economic burden after 6 months of intervention.

Methods

Study Design

This is a longitudinal quasi-experimental study that will be conducted in 2 phases. It is important to note that within the scope of this study, it is difficult to achieve a controlled experimental design. There is no randomization, and the same group of subjects are to be compared before and after the intervention. The experimental condition may be systematically different across the time frame. Considering this limitation, we chose a quasi-experimental design for this study. [33]

Phase 1 of the study is observational, and no intervention is administered. Participants (previously diagnosed and under follow-up as well as new patients) were recruited prospectively from pediatric neurology clinic, department of Pediatrics, Advanced Pediatrics Center, Post Graduate Institute of Medical Education & Research (PGIMER), Chandigarh, India. Detailed information about the study was provided to the children and their caregivers. After providing consent to participate in the



XSL•FO
RenderX

study, the primary caregivers were interviewed for demographic information, clinical information, and information related to their economic status and financial burden of disease caused by DMD. The QoL of patients and caregivers was assessed with the EuroQoL 5-Dimension 5-Level (EQ-5D-5L) scale and the World Health Organization Quality-of-Life Scale (WHOQOL-BREF), respectively. After recruitment into the study, the patients were followed up for 6 months. Routine treatment as per institutional norms was given during this period. The primary caregiver was contacted via telephone monthly for data collection on economic burden. After the 6 months, the participants entered into the next phase (ie, phase 2).

Parallelly, during phase 1, the PCC intervention model was developed. The rationale behind developing the care model was to provide basic information about DMD and treatment options to the patients and their parents or caregivers so that they could participate effectively in the process of obtaining comprehensive care in a resource-limited setting. The intervention includes information about the disease, an instructional booklet, and a workbook to encourage compliance. This study also includes a teleconsultation with pediatric neurologist and the rehabilitation team. The sessions are designed to facilitate caregivers in decision-making through active participation in every stage of the disease. This set of interventions are collectively referred to as the Comprehensive DMD-Telecare Model.

Phase 2 is the interventional phase of the study, which commences once the patient has completed phase 1 (ie, the first 6 months of the study). During phase 2, patients and their parents or caregivers are given a set of interventions developed during phase 1. The patients are followed up prospectively for the subsequent 6 months (Figure 1), and data on economic burden are recorded telephonically on monthly basis. Children are visiting the health facility just twice during the follow-up period (ie, at the beginning and at the end of phase 2). This reduced the number of in-person visits the patients had to make to the health facility.

Figure 1. Overview of study design. DMD: Duchenne muscular dystrophy; OPD: Outpatient Department; PCC: patient-centered care; QoL: quality of life.

Ethics Approval

Approval for this study was granted from the ethics committees of PGIMER (IEC-01/2021-1884) and Lovey Professional University (LPU/IEC/2021/01/24). The patients and their caregivers were informed about the study and provided consent before recruitment. Information collected from the patients and their caregivers will be anonymized. The study protocol was registered with the Clinical Trials Registry India (CTRI/2021/06/034274).

XSL•FO
RenderX

Setting and Sample Size Considerations

Patients were recruited prospectively in a consecutive manner from the Pediatric Neurology Clinic of the Advanced Pediatric Center at PGIMER in Chandigarh, India. This institute caters to approximately 7 north Indian states, namely, Punjab, Haryana, Himachal Pradesh, Jammu and Kashmir, Uttarakhand, Bihar, the northwestern part of Uttar Pradesh, and the Union Territory of Chandigarh.

The sample size estimation for the primary outcome was in accordance to changes in patients' health-related QoL (HRQOL) questionnaire scores. The QoL scores were assessed in the observational phase (0-6 months) and compared with the QoL scores in the intervention phase (7-12 months). A clinical meaningful difference based on the minimum important difference from HRQOL was 0.1 [34], along with an SD of 0.2 [35] and an allocation ratio of 1:1. The estimated sample for the study was 126 (63 patient in each phase) to achieve a level of significance of 95% CI at a power of 80%, accounting for a 10% dropout rate. The total sample size was 140, with 70 patients in each phase.

Study Population

The study population comprises families or caregivers with boys aged between 5 and 15 years who were genetically diagnosed with DMD and are seeking consultation at the pediatric neurology clinic of the government tertiary care center. Caregivers defined as the persons who look after the patients in the hospital or at home (parents or family members). This excludes hospital staff and paid workers hired by the family.

Selection Criteria

Boys with DMD presenting to the Pediatric Neurology Clinic were screened for enrollment in the study. The selection of participants was carried out by a pediatric neurologist. Those who fulfilled the inclusion and exclusion criteria were included in the study after providing informed consent. Textbox 1 lists the inclusion and exclusion criteria for this study.

Textbox 1. Inclusion and exclusion criteria for this study.

Inclusion criteria

- Families with boys aged 5 between 15 years who have Duchenne muscular dystrophy (DMD) or Becker muscular dystrophy (BMD) and display clinical symptoms and creatine kinase (CK) levels elevated 10 times or more the normal level
- Laboratory genetic confirmation of DMD or BMD by multiplex ligation-dependent probe amplification (MLPA), polymerase chain reaction (PCR), next-generation sequencing (NGS), or muscle biopsy (showing absence of dystrophin expression on immunohistochemistry)
- Caregivers of the patients with who have access to a smartphone and internet connection

Exclusion criteria

- Caregivers and patients who are unwilling to participate or unable to comply with the study protocol and visits
- Caregivers and patients who did not provide consent to participate

Intervention Program

Routine Care

Boys with clinical symptoms suggestive of DMD were first consulted and evaluated in the pediatric neurology clinic. After detail clinical investigations, a treatment plan for the patient was decided as per the institutional protocol for the management of muscular dystrophies and discussed with the patient. The patient was required to visit the health facility routinely once every 3 months. For multispecialty care, patients visited different subspecialists as required. Physiotherapy and orthosis appointments, along with visits to specialty care units, increase hospital visits, often leading to confusion, treatment nonadherence, and loss to follow-up. The components of routine management are given in Textbox 2.

XSL•FO
RenderX

Textbox 2. The components of routine management as per institutional protocol (standard operating care).

1. Confirm diagnosis: clinical examination, investigations, confirmation of diagnosis with genetics, and muscle biopsy
2. Family counseling
3. Baseline assessment of motor attributes with the 6-Minute Walk Distance Test, Time Function Test, and Vignos and Brooke scales
4. Baseline cardiac, respiratory assessment, spine, bone health, and endocrine evaluation
5. Oral supplementals of calcium and vitamin D
6. Nighttime ankle-foot orthosis
7. Physical therapy muscles strengthening and stretches to reduce contractures
8. Vaccination (immunization)
9. Steroids as per standard guidelines
10. Dietary advice
11. Advice on play and leisure
12. Three monthly clinical check-ups for disease progression, monitoring for weight, height, blood pressure, ophthalmic evaluation, bone health, and steroid side effects (these visits may be more as per disease progression requirement).
13. Prenatal diagnosis, carrier screening, and genetic counseling

PCC: Comprehensive DMD-Telecare Model

The rationale behind developing the PCC model for patients with DMD was to (1) provide basic information to the patient and their parents or caregivers so that they can effectively understand the disease and participate in the process of obtaining comprehensive care in a resource-limited setting and (2) create awareness about the importance of managing the disease not only pharmacologically but also by improving QoL.

After a systematic review of literature, the intervention designed was based on the Theory of Planned Behavior and tailored to each stage of the study [36]. The conceptual model of PCC is given in Figure 2. The telecare component was added to the model considering the challenges that patients and their caregivers experience when having to travel to the heath care facility frequently, especially in low- and middle-income countries (LMICs). The components of the intervention are provided in Table 1.

The purpose of the intervention is to reduce the number of in-person visits the patient has to make to the clinic. The planned physical follow-up to the health facility during phase 2 is at 6 months. Families are called for physical follow-up only if indicated and instructed by the clinician within 6 months. These visits are recorded.

Protocol material for the Comprehensive DMD-Telecare Model is circulated among pediatricians and pediatric physiotherapists working at the Pediatric Neurology Clinic, School of Public Health experts at PGIMER, and caregivers or parents.

A preliminary version of this package was circulated among specialists for consensus validation and modified according to the feedback received. Thereafter, it was pilot tested among 5 patients and their caregivers. Further corrections were made as needed. Textbox 3 lists the outcomes of the study.

Figure 2. Overview of patient-centered care (PCC): intervention model. DMD: Duchenne muscular dystrophy; PPT: PowerPoint presentation.

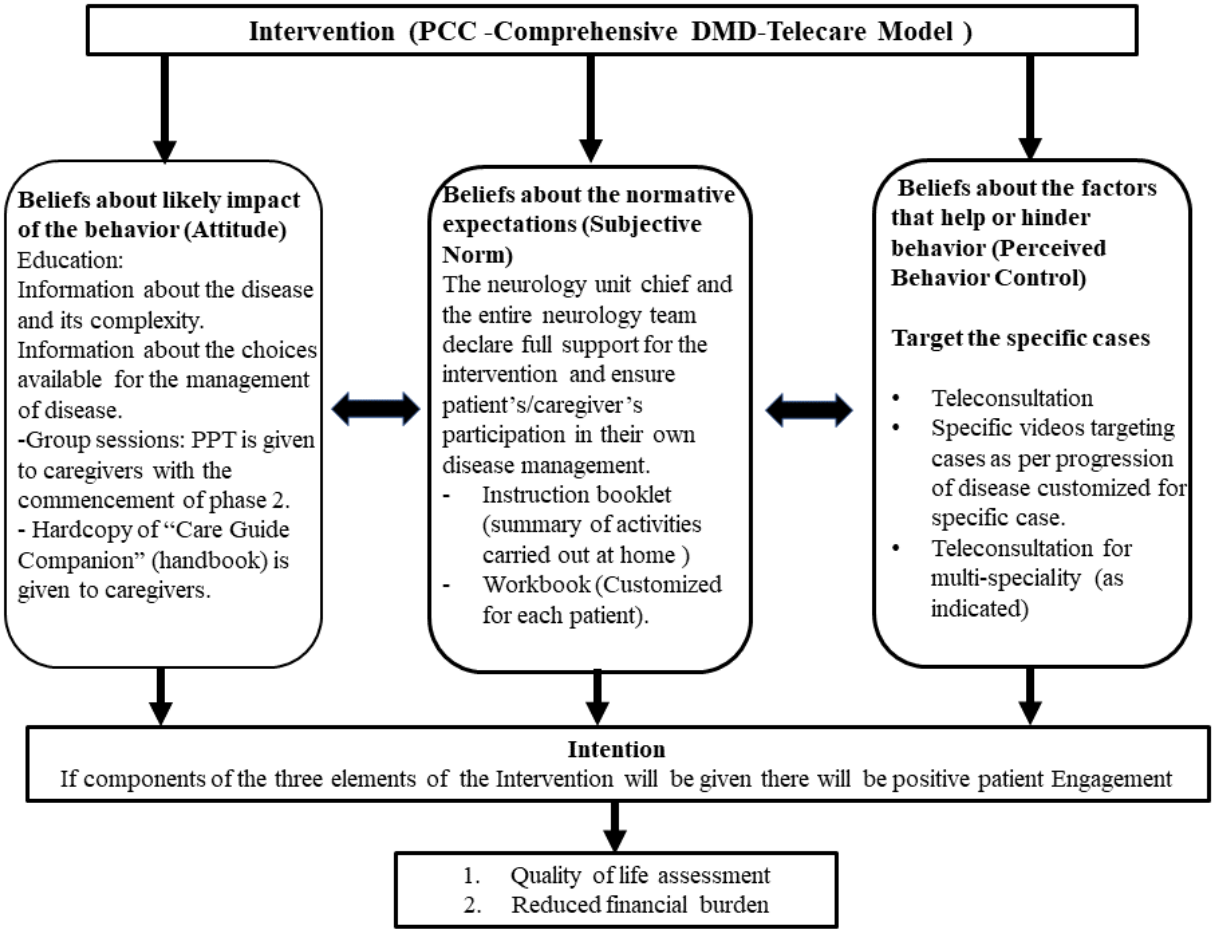

Table 1. Components of the intervention.

Component	Description
Informational session about the disease	Information sessions are carried out via PowerPoint presentation, and a "Care Guide Companion" booklet is provided (both hard copy and digital). The booklet is designed to helping patients and their caregivers participate in decision-making for their treatment. The components of the booklet include (1) basic information related to DMD[a], (2) management of DMD, (3) role of the care provider team, and (4) support groups to help people living with DMD.
Instructions and checklist	Instructions are given to the patients and their caregivers to make them understand all the activities that will be carried out once they enter phase 2 of the study. Audiovisual media and images containing instructions for stretches or physio-therapy and physical activity are provided to the family.
Compliance diary	The patient is expected to comply with the prescribed procedures and medications. A customized daily planner is introduced to each patient in phase 2 to increase their adherence to the protocol. This contains periodic monitoring of weight, height, blood pressure, daily medication (eg, steroids, ACE[b] inhibitors, calcium, and vitamin D), and daily exercise routine. Some clinical evaluations are expected to be performed at home (eg, Gower sign, Vignos score, Brookes scores, etc) which are monitored by the research team over the phone.
Teleconsultation	A total of 3 monthly video teleconsultations are given to the patients by clinicians to provide diagnostic or therapeutic advice electronically. The patient does not have to visit the clinic in person. This is done through: (1) review videos that the family shares with the care team regarding the patient's present state of illness. These videos are recordings of physical activities that the patient can perform at home, which are share with the team for evaluation purposes; and (2) customized videos: As per the clinical requirements, customized videos are shared with patients to address any additional needs.
Multidisciplinary teleconsultation	Not all subspecialists are needed at all ages or stages, but they must be accessible if necessary.

[a]DMD: Duchenne muscular dystrophy.

Textbox 3. Study outcomes.

Primary outcomes

1. Difference in quality of life (QoL) with and without the intervention
2. Difference in out-of-pocket (OOP) expenses incurred by patients and their caregivers with and without the intervention
3. Development of patient-centered care (PCC) model known as the Comprehensive Duchenne muscular dystrophy (DMD)-Telecare Model

Primary outcome measures

1. Change in QoL mean scores in phase 1 (0-6 months) and phase 2 (7-12 months) of the study
2. Change in mean OOP expenses incurred by the patients and their caregivers with and without the intervention

Secondary outcomes

1. Socioeconomic determinants of primary outcomes.
2. Feasibility of follow-up via telephone
3. Pattern of health care utilization for different stages of DMD
4. Neuromuscular QoL in the pediatric age group
5. Opinions and experiences related to the challenges faced by stakeholders during the management of DMD (noted verbatim)

Secondary outcome measures

1. Demographic data and socioeconomic status in terms of means and percentages
2. Compliance with telephone follow-up and satisfaction index on Likert scale
3. Mean score of neuromuscular QoL in the pediatric age group
4. Thematic analysis of the qualitative data

Data Collection

At the time of recruitment, primary caregivers are interviewed on their social and demographic characteristics and QoL. Further, after the initiation of phase 1, these caregivers are contacted again prospectively to assess the economic burdens they face by collecting data on out-of-pocket (OOP) expenses incurred during the treatment of DMD. The data on economic burden include information on household consumption expenditure, patient-level expenses incurred on diagnosis and treatment related to DMD, and coping mechanisms for dealing with DMD. A pretested semistructured schedule, adapted from previous studies in similar settings, is used to interview the patients [37-39]. Cost-of-illness (COI) analysis is carried out to assess OOP expenses, which are further classified as direct and indirect expenses [40]. Expenditure on the diagnosis, drugs or consumables, hospitalization, user fee, or procedure fee is considered direct health care expenditure. Transportation, boarding, loading, and food are taken as direct non–health care expenditures. Wage or income loss by the accompanying caregivers during the period of treatment is considered an indirect expenditure.

Information on economic burden is gathered from the caregivers throughout the follow-up period of 12 months. Data are collected during their physical visits as well as telephonically every month.

HRQOL of the patients and their caregivers are gathered at the baseline and then at the completion of phases 1 and 2. QoL of caregivers is also recorded at the 3 data points (baseline, end of phase 1, and end of phase 2). The study design is further explained in Figure 1.

Data Management and Analysis

Primary data are first entered in Epi Info software (version 7; Centers for Disease Control and Prevention). Data will be analyzed using both Epi Info 7 and SPSS software (version 23; IBM Corp). Mean OOP expenditure incurred due to the treatment modalities will be calculated. The OOP expenditure will be reported in Indian rupees. For international comparison, expenses will be converted to US dollars using an appropriate conversion rate. Indirect expenditure will be calculated for the duration of follow-up treatment using a human capital approach by assessing the wage loss of the caregivers [41]. Financial risk will be assessed in terms of catastrophic health expenditure and distress financing. An expenditure on DMD treatment that exceeds the threshold of 40% of nonfood household consumption expenditure is considered a catastrophic health care expenditure [42,43]. Households that had to either borrow money (with or without interest) or sold their assets (such as land, home, cattle, etc) to cope with DMD-related expenditure will be classified as having faced distress financing [38,44,45]. Multiple logistic regression analysis will be performed to examine the risk of catastrophic health expenditure and distress financing with covariates, including age, income status, treatment modality, education, locality, and stage at the time of diagnosis. Sensitivity analysis will be carried out to assess the prevalence of catastrophic expenditure at varying cutoff levels (ie, 20%-50%).

XSL•FO
RenderX

The HRQOL of the patients will be assessed by the EQ-5D-5L tool. This tool comprises the EQ-5D descriptive system and a visual analog scale (EQ VAS). The EQ-5D-5L descriptive system has 5 dimensions (ie, mobility, self-care, usual activities, pain or discomfort, and anxiety or depression). Each of these dimensions has a response in the form of 5 levels of perceived problems: no problems (level 1), slight problems (level 2), moderate problems (level 3), severe problems (level 4), and extreme problems (level 5). Thus, a unique health state is defined by combining 1 level from each of the 5 dimensions. The EQ VAS records the patient's self-rated health on a VAS, where the end points are labeled as "The best health you can imagine" and "The worst health you can imagine." The analysis of the QoL utility scores based on the EQ-5D-5L tool will be done as recommended in the user guide. Each of the patient's condition or state at a particular time period will be referred to in terms of a 5-digit code. For example, state 11111 implies no problems on any of the 5 dimensions, while state 55555 indicates extreme discomfort in each of the dimensions. Each of these states are further converted into a single index utility value based on the recently generated tariff value set for the Indian population [46,47].

As mentioned earlier in this paper, the self-administered WHOQOL-BREF tool is used to assess the QoL of caregivers. This tool has 26 items describing 4 QoL domains, namely, physical health (7 items), psychological health (6 items), social relationships (3 items), and environmental health (8 items). It also contains items for general QoL and overall health (2 items). The response to each item is recorded in 5 levels and scored from 1 to 5. The raw scores will be converted into transformed scores ranging from 4 to 20. Later, these transformed scores will be converted into main domain scores ranging from 0 to 100, with higher scores indicating better QoL [48].

Correlations of HRQOL in children and QoL of caregivers in all 4 domains at the baseline will be assessed with socioeconomic status (SES), COI, and also with each other. Multiple linear regression analysis will be conducted to address the confounders (eg, age at baseline, family structure, type of disease, family history, family structure, education, and SES).

Economic burden and QOL data will be analyzed as per the study objective, and comparative analysis will be done to justify the hypothesis. Percentage, mean, and SD values will be recorded, and the chi-square test, paired *t* test, and Mann-Whitney *U* test will be carried out for statistical analysis. SPSS software (IBM Corp) will be used for the analyses.

Results

Study enrollment was completed in March 2022 with a total of 100 children with DMD and their caregivers (125% of the target). All 100 patients and their caregivers were followed up for 6 months in phase 1 of the study, which was completed in July 2022. The intervention was administered to 66 patients and their caregivers (94.3% of the target population) in phase 2. The participants were further followed for the subsequent 6 months, and phase 2 ended in December 2022. We are in the process of data entry and data cleaning. Initial data show that the children range in age between 5 and 15 years at enrollment, with a mean age of 8.3 (SD 1.9) years. Most of the children (56/100, 56%) enrolled in this study are in the late ambulatory disease (stage 3), and only 1 (1%) child was in a late nonambulatory stage at the time of enrollment. However, these dynamics changed swiftly with the progression of the disease.

Primary caregivers enrolled (n=100) at the baseline in the study were mostly mothers (58/100, 58%), with fathers comprising 38% (38/100) of the caregivers. Only 57% (57/100) of caregivers had some knowledge about DMD before enrollment. About 75% of the caregivers were educated more than high school, and 8.2% of them did not receive any formal education. More than half (51/100, 51%) the patients were had upper-middle SES, and (3/100, 3%) had lower SES. Because this study is only in the data entry and data cleaning phase, no impact data are available to report on the study objectives, aims, and hypotheses. The findings are expected to be published in 2024.

Discussion

This quasi-experimental study is expected to give baseline data about the economic burden faced by families who have children living with DMD for the first time in the Southeast Asian region. The PCC model (intervention) developed during the study period is based on individual needs and is a part of standard operating care (SOC). The intervention is mainly focused toward nonambulatory patients, as it is difficult for them to travel to health facilities. The health facility is actively approaching these patients to streamline their disease management and reduce loss to follow-up. Later, we also expect to evaluate whether this PCC model (intervention) can help reduce the financial burden faced by caregivers of children with DMD and help increase the QOL of both patients and their caregivers. The intervention has been designed considering the needs of all stakeholders (patients, parents or caregivers, and health care providers) by conducting group discussions, which are essential for the success of any intervention. The effectiveness of the program will be evaluated by collecting postintervention data.

The care required for a rare disease like DMD is not the same as usual medical care. For rare diseases, the patient- or caregiver-physician relationship grows with time, along with an evolution in the knowledge of the disease and its management strategies. As the disease outcomes and management are formative, the health care provider must inform and engage patients and their caregivers as an interactive partner to encourage compliance and adherence to the SOC. Most of the time, treatment seeking by the patients is limited by scarce knowledge about the disease, lack of availability of appropriate multidisciplinary health care, and limited access to treatment modalities [49]. The involvement of multiple disciplines is often overlooked by the health care sector. In addition to medical management, self-care, as well as caregiving by the patients' parents, is very important. Patient engagement when managing a disease is very promising, as the patient takes ownership of his or her health. PCC is one such intervention that ensures patient involvement. Patient or family engagement improves health outcomes and reduces OOP health expenditures. Patient engagement, health outcomes, and health expenditure depend

XSL•FO
RenderX

on the health care delivery system of the geographical region. The way that the health care delivery system functions depends on preferences, values, cultural traditions, and socioeconomic conditions in a given region [50].

The model will have more geographical coverage through teleconsultation, especially considering the COVID-19 era where travelling is restricted. Once the model is proven successful, it can be replicated for managing other chronic rare diseases. Nevertheless, this study has certain limitations, as out study design is noncontrolled, there is no randomization, and a single group is compared before and after the intervention. The experimental conditions may be systematically different across the study time frame. Our study aims to analyze economic burdens among ambulatory patients with DMD visiting the health care facility and are mostly within the age group of 5 to 15 years. However, previous studies have shown that that the maximum financial burden is faced in the later stages of disease (Stage 5, late nonambulatory), but this group is not covered in this study.

There have been studies conducted on QOL and health expenditure for DMD in Europe and North America, but no such study exists from the Asian region. Therefore, the results from this study will contribute to new scientific evidence on effectiveness of PCC for rare diseases in LMICs, where there is a paucity of research on this topic. The study has public health implications in generating evidence on the effectiveness of the intervention by considering patients' involvement in managing DMD. This can guide policy makers on formulating policies or guidelines for a more patient-centric program to manage a chronic, lifelong rare disease not only in India but also in other LMICs as well.

Acknowledgments

The authors express their sincere thanks to the team at the Pediatric Neurology Clinic of the Advanced Pediatric Center Postgraduate Institute of Medical Education and Research (PGIMER) in Chandigarh, India.

All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided APF support for the publication of this article.

Abstract

Background: Delays in reviewing issued laboratory results in emergency departments (EDs) can adversely affect efficiency and quality of care. One opportunity to improve therapeutic turnaround time could be to provide real-time access to laboratory results on mobile devices available to every caregiver. We developed a mobile app named "Patients In My Pocket in my Hospital" (PIMPmyHospital) to help ED caregivers automatically obtain and share relevant information about the patients they care for including laboratory results.

Objective: This pre- and posttest study aims to explore whether the implementation of the PIMPmyHospital app impacts the timeliness with which ED physicians and nurses remotely access laboratory results while actively working in their real-world environment, including ED length of stay, technology acceptance and usability among users, and how specific in-app alerts impact on its effectiveness.

Methods: This single-center study of nonequivalent pre- and posttest comparison group design will be conducted before and after the implementation of the app in a tertiary pediatric ED in Switzerland. The retrospective period will cover the previous 12 months, and the prospective period will cover the following 6 months. Participants will be postgraduate residents pursuing a ≤6-year residency in pediatrics, pediatric emergency medicine fellows, and registered nurses from the pediatric ED. The primary outcome will be the mean elapsed time in minutes from delivery of laboratory results to caregivers' consideration by accessing them either through the hospital's electronic medical records or through the app before and after the implementation of the app, respectively. As secondary outcomes, participants will be queried about the acceptance and usability of the app using the Unified Theory of Acceptance and Use of Technology model and the System Usability Scale. ED length of stay will be compared before and after the implementation of the app for patients with laboratory results. The impact of specific alerts on the app, such as a flashing icon or sound for reported pathological values, will be reported.

Results: Retrospective data collection gathered from the institutional data set will span a 12-month period from October 2021 to October 2022, while the 6-month prospective collection will begin with the implementation of the app in November 2022 and is expected to cease at the end of April 2023. We expect the results of the study to be published in a peer-reviewed journal in late 2023.

RenderX

Conclusions: This study will show the potential reach, effectiveness, acceptance, and use of the PIMPmyHospital app among ED caregivers. The findings of this study will serve as the basis for future research on the app and any further development to improve its effectiveness. Introduction

Background

Emergency department (ED) overcrowding is a global health problem [1], leading to prolonged ED length of stay (ED-LOS). ED-LOS is the time interval between the patient's arrival in the ED for registration or triage to disposition from the ED, either to be admitted to a hospital, discharged home, or transferred to another care setting. ED-LOS is considered as a key indicator of the performance, quality, and operational efficiency of an ED and, more broadly, the entire hospital to which the ED belongs [2]. It also serves as a benchmark metric between institutions. Prolonged ED-LOS, that is, stays exceeding 6 hours (with cutoffs ranging from 4 to 48 hours [3]), can adversely affect efficiency and quality of care, patient outcomes, and patient satisfaction [4].

According to the conceptual input-throughput-output model proposed by Asplin et al [5], ED congestion is partitioned into 3 interdependent components in terms of patient flows into, through, and out of the ED, respectively. The entire laboratory testing process, also known as therapeutic turnaround time (TAT) and part of the throughput component, is a major contributor to prolonging ED-LOS [6,7]. Laboratory tests are ordered in nearly 48% of ED visits [8], and 70% of patient-management decisions are based on these tests [9]. Numerous mitigation strategies to minimize the intralaboratory analytic time, such as laboratory automation and digitalization, have been implemented [10,11]. Yet, it is estimated that up to 96% of the delays that contribute to the therapeutic TAT occur in the pre- and postanalytical phases outside of the central laboratory [12,13]. In the latter case, caregivers' delayed awareness and timely review of available laboratory results have been described as the largest component of perceived therapeutic TAT [11], strongly contributing to prolonged hospital LOS [14]. This delay may be partly related to the fact that busy, multitasking ED physicians and nurses are cognitively distracted from reviewing laboratory results in a timely manner in the absence of individualized, automated real-time prompts. Prompt awareness of results' availability in real time requires health care personnel to regularly access electronic medical records (EMR), leading to incessant and time-consuming trips to computer workstations, thus distracting them from patient care in an extremely challenging and changing environment.

Previous Work

Targeted interventions to reduce the postanalytical TAT phase may contribute to shortening ED-LOS, but mobile digital health solutions to achieve this goal are scarce. In a previous study [15], we described the user-centered development and early technology acceptance evaluation of a mobile app called "Patients In My Pocket in my Hospital" (*PIMPmyHospital*). The app was designed to help ED caregivers obtain relevant information in real time for the patients they care for, including laboratory and imaging results. The app also offers an end-to-end encrypted chat to provide a remote communication channel between caregivers caring for the same patients. In a randomized controlled pilot trial [16], the time required for ED physicians and nurses to review laboratory results after their release was significantly reduced by 92% using the app compared to the usual procedure in a semisimulated model. However, the potential effectiveness of this app in mitigating ED-LOS by taking cognizance of laboratory results in a shorter time frame than usual remains to be evaluated in daily clinical ED practice.

Objectives

In this study, we present the protocol for a pre- and posttest study. Its objective is to evaluate whether the use of the *PIMPmyHospital* app alters ED physicians' and nurses' temporal efficiency to access laboratory results more quickly while actively working in an ED. Temporal efficiency will be assessed by measuring the time between the release of the laboratory results in the clinical information system and their acknowledgment by these clinicians. To our knowledge, no app that can access laboratory results in real time in the ED has been described to date [17]. The study will be structured according to the "Population," "Intervention," "Comparison," and "Outcome" framework as follows: (1) participants: medical and nursing staff working in the pediatric ED; (2) intervention: implementation of the mobile app in the pediatric ED; (3) comparison: remote access to laboratory results in the pediatric ED through the app versus standard access to laboratory results prior to its implementation; (4) outcomes: times to access laboratory results, ED-LOS, technology acceptance, and app's usability among users, and how specific in-app alerts impact on its effectiveness.

XSL•FO
RenderX

Methods

Study Design

We will conduct an 18-month, single-center, nonequivalent comparison group, pre-post study. We will compare the control and experimental groups on outcome measures before (12-month period) and after (6-month period) the implementation and use of the app. This study protocol adheres to the Standard Protocol Items: Recommendations for Interventional Trials 2013 Checklist [18]. All data will be deidentified. The study will be conducted according to the principles of the Declaration of Helsinki [19] and Good Clinical Practice guidelines [20]. It is our intention to present these at scientific congresses and to publish the results in an international peer-reviewed journal, irrespective of the magnitude or direction of effect. Only deidentified data will be available to researchers for analysis. The study is registered at ClinicalTrials.gov on September 28, 2022 (NCT05557331).

Participants

Eligible participants will be postgraduate residents pursuing a less than 6-year residency in pediatrics, pediatric emergency medicine fellows, and registered nurses from the pediatric ED (aged >18 years). Written informed consent will be obtained from each participant in the experimental group after full information disclosure prior to study participation. On the first day, after completing the informed consent form, participants will be asked to download the app to their personal smartphone through the secure institutional Microsoft Intune portal (Microsoft Corporation). They will then be required to attend a unique standardized 5-minute introduction course to the app and its functionality by the study investigators, but they will not receive specific instructions on how often to use the app. The participants will remain the same throughout the intervention period. No one will be asked to advise on the interpretation of the results.

Setting

The study will take place in the pediatric ED of a tertiary referral and major trauma hospital in Switzerland, with an annual volume of 35,000 visits. This should represent approximately 16,600 visits over the 6-month prospective intervention period, of which approximately one-half could potentially benefit from laboratory tests. The ED has 14 centrally monitored treatment rooms, a resuscitation room, a 5-bed short-term observation room (ie, <24 hours), a plaster room, a hypostimulation room, and a dedicated interview room. The patient population consists of local children from birth to 16 years of age with medical, surgical, and traumatology emergencies, as well as transfer cases from other hospitals in Switzerland or children located in neighboring France.

The usual number of residents is 10 on a monthly basis during a 4-month period. They provide coverage for 6-7 overlapping shifts, which begin at different times, with each shift ranging from 10 hours (9 hours of patient care, 1 hour of recovery) to 12 hours (12 hours of patient care, no recovery time at night) on weekdays and 6 shifts on weekends to cover a 24-hour day (Table 1). During the intervention schedule, residents typically work 3-4 night shifts followed by 72 hours off, then 3-5 consecutive day shifts before 2 days off, followed by 2-day shifts. This pattern repeats throughout the month, with occasional additional days off or vacations. The 14 fellows (some of whom are part-time) work in an irregular combination of 6 overlapping 8-12 hour shifts on weekdays and 3 shifts on weekends (Table 1). Finally, 17 nurses out of a total of 43 cover a 24-hour day. This represents a total coverage of 70-78 hours, 30-48 hours, and 102 hours per day for residents, fellows, and nurses, respectively. The ED uses the Canadian Triage Acuity Scale [21] to guide patient treatment based on medical-surgical urgency. On average, each resident sees about 300 patients per month and fellows 50-70, with a ratio of medicine: surgery-trauma cases of 2/3:1/3. The standard physician-to-patient ratio ranges from 1:5 to 1:7 and varies according to disease acuity and time of the visit. The nurse-to-patient ratio ranges from 1:3 to 1:5. Caregivers see patients on a first-view [22], on-site, 24/7 basis. Whether they work 8-, 10-, or 12-hour shifts, they all work in the same area, have access to the same patient volume, and see the same patient complaints. They have full, secure 24/7 electronic access to laboratory results.

The PIMPmyHospital Mobile App

Information regarding the app has been published previously [16]. In brief, the app was developed iteratively following a user-centered approach starting with the identification of the main functionalities that meet end-user needs [15]. The system operates on a client-server architecture. Four microservices developed on the Java Spring Boot framework ensure (1) transmission of patient information, (2) access to real-time laboratory results, (3) the trigger of push notifications, and (4) exchange of information between caregivers through an instant messaging system. These microservices exchange information with the front end developed in the Angular and Ionic frameworks through a restful app programming interface. Patient medical data are not stored on the app itself, but in the institution's EMR on secure servers to which the app connects. The exchange of data between the app and these servers is secured by the use of JSON web tokens obtained during the authentication of caregivers through a Keycloak identity and access management solution. User authentication on the device relies both on a login password and a specific certificate installed on the user's device. The app runs on Google's Android and Apple's iOS operating systems.

The app's interface features a home page with a personalized view of the patients that each caregiver is taking care of, together with associated information (eg, patient identity, time since admission, and patient's geospatial location within the ED) and clickable actions next to them [16]. In particular, dropdown contextual tabs provide real-time access to laboratory results retrieved from the hospital patient's EMR. Visual push notifications occur as soon as new results are made available. The entire patient management process is available to the caregiver in the palm of their hand and can be accessed at any time while on the go, hence the app's name "Patients in my Pocket."

Procedure and Intervention

This is a pre-post study. Before the implementation of the app, EMR-based data from the past 12 months will be collected retrospectively. These data will include the times (ie, HH:MM:SS) that results issued by the central laboratory were available on the institutional EMR as well as the times at which these results were accessed by caregivers through conventional computerized workstations. After the implementation of the app, data will be collected prospectively over a 6-month period of use. This will include the times (HH:MM:SS) when the results issued by the central laboratory are made available through the app on caregivers' smartphones and access times as well as concurrent or preferred access times on the conventional computerized workstations should this occur. Individual acceptance of the app on the first day (a priori) and then on the last day of the intervention will be evaluated through the Unified

XSL•FO
RenderX

Theory of Acceptance and Use of Technology (UTAUT) [23]. Usability of the app will be measured by the System Usability Scale (SUS) [24]. Figure 1 shows the study procedure, and Table 2 presents the study schedule. Use of the app will be on a 24-hour basis and at the discretion of participants.

Technology Acceptance Terminology and Definition

We use technology acceptance to refer to an initial acceptance of use, as recently defined by Nadal et al [25], to explicitly distinguish between the different temporal stages of technological acceptance. It refers to users' first interactions with the app at the preadoption stage before sustained acceptance of its use in the postadoption stage.

Outcomes and Measures

Primary Outcome: Time to Laboratory Access

The primary outcome will be the mean elapsed time in minutes between the delivery of the laboratory results and the caregiver accessing them, both before and after the implementation of the app.

Secondary Outcome: Technology Acceptance and Usability

The secondary outcomes will be the technology acceptance and usability of the app. The 8-construct, 31-item UTAUT [23] will be used to measure app acceptance and intention to use. This is a 5-point Likert-type scale (1: strongly disagree, 2: moderately disagree, 3: neutral [neither disagree nor agree], 4: moderately agree, and 5: strongly agree). Usability of the app will be measured using the SUS designed by Jordan [24]. According to the International Organization for Standardization, the SUS assesses effectiveness (ie, the ability of users to use the product), efficiency (ie, the effort to use the product), and satisfaction (ie, how the users felt when using the product). It comprises a 10-item questionnaire with 5 response options for each item

XSL•FO
RenderX

based on their level of agreement, ranging from 1 (strongly disagree) to 5 (strongly agree). According to the scoring system by Jordan [24], for odd-numbered (1, 3, 5, 7, and 9) statements (the positively-worded items), the score contribution is equal to the scale position minus 1 (eg, strongly agree: 5–1=4). For even-numbered (2, 4, 6, 8, and 10) statements (the negatively worded items), the score contribution is equal to 5 minus the scale position (eg, strongly agree: 5–5=0). Each score contribution falls within the range of 0 to 4. Participants' scores for each item are then added up together and multiplied by 2.5 to convert the original scores of 0-40 to 0-100. Although the scores range from 0 to 100, these are not percentages of usability. The higher the score, the better the usability. To obtain a SUS score of 100, the respondent must answer 5 to all odd questions and 0 to all even questions. The original SUS items are presented in Multimedia Appendix 1. When translating the SUS questionnaire from its original version to French [26], we replaced the general term "system" with the specific term *PIMPmyHospital*. Another secondary outcome will be the mean ED-LOS per patient measured from the point when patients are triaged in the ED to discharge from the ED, defined as patients leaving the ED, whether admitted to the intensive care unit or ward, transferred to another hospital for admission, discharged home, or those who left without being seen. These data will be extracted from the hospital administrative electronic database. Finally, we will determine whether specific alerts, such as a flashing icon or sound for reported pathological values of laboratory results, have an impact on the results.

Data Transfer, Safety, and Privacy

Access to the app is controlled through a 2-factor authentication process. An enterprise environment is created on the health care smartphone using the Microsoft Intune software (Microsoft Corp.), for both Android and iOS operating systems. This environment ensures that the app is run in a secure context where only an authorized app can be installed. This environment also enables the installation of a certificate that serves as a second authentication factor, while the first factor is the user's login and password. Access rights are managed by the Active Directory group, which enables access to ED caregivers only. All data collected by the app are transmitted securely through a hypertext secure transfer protocol and stored exclusively on the hospital's secured internal server.

Data Collection

Electronic data will be extracted from the institutional data lake. The data lake stores all data and events from the EMR information system in a database and can be retrieved using Simple Protocol and RDF Query Language (SPARQL) queries. In the preintervention period, the time stamp of the laboratory results on the EMR will be identified as the time of issuance of the said results. Access to these results by the physicians and nurses will be defined by the time stamp of the first access to the laboratory results' viewer on the EMR. Access to results on the app will be computed either by the time stamp of the push notification access or to the dedicated page on the app. No other patient-level data such as identifiers or clinical characteristics will be collected. Collected data will be transmitted to the REDCap database web app (REDCap, Vanderbilt University) hosted by the hospital for analysis.

Blinding

Although neither the participants nor the study investigators can be blinded to the intervention, both will be blinded to the results of the study until their final analysis by the statistician. Participants will be informed only of the overall purpose of the study, which is to evaluate the effects of the app on quality of care, but not about the aim of reducing the time to access laboratory results in order to minimize bias. The statistician will remain blinded to allocation until the final analysis.

Sample Size

Physicians in the pediatric ED see on average 900 patients over 3 months. Assuming an intraclass correlation of 0.1 in time between delivery of the laboratory results and the caregiver accessing them, 5253 individual patients are required to have a 90% chance of detecting, as significant at the 5% level, a decrease in a time difference of 0.5 SD. This represents approximately 18 physicians including 100 patients per month over 3 months. In order to obtain 18 physicians, we will recruit physicians over 2 consecutive rotation periods.

Statistical Analysis

The association of app use with the time between delivery of the laboratory results and their access by caregivers will be assessed using generalized estimating equations with an exchangeable correlation structure to account for the nested structure of the outcome (ie, time) within the physicians. To account for potential differences in case-mix and physician characteristics, we will use multivariable generalized estimating equations. The covariates will be as follows: (1) the triage acuity scale, (2) type of pathology (medical, surgical-traumatological, psychiatric), (3) experience of the caregiver expressed in years since certification, (4) patient age, (5) patient sex, (6) workload represented by the number of patients present in the emergency room, (7) time of day or night, (8) day of the week, and (9) month of the year (seasonal variability). To account for the possible effect of exogenous factors that would impose an asymmetry in the data (skewness on the right) by extending the awareness of laboratory results, we will identify these factors as the study progresses prospectively and take them into account in the final analysis. The same analyses will be performed for the nurses. We will carefully monitor and evaluate through descriptive analyses any differences between nurses' and physicians' frequency access to laboratory results. If the target sample size cannot be reached, we will first extend the prospective data collection period by 3 months (deemed ethically acceptable as not impacting patients) or present only the results of qualitative user experience interviews.

For the technology acceptance self-administered survey questionnaire, scores on the 8 technology acceptance constructs will be described using descriptive statistics. Items on the SUS questionnaire will be described using frequencies. Analyses will be carried out using R software (R Core Team) [27]. All statistical tests will be 2-sided, with an α risk of .05.

XSL•FO
RenderX

Ethics Approval

The study protocol received a declaration of no objection by SwissEthics on October 18, 2022 (Req-2022-01156), which stated that the need for approval was waived as its purpose was to examine the effect of the intervention on health care providers and thus it does not fall within the scope of the Swiss Federal Law on Human Subject Research, with a waiver of written informed consent.

Data available to research team members will only contain deidentified, coded information. All records that contain personal identifiers, such as consent forms and UTAUT and SUS questionnaires, will be stored separately from study records. Each participant file will be identified by a code number. Study data will not be released to any other individual outside the research team. Only deidentified data will be published and available to researchers for analysis. There will be no financial compensation or incentive for participants.

Dissemination Policy

Only study investigators will have the right to access and analyze the data for dissemination purposes. The principal investigator will oversee dissemination activities to ensure that team members with the necessary subject matter expertise are involved in every aspect of dissemination. We plan to disseminate the results of this study through peer-reviewed publications, conferences, as well as other avenues as appropriate, regardless of the findings.

Results

Retrospective laboratory data will be arbitrarily collected from October 31, 2021, to October 31, 2022. Prospective data will be collected from the start of enrollment on November 1, 2022, through April 30, 2023. We anticipate an analysis of the results by mid-2023 and expect the results to be published in late 2023.

Discussion

Strengths and Perspectives With the Existing Literature

To the best of our knowledge, there are no previous studies describing the effectiveness of a mobile app to provide real-time mobile access to laboratory results in EDs [17]. This study protocol is the first to propose the exploration of the potentially beneficial effect of such an app on the reduction of therapeutic TAT and its acceptance and usability by end users. The study investigators anticipate that implementation of the app will shorten times to consideration of laboratory results among participants who use it compared to those who have not used it previously. We plan to generate a stronger evidence base for a broader implementation of dedicated mobile apps for remote, real-time access to laboratory results in EDs. We also expect good acceptance of the app as well as good usability. One of the strengths of this study is the use of an app whose iterative design and development involved a multidisciplinary end user–centered approach [15]. In addition, the app's ability to reduce the time taken by pediatric ED caregivers to consider laboratory results has already been the subject of a randomized controlled pilot trial in a semisimulated ED environment [16]. This study will attempt to verify its encouraging results in a real environment with its spatial and temporal constraints and inherent human factors.

In terms of implications, the use of dedicated mobile apps could represent a paradigm shift where information would come directly and synchronously to caregivers rather than having to travel to retrieve it. A shorter TAT for the postanalytical phases could be associated with a shorter ED-LOS and thus improve the quality of care and patient satisfaction. Moreover, such a solution could be extended to other care units where the use of mobile apps would make it possible to get rid of the distances and delays to access laboratory results.

Limitations

This study has some limitations. First, participants who agree to be prospectively enrolled may be interested or engaged in digital health promotion in general and mobile technologies in particular, influencing their a priori motivation to use the app. If so, this should be reflected in the UTAUT questionnaire, which is an outcome of interest. Second, the study will be conducted in a pediatric ED, which may limit the generalizability of the findings to adult EDs. For example, the acuity of age-specific diseases may imply a different awareness in the consideration of laboratory results. Other limitations may be identified during the study itself and will be noted after their identification.

Conclusions

Our intervention can serve as a foundation for a broader implementation of supportive mobile apps for in-hospital caregivers to improve the timely availability of EMR-derived results and the efficiency of care by reducing therapeutic TAT and ED-LOS.

Acknowledgments

We are grateful to Rosemary Sudan (freelance technical editor) for providing editorial assistance. This study received no funding.

Data Availability

Data sharing is not applicable to this paper as no data were generated or analyzed during the preparation of this protocol. The final data sets established and analyzed during the study will not be publicly available. An anonymous copy of the final data sets underlying publications resulting from this study will be available from the corresponding author upon reasonable and approved request.

Authors' Contributions

FE was responsible for the concept and design of the study, responsible for the literature search, and drafted the manuscript. CT and RR contributed to the critical review of its content with the support of RT, AB, and MR. DSC contributed to the design and statistical analysis plan of the study and contributed to the drafting of the manuscript. FE was responsible for the development of the project software with the support of RT, AB, MR, and JNS. FE and JNS oversaw the development of the project software. JNS was the main study coordinator, responsible for the concept and design of the study, responsible for the overall conduct of the study, and drafted and oversaw the writing of the manuscript. All authors have contributed to, seen, and approved the final submitted version of the manuscript and take responsibility for the integrity of the data and the accuracy of the data analysis. The corresponding author (JNS) confirms that he will have full access to participants' data and endorses the final responsibility for the submission. He further affirms that the manuscript is an honest, accurate, and transparent account of the study being reported; that no important aspects of the study have been omitted, and that any deviations from the study plan will be explained.

Conflicts of Interest

FE and JNS are owners of the PIMPmyHospital app. The app is currently not commercially available. FE, RT, AB, MR, and JNS declare individual intellectual property rights on this app and, as employees of Geneva University Hospitals, indirect institutional rewarding through its potential future commercialization (without personal enrichment). The authors declare no other relationships or activities that could appear to have influenced the submitted work. All authors have completed the International Committee of Medical Journal Editors uniform disclosure form and declare no support from commercial entities for the submitted work, and no financial relationships with any commercial entities that might have an interest in the submitted work in the previous 3 years.

Abstract

Background: In manufacturing industries, tasks requiring poor posture, high repetition, and long duration commonly induce fatigue and lead to an increased risk of work-related musculoskeletal disorders. Smart devices assessing biomechanics and providing feedback to the worker for correction may be a successful way to increase postural awareness, reducing fatigue, and work-related musculoskeletal disorders. However, evidence in industrial settings is lacking.

Objective: This study protocol aims to explore the efficacy of a set of smart devices to detect malposture and increase postural awareness, reducing fatigue, and musculoskeletal disorders.

Methods: A longitudinal single-subject experimental design following the ABAB sequence will be developed in a manufacturing industry real context with 5 workers. A repetitive task of screw tightening of 5 screws in a standing position into a piece placed horizontally was selected. Workers will be assessed in 4 moments per shift (10 minutes after the beginning of the shift, 10 minutes before and after the break, and 10 minutes before the end of the shift) in 5 nonconsecutive days. The primary outcomes are fatigue, assessed by electromyography, and musculoskeletal symptoms assessed by the Nordic Musculoskeletal Questionnaire. Secondary outcomes include perceived effort (Borg perceived exertion scale); range of motion of the main joints in the upper body, speed, acceleration, and deceleration assessed by motion analysis; risk stratification of range of motion; and cycle duration in minutes. Structured visual analysis techniques will be conducted to observe the effects of the intervention. Results for each variable of interest will be compared among the different time points of the work shift and longitudinally considering each assessment day as a time point.

Results: Enrollment for the study will start in April 2023. Results are expected to be available still in the first semester of 2023. It is expected that the use of the smart system will reduce malposture, fatigue, and consequently, work-related musculoskeletal pain and disorders.

Conclusions: This proposed study will explore a strategy to increase postural awareness in industrial manufacturing workers who do repetitive tasks, using smart wearables that provide real-time feedback about biomechanics. Results would showcase a

XSL•FO
RenderX

novel approach for improving self-awareness of risk for work-related musculoskeletal disorders for these workers providing an evidence base support for the use of such devices.

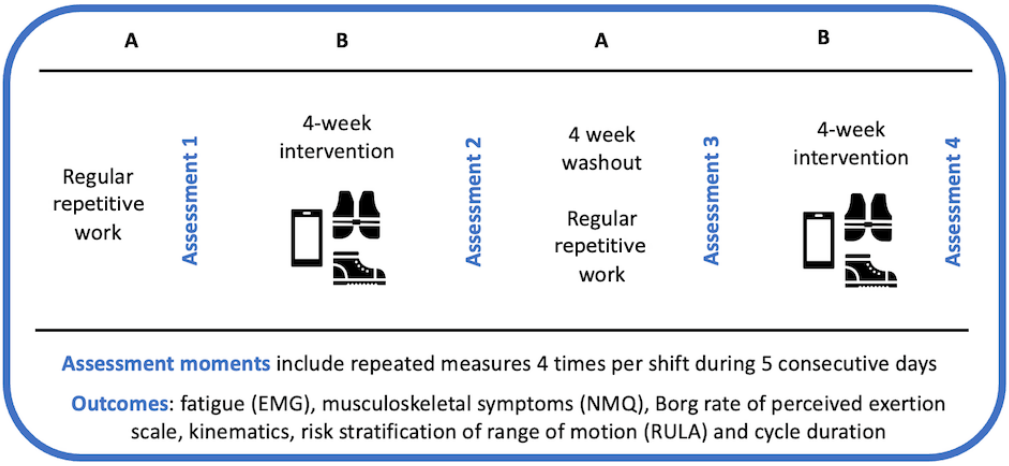
Introduction

The agenda for decent work, initially promoted by the World Labor Organization, and recently connected to the sustainable development goals of the United Nations [1], includes safety and security at work as one of its strategic axis [2]. The quest to fulfill this axis also reflects the increased demand from consumers regarding concerns about the development of fair and sustainable products. In the same line of concerns, some companies issue bonds incorporating the fulfillment of objectives related to the reduction of accidents at work [3]. Thus, the opportunities offered by the technological developments of the so-called Industry 4.0 could positively influence the indicators related to this set of objectives and concerns, namely with regard to musculoskeletal injuries. Musculoskeletal disorders (MSDs) are the most prevalent work-related health issues and one of the most critical public health problems worldwide [4,5]. Work-related musculoskeletal disorders (WMSDs) are mainly caused by the execution of work tasks and the environment in which work is performed [4]. In the manufacturing industries, tasks requiring excessive force, poor posture, high repetition, and long duration, which induce fatigue and which are stressful, lead to an increased risk of MSDs [4,6,7]. The consequences of WMSDs have a significant and wide-ranging financial impact on both the social and individual levels [8]. In Europe, about 3 of every 5 workers report MSDs. In assembly and manufacturing workers, the most common types of MSDs reported are back pain (55%) and muscular pain in the neck, shoulder, and upper limbs (47%), followed by the lower limbs (33%) [4]. MSDs are responsible for 15% of the total number of (disability-adjusted) life years. Furthermore, more than half (53%) of the workers with MSDs report work absenteeism. Therefore, a high burden on the economy and health care systems is not surprising. In addition, the individual, coworkers, and families are also affected, directly or indirectly, by the injured workers with an associated decrease in physical and mental health and quality of life [9,10].

Due to the high prevalence of musculoskeletal complaints and diseases, and the high associated burden, a significant effort has been made in the prevention of WMSDs [10]. Assessing exposure to risk factors of WMSDs is among the most successful strategies [11]. One of these emerging approaches is wearable devices [11-14]. These are rapidly developing, fostering the promotion of individual healthier lifestyles. Smart workwear is technology embedded into clothing that contacts the skin. This technology can monitor heart rate and movement delivering holistic information on fatigue and body stress. The real-time feedback of data provided can enhance the monitoring of health status, perhaps enabling earlier diagnosis or, in turn, hastening the integration of injury and illness prevention strategies [13,15]. Thus, comfortable smart workwear with movement and posture monitoring seems an adequate solution for the assessment of WMSDs risk and prevention of WMSDs. Although recent advances have been made in posture assessment and monitoring, few studies focus on compensatory adaptations that provide feedback to the user [16,17]. Injury prevention, due to inadequate posture or muscle fatigue, may be engaged with educational information and biofeedback delivered to the operator in real-time conditions or at strategically selected intervals of time during the work shift. Providing individual feedback to the worker may help decrease the exposure of individual workers to ergonomic risk factors and consequently, injury [18].

Thus, this study protocol aims to detect muscle fatigue related to repetitive activities and to explore a smart wear system for correcting biomechanics and reducing fatigue. The system involves the use of a wearable sensorized jacket and shoes and real-time feedback delivered to the worker. This system was created with the aim of preventing the unconscious development of awkward postures, compensatory movements, and fatigue, predisposing to injuries over time. The system will be tested through a single-subject experimental design with human subjects performing a repetitive task in real industry settings. The development of research in a real context on the factory floor raises different challenges. One of these challenges concerns the interference that investigation activities make in the normal production cycle. Thus, the methodological options should consider the least possible impact for the typical activities carried out there. In this sense, within the range of experimental work options, a single-subject experimental design will be able to contribute to these requirements.

Methods



Design and Setting

A longitudinal single-subject experimental design following the ABAB sequence [19] will be developed in a manufacturing industry real context. In the ABAB design, first, a baseline is determined (A), then the intervention is introduced, with the use of the smart wear and real-time feedback to the worker for the first time (B). Next, the intervention is withdrawn, returning to the baseline condition (A). Finally, after baseline stability is reestablished, the intervention is presented (B) for the second time [1,2]. All 4 periods will end with an assessment of the selected outcomes. Figure 1 depicts the study flow. Generally, in this study design, the research is done very thoroughly on 3

XSL•FO
RenderX

to 5 subjects. The interest is always in the meticulous examination of each participant individually, not in the group's average performance. Multiple single-subject experimental studies also present the opportunity to consider not only the individual variables but also analyze the trial at the environmental level [19,20].

Figure 1. Study flow diagram. EMG: electromyography; NMQ: Nordic Musculoskeletal Questionnaire; RULA: Rapid Upper Limb Assessment.

Ethics Approval and Consent to Participate

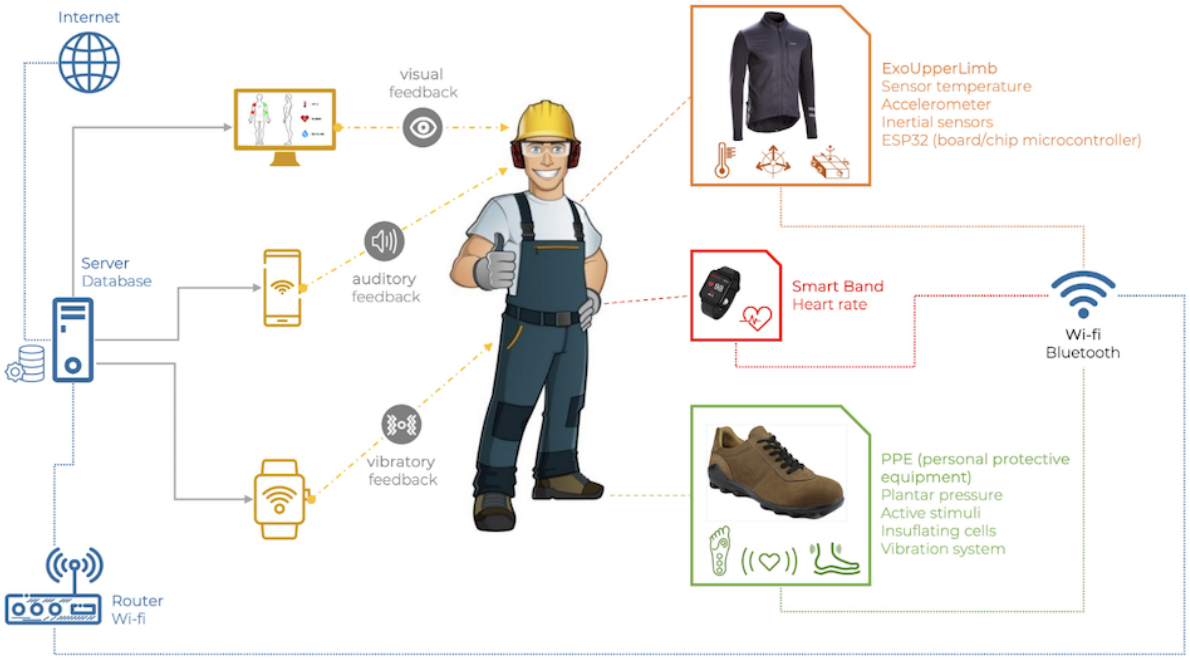
All participants will give informed consent to participate. All procedures are handled according to the Declaration of Helsinki and regulatory legislation, which includes approval by an ethics committee. The protocol is under review by the Ethics Committee of the University of Aveiro (17-CED/2023). Data will be processed complying with the European General Data Protection Regulation.

Participants, Eligibility, and Recruitment

This study will include 5 active workers from an industrial manufacturing setting of household appliances in the Region of Aveiro, Portugal. To be included, workers must be aged between 35 and 45 years and have a work experience with the tested workstation for at least 6 months. Exclusion criteria are (1) history of vestibular disorders, (2) neurological, respiratory disease, or spinal surgery, (3) structural spinal problems, (4) medication or a health condition affecting balance, and (5) regular treatments for a musculoskeletal condition.

The workers will be recruited by the occupational health department, which will provide the identification numbers of each selected worker as well as shoe and clothing sizes.

Study Procedure



A specific task representing a repetitive movement was chosen. The task consists of the vertical screw tightening of 5 screws in a standing position into a piece placed horizontally. A first assessment period will be executed to analyze baseline repetitive work (A) outcomes. Subsequently, the workers will use the smart wearables and be provided with real-time feedback for 4 weeks (B). A second assessment (assessment 2) will be performed to explore the efficacy of the system. Afterward, the workers will have a washout period of 4 weeks to reestablish baseline repetitive work condition (A), followed by assessment 3. Finally, a second 4-week period of intervention (B) and consequent assessment 4, will take place (Figure 1). Each assessment moment will be accomplished in 5 consecutive days, in 4 periods of the day, which includes measurements for each period of 5 cycles of the performed task in the first 10 minutes after starting the shift (to avoid the warm-up period), 10 minutes before the break time, 10 minutes after the break, and 10 minutes before the end of the day's shift. All tests will be performed guaranteeing that in the anterior 48-hour period each individual did not participate in strenuous physical activities, which may affect the selected outcomes.

Smart Wearable Systems

The smart wearable systems consist of a sensorized jacket, smart footwear, a smart band, and a feedback system provided to the worker. The sensorized jacket aims to monitor the upper limb (shoulder flexion/extension and abduction/adduction and elbow flexion/extension) and trunk (lumbar flexion/extension) with strategically placed inertial measurement unit (IMU) systems and body temperature with a temperature sensor. Smart footwear consists of a shoe equipped with a set of 6 sensors Force Sensitive Resistors (Sensitronics), to map plantar pressures. The sensors have a 30-mm diameter and work in a 0-300–N force range. They were assembled in a custom substrate printed by RokuPrint (RP 2.2, RokuPrint GmbH). A smart band will monitor heart rate. The main system architecture is presented in Figure 2.

XSL•FO
RenderX

Figure 2. Main system architecture. PPE: Personal Protective Equipment.

Data Collection and Outcomes

The primary outcomes are fatigue and musculoskeletal symptoms. Fatigue will be assessed by electromyography (EMG) and musculoskeletal symptoms by the Nordic Musculoskeletal Questionnaire [21].

Secondary outcomes include perceived effort, assessed by the Borg Rating of Perceived Exertion (RPE), range of motion of the main joints in the upper body and trunk, speed, acceleration, and deceleration of movement, through motion analysis, risk stratification of range of motion of the upper limb and trunk based on limits defined in the Rapid Upper Limb Assessment (RULA) [22], and cycle duration in minutes.

For patient characterization, baseline questionnaires including sociodemographic data, physical activity level, quality of life, anxiety and depression, insomnia and sleep quality, fatigue, and pain and disability will be collected. Table 1 displays the assessment flow.

[g]RULA: rapid upper limb assessment.

[h]RPE: rate of perceived exertion.

Instruments

Electromyography

EMG recording will be conducted using the Cometa EMG wireless portable system (Covidien Kendall) with disposable silver 24-mm surface electrodes. Electrode application will proceed following the recommended procedures of skin preparation: shaving of the area; rubbing and cleaning with alcohol; following a 10-minute resting time to reduce skin impedance [23]. The EMG electrodes will be placed according to manufacturer's recommendations on the upper trapezius, posterior deltoid, triceps medial, biceps brachii, the lumbar portion of the erector, biceps femoris, tibialis anterior, and gastrocnemius. All trials will be visually examined for signal quality and measurement errors. Muscle activity data will be collected with a sampling rate of 2000 Hz. EMG data will be processed with a customized MATLAB script (R2017b, MathWorks), where a fourth-order Butterworth band-pass filter from 10 to 500 Hz will be applied to minimize the appearance of electromyographic artifacts [24]. EMG signal will be normalized using a method that divides each point that constitutes the processed EMG by the peak value acquired from the same EMG. The root-mean-square of the EMG data and the averaged rectified value will be calculated to determine the signal amplitudes. Muscle fatigue will be characterized by median frequency and amplitude.

Motion Analysis

A 3D biomechanical motion analysis for kinetics and kinematics parameters will be recorded with the Vicon-Nexus 3D motion capture system (Vicon Vero, v2.2). Reflective markers (clusters) will be placed on the midpoint between the left shoulder and left elbow, the midpoint between right shoulder and right elbow, the midpoint between the left elbow and left wrist, the midpoint between the right elbow and right wrist, and seventh cervical vertebra and sacral region (midpoint between right posterior superior iliac and left posterior superior iliac) [25]. Additional markers will be placed on the screwdriver (top of the shaft) by the same experienced examiner. 3D marker trajectory data will be collected at 100 Hz with 6 cameras. Before starting the calibration, all reflective objects will be removed from the workspace so that they do not interfere with the recording. Necessary care will be taken to warrant that the worker's clothing is also nonreflective [26]. Prior to the assessment of the subjects, the workstation will be prepared following the recommended procedures of calibration of both optical and video reference cameras according to the manufacturer's recommendations manual. The kinematic variables of interest are the range of motion of the neck, trunk, shoulder and elbow, speed, acceleration, and deceleration. The range of motion will be calculated as the maximum minus minimum joint angle in each selected sample.

XSL•FO
RenderX

Questionnaires

Overview

For all the questionnaires, the Portuguese-validated version will be used.

Musculoskeletal Symptoms

To assess MSDs and symptoms associated with the working population, the Nordic Musculoskeletal Questionnaire will be used [21]. This questionnaire encompasses 27 questions (3 questions related to the 9 anatomical regions: neck, shoulders, wrists/hands, upper back, low back, hips/thighs, knees, and ankles/feet) with a binary response (yes or no) and a question to rate pain on a numerical scale [21]. This questionnaire presents a good test-retest reliability and good internal consistency [21]. To assess musculoskeletal symptoms before and after the shift on evaluation days, only the first question will be used and adapted for the recall period; instead of the last 12 months, a period of the last 8 hours will be considered.

Perceived Exertion

The Borg RPE scale is a tool for measuring an individual's effort and exertion, breathlessness, and fatigue during physical work and so is highly relevant for occupational health and safety practice. In this scale, 6 corresponds to "No Effort" and 20 corresponds to "Extremely Hard" [27].

Ergonomic Risk

The RULA was selected to assess ergonomic risk in this study. This tool was developed to assess workers' exposure to ergonomic risk work associated with musculoskeletal injuries of the upper limbs, taking into consideration biomechanical and postural load requirements of work task demands on the neck, trunk, and upper limbs. This instrument provides a simple scoring method based on the range of motion, which can identify joints at risk. The output of the RULA assessment tool is the final RULA score, which is a single score that represents the level of MSD risk for the job task being evaluated, ranging from a minimum of 1 to a maximum of 7 points [22].

Physical Activity Level

The level of physical activity will be assessed with the Rapid Assessment of Physical Activity questionnaire (RAPA). This version presents good internal and construct validity [28]. The RAPA evaluates the level and intensity of leisure-time physical activity, as well as strength and flexibility training in a 9-item, self-administered questionnaire [28].

Quality of Life

Participants' quality of life will be assessed with the Portuguese version of the EUROHIS-QOL 8-item index questionnaire [29]. This questionnaire presents a good internal consistency, test-retest reliability as well as construct, discriminant, and convergent validity [29]. In this quality-of-life measure, each of the domains (physical, psychological, social relationships, and environment) is represented by 2 items. The result is a global index, calculated from the sum of the 8 items, with a higher value corresponding to a better perception of quality of life [30].

Depression and Anxiety Symptoms

The Patient Health Questionnaire-9 (PHQ-9) will be used to assess signs of depression [31]. This tool reports to the last 2 weeks and consists of a depression module with 9 items, using a 4-point response scale, ranging from "0" (not at all) to "3" (nearly every day). The PHQ-9 presents good internal consistency, convergent validity, and criterion validity. Total scores of 5, 10, 15, and 20 represent cut points for mild, moderate, moderately severe, and severe depression, respectively [32]. Anxiety-related signs and their severity will be assessed by the General Anxiety Disorder 7-item scale (GAD-7) [33]. The GAD-7 index is obtained by adding the scores from the questionnaire, after having assigned 0 to 3, depending on the severity. The cutoff points 5, 10, and 15 classify the anxiety as none/normal (0-4), mild (5-9), moderate (10-14), and severe (15-21). In general, anyone who scores 8 or above can be considered as having significant anxiety symptoms [34]. This scale presents cultural adaptation, excellent internal consistency, internal validity, and very good reliability [33].

Sleep Quality

The Basic Scale on Insomnia Complaints and Quality of Sleep (ie, BaSIQS) questionnaire is based on a set of 7 questions assessing nocturnal experiences in terms of subjective sleep quality and symptoms of insomnia [35]. Except for the final 2 items, which are scored on a reversed 5-point Likert scale, all items are scored on a scale of 0 to 5, with higher scores indicating poorer sleep. The results on reliability, validity, and accuracy support the use of this questionnaire for research and practical purposes [35].

Subjective Fatigue

Fatigue will be assessed with the Functional Assessment of Chronic Illness Therapy- Fatigue. This 13-item tool measures an individual's level of fatigue during their usual daily activities over the past week. Scoring is based on a 4-point Likert scale (4=not at all fatigued to 0=very much fatigued), with a ranging total score of 0 to 52 (0=worst possible score; 52=best possible score indicating no fatigue) [36]. This questionnaire presents high internal consistency, good convergent and divergent validity, and satisfactory test-retest reliability [37].

Data Management and Monitoring

The collection and data storage will be made in digital format, including those from the questionnaires. The entered data will be checked for completeness, validity, and plausibility by a member of the research team.

Data Analysis

Structured visual analysis techniques will be conducted to observe the effects of the intervention using a Single-Case Visual Analysis package for R. Graphical (RStudio) representations of data for each participant will be plotted considering primary and secondary outcomes on the y-axis and time on the x-axis. The results for each variable of interest will be compared in-between the different time points of the work shift and longitudinally considering each assessment day as a time point.

XSL•FO
RenderX

For each outcome (primary or secondary) and each moment mean, median, range, and stability envelope will be calculated. The level of change and difference between the first and last values of each period will be compared. The next step includes the calculation trend using the split middle method of trend estimation. After this procedure, percent of data points within the stability envelope (80% of data points between ±25% of median) will be considered. The final step is using the "freehand method" to evaluate data path [38].

Results

Enrollment for the study will start in April 2023. We plan to complete the post assessments of the last worker in April 2023. The results are expected to be available still in the first semester of 2023.

Discussion

Significance of the Study

Given the high prevalence of WMSDs and the associated economic and personal burden, preventive measures such as smart wear for monitoring and providing feedback are crucial. The smart wearables analyzed under this study aim to create awareness of WMSDs risk and empower the worker to reduce the associated risk and have a healthier work environment and higher quality of life. Investing in preventive measures is especially rewarding, since workers in countries and sectors where more preventive measures are in place are less likely to report MSD complaints [10]. Consequently, preventive measures result in an increase in economic benefits for the industries with greater production and worker adherence to these jobs.

The proposed study is, to our best knowledge, one of the first to use devices that provides real-time feedback to industrial workers about posture. This real-time feedback will include the body location at risk, which can lead to the correction of body biomechanics. Posture and movement monitoring technology can help detect and subsequently reduce the compensatory movement patterns, promoting a decrease in fatigue and musculoskeletal symptoms.

Strengths and Limitations

This study is a single-case experimental design. This method design was primarily developed to assess individual behavior. Given the main goal is to develop and test smart wear for reducing fatigue and poor biomechanics, a single-subject approach seems adequate. This design enables the possibility of rapidly determining if the wearables are effective. Immediate changes can be observed firsthand, quickly, and in individual participants. Consequently, adjustments can be rapidly made, if necessary. Contrary to the single-subject approach, a large sample statistical approach will require weeks or months of participant testing, mean calculations, and statistical analyses before the effectiveness may be determined. Conceptually, the treatment condition must influence individual behavior and assure both research intra- and interparticipant replication. Therefore, an ABAB design will be executed, assuring both intra- and interparticipant intervention and control [38]. Graphical analysis of the variability of each outcome, in each of the repeated measures in time, will be performed to explore the possible indicators of fatigue when performing the selected activity.

Conclusions

This proposed study will explore a strategy for reducing fatigue and musculoskeletal symptoms in industrial workers, possibly preventing WMSDs, using smart wearables that provide real-time feedback about biomechanics. Results would showcase a novel approach for improving postural awareness and self-awareness of risk for WMSD providing an evidence-based support for the use of such devices. Further research could explore other health indicators and individualized approaches to prevent similar health risks.

Acknowledgments

This study was developed in the scope of the Project Augmented Humanity (POCI-01-0247-FEDER-046103 and LISBOA-01-0247-FEDER-046103), financed by Portugal 2020, under the Competitiveness and Internationalization Operational Program, the Lisbon Regional Operational Program, and by the European Regional Development Fund.

Abstract

Background: Lack of physical activity is a common issue with detrimental consequences for the health of people with severe mental illness (SMI). Existing physical activity interventions show suboptimal effects as they require substantial cognitive skills, including goal setting and writing, whereas cognitive deficits are common in this population. To bolster the effectiveness of physical activity interventions, self-control training (SCT), in which users practice the ability to override unwanted thoughts and behaviors, can be used in addition. Recent research has demonstrated the initial effectiveness of a mobile SCT app, but this has not been studied in psychiatric clinical practice.

Objective: This study aims to evaluate to what extent adding a mobile SCT app designed for and with people with SMI to a mobile lifestyle intervention aimed at increasing physical activity increases physical activity and self-control levels.

Methods: A mixed methods approach incorporating 2 single-case experimental designs (SCEDs) and qualitative interviews was used to evaluate and optimize SCT. Overall, 12 participants with SMI will be recruited from 2 organizations offering outpatient and inpatient care to people with SMI. Each experiment will include 6 patients. SCED I is a concurrent multiple-baseline design across participants that explores initial effectiveness and optimal intervention duration. Using accelerometry and experience sampling questionnaires, participants' physical activity and self-control will be monitored for ≥5 days from baseline, followed by the sequential introduction of Google Fit, the physical activity intervention, for 7 days and the addition of SCIPP: Self-Control Intervention App for 28 days. SCED II is an introduction/withdrawal design in which optimized SCT will be introduced and withdrawn to validate the findings from SCED I. In both experiments, the daily average of total activity counts per hour and the state level of self-control will serve as the primary and secondary outcome measures. Data will be analyzed using visual analysis and piecewise linear regression models.

Results: The study was designated as not subject to the Dutch Medical Research Involving Human Subjects Act by the Medical Research Ethical Committee Oost-Nederland and approved by the Ethics Committee/domain Humanities and Social Sciences of

XSL•FO
RenderX

the Faculty of Behavioural, Management, and Social Sciences at the University of Twente. Participant recruitment started in January 2022, and we expect to publish the results in early 2023.

Conclusions: The mobile SCT app is expected to be feasible and effective. It is self-paced and scalable and can increase patient motivation, making it a suitable intervention for people with SMI. SCED is a relatively novel yet promising method for gaining insights into whether and how mobile apps work that can handle heterogeneous samples and makes it possible to involve a diverse population with SMI without having to include a large number of participants.

Introduction

Background

Approximately 1% of the world's population lives with severe mental illnesses (SMIs) such as schizophrenia (20 million) or bipolar disorder (46 million) [1]. Although their experiences are diverse, many are faced with multifaceted psychosocial problems in daily life, including difficulties in employment, housing, relationships, and finances and physical health inequalities [2]. An especially poignant problem in this group is the lack of physical activity and increasing sedentary behavior. Compared with healthy controls, people with SMI are more sedentary, less physically active, and less likely to meet physical activity guidelines [3]. This has a broad range of detrimental consequences for the physical and mental health of people with SMI, including reduced quality of life, increased risk of cardiovascular disease, and increased symptom severity [2,4,5]. Fortunately, even minor improvements in physical activity can prevent problems with physical health and deterioration of psychiatric symptoms in people with SMI and, thus, improve their quality of life [2,6,7].

The Role of Self-control in Successful Behavior Change

Clearly, there is an urgent need to improve physical activity in this extremely vulnerable group. However, existing physical activity interventions have several limitations when used in the population with SMI. First, many interventions are delivered by professionals, requiring additional time from already overworked staff [7,8]. For example, behavioral physical activity interventions targeted at people with SMI typically involve biweekly or weekly 60- to 120-minute sessions of counseling [9]. In addition, most physical activity interventions developed for people with SMI are not based on theory [9]. When they are, interventions are often solely underpinned by cognitive and reflective models of behavior change, including the Theory of Planned Behavior, Social Cognitive Theory, and the transtheoretical model [9-11]. Such interventions require substantial cognitive skills, including goal setting, reflecting on behavior, and writing, to produce effects [10]. This makes these interventions especially hard to use for people with SMI because of the vulnerabilities that are common in this target group related to cognitive deficits in memory and attention, low literacy rates, and apathy [12-17]. Finally, although behavioral theories are helpful in predicting behavioral intentions, these intentions do not necessarily relate to accompanying behavior changes, for example, increased physical activity [10,18]. This might explain why there is currently no reliable evidence that physical activity interventions result in better long-term physical health in people with SMI [9]. To address all the aforementioned issues, we need to better target physical activity interventions to vulnerable groups, including people with SMI.

This requires interventions that patients can work on independently; that do not require a high level of cognitive skills; and that target the intention-behavior gap that is common in interventions that are based on cognitive, reflective models. A promising focal point of these interventions is self-control—the ability to prevent or override unwanted thoughts or behaviors in favor of higher-order goals [19]. Studies have shown that self-control plays an important role in a broad range of goal-directed behaviors, including academic achievement, aggression regulation, and healthy eating and physical activity [19]. According to Friese et al [20], the role of self-control can be explained through three interacting components: (1) reflective processes such as personal goals, (2) impulsive processes such as automatic approach and avoidance tendencies, and (3) self-control abilities that allow for the control of impulsive processes and transfer of reflective processes into behavior. Owing to the large body of evidence that shows the relationship between self-control and health behaviors, self-control is an important element of many existing interventions. Even so, these mostly focus on self-control as a reflective process and teach reflective strategies such as goal setting, mental contrasting, and mental transformations [21], whereas interventions that address impulsive processes are underrepresented.

A conceptually different intervention is self-control training (SCT). SCT focuses on improving self-control abilities through repeated practice of self-control. In line with the impulsive processes described by Friese et al [20], individuals practice self-control by suppressing automatic tendencies in low-stakes areas for a predetermined period, often 2 weeks. A common paradigm is the use of the nondominant hand for everyday tasks such as writing or opening doors. This practice is then expected to transfer to behaviors for which self-control matters, such as physical activity. SCT is based on the strength model of self-control [22]. It states that all acts of self-regulation draw from a common, limited resource of self-control. Upon repeated exertion, this common resource becomes depleted, resulting in

XSL•FO
RenderX

impaired inhibition and goal-directed behavior until the resource is renewed. Although this theory suggests that exerting self-control has negative short-term effects, it also states that the repeated use of self-control strengthens the capacity for self-control in the long run, akin to a muscle.

Traditionally, participants receive face-to-face or written instructions from researchers or health care staff to perform self-control tasks [23,24]. These paper-based versions of SCT consistently show that this practice results in increased self-control [24-26]. As such, SCT has multiple advantages in clinical practice. It is easy to administer, does not require much time and effort from participants, and can be a valuable addition to existing treatment and interventions by means of its focus on the automatic aspect of self-control. However, face-to-face delivery of SCT can take up the precious time of (health care) professionals. To prevent this, delivery of SCT can also be done digitally using either web-based applications or mobile apps.

A mobile app specifically has advantages for the delivery of SCT in clinical practice. First, an app is scalable and easy to implement as it can be accessed by many people without requiring time from already overworked health care staff [27]. Second, design principles such as gamification can be applied to support people who are not that motivated to use SCT. This is especially relevant in populations with low treatment motivation, such as psychiatric patients [28,29]. To involve these target groups, persuasive strategies can be embedded in the design of the app to increase adherence and engagement [30,31]. Adding persuasive features such as rewards, reminders, and personalization to an SCT app can support users in using the intervention as intended, resulting in more positive outcomes. As an app can increase motivation and does not require a high level of cognitive effort, it can be a suitable way to bolster self-control and, thereby, increase the level of physical activity in people with SMI. The first results of using such an SCT app demonstrated that, among 204 healthy young adults who used a mobile SCT app, 10 days of app-based SCT already significantly increased self-control, whereas participants in the control and email conditions showed no improvement [32].

Overall, a large body of research has shown that SCT strengthens self-control [24-26]. However, similar to the effect sizes of cognitive physical activity interventions [33], the effect sizes of SCT alone on behavior are small [25]. Hence, we argue that multiple complementary interventions should be offered that address reflective processes, impulsive processes, and self-control abilities to produce meaningful changes in health behavior. To illustrate, reflective interventions focused on goal setting can be used to create physical activity intentions and directly stimulate behavior change. SCT can be added to these interventions to address the impulsive processes related to self-control, thereby increasing individuals' general self-control capacity and indirectly supporting behavior change. When general self-control capacity is high, individuals are more likely to inhibit the dominant response of remaining sedentary and are expected to instead go for a walk—in other words, they are more likely to put their intention of walking into practice. This suggests that SCT could be added to many existing cognitive interventions to increase participants' self-control and, thus, decrease the intention-behavior gap and bolster the effectiveness of interventions. Surprisingly, despite the large body of evidence showing SCT's potential [24-26,32], it has not been studied in combination with existing cognitive interventions yet. In addition, despite its straightforward nature, SCT has rarely been applied and studied in psychiatric clinical practice.

Study Objectives

Therefore, this study further explores a mobile SCT app and the assumption that it can be used to bolster the effectiveness of existing physical activity interventions. It does so specifically in the vulnerable population of people with SMI. The primary objective is to assess the effect of adding a mobile SCT app to a mobile lifestyle intervention aimed at increasing physical activity (Google Fit) on physical activity levels in people with SMI. The secondary objective is to examine the effect of this combined intervention on self-control directly. Finally, we will explore how long SCT should be offered to produce beneficial outcomes on physical activity and whether and which individual characteristics of patients influence SCT effects.

Methods

Ethics Approval

This study has been designated as not subject to the Dutch Medical Research Involving Human Subjects Act by the Medical Research Ethical Committee Oost-Nederland (approval 2021-13232). Consequently, it has been approved by the Ethics Committee/domain Humanities and Social Sciences of the Faculty of Behavioural, Management, and Social Sciences at the University of Twente (approval 211301) and the research committees of Dimence Groep and GGz Centraal. In addition, this study has been registered at *CCMO Toetsingonline* from the Dutch Central Committee on Research Involving Human Subjects (file NL79450.091.21). This portal will also be used to report (serious) adverse events if they occur.

Study Design

This study will be conducted using a series of 2 single-case experimental designs (SCEDs): a concurrent multiple-baseline design across participants (SCED I) [34,35] and an introduction/withdrawal design (SCED II). SCED is a family of high-quality experimental designs that can be used to draw causal inferences about the relationship between the intervention and the outcome [36,37]. In an SCED, the intervention is systematically manipulated across multiple phases of introduction and withdrawal while the outcome variable is measured repeatedly and frequently [36-38]. In this way, individual patients function as their own controls. An overview of both experiments according to the SCRIBE (Single-Case Reporting Guideline in Behavioral Interventions) guidelines [39] is provided in Table 1.

XSL•FO
RenderX

Table 1. Single-Case Reporting Guideline in Behavioral Interventions design elements of single-case experimental designs (SCEDs) I and II.

	SCED I	SCED II
Design	• Multiple baselines across participants	• Introduction-withdrawal
Duration	• 52 days	• Approximately 42 days (28-70 days)
Sequence of phases	• A-B-C+follow-up	• B-C-B-C
Description of phases	• Phase A—baseline: 5 days minimum; no intervention, only monitoring of physical activity and self-control • Phase B—Google Fit: 7 days minimum; only Google Fit intervention is administered • Phase C—Google Fit+SCT[a]: 28 days minimum; Google Fit and SCT intervention are administered simultaneously • Follow-up: 3 days minimum; no intervention, only monitoring of physical activity and self-control	• Phase B—Google Fit: 7 days; only Google Fit intervention is administered • Phase C—Google Fit+SCT: 7-28 days minimum; optimal phase length is determined from findings of SCED I; Google Fit and SCT intervention are administered simultaneously
Main outcomes	• Average TACs[b] per hour, measured continuously throughout the trial (at least 5 measures per phase) • Daily self-control, measured twice daily throughout the trial (at least 5 measures per phase)	• Average TACs per hour, measured continuously throughout the trial (at least 5 measures per phase) • Daily self-control, measured twice daily throughout the trial (at least 5 measures per phase)
Randomization	• Baseline duration is randomized with restriction to have at least 5 baseline observation days and 3 measurements	• Not randomized

[a]SCT: self-control training.

[b]TAC: total activity count.

There are several reasons for using SCED to evaluate interventions in people with SMI. First, SCEDs require only a small number of participants—typically 3 to 6. This makes it more feasible to recruit a sufficient number of participants and requires less time and financial resources from both staff and patients. Furthermore, SCEDs can handle heterogeneous samples as participants function as their own controls. This makes it possible to involve the diverse population with SMI, who may present with comorbidities and a broad range of psychosocial problems. Finally, SCEDs enable research into the working mechanisms of SCT, which is required [25] but nearly impossible to achieve through a randomized controlled trial (RCT) as an intervention is treated as a coherent whole, making it hard to open the black box of the studied intervention [40]. Overall, this makes SCEDs very suitable for the evaluation of interventions [41,42] and an excellent and feasible alternative to classic experimental designs such as the RCT.

In total, 2 SCED experiments are used to address different aspects of the overall research aim. SCED I is used to (1) determine the initial effectiveness of the intervention, (2) explore for which patients SCT may be most effective, and (3) determine how long SCT should be offered for optimal effects. The design of SCED I is A-B-C+follow-up, where A refers to the baseline phase, B is the physical activity intervention alone (Google Fit), and C is the combination of physical activity intervention+SCT intervention, followed by a follow-up in which patients are monitored but no interventions are administered. In addition, SCED I uses a mixed methods design incorporating qualitative interviews to provide insights into patients' experiences with both the mobile SCT app and the participation in an extensive longitudinal study. To explore the onset and duration of SCT effects on self-control, SCT is offered for 4 weeks instead of the customary 2 weeks [43]. This information will be used to determine whether SCT should be offered 1, 2, 3, or 4 weeks in SCED II.

The main aim of SCED II is to validate the effectiveness of the optimized intervention—in terms of duration and experience—based on the findings from SCED I. The design of SCED II is B-C-B-C, where, again, B refers to the physical activity intervention alone and C refers to the combination of physical activity intervention+SCT intervention. In both experiments, 6 participants will be monitored for at least one baseline phase and one intervention phase, with each phase lasting at least 5 data points following SCRIBE and What Works Clearinghouse guidelines [36,37,44]. Given that physical activity is measured continuously and self-control is measured twice a day, this will result in at least 28 data points during intervention phase C in SCED I and between 7 and 28 data points during intervention phase C in SCED II.

Randomization and Blinding

We will randomly assign participants to different baseline, intervention phase B, and follow-up durations in SCED I. All are drawn a priori using the web-based random number generator Research Randomizer [45] with the restriction of having at least 5, 7, and 28 baseline observation days, respectively. In SCED II, phase length will not be randomized as the optimal intervention length will be derived from SCED

XSL•FO
RenderX

I. Phase order will not be randomized in both experiments as we are interested in the additive effect of SCT over Google Fit only.

Owing to the nature of the intervention, in which apps are used by participants, it is not possible to blind participants to the phase. The researchers responsible for supporting participants in transferring between phases will not be blinded to the phase for the same reason. Where possible, researchers only involved in data entry, processing, and analysis will be blinded to the phase to improve the reliability of the findings [36].

Participants

A total of 12 people with SMI will be recruited from the clinics of 2 large Dutch mental health care organizations: Dimence Groep and GGz Centraal. To meet quality standards, an SCED should include at least 3 participants [37,44,46]. To account for the high dropout rates common in the psychiatric population, we will include 6 participants in both SCEDs. Participants will receive €50.00 (US $56.00) for taking part. To promote continued commitment to the longitudinal design, participants will receive €10.00 (US $11.00) at the start, €20.00 (US $22.50) midway, and €20.00 (US $22.50) at the end of the study.

Participants need to meet the inclusion criterion of having an SMI, including but not limited to schizophrenia, bipolar disorder, and major depression, following the Dutch consensus definition of SMI [47]: (1) requires treatment (ie, no symptomatic remission), (2) is associated with severe limitations in social or societal functioning (ie, no functional remission) that result in and are caused by a psychiatric disorder, (3) is not transient (ie, is structural, chronic, or long-term [at least several years]), and (4) requires coordinated care from professional caregivers in care networks to realize the treatment plan.

As the study will be introduced only to people currently receiving care for their SMI at an outpatient clinic or residing in an inpatient clinic, all participants will, on principle, be expected to meet the consensus definition, and no specific diagnosis will be determined. If doubt exists about whether a participant meets this criterion, the health care provider responsible for the patient (Dutch: *persoonlijk begeleider*) will determine whether the participant has an SMI following the consensus definition. In addition, participants must be aged ≥18 years, receive outpatient treatment or reside in an inpatient clinic for at least the data collection period, have sufficient opportunity to be physically active (eg, not be confined to a bed or bedroom), have an intention to improve physical activity as assessed using the single-item assessment of stages of change adapted for healthy behavior [48,49], and provide voluntary consent to participate. Participants are excluded if they do not want to (further) improve their physical activity. This is due to the nature of the SCT intervention—SCT supports putting an existing goal into practice (ie, tackling the intention-behavior gap) but does not support patients who are unwilling to improve physical activity. In a similar vein, SCT is also not expected to be effective for people who already meet their physical activity goals. Participants are also excluded if repetitive behavior may potentially aggravate a patient's disorder or symptoms (eg, obsessive-compulsive disorder) as evaluated by the health care provider or patient. Owning a mobile phone is not an inclusion criterion as participants who do not own a mobile phone will be provided one for the duration of the study.

To recruit participants, the study will be introduced to patients receiving treatment or residing in the clinics via short presentations and flyers distributed by the researchers. We specifically decided to do the initial introduction to the study via researchers rather than the health care provider to avoid any (perceived) role conflicts between health care providers and patients, for example, when the health care provider also makes decisions about patients' leave in a forensic psychiatric context. If patients are interested in the study, they will be able to sign up directly with the researcher (in person or by email), after which we will discuss with their health care provider whether participation is safe, appropriate, and feasible for this patient.

When possible, only 1 patient from each clinic will be selected. This ensures that SCT is tested in different types of patients, staff, and clinics and prevents social comparison effects as patients from the same clinic could challenge each other to be more physically active. Patients not selected will be invited to participate in SCED II or, if not possible, will be offered to use the intervention after the study.

Interventions

The interventions consist of 2 mobile apps designed to improve physical activity. The first is SCIPP: the Self-Control Intervention App, which was specifically designed for this study, and the second is Google Fit, a mobile lifestyle intervention aimed at increasing physical activity.

SCIPP: the Self-Control Intervention App

SCIPP is a mobile app based on the pen-and-paper format of SCT [24-26]. SCIPP is available on Android and provides users with a new daily challenge for 14 days. This daily challenge asks users to perform an everyday activity—such as opening the door or turning on the light—with their nondominant hand. After accepting the challenge, users are reminded of the daily challenge 4 times a day. After 14 days, the app notifies the user that the training has concluded. By restarting the app, the intervention can be used for a longer period—in the case of this study, up to 28 days.

We have previously established the feasibility and preliminary effectiveness of mobile SCT in young adults [32]. This study showed that self-control did improve in participants who used an SCT app, whereas self-control did not increase in participants who received SCT via email and participants in a control group that did not receive SCT. The app was then redesigned with and for people with SMI to meet their cognitive capabilities and preferences following a participatory design study [50]. It meets the following requirements for suitable SCT from the patients' perspective: (1) behavior change is framed as a shared, unpredictable process; (2) visual rewards and explanations are given; (3) the app uses reduced textual and numerical information; and (4) the app provides accessible means for feedback and personal goals. In addition, the app sends reminders throughout the day to remind users of the daily challenge. This was considered specifically important as reminders appeared to be the main advantage of an app over email in the previous study [32]. Participants in the app

XSL•FO
RenderX

condition of the previous study appreciated the reminders and even requested more, whereas participants in the email condition indicated that they often forgot about tasks and would have liked to have reminders. Finally, the SCT app also incorporates several other persuasive features to promote engagement and adherence [30,51,52], including reduction, self-monitoring, social role, praise, personalization, real-world feel, and liking. Reduction and self-monitoring features reduce complex behavior in simpler, smaller tasks and allow users to track their performance on these tasks. In the SCT app, this means that users monitor daily self-control challenges (Figures 1-2). Social role and praise enable users to form a social relationship with the app, which provides praise when the target behavior is performed. In the SCT app, this is embedded in the virtual coach Scipp (Figure 3). Personalization and real-world feel were incorporated through tangible, personalized goals and feedback (Figure 4), whereas liking refers to the look and feel of the app and is incorporated into the overall minimalist, colorful esthetic used.

Figure 1. Screenshot of daily challenges with reminders in SCIPP: the Self-Control Intervention App. Daily challenges are easily found on the main page and explained visually. Users receive 4 daily reminders of the daily challenge.

XSL•FO
RenderX

Figure 2. Screenshot of the process page with a winding mountain path in SCIPP: the Self-Control Intervention App. Users self-monitor daily challenges. As behavior change is an unpredictable process, the mountain visualization includes ups and downs, and participants can also report when they were not able to do a challenge.

Figure 3. Screenshot of virtual coach Scipp in SCIPP: the Self-Control Intervention App. Virtual coach Scipp praises users for completing challenges. She also frames behavior change as a shared process and invites users to celebrate success with their broader social network after certain milestones, such as the first successful day of self-control training.

XSL•FO
RenderX

Figure 4. Screenshot of providing feedback on challenge difficulty in SCIPP: the Self-Control Intervention App. Users can set their own motivation for training self-control and provide feedback on the difficulty of the challenges. Once training is completed, this initial goal is shown to the users and can be adapted if needed.

Google Fit

Google Fit is a freely available mobile health tracking platform developed by Google in collaboration with the World Health Organization and the American Heart Association. Google Fit can be considered a goal-directed, cognitive intervention that incorporates various behavior change techniques to motivate the user to be more active. These include the ability to set a personal activity and step count goal, self-monitor activities in a personal dairy, and receive customized feedback based on health and activity history. To monitor physical fitness activities, Google Fit uses sensors from the user's mobile device or external activity trackers. It translates each minute of moderately intense activity into a Heart Point, and more intense activities result in more points. In addition, the number of steps is tracked. It is available on the Android and iOS operating systems, but in this study, only the Android version will be used.

Google Fit was selected as the physical activity intervention in this study in line with the rationale provided in the Introduction section—it does not require additional support from staff; it is based on reflective processes of self-control (ie, a focus on cognitive processes such as goal setting) and, thus, can be complemented with the novel SCT intervention; and it is likely suitable for the cognitive abilities of people with SMI. The latter was determined based on the assessment of the Regional Public Health Services of the Netherlands, which assessed Google Fit as reliable, theory-informed, secure, and user-friendly, including short, concrete text free of difficult jargon or medical terms [53]. Although no evidence is available regarding the effectiveness of Google Fit in increasing the physical activity of people with SMI, it has been successfully used in people with poor mental health [54].

Material and Measures

Overview

The primary study parameters are daily physical activity and self-control. Daily physical activity will be measured using a wearable accelerometer, the ActiGraph GTX+ [55,56]. Daily self-control will be measured via experience sampling.

Physical Activity

The ActiGraph GT3X+ and ActiLife software (version 6.8.0; ActiGraph) will be used to measure and analyze physical activity. The accelerometer is worn on the right hip and held in place with an elastic strap between 2 belt loops. Patients without belt loops will use a pouch pinned at the same location. The ActiGraph GT3X+ has a high inter- and intra-instrumental reliability [57] and validity [56]. It has been used successfully in previous studies with people with SMI to examine physical activity and sedentary behavior [6,58,59]. None of these studies reported usability, safety, or other issues related to the use of the ActiGraph GT3X+ in this population, which makes it a reliable, valid, and appropriate choice for measuring physical activity in this study.

Physical activity is operationalized as the daily average of total activity counts per hour, which is a continuous and detailed outcome variable of physical activity [6]. More counts indicate a higher level of physical activity. Following existing procedures for valid measurement of physical activity using the ActiGraph

XSL•FO
RenderX

GT3X+ in this population, a wear time of >6 hours per day for at least 3 days will be used as the criterion for sufficient measurement [6,58].

Daily Self-control

To distribute questionnaires, the mobile survey distribution platform Ethica Data [60] will be used. Ethica is a web-based platform that is designed for researchers to create, modify, and distribute momentary surveys for experience sampling research. It allows researchers to obtain and view the data of the participant in real time to identify possible errors while the study is still running. Furthermore, it amplifies the ecological validity, possibilities, and reliability of frequent data collection [61]. Participants use their smartphones to complete the surveys. This reduces strain on participants as they do not have to carry with them additional study-related materials. Finally, trigger logistics help reduce participant burden by sending automatic reminders to fill out surveys [62].

Daily self-control will be measured using 2 items from the State Self-Control Scale [63] and 2 items specifically developed for this study. Participants use a 5-point slider ranging from 1 (*not at all*) to 5 (*very much*) to reflect on recent self-control experiences. All questions start with "In the past couple of hours..." Participants answer questions about decision-making ("it's hard to make up my mind about even simple things"), subjective feelings of ego depletion ("I had less mental and emotional energy than I normally have"), goal-directed behavior ("I was able to do what I had planned"), and inhibitory control ("I was able to resist temptations"). We have previously used this questionnaire to measure daily self-control in students [64] and rephrased the items for people with SMI to improve clarity and brevity. A small pilot study with 5 patients receiving outpatient psychotherapeutic care showed that the rephrased items had high face validity, feasibility, and comprehension [65].

Trait Self-control and Cognitive Control

Generalization measures assess the intervention effect on untrained tasks and are important to establish the external validity in SCEDs [36]. The SCRIBE guidelines [37] recommend that generalization measures are taken repeatedly, although not as frequently as the main outcome measures. In this study, trait self-control and cognitive control are used as generalization measures and assessed every 5 days (at least once per phase). This combination of measures is used as self-control is a multifaceted construct and it is recommended to use more than one type of measurement instrument to assess it [66].

Trait self-control is measured using the Brief Self-Control Scale (BSCS). The BSCS is a validated, brief, and psychometrically sound measure of individual differences in self-control that consists of 13 items [19,66,67]. The BSCS measures several aspects of trait self-control, including inhibitory and initiatory control [68]. Participants rate the extent to which a statement, for example, "I am good at resisting temptation," matches them on a 5-point Likert scale ranging from 1 (*not at all*) to 5 (*very much*). A total score for self-control will be created by taking the sum of all items after recoding negatively phrased items (Cronbach α=.83-.85 [69]). Higher scores indicate higher levels of self-control, which has a medium effect on behavioral outcomes, showing criterion validity [70].

Cognitive control will be measured using the go/no-go task. This is a well-studied measure of cognitive control and has been used in previous research to assess self-control [32]. In the go/no-go task, participants are instructed to respond to target stimuli but must refrain from responding to nontarget stimuli, which requires suppressing a behavioral response. In this study, we will use average reaction time as the main parameter of cognitive control, with shorter reaction times reflecting more self-control [32,71].

Sociodemographics and Covariates

To describe the characteristics of the participants, we will collect information about their age and gender. To explore possible covariates or moderators of the intervention effect, we will collect data on body weight, height, stage of change, and clinic type (outpatient or inpatient) and monitor intervention use (number of completed challenges and self-reported success of each challenge).

Experience and Feasibility Measures

Once the study is complete, patients' perspectives will be gathered during short semistructured interviews. The interviews will focus on participants' experiences with the SCIPP app, possible points of improvement, and their perceived effectiveness of SCT. This information will be used to optimize digital SCT training as well as understand the feasibility of using SCED methodology in people with SMI.

Procedure

Participants will be visited by a member of the research team 1 day before the start of the experiment. The researcher will help the patient install all necessary apps on the patient's mobile phone. Next, the researcher will fit the accelerometer to the patients' hip or belt and demonstrate how to take it off. Finally, the researcher will help participants fill out the baseline questionnaires.

During the baseline phases, physical activity and self-control will be monitored, but no interventions will be administered. To monitor physical activity, the patient will wear the accelerometer each day from 9 AM to 11:59 PM except when sleeping or during activities that involve water, such as showering or swimming. To measure daily self-control, they will be prompted to fill out a morning survey between 11 AM and 1 PM and an evening survey between 7 PM and 9 PM. Reminders for both surveys will be sent after 30 and 60 minutes.

At the start of intervention phase B, the researcher will visit the patient and help set up Google Fit by entering their activity goals (number of steps and number of Heart Points), wake-sleep schedule, weight, and height. Next, the researcher will demonstrate where to find and how to use the primary functions of Google Fit. This will enable patients to self-monitor their activity and receive personalized coaching. During the withdrawal phases of SCED II, the researcher will also deactivate the SCT app and explain to the patient that this app will not be used for the next phase.

XSL•FO
RenderX

At the start of intervention phase C, the researcher will visit the patient and help set up SCIPP by entering the personal goal and dominant hand. The researcher will also inquire about their experiences with participation so far and provide additional instructions regarding Google Fit, the accelerometer, or Ethica, if required. The next day, the patient will receive the first self-control challenge and continue to receive and complete challenges throughout the phase. The researcher will return every 7 days to answer questions and, if necessary, reset the app to extend use up to 28 days until the phase is completed.

Follow-up follows the same procedure as the baseline phases. The researcher will visit the patient to disable all apps on the patient's phone except Ethica, which is used for data collection. Once the study is completed, the researcher will make a final visit to collect the accelerometer and reactivate any apps that the patient wishes to continue using. In SCED I, the researcher will also conduct the postintervention interview during this visit.

Data Analysis

Overview

Data analysis will include both visual and supplementary statistical analyses of the time-series data for both SCED I and II [36,42]. Data analysis will be performed using Microsoft Excel (Microsoft Corp), the web-based Tau-U calculator accessible via Single Case Research [72], and R (version 1.4; R Foundation for Statistical Computing) [73] and separately for the primary and secondary outcomes.

To prepare the data for analysis, we will score the primary outcome of physical activity as the daily average of total activity counts per hour. The secondary outcome of daily self-control will be scored as the daily average of the 4 self-control items. Next, we will use the median average deviation to identify and remove outliers. The median average deviation uses the median to identify scores that deviate 3.5 times from the median as outliers using a 95% CI. It is specifically recommended for use in small-sample studies, including SCEDs [74].

As both experiments collect continuous data that are averaged on a daily level, our missing data approach primarily consists of making full use of data that are available. To illustrate, self-control will be measured in the morning and evening. If the morning data are missing, the afternoon data will be used to calculate the level of self-control for that day. If no data are available on a given day, we will use multiple imputation to impute missing data. Multiple imputation methods have recently been developed specifically for use in SCED studies and have several advantages over other missing data approaches, including retention of collected data, maintenance of the design structure of an SCED, reduction of bias, and the ability to capture and communicate uncertainty regarding imputed scores [75].

Visual Analysis

SCED data are primarily interpreted visually [36]. To do so in this study, physical activity and state self-control data will be presented as a time-series graph, with days on the horizontal axis, physical activity or self-control on the vertical axis, and phase changes presented as vertical lines. As recommended by the What Works Clearinghouse guidelines [44,46], we will consider 6 features to examine within- and between-phase data patterns visually: level, trend, variability, overlap, immediacy, and consistency. The phase contrasts to be compared in SCED I are A versus B (baseline with Google Fit only), B versus C (Google Fit only with Google Fit+SCT), and A versus C (baseline with Google Fit+SCT). The phases compared in SCED II are B versus C (Google Fit only with Google Fit+SCT).

Within phases, *level* refers to the mean of all data points in 1 phase and is used to compare changes between phases [36]. *Trend* is the slope of the best-fitting trend line for all data in a phase and is used to determine trends toward (spontaneous) improvement or decline. *Variability* expresses the SD of data about the trend line and is used to calculate the percentage of overlap between data collected in different phases.

Between phases, *overlap* is the proportion of overlap between data from 2 phases, where less overlap indicates stronger intervention effects. The specific nonoverlap index we will use is the Tau-U summary index [76], which is a family of 4 indexes that calculate nonoverlap in relation to the trend. It is expressed by "the percent of data that improve over time considering both phase nonoverlap and Phase B trend, after control of Phase A trend" [76]. Using Tau-U allows for the exploration of, for example, how much the physical activity of a patient has increased after using the SCIPP app while considering a possible increase in physical activity levels that may have already been initiated by Google Fit during the previous phase.

Immediacy compares the extent to which the level, trend, and variability of the last and first 3 data points of subsequent phases are discriminably different. In SCED I, immediacy is used to examine whether SCT effects are immediate or cumulative and to make decisions about the appropriate phase length in SCED II. Finally, *consistency* involves examining whether data patterns (level and trend) are consistent in phases with the same condition, where more consistent patterns provide greater certainty for a causal relationship between the intervention and outcome. This will be used in SCED II to examine whether physical activity reaches similar level and trend effects in both B phases (Google Fit only) and both C phases (Google Fit+SCT).

Piecewise Linear Regression Analysis

To supplement the visual analysis, we will conduct piecewise linear regression analyses (PLMs) using the *scan* package [77]. PLM is an approach to analyzing time-series data that are segmented into phases, including SCEDs [77,78]. The PLM model calculates 4 parameters (intercept, trend, level, and slope) separately for data from each phase, allowing for a comparison between phases. In this case, *intercept* refers to the performance at the start of the study, *trend* effects refer to the continuous increase in the behavior over time, *level* effects refer to the constant and instant effect of the intervention, and *slope* effects refer to the change in continuous increase initiated by the intervention.

Using the PLM, we will construct a linear model for each individual patient, including a *P* value, R^2 effect size, and beta

XSL•FO
RenderX

weights for trend, level, and slope effects. We will use a cutoff of $P<.05$ to determine significant effects.

In SCED I only, we will also construct a multilevel PLM to aggregate single-case findings across all participants included. Aggregation improves the external validity of the findings by providing overall trend, level, and slope effects and allows for the exploration and quantification of moderation effects using random slopes [77]. First, we will include random slopes in the multilevel PLM to examine whether trend, level, and slope effects differ significantly between participants. If this is the case, we will subsequently consider the interactions between body weight, height, stage of change, clinic type, intervention use, trait self-control, and cognitive control as potential moderators of the effect. As there are no existing hypotheses about moderation, we will not use confirmatory *P* values in this analysis but merely report any findings as preliminary and exploratory.

Reliable Change in Generalization Measures

We will explore individual changes in generalization measures of trait self-control and cognitive control by comparing the means of pre- and postintervention scores obtained during baseline, end of intervention phase C, and follow-up.

Qualitative Analysis of Experience

Interview data will be analyzed inductively using thematic analysis [79] to organize data into overarching themes related to usability and feasibility of the SCIPP app and SCED methodology according to people with SMI.

Results

Funding for this study was obtained in July 2020 by The Netherlands Organisation for Health Research and Development (project 555003023). It was approved by the Ethics Committee/domain Humanities and Social Sciences of the Faculty of Behavioural, Management, and Social Sciences at the University of Twente in November 2021 and the research committees of the participating mental health care facilities in January 2022. Recruitment for the study started in January 2022, and 6 participants have been included as of March 2023. We expect to publish the results in summer 2023.

Discussion

Expected Findings

Earlier studies have shown that SCT using the nondominant hand paradigm can increase self-control in healthy populations [24-26]. Self-control is a key mechanism in translating physical activity intentions into practice [80,81]. Therefore, interventions targeting self-control may be a viable strategy for improving physical activity in people with SMI. Many people with SMI experience poor physical health yet are barely targeted in preventive and health promotion research, leading to large systemic inequality [82]. In addition, people with SMI face a number of social, cognitive, physical, psychological, and sensory impairments, which may make cognitively based physical activity interventions less accessible [83,84]. However, further studies are needed to evaluate the effect of combining SCT and regular physical activity interventions on physical activity in this target group. This study will provide initial insights into whether this is the case.

SCIPP, the SCT app that will be used in this study, is expected to be feasible, effective, and suitable for people with SMI. First, it brings SCT to the digital era as it is delivered via a mobile app. Among other things, an app can be used by patients individually, on their own time, and at their own pace; is scalable; and can increase patient motivation and adherence, making it a suitable instrument to target people with SMI [85]. Previous research has indeed shown that there is a need for well-designed mobile apps to further improve treatment of hard-to-involve patient populations [86]. Second, based on earlier research on SCT and a specific study on an SCT app, it is expected that SCIPP will be effective. We have previously developed and pilot-tested a functioning prototype of an SCT app aimed at students and found that self-control increased after just 10 days [32]. Even though this was studied in a different target group, it still shows the potential of this app to bolster self-control as it is expected that the underlying mechanisms of self-control practice are similar across populations. The findings of this previous study were used to further develop the SCT app, resulting in SCIPP. This study especially highlighted the importance of reminders to ensure that participants did not forget about the SCT tasks throughout their day. Second, SCIPP was specifically designed with and for this target group following a participatory design process in which patients were structurally involved in app development via 3 design workshops. Products designed through a participatory design approach often have a better user experience and usability as they fit more closely with users' needs [84,87]. Indeed, usability tests with 3 patients with SMI who were not involved in the design workshops showed that patients had a high level of satisfaction and intention to use SCIPP. Interventions are expected to benefit from this improved fit in multiple ways, including increased effectiveness [87], adherence [88,89], and adoption. Therefore, we expect that the mobile SCT app will provide an effective and suitable way to train self-control in the population with SMI. This should not be considered a stand-alone psychological treatment, but following this trial, the app could be implemented alongside any intervention aimed at improving the lifestyle of people with SMI to bolster its effectiveness.

To examine SCIPP in concert with Google Fit, we will use 2 SCEDs. The classic RCT is—despite its shortcomings—still the most dominant design for eHealth evaluation [41]. However, assembling the homogeneous population that is required for controlled trials is difficult or even impossible to achieve because of the relatively high number of patients with comorbidities. The fact that people with SMI are considered difficult to involve in larger trials such as RCTs may explain the lack of studies on their physical activity levels. This illustrates a paradox: even though vulnerable populations require more research to improve care, they are very hard to involve in classic study designs, which results in an underrepresentation in scientific literature, which in turn further aggravates inequalities [90]. SCEDs provide a good method to address this paradox as they allow for high-quality experimental research by intensively monitoring a limited number of patients. The

XSL•FO
RenderX

first studies show that SCEDs are very suitable for the evaluation of eHealth interventions [41,42] and offer an excellent and feasible alternative to more classic experimental designs such as the RCT. However, although SCEDs appear to be a fitting research design, they have not been used to study eHealth physical activity interventions developed for people with SMI. This implies the need for more studies that apply SCEDs. Consequently, this project will apply 2 SCEDs to evaluate the effectiveness of combining a cognitive-based physical activity intervention with a mobile app to train self-control. This study will also explore people with SMI's experiences of being involved in such an extensive longitudinal study. As such, these findings will also allow other researchers to learn the benefits and pitfalls of applying this relatively novel design to the evaluation of other eHealth interventions.

Strengths and Limitations

A major strength of this study is the combination of 2 approaches to SCED: the multiple-baseline design across participants and the introduction/withdrawal design. The first experiment will allow us to demonstrate whether mobile SCT is effective, for whom it may be most effective, and for how long it should be offered for optimal effects. In addition, the qualitative interviews provide insights into how to optimize the mobile SCT app as well as insights into participation in an extensive longitudinal study from the perspective of people with SMI. This knowledge will be directly applied to the second experiment, in which the optimized intervention will be offered to a new set of patients to validate these findings.

Second, the study also uses accelerometry to assess the physical activity of people with SMI objectively. The use of accelerometry data substantially improves the reliability, validity, and level of detail of data on sedentary behavior and physical activity compared with often-used self-reports in which physical activity levels are consistently overestimated [91-93].

The main limitation is that there is no certainty that people with SMI will persist in SCT, faithfully wear the accelerometer, and provide answers to the daily questionnaires for the considerable study duration of 7 weeks. Nonadherence is a major challenge for any longitudinal study, including N-of-1 designs such as SCED [94]. However, it is specifically challenging in people with SMI [95], and studies suggest that low self-control may also further contribute to low adherence [96]. As this study is both longitudinal and will target individuals with SMI (who commonly have lower self-control than the general population [97]), nonadherence may thus be expected. To address this limitation, we will take additional measurements to avoid complete loss of data (eg, 2 daily measures of self-control instead of 1), schedule regular phone calls and visits by the researcher, and offer financial incentives for continued participation in the study, all strategies associated with better adherence [98-100]. Explicitly reporting on the success of these strategies both from a quantitative (eg, use data) and qualitative (eg, patient interviews) perspective will also help other researchers make more informed decisions about the design of SCED studies specifically in the population with SMI.

Acknowledgments

This project is funded by The Netherlands Organisation for Health Research and Development (project 555003023).

Data Availability

All data generated during the study will be coded and handled confidentially and anonymously in accordance with the European Union General Data Protection Regulation and the Dutch General Data Protection Regulation Implementation Act. The coded data will be stored at the University of Twente for a period of 15 years. During this period, coded data will be available through the corresponding author upon reasonable request. After the period of 15 years, data will be stored in long-term storage at the Data Archiving and Networked Services by the Royal Netherlands Academy of Arts and Sciences.

Authors' Contributions

TD, HK, SMK, NB-dJ, GDSL, JD, and YB designed the trial. TD, HK, TH, SES, and HK designed the mobile self-control training app. TH, SES, JD, and YHAB will facilitate patient contact and recruitment. TD wrote the manuscript draft. HK provided substantial review, proofreading, and editing. All authors critically revised the manuscript and approved the final version.

Abstract

Background: The upper airways are formed by the nasal cavities, pharynx, and larynx. There are several radiographic methods that allow evaluation of the craniofacial structure. Upper airway analysis in cone-beam computed tomography (CBCT) may be useful in diagnosing some pathologies such as obstructive sleep apnea syndrome (OSAS). OSAS prevalence has increased significantly in recent decades, justified by increased obesity and average life expectancy. It can be associated with cardiovascular, respiratory, and neurovascular diseases, diabetes, and hypertension. In some individuals with OSAS, the upper airway is compromised and narrowed. Nowadays, CBCT is widely used in dentistry by clinicians. Its use for upper airway assessment would be an advantage for screening some abnormalities related to an increased risk of pathologies such as OSAS. CBCT helps to calculate the total volume of the airways and their area in different anatomical planes (sagittal, coronal, and transverse). It also helps identify regions with the highest anteroposterior and laterolateral constriction of the airways. Despite its undoubted advantages, airway assessment is not routinely performed in dentistry. There is no protocol that allows comparisons between studies, which makes it difficult to obtain scientific evidence in this area. Hence, there is an urgent need to standardize the protocol for upper airway measurement to help clinicians identify at-risk patients.

Objective: Our main aim is to develop a standard protocol for upper airway evaluation in CBCT for OSAS screening in dentistry.

Methods: To measure and evaluate the upper airways, data are obtained using Planmeca ProMax 3D (Planmeca). Patient orientation is performed in accordance with the manufacturer's indications at the time of image acquisition. The exposure corresponds to 90 kV, 8 mA, and 13,713 seconds. The software used for upper airway analysis is Romexis (version 5.1.O.R; Planmeca). The images are exhibited in accordance with the field of view of 20.1×17.4 cm, size of 502×502×436 mm, and voxel size of 400 µm.

Results: The protocol described and illustrated here allows for automatic calculation of the total volume of the pharyngeal airspace, its area of greatest narrowing, its location, and the smallest anteroposterior and laterolateral dimensions of the pharynx. These measurements are carried out automatically by the imaging software whose reliability is proven by the existing literature. Thus, we could reduce the possible bias of manual measurement, aiming at data collection.

Conclusions: The use of this protocol by dentists will allow for standardization of the measurements and constitutes a valuable screening tool for OSAS. This protocol may also be suitable for other imaging software. The anatomical points used as reference are most relevant for standardizing studies in this field.

Introduction

The upper airways are formed by the nasal cavities, pharynx, and larynx. The pharynx (portion most susceptible to collapse) is divided into 3 parts: nasopharynx, oropharynx, and hypopharynx [1,2]. The nasopharynx begins in the choanae (posterior opening of the nasal cavities) and ends on the hard palate. The oropharynx ranges from the uvula to the epiglottis. The hypopharynx spans the area from the epiglottis to the vocal cords, where the trachea begins [1,2].

There are several radiographic methods that allow the evaluation of craniofacial structure. Profile teleradiography, cone-beam computed tomography (CBCT), axial computed tomography (CT), and magnetic resonance imaging are some examples of imaging modalities that allow for this evaluation. Among these auxiliary diagnostic means and comparing those that are available to dentists, CBCT has demonstrated usefulness in 3D evaluation of the airways. For example, the time and radiation exposure in CBCT are considerably shorter than those in CT [1-3]. Profile teleradiography provides a quick 2D assessment of the upper airways but can only depict the 2D morphology and has prone of numerous superimpositions [4-6].

Furthermore, CBCT images are not magnified and are recorded on a 1:1 scale, which permits accurate and direct dimensional measurements [4-6]. Although a radiographic examination, CBCT has a far more favorable risk-to-benefit ratio. It helps determine the total volume of the airways and their area in the different anatomical planes (sagittal, coronal, and transverse) and identify the regions with the highest anteroposterior and laterolateral constriction of the airways [1].

Upper airway analysis in CBCT is useful to help diagnose some pathologies such as the obstructive sleep apnea syndrome (OSAS).

The OSAS is defined by repeated episodes, greater than 5 per hour, of partial or total obstruction of the upper airways during sleep, leading to airway obstruction (apnea) or reduced airflow (hypopnea). An apnea event, by definition, should last at least 10 seconds and is usually associated with sleep or microarousal fragmentation. Hypopnea can be defined as a reduction in ventilation (at least 50%) with an oxygen desaturation of ≥4% [4-11].

This pathology has a relevant negative impact on patients' daily lives and its prevalence has increased significantly in recent decades worldwide, justified by increased obesity and average life expectancy. Benjafield et al [12] estimated that around the world, approximately 1 billion adults aged 30-69 years experience OSAS, of whom more than 45% (425 million) of adults present moderate to severe OSAS requiring treatment [8]. There is a wide geographical variation in the prevalence of OSAS, with some countries having a prevalence above 50%. OSAS is highly underrecognized, and it is estimated that 82% of men and 93% of women with OSAS in the United States are not diagnosed [12-14]. The clinical presentation of OSAS includes fatigue, daytime sleepiness, and snoring. If not treated, it can be associated with cardiovascular (coronary artery disease, arrhythmias, hypertension, congestive heart failure, and stroke), respiratory (exacerbation of asthma, respiratory dysfunction in chronic obstructive pulmonary disease, pulmonary embolism, and pulmonary hypertension), and neurological diseases (frustration, distress, neurocognitive dysfunctions, and attention deficit) and diabetes [4-11].

In OSAS, despite respiratory effort, there is a repetitive total or partial collapse of the upper airways. In normal situations, the genioglossal muscle contracts at each inspiration in order to avoid the posterior movement of the tongue aided by the lift and tensor muscles of the palate, geniohyoid, and stylopharyngeus [4-11]. Together, these muscles ensure continuous air passage through the airways. However, in some individuals, the upper airways are compromised and narrowed as a result of the deposition of adipose tissue in the pharyngeal muscles and parapharyngeal pathways or due to anomalies in the craniofacial structure [4-11].

One of the regions relevant to the pathophysiology of OSAS is the oropharynx. Steffy et al [1] related the constriction value of the oropharynx with the risk of developing OSAS. An area of <52 mm^2 is considered as having a high risk of OSAS; 52-100 mm^2, intermediate risk; and >100 mm^2, low risk [1,10]. Obstruction may arise at different levels of the oropharynx, being more frequent in the retropalatal, retroglossal, and epiglottis areas [10,11].

Due to the severity of this syndrome, multidisciplinary intervention is essential. The role of the dentist in OSAS is essentially 2-fold: contributing to early diagnosis and therapy. This clinician has the possibility to make a direct observation of the palate's soft and oropharyngeal tissues (eg, tonsil region and tongue), can identify breathing difficulties and breathing type (nasal or oral), and has easy access to the cervical region, which helps assess its volume or even measure the cervical perimeter [12]. Furthermore, according to the American Academy of Dental Sleep Medicine, the dentist plays a key role in screening and can help to reduce the number of undiagnosed or untreated patients with OSAS [13].

Currently, CBCT is used in dentistry. Its additional use for upper airway assessment would be an added value for the screening of some abnormalities related to an increased risk of OSAS. Studies on airway measurement methods have revealed that there is no objective and consensual methodology [14,15], which makes it difficult to obtain scientific evidence in this area. There is an urgent need to standardize the protocol and to develop a simple workflow for upper airway measurement, which is the aim of this study.

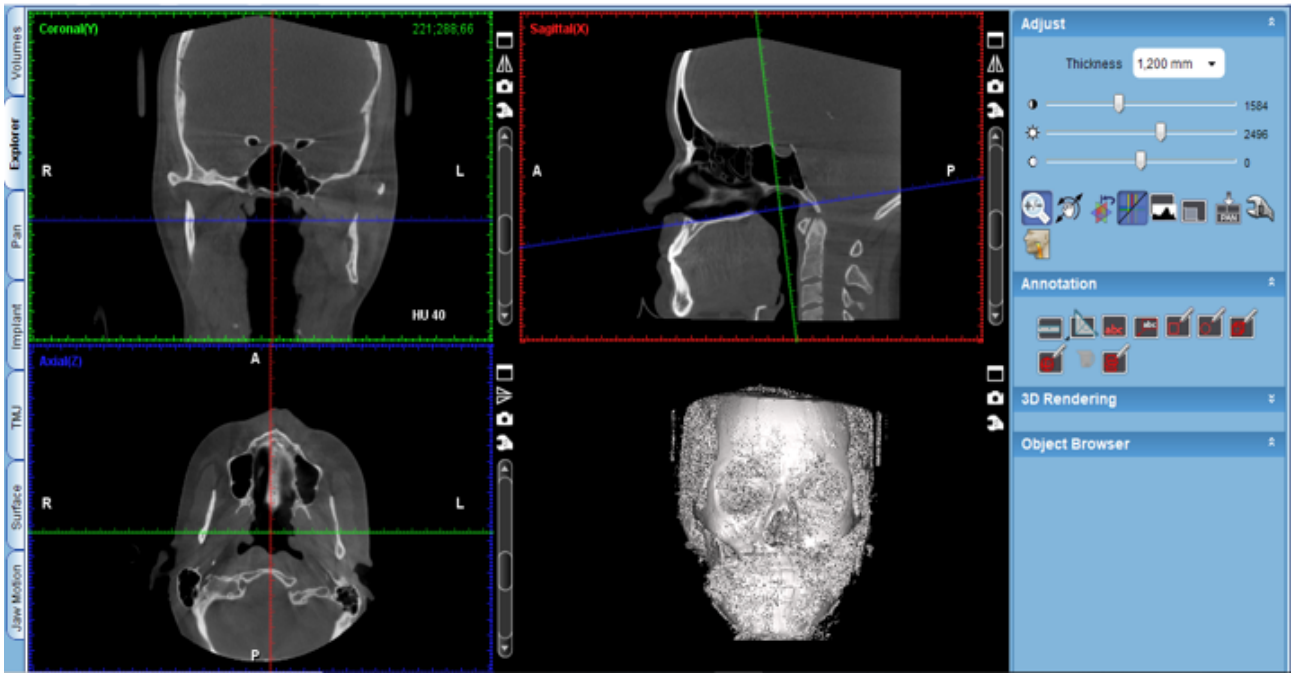
Methods



Ethical Considerations

This study was integrated in the project number 27 of the Faculty of Dental Medicine, Catholic University of Portugal, and approved by the Ethics Committee for Health (272022; January 21, 2022). The authors ensured conditions of anonymity and confidentiality that are required for such studies in Portugal.

Data Collection

To measure and evaluate the upper airways, data were obtained using Planmeca ProMax 3D (Planmeca) and in accordance with the manufacturer's indications regarding patient orientation at the time of image acquisition: with the patient standing and with his/her head oriented along 3 vertical references—the facial midline (glabella, subnasal, and mentum), endocant of the eye, and the parietal bone (Figure 1). The patient's head should also be oriented along a horizontal reference—next to the chin. The exposure corresponds to 90 kV, 8 mA, and 13,713 seconds. Others imaging devices can be used to obtain the CBCT image.

Figure 1. Correct orientation of the planes according to the inclination of the airways.

Data collected through CBCT is intended to be used to develop a standard method or protocol for upper airway evaluation.

To develop this protocol, we consulted the radiographic database of the Dental Clinic of the Faculty of Dental Medicine, Catholic University of Portugal, which has a Planmeca ProMax 3D (Planmeca) device. We searched for patients who had complete CBCT (maxilla and mandible) images to perform the analysis.

Data Analysis

The software used for upper airway analysis is Romexis (version 5.1.O.R; Planmeca). The images are exhibited in accordance with the field of view of 20.1×17.4 cm, size of 502×502×436 mm, and voxel size of 400 µm.

The measurements performed for all the CBCT images were as follows: total volume of the pharyngeal airspace, its area and its location, and the smaller dimensions of the anteroposterior and lateral pharynx (these measurements are illustrated in the *Results* section).

The protocol is as follows:

1. Activate the "Extract airways" tool in the box on the right with the title "Adjust" (Figure 2).
2. Then, enlarge the sagittal cut window in the box that appears on the "Airways Tool" screen to keep the threshold at 500 and mark the first point at the level of the posterior nasal spine (Figure 3).
3. Then, continue delimiting the airway following its curvature and mark a last point at the level of the middle of the fourth cervical vertebra (Figure 4).
4. Select, again, the option "Extract airways," and in the box that appears with the name "Airways Tool" adjust the variable that defines the airway limits (a standard adjustment value should be used for all patients so that it is possible to establish adjustments; in this case, the standardized value was 736). Then, the value of the total volume ("airway volume") appears (Figure 5).
5. Place the cursor over the box where the total volume value appears. In the same box will appear the value of the minimum airway area ("min area") (Figure 6).
6. Enlarge the window containing the axial plane and, from the narrowest area of the airway, select in the box on the right with the heading "Annotation" the tool "Measure Length" and measure the anteroposterior and laterolateral dimensions (Figure 7).
7. Record all obtained values.

To ensure the reproducibility of the protocol, all researchers performed the measurements, and patients were categorized into those at risk for OSAS (highest anteroposterior and

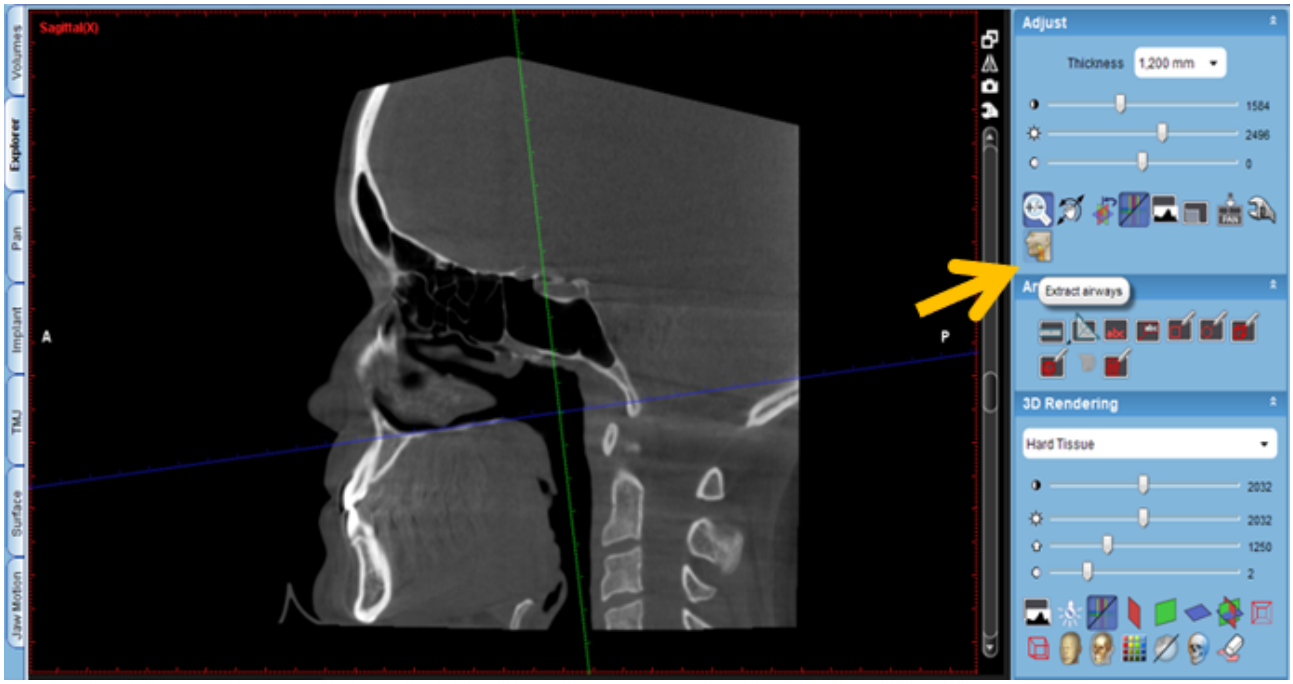
laterolateral constriction of the airways of <52 mm^2 or 52-100 mm^2) or those at no risk (>100 mm^2).

Figure 2. Selection of the tool "Extract Airways" and marking of the points following the curvature of the airways.



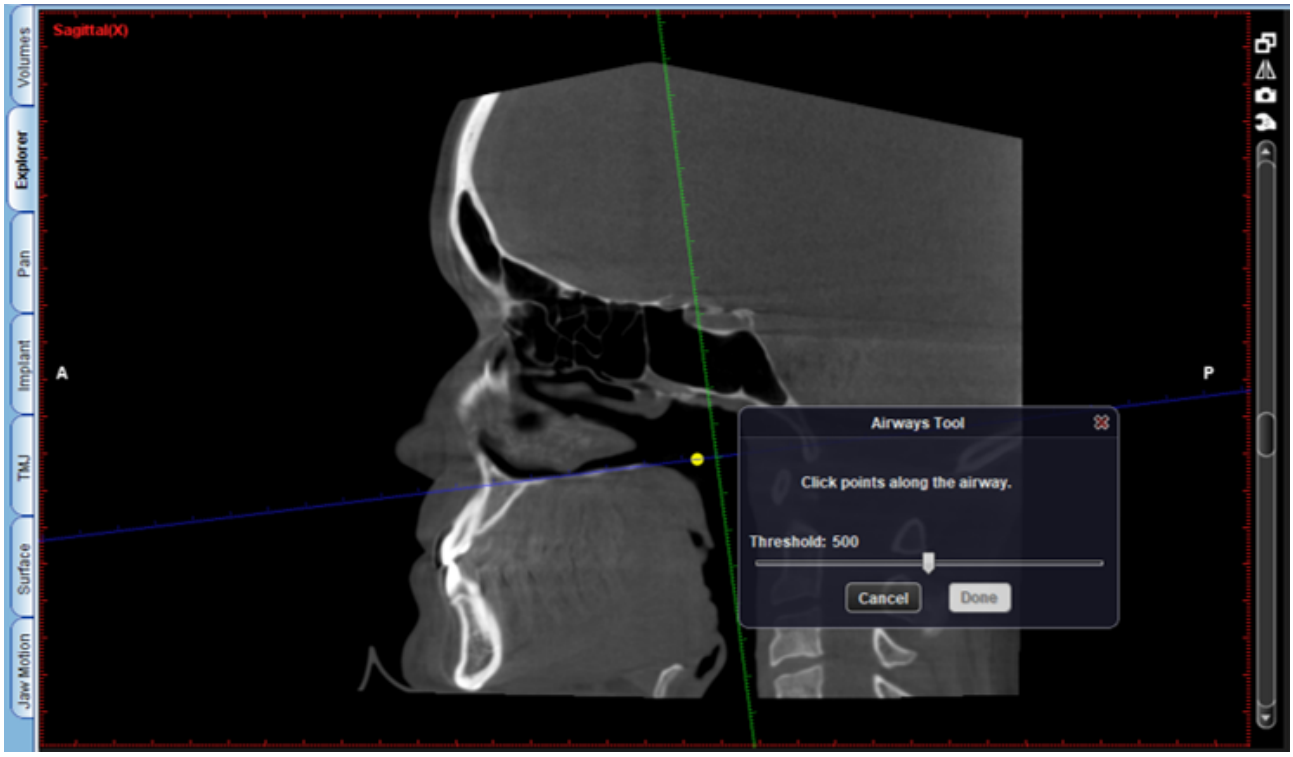


Figure 3. Keeping the threshold at 500 and marking the first point.

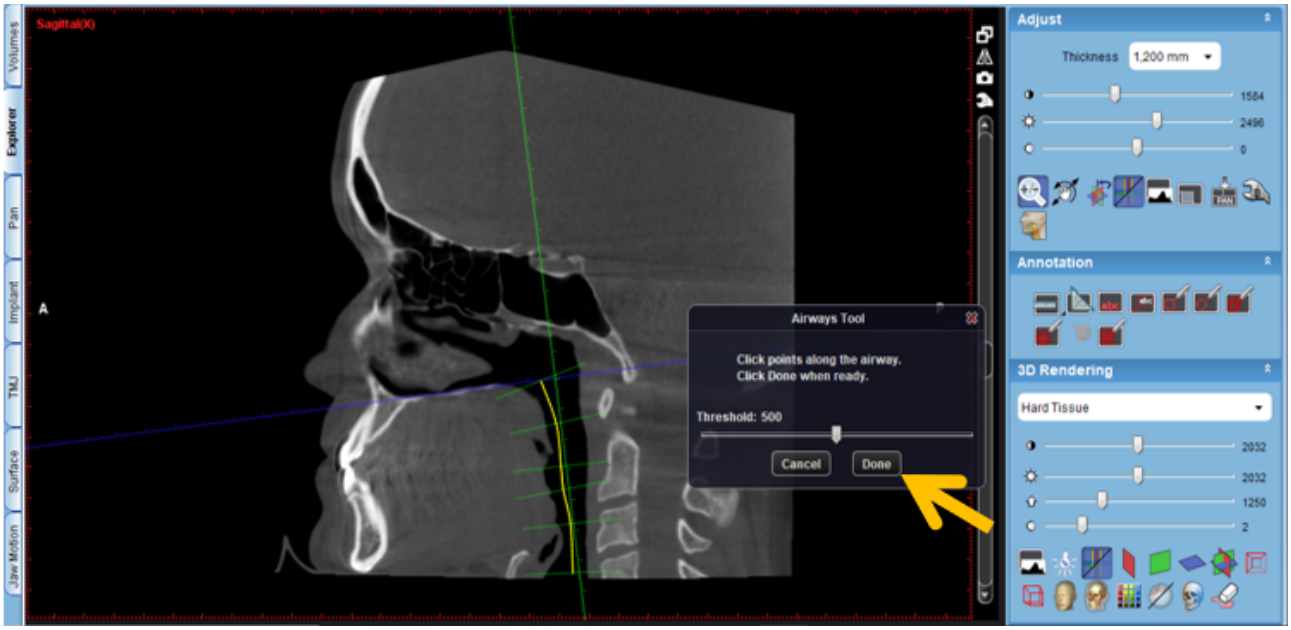
Figure 4. Delimitation of the airway following its curvature.



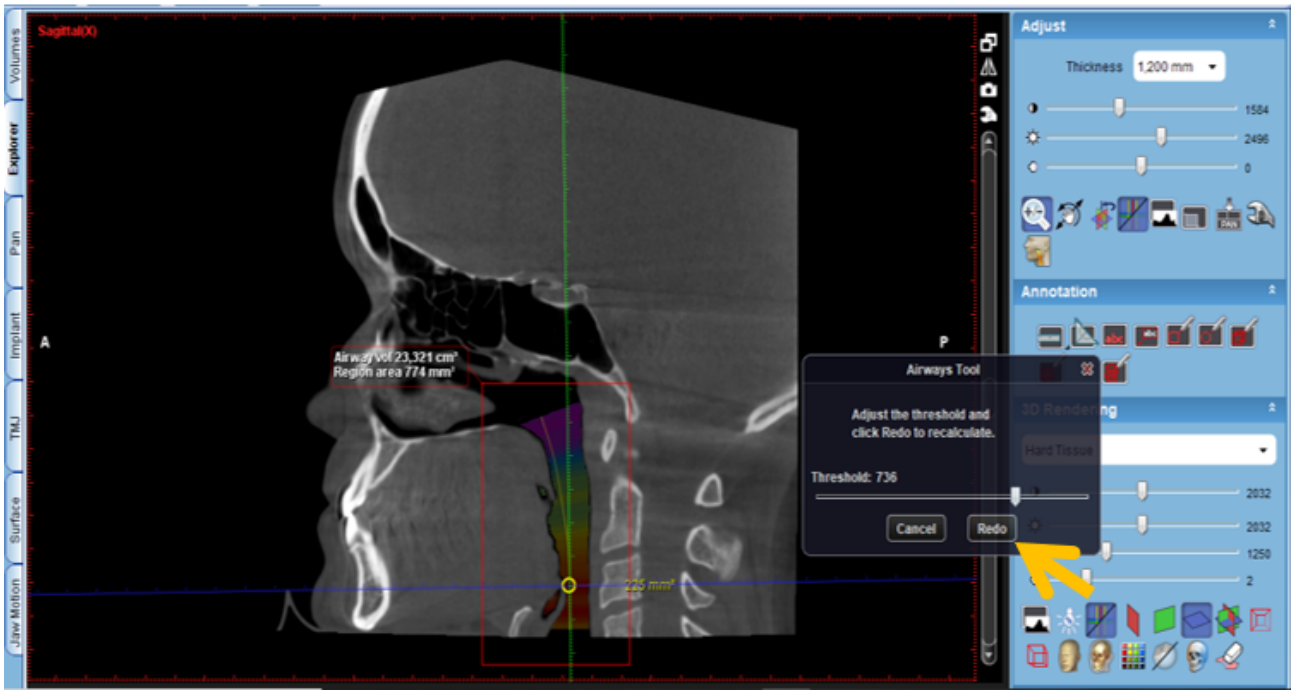


Figure 5. New selection of the option "Extract airways," and in the box that appears with the name "Airways Tool" the variable that defines the image limit is adjusted (standardized value for all patients=736).

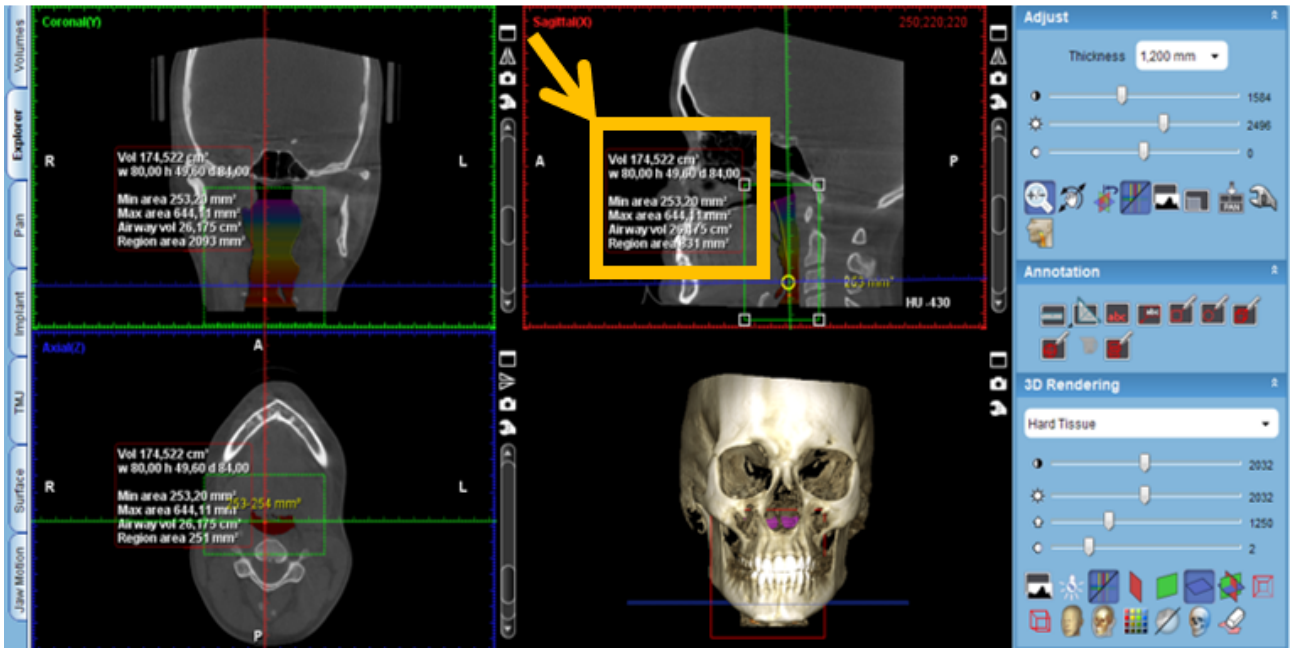
XSL•FO
RenderX

Figure 6. Calculation of the value of the total volume and the value of the minimum airway area ("min area").



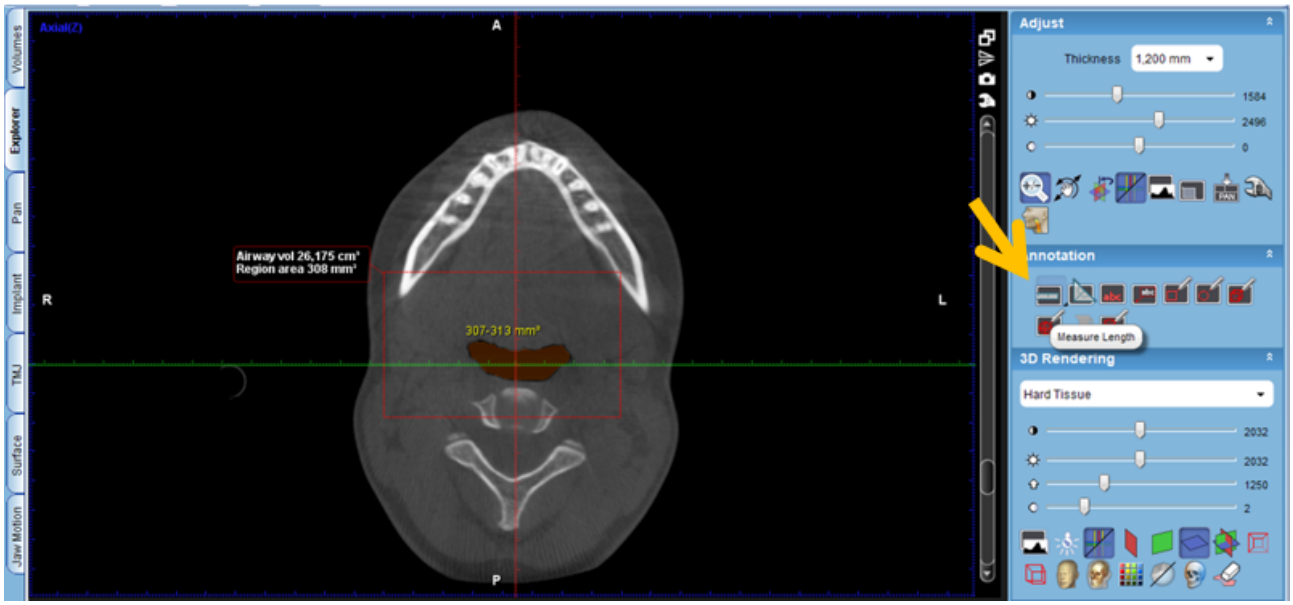


Figure 7. Anteroposterior dimension measurement.

Results

To establish this protocol, CBCT images of 30 patients were used (56% for males and 44% for females), and, in cases where an area of <52 mm^2 or 52-100 mm^2 was detected, the patient was contacted and referred to the hospital for diagnostic confirmation tests.

No differences were found between measurements obtained by the different researchers following the protocol described.

The protocol that the authors suggested for evaluation of the upper airways in CBCT allows for automatic calculation of the total volume of the pharyngeal airspace, its area of greatest narrowing, its location, and the smallest anteroposterior and laterolateral dimensions of the pharynx [15-18]. The measurement is performed automatically by the imaging software whose reliability is proven by the existing literature [16]. Thus, we reduce the possible bias of manual measurement, aiming at data collection.

Discussion

Principal Findings

The literature revealed no consensual and objective methodology for upper airway measurement. The lack of standardization in the definition of anatomical limits makes it impossible to subsequently make comparisons between different studies [19,20]. Recently, with the evolution of software, it is possible to perform upper airway measurement in a fast automatic analysis in an accurate, reproductible, and practical way. Its simplicity and speed allow this analysis to be adopted by all professionals. It is important to note that simplicity is not

XSL•FO
RenderX

achieved in the detriment of any decrease in viability and reliability in the measurement of airways [16].

The CBCT helps measure the total volume of the pharyngeal airspace, its area of greatest narrowing in 3 different anatomical planes (sagittal, coronal, and transversal), its location, and the smallest anteroposterior and laterolateral dimensions of the pharynx [14-16]. Steffy et al [1] related the constriction value of the oropharynx with the risk of developing OSAS. An area of <52 mm^2 is considered as having a high risk of OSAS; 52-100 mm^2, intermediate risk; and >100 mm^2, low risk [1]. Compared to the other radiographic methods described in the literature, usually available to the dentist, such as profile teleradiography and CT, the CBCT, as previously mentioned, presents more advantages. It is possible to acquire the same or better images with less radiation and less time of exposure. The assessment protocol for CBCT described herein constitutes a valuable screening tool for OSAS, which allows clinicians to refer the patient to the hospital for diagnosis confirmation. To establish this protocol, CBCT images of 30 patients were used, and in cases where an area of <52 mm^2 or 52-100 mm^2 was detected, the patient was contacted and referred to the hospital for diagnostic confirmation tests.

Limitations and Strengths

The protocol's main limitations are related to the position at which this examination is performed. The patient undergoes the examination in a standing position and not in a supine position, which may introduce false negatives here or cause a suspected hypothesis to be discarded. In addition, the step responsible for adjusting the threshold is characteristic of each examination. This threshold adapts the difference between the shades of gray in each voxel of the airway and the rest of the area. However, in general, Zimmerman et al [19] verified, in a systematic review, that most studies measuring the airways have high intraexaminer reliability. Although in this study, no CBCT image was purposely acquired, currently, it is known that it is a comprehensive examination that allows numerous interpretations and simulations from a very low radiation dose. Nevertheless, the ALARA (ie, *As Low As Reasonably Achievable*) principle should be respected, reserving the execution of these examinations for cases in which they are strictly necessary [19,20].

However, despite these limitations and due to the automatic measurements performed by the system, this protocol in CBCT constitutes a good patient screening tool that will help standardize the measurements and ensure that they are performed in a reproductible, accurate, and simple way while the comfort of and benefit for the patients increases.

Conclusions

This protocol provides a new standardized tool to identify patients at the risk of OSAS by using CBCT and contributes to the detection of upper airway–related pathologies, such as OSAS, in patients visiting the dental clinics, using these devices and software. This protocol will have a significant impact in reducing the subdiagnosis of this pathology, contributing to its treatment and subsequently the prevention of serious comorbidities associated with OSAS. Our protocol may also be suitable for other imaging software. The anatomical points used for reference are most relevant for standardizing studies in this field and for software evaluation to reduce bias.

Abstract

Background: Filgotinib was approved in Germany for treating patients with moderate to severe active ulcerative colitis in November 2021. It represents a preferential Janus kinase 1 inhibitor. The FilgoColitis study began recruiting immediately after approval and aims to assess filgotinib effectiveness under real-world conditions with a particular focus on patient-reported outcomes (PROs). The novelty of the study design is the optional inclusion of 2 innovative wearables, which could provide a new layer of patient-derived data.

Objective: The study investigates quality of life (QoL) and psychosocial well-being of patients with active ulcerative colitis during long-term exposure to filgotinib. PROs related to QoL and psychometric profiles (fatigue and depression) are collected alongside with disease activity symptom scores. We aim to evaluate physical activity patterns collected by wearables as an addition to traditional PROs, patient-reported health status, and QoL in different phases of disease activity.

Methods: This is a prospective, single-arm, multicentric, noninterventional, observational study with a sample size of 250 patients. QoL is assessed with validated questionnaires: the Short Inflammatory Bowel Disease Questionnaire (sIBDQ) for the disease-specific QoL, the EQ-5D for the general QoL, and the fatigue questionnaire (Inflammatory Bowel Disease-Fatigue [IBD-F]). Physical activity data are collected from patients using wearables (SENS motion leg sensor [accelerometry] and smartwatch, GARMIN vívosmart 4).

Results: The enrollment started in December 2021 and was still open at the date of submission. After 6 months of study initiation, 69 patients were enrolled. The study is expected to be completed in June 2026.

Conclusions: Real-world data for novel drugs are important to assess effectiveness outside of highly selected populations represented by randomized controlled trials. We examine whether patients' QoL and other PROs can be supplemented with physical activity patterns measured objectively. Use of wearables with newly defined outcomes represents an additional observational tool for monitoring disease activity in patients with inflammatory bowel disease.

Introduction

Background

Ulcerative colitis (UC) is a chronic disease, which affects the digestive system and therefore, belongs to inflammatory bowel diseases (IBDs). Worldwide, more than 1.8 billion patients have been diagnosed with UC [1] with an ever-increasing trend [2,3].

UC has a chronic recurrent course of disease. Patients with UC have recurrent diarrhea, abdominal pain, nausea, weakness, or anemia, among other symptoms. As a result, the patients' quality of life (QoL) and well-being can be impaired [4,5].

Currently, there are already many targeted therapies for moderate to severe UC. The use of biologics and other small molecules in patients with UC is increasing. Nevertheless, effectiveness is only approximately 30%. Recently, new modes of action have been introduced. In 2019, tofacitinib became the first Janus kinase (JAK) inhibitor approved in UC. However, as a pan JAK inhibitor, it has elicited some serious adverse events. Due to several Dear Doctor Letters (Rote-Hand-Brief), its acceptance by physicians has declined. Filgotinib is the first oral preferential JAK1 inhibitor, with fewer side effects expected than with a pan JAK inhibitor, approved for UC in Europe as of November 2021. Because pivotal studies with narrow predefined inclusion criteria do not always reflect treatment in routine clinical practice, the FilgoColitis study was established to reflect use under real-world conditions.

The novelty of the study design is the optional inclusion of 2 innovative wearables, which could provide a new layer of patient-derived data. Correlations with disease activity and QoL have been established before [6-8], but the cohort sizes were small and not in a longitudinal setting around targeted therapy. Therefore, real-world studies to assess the effect of digital health tools on disease activity are still needed [9].

Objectives

This study aims to investigate the QoL and psychosocial well-being of patients with UC on filgotinib therapy over the long-term course of different disease phases under routine conditions. Therefore, we aim to use wearables additionally and collect patient-reported outcomes (PROs) related to QoL and psychomotor profiles (fatigue and depression), including physical activity, under real-world conditions.

Using wearables, we aim to investigate whether physical activity data are related to QoL in patients with UC and whether there is an association between physical activity patterns, health status, and QoL, and additionally to define a new outcome in UC treatment. Furthermore, we will evaluate the safety profile of filgotinib therapy considering (serious) adverse events.

Methods

Study Design

The FilgoColitis study is a prospective, single-arm, multicentric, investigator-initiated, noninterventional observational study.

Outcomes

Primary Outcome Measure

The disease-specific QoL of patients with UC during long-term course of therapy is the primary outcome and is assessed with the help of the validated and internationally widely applied Short Inflammatory Bowel Disease Questionnaire (sIBDQ, German version), which contains 4 domains: bowel symptoms, emotional health, systemic systems, and social function [10]. Thereby, the different disease phases will be considered and examined.

Secondary Outcome Measures

As a secondary outcome, the safety profile of the filgotinib treatment will be explored, taking (serious) adverse events into account. Furthermore, clinical parameters such as the disease activity using the partial Mayo Score (pMayo, and additionally PRO2) and the Montreal Classification are assessed. In addition, the therapy deemed necessary and useful for the patient by the physician is recorded. The general QoL using the validated questionnaire EQ-5D-5L (which essentially consists of 2 pages: the EQ-5D descriptive system and the EQ visual analog scale [EQ-VAS]) is documented. The descriptive system comprises 5 dimensions: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression. Each dimension has 5 levels: no problems, slight problems, moderate problems, severe problems, and extreme problems [11].

Fatigue is highly prevalent among patients with IBD [12]; therefore, the fatigue questionnaire (Inflammatory Bowel Disease-Fatigue [IBD-F]) is used in the study [13]. The scale of the IBD-F questionnaire was developed to be used for the diagnosis of fatigue or monitoring fatigue levels over time. The German version of the questionnaire has been published recently [14].

Additional Exploratory Outcome Measures

Wearables will be given to patients to collect their physical activity data, such as the number of steps per day, pulse rate, calories burned per day, physical activity patterns (day and night), stress, sleep rhythm, and sleep quality. We aim to examine the correlation between physical activity, stress, sleep, disease phases, and the patients' psychosocial impairment. The used wearables are (1) an accelerometry-based sensor (SENS motion, Class 1M medical device), which is attached to the thigh of one leg, and (2) a smartwatch (GARMIN vívosmart 4). The wearables are adapted for German server–based documentation of the physical activity parameters (number of steps per day and speed), pulse rate, calories per day, physical

XSL•FO
RenderX

activity patterns (day and night), rhythm and quality of sleep, and stress level.

Statistics

Overview

This study is descriptive, and no formal hypotheses are tested. Patient and clinical characteristics are described to capture the baseline situation of patients treated with filgotinib. Descriptive statistics are used to summarize patients' demographics and baseline data. Specifically, for continuous variables, the mean, 95% CI for the mean, SD, median, and IQR are reported. For discrete variables, the frequency and number of missing observations are reported.

In this noncomparative observational study, the primary end point is analyzed as the mean change (the difference in scores between the 2 time points) in sIBDQ values from baseline to week 10 and is presented along with the 95% CI. For sIBDQ scores (total), mean changes from baseline to week 10 (week 52 and week 104) are calculated with a 1-sample *t* test for differences between paired observations (or a nonparametric analog).

Patients' sIBDQ QoL is summarized and compared concerning the following: (1) mean change from baseline to assessment points during the study and (2) at each analysis time point, the number of patients who have completed the questionnaire is reported as a percentage of eligible patients. Data will be collected at visit 1 (ie, at baseline) and then at approximately week 10, and every 6 months up to 2 years.

Repeated Measurements Over Time

Each subject is assumed to have his or her mean response curve that explains how the sIBDQ score changes over time (intraindividual changes). A mixed effects model is used to model individual sIBDQ response curves over time.

Justification of Sample Size

The difference in sIBDQ scores from baseline to week 10 (week 52 and week 104) will be analyzed. The null hypothesis is that the average difference is zero. The alternative hypothesis is that the average difference has a nonzero value. Based on the results of a previous study [15], we aim to demonstrate a difference of 7 points or more with an α of .05, assuming an SD of 12, and assuming that each pair of measurements on the same individual correlates with approximately 0.5. With a sample size of 250 subjects, a power of >90% is achieved to detect the above mean of paired differences with a 2-tailed paired *t* test [16].

Exploratory Data Analysis

As an exploratory data analysis, correlations between the pMayo and exercise data and psychomotor data (such as sleep quality, stress, and fatigue) will be calculated.

Definition of the Study Population

This prospective observational investigator-initiated trial will be conducted with 250 participants at approximately 50 sites all over Germany. The gender ratio will be balanced.

Selection of Study Sites

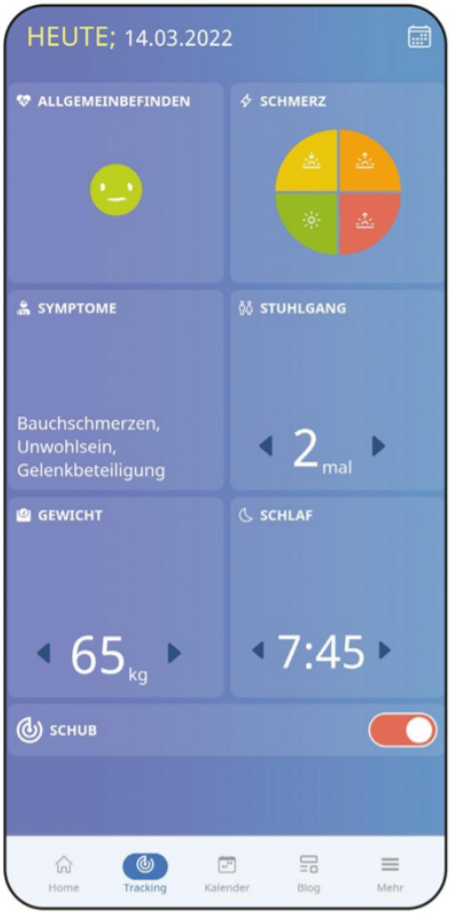
Sites are IBD-experienced hospitals or gastroenterology practices in Germany. Site selection will be made by the study investigators. By signing the investigator agreement, each site confirms its fulfillment of all formal requirements for inclusion in the study and guarantees its compliance with data privacy laws and any other regulations about the execution of this observational study.

Participant Criteria

The inclusion criteria for the FilgoColitis study include (1) the confirmed diagnosis of UC (according to the current guidelines from the German Society for Gastroenterology, Digestive and Metabolic Diseases and European Crohn's and Colitis Organization), (2) the initiation of therapy with filgotinib at the physician's discretion regardless of potential study participation, (3) age of the patient between 18 and 80 years at inclusion, and (4) in-label use according to filgotinib product information. The exclusion criteria include (1) planned surgical intervention with hospitalization, (2) history of malignant disease (except "nonmelanoma skin cancer"), and (3) contraindications for treatment with filgotinib (according to the product information).

Study-Specific Examinations: The Use of Wearables

Within the scope of the additional examination, the 2 accelerometry-based wearables (SENS motion accelerometry leg sensor, and GARMIN smartwatch) will be provided by the clinical research organization. Participation in the additional examination is voluntary.



The wearables aim to improve data collection of physical activity behavior. Activity and psychomotor data are recorded by the provided trackers and transmitted to the server via the MyTARGET app.

The MyTARGET app (Figure 1) is a therapy support app for people with IBD. It was developed by the competence network IBD (Kompetenznetz Darmerkrankungen) and the German Association of Gastroenterologists (Berufsverband Niedergelassener Gastroenterologen Deutschlands) in close cooperation with experienced gastroenterologists, physician assistants, and patients to provide the best possible support for patients in their daily lives. The app is freely accessible and can be used by anyone. Within the app, there is a specific FilgoColitis study area, where only study participants have access via a QR code. In this area, patients can connect their wearables to their smartphones via Bluetooth. Once the devices are connected, a secure data transfer of the movement data to the study servers can take place assisted by the MyTARGET app. All data are stored only on the study server and are not passed on to the GARMIN company. The patients also receive a small output of their movement data.

XSL•FO
RenderX

Figure 1. Homescreen and tracking area of the MyTARGET app.

The GARMIN watch may be worn for the entire study period of 24 months (day and night). If the physician and patient agree, it is desirable to be worn during the 10-week induction phase (day and night) or at least in the following 7 days after the baseline visit. For the follow-up visits, the GARMIN watch, if used, may be worn for 7 days after each follow-up visit (day and night).

If desired by the patient, the SENS motion sensor may be worn from the baseline visit and at each follow-up visit for 7 days (day and night). Both wearables may also be worn 3 days before the start of filgotinib therapy (baseline visit), if applicable. These movement data are not made available to the treating physician in a direct temporal context so as not to influence therapeutic decisions.

Schedule of Visits

Visits at the study site are scheduled at inclusion (baseline visit week 0) and during follow-up (week 10, month 6, 12, 18, and 24). Follow-up visits are not fixed scheduled visits but are to occur when the study participant sees his or her physician as part of routine treatment.

Documentation

Data are recorded using case report forms at the study sites and are transferred to an electronic case report form at the site. Data outlined in Table 1 are recorded during the baseline examination and at follow-up. In addition, each (serious) adverse event is recorded.

The movement data of the additional wearable examination are recorded and stored locally as soon as the patient puts them on (Textboxes 1 and 2). Data are transferred from the wearables to the MyTARGET app on the patient's smartphone via Bluetooth. The patient is given access to the study area via an individual QR code within the app. In this QR code, a digital pseudonym is stored, which enables the assignment of the movement data to the patient's own study number. When the wearables and app are connected via Bluetooth, the data are automatically transferred from the devices to the MyTARGET app on the study participant's cell phone and from there to the study server (Figure 2). There, the movement data are merged with the site-based collected data on the patient's pseudonym.

Patient Identification

All patient data are pseudonymized. Each patient will be identified by a patient identification number assigned at each study site. The investigator will keep a patient identification list, documenting the patient identification number with the patient's full name, date of birth, sex, and date of informed consent.

The patient identification list is part of the investigator's file and will remain at the site. The patient identification number comprises a 3-digit clinic number and a consecutive 3-digit number of recruited patients per study site.

Study

Start of Patient Participation

Any patient who meets the inclusion and exclusion criteria of the study is a potential candidate. All potential candidates who come to the attention of the investigator will be consecutively informed of the opportunity to participate in the study. Written informed consent will be obtained before the commencement of documentation.

End of Patient Participation

The observation of each patient ends according to the schedule with the last study visit (month 24), after 2 years. A patient's participation in the study will be terminated prematurely if at least one of the following criteria is met: (1) withdrawal of informed consent or death of the patient, (2) change of diagnosis, (3) lack of medical justification for further participation in the study, (4) premature termination of the complete study, or (5) subsequent discovery that not all inclusion criteria are met or that any exclusion criteria are met at baseline. A change in therapy does not result in study dropout. Furthermore, patients may be declared as lost-to-follow-up if they are no longer available and thus could not be documented at more than 2 consecutive visits.

Study Duration

This prospective study is planned for over 3.5 years (including 18 months of recruitment and 24 months of follow-up documentation per patient). The complete study is considered to have ended after all queries from the study coordination center have been answered by each study site, at the latest, 2 months after the last visit of the last patient.

Data Quality, Quality Control, and Assurance

The input fields in the web-based documentation form are stored with an input logic to avoid incorrect entries. In addition, remote monitoring of the data is permanently carried out and, if necessary, corresponding queries are made. Approximately 30% (n=75) of documented cases will be reviewed via in-house or on-site monitoring. Within the on-site monitoring, all study-relevant documents will be inspected and checked for completeness and current validity. In case of missing or implausible data, queries are generated and forwarded to the corresponding study site. This process is described in more detail in the monitoring manual.

Data Collection

Data collection of questionnaires (clinical data) and wearables data will take place on secured web servers based in Germany. The data will be transmitted and evaluated pseudonymously.

XSL•FO

Ethics Approval and Regulatory Aspects

The principal investigators and CED Service GmbH in Kiel are responsible for obtaining the required ethics committee approval as well as compliance with data protection regulations. Approval is obtained from the ethics committee of the medical faculty of the University of Kiel (D 609/21). The German Federal Institute for Drugs and Medical Devices (Bundesinstitut für Arzneimittel und Medizinprodukte), the "Kassenärztliche Bundesvereinigung," the "Spitzenverbände der Krankenkassen," and the "Verband der Privaten Krankenversicherungen e.V." have been notified of this noninterventional study according to §67 of the German Medicinal Products Act (Arzneimittelgesetz). A final report will be sent to the responsible federal authority after completion of the data collection according to §67 (6) of the German Medicinal Products Act. Furthermore, the study is published in the public German Clinical Trials Register (DRKS00027327).

Before enrollment in the study, the investigator will inform each patient of the nature, significance, risks, and scope of the study and the patient's right to withdraw from the study at any time without prejudice. The patient will be given an informed consent form describing the study in nonscientific and generally understandable language. Each patient must consent in writing to participate in the study. The patient must be given sufficient time to decide and ask questions before signing the consent form.

Results

The enrollment commenced in December 2021 and was still open at the date of submission. The study is expected to complete in June 2026. After 6 months of study initiation, 69 patients were enrolled in FilgoColitis. The median age of patients is currently 41.7 (IQR 28.7-56.0) years; 52% (n=36) of patients were male and had a disease duration of 7.4 (IQR 4.3-14.8) years. In total, 90% (n=62) and 23% (n=16) of patients were pretreated with biologics and small molecules, respectively. Wearables were accepted by 80% (n=55) of patients.

Discussion

The Rationale for the Study

Treatment of moderate to severe UC remains challenging with approximately 30% of patients benefiting from biologics. Further modes of action are therefore needed. JAK inhibitors play a role by inhibiting the Janus kinase/signal transducers and activators of transcription pathway, thereby slowing down the inflammatory process [17].

The first to market in 2019 was a pan JAK inhibitor, tofacitinib. It is hoped to achieve a more specific effect by inhibiting individual JAKs in a more targeted manner: filgotinib is a JAK1 preferential inhibitor, and therefore fewer side effects are expected.

The pivotal SELECTION study [18] showed significantly higher efficacy (clinical remission) in patients receiving 200 mg filgotinib therapy when compared to a placebo in both the induction and maintenance phases. The incidence of serious adverse events was not higher in the filgotinib groups compared to the placebo group.

The safety profile and the effectiveness of objective disease scores as well as PROs under real-world conditions have not yet been studied. Therefore, the FilgoColitis study was initiated shortly after approval in Germany and Europe. The study focuses on PROs, which will be collected both subjectively via questionnaires but also using wearables to provide objective data on activity behavior and psychomotricity. In addition to abdominal pain, fatigue is reported by many patients as a common complication [12]. Therefore, the IBD-F is applied, for which the German version has recently been validated [14]. The scale of the IBD-F questionnaire was developed to be used in the diagnosis of fatigue or to monitor fatigue levels over time. The IBD-F scale consists of 3 sections: section I identifies the level and duration of fatigue, section II assesses the impact of fatigue on daily activities, and section III identifies causes and other factors related to fatigue. The FilgoColitis study will analyze if there is a correlation between the objective movement measures, disease activity, and fatigue.

Justification for Study Design

The study is conducted nationwide and multicentrally with specially selected sites to achieve higher representativeness of the study results for the entire population. Since the study's primary objective is to observe the effects of filgotinib therapy on QoL and psychomotor markers, a single-arm study design is warranted. Furthermore, the study aims to investigate to what extent it is possible to have an additional observational outcome tool for monitoring disease activity in patients with IBD by using wearables.

Wearables

Since exercise and sleep are associated with QoL, 2 wearables are used in this study to enable measurement of the patients' movement and sleep comprehensively. We hypothesize that early changes in wearable parameters (eg, increase of step counts and normalization of heart rate variability) are potentially associated with long-term improvement of QoL. Other studies show similar results. van Langenberg et al [19] reported significantly poorer sleep quality and less physical activity in patients with Crohn disease compared with healthy control subjects, as measured by an accelerometer over 7 days. Similarly, Wiestler et al [6] found significant associations between physical activity and the disease-specific QoL and disease activity in patients with IBD.

In the FilgoColitis study, 2 wearables are used. The leg accelerometry sensor SENS motion is a medical device, whereas the GARMIN smartwatch vívosmart 4 is a simple fitness watch. We aim to show that nonmedical devices can also be used in clinical studies to measure physical activity and can be related to other important outcomes. The advantages of nonmedical devices are higher affordability and easier usability. Thus, we hope to be able to scientifically demonstrate in the FilgoColitis study that less expensive, widely used devices are also suitable for the monitoring of patients with UC. Nevertheless, it must be noted that nonmedical devices can also be less valid and accurate. In an unpublished field study prior to commencement

XSL•FO
RenderX

of the FilgoColitis study, we successfully showed the comparability of both wearables in an on-site test (data not shown).

To achieve meaningful results from the additional examination, the researchers are dependent on a high level of compliance from the study participants. For the success of the study, patients who voluntarily participate in the additional examination must wear their wearables at the desired times for the desired duration. However, since the FilgoColitis study is noninterventional and due to its voluntary nature in the additional examination, decreasing compliance of study participants must be expected. Because of the longer study duration, patients may forget to put the wearables back on for the visit or to transfer their data. Willingness to wear a watch or leg sensor visibly on the body may also drop over the study course. These assumptions were made based on findings from researchers in other digital studies where a decline in compliance over the course of the study was observed. One review showed that compliance is usually very high at the start of the study and then declines rapidly over the first weeks and months. However, success factors such as user training, health education, and maintaining strong participant motivation were also identified to positively influence compliance [20].

The compliance of the study participants cannot be enforced, but the framework conditions can be designed in the best possible way to achieve the highest possible compliance. Therefore, measures were also introduced in the FilgoColitis study, such as the creation of detailed instructions and web-based tutorials or active technical support by the study team. If the study size is smaller than expected due to low compliance, statistical recalculations must be performed to ensure that the results are still statistically meaningful. Nevertheless, if compliance within additional examination is so low that no meaningful results can be obtained, as a consequence the results can only be examined in relation to the primary and secondary outcome measures. However, due to the measures mentioned above, we hope to achieve the highest possible compliance of the study participants.

The use of new technologies such as smartwatches or leg sensors has many advantages in studies. Examples are higher recruitment rates, faster feasibility of the study, and the collection of a broader range of health data [21,22]. Atreja et al [23] summarize in the review on remote monitoring of patients with IBD that in the near future this rapidly evolving technology will become a mainstream tool in standard patient care practices. Nevertheless, certain obstacles must also be expected. Technical problems may occur at any time, which means that important participant movement data cannot be recorded or transmitted and is therefore lost. In addition, the additional examination is not feasible for everyone. Patients without their own smartphones cannot participate, and certain prior knowledge of smartphone use is also assumed. Due to the partly complicated procedure, older people may be excluded due to excessive demands or lack of knowledge. However, studies show that older people are generally positive about smartwatch technologies for measuring PROs. According to Manini et al [24], the aspect of user-friendliness is one of the most important points that must be given special consideration during design. Therefore, elements such as detailed explanations and descriptions, big visible buttons, and a frequently asked question area were added to the MyTARGET study app. The goal was to create the greatest possible user-friendliness, so that older study participants are also attracted to the additional examination within the FilgoColitis study.

Strengths and Limitations

The FilgoColitis study is the first large real-world study of filgotinib. One strength is the prospective design of the study. In addition, the primary outcome parameter is a PRO, namely QoL. In particular, the assessment of fatigue represents a modern approach in IBD research. Finally, the use of new technologies that objectively measure exercise, sleep, and stress behavior makes the study unique.

The study also has some limitations: a selection bias cannot be excluded in the FilgoColitis study and should also be considered in future analyses. To recruit a broad representative population of study participants and overcome the selection bias, we distributed the study sites all over Germany and included patients with a large age range (18-80 years). In addition, physicians consecutively enrolled eligible patients in the study. Moreover, filgotinib is the first oral preferential JAK1 inhibitor, and its approval has also opened up new strategies for the treatment of patients with UC. Due to the newly emerging treatment opportunities, it can be assumed that mainly last liners, meaning patients who have already taken several biologics without success, will receive the new drug and will be included in the study. Accordingly, it can be assumed that these patients tended to be in poor health prior to study inclusion and have a low QoL. However, the effect that filgotinib may have on QoL can still be well examined by surveying QoL at baseline. Thus, individual improvement or worsening of QoL over the course of the study can be evaluated for all participants without bias regarding the prevailing health status. The selection bias is tried to be avoided accordingly.

In addition, the FilgoColitis study is conducted using written questionnaires completed by the patients and physicians. On the one hand, we do not see limitations with regard to the physicians, since the remote monitoring system allows queries to be asked at any time regarding open or unclear answers. On the other hand, however, there could be omitted questions or illogical answers with regard to the patients, which could negatively influence the analysis of the study objective. To counteract this limitation, however, the attending physicians and the trained study nurses work closely with the patient so that questions can be asked at any time in the event of ambiguities or problems. In this way, as many missings as possible are to be avoided.

Nevertheless, with our efforts to eliminate the mentioned limitations, we aim to use the observational FilgoColitis study to draw significant correlations between the QoL and psychosocial well-being of patients with UC on filgotinib therapy over the long-term course under real-world conditions. With the results of the study, we intent to assist physicians in making future treatment decisions regarding the prescription of filgotinib.

XSL•FO
RenderX

Conclusions

In summary, in the FilgoColitis study, we aim to find out how the new JAK1 inhibitor filgotinib affects the QoL of patients with UC in clinical practice with real-world conditions and how safe the therapy is. By using wearables, we assume to obtain superior data to assess patients' QoL. We also hope to prove that the use of wearables could be an additional observational outcome tool to monitor disease activity in patients with IBD. With the multicenter approach, large study population, and long study duration, we aim to obtain meaningful and valid data on the safety and effects of filgotinib therapy.

Acknowledgments

This study is supported by Galapagos NV. The authors are grateful to all parties involved in the study, the sites, and the participants.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

BB, SS, and SPD contributed to the design of the study protocol. All authors were involved in writing the first draft of the manuscript and contributed to the revision of the draft and final approval of the version to be published.

Conflicts of Interest

BB has received consulting fees from AbbVie, MSD, Shire, Ferring, Hospira, Takeda, Movetis, Shield Therapeutics, Pfizer, Biogen, Janssen, Hexal, and Celgene; received financial support for lectures and teaching from AbbVie, Ferring, MSD, Merckle, Falk, HLR, Shield Therapeutics, Pfizer, Celltrion, Takeda, Janssen, and Mundipharma; and received grant and financial support for research from AbbVie and Ferring. SS has received personal fees from Abbvie, Arena, BMS, Biogen, Celltrion, Celgene, IMAB, Gilead, MSD, Mylan, Pfizer, Fresenius, Janssen, Takeda, Theravance, ProventionBio, Protagonist, and Falk.

Abstract

Background: Chronic pain (CP) and its management are critical issues in the care pathway of patients with breast cancer. Considering the complexity of CP experience in cancer, the international scientific community has advocated identifying cutting-edge approaches for CP management. Recent advances in the field of health technology enable the adoption of a novel approach to care management by developing integrated ecosystems and mobile health apps.

Objective: The primary end point of this pilot study is to evaluate patients' usability experience at 3 months of a new digital and integrated technological ecosystem, PainRELife, for CP in a sample of patients with breast cancer. The PainRELife ecosystem is composed of 3 main technological assets integrated into a single digital ecosystem: Fast Healthcare Interoperability Resources–based cloud platform (*Nu* platform) that enables care pathway definition and data collection; a big data infrastructure connected to the Fast Healthcare Interoperability Resources server that analyzes data and implements dynamic dashboards for aggregate data visualization; and an ecosystem of personalized applications for patient-reported outcomes collection, digital delivery of interventions and tailored information, and decision support of patients and caregivers (PainRELife app).

Methods: This is an observational, prospective pilot study. Twenty patients with early breast cancer and chronic pain will be enrolled at the European Institute of Oncology at the Division of Medical Senology and the Division of Pain Therapy and Palliative Care. Each patient will use the PainRELife mobile app for 3 months, during which data extracted from the questionnaires will

XSL•FO
RenderX

be sent to the *Nu Platform* that health care professionals will manage. This pilot study is nested in a large-scale project named "PainRELife," which aims to develop a cloud technology platform to interoperate with institutional systems and patients' devices to collect integrated health care data. The study received approval from the Ethical Committee of the European Cancer Institute in December 2021 (number R1597/21-IEO 1701).

Results: The recruitment process started in May 2022 and ended in October 2022.

Conclusions: The new integrated technological ecosystems might be considered an encouraging *affordance* to enhance a patient-centered approach to managing patients with cancer. This pilot study will inform about which features the health technological ecosystems should have to be used by cancer patients to manage CP.

Introduction

Chronic Pain in Patients With Cancer

Chronic pain (CP) and its management are critical issues in the care pathway of patients with breast cancer. Accruing evidence stated that 30% of breast cancer survivors reported CP, which is likely to persist up to 10 years after the end of cancer-specific treatments [1-3]. CP might rise throughout the care pathway due to surgical procedures and chemotherapy-induced toxicities. In particular, in the population of individuals with breast cancer, different causes of pain incidence have been identified: 25%-60% related to postsurgical pain; 47% pertaining to adjuvant hormonal treatments (including aromatase inhibitors); and finally, 58% related to long-term chemotherapy-induced toxicities [4]. The experience of CP interferes with psycho-emotional well-being (eg, increasing anxiety, depression, and fatigue), psychological adaptation to the disease, personal relationships (eg, partners, family members, and colleagues), and then return to work [1,5]. Furthermore, when CP is not promptly recognized, it may alter patients' health-related quality of life, thereby impacting health status, disease, and medication adherence [1,6,7]. Compared to those without CP, patients with breast cancer experiencing CP showed low adherence to anticancer treatments (eg, hormone therapy), with a demonstrated reduction in treatment effectiveness and a 5-year survival rate [1].

Furthermore, compared to hospitalized patients, out-of-hospital patients with cancer have lower pain relief [8]. In particular, patients who live in regions with poor medical resources, an inadequate health system, or low health literacy have an increased risk of experiencing high levels of pain and related disabilities [9]. Besides, this difference in pain management is produced by the fragmented management of cancer survivors [10], causing nonadherence to treatments and follow-ups, poor control of the side effects, and long-term physical and psychological consequences. Thus, the international scientific community has advocated the urgency to introduce interventions that can favor a timely identification of cancer-related CP, which could guarantee continued and tailored management.

Health Integrated Ecosystems for Cancer Chronic Pain Management

Recent advancements in the field of information and communication technology enable the adoption of a novel and challenging approach to care management in the oncological domain throughout the development of integrated ecosystems [11,12]. A growing and consistent series of studies assert that new integrated health technologies have the potential to improve CP management in patients with cancer and overcome current limitations [12-16]. Furthermore, studies suggested that health technology might well manage physical and psychological morbidities associated with pain experience by allowing continuous monitoring [15] of clinical health status in real time and transmitting these data to their health care providers, incorporating them into patients' electronic health records [15,17,18].

Among existing supportive tools for CP, mobile health apps have been increasingly applied [13,14] and they help patients with cancer to monitor and reduce pain experience by promoting self-management skills and improving their quality of life [8,14]. Furthermore, mobile apps, if interconnected with the health technology ecosystem and managed by health care providers, increase the patient's involvement in their care pathway [12]. Overall, this type of technology architecture might achieve different clinical outcomes. First, it monitors the physical and psychological well-being of the patients through self-report questionnaires and momentary ecological assessments (eg, using e-diary), in particular, regular administration of standardized self-report questionnaires and momentary ecological assessments, such as e-diary, effectively track variation in physical and psychological symptomatology, allowing an evaluation of affective instability in CP [15,19]. Second, it favors bidirectional and well-timed communication between health care professionals and patients [7,16], for example, patient-reported outcome measures can be managed by mobile health apps and stored in patients' electronic health records, favoring a fast and direct clinical response to alarm conditions [20]. Third, it permits scheduled clinical follow-ups, reducing the risk of failing continued clinical monitoring during, for example, the survivorship phase [12]. The strategy is meant to improve the quality of care for both outpatients and inpatients.

XSL•FO
RenderX

This latter statement is coherent with the National Cancer Institute declaration [21] that has remarked on the importance of building a strong and consolidated connection between inpatients and outpatients, reducing the risk that cancer survivors, after the end of active treatment, move out from the care system. Fourth, it boosts patients to be more involved in their treatment decisions, permitting them to achieve a shared decision about their care pathway throughout the implementation of decision aids. According to the American Society of Clinical Oncology international guidelines [21] for pain management, patients with breast cancer can choose between pharmacological and nonpharmacological treatments. Thus, patients with breast cancer experiencing CP have to face a series of preference-sensitive decisions related to the treatments and their consequences in the short, medium, and long term [22,23]. Accruing evidence [24,25] has stressed the critical role of decision aids as an excellent strategy to increase the probability of getting a shared and involved decision. Decision aids are tailored tools designed to deliver evidence-based information on the disease, available treatments, and associated risks; additionally, they may help patients think about the treatment alternatives according to a personal outlook [24,25]. Overall, health technologies are recognized as facilitators of shared decision-making (SDM), reducing decisional conflict and enhancing patient satisfaction.

Implementing SDM models improves patients' knowledge and consolidates the comprehension of their treatment preferences [24,26]. Evidence highlighted that, when implemented on mobile apps, decision aids may support patients by raising awareness of treatment preferences, reducing decisional conflict, and improving adherence to medical treatments [27-30] and SDM [31-33]. We argue that the implementation of the decision aid in clinical practice might be beneficial for patients with early breast cancer in the initial stages of the clinical pathway, that is, immediately after the surgery, when the patients have to face a series of preference-sensitive decisions related not only to the anticancer treatments but also to the management of the pain.

PainRELife Integrated Big Data Ecosystem and Usability Approach

Despite the importance of health technologies in CP management, only some studies have provided integrated technological solutions supporting health care providers in patient management [20]. In addition, available studies have several methodological limitations (eg, small sample size and short follow-up period). Therefore, additional studies are often needed to evaluate the feasibility and usability of such health technology solutions in the clinical practice for supporting patients with CP throughout the care pathway. The evaluation of the user's usability experience is a fundamental prerequisite to increasing the success rate in implementing technologies into routine clinical practice [34] and gives reliable and quantitative information on the quality of e-tools. While the development of new mobile apps should rely on usability testing and patient-centered design process that integrates patients' needs [34], before testing for effectiveness and improving adoption and compliance [35].

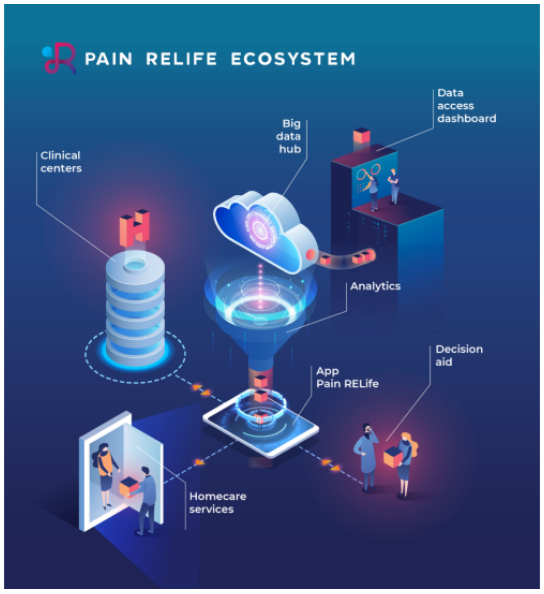
This pilot study offers an opportunity to test the patients' usability experience of an integrated technological ecosystem for CP management (PainRELife) in a sample of patients with early breast cancer. Once the usability and effectiveness of PainRELife will be proven, this ecosystem might fill the gap between hospital and home care settings, collecting ongoing, and integrated patient-centered data with the 3-fold future aim to (1) carry out ecological monitoring of the physical and psychological pain experience of the patients; (2) obtain psychoeducational information on pain and available treatments; (3) explore of patients' preferences and support in SDM on pain treatment options between the physicians and the patients.

Methods

Primary End Point

The primary end point of this pilot study is the evaluation of patients' usability experience after 3 months of using a new digital and integrated technological ecosystem (engagement, judgment on usability, aesthetics, quality of given information, personal perception, and perceived impact on behaviors; *Nu* Platform connected with the PainRELife app) for patients with early breast cancer experiencing CP.

Secondary End Points



Secondary end points concern the following aspects: (1) assessing the usability of the mobile app in terms of the number of access and usage time; (2) assessing changes in self-efficacy related to CP; and (3) assessing SDM processes between patients and health care professionals.

Study Design

This is an observational, prospective pilot study nested in a large-scale national project named "PainRELife, *Sustainable and integrated big data ecosystem for continuity of care and decision support for patients with pain*" (ID 1173269). The PainRELife project aims to develop a cloud technology platform ("Big data HUB") that is able to interoperate with institutional systems (eg, national electronic health records) and patients' devices to collect integrated health care data (Figure 1).

XSL•FO
RenderX

Figure 1. Elements involved in the PainRELife ecosystem and their interconnections.

PainRELife Integrated Big Data Ecosystem

The PainRELife is composed of 3 main technological assets integrated into a single digital ecosystem (Figure 1) that were developed during the first year of the project through a collaboration between technical partners and clinical aspects (January 2020 to June 2021).

1. A Fast Healthcare Interoperability Resources (FHIR)–based cloud platform (*Nu* platform) that enables care pathway definition and data collection. The digitized care pathways managed through the *Nu* platform were developed following a consensus procedure that included both the available guidelines and recommendations on CP management and the local experience at the referral centers involved in the project. The digitalized care pathways for pain management became accessible to health care professionals for the data collection on pain, psychological well-being, and decision preferences about treatment options. In particular, the *Nu* platform is the intuitive interface that will be used by health care providers and will permit them to collect and store clinical data (eg, diagnosis, comorbidities, treatments, drugs, pain, anxiety, depression, and emotional distress) and an ongoing monitoring of the patient's health status (from the diagnosis to the follow-ups).
2. A big data infrastructure connected to the FHIR server that analyzes data and implements dynamic dashboards for aggregate data visualization aimed to provide a population-based view for researchers and governance. The dashboards were designed to provide an at-a-glance overview of the population tendencies with respect to the different measures and monitoring procedures. Since these dashboards are not designed for patients, they were not evaluated in this protocol.
3. An ecosystem of personalized apps for patient-reported outcomes collection, digital delivery of interventions and tailored information, and decision support for patients and caregivers (PainRELife app).

The integration of these 3 aspects and the involvement of relevant stakeholders within the CP management process allows the definition of PainRELife as an ”integrated ecosystem.“

Key Features of PainRELife Mobile App

The PainRELife app was developed to interoperate with the *Nu* platform through the FHIR standard, establishing a bidirectional communication channel between health care providers and patients. The PainRELife app has been designed following 3 different steps. First, an extensive and qualitative literature analysis has been performed to define the main issues for patients with breast cancer experiencing CP [36]. In addition, the impact of CP on psychological functioning has been analyzed as the role of the caregivers in the management of the CP experience and how CP impacts different dimensions of the quality of life (sexuality, employment, and returning to work, and psycho-emotional and social determinants). Furthermore, unmet needs in managing CP were evaluated considering multilevel determinants such as sociodemographic, psychological, social, and clinical variables [36]. Finally, the role of technologies in the health care system has been explored to understand the most important aspects that should be considered in the design and development of health technologies. Based on this qualitative analysis, a set of preliminary contents and mock-ups of the mobile app have been developed.

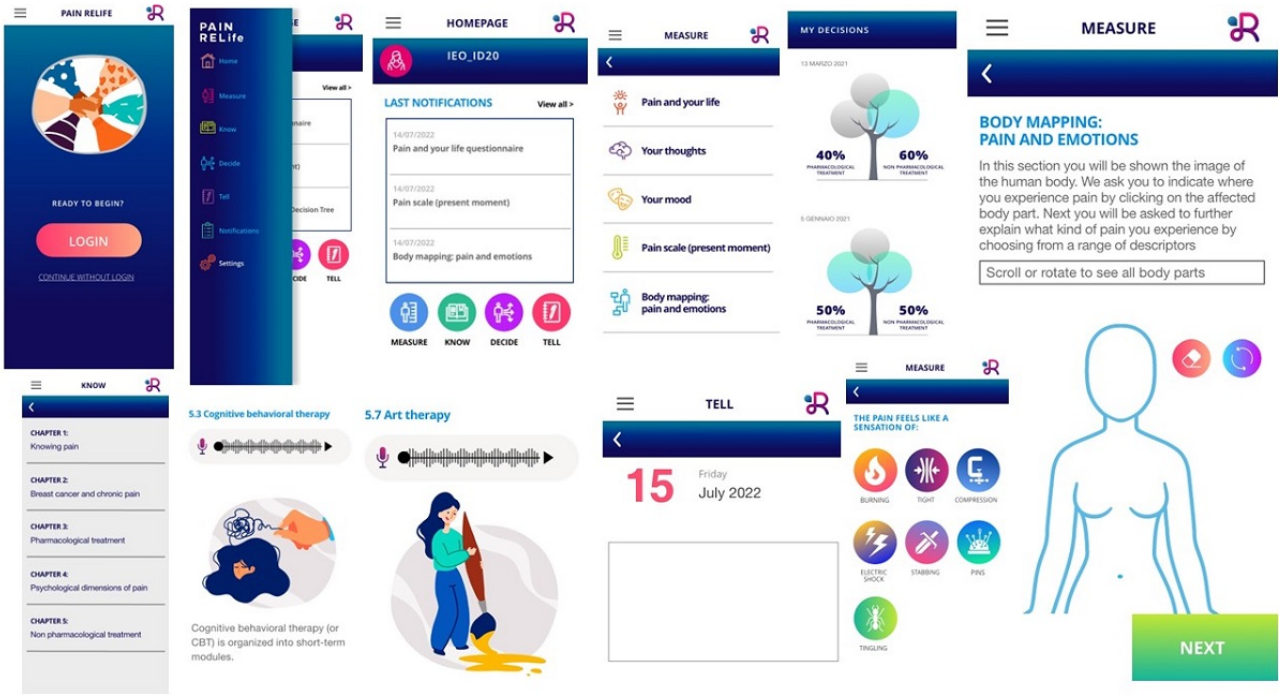
Second, a series of semistructured interviews have been conducted with female patients with breast cancer (N=6) to implement a user-centered design process of the CP mobile app. The semistructured interviews had 3 main goals: evaluating the perceived use of technological support for pain management and the current experience of the patients with the health technologies; evaluating possible interface, contents, functionality, and quality of the mobile app; evaluating a preuser experience of the mobile app through an ad hoc storyboard. Overall, the storyboard is a method used to provide a brief overview of a new mobile app. The storyboard illustrates the main sections of the mobile app and explains the circumstances in which the mobile app should be used.

XSL•FO
RenderX

Finally, all contents of the mobile app have been revised and discussed by an expert group. The group composed of oncologists, palliative physicians, psychologists, and patients. The obtained suggestions have been integrated into the PainRELife app's last version.

The PainRELife app has been organized into 3 main sections (Figure 2):

1. *Educational Section*: In this section, patients gather evidence-based information on CP and breast cancer. This section aims to improve health literacy using evidence-based information about CP experience during the care pathway (from diagnosis to survivorship). This section contains information on a wide array of topics related to breast cancer diagnosis, cancer pain experience, treatments for CP (pharmacological and nonpharmacological), associated benefits and side effects, and psychological comorbidities. The contents of this section are organized as text, video, and audio files in order to increase the usability rate within different groups of patients with breast cancer.
2. *Pain and Psychological Wellbeing Assessment Section*: It contains a set of self-reported measures evaluating psychological well-being (Hospital Anxiety and Depression Scale; Pain Catastrophizing Scale) [37,38] and pain experience (Brief pain inventory; Visual Analogue Scale [VAS]) [39,40]. This section also includes an e-diary and pain and emotions body mapping exercise. In addition, the e-diary aims to monitor the emotional, cognitive, behavioral, and physical aspects of the CP experience. At the same time, the pain and emotion body mapping exercise request the patients to localize pain and emotions associated using a digital representation of the body (Figure 2). The self-reported measures were implemented with a specific interval time for a total of 3 months with automatic push notifications: Hospital Anxiety and Depression Scale and Pain Catastrophizing Scale monthly; VAS, pain and emotions body mapping exercise, and e-diary each week; and Brief pain inventory 2 times a month. The aim of this section is to (1) permit ongoing monitoring of the patients by health care providers when they are at home and during the follow-up phase and (2) improve the patients' awareness about their own emotional and physical well-being through specific self-monitoring tasks. Overall, the patients will fill questionnaires in the PainRELife app for 3 months. PainRELife app will send an alert to recall the questionnaires.
3. *Decision Aid Section*: It is one of the app's key features (Multimedia Appendix 1). The decision aid comprises 2 parts—profiling patients' preferences and decision tree for CP treatments. In the first part, each patient fills a set of visual analog scales (ranging from 0 to 100) evaluating the general features of the pharmacological and nonpharmacological treatments. The VAS have been designed, considering the key determinants of the patient's treatment decisions suggested by the evidence [41-45]. The pharmacological treatments such as the perception of efficacy, motivation, and general beliefs (3 items); association between drug dosage and tolerability (3 items); the importance of the speed of the effect on pain reduction (1 item); risk of physical dependence (1 item); modality of administration (3 items); side effects tolerability (1 item); the impact of the consumption on cognitive functioning (1 item) are evaluated in detail. On the contrary, the nonpharmacological treatments evaluated efficacy perception, motivation, and general beliefs (3 items); attitude toward interventions that act of mental representations and emotions behind the pain experience (1 item); attitude toward interventions mind-body (1 item); attitude toward interventions that might drive to immediate pain relief (1 item); attitude to short-term interventions (1 item) and that might be implemented autonomously and at-home (1 item); attitude toward interventions that self-administered (active role vs passive role) (1 item); attitude toward interventions that are conducted in a group versus separately (2 items).



In the second part, patients have to complete a decision tree. A decision tree has been defined as a sort of "abstract structure" able to increase knowledge about the choice that should be performed. The decision tree supports an informed and shared decision [46,47]. Through the decision tree, each patient will compare individual use associated with pharmacological and nonpharmacological treatments. In addition, each patient will identify each option (pharmacological vs nonpharmacological treatments), advantages, and disadvantages. Each of them will be assigned a value ranging from 1 to 10 (advantages-gains) and from −1 to −10 (disadvantages-losses). The total value obtained, given by the sum of the advantages and disadvantages for each option, permit to calculate the individual use associated with each treatment. Each patient is trained to fill the decision aid after 15 days from the discharge to the hospital, at 1 month from surgery, and at 3 months before the clinical follow-ups. The final aim of the decision aid is to support the construction and expression of patients' preferences about current treatments for CP by comparing pharmacological versus nonpharmacological treatments.

Overall, the information collected by the PainRELife app through the self-reported measures and e-diary will be stored in the *Nu* platform and managed by the health care providers (oncologists, nurses, and psychologists) in order to monitor the health and psychological status of the patients and permitting the early identification of at-risk situations. Patients may see the results obtained in each self-reported measure and other tasks of the PainRELife app and are trained to contact the health care professionals for any questions about these issues. The results obtained in the assessment performed through PainRELife app will be discussed in the following clinical consultation.

The PainRELife app will be installed on the patient's mobile phone, and if the patient does not have a personal mobile phone, it will be provided by the researcher (Multimedia Appendix 2). The PainRELife app can run on IOS and Android operating systems. To ensure timely communication with the hospitals and the physicians, relevant contact information will also be explicitly provided to the participants within the PainRELife app.

Figure 2. English version of the application PainRELife.

Participants

In this study, 20 participants consecutively admitted at Istituto Europeo di Oncologia (IEO) at the Division of Medical Senology and the Division of Pain Therapy and Palliative Care with a diagnosis of breast cancer and CP will be enrolled. Such a sample size is recommended for 1 group [48,49]. Other studies suggested that in order to record a higher percentage of usability errors, it is advisable to enroll a sample of more than 12 participants [50]. Furthermore, within the PainRELife project, a mobile app was also configured for patients experiencing chronic pain post stroke and tested in a referral center for neurological rehabilitation. Thus, a parallel data collection will be conducted on a sample of 20 participants consecutively admitted at Casa di Cura Policlinico. The present protocol refers solely on IEO patients.

Selection Criteria

Inclusion criteria include (1) patients >18 years; (2) having an early breast cancer diagnosis; (3) having undergone surgical intervention for breast carcinoma (quadrantectomy, mastectomy ± lymph node dissection); (4) the presence of postsurgical pain with a score ≥3 in the Numerical Rating Scale (NRS) or VAS; (5) patients with internet access and a personal smartphone; and (6) patients who have read and signed the informed consent.

Exclusion criteria include (1) the presence of primary psychiatric or neurological conditions preventing the ability to use the mobile app and the capacity to express free consent to join the study; (2) the presence of other medical conditions which imply an active antalgic treatment; and (3) patients who refused to sign the informed consent.

Measures

Patient Demographic and Medical Variables

Age, gender, education, marital status, cancer diagnosis, type of surgery, oncological treatments, and comorbid medical disorders were collected through electronic medical records and self-reports.

Pain Self-Efficacy Questionnaire

The PSE is a self-administered questionnaire composed of 10 items rated on a 7-point Likert scale from "*not at all confident*" to "*completely confident.*" The Pain Self-Efficacy Questionnaire (PSEQ) [51,52] measures self-efficacy while performing activities of daily living, despite experiencing pain. The total score of the PSEQ ranges from 0 to 60. The PSEQ has been validated for Italian culture by Chiarotto et al [52] and showed high internal consistency (Cronbach α=.94).

Nine-Item Shared Decision-Making Questionnaire

The 9-item Shared Decision-Making Questionnaire (SDM-Q-9) [53] is a self-administered questionnaire composed of 9 items on a 6-point Likert scale from "*completely disagree*" to "*completely agree.*" The SDM-Q-9 evaluates patients' perception of SDM and their level of involvement during the consultation, as well as the information received on possible treatments and potential risks and benefits of being involved in the decision-making process. The SDM-Q-9 showed high internal consistency in the original validation (Cronbach α=.94).

Mobile Application Rating Scale

The Mobile Application Rating Scale (MARS) [54] is a self-administered questionnaire specifically created to rate the quality of eHealth apps [55], and it is composed of 6 different sections (A, B, C, D, E, and F) for a total of 29 items with 5 possible answers. It assesses the quality of the app according

XSL•FO
RenderX

to 4 specific dimensions: engagement experienced while using the app (A); functionality (B), aesthetics (C), quality of the information received (D), as well as the subjective perception of app quality (E) and the perceived impact on the app toward knowledge, attitudes, and probability to change user behaviors (F). The MARS showed a high internal consistency (Cronbach α=.90) and good psychometric properties [56].

VAS and NRS

The VAS and NRS [57] are unidimensional assessment scales for evaluating pain intensity. The first one graphically represents the amplitude of perceived pain through a 10-cm predesigned line. The left extremity corresponds to the "*absence of pain*," whereas the right represents the "*worst pain possible*." Next, the patient will be asked to draw a sign on the line representing the level of experienced pain. In the NRS scale, similarly, patients will be asked to verbally specify the number corresponding to their experienced pain, according to the following numerical graduation: (0: "*no pain*," 1-3: "*mild pain*," 4-6: "*moderate pain*," 7-10: "*severe pain*"). The use of the VAS or NRS is determined by the patient's degree of cognitive functioning.

Recruitment and Follow-ups

Patients admitted to the Division of Medical Senology of the IEO will be enrolled by the palliative care physician and a trained psychologist from the Applied Division of Cognitive and Psychological Science. The patients enrolled will have an interview with the psychologist responsible for the data collection. The psychologist will install the PainRELife app and create a personal account. Each patient will use the app for 3 months, during which data extracted from the questionnaires will be sent to the *Nu* platform. Furthermore, at baseline (T0), each patient will fill a set of questionnaires (PSEQ, SDM-Q-9, and VAS or NRS), while at 3 months (T1), each patient will fill the same questionnaires and MARS.

The palliative care physician and the psychologists in charge of data collection will monitor the information transmitted from the PainRELife app to the *Nu* platform for the whole period of testing.

Patients will be informed that neither the platform nor the app will replace the clinical consultation. Furthermore, for any necessity, patients have to get in contact with the pertaining division.

A monthly telephonic interview will be provided to maintain motivation and monitor and detect any psychological, physical, and technical problems. In addition, this program includes 3 calls: 1 at the end of week 4, week 8, and week 12. Each call will last about 10 minutes and address concerns related to the use of the app or their involvement in the pilot study. Data collected through the PainRELife app will be sent to the *Nu* platform and consequently managed by the physician responsible for data collection.

Statistical Considerations

All statistical analyses will be performed through SPSS (version 26; IBM Corp). Data analyzed will be referred to the primary end point, such as usability experience and app quality, which is assessed by the MARS questionnaire. The questionnaire delivers a mean quantitative score for each subscale (A, B, C, D, E, and F), with a mean score from 1 to 5 for the given answers and a total mean score of app quality and the subjective quality perceived by the patients. High mean scores (range 3-5) indicate a good qualitative level of app usability, both considering the global quality and the specific subdimensions [58]. Descriptive statistics of all the questionnaires included in the app will also be processed. Considering the secondary end points, the mean and SD of the PSEQ questionnaire scores will be calculated at T0 (baseline) and T1 (at 3 months) and compared using an appropriate statistic test. PSEQ mean scores will be interpreted according to the established normative reference values [52]. Furthermore, the number of accesses and usage time for each app section will be collected and analyzed. This additional analysis will provide insights into compliance (considering the total number of accesses required by the care pathway) and the perceived usefulness of the educational and decision aid sections.

According to the SDM-Q-9, the questionnaire's total raw score will be obtained by summing all the scale items, ranging from 0 to 45. Since it is more comprehensible, the raw score will be transformed into an interval scale from 0 to 100 (where 0 indicates the lowest possible level of SDM and 200 pinpoints the highest level of SDM) by multiplying the raw score by 20/9. Lastly, bivariate correlations among the questionnaires administered at T1 will be computed. Specifically, a positive correlation between the quality of the app scores (measured by MARS), the perceived self-efficacy despite the presence of pain (measured by PSEQ), and SDM scores (measured by SDM-Q-9) is expected.

Ethics Approval

This pilot study follows the principles stated in the Declaration of Helsinki and subsequent amendments and the Good Clinical Practice Guideline. This protocol was assessed and certified by the ethical board of the European Institute of Oncology (approval number R1597/21-IEO 1701). Informed consent will be obtained from all participants. The informed consent will contain detailed information on the aims and the procedures of the study, as well as on the analysis plan, risks, and benefits for the participants. Participation in the study will be voluntary, and participants will not receive any compensation.

Furthermore, the study data are deidentified. Data will be stored in the IEO databases for 10 years. The study will comply with national and local data protection legislation. Further, all data will be anonymized. Data will be stored in the IEO databases for 10 years.

Results

The recruitment process started in May 2022 and ended in October 2022.

XSL•FO
RenderX

Discussion

Principal Expected Findings

Considering the complexity of CP experience in the cancer domain, the international scientific community has advocated identifying cutting-edge approaches for CP management. A growing body of studies [8,10,20,31,58] has underlined that health technology solutions might be considered an encouraging and challenging opportunity to enhance patient-centered care and increase patient participation in the care pathway, SDM, and health-related quality of life. This pilot study protocol described here and testing patients' usability experience at 3 months of a digital and integrated ecosystem (PainRELife mobile app and *Nu* platform) for CP in a sample of patients with early breast cancer will permit to achieve of a series of key expected outcomes enriching results obtained from the previous studies.

The *first expected outcome* concerns the possibility of collecting a set of patient-based evidence about the usability experience of the PainRELife mobile app, which will permit to tune of the future version of this type of health technological solutions for patients with chronic pain. More specifically, the results about usability will permit to identify which features (in terms of functionality, aesthetics, and quality of the information provided) a mobile app for CP management should have to be used by patients to manage their care pathway and which are the patient's beliefs about the perceived impact on health behaviors (eg, "*The mobile App will help me to improve health literacy about my pain permitting me to adopt behaviors able to reduce CP*"). A second expected outcome concerns the possibility of overcoming limitations highlighted by earlier studies about health technologies for the patient's clinical management (eg, inadequate sample size or follow-ups) [20]. Indeed, using a pilot study design to evaluate usability experience will inform future studies evaluating effectiveness, thereby increasing the probability of achieving a better implementation of such integrated ecosystem into routine clinical practice and increasing user retention.

A third expected outcome concerns the patient's home monitoring, contributing to reducing barriers to pain management related to poor medical resources, inadequate health system, and low health literacy [9]. In particular, we argue that the direct communication between the *Nu* platform (health care professionals' perspective) and the PainRELife mobile app (patients' perspective) will permit the ongoing tracking of outpatients' physical and psychological health status, allowing physicians to recognize alarm signals promptly. Furthermore, such an integrated ecosystem will permit monitoring clinical follow-ups, reducing the risk of patients' dropout.

Finally, a fourth expected outcome is implementing the decision aid to improve patients' ability to participate in their clinical decision, providing a better portrayal of patient SDM processes in pain management. In addition, we argue that the integration of a decision aid in *the* PainRELife mobile app will allow patients with breast cancer to deal with preference-sensitive decisions by clarifying their needs, values, and expected outcomes associated with the treatment for CP. Also, data collected through the decision aid and shared with the physician will permit us to understand the patient's perspective before the clinical consultation better. This better knowledge about patient perspective will facilitate patient and doctor interaction and consequently will support the achievement of a shared decision about CP care.

Limitations

Despite the innovative clinical and methodological aspects of the current usability study protocol, some limitations should be considered. First, the patient's usability experience of the PainRELife app is evaluated by MARS administration without measuring outcomes related to the care process and the clinical workflow. However, physicians' perspectives and related clinical workflow have been considered in the design phase of the PainRELife *ecosystem*, both for developing the *Nu* platform (the interface used by the physician) and for the PainRELife app (the interface used by the patient). As reported, the digitized care pathways (managed through the *Nu* platform and PainRELife app) were developed following a consensus procedure that included both the available guidelines and recommendations on CP management and the local experience at the referral centers involved in the project (IEO and Casa di Cura Policlinico). This could have contained the risk of implementation bias. Second, a monthly telephonic interview is performed by a trained researcher for the monitoring of usage and concerns to maintain patient involvement in the study, reducing the risk of dropout and increasing the quality of the data collected. Notwithstanding, we have to consider the risk that monthly telephonic interviews are the outcome measures. Indeed, patients might have increased the usage of the PainRELife app to satisfy research expectations (*social desirability effect*) and because the researcher has dedicated attention to the participant (*Hawthorne effect*).

Finally, the last limitation concerns the decision to use a single-group instead a 2-group design for evaluating usability experience according to Julious [49] guidelines for a pilot study. A study design with 2 groups (intervention vs control group) could have also permitted an evaluation of differences in pain management associated with using the PainRELife app. This type of information could have informed a future effectiveness study.

Conclusions

We expect to provide a set of suggestions for the development and implementation of this health technology into routine clinical practice. Data from this pilot study will inform the conduction of full-powered studies testing the efficacy and impact of digital support systems for CP management. Further, the future implementation of this integrated ecosystem will improve CP management in patients with cancer and SDM models through decision aid.

Abstract

Background: The UK National Health Service (NHS) has introduced a digital social prescribing (DSP) system to improve the mental health of the aging population. In Korea, an ongoing pilot social prescribing project has been implemented for older individuals in rural areas since 2019.

Objective: This research aims to develop a DSP program and to evaluate the effectiveness of the digital platform in rural areas of Korea.

Methods: This study was designed as a prospective cohort method for the development and effectiveness evaluation of rural DSP in Korea. The study divided participants into four groups. Group 1 will continuously implement the existing social prescribing program, group 2 implemented the existing social prescribing program but was switched to DSP in 2023, group 3 newly started the DSP, and the remaining group is the control. The research area of this study is Gangwon Province in Korea. The study is being conducted in Wonju, Chuncheon, and Gangneung. This study will use indicators to measure depression, anxiety, loneliness, cognitive function, and digital literacy. In the future, the interventions will implement the digital platform and the Music Story Telling program. This study will evaluate the effectiveness of DSP using difference-in-differences regression and cost-benefit analysis.

Results: This study was approved for funding from the National Research Foundation of Korea funded by the Ministry of Education in October 2022. The results of the data analysis are expected to be available in September 2023.

Conclusions: The platform will be spread to rural areas in Korea and will serve as the foundation for effectively managing the feelings of solitude and depression among older individuals. This study will provide vital evidence for disseminating DSP in Asian countries such as Japan, China, Singapore, and Taiwan as well as for studying DSP in Korea.

Introduction

Globally, those 65 years or older accounted for 10% of the population in 2022. This number is expected to reach 16% worldwide by 2050 and exceed 20% in all high-income countries [1]. The aging of the global population presents the need to introduce various medical systems.

In the era of aging populations, both the physical and mental health of older individuals should be considered. Depression, solitude, and dementia are emerging social problems [2]. Previous studies have shown that an average of 13%-15% of older individuals 65 years or older experience social solitude, and those 80 years or older and in rural areas experience more social solitude [3,4]. In addition, 6%-13% of older individuals 65 years or older experience loneliness [5,6]. These feelings of social solitude and depression among individuals older than 65 years indicate the vulnerability of mental health in this population, which is highly likely to lead directly to suicide risk and deterioration of physical health.

Due to the current era of aging, the health problems of older individuals cause limitations for the medical personnel and resources of primary health care facilities in local communities. They also lead to financial difficulty for national insurance, which increases the medical burden at the national level [7].

The UK National Health Service (NHS) has introduced a social prescribing system to reduce the workload of primary health caregivers. Currently, the United Kingdom's primary health caregivers, accounting for one-third of general practitioners, use social prescribing [8]. This system provides a nonclinical social prescribing program through link workers who have been trained in using community resources rather than the clinical medical system. Representative programs of social prescribing include gardening, dance, music therapy, and social activities. Social prescribing is aimed at improving the health of the local community in particular; however, it aims to reduce and minimize the solitude of older individuals 65 years or older; strengthen the local services, the network of the local community, and the efficiency of medical resources; alleviate the burden on primary care; and improve health and welfare services [2].

Previous studies have reported the effects of social prescribing systems on older individuals in various countries. Gardening, nature-friendly activities, and art activities have been found to positively affect the mental health of older individuals [9-11]. In addition, studies identified the effects of social prescribing in increasing self-esteem, improving mental well-being, reducing loneliness, and decreasing the use of medical services among older individuals 65 years or older who felt social isolation and had severe depression [12,13].

In Korea, a pilot project is being implemented for older individuals in rural areas since 2019. The first social prescribing program was performed for 10 weeks; the 10th social prescribing program was implemented in 2022. The social prescribing programs provided were music storytelling, allotment farming, kalimba music therapy, self-help group, and digital literacy strengthening education. These social prescribing programs in Korea reduced the average depression and loneliness of the participating older individuals and enhanced social participation [14-17].

Various experts emphasize the lack of evidence and research on implementing a sustainable system for the social prescribing system as a limitation [18]. The United Kingdom has developed and operated a digital social prescribing (DSP) system to solve these problems using digital platforms. A representative DSP in the United Kingdom is Elemental Software, now under the name Access Health, Support and Social Care, which is mainly responsible for monitoring, observing, and supporting patients from the time when social prescribing is requested. The DSP platform provides health risk analysis, an attendance tracker, health impact measurement, aggregate reporting, befriending services, web-based home resources, grocery collection and pharmacy delivery services, local food bank access, and NHS app library services. As of October 2022, more than 10,000 social prescribing sites have been registered on this DSP platform, and 160 social prescribing service providers use the platform.

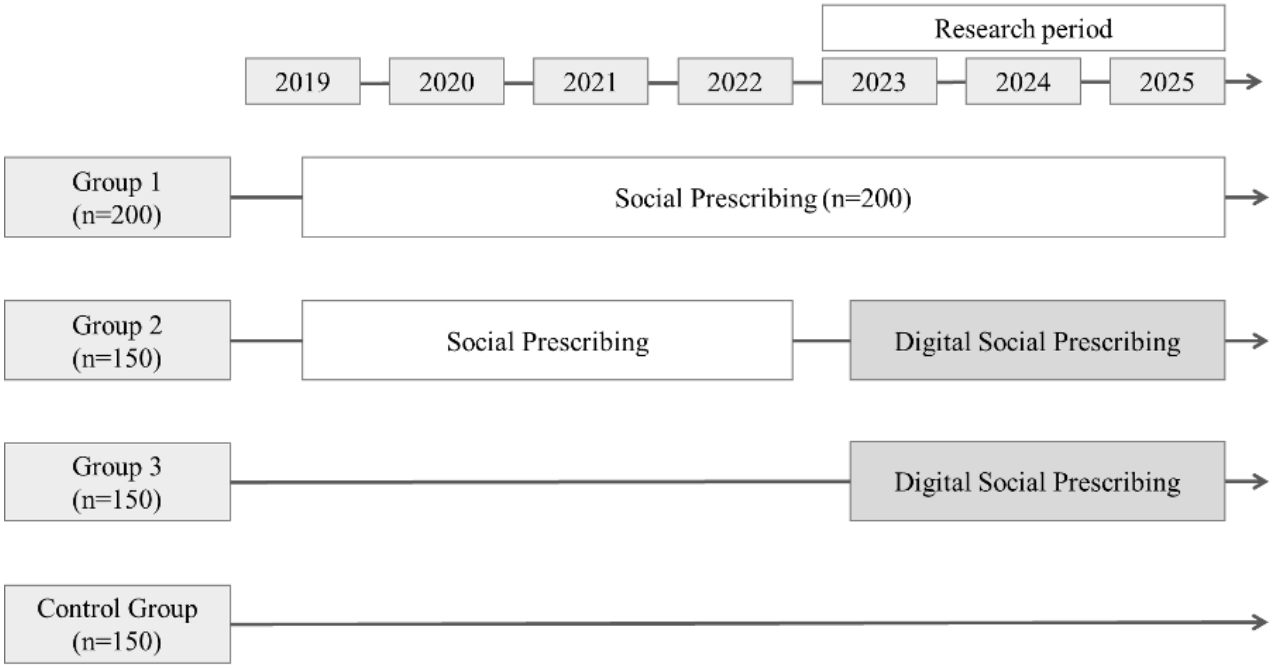
Korea has problems similar to the United Kingdom, such as a lack of primary health care personnel and resources in rural areas and insufficient finances for the National Health Insurance [19]. However, Korea is a digital powerhouse among Organisation for Economic Co-operation and Development (OECD) countries with the highest internet penetration rate of 99.9% as of 2021 [20]. The Korean government launched a digital platform in November 2021 and announced that rural areas will be provided with all services through the digital platform. Therefore, it is imperative to develop and operate the existing rural social prescribing model as DSP.

Therefore, this research aims to develop a Korean rural social prescribing program as DSP and to study the possibility of providing and expanding the digital platform to rural areas in Korea, like the Elemental platform in the United Kingdom. Specifically, the first goal is to conduct an economic evaluation by comparing DSP with existing social prescribing programs. Furthermore, it aims to evaluate the effectiveness of reducing depression and solitude when DSP is provided, as the existing social prescribing program does. Finally, it aims to study scenario modeling that extends to Gangwon Province in Korea.

Methods

Study Design

This study is designed as a prospective cohort method for the development and effectiveness evaluation of rural DSP in Korea. The study period is designed to be 3 years in total. The study framework was divided into stages by year. The study is designed by dividing participants into four groups. Group 1 will continuously implement the existing social prescribing program,



XSL•FO
RenderX

group 2 implemented the existing social prescribing program but was switched to DSP in 2023, group 3 newly started the DSP, and the remaining group is serving as the control.

Research Area

The research area of this study is the Gangwon Province in Korea. The study was conducted in three cities—Wonju, Chuncheon, and Gangneung—which belong to Gangwon Province (Figure 1). Gangwon Province is one of 16 cities/provinces/districts and is among the major regions of Korea. It has a population of 1,555,876, accounting for 2% of the total population of Korea. The older adult population accounts for 22.2% of this population, making Korea a superaged society with the third-highest aging ratio among the 17 cities/provinces/districts in Korea. Chuncheon, Wonju, and Gangneung are three densely populated cities in Gangwon Province with 361,056 people in Wonju, 361,056 in Chuncheon, and 215,322 in Gangneung. In addition, Wonju, Chuncheon, and Gangneung were selected as research areas because the research team works in these areas.

Figure 1. Research framework.

Study Participants

The participants in this study were older individuals 65 years or older living in Gangwon Province and satisfying the following conditions. Participants had to be older individuals with depression, living alone, and with weak cognitive function. They were recruited after being diagnosed by health care professionals (doctors and nurses) of public health and health service centers. These conditions are the same as those of the existing Korean rural social prescribing model to enable a comparison of the existing model with the DSP model in the future.

Study Instruments

Depression

Older individuals with depression living in rural areas who participate in DSP will be evaluated using the Geriatric Depression Scale Short Form–Korean Version (GDS-K). The GDS is a self-report measurement tool developed by Yesavage [21] to evaluate depression in the older adult population. The GDS-K was developed by modifying and supplementing this measurement tool with expressions that are easy to understand and fit the emotions of older individuals in Korea. Scores range from 0 to 15, with higher scores indicating more severe depressive symptoms. A score of 5 or less is classified as normal, a score of 6-9 as severe depressive symptoms, and a score of 10 or more as depression [22,23].

Anxiety

Anxiety will be measured using the Korean version of the Goldberg Short Screening Scale for Anxiety (GSSA) [24,25]. The GSSA consists of nine items on anxiety. The higher the GSSA score, the higher the anxiety level.

Loneliness

The Revised UCLA Loneliness Scale will be used to measure social loneliness and solitude [26]. This tool consists of 20 items and is scored out of 20 by responding yes or no. The closer to 20 points, the higher the loneliness. A tool will be used that verifies validity and reliability after translating into Korean [27].

Cognitive Function

The Mini-Mental State Examination–Korean Version (MMSE-K) measures overall cognitive function [28]. This tool consists of 30 points, including orientation, memory registration, memory recall, attention and calculation, language skills, and visual composition. A score of 19 or less indicates definitive dementia, a score of 20 to 23 indicates suspected dementia, and a score of 24 or higher is considered normal.

XSL•FO
RenderX

Digital Literacy

Digital literacy will measure using the eHealth Literacy Scale (eHEALS) [29]. This tool investigates 23 items in five areas—operational internet skill, information navigation, communicational/social internet skill, creative skill, and mobile internet skill—on a 5-point Likert scale.

Ethics Approval

The ethics committee of Yonsei University approved this study (REC No. 1041849-202304-SB-073-01). Written informed consent will be obtained from all participants, and the purpose of this study will be carefully explained to them after their permission.

Results

This study began in October 2022 with support from the National Research Foundation of Korea. The results of the data analysis are expected to be available in September 2023.

Digital Platform: Electronic Medical Record

Existing social prescribing is performed by patients with doctors, link workers, social prescribing sites, and social prescribing programs. Developing a digital platform allows these to be integrated into one platform. This study will develop a platform through which patients can consult doctors, receive a social prescribing program, communicate with link workers and social prescribing sites, and perform the program. Currently, the Elemental Software program is a representative DSP platform in the United Kingdom [30].

Music Story Telling Program

The Music Story Telling (MST) program is a social prescribing program based on the theoretical evidence of music therapy and psychological counseling technology. It received a registration patent for service from the Korean Intellectual Property Office in 2013. The MST program is being provided as one of the rural social prescribing programs in Wonju City in Korea, and its effectiveness has been shown through previous research [15].

Data Analyses

Stata SE 16 (StataCorp) is used for statistical data analysis, and visual analysis will be performed using GraphPad Prism (GraphPad Software, Inc.). We will implement two statistical approaches to understand the effectiveness of rural DSP in Korea. The first tests the effectiveness of DSP, and the second is the economic analysis of DSP.

First, to test the effectiveness of DSP, pre-post comparison for each indicator will be performed using paired *t* test, and the effectiveness of the social prescribing program will be analyzed for each indicator with difference-in-differences regression. In difference-in-differences regression, control variables are input based on the Anderson model to control external factors as much as possible. Statistical significance is analyzed under the significance probabilities of .05, .01, and .001 at the 95% CI. The above statistical method analyzes the intervention effect by dividing it into four research-designed groups.

Second, a cost-benefit analysis is conducted for the economic evaluation of DSP. Cost-benefit analysis is a technique for evaluating input costs and benefits by converting them into monetary values. Costs are estimated as expenses spent on DSP, and benefits are estimated by dividing them into “direct benefits,” which are primary medical costs saved through disease prevention and treatment, and “indirect benefits,” which are incidental results such as improvement in productivity caused by care, prevention, and treatment. The decision indicator for economic evaluation will be finally evaluated based on decision rules using net present value (equation 1) and cost-benefit ratio (equation 2).

Discussion

Expected Findings

As a result of this study, it is expected that an evaluation of the effectiveness of DSP in Korea will be provided. This will include an assessment of the suitability of digital platforms and social prescribing electronic medical records (EMRs) in the Korean context. The study will also aim to propose a model that is appropriate for Korea, taking into account the unique features of the Korean health care system.

Furthermore, by conducting an economic evaluation, this study will provide scientific evidence for expanding the pilot program of social prescribing nationwide in Korea. The results of the economic evaluation will be used to make evidence-based decisions about the allocation of resources and funding for social prescribing initiatives. This will enable policy makers to make informed decisions about how best to invest resources to promote health and well-being in the Korean population.

Overall, this study has the potential to make a significant contribution to the development of social prescribing initiatives in Korea. By providing a comprehensive evaluation of the effectiveness of DSP, as well as proposing a suitable model for digital platforms and social prescribing EMRs, this study will help to ensure that social prescribing initiatives in Korea are evidence based and effective.

DSP Effect

Among the social prescribing programs implemented in rural Korea, MST, allotment farming programs, and self-help groups have already been identified as effective. If MST is developed as a DSP among these social prescribing programs and provided to older individuals in rural areas, it is expected to be effective in improving participants’ digital literacy in the long-term. A previous study on social prescribing in Korea showed that improved digital literacy in older individuals receiving social prescribing effectively prevents cognitive function deterioration [17].

Globally, social prescribing programs are being converted to DSP programs, and studies on their effects are being published. One study showed that DSP reduced the use of medical facilities, including primary health care [31]. Despite the rapidly aging population structure in rural areas of Korea, a shortage of

XSL•FO
RenderX

medical facilities and personnel remains [32]. Hence, DSP can reduce the need for participating older individuals to visit inadequate medical facilities in rural areas of Korea.

Digital Platform

Korean DSP will be provided by developing and using a digital platform. Although social prescribing programs are continuously being developed and expanded using the digital platform, mainly in the United Kingdom, study cases remain insufficient [33,34]. Elementary Software is a representative example of a digital platform for social prescribing in the United Kingdom [18]. As of August 2022, a cumulative total of 213,757 patients used Elementary Software for social prescribing services [18]. If the study results indicate that DSP is effective, it is expected that digital platforms such as Elementary Software will be widely expanded in Korea. Accordingly, a wide range of big data databases will be automatically collected from the digital platform, and evidence-based DSP studies are expected to be performed.

In terms of the limitations of the existing social prescribing study, there was a significant limitation in data collection to conduct the study on older individuals who participate in social prescribing [35]. Digital platforms will be a cornerstone for developing data-oriented regionally customized programs for older individuals in rural areas participating in social prescribing in the future.

Social Prescribing EMRs

In Korea, 97.3% of hospitals use EMR systems in line with the development of information and communication technology [36]. The EMR system has advantages in that it makes managing patient data easier. Furthermore, it programmatically protects personal information. DSP also establishes social prescribing EMRs through the digital platform, which is used to record hospitals, link workers, and sites that provide social prescribing in the region for each patient. Data are gathered so that sustainable social prescribing can be performed. These data are expected to be evidence for tracking and managing the patient's condition.

Economic Evaluation

Social prescribing programs have been developed, spread, and conducted worldwide, including in Australia, Singapore, Denmark, and Korea, centering on the United Kingdom. A previous study revealed that unnecessary use of primary health care decreased due to social prescribing, thereby reducing unnecessary medical expenses [8]. However, studies on the economic cost-effectiveness of social prescribing programs in the local community are insufficient [31]. There are no cost-effectiveness studies of social prescribing programs in Korea. Therefore, this study plans to conduct an economic evaluation of the social prescribing program in Wonju City, which has been performed since 2019, using cost-effectiveness analysis. The evaluation is expected to prove that the social prescribing program is more cost-effective than the cost of primary health care for older individuals in rural areas in Korea. In addition, an economic evaluation will be carried out cost-effectively when it is developed as a DSP and conducted in rural areas. Accordingly, it will be possible to compare the economic evaluation of existing social prescribing programs and DSP programs, and it is expected to prove the effect hypothesis of digitalized social prescribing.

Limitations

This study has several limitations. First, Korea has a low level of social awareness about social prescribing programs. Hence, there was a limitation regarding asking study participants and stakeholders for insights on this project. Second, because there is no digital platform for social prescribing, most of the study period was used for technology development, making the study period practically insufficient. Third, the digital literacy of Korean older adults in rural areas was low. Thus, when social prescribing is converted to DSP, it is highly likely that the study participants will have difficulty completing the program.

Conclusions

As the aging population grows rapidly in Korea, institutional policies using local community resources are needed to reduce the growing burden on primary health care. A review of the current literature shows that social prescribing, spreading worldwide and mainly in the United Kingdom, is effective in improving depression and solitude in older individuals. Therefore, the pilot project for the social prescribing program in rural Korea is being implemented, and its effectiveness has been identified.

However, the existing social prescribing system lacks sustainability due to the limitations of personnel and resources. Therefore, a social prescribing program is being developed using a digital platform. The platform will be spread to rural areas in Korea and will serve as the foundation for effectively managing the feelings of solitude and depression among older individuals. This study will provide vital evidence for disseminating DSP in Asian countries such as Japan, China, Singapore, and Taiwan as well as studying DSP in Korea.

Acknowledgments

We greatly appreciate the Healthy City Research Center at Yonsei University for implementing the Social Prescribing pilot project.

This research was supported by Regional Innovation Strategy through the National Research Foundation of Korea funded by the Ministry of Education (2022RIS-005) and by the National Research Foundation of Korea grant funded by the Korea government (No. 2021R1C1C2005464).

Abstract

Background: Sexual and gender minority (SGM) adolescents and young adults (AYAs) are at increased risk of HIV infection, particularly in the Southern United States. Despite the availability of effective biomedical prevention strategies, such as pre-exposure prophylaxis (PrEP), access and uptake remain low among SGM AYAs. In response, the Louisiana Department of Health initiated the LA TelePrEP Program, which leverages the power of telemedicine to connect Louisiana residents to PrEP. A virtual TelePrEP Navigator guides users through the enrollment process, answers questions, schedules appointments, and facilitates lab testing and medication delivery. To increase the participation of SGM AYAs in the program, the TelePrEP program partnered with researchers to develop a chatbot that would facilitate access to the program and support navigator functions. Chatbots are capable of carrying out many functions that reduce employee workload, and despite their successful use in health care and public health, they are relatively new to HIV prevention.

Objective: In this paper, we describe the iterative and community-engaged process that we used to develop an SMS text messaging–based chatbot tailored to SGM AYAs that would support navigator functions and disseminate PrEP-related information.

Methods: Our process was comprised of 2 phases: conceptualization and development. In the conceptualization phase, aspects of navigator responsibilities, program logistics, and user interactions to prioritize in chatbot programming (eg, scheduling appointments and answering questions) were identified. We also selected a commercially available chatbot platform that could execute these functions and could be programmed with minimal coding experience. In the development phase, we engaged Department of Health staff and SGM AYAs within our professional and personal networks. Five different rounds of testing were conducted with various groups to evaluate each iteration of the chatbot. After each iteration of the testing process, the research team met to discuss feedback, guide the programmer on incorporating modifications, and re-evaluate the chatbot's functionality.

Results: Through our highly collaborative and community-engaged process, a rule-based chatbot with artificial intelligence components was successfully created. We gained important knowledge that could advance future chatbot development efforts for HIV prevention. Key to the PrEPBot's success was resolving issues that hampered the user experience, like asking unnecessary questions, responding too quickly, and misunderstanding user input.

Conclusions: HIV prevention researchers can feasibly and efficiently program a rule-based chatbot with the assistance of commercially available tools. Our iterative process of engaging researchers, program personnel, and different subgroups of SGM

XSL•FO
RenderX

AYAs to obtain input was key to successful chatbot development. If the results of this pilot trial show that the chatbot is feasible and acceptable to SGM AYAs, future HIV researchers and practitioners could consider incorporating chatbots as part of their programs.

Introduction

Background

Sexual and gender minority (SGM) adolescents and young adults (AYAs) continue to be at increased risk of HIV infection [1]. The stigma of being a sexual or gender minority and the concomitant isolation, rejection, racism, marginalization, and discrimination experienced by these youth contribute to their elevated risk of HIV acquisition [2,3]. Focal points of new HIV cases among SGM are New Orleans and other southern municipalities where 50% of the new HIV cases among SGM are being diagnosed [4]. Biomedical prevention strategies, particularly pre-exposure prophylaxis (PrEP) that reduces the risk of acquiring HIV by 92%-99% [5-9], are highly efficacious. Yet, PrEP uptake is low among SGM AYAs [10]. To realize the full benefits of PrEP, we must increase access and continued engagement in PrEP services by individuals most at risk of acquiring HIV, especially SGM AYAs residing in the South.

In response to this need, the Louisiana Department of Health initiated the Louisiana (LA) TelePrEP Program in 2019. LA TelePrEP provides a novel and convenient way for Louisiana residents 18 years of age or older to access PrEP through telemedicine. A TelePrEP Navigator guides users through the enrollment process, answers questions, schedules virtual medical appointments, and facilitates lab testing and medication delivery. The Navigator also facilitates access to ancillary services including insurance enrollment. The entire enrollment process can be done remotely by completing the self-enrollment form accessible on the LA TelePrEP website [11] or doing so with support from the Navigator. Unfortunately, participation of SGM AYAs in the Program is limited. From 2018 to 2020, only 52 SGM AYAs had contacted the Program, and only 12 were below the age of 21 years. Increasing the reach of the LA TelePrEP services to SGM AYAs is vital to curbing the further spread of HIV in this community. In 2020, the LA TelePrEP Program partnered with researchers from the Adolescent Medicine Trials Network in efforts to increase participation of SGM AYAs in the LA TelePrEP Program. This collaboration aims to extend the Program's current outreach efforts and support the Navigator's functions by developing a chatbot (PrEPBot) and PrEP-focused social media messaging campaign targeting SGM AYAs.

Chatbots for Public Health

A chatbot is an automated system that mimics informal human-to-human conversation [12]. Chatbots can vary greatly in technical sophistication and capabilities. Artificial intelligence (AI)–based chatbots use natural language understanding and machine learning to provide conversational, contextualized responses (ie, human-like) based on input from users. Simpler chatbots can be programmed using rule-based conversations that are scripted but have limited capacity for recognizing free text input. Many companies provide programmable communication tools to develop application programming interface chatbots that can be integrated with various messaging platforms. Chatbots have been widely adopted in education, e-commerce, consumer banking, entertainment, travel, transportation, and logistics, and their use has led to documented benefits for both employers and customers [13]. Chatbots can be accessed around the clock and reduce employee workload by scheduling appointments, setting reminders, answering questions, locating services, and disseminating information. These functions transfer to health care and public health settings [14]. Chatbots have also been used as interventionists. For instance, Woebot is a "talk therapy" chatbot embedded within Facebook Messenger that has been shown to reduce symptoms of depression and anxiety [15,16].

Despite the wide use of chatbots in other public health areas, the migration of chatbots to HIV prevention efforts has been slow [17]. In 2020, The Joint United Nations Program on HIV/AIDS launched Eli [18,19], a chatbot designed to engage youth in text-based conversations focused on issues critical to healthy youth development such as family, relationships, and sexual health. Eli addresses HIV prevention by providing reasons why testing is important, where and how to get tested, and the importance of starting treatment if HIV test results are positive [18]. The initial response suggests that this type of service targets an important need. In the first week alone, over 12,000 users engaged with the service, and Eli answered over 150,000 questions [18,19]. Eli's success supports exploring text-based chatbot options for other prevention strategies, such as PrEP, among SGM AYAs. Chatbots may help overcome the stigma and discrimination often faced by SGM AYAs by providing a medium to communicate sensitive information and connect to prevention services privately [20]. With extensive community engagement, an SGM AYA–targeted PrEPBot could provide concise, high-quality information, respond to requests rapidly, have 24-hour access, and connect interested users with

XSL•FO
RenderX

either a TelePrEP Program Navigator or the enrollment website to learn more.

Goal of This Protocol

In this paper, we describe the iterative process that we used to develop an SMS text messaging–based chatbot tailored to SGM AYAs that would support Navigator functions and disseminate PrEP-related information. Lessons learned and suggestions that researchers could consider in future application of SMS text messaging–based chatbot technology for HIV prevention efforts were also included. The process we describe in this paper was conducted as part of a parent study designed to increase participation of SGM AYAs in the Louisiana TelePrEP Program. The parent study consisted of a web-based survey and structured focus groups whose findings were used to develop the chatbot and the targeted social media campaign. The institutional review board (IRB) approval for the study included permission to beta-test the chatbot. The testers were not considered to be research participants since their function was to provide recommendations and feedback regarding the functionality of the chatbot. In a separate paper, we will describe the development of the social media campaign and report the findings.

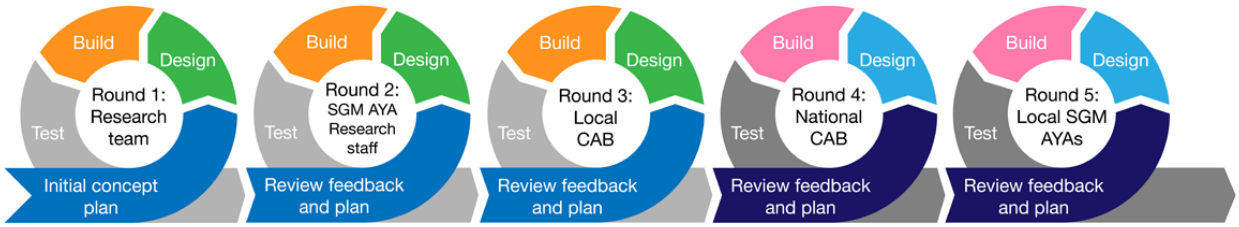
Methods

Phase I—Conceptualization

Prior to chatbot development, the research team met with the TelePrEP Navigator weekly to discuss job responsibilities, program logistics, and interactions with users to identify tasks that would ideally be programmed into the chatbot. The discussions were guided by the following questions: (1) What are your primary responsibilities as a TelePrEP Navigator? (2) What tasks take up most of your time? (3) If you could gain another "human" team member, what would you want them to be able to do? (4) What are the main reasons people contact the TelePrEP Program? and (5) What are the most common questions that people ask you about PrEP and the TelePrEP Program?

Through these conversations, we learned that some of the most time-consuming elements of the navigator's role were discussing PrEP eligibility, facilitating the enrollment process, scheduling appointments, identifying and overcoming PrEP access barriers (eg, insurance), and answering general questions. At our meetings, concerns about the chatbot seeming overly robotic and using inaccessible language that would deter our target population from engaging with the chatbot were also shared.

It was decided that an AI-based chatbot would best meet our functional needs while being "personable." After further investigation, it was realized this type of chatbot required considerable technical expertise, financial resources, and time that were beyond the scope of the project. Instead, we opted to use a rule-based chatbot that was still capable of carrying out all of the functions that would improve Navigator efficiency. A rule-based chatbot was more appropriate for the scope of the project and could be developed using commercially available application programming interface chatbot platforms, such as Twilio [21]. We hired an undergraduate computer science student and proceeded with development using Twilio.



Phase II—Iterative Community–Engaged Development Process

Overall Process

To balance the need to program functions that would support the Navigator while ensuring that the chatbot was user-friendly and accessible to our target population, principles of user-centered design were used to guide our development process [22]. We intentionally engaged Department of Health staff and SGM AYAs within our professional and personal networks. Our iterative process involved multiple stages of testing starting with those directly involved with the project, and each sequential stage approaching real-world conditions to better evaluate the functionality of the chatbot (Figure 1).

In the initial testing phases, we developed unique profiles of hypothetical users from information gathered during the conceptualization phase (see Textbox 1). Each tester was assigned a different profile to use when interacting with the chatbot. Through these conversations, the testers identified areas in need of improvement, technical glitches, typos, and issues with language and terminology.

Figure 1. A diagram of the iterative community–engaged development process. AYA: adolescents and young adults; CAB: community advisory board; SGM: sexual and gender minority.

RenderX

Textbox 1. The unique profiles of hypothetical users assigned to testers during the initial testing phase.

Scenario A

- You want to get on pre-exposure prophylaxis (PrEP)
- You’re 18 years old
- You have private insurance
- You’re on your parents’ insurance
- You don't have any questions

Scenario B

- You want to get on PrEP
- You’re 16 years old
- You have public insurance
- You’re on your own insurance plan
- You don’t have any questions

Scenario C

- You want post-exposure prophylaxis (PEP)
- You’re 20 years old
- You were exposed 24 hours ago
- You already have a doctor you see

Scenario D

- You want PEP
- You’re 29 years old
- You were exposed 4 days ago
- You don't have a doctor already

Scenario E

- You want to know if you're eligible for PrEP
- You’re 26 years old
- You're not living with HIV
- You’ve had anal sex recently
- You're unsure of your partner’s status
- You don’t always use condoms
- If you’re eligible, you don’t want to get on PrEP today
- If you’re ineligible, you don't have any more questions

Scenario F

- You have questions about PrEP
- You want to know how PrEP works
- You also want to know if you have to take it everyday

We used 3 groups of testers in the initial testing phase. First, the research team, other HIV research staff, and a local community advisory board (CAB) evaluated the functionality of the prototype chatbot. The research team was comprised of 2 HIV researchers, 1 senior biostatistician, 1 research coordinator, an undergraduate computer science student, and the TelePrEP Navigator. Our second group of testers were 3 SGM AYA research staff who worked on other HIV-focused projects. Third, the prototype was tested by 8 members of a Louisiana-based youth CAB who were identified as SGM AYA and had a working knowledge of the project.

In the later testing phase, SGM AYAs who had no familiarity with the project were engaged. We convened 2 groups to provide

XSL•FO
RenderX

feedback on the chatbot's functionality. The first was comprised of 8 members of the ATN National CAB, and the second consisted of 5 SGM AYAs recruited from our networks. At the start of each testing session, we provided a brief description of the TelePrEP Program and then instructed the participants to freely engage with the chatbot. No additional instructions were provided. After each iteration of the testing process, the research team met to discuss feedback, guide the programmer on incorporating modifications, and test the chatbot to ensure feedback had been properly integrated.

Initial Development

Our first charge was to create flow diagrams to provide a visual representation of anticipated conversations between the chatbot and potential users. We relied heavily on the navigator's experiences interacting with TelePrEP contacts as the foundation for designing the structure and content of these conversations. We focused our initial efforts on PrEP eligibility, facilitating the enrollment process, scheduling appointments, and identifying and overcoming PrEP access barriers (eg, insurance).

Flow diagrams were created using presentation software (Figure 2) that the programmer would then translate to the Twilio platform using JavaScript coding. Conversation flows were designed based on relevant user characteristics and intent. For example, age and insurance status were important considerations for both program eligibility and addressing privacy implications for those on parents' insurance. In addition to the flow diagram, we created a document to list all conceivable variations of user input in each step of the conversations (eg, yes, yeah, sure, and yup) to minimize the chatbot misunderstanding or misinterpreting communications. We incorporated scheduling appointments with a navigator by inserting a link that directed users to a Calendly calendar [23].

We initiated our iterative testing process as described earlier. After each testing session, the team discussed feedback and proposed solutions that we would route back to the programmer to make the modifications.

Figure 2. Initial chatbot conversation flow diagram. PrEP: pre-exposure prophylaxis.

XSL•FO
RenderX

Programming Refinements and Ongoing Development

Our initial approach proved efficient for programming straightforward conversations that had limited variation in response options. PrEP eligibility, program enrollment, and scheduling conversation flows were easy to design since users could only respond yes or no. It was quickly realized that dichotomous responses could not be used to answer general program and PrEP-related questions. As we began to program the most commonly asked questions, we noted the nearly infinite ways the questions could be posed and the strong potential for typos, abbreviations, and colloquialisms that, if not entered verbatim, the chatbot would not understand. Furthermore, as the volume of conversation flows became more expansive and iterative changes more frequent, we realized that programming was inefficient and time-consuming. We needed to find an alternative approach for chatbot development.

Twilio tech support advised us to take advantage of additional tools in their platform that did not require a skilled programmer, specifically Studio and Autopilot. Studio is a visual workflow builder that uses drag-and-drop tools as well as custom code for rapid chatbot development. Our research coordinator, who had no experience with programming or chatbots, quickly learned how to navigate Studio and was able to easily make modifications to the chatbot that previously could only be handled by the programmer. We relied on the Autopilot tool to facilitate programming of commonly asked questions. Autopilot is an AI platform that can identify and respond to free text input and could be integrated into our existing rule-based design structure.

Once we incorporated the most common questions and formulated initial responses, we continued our iterative development process by engaging with the National ATN CAB and SGM AYAs in our personal networks. Through this process, the list of questions was expanded, and our responses were revised. This was especially important for colloquial use of certain terms. We could not feasibly integrate all possible questions and variations in wording of preprogrammed questions. Autopilot was able to understand slight variations in question wording and allowed us to program new variations as testers introduced additional ways to pose questions. In the event the chatbot could not understand a question, users would be sent to a frequently asked questions (FAQ) page on the TelePrEP website. Our final round of SGM AYA testers had minimal recommendations for changes and gave overall positive feedback on their experience. Through our highly collaborative and community-engaged process, we successfully created a rule-based chatbot with AI components to improve TelePrEP Navigator efficiency and increase access to the TelePrEP Program among young SGM AYA.

Ethical Considerations

The parent study which included the beta testing described in this paper was approved by the Tulane IRB (2021-207). The role of the testers was to evaluate the chatbot to improve its functionality. They were not considered to be research participants.

Results

Recommendations for Chatbot Development

During our iterative development process, we gained important knowledge that could advance future chatbot development efforts for HIV prevention among SGM AYAs. In this section, we identify issues that hampered the user experience (UX) and describe our strategies for resolving them.

- Sending too many messages for a single response: Testers complained that many chatbot messages were too long, and they preferred concise responses in as few messages as possible. When feasible, it was programmed one response per message ensuring that responses were 160 characters or less, the limit for a single SMS text message.
- Asking unnecessary questions: The conversation flow was streamlined removing redundancies and unnecessary questions or branches. For example, we initially programmed questions that facilitated the enrollment process but were unnecessary to achieve the goal of linking the user to the TelePrEP Program. For instance, we had initially programmed the chatbot to ask the user for their insurance information. However, the user would have to provide this information to the navigator when enrolling, making this question redundant and unnecessary (Figure 2).
- Responding too quickly: Though chatbots are lauded for their ability to immediately respond, testers expressed that receiving responses so quickly was jarring or too robotic. A 5-second delay was programmed to more closely mimic the natural flow of texting conversations.
- Misunderstanding user input: As is common with all chatbots, testers encountered situations in which the chatbot could not interpret user input. In the initial stages of development, the chatbot would continuously ask for clarification when it did not understand a user's input. Users became annoyed when the chatbot continued asking for clarification after a number of failed attempts. We programmed the chatbot to direct the user to the navigator after 2 consecutive failed attempts to understand the user's input.
- Directing users to external links: Directing users to external links discouraged them from continuing to interact with the chatbot. Whenever feasible, the chatbot was programmed to provide information directly to the user. For instance, programming responses to the myriad of possible user questions was overwhelming, so we initially directed the user to our FAQ page. To reduce the number of times users were directed to the FAQ page, responses were programmed that could address multiple questions, and users were only directed when absolutely necessary (see Textbox 2).

XSL•FO
RenderX

Textbox 2. Using the Autopilot tool within Twilio, similar questions were assigned single responses that could more appropriately answer users' queries.

Question group 1

- Can I stop using condoms?
- How effective is pre-exposure prophylaxis (PrEP) at preventing infection?
- How effective is PrEP at preventing HIV?
- How effective is PrEP?
- Is PrEP effective?
- How well do doctors trust PrEP?
- Does PrEP really prevent HIV?
- Why should I take PrEP?
- Why take PrEP?
- Does it work well?
- How well does PrEP prevent HIV?
- How well does PrEP work?
- How good is PrEP?
- Does PrEP work?

Combined answers 1

- PrEP is highly effective when taken as indicated. The once-daily pill reduces the risk of getting HIV from sex by more than 90%. Among people who inject drugs, it reduces the risk by more than 70%. (Your risk of getting HIV from sex can be even lower if you combine PrEP with condoms and other prevention methods).

Question group 2

- Will hormone replacement therapy interact with PrEP?
- Will my medicine interact with PrEP?
- Will PrEP interact with other pills I take?
- Does Descovy interact with other medicine?
- Does Truvada interact with other medicine?
- Does PrEP interact with other medicine?
- What about poppers?
- Can I use mushrooms while I'm taking PrEP?
- Can I mix cocaine and PrEP?
- Can I use poppers while I'm on PrEP?
- Do poppers interact with PrEP?
- Does molly interact with PrEP?
- Can I take molly while I'm on PrEP?
- Does marijuana interact with PrEP?
- Does cocaine interact with PrEP?
- Can I smoke weed while I'm on PrEP?
- Does PrEP interact with marijuana?
- Does PrEP interact with weed?
- Can I use drugs when taking PrEP?
- Can I do drugs and take PrEP?

Combined answers 2

- Recreational drugs are not known to interact with either Truvada for PrEP or Descovy for PrEP. While PrEP generally has few interactions with prescription medicine, please consult your PrEP provider for information about how PrEP interacts with other medications.

Discussion

Principal Findings

This project demonstrates that a small team of behavioral researchers and staff can create a functional SMS text messaging–based chatbot to support a state-sponsored TelePrEP Program. We learned that it was important to dedicate sufficient time to the conceptualization process to ensure that the chatbot's functions would address the needs of the Navigator and efficiently link the users to the TelePrEP Program. Our iterative process of engaging researchers, Program personnel, and SGM AYAs to obtain input was key to our success.

We will pilot the chatbot in tandem with the launch of the social media messaging campaign. To evaluate the acceptability of the chatbot, a survey was created based on an existing chatbot evaluation with some modifications [24]. These questions assess users' demographics, intent of engaging with the chatbot, as well as their experiences using the chatbot. Chatbot users will receive a link to the 5-minute Qualtrics survey at the end of a chatbot conversation or, for incomplete conversations, a message with the link will be sent 15 minutes after the last interaction. Participants will be compensated US $5 for completing the survey. We will monitor usage and identify glitches or other unaccounted for issues that can be addressed when refining the chatbot. We will publish the results of this pilot trial and lessons learned in a subsequent manuscript.

Implications

The implementation of chatbots and AI tools within messaging platforms has paralleled the surge of mobile phone use among AYAs [25,26]. However, chatbots are relatively new to the public health arena. A 2022 scoping review assessing the research base for the use of chatbots in public health identified the need for more research describing the development process and evaluating the efficacy and effectiveness of these chatbots [25]. The breadth of information shared in both this paper and an upcoming paper evaluating the feasibility and acceptability of the PrEPBot will begin to address this gap in the literature.

Community engagement was an essential component of our chatbot development process. Community members helped us to refine the chatbot language to be accessible and familiar to the end user as recommended by Barreto et al [27] in their study of chatbots for promoting child health. They also helped us to identify the type of questions users would ask and the information to be provided. With their assistance, we were also able to identify strategies to create a streamlined experience. For example, the number of "failed responses" was limited, so if the system failed to provide a direct answer after 3 attempts, it would automatically triage the user to the navigator [28]. Another important consideration was to ensure that the information provided by the chatbot was reliable and valid [28]. To develop the FAQ section, we drew upon publicly available information from trusted sources, such as the US Centers for Disease Control and Prevention [29] and the San Francisco AIDS Foundation [30]. Participation from the community helped us to incorporate information in the FAQs that resonated with and was relevant to SGM AYAs [27,31].

In developing chatbots for public health, programming and end user fees must also be considered [27]. We opted for SMS text messaging because of its low cost and wide accessibility. A readily available, easily deployable platform was used to program and host our cloud-based, chatbot conversation flow. We also noted that aside from labor, development costs were negligible. There was no charge to use the platform aside from the charges associated with sending and receiving SMS text messages during testing sessions, which cost US $60. We hope the PrEPBot's inherent value as a low-cost SMS text messaging–based chatbot rather than as an independently designed app with a custom UX design will increase accessibility and ease of maintenance.

Limitations

There were factors that limited our chatbot development process. Limited budget and technical expertise did not allow us to create a chatbot with advanced AI and natural language processing capabilities that could enhance the UX and better meet user needs. Though our community-engaged and iterative process was a major strength, we could have incorporated additional stages of testing to further refine the chatbot prior to launch.

Conclusions

Chatbot development tools are accessible, user-friendly, and relatively inexpensive. An undergraduate computer science student and a research coordinator with no prior experience could successfully oversee programming and testing. Our experience proves that HIV prevention researchers can feasibly and efficiently program a rule-based chatbot with the assistance of commercially available tools.

Acknowledgments

The TelePrEP Chatbot project is a program project grant funded by the Adolescent Medicine Trials Network (ATN) for HIV/AIDS Interventions at the National Institutes of Health (U24HD089880). The Eunice Kennedy National Institute of Child Health and Human Development is the primary funder of this network, with the support of the National Institute of Mental Health, National Institute of Drug Abuse, and National Institute on Minority Health and Health Disparities. In addition to the authors, the following team members made contributions to help us develop this chatbot: Monika Nayak, Jong-Yun Park, Emma De la Rosa, Sean Sylve, Laniece Thomas, Demi HS Ward, and Alex Yu. We would also like to especially acknowledge the contributions of our community members: Neil Fitzpatrick, Fredy Garcia, Rankin Hobbs, Marcus Shacknow, and Justin Villareal, and the members of the nolaHYPE Community Advisory Board and the National ATN Community Advisory Board.

Abstract

Background: Human health status can be measured on the basis of many different parameters. Statistical relationships among these different health parameters will enable several possible health care applications and an approximation of the current health status of individuals, which will allow for more personalized and preventive health care by informing the potential risks and developing personalized interventions. Furthermore, a better understanding of the modifiable risk factors related to lifestyle, diet, and physical activity will facilitate the design of optimal treatment approaches for individuals.

Objective: This study aims to provide a high-dimensional, cross-sectional data set of comprehensive health care information to construct a combined statistical model as a single joint probability distribution and enable further studies on individual relationships among the multidimensional data obtained.

XSL•FO
RenderX

Methods: In this cross-sectional observational study, data were collected from a population of 1000 adult men and women (aged ≥20 years) matching the age ratio of the typical adult Japanese population. Data include biochemical and metabolic profiles from blood, urine, saliva, and oral glucose tolerance tests; bacterial profiles from feces, facial skin, scalp skin, and saliva; messenger RNA, proteome, and metabolite analyses of facial and scalp skin surface lipids; lifestyle surveys and questionnaires; physical, motor, cognitive, and vascular function analyses; alopecia analysis; and comprehensive analyses of body odor components. Statistical analyses will be performed in 2 modes: one to train a joint probability distribution by combining a commercially available health care data set containing large amounts of relatively low-dimensional data with the cross-sectional data set described in this paper and another to individually investigate the relationships among the variables obtained in this study.

Results: Recruitment for this study started in October 2021 and ended in February 2022, with a total of 997 participants enrolled. The collected data will be used to build a joint probability distribution called a Virtual Human Generative Model. Both the model and the collected data are expected to provide information on the relationships between various health statuses.

Conclusions: As different degrees of health status correlations are expected to differentially affect individual health status, this study will contribute to the development of empirically justified interventions based on the population.

Introduction

Background

Advances in information technology such as artificial intelligence and the internet of things enable new approaches to human health care [1-5]. Digital data collected through various measurements can be used together to approximate the current health status of humans. Better approximation allows for more personalized and preventive health care by informing the potential risks and developing appropriate interventions and solutions to achieve predictive, preventive, and personalized medicine [6,7]. Elucidating the modifiable risk factors related to lifestyle, diet, and physical activity will help to ensure optimal approaches for individuals in contrast to populations [6,7].

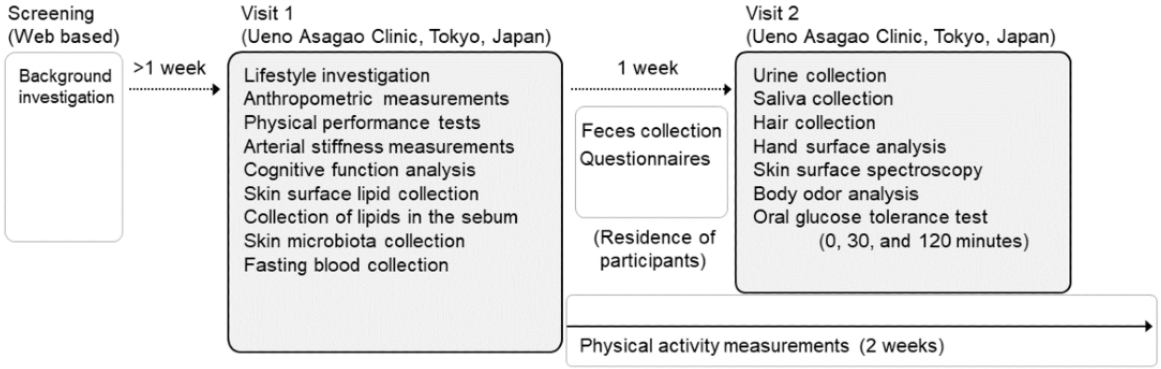
Big data obtained from the results of health examinations or clinical trials may contain a variety of individual laboratory measurements. Using such data, we can train a generative model that reasonably approximates the joint probability distribution. The resulting generative model may contain undiscovered structures among the data and facilitate a better understanding of the data, estimation of missing or corrupt values, detection of outliers, and prediction of unknown data (eg, patient diagnoses) [8-10]. In addition, a generative model can generate synthetic data for various applications, which alleviates privacy concerns when third parties use health care data.

Recent advancements in generative models, particularly those with deep learning, allow the estimation of a joint probability distribution from a high-dimensional data set. We are training this statistical model, hereafter called a Virtual Human Generative Model (VHGM), by combining a commercially available health care data set containing large amounts of relatively low-dimensional data with the high-dimensional, cross-sectional data set described in this paper. In our first incarnation of the VHGM, we incorporated demographics such as age and sex; anthropometrics; biochemical and metabolic profiles of urine, blood, and blood after a glucose tolerance test; vascular, gait, cognitive, and motor functions; RNA, proteins, and metabolites in skin surface lipids (SSLs) [11]; bacterial profiles of the mouth, skin, intestine, scalp; and body odor of the armpit, sole, and scalp. One of the challenges in developing such a high-dimensional statistical model is obtaining the training data set. Deep learning technologies normally require a large amount of data, typically millions or even billions of records. Such data sets for health care measurements, however, are not available. Constructing a new high-dimensional data set with a sufficiently large sample would require prohibitively high financial resources. Therefore, we aim to create a model by combining a large commercially available health care data set (containing >1 million records but relatively low dimensional) with a smaller high-dimensional, cross-sectional data set containing approximately 1000 records. In this study, we describe the details of the protocol for obtaining this cross-sectional data set. Combining these data sets will be discussed in a separate publication.

Objective

The primary objective of this study is to obtain multidimensional and comprehensive health information to build a data set that will serve as the basis for statistical models such as the VHGM. The secondary objective is to use the same data set to explore the individual relationships among the multidimensional data obtained.

Methods



Study Design

A single-center cross-sectional observational study was conducted with adult men and women living in narrowly defined metropolitan areas of Japan (Tokyo, Kanagawa, Chiba, Saitama, Ibaragi, Tochigi, and Gunma prefectures). All measurements were performed by trained research coordinators and medical doctors using standard operating procedures during 2 outpatient visits to the Ueno Asagao Clinic (Tokyo, Japan), 1 week apart

XSL•FO
RenderX

(Figure 1). The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines were applied according to the study objectives [12].

Figure 1. Experimental scheme. Participants were assessed by an initial screening and 2 visits, with a 1-week interval between visits during which they completed a questionnaire and fecal samples were collected. Daily activity was measured continuously over a 2-week period.

Ethics Approval, Informed Consent, and Participation

The study was approved in October 2021 by the institutional review board (IRB) of the Kao Corporation (Tokyo, Japan; approval #K0023-2108) and the Preferred Network, Inc (Tokyo, Japan; approval #ET22110047). Eligibility was evaluated by asking potential participants a few brief questions. After explaining to potential participants that the data obtained in this study may be published after an anonymization process; that statistical models may be created from the obtained data; and that the created statistical models may be provided to external research institutions, commercial companies, and other third parties, they decided whether to participate. All participants provided written informed consent to participate in this study. The consent form explains in detail which data would be used in the study and obtains consent for the use of anonymized data. Participants of this study were provided with digital points worth approximately US $250, which could be used to alleviate any expenses associated with their participation in this study. This trial is registered with the University Hospital Medical Information Network (UMIN; UMIN000045746).

Participants and Eligibility

Eligible participants were consecutively recruited over a 5-month period from October 2021 to February 2022. The participants were recruited via a website administered by TES Holdings (Tokyo, Japan). We did not perform a formal sample size calculation but set a sample size of 1000 adults to be recruited based on a preliminary calculation that the accuracy of the statistical modeling would not be improved by enrolling >1000 participants. Participants were added and converted to age groups by decade (20-29, 30-39, 40-49, 50-59, 60-69, and >70 years) to evaluate the age of the participants as a numerical value and by sex.

The inclusion criteria were as follows: (1) Japanese men and women aged ≥20 years, (2) individuals who were able to complete the questionnaires and surveys, and (3) individuals who understood the study and could provide written consent. Exclusion criteria were as follows: (1) individuals undergoing hospitalization for serious diseases (diabetes, hypertension, arteriosclerosis, heart disease, malignancy, Alzheimer disease, etc), (2) individuals who could not come to the outpatient unit by themselves, (3) individuals with dementia or suspected dementia, (4) individuals aged ≥60 years who had not received at least 2 doses of the COVID-19 vaccine at least 2 weeks before the visit, (5) individuals who developed symptoms suspicious of COVID-19 infection during the 2 weeks before the visit, (6) individuals who had a pacemaker, (7) individuals who were pregnant or may become pregnant, (8) individuals who had 200 mL of blood drawn within 1 month of the start of this study or >400 mL of blood drawn within 3 months (blood donation, etc) of the start of this study, and (9) individuals whose participation in the study was deemed inappropriate by the study investigators.

Lifestyle Investigation and Questionnaire

Trained physicians or study coordinators collected information about the participants regarding sex; age; years of education; occupation; medical history; diseases under treatment medication use; smoking habits; alcohol consumption habits; and, for participants aged ≥75 years, nursing care requirements. A 3-day food consumption record for each participant as well as information on hygiene, dental hygiene, and bathing habits; health-related attitudes; skin, scalp, and body odor concerns; hair loss awareness; and, in women, menstrual cycle, were collected. During the study period between visits 1 and 2, participants completed a dietary habits survey using the brief-type self-administered diet history questionnaire [13], the international physical activity questionnaire [14,15], a questionnaire for medical evaluation of old-old [16], a dietary habits questionnaire [17], the Athens insomnia scale [18,19], the Oguri-Shirakawa-Azumi sleep inventory middle-aged and aged version [20], the Berlin questionnaire [21], the World Health Organization—Five Well-Being Index [22], the brief job stress questionnaire [23], the Chalder fatigue scale [24], the Center for Epidemiologic Studies Depression Scale [25,26], the fatigue feelings questionnaire [27], the sun exposure questionnaire [28], the 10-item personality inventory [29,30], the Oxford happiness questionnaire [31], the overactive bladder symptom score [32], the international consultation on incontinence questionnaire–urinary incontinence short form [33], the fecal incontinence quality of life scale [34], the neurogenic bowel dysfunction score [35], the Kupperman menopausal index [36], a modified menstrual distress

XSL•FO
RenderX

questionnaire [37,38], climacteric and senescence scores [39], and the Edinburgh postnatal depression scale for those 3 years post partum [40].

Anthropometric Measurements

Height was measured using a clinical stadiometer. Body weight and body composition, including body fat percentage, body fat mass (kg), lean body mass (kg), total body water (%), and basal metabolic rate (kcal), were measured using a digital bioimpedance scale (InBody 770K, InBody Corp). Visceral fat area and waist circumference were measured using a bioimpedance-type visceral fat meter (EW-FA90; Panasonic Corporation) [41]. Hip circumference was determined using a measuring tape.

Physical Performance Tests

Grip Strength Test and Timed Up-and-Go Test

Grip strength was measured using a Smedley spring-type dynamometer (Grip-D, Takei Scientific Instruments Co, Ltd) [42]. The average value of 2 measurements was recorded. A timed up-and-go test was administered to measure the time required to stand up, walk 3 m, turn, walk back to the chair, and sit down [43].

In-Laboratory Gait Parameter Measurement

In-laboratory gait parameters and foot pressure patterns were determined as described previously [44]. Gait speed was measured using a sheet-type pressure sensor (Anima Corporation) placed at the center of a 6.4-m walkway. The measured gait parameters included the following: general parameters—speed (cm/s) and cadence (steps/min); spatial parameters—step length (%), step width (%), gait angle (degree), and toe angle (degree); and temporal duration parameters—double support phase (%), swing phase (%), and stance phase (%) [45]. An average measurement of the 4 trials was obtained for each participant. The foot pressure patterns were measured simultaneously using the sheet-type pressure sensor. The gait parameters and foot pressure on the left and right feet were recorded bilaterally.

Physical Activity Measurement

Daily physical activity, gait speed, and number of steps were monitored using a triaxial accelerometer (HW-100, Kao Corporation) that allowed for 14 days of continuous recording, as previously reported [44]. Effective days were defined as the days when the accelerometer was worn for at least 10 hours per day and for at least 7 days [46,47]. The participants used the walking speed measurement app (Chami, InfoDeliver Co Ltd) on their smartphones for 14 consecutive days. The smartphone app that measures walking speed uses a step counter and GPS [48,49]. Walking speed data, including the time of measurement, number of steps, and distance walked, were collected on a dedicated server.

Blood Pressure and Arterial Stiffness Measurements

Heart rate, systolic blood pressure, and diastolic blood pressure were measured with the participants in a sitting position using a VS-2500 Vascular Screening System (Fukuda Denshi Co, Ltd). Measurements of the cardio-ankle vascular index and ankle brachial index were obtained while the participants assumed a supine position using the VS-2500 Vascular Screening System with an electrocardiogram, phonocardiogram, and brachial and ankle artery pressures and waveforms [50]. The cardio-ankle vascular index was automatically calculated for the left and right sides, and both values were used for analysis.

Blood, Urine, Saliva, and Hair Collection

Blood samples were obtained from a peripheral vein after overnight fasting or glucose loading. Serum samples were obtained by centrifuging (1500 × g, 15-24 °C, 10 min) blood allowed to stand at room temperature (18-25 °C) for 15 minutes. Plasma samples were obtained by centrifuging (1500 × g, 4 °C, 10 min) blood samples collected in tubes containing EDTA-disodium salt dihydrate or sodium fluoride (glucose). Plasma samples obtained during the oral glucose tolerance test were distributed into tubes containing EDTA-dipotassium salt dihydrate and dipeptidyl peptidase IV inhibitors or sodium fluoride (glucose). Blood samples for ammonia measurements were collected in tubes containing a deproteinizing reagent. Freeze-thaw was performed only once between the collection of biological samples, and all plasma and serum samples were stored at −80 °C until analysis.

Urine samples (4-6 mL) were collected from participants in the morning after overnight fasting for at least 12 hours. All urine samples were stored at −20 °C until laboratory analysis.

Saliva samples were extracted using a standard protocol [51,52]. Saliva samples were obtained from participants seated in a quiet room in the morning between 08:30 AM and 11:30 AM. Participants were asked to accumulate saliva in their mouths and spit into a sterile plastic tube every minute for 20 minutes. The saliva volumes (gram) were weighed in the tube after sample collection [53]. The saliva secretion rate (mL/min) was calculated by dividing the amount of saliva collected by the collection time (20 min). Whole saliva samples were centrifuged at 14,970 × g for 10 minutes at 4 °C, and the supernatant and pellet were stored at −80 °C until analysis. To measure salivary nitrate and nitrite concentrations, the salivary supernatants were mixed with an equal volume of methanol and centrifuged (21,600 × g, 4 °C, 15 min). The supernatants were analyzed using high-performance liquid chromatography (HPLC; ENO-30, Eicom Corp).

All hair samples were collected from the occipital scalp area of each participant. Hair samples were obtained from the edge of each participant's scalp. Hair thickness was measured with a thickness gauge near the root tip for 10 randomly selected hair fibers from each participant (type 547-401; Mitutoyo Corp). The measured thickness usually corresponds to a small diameter when the cross-sectional shape of the fiber is oval. The curvature of the hair fiber was measured by image analysis of a 2D image of each hair fiber [54].

Laboratory Analysis

Hematologic parameters, such as white blood cells, red blood cells, hemoglobin level, hematocrit level, platelet cells, mean corpuscular volume, and mean corpuscular hemoglobin, were measured in whole blood samples using standardized methods.

XSL•FO
RenderX

The following blood biochemistries and blood electrolytes were measured using standardized methods according to the standard operating procedures of the Health Sciences Research Institute, Inc (Kanagawa, Japan): sodium, potassium, chlorine, calcium, inorganic phosphorus, iron, magnesium, total protein, albumin, albumin:globulin ratio, total bilirubin, aspartate aminotransferase, alanine aminotransferase, γ-glutamyl transpeptidase, alkaline phosphatase, lactate dehydrogenase, creatine phosphokinase, uric acid, urea nitrogen, creatinine, serum triglycerides, total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, glucose (plasma), hemoglobin A_{1c}, ammonia, high-sensitivity C-reactive protein, cortisol, triiodothyronine, thyroxine, dehydroepiandrosterone, testosterone, estradiol, progesterone, follicle-stimulating hormone, luteinizing hormone, prolactin, insulin, free fatty acids, total ketones, acetoacetic acid, and 3-hydroxybutyric acid. Plasma inflammation marker levels were measured by Kao Corporation using a Bio-Plex Pro Human Cytokine Screening Test Kit (Bio-Rad Laboratories Inc, Hercules). The following 27 cytokines were quantified: basic fibroblast growth factor, eotaxin, granulocyte colony-stimulating factor, granulocyte-macrophage colony-stimulating factor, interferon-γ, interleukin (IL)-1β, IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, interferon-γ–induced protein 10, monocyte chemoattractant protein-1, macrophage inflammatory protein-1α, macrophage inflammatory protein-1 β, platelet-derived growth factor, regulated upon activation in normal T cell expressed and presumably secreted, tumor necrosis factor-, and vascular endothelial growth factor.

Glucose, protein, bilirubin, urobilinogen, ketone bodies, creatinine, occult blood reaction, pH, and gravity were measured in the urinary samples.

Salivary oxytocin concentrations were quantified using an enzyme-linked immunosorbent assay kit (Enzo Life Sciences, Plymouth Meeting). Salivary oxytocin concentrations were evaluated in duplicate and determined using the Epoch2 microplate reader (BioTek Instruments, Inc). Bovine serum albumin (Bio-Rad Laboratories, Inc) was used as a standard to calculate the salivary total protein concentration. The salivary oxytocin concentration was normalized by the salivary total protein concentration in each sample (pg/mg protein), as previously described [55].

Oral Glucose Tolerance Test

Other than the participants diagnosed with diabetes or other potentially serious illnesses, all participants underwent an oral glucose tolerance test at visit 2 after fasting overnight. After the fasting blood sample was collected, a 75-gram glucose load was ingested. Blood samples were obtained at 30 minutes and 120 minutes after the glucose load. Glucagon, active glucagon-like peptide-1, total glucose-dependent insulinotropic peptide from plasma, insulin, growth hormone, and insulin-like growth factor 1 from the serum were measured using enzyme-linked immunosorbent assay kits (glucagon: Mercodia; active glucagon-like peptide-1: Immune Biology Laboratories; total glucose-dependent insulinotropic peptide: Merck KGaA; and growth hormone and insulin-like growth factor 1: R&D Systems). Plasma glucose and serum insulin were assessed according to standard procedures at the laboratory at Health Sciences Research Institute, Inc (Kanagawa, Japan).

Liquid Chromatography–Tandem Mass Spectrometry Analysis

Chiral Amino Acid Analysis

According to a previous report [56], human plasma was mixed with an aqueous methanol solution and centrifuged at 2130 × g for 10 minutes at 4 °C to remove proteins. After derivatization using 6-aminoquinolyl-N-hydroxysccinimidyl carbamate, the reaction solution was subjected to chiral tandem liquid chromatography–tandem mass spectrometry (LC-MS/MS).

Lipid Mediator Analysis

Quantification of lipid mediators was performed using LC-MS/MS, as previously described [57,58]. The plasma was mixed with methanol and centrifuged (20,000 × g, 10 minutes, 4 °C), and the solid-phase extraction was carried out using an Oasis hydrophilic-lipophilic balance solid-phase extraction cartridge (Waters Corporation). Lipid mediators were analyzed using an UltiMate3000 liquid chromatography (LC) system (Thermo Fisher Scientific) coupled with a QTRAP5500 triple-quadrupole mass spectrometer (AB Sciex Pte Ltd) equipped with an electrospray ionization source.

Vitamin D Metabolites Analysis

The plasma samples were loaded into Chem Elut S (Agilent Technologies), held for 10 minutes at room temperature and eluted with ethyl acetate. The supernatant was evaporated to complete dryness under a nitrogen stream, and *N*-methyl-1,2,4-triazolinedione solution was added. The reaction solution was subjected to LC-MS/MS. Vitamin D metabolites were analyzed using a QTRAP6500 triple-quadrupole mass spectrometer (AB Sciex Pte Ltd) equipped with a Nexera X2 LC system (Shimadzu). For the quantification of vitamin D metabolites, each peak area of the species was standardized by the peak area of each internal standard.

Polyamine Analysis

Plasma samples were mixed with an internal standard solution containing putrescine-d6, spermine-d20 (C/D/N Isotopes), and spermidine-d8 (Toronto Research Chemicals Inc). Acetonitrile (Kanto Chemical Co, Inc) was added to the plasma, and the precipitate was removed by centrifugation at 20,400 × g for 10 minutes at 4 °C. Amino Tag Wako Borate Buffer, 3-aminopyridyl-N-hydroxysuccinimidyl carbamate (APDS) reagent, and APDS Tag Wako Eluent Buffer (Fujifilm Wako Pure Chemical Corporation) were added to the supernatant. Mass spectrometric analysis of the resulting samples was performed by LC-MS/MS (selected reaction monitoring) using an LC system (ACQUITY Premier System, Waters Corporation) coupled with a Xevo tandem triple-quadrupole-mass spectrometry (MS; Waters Corporation) equipped with a heated electrospray source. For quantification of polyamines, the peak areas of putrescine, spermidine, and spermine were standardized by the peak area of each internal standard.

XSL•FO
RenderX

Hair Loss Determination

Male-pattern and female-pattern hair loss were determined according to the Japanese Dermatological Association's Guidelines for the diagnosis and treatment of male- and female-pattern hair loss, 2017 version [59]. Male-pattern hair loss was classified by combining the classification method by Norwood [60] and the type II vertex in the classification method by Takashima et al [61], with the type II vertex further divided into 2 groups according to the severity of hair loss. Photographs obtained with a Nikon D5600 from the top of the man's head and hairline observed from the side were used to classify male-pattern hair loss.

To classify female-pattern hair loss, women's thinning hair was determined using a total score (0-20 points) of hair appearance (0-10 points), vellus hair rate (0-5 points), hair shedding (0-2 points), and single hair follicular unit (FU; 0-3 points) [62]. A photograph of the midline of the top of the woman's head was obtained. Using photographs of midline partings, a 5-point scale based on the hair density scale by Sinclair was given a score of 0 to 10 and used to determine thinning of hair in women. An enlarged photograph (20× magnification) of the midline connecting the ears was taken with a digital microscope (KH-7700, Hyrox Co, Ltd), and the numbers of black hairs and gray hairs in a 0.21-cm^2 area and hair diameter were measured using Image-Pro Plus (ver6.1, Hakuto Co, Ltd). Scores of 0 (vellus hair rate <20%) and 5 (vellus hair rate ≥20%) were used to determine thinning of hair in women. To apply these measurements to determine the initial thinning of hair in women, hair shed during washing was collected with a net (draining net stocking type shallow type for drain holes), and the amount of hair shed (from 10 to 750 hairs) was self-evaluated in 6 stages. The number of hairs lost was divided by the time since the previous hair wash, and the amount of hair shedding was determined. Shedding of 10 to 200 hairs was scored as 0, and hair shedding of ≥400 hairs was scored as 2. The ratio of single hair FUs in the 0.21-cm^2 area was measured from a 20× magnification image. Single hair FU ratios were scored for women as follows: <25%, score of 0; ≥25% and <50%, score of 1; ≥50% and <75%, score of 2; and ≥75%, score of 3.

Hand Surface Analysis

Participants were instructed to wash their hands with a commercially available soap [63]. The amount of lactic acid was measured by placing an acrylic cylinder with an inner diameter of 1.5 cm on the hand, adding pure water, and pipetting the mixture. The concentration of l-lactic acid was measured using Lactate Pro 2 (ARKRAY Co Ltd, Inc) with the extracted solution [64]. The measurements were performed twice, and the values were averaged. The skin pH was measured using a multiskin measuring instrument and a skin pH meter (pH 905; Courage+Khazaka Electric GmbH). The surface temperature of the hand was measured using a noncontact thermometer (Shenzhen Hezhizhou Technology Co, Ltd) [65].

Lipids in the Stratum Corneum and Sebum Analysis

Stratum corneum from the forehead were obtained by stripping with adhesive acrylic film (No. 465 #40, Teraoka Seisakusho). According to a previous report [66], ceramides, free fatty acids, cholesterol, and cholesterol sulfate profiles of the stratum corneum samples were determined using reverse-phase LC-MS.

Face sebum was collected from the forehead using 2 pieces of cigarette paper (Blue double, Rizla Ltd). The sebum was extracted using chloroform or methanol for MS analysis. Sebum MS analysis was performed using flow injection analysis coupled with MS with an ultrahigh performance LC system (Vanquish, Thermo Fisher Scientific) containing a Q-Exactive Focus (Thermo Fisher Scientific) equipped with a heated electrospray source. The Fourier transform MS full-scan mode was used.

Body Odor Analysis

Participants were instructed not to use products such as deodorants or antiperspirants on their armpits, scalp, and soles of the feet during the night before collection of the body odor sample. Body odor was analyzed using solid-phase microextraction–gas chromatography–MS (SPME-GC-MS). Scalp odor samples were collected by pressing an oil-blotting film (3M Japan) against the parietal scalp ≤4 times at 6 different places and were then stored in a glass vial, immediately frozen, and stored at −80 °C until analysis. Each scalp odor sample was transferred to a 20-mL clear glass vial with a silicone or polytetrafluoroethylene crimp cap for SPME-GC-MS analysis. To collect samples for axillary odor analysis, a cotton pad (Katte Gauze, Ryugu Co, Ltd) infiltrated with 1.2 mL of distilled water was used to swab a 10-cm^2 area from the armpit at least 10 times for each participant. Foot odor samples were collected from the soles of the feet in the same manner. Each swabbing pad was stored in an aluminum bag with a zipper, immediately frozen, and stored at −80 °C until analysis. Each swabbing pad was centrifuged (6000 revolutions/min, 10 min), and the supernatants were acidified (pH 5.0) with 0.01 N hydrogen chloride and transferred to a 10-mL clear glass vial with a silicone or polytetrafluoroethylene crimp cap for SPME-GC-MS analysis.

Skin Surface Spectroscopy

Advanced Glycation End Product Analysis

The accumulation levels of advanced glycation end products (AGEs) in the skin were measured using an AGE reader (DiagnOptics Technologies) according to the specific protein modifications and fluorescent properties of AGEs [67].

Laser Speckle Blood Flowmetry

Facial skin blood flow was measured using laser speckle flowgraphy (a prototype based on LSFG-ANW, Softcare Co, Ltd) [68]. An industrial digital camera (DFK0818UP1300, The Imaging Source GmbH) with a lens (VS-1300VM, VS Technology Corporation) was used to record a series of moving images at a rate of 30 frames/s.

Cognitive Function Analysis

Cognitive function was assessed using the computer-administered neurocognitive test battery Cognitrax (CNS Vital Signs), for which the validity and reliability have been confirmed [69]. Cognitrax comprises the following battery of tests: a verbal memory test evaluating word learning, word memory, and word recognition, as well as immediate and

XSL•FO
RenderX

delayed recall; visual memory test evaluating shape learning ability, shape memory, and shape recognition, as well as immediate and delayed recall; finger-tapping test evaluating motor speed and fine motor control; symbol-digit test evaluating complex information processing accuracy, complex attention, visual perceptual speed, and information processing speed; stroop test evaluating simple reaction time, complex reaction time, stroop reaction time, inhibition and disinhibition, and frontal or executive skills; shifting attention test evaluating executive function, shifting sets (rules, categories, and rapid decision-making), and reaction time; and continuous performance test evaluating the ability to maintain sustained attention, choice reaction time, and impulsivity. A composite neurocognitive index and cognitive domain scores were generated on the basis of the 7 tests.

Microbiota Analysis

Intestinal microbiota analyses were performed as previously reported [70,71]. Briefly, the participants were instructed to use an FS-0002 tube kit (TechnoSuruga Laboratory Co Ltd) containing guanidine thiocyanate solution to collect fecal samples and store them in a refrigerator (≤4 °C) between visits. Zirconia beads were added to the samples, milled at 5 m/s for 2 minutes using a FastPrep 24 Instrument (MP Biomedicals), and centrifuged for 1 minute at 2350 × g. Bacteria were identified on the basis of the 16S recombinant DNA V3-V4 region. Fragments of the polymerase chain reaction (PCR) mixtures were purified by electrophoresis on 1% agarose gels, followed by PCR Cleanup Filter Plates (Merck Millipore). Illumina paired-end sequencing was performed using the 2 × 300 cycle paired-end method and the MiSeq system (Illumina).

Skin microbiota were collected from the scalp and cheek. To collect scalp microbiota, the hair was parted with a rubber-gloved hand to expose the frontal area of the scalp, and to collect facial skin microbiota, a custom-made sampling template was used to allow for consistent sampling of 4 cm^2 of the cheek areas. A sterile swab (Nippon Becton Dickinson Company, Ltd) soaked in BBL-prepared saline solution (Becton, Dickinson and Company) was rubbed onto the scalp surface or the designated cheek areas. The head of the swab was cut and placed into a microtube. All samples were frozen at −80 °C until use. The V1-V2 hypervariable region was used as the target for 16S ribosomal RNA (rRNA) gene sequencing. DNA extraction, DNA library preparation, and DNA sequencing were performed by BIKEN Biomics Inc using their standard procedures.

To analyze the saliva microbiota, part of a whole saliva pellet resuspended in sterile water was collected in a 1.5-mL tube and centrifuged for 10 minutes at 15,000 × g at 4 °C. After removing the supernatant, the pellet was stored at −80 °C until the samples were analyzed by Genome Lead Co, Inc. DNA was extracted from each sample using both enzyme treatment and the beads-beating methods (Promega). Then, DNA was extracted from the samples using zirconia beads (EZ-Beads; Promega) and Genfind v2 (Beckman Coulter). The composition of the saliva microbiota was assessed by high-throughput sequencing of the 16S rRNA gene of the V1-V2 region using the Illumina NovaSeq Platform (Illumina). The V1-V2 regions of the 16S rRNA genes from each sample were amplified using primers containing 1 random base sequence at the N position. The 2× KAPA HiFi HotStart ReadyMix (KAPA Biosystems) was used for amplicon PCR and index PCR. Both the PCR products were purified using AMPure XP beads (Beckman Coulter). The amplicon PCR products were purified using AMPure XP beads (Beckman Coulter). NovaSeq sequencing was performed using the NovaSeq 6000 Reagent Kit v1.5 (500 cycles; Illumina) using a 251-bp paired-end sequencing protocol. All 16S rRNA raw sequence data were analyzed using the open-source QIIME2 platform [72], version 2021.2 (qiime2-2021.2).

SSL-RNA Analysis

The SSLs collection and SSL-RNA purification were performed as described previously [11]. In brief, an oil-blotting film (3M Japan) was used to wipe the forehead, cheeks, face line, nose, and chin or parietal scalp and stored in a glass vial at −80 °C until analysis. The oil-blotting film was cut into small pieces and homogenized in 1.45 mL of QIAzol (QIAGEN). The SSLs were extracted by placing the supernatant in a tube, adding chloroform, vortexing the mixture for 10 seconds, centrifuging the mixture at 12,000 × g for 15 minutes at 4 °C, and transferring the upper phase to a fresh tube. A RNeasy Mini Kit and QIAcube (QIAGEN) with concomitant DNase I treatment were used to purify the RNA, following the manufacturer's instructions.

Sequence library preparation was performed using the Ion AmpliSeq Transcriptome Human Gene Expression Kit (Thermo Fisher Scientific), following our previously described modified protocols [11,73,74]. Briefly, the RNA solution was combined with VILO Reaction Mix, SuperScript III enzyme, and T4GP32 (New England Biolabs). The target DNA was amplified using cDNA solution, Ion AmpliSeq HiFi Mix, T4GP32, and the Ion AmpliSeq Transcriptome Human Gene Expression Core Panel with incubation for 20 cycles. We purified the amplified DNA library by binding it to AMPure XP beads (Beckman Coulter), according to the manufacturer's protocol. A High-Sensitivity D1000 ScreenTape on an Agilent 4200 TapeStation was used to assess the quality of the DNA library. After confirming the quality of the DNA library, the purified library solution was combined with the Ion AmpliSeq HiFi Mix, Ion AmpliSeq Transcriptome Human Gene Expression Core Panel, and VILO Reaction Mix to produce the reaction solution. The adapter sequence was ligated to the library by adding Switch solution, Ion Xpress barcode adapters, and DNA ligase to the reaction solution and then incubating the mixture. The libraries were eluted from the beads using Library Amp Mix (Thermo Fisher Scientific) containing Library Amp Primers. An aliquot of the PCR product was purified using AMPure XP beads, and the supernatant was transferred to fresh PCR tubes. The quality of the sequence library was assessed using the High-Sensitivity D1000 ScreenTape on the Agilent 4200 TapeStation. An Ion Library TaqMan Quantitation Kit (Thermo Fisher Scientific) was used to quantify the library. After loading the DNA library in the Ion Chef System (Thermo Fisher Scientific), the template was prepared and the chip was loaded, and the Ion S5 XL System (Thermo Fisher Scientific) was used to perform the RNA sequencing.

XSL•FO
RenderX

SSL-Protein Analysis

Proteins for SSL-protein analysis were prepared using S-trap micro columns (ProtiFi), according to the partially modified procedure described in the manufacturer's protocol. In this study, sodium deoxycholate and sodium lauryl sulfate were used for the protein solubilization solution. Following the removal of SSL-RNA from the upper layer, 2-propanol was added to the residual solution. After centrifuging at 14,000 × g for 5 minutes, the precipitate was dissolved in a protein solubilization solution and applied to an S-trap column. The eluted tryptic digest was concentrated under reduced pressure and desalted using styrene divinylbenzene polymer GL-Tip (GL Sciences) according to the manufacturer's protocol. The peptide mixtures were subjected to LC-MS/MS. LC separations were performed with a nano-HPLC system Ultimate 3000 (Thermo Fisher Scientific) using an Acclaim PepMap 100 analytical column (Thermo Fisher Scientific). MS detection was performed with a Q-Exactive Plus (Thermo Fisher Scientific) in positive-ion mode and operated in the data-dependent acquisition mode and data-independent acquisition mode. Analysis of the acquired data was performed using Mascot database search (Matrix Science) and DIA-NN software (version 8.1; GitHub) [75].

SSL-Metabolite Analysis

The SSLs for metabolite analysis were collected by wiping oil-blotting paper around the neck below the face line, and the samples were stored in glass vials at −80 °C until use. To extract metabolites, the oil-blotting film was cut into small pieces and placed in a glass vial with methanol. The supernatant was filtered through a DISMIC-13HP 0.45-µm syringe filter (Advantec) and concentrated under reduced pressure until dry. Each sample was redissolved in 80% (volume/volume) methanol and filtered through a DISMIC-13HP 0.45-µm syringe filter. A portion of the filtrate from each sample was mixed in equal volumes to create a pooled quality control sample.

SSL-metabolite analysis was conducted using an ExionLC system (AB Sciex) coupled to an AB SCIEX X500R electrospray-ionization quadrupole time-of-flight high-resolution MS (AB Sciex). The LC system comprises a 2-channel pump, a degasser, a column oven, an autosampler, and a controller. LC was performed by injecting the sample onto an L-column3 C18 reversed-phase column (Chemicals Evaluation and Research Institute).

We used the sequential window acquisition of all theoretical mass spectra. In total, LC-MS analysis was performed in 10 batches. The quality control dilution series was used to confirm the linearity of the metabolites. Data processing, including automatic peak finding, locally weighted scatterplot smoothing normalization, and identification via spectra matching, was performed using MS-DIAL (version 4.7; downloaded from the PRIMe website) [76]. All automatically detected peaks were checked manually, and the linearity of each metabolite was checked using diluted quality controls, excluding peaks with low linearity ($r \leq 0.85$).

Statistical Analysis

Data Management

The data of each participant were managed using an electronic database and case record forms. There were 2 levels of data quality control. The first level of quality control was conducted by the investigators while entering the records into the case record form. For the second level, an independent group conducted data monitoring and validation. An electronic database served as a double-entry system to further ensure accurate data input.

VHGM Analysis

We will construct a generative model to capture the joint distribution among the aforementioned health care attributes. As the attributes comprise both numerical and categorical values, a model that can handle this type of heterogeneity must be selected. To this end, we will use the heterogeneous incomplete variational autoencoder (HIVAE) [8]. The HIVAE is an extension of a variational autoencoder [77] in which a different likelihood function can be selected depending on the attribute type. For example, we will input the normal distribution for weight and height and the categorical distribution for sex (male, female, and other). Given a set of observed attributes as inputs, we can use the trained model to estimate the parameters of the (conditional) probability distribution of each attribute, including the missing ones. The objective function of HIVAE is called the evidence lower bound, which measures the discrepancy between the training data set and the model. We will separate the entire data set into training and testing sets and train the model to minimize the evidence lower bound to fit the training data set.

We will evaluate the performance of the trained model in terms of 2 perspectives: (1) predictability of missing attributes and (2) representability of the empirical distribution. For the first perspective, we will randomly generate missing patterns on the testing set and measure the prediction accuracy. For the second perspective, we will manually compare the joint distribution of the model and the data on several attribute pairs that would have a strong relationship (eg, age and blood pressure) to ensure that there is no notable discrepancy.

Individual Relationships Among the Obtained Multidimensional Data

Normally distributed data will be presented as mean (SD), median (IQR), and number (%), and nonnormally distributed data will be presented as IQR and number (%). The Kolmogorov-Smirnov test will be used to test whether the values of the variables are normally distributed. Analyses of both per-protocol and intention-to-treat groups will be conducted. The areas under the receiver operating characteristic curve (AUCs) and incremental AUCs will be calculated according to the trapezoidal rule from the measurements at each time point during the oral glucose tolerance test. Regression analysis will be used to explore the independent effects of each variable on secondary outcomes. We will examine the relationships among the overall outcomes. Correlations among the overall outcomes will be evaluated using both Pearson correlation coefficient and Spearman rank correlation. In addition, appropriate stratification

XSL•FO
RenderX

and partial correlation analyses will be performed in the overall interaction analysis. All statistical analyses of the data will be performed using SPSS software (version 21.0; IBM Corp), SAS (version 9.4; SAS Institute Inc), and R software (R Foundation for Statistical Computing).

Results

The study was registered at University Hospital Medical Information Network on October 14, 2021. Recruitment was started on October 19, 2021, and ended on February 25, 2022. A total of 997 participants were enrolled in the study. Sample analysis will be performed from February 2022 to March 2023. Data analysis will be conducted in 2023, and the final report will be available in 2024.

Discussion

Principal Findings

High-dimensional cross-sectional studies are rarely conducted. We believe that there are several methods to use such data sets. We plan to provide the VHGM that we are developing as a commercial service via an application program interface (API) on the internet. Any application program can send a query to the VHGM, such as *what is the mean and variance of systolic blood pressure of Japanese adults? (marginal probability)*; *what is the probable distribution of blood glucose levels given my age, sex, and lifestyle (excursive, drinking, and smoking habits)? (conditional probability)*; and *what would my estimated cognitive function index be if my age were 10 years older (counterfactual inference)*. We are expecting to discover many innovative health care applications using the VHGM API.

Strengths and Limitations

Our exploration of individual relationships among the thousands of variables in the data set is expected to reveal previously unknown relationships, which may lead to a new health care hypotheses and further studies, including those aimed at constructing new intervention tests. Thus, this cross-sectional data set will lead to new discoveries in health care research.

Limitations of this protocol include its cross-sectional study design at a point in time, the fact that recruitment (via a website) was restricted to those who could participate in person to perform the survey. In addition, our sampling methods, such as the study's inclusion criteria and the decision by the responsible physician whether to allow participation, may have introduced a selection bias, making it difficult to generalize our findings to the population. Appropriate weighting can be applied to reduce the impact of selection bias on the estimates. If any modifications to this study design are necessary, we will notify the IRB and submit a study protocol with the necessary changes for IRB review. Thus far, data on preventive medicine and health care have been obtained on an opportunistic and time-consuming basis, using funds as needed. The data obtained from this study have the potential to provide a standardized model for the Japanese population regarding health care and to reveal public health implications. Using a larger sample size would reduce the risk of type II errors.

Conclusions

The results of this study may provide evidence for the future application of a VHGM based on a joint probability distribution model in clinical health care practice.

Acknowledgments

The primary sponsor of this study is Kao Corporation (Tokyo, Japan). None of the authors have received any specific funding for this study. The funders had and will not have a role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Data Availability

The data are not publicly available owing to ethical restrictions. Owing to the nature of this research, the participants of this study did not agree to share their data publicly, and thus, supporting data are not available. The statistical properties of the data are approximated in the model and are available via an application program interface.

Authors' Contributions

M Hibi, S Katada, A Kawakami, KB, and HM designed the trial. S Katada, A Kawakami, KB, and MO were responsible for data curation. S Katada, A Kawakami, KB, MO, KS, T Hasumura, YA, T Fushimi, TA, S Kawano, RK, NC, ZG, KH, KO, YS, SY, and HM analyzed the data. S Katada, KS, NY, YA, T Fushimi, T Fujimatsu, S Kawano, RK, ST, Y Yamamoto, M Haneoka, KK, T Hideshima, ES, JS, A Kirino, TS, YT, MY, S Nagase, T Hirano, RF, Y Yamashiro, YN, and N Ojima performed data acquisition. S Katada, AM, NY, T Hasumura, TA, RK, ST, Y Yamamoto, M Haneoka, ES, JS, A Kirino, HT, S Nakamura, TS, MY, S Nagase, RF, Y Yamamoto, N Ojima, MS, N Oya, YM, and KM were responsible for methodology. S Katada, KS, S Nagase, RF, and Y Yamashiro provided research resources. NC, ZG, KH, KO, YS, and SY were responsible for software. TO supervised the trial. M Hibi and HM wrote the original draft. All authors critically revised the manuscript and approved the final version.

Abstract

Background: Digitalization and information and communication technology (ICT) promote effective, efficient individual and community care. Clinical terminology or taxonomy and its framework visualize individual patients' and nursing interventions' classifications to improve their outcomes and care quality. Public health nurses (PHNs) provide lifelong individual care and community-based activities while developing projects to promote community health. The linkage between these practices and clinical assessment remains tacit. Owing to Japan's lagging digitalization, supervisory PHNs face difficulties in monitoring each department's activities and staff members' performances and competencies. Randomly selected prefectural or municipal PHNs collect data on daily activities and required hours every 3 years. No study has adopted these data for public health nursing care management. PHNs need ICTs to manage their work and improve care quality; it may help identify health needs and suggest best public health nursing practices.

Objective: We aim to develop and validate an electronic recording and management system for evaluating different public health nursing practice needs, including individual care, community-based activities, and project development, and for determining their best practices.

Methods: We used a 2-phase exploratory sequential design (in Japan) comprising 2 phases. In phase 1, we developed the system's architectural framework and a hypothetical algorithm to determine the need for practice review through a literature review and a panel discussion. We designed a cloud-based practice recording system, including a daily record system and a termly review system. The panels included 3 supervisors who were prior PHNs at the prefectural or municipal government, and 1 was the executive director of the Japanese Nursing Association. The panels agreed that the draft architectural framework and hypothetical algorithm were reasonable. The system was not linked to electronic nursing records to protect patient privacy. Phase 2 validated

XSL•FO
RenderX

each item through interviews with supervisory PHNs using a web-based meeting system. A nationwide survey was distributed to supervisory and midcareer PHNs across local governments.

Results: This study was funded in March 2022 and approved by all ethics review boards from July to September and November 2022. Data collection was completed in January 2023. Five PHNs participated in the interviews. In the nationwide survey, responses were obtained from 177 local governments of supervisory PHNs and 196 midcareer ones.

Conclusions: This study will reveal PHNs' tacit knowledge about their practices, assess needs for different approaches, and determine best practices. Additionally, this study will promote ICT-based practices in public health nursing. The system will enable PHNs to record their daily activities and share them with their supervisors to reflect on and improve their performance, and the quality of care to promote health equity in community settings. The system will support supervisory PHNs in creating performance benchmarks for their staff and departments to promote evidence-based human resource development and management.

Introduction

Background

Digital technologies promote innovation in health care and nursing [1]. Notably, a previous study categorized different applications of information and communication technology (ICT) in nursing practice into assessment, clinical intervention, health promotion, and service organization [2]. Regarding assessment, nurses have used electronic clinical recording systems [3] to assist in clinical decision-making for individual care [4], meet patients' health needs [5], and reduce overwork time and medical care expenditure [6]. Meanwhile, ICT-based health promotion programs can improve community health [7]. ICT also ensures efficient staffing and supports health workers' decision-making, communication, training, and health system management [1]. Therefore, digitalization and ICT promote effective and efficient care for individuals and communities. However, previous research has primarily focused on hospital- or clinic-based individual care [8]; little work has been done on the function of ICT in public health nursing [2].

Clinical terminology or taxonomy and its framework help visualize the classification of patients and nursing practice and improve health equity in multidisciplinary settings [9-14]. Nursing practices are based on nursing diagnosis systems [11] and interventions [12]. Focusing on patient outcomes is essential to improve nursing care and management quality [13,14]. However, while prior studies examine individual patients, knowledge about public health nursing is scarce. Under each country's different cultures, policies, and health care systems, public health nurses (PHNs) provide a wide range of lifelong care, support at the group level, and community-based activities. They also create policies, programs, projects, and health care systems that meet the needs of each community [15]. Individual care takes up most of a PHN's time [16], making it difficult to perform community-based activities and assessments [17], which are the basis of developing needs-oriented projects. Although these projects are vital for improving health equity in the community [18], evaluating the necessity of these practices and their linkage depends on the PHN's tacit knowledge. Therefore, in this field, assessment items core to clinical reasoning considering sociocultural backgrounds are required.

Given the rapidly changing health care needs that affect services, systems, and staffing [8], digitalization is still recent, especially in PHN [19]. The COVID-19 pandemic has accelerated the shortage of PHNs and digitalization in Japan [20]. Approximately 70% of PHNs in Japan work as prefectural or municipal public servants [21] and work in various departments. As Japan has the world's oldest population and the lowest birth rate, the national government must encourage digitalization and reduce the number of civil servants by half by 2040 [22]. Therefore, the total number of PHNs will potentially be halved by 2040. To ensure the quality of public health nursing, Japan has a national license system for PHNs [23]. Additionally, supervisory PHNs must manage practices in each department [24] while assessing the workloads of their staff and developing their competencies. Owing to the lack of ICT systems, supervisory PHNs may be unable to understand the happenings in each department and the performance and competencies of each staff member. An ICT system is needed to support their management and human resource development.

Furthermore, electronic record systems collect data on nursing care and promote evidence-based management in hospitals [6,10-13,25,26]. The Omaha system also enhances such management for each patient in community settings [14]. In Japan, the national government conducts a public health nursing activities survey every 3 years [27]. To this end, randomly selected prefectural or municipal PHNs gather data on their daily activities and the required hours [27]. However, no study has applied these data to elucidate public health nursing care management. To encourage evidence-based practices and nursing management, PHNs require an electronic recording and management system that identifies health needs and suggests the best public health nursing practices. The system would help PHNs think about their daily activities and share information

XSL•FO
RenderX

with their supervisors to improve the quality of care and competencies, thus ensuring health equity in the community.

Objective

This study will develop and validate an electronic recording and management system to evaluate the necessity of different public health nursing practices—including individual care, community-based activities, and project development—and to determine their best practices.

Methods

Study Design

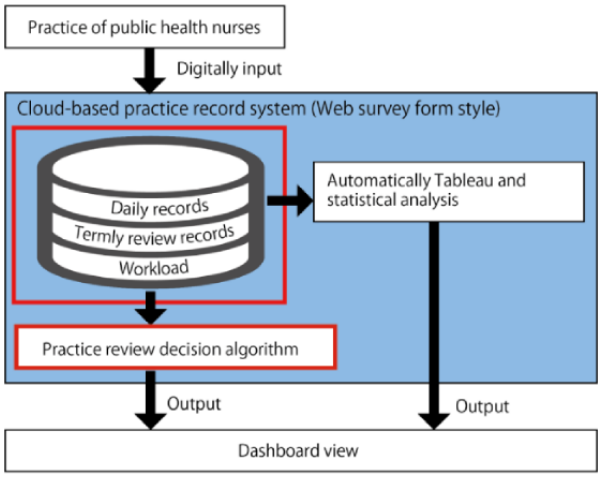
This study used an exploratory sequential design, which was conducted in Japan [28]. This design was suitable for exploring unknown questions using qualitative methods and developing a new instrument that can be validated by quantitative research analysis [28]. This study has 2 phases. Phase 1 will include a panel discussion to develop a structure for the electronic recording and management system. Phase 2 will confirm the validity of the proposed items through interviews with expert PHNs and a nationwide survey of PHNs.

Participants

The research team worked in public health nursing, home care nursing, public health, statistics, and computer sciences. This study is divided 2 phases. In phase 1, the research team conducted a literature review and a panel discussion that included 3 supervisors with experience working as prefectural or municipal government PHNs and 1 executive director of the Japan Nurse Association. The criteria for convening the expert panels meeting were to gather their opinions on the draft architectural framework—a hypothetical algorithm to determine the need for practice review; moreover, each item was developed by the research team.

In phase 2, the participants of interviews will be supervisory PHNs in prefectures or municipalities. Additionally, to ensure nationwide representation, we will include supervisory PHNs and midcareer PHNs with experience working in all local governments in Japan except those that completed the interviews. The inclusion criteria of midcareer PHNs have their cases and experience working for 6 to 20 years. The exclusion criteria for them are a managerial position.

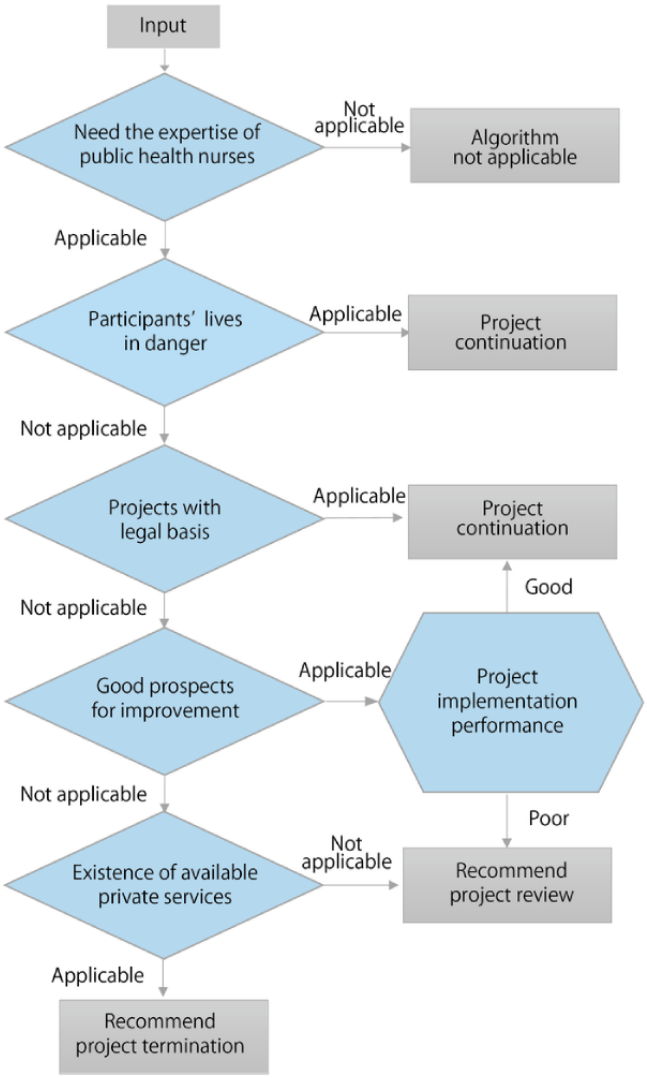
Recruitment



In phase 1, the research team recruited a panel of experts using snowball sampling. In phase 2, they recruited 5 to 10 supervisory PHNs as participants, who worked in prefectures or municipalities to avoid bias in the functions and roles of public health centers. Before starting the nationwide survey, we sent letters, including the study description, to supervisory PHNs. We used a mailing list of all supervisory PHNs from the Ministry of Health, Labour and Welfare to announce the survey by email. We expect approximately 530 local governments to participate based on a collection rate of 30% in a previous study that used a similar survey methodology [29].

Procedures

Phase 1: Develop an Architectural Framework



Based on a literature review [6,25-27,30-32] and discussions at 10 meetings, the research team created an architectural framework (Figure 1) for an electronic recording and management system. This study reports the construction of the system in the blue background area, especially the development of the system input items, and the hypothetical algorithm based on the practical experiences in the red frame areas. The data will be stored on a server contracted by the research team. The system can be accessed via a web browser on a touchscreen device or personal computer. We will collect data through a web-based survey form and a cloud-based practice recording system. Statistical analysis will be performed based on the data, and the results will be presented on the dashboard view as tables or graphs. Figure 2 shows the hypothetical algorithm to determine the need for practice review. Based on each PHN's assessment regarding individual care, community activities, and project implementation, an algorithm will suggest appropriate practices and directions for improvement.

Figure 1. An architectural framework for an electric recording and management system.

XSL•FO
RenderX

Figure 2. A hypothetical algorithm for determining the need for practice review.

Phase 2: Confirming the Validity of the Proposed Items

In phase 2, the validity of the proposed items will be tested using interviews with expert PHNs and a nationwide questionnaire survey of supervisory and midcareer PHNs.

The semistructured interviews with supervisory PHNs will be conducted over a web-based meeting system. We will confirm that the validity of the survey items comprising each unit constructed in phase 2 is relevant to the cases handled by PHNs (ie, to verify that the PHNs will be able to answer the question). We will send the survey items to the interviewees in advance, including the items comprising the unit constructed in phase 1 and a semistructured interview guide. To protect the interviewees' privacy, we will not record the interviews. To ensure the trustworthiness of the qualitative phase and to protect the interviewees' privacy, 2 researchers will conduct the semistructured interviews in pairs, one acting as an interviewer and the other taking notes. After the interviews, we will send a memo of the content to the interviewees over email for confirmation. Based on the results, we will revise each item in the system and finalize it.

The nationwide survey will be conducted using a web-based form, and a URL or QR code for the survey will be distributed to supervisory and midcareer PHNs. We will ask the research participants to (1) select one highly necessary and one less necessary element of individual care, community-based activities, and project development that they have performed within the last month; and (2) enter select cases into our system and summarize them. The level of necessity of each activity will be measured using a 10-point Likert scale from 1 (very unnecessary) to 10 (highly necessary). Additionally, we will ask participants about the importance and incomprehensibility of each item and whether to include any additional items. Responses will be sent directly to the researcher (ie, they will not go through the supervisory PHNs).

Data Analysis

In the qualitative phase, 3 researchers will read the interview transcripts (confirmed by the interviewees) and classify the contents in terms of the survey items using the content analysis method [33]. We will combine expressions with similar meanings into a single concept, whereas contradictory data will be left as is. After consulting with the project's supervisory PHNs, we will revise the survey items. The items for the nationwide survey will be finalized after all the project members confirm their validity.

XSL•FO
RenderX

The nationwide survey will be conducted through a descriptive analysis of the components of the system and the subjective necessity of PHN practices. In this survey, PHNs will answer based on 2 types of activities: (1) highly unnecessary and (2) highly essential. We want to compare these 2 categories and confirm whether the items will effectively work to help identify the differences between each activity in terms of necessity. We will use Cronbach α to measure the degree of agreement between the importance calculated when the responses were applied to the system developed in phase 1 and the subjective importance expressed by PHN interviewees. We will also perform a decision tree or random forest analysis with the PHN's subjective sense of significance as the outcome and the system configuration items as explanatory variables. The model with the highest prediction accuracy will be compared with the system created in phase 1. Finally, the panels will verify the nationwide survey results to confirm the external validity and consider whether the system may be improved based on the findings.

Ethical Considerations

This study will be conducted following the Declaration of Helsinki. Ethical approval for this study was obtained from the Research Ethics Committee of the Faculty of Medicine of the University of Tokyo, review number ID=2022114NI, 2022114NI-(1), 2022114NI-(2). We will explain the study's purpose and methods to the interviewees and advise them that their privacy will be protected in written form. Informed consent will be obtained from each participant. For the nationwide survey, only those who agree to participate in the study will be asked to respond to the questionnaire.

Results

Overview

This study was supported by the Ministry of Health, Labour and Welfare Japan research grant, which was acquired in April 2022. Interviews for supervisory PHNs were started in September 2022. Additionally, participants in the nationwide survey will be recruited in December 2022. The estimated date of the nationwide survey's completion will be January 2023. The preliminary results will be submitted for publication in December 2023.

Items From a Cloud-Based Practice Record System

In phase 1, the panels agreed that the draft architectural framework and a hypothetical algorithm were reasonable. After meetings with them, we decided that the system should not be linked to electronic nursing records to protect the privacy of each individual case. Items from a cloud-based practice record system are depicted in Tables 1 and 2. The items were divided into 2 domains. The first was a daily record system regarding individual care, community activities, and developing needs-oriented projects, whereas the second was their termly review system. Based on the Omaha system framework [14], we added assessment items from the perspectives of the individual, the family, and the environment, especially for individual care. We used 9 categories regarding a national survey of public health nursing activities [27]: infectious disease, intractable disease, disability, mental health, maternal and child health, health promotion, aging and long-term care, occupational health, and child welfare.

After developing the parts of the system, the researchers entered the data using typical vignette cases based on the national examination level and modified the items based on the results. The expert panels also filled in the items. However, the vignette cases were more straightforward than the actual clients. Therefore, we will ask PHNs to answer each item in the nationwide survey based on their actual cases (see below for more information).

Table 1. Items from a cloud-based practice record system: individual care.

System, unit, category/domain, and examples of items	Items, n
Daily record system (N=71-89[a])	
Transdomain items (n=69)	
Demographics of the PHNs[b]	5
PHN ID	
Dates	
Districts	
Activity domains	
Time consumed	
Necessity	44
Individual	
Symptom: acute deterioration of medical condition	
ADL[c]: dependent in basic ADLs	
Acceptance: refusal of support, consultation, or treatment	
Treatment: need medical care at home	
Communication: difficulty in communication	
Social support: absence of key persons	
Emergency: risk of self-injury	
Family	
Symptom: family member's poor health	
Acceptance: family member's refusal of support, consultation, or treatment	
Communication: family member's lack of problem awareness and coping skills	
Social support: family member's absence of someone to consult	
Emergency: domestic violence	
Environment	
Housing: unsanitary living environment	
Social resource: lack of social resources available	
Economic: economic deprivation (insufficient income)	
Neighborhood: trouble with neighbors	
Daily review: the problem is worsening or is expected to worsen	9
Activity selection: cooperation of community residents is necessary to solve the problem	6
Task load: how irritated, stressed, and annoyed did you feel during the task?	5
Domain-specific items (N=2-20[a])	
Necessity	
Infectious disease: risk of outbreak	10
Intractable disease: support immediately after diagnosis or discharge	5
Disability: problems in employment or social participation	5
Mental health: disturbance of life rhythm	2
Maternal and child health: caregiver's risk in life history (eg, history of childhood abuse)	5
Health promotion: refusal of specific health guidance	7
Aging and long-term care: behavioral and psychological symptoms of dementia	4
Occupational health: young caregiver	20

[a]Number of items depends on the domain.

[b]PHN: public health nurse.

[c]ADL: activities of daily living.

Table 2. Items from a cloud-based practice record system: community-based activities and project development.

Unit, category/domain, and example of items	Items, n
Daily record system (N=26)	
Demographics of the PHNs[a]	5
PHNs ID	
Dates	
Districts	
Activity domains	
Time consumed	
Necessity: risk to the life and well-being of the participants	4
Daily review: fewer participants in the activity/project than expected	3
Activity selection: people who have interrupted their participation and need individual follow-up	2
Task load: decreased involvement of residents in the operation of activity/project	12
Termly review system (N=57)	
Necessity: data available that support the necessity	12
Termly review	
Prediction and evaluation: initial health issue resolved and low probability of relapse	10
Disparity: inequity in service provision between regions or target groups	3
Substitutability: alternative private services available	5
Institutional issue: end of the year as a subsidized project	2
Resource: lack of cooperation with key persons in the district	8
Aggregated: long-term and large number of PHN inputs determined the project is less necessary	3
Activity selection	
Community-based activities to project development: enactment or amendment of laws related to activities/project	10
Project to community-based activities: necessity to modify the operation of the project depending on the district	4

[a]PHN: Public health nurse.

Daily Record System

The daily record system has 5 units: (1) demographic information of PHNs, (2) assessment of the necessity, (3) daily review, (4) activity selection, and (5) task load [34]. PHNs will enter related data daily, as described below.

1. Demographics of the PHN unit. PHNs will input their IDs, dates of their activities, districts, activity domains, and the time required for each activity.
2. Assessment of the necessity unit. The “necessity unit” determines how necessary each PHN activity is. The necessity of an individual case is determined by checking an applicable option (applicable, not applicable, or unknown) for each of the necessity judgment items in the domain to which each case corresponds to determine clinical urgency and any problems. The level of necessity of community-based activities and project development practices will be determined by checking the transdomain items and recording the number of people—the activity and practice targets.
3. Daily review unit. It evaluates PHN activities to determine whether they are appropriate and worth continuing. Items are distributed across the individual care, community-based activity, and project development subsets.
4. Activity selection unit. It examines movements across the different types of PHN activities. Individual care practices

XSL•FO
RenderX

include items that speak to or can develop into community-based activities and project development practices.

5. Task load unit. It determines the difficulty level of each activity. Individual care difficulty will be measured using the Japanese version of the National Aeronautics and Space Administration task load index. This considers mental, physical, and temporal demands, level of effort, performance, and frustration [34].

Termly Review System

The termly review system assesses each activity by collecting monthly or semiannual daily reports and inputting additional items, including (1) necessity, (2) the termly review, and (3) activity selection units.

1. Necessity unit. It consists of items that determine the necessity of community-based activities and project development from a long-term perspective. The term review unit in individual care activities is automatically checked based on accumulated daily reports.
2. Termly review unit. The termly review items for community-based activities and project development will be itemized regarding forecasting and evaluation, gaps, substitutability, institutions, and limitations.
3. Activity selection unit. The activity selection unit in the termly reviewed system determines guidelines for the future activities of each PHN. The individual care subsection includes accumulated daily reports and additional items that choose complexity, multiproblematic cases, and rapid changes in social needs. Meanwhile, the community-based activities and project development subsections comprise automatic checks based on accumulated daily reports and items involved in transitions between activity types, such as health crises or government policy changes.

Discussion

Principal Findings

This study will develop and validate an electronic recording and management system to evaluate the necessity of different public health nursing practices and accordingly consider how public health nursing practices may be improved; specifically, the system will focus on practices that fall into the categories of individual care, community-based activities, and project development. This study has several strengths. Validated items will evaluate the necessity of different public health nursing practices, suggest the best ones, and show the clinical reasoning of PHNs. The system will enable PHNs to record their daily activities and share them with their supervisors to reflect on and improve their assessment and the quality of care to promote health equity in community settings.

This study focuses on the links between individual care, community-based activities, and project development to assess the need for continued care. Most studies showed the framework and items of nursing assessment, interventions, and outcomes for individual patients [10-14]. By contrast, PHNs promote health equity and individual, family, and community health through direct care and policy development [15]. However, PHNs are often too busy with individual care to assess community health needs and implement population-wide activities [17]. By offering new insights into PHNs' tacit knowledge, this study can also inform the best practices for them. Additionally, senior and managerial PHNs play a vital role in bridging community needs assessment and grassroots projects in ways that support novice PHNs. Clarifying and translating PHNs' tacit knowledge into explicit knowledge would be essential to developing health care systems [35].

The result of this study will show the required time and burden for PHNs regarding each activity. Health care organizations required help ensuring high-quality care, owing to limited staff and other resources [36]. In this context, it is necessary to optimize human resources in health care. Identifying benchmarks for and measuring staff performance is crucial for effective human resource management and person-centered care [37]. Therefore, supervisory PHNs need to be able to identify the performance of each staff member and the effectiveness of their activities. Our system will support supervisory PHNs in promoting evidence-based human resource development.

Moreover, because the system requires PHNs to record their daily activities, it will enable PHN directors and staff to reflect on their practice periodically. Sharing the results of their daily activities with tier supervisors can help PHNs improve their performance and provide appropriate care for individuals, families, aggregates, and communities. Therefore, this study will improve the quality of care and address community health inequities.

Limitations

This study has some limitations. First, due to the ongoing COVID-19 pandemic, we can only interview a few participants; additionally, we expect the response rate for our nationwide survey to be low. Meanwhile, it is also notable that our study participants will likely be health care workers interested in the study. While we will work to ensure that our sample will be nationally representative by asking all local governments in Japan to participate, this study will still be subject to this selection bias. We will be sure to carefully analyze and interpret the data accordingly.

Conclusions

This exploratory sequential study will attempt to develop and validate an electronic recording and management system to evaluate the necessity of different public health nursing practices and determine best practices. The results will offer insights to develop a system that can help PHNs reflect on their daily routines and create benchmarks that can inform, thus improving on-the-job training by supervisory PHNs. This system will strengthen evidence-based public health nursing practices and management while improving the quality of care to enhance health equities in community settings.

Abstract

Background: Being physically active is critical to successful aging, but most middle-aged and older adults do not move enough. Research has shown that even small increases in activity can have a significant impact on risk reduction and improve quality of life. Some behavior change techniques (BCTs) can increase activity, but prior studies on their effectiveness have primarily tested them in between-subjects trials and in aggregate. These design approaches, while robust, fail to identify those BCTs most influential for a given individual. In contrast, a personalized, or N-of-1, trial design can assess a person's response to each specific intervention.

Objective: This study is designed to test the feasibility, acceptability, and preliminary effectiveness of a remotely delivered personalized behavioral intervention to increase low-intensity physical activity (ie, walking) in adults aged 45 to 75 years.

Methods: The intervention will be administered over 10 weeks, starting with a 2-week baseline period followed by 4 BCTs (goal-setting, self-monitoring, feedback, and action planning) delivered one at a time, each for 2 weeks. In total, 60 participants will be randomized post baseline to 1 of 24 intervention sequences. Physical activity will be continuously measured by a wearable activity tracker, and intervention components and outcome measures will be delivered and collected by email, SMS text messages, and surveys. The effect of the overall intervention on step counts relative to baseline will be examined using generalized linear mixed models with an autoregressive model that accounts for possible autocorrelation and linear trends for daily steps across time. Participant satisfaction with the study components and attitudes and opinions toward personalized trials will be measured at the intervention's conclusion.

Results: Pooled change in daily step count will be reported between baseline and individual BCTs and baseline versus overall intervention. Self-efficacy scores will be compared between baseline and individual BCTs and between baseline and the overall intervention. Mean and SD will be reported for survey measures (participant satisfaction with study components and attitudes and opinions toward personalized trials).

Conclusions: Assessing the feasibility and acceptability of delivering a personalized, remote physical activity intervention for middle-aged and older adults will inform what steps will be needed to scale up to a fully powered and within-subjects experimental design remotely. Examining the effect of each BCT in isolation will allow for their unique impact to be assessed and support design of future behavioral interventions. In using a personalized trial design, the heterogeneity of individual responses for each BCT can be quantified and inform later National Institutes of Health stages of intervention development trials.

Introduction

The health benefits of physical activity (PA) are wide ranging, from reducing all-cause mortality and cardiovascular disease risk [1,2] to improving mental health [3]. However, most Americans fail to meet recommended levels of PA, with a prevalence of inactivity increasing as people age [4,5]. This age-related decline in activity is concerning as the benefits of PA are particularly potent as we get older [6]. The development of effective PA interventions such that everyone meets national guidelines remains a central goal, but recent research findings have shown that even small increases in PA offer health benefits [1,2]. Furthermore, a nonlinear dose response exists between PA volume and disease risk reduction, with the greatest drop in risk seen in very inactive older adults who increase PA by even a small amount [2]. Low-intensity PA, such as walking, has been identified as an effective and well-accepted modality, with increases of as little as 1000 steps per day found to lower the risk of mortality [2].

While the evidence demonstrating health benefits for older adults from even small amounts of PA is reassuring [2], questions remain on the most effective ways to encourage any positive change in PA among this population. While there have been numerous PA interventions for older adults, few have shown more than modest improvements [7]. One plausible reason is that many of these studies have been conventional randomized controlled trials (RCTs) with little consideration for active components of behavior interventions, no consideration for heterogeneity of treatment effects, and a mean outcome effect calculated, for example, pre-post change in daily step count for the hypothetical "average" older adult. While between-subjects RCTs are the gold standard of research trials, this design cannot calculate individual heterogeneity of treatment effects, as individuals are only exposed to 1 condition—the single condition to which they were randomized [8]. Even in clinically significant between-subject RCTs, some participants increase in activity, while others show no change or even decrease in activity in response to the intervention.

To address these concerns, some RCT designs focus on within-person behavior change with exposure to multiple interventions. Personalized trial designs, otherwise known as "N-of-1" trial designs, use a within-subject experimental approach to evaluate the outcomes of different interventions specific to that subject [9,10]. For example, a personalized trial can provide a quantitative estimate of the effects of distinct behavioral interventions on a single participant by observing the participant continuously over a given period with the different interventions occurring at scheduled time points. Observing the effects of multiple interventions can determine the quantitative effect of each specific intervention on an individual participant. This means effect sizes for each intervention can be confirmed for that participant rather than relying on aggregate findings that include data from other participants.

Personalized trials have been used to study fatigue, depression, back pain, and preventive behaviors [11,12], but they have not been widely employed in real-world clinical practice because the delivery of such an approach has been perceived as overly burdensome for clinicians and patients [13]. However, with the advent of smartphones, cloud computing, and biometric or activity trackers, platforms can now be developed to conduct N-of-trials more feasibly. N-of-1 trials using this technology can allow researchers to deliver behavioral interventions and obtain real-world data remotely, often in real time.

Extensive research has attempted to untangle those key elements, known as behavior change techniques (BCTs), that contribute to successful changes in behaviors such as smoking, diet, or PA [14,15]. From this body of research, we first focused on those that have been associated with improvements in PA [16] and then narrowed our intervention selection down to 4 BCTs that were most strongly associated with a change in walking and could be delivered effectively using our trial design. The 4 BCTs selected are goal setting, self-monitoring of behavior, action-planning, and feedback on behavior.

This study protocol is designed to evaluate the feasibility and acceptability of a randomized personalized trial that will serially deliver 4 BCTs in random order to promote low-intensity PA. The trial will recruit 60 adults aged 45-75 years. The protocol will integrate wearable technology (ie, Fitbit) capable of measuring participant activity (eg, step count and heart rate) with SMS text messaging and survey delivery via smartphone such that the research team can conduct the study remotely and collect data continuously. The study's primary outcomes will be within-person changes in daily steps and participant satisfaction with personalized trial approach components. Secondary outcomes include self-efficacy for walking and participant attitudes and opinions toward personalized trials.

Methods

Design

The purpose of this study is to determine the feasibility, acceptability and preliminary effectiveness of using personalized or N-of-1 methods to increase low-intensity walking by 2000 steps per day for 5 days each week in a remote research study. Participants can accumulate these additional 2000 steps across the course of the day and do not have to do so in a single bout. The study will recruit Northwell employees aged 45 to 75 years old and use 4 BCTs that have been shown as effective in encouraging increases in PA.

The study design comprises 2 main parts. Part 1 entails a series of 4 phases (see Figure 1) where participants will be recruited to help develop the content and processes for the second main

XSL•FO
RenderX

part, which is the intervention—a personalized trial series. Up to 60 participants will participate in the initial series of 4 phases undergoing focus groups, interviews, and surveys to elicit feedback concerning the clarity of instructions and convenience of messaging. They will provide feedback on key aspects of study design, including BCT choices, BCT descriptions, materials, and electronic delivery methods such as SMS text messaging and email receipt. Up to 10 of the 60 participants will engage with study materials and procedures as "mock participants," interacting remotely and providing feedback about the ease and acceptability of study procedures to further refine study materials and procedures.

The second main part of the study entails an intervention, where 60 participants (who were not involved in the earlier phases of focus groups and user testing) will be recruited for a 10-week personalized trial assessing the impact of 4 BCTs, assigned in random order, on their walking behavior. Participants will be sent a Fitbit Charge 4 tracker that will monitor the number of steps taken per day. At the end of each 2-week intervention period, participants will complete a survey stating their satisfaction with the specific single BCT delivered during that time. Each BCT will be presented for 2 weeks during the 8-week active intervention in a randomly selected order (see Figure 2). Our study statistician, who is not involved in recruitment, will generate a list of assignments using block randomization, which they will then provide to our project manager. Participants will be assigned a BCT sequence if they complete the baseline and meet all adherence criteria.

At the end of their 10-week trial, participants will receive a detailed summary of their observed data and a final, comprehensive satisfaction survey regarding the overall personalized trial design. The summary will help participants learn more about their responses to each of the 4 BCTs. The satisfaction survey will inform investigators about the feasibility of personalized study design for future research and clinical applications.

Participants, Recruitment, and Screening

Potential participants will be Northwell Health employees who are community residing, 45 to 75 years old, healthy, report that they walk regularly without health and safety issues, and express an interest in participating in a personalized trial to increase their walking.

The study will use Northwell Health's existing employee networks to recruit eligible participants. Potential participants

XSL•FO
RenderX

may be recruited via the following measures: (1) advertisement emails to those who previously expressed an interest in participating in a personalized trial, (2) flyers circulated within the Northwell Health network, and (3) Northwell Health employee social media sites such as Northwell's employee-only Facebook group.

Interested participants will first be invited to complete a "Screening Survey" where they must respond to inclusion and exclusion criteria. Clinical research coordinators will review these data and determine whether a potential participant is eligible to participate.

Ethics Approval

The protocol and consent processes have been approved by the institutional review board (IRB; 20-1166) at Northwell Health's Feinstein Institutes for Medical Research. The study protocol conforms to the ethical guidelines of the 1975 Declaration of Helsinki as reflected in a priori approval by the institution's human research committee, Northwell Health Institutional Review Board. The consent document will contain all the elements of informed consent required by applicable federal regulation for the protection of human subjects and elements of authorization required by the Health Insurance Portability and Accountability Act Privacy Rule.

Consent Process

The consent will be presented electronically as an IRB-approved information sheet for the pretrial phases and as a full, IRB-approved informed consent form requiring a digital signature for the intervention. As consent for the intervention will be obtained remotely, the electronic platform will be designed such that the consent form is easy to navigate. We will use interactive, electronic-based technology to present information about the research in a variety of different modalities to facilitate understanding before participants document their consent (eg, print and video formats). The consent document will contain all the elements of informed consent required by applicable federal regulation for the protection of human subjects and elements of authorization required by the Health Insurance Portability and Accountability Act Privacy Rule and will begin with a concise and focused presentation of the key information that is most likely to assist participants in understanding the reasons why they may or may not want to participate in the research. These descriptions will be carefully scripted in language that persons with a sixth-grade education can understand; key information will include a brief description of the participant's proposed involvement, potential risks, and benefits of participation. Voluntary participation affirming participants that they have the right to stop at any time without impact to their employment or care will be emphasized. Potential participants must demonstrate comprehension of the informed consent form by responding to 4 questions about the trial prior to documenting their consent. Their electronic informed consent will be obtained prior to enrollment in the project for those individuals who are eligible. Participants will receive a copy of their signed informed consent form via SMS text message. Since consents are obtained electronically, they will remain in our Research Electronic Data Capture database (Vanderbilt University) indefinitely. The IRB-approved informed consent is included in Multimedia Appendix 1.

Privacy and Confidentiality

Given that study activities involve no more than minimal risks encountered in daily life (ie, increased time spent walking by healthy, working individuals), this study does not require oversight by a Data Safety and Monitoring Committee. Rather, the study has received National Institutes of Health approval for a safety monitor. This safety monitor will be assigned to periodically review and evaluate project data for participant safety, scientific integrity, and trial progress. There is no additional risk with using a Fitbit activity monitor for research as compared to using the device as a consumer, including mild skin irritation (ie, contact dermatitis) which occurs among a small proportion of users. One risk of taking part in this study is the possibility of a loss of confidentiality or privacy. The risk of loss of confidentiality will be minimized by securely storing data including protected health information in a Northwell-approved database and minimizing the use of protected health information.

Participant Compensation

Participant compensation will vary according to the part of the study in which the participant is involved. Participants in the 4 pretrial phases will receive 5000 points credited to their Northwell MyRecognition account (roughly equivalent to US $25) for attending a focus group, participating in an interview, or completing their mock study procedures.

For the intervention, involving 10 weeks of study participation, participants will receive a pay card valued at US $100 for completing all study requirements. Additionally, participants in the intervention will be able to keep their Fitbit, valued at US $150.

Focus Group Procedures

Up to 60 participants will participate in the first 4 pretrial phases of the study. They will be invited to participate in 1-on-1 interviews (up to 20 participants), focus groups (up to 30), or mock testing (up to 10). Participants will provide feedback on key aspects of study design such as BCT descriptions, study workflow remotely (ie, remote screening, informed consent process, and demographic questionnaire), and remote survey administration (ie, satisfaction and self-efficacy surveys).

Participants in the focus groups and 1-on-1 interviews will be presented with study materials and potential aspects of study designs. Participants will then be asked questions on the clarity and readability of that content—for example, IRB-approved questions such as "Do the descriptions make sense?" and "What would motivate someone to participate in this study?" These focus groups and interviews will be conducted by a trained facilitator with a principal investigator and note-taker present. Ten of the 60 participants will engage in mock testing of study materials and procedures, providing feedback to the study team on the acceptability of these procedures. This will allow the study team to develop and refine the workflow and infrastructure remotely.

XSL•FO
RenderX

Personalized Trial Series Procedures

As noted earlier, an intervention in the form of a personalized trial series will follow the pretrial phases This series will comprise a single trial for each eligible participant that includes a 2-week baseline period and 8 weeks of study intervention, testing 1 BCT at a time each for a 2-week period. During baseline, participants must maintain 80% compliance with Fitbit wear (ie, device is worn a minimum of 10 waking hours on a given day) and responses to questionnaires to be eligible for the intervention period.

Intervention Onboarding

If participants consent, they will receive an "Onboarding Survey" to complete. This form will collect the participant's demographic information and necessary contact information so that the study team can ship the activity tracker and study materials. Once research staff confirm that the participant has completed the required onboarding tasks, an initial study kit, which includes a Fitbit Charge 4 and printed materials to guide the participant through the study, will be shipped to them. The printed materials will instruct participants how to download an app to their personal smartphone so they can use the Fitbit as well as instructions on how to charge and synchronize it. Anonymous study accounts will be created to protect the privacy of the participant.

Intervention Baseline

Participants will be mailed a study kit including a Fitbit Charge 4 device and printed study materials. The study materials will include the participant's start date and instructions on how to download the Fitbit app to their smartphone so they can pair the Fitbit device. All baseline periods will begin on a Monday, and no more than 20 participants will be permitted to begin on the same day.

The baseline period will be 2 weeks in duration. Potential participants will not receive any text message BCT interventions during baseline, but they will be asked to wear their Fitbit all day and night (as tolerated), sync their Fitbit device at least every 2 days, and respond to 1 text message per day to ensure they are receiving communications.

At the end of the baseline period, a clinical research coordinator will review individual adherence to Fitbit wear and responsiveness to the daily surveys. Adherence to Fitbit wear will be defined as having at least 600 minutes (10 hours) of heart rate activity per day. SMS text message adherence will be defined as having responded to the daily message. Baseline participants who do not achieve at least 80% adherence to both Fitbit wear and SMS text message responses during the 2-week baseline period will be withdrawn from the study. Those who maintain at least 80% adherence will be randomized to 1 of 24 sequences of 4 BCTs received 1 at a time, switching every 2 weeks (see Figure 2). Enrollment will continue until up to 60 participants have been randomized.

Main Intervention—BCT Sequences

Participants who successfully complete the baseline period will receive a random sequence of BCT interventions over the next 8 weeks during which a BCT message is delivered daily for a 2-week period. For example, goal-setting messages will be sent for 2 weeks, then self-monitoring prompts for 2 weeks, and so on for action planning and feedback. On the day before each new 2-week period, participants will be sent a message describing which BCT is coming next. BCT messages will be automatically delivered each day, and the participant's own data from baseline and the previous day will be used to generate messages. A description of BCTs employed and sample messages is provided in Table 1.

Participants will also receive a biweekly survey to assess their satisfaction with the BCT intervention sent over those 2 weeks and a self-efficacy survey assessing their confidence in their ability to walk for varying periods of time. Participants may receive additional SMS text messages to those outlined above with reminders to sync their data if needed.

Table 1. Description of behavior change technique intervention content.

Content	Modalities	Sample SMS text message prompt
Goal setting	SMS text message is delivered daily to encourage the participant to set a goal of beating their average daily step count during baseline.	"Is your goal today to walk an extra 2000 steps more than your baseline average?"
Self-monitoring of behavior	Ongoing self-monitoring is prompted by a daily text message delivered each morning. The baseline average is included in the message.	"Check your Fitbit dashboard for yesterday's activity. Did you take an extra 2,000 steps more than your baseline average?"
Feedback on behavior	An SMS text message is delivered each morning stating whether or not the goal had been met on the day prior (Fitbit step data are collected remotely)	"You met your goal yesterday. You walked 2000 steps more than your baseline average." "You did not meet your goal yesterday of walking at least an extra 2,000 steps more than your baseline average"
Action planning	An SMS text message is delivered each morning encouraging the participant to plan for an additional walking session. The baseline average is included in the message.	"Take one minute and plan how, where, and when today you can walk an extra 2000 steps over your baseline."

Postintervention

Upon completion, participants in the intervention will receive an individual report that presents changes in their own walking behavior in relation to their selected BCTs. Participants will also receive a final survey concerning their satisfaction with the personalized trial design and their attitudes and opinions toward personalized trials. After receiving the report, clinical research

XSL•FO
RenderX

coordinators will notify the participant that they have completed the study, remind them of the US $100 pay card for completing the study, and instruct them to unlink the Fitbit device from the anonymous study account. Participants will also be invited to contact the study team for any remaining questions.

Retention Plans During Intervention

The study has a well-formulated action plan for participant retention: when a participant fails to sync their device or respond to questionnaires for 2 consecutive days, they will receive an automated message notifying them that they have dipped below the benchmark. If improvement is not seen within another 2 days, the clinical research coordinator will reach out to the participant by text/phone/email and troubleshoot issues. Retention rates will be reported in weekly team meetings and, if needed, the study will institute additional incentives such as a weekly regret lottery to ensure compliance with study procedures and retention of study participants. A regret lottery is a method adopted from behavioral economics where participants are entered into a money- or prize-based lottery for which prize receipt is contingent upon participants' achievement of protocol adherence goals [17].

Measures and Analysis: Data Integrity

The study data manager will be responsible for ensuring the integrity of data collected and the preparation of the data for statistical analysis. The data manager is available to provide data to the safety office upon the safety monitor's request in between monthly reports.

Responses from interviews and focus groups in the pretrial phases will be tabulated into documented themes for consideration in the intervention design, such as acceptable levels of participant burden (eg, optimal number of SMS text messages per week) and consensus on design features including the content of messaging.

For missing data, the plan is to invest in collecting data as completely as possible. Given the preliminary work to refine the BCT description and study design prior to the 60 personalized trials, we anticipate minimal missing data in recording participant responses. Intention-to-treat analysis will be used. In the unlikely case of missing data, we will examine the missingness pattern and its association with any phenotypes, thus identifying potential confounders and use multiple imputation approaches.

Primary Outcomes

Within-Person Change in Daily Steps

The Fitbit device continuously collects the number of steps taken by each participant. These data can be examined at a daily level, and the study will aggregate daily step counts for both the baseline and intervention periods [18]. This will allow the research teams to compare the daily step count between each period to see if any change occurs.

Participant Satisfaction With Personalized Trial Components

At the end of the intervention period and after receiving their individual study report, the participant will receive a satisfaction survey comprising nine items with 4-point Likert scales. Each item is preceded by the prompt "How satisfied were you with the following?" and the 4-point scale ranges from "Not at all satisfied" to "Very satisfied."

Secondary Outcomes

Self-Efficacy for Walking

Self-efficacy has been shown to predict longer-term behavior, mediating the relationship between positive experience and PA [19]. At the end of the baseline period and every 2 weeks during the intervention period, participants will complete the Self-Efficacy for Walking Scale [20]. It is a validated 10-item survey assessing the participant's confidence in their ability to walk for a given duration. The phrase "I BELIEVE THAT I CAN WALK" precedes all of the 10 sentences with each one specifying a different amount of time (eg, "For 5 minutes at a moderately fast pace without stopping"). The first item in the survey specifies 5 minutes of walking and the amount increases by 5 minutes with each subsequent item such that the final item specifies 50 minutes of walking. The questions are scored on an 11-point scale, which ranges from "Not at all confident" to "Highly confident" with "Moderately confident" in the middle.

Participant Attitudes and Opinions About the Personalized Trial Implementation

To measure attitudes and opinions about personalized trial implementation, participants will be asked to respond to an 11-item survey on a 7-point scale. This survey is modified from the widely used system usability scale [21]. Each item asks about some aspect of the personalized trial. For example, 1 item reads "The materials I received in the mail were clear and easy to follow" and another reads "I needed to learn a lot of things before I could get going with my personalized trial." These statements will prompt the participant to indicate how much that statement applies to them; on one end of the scale reads, "Strongly disagree," and the other reads, "Strongly agree."

Primary Analyses

Means and SDs for daily steps will be reported for the baseline period and for each BCT intervention period. The effect of the overall intervention relative to baseline will be examined using generalized linear mixed models with an AR(1) (autoregressive order of 1) model that accounts for possible autocorrelation and linear trends for daily steps across time. The overall intervention effect will be tested based on whether the coefficient of the time effect is positive. Additional generalized linear mixed models will be examined to identify the effects of individual BCTs on daily steps. For these AR(1) models, fixed effects will be specified for each BCT intervention and random effects will be specified for each participant. We will adopt a novel Bayesian distributed lagged model to further explore the extent of carryover effects [22]. For participant satisfaction with personalized trial components, responses to the questions will be reported with means and SDs. The distribution of participant responses for each item assessing satisfaction will be displayed using a bar graph.

XSL•FO
RenderX

Secondary Analyses

Means and SDs for self-efficacy will be reported for the baseline period and for each BCT intervention period. To identify whether self-efficacy for walking mediates the effect of the BCT intervention on daily steps, we will perform the analysis in 3 steps. First, we will estimate the effects of the BCT intervention on self-efficacy. This step will be examined using linear mixed-effects models, which include a random participant effect, fixed effects for the BCT intervention, a fixed time effect, and fixed BCT-time interaction. Next, we will estimate the effect of the BCT intervention on daily steps using linear regression. Finally, we will estimate the indirect effect of the BCT intervention on daily steps via the proposed mediating variable of self-efficacy. This will use natural effects models for effect decomposition into direct effect and indirect effect, mediated by an increase in self-efficacy, relative to baseline [23,24]. Participant attitudes and opinions toward personalized trials will be reported with means and SDs. Bar graphs will be used to display the distribution of participant responses for each item.

Sample Size Justification

Sample size was based on the primary outcome for within-person change in daily steps due to the overall BCT intervention. As this is a feasibility trial, sample size estimates were calculated based on the effect of the overall intervention, not the individual BCT interventions. The effect size is obtained from a previous study [25]. Using a paired *t* test with the effect size of 0.404 and type I error of 0.05 (2-sided), we obtain a power of 80% when comparing the number of steps during BCT period with the baseline period for 50 subjects. We expect a change in step of 2000 between the baseline and BCT periods. We obtained a pooled standard error of 4989.77 from Pinto et al [25], from a SE of 2476 (preintervention period) and 3555 (postintervention period). To achieve a total of 50 participants with complete data, under an assumed 15% attrition, we anticipate randomizing up to 60 participants. This sample size will ensure adequate size to obtain a preliminary assessment of this trial's feasibility, which will be determined by the effectiveness of the overall BCT intervention on PA behavior and participant scores on the satisfaction survey. The number of assessment measures and treatment repetitions per trial are based on expert recommendations by the study statistician and their estimations about the maximal duration of the trial to maintain patient engagement.

Results

The project was funded in 2021, and enrollment was completed in February 2022. Data analysis is currently underway, and the first results are expected to be submitted for publication in June 2023.

Discussion

Principal Findings

This study will evaluate the feasibility and acceptability of a randomized personalized trial to promote low-intensity PA in middle-aged and older adults. Sixty adults aged 45-75 years old will receive 4 BCTs, one at a time, for a 2-week each. The study will be conducted remotely, using automated SMS text messaging and survey delivery, and wearable technology to monitor participant activity. The study's primary outcomes will be within-person changes in daily steps and participant satisfaction with personalized trial approach components. This study's findings will deliver insights into 2 main areas of research interest. First will be the feasibility of delivering a series of individual BCTs in a personalized design to influence PA behavior. Most studies to date have incorporated multiple BCTs in their intervention, which limits our understanding of each BCT's specific impact. Second is the feasibility and acceptability of the personalized trial design as measured by participant satisfaction and completion of trial measures. This approach offers the promise of unique findings that will be used to support later National Institutes of Health stages of intervention development trials. Personalized trials are just one of several innovative trial design approaches being used to address the limitations of classic RCTs. The multiphase optimization strategy and the sequential multiple assignment randomized trial are 2 prominent examples of the many adaptive approaches now being used to facilitate more effective trials and garner greater insights about the component parts that make an intervention successful [26-29]. What is unique about the personalized trial approach is its ability to deliver insights regarding the heterogeneity of effect from a given intervention and support personalized recommendations for each individual [30].

Limitations

There are a number of potential limitations to this study. The first is that there may have been some reactivity to wearing the Fitbit device that could have impacted the baseline step counts. In a future study, where the goal of the study is to examine reactivity to devices and calibrate the effectiveness of commercially available activity trackers like Fitbit, research-grade accelerometers (which do not display steps or other metrics) could be used along with Fitbit devices for a longer duration of time to enhance the data collection. The second limitation is that there is no maximum threshold of activity rather participants will be included if they felt they could benefit from walking more each day. This may lead to the inclusion of participants who are already quite active and could result in a ceiling effect and limit generalizability to less active adults. The third limitation is that the participants may turn on features in the Fitbit app that could deliver additional BCTs (such as adding friends or joining challenges) not part of the intervention. A final limitation is that all participants will be employees at the same health care organization, thus limiting the generalizability of findings.

Conclusions

This remotely delivered study will contribute broadly to the science of PA behavior change in middle-aged and older adults. BCTs are seen as key components of behavior change, but the influence of specific BCTs is not well understood [31,32]. The findings from this study will provide insights into the extent to which individual BCTs are effective in changing PA behavior. Furthermore, it will demonstrate if the influence of BCT on

XSL•FO
RenderX

walking is consistent across participants or if large individual heterogeneous treatment effects exist [32]. How older adults engage with the technical components of this trial, such as wearable devices and remote onboarding, will inform current practice and offer a foundation for the development of larger personalized trials. In conclusion, this study offers a vision of conducting future series of trials where personalized data derived from wearable sensors, rather than generic guidelines, are used to inform the selection of intervention components for each individual.

Data Availability

This trial was preregistered on ClinicalTrials.gov (NCT04967313) and data will be made available on the Open Science Framework [33].

Conflicts of Interest

None declared.

Abstract

Background: Molecular point-of-care testing (POCT) used in primary care can inform whether a patient presenting with an acute respiratory infection has influenza. A confirmed clinical diagnosis, particularly early in the disease, could inform better antimicrobial stewardship. Social distancing and lockdowns during the COVID-19 pandemic have disturbed previous patterns of influenza infections in 2021. However, data from samples taken in the last quarter of 2022 suggest that influenza represents 36% of sentinel network positive virology, compared with 24% for respiratory syncytial virus. Problems with integration into the clinical workflow is a known barrier to incorporating technology into routine care.

Objective: This study aims to report the impact of POCT for influenza on antimicrobial prescribing in primary care. We will additionally describe severe outcomes of infection (hospitalization and mortality) and how POCT is integrated into primary care workflows.

Methods: The impact of POCT for influenza on antimicrobial stewardship (PIAMS) in UK primary care is an observational study being conducted between December 2022 and May 2023 and involving 10 practices that contribute data to the English sentinel network. Up to 1000 people who present to participating practices with respiratory symptoms will be swabbed and tested with a rapid molecular POCT analyzer in the practice. Antimicrobial prescribing and other study outcomes will be collected by linking information from the POCT analyzer with data from the patient's computerized medical record. We will collect data on how POCT is incorporated into practice using data flow diagrams, unified modeling language use case diagrams, and Business Process Modeling Notation.

Results: We will present the crude and adjusted odds of antimicrobial prescribing (all antibiotics and antivirals) given a POCT diagnosis of influenza, stratifying by whether individuals have a respiratory or other relevant diagnosis (eg, bronchiectasis). We will also present the rates of hospital referrals and deaths related to influenza infection in PIAMS study practices compared with a set of matched practices in the sentinel network and the rest of the network. We will describe any difference in implementation models in terms of staff involved and workflow.

XSL•FO
RenderX

Conclusions: This study will generate data on the impact of POCT testing for influenza in primary care as well as help to inform about the feasibility of incorporating POCT into primary care workflows. It will inform the design of future larger studies about the effectiveness and cost-effectiveness of POCT to improve antimicrobial stewardship and any impact on severe outcomes.

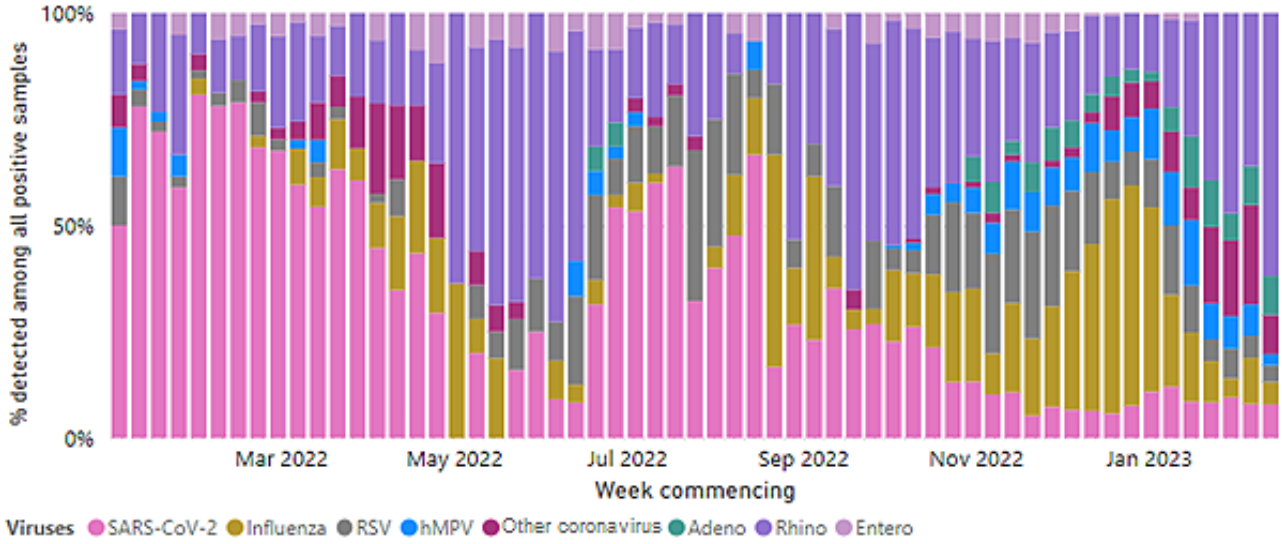
Introduction



Rapid Testing for Influenza in a Postpandemic Health Service

Measures to limit SARS-CoV-2 transmission during the COVID-19 pandemic coincided with a marked decrease in infections caused by other respiratory viruses [1,2].

After the lifting of COVID-19 containment measures, the robust return of influenza, seasonal coronaviruses, parainfluenza virus, and respiratory syncytial virus (RSV) was observed in many countries including the United Kingdom [3].

Figure 1 and Table 1 show data from the English national sentinel surveillance network as of the end of November 2022. Influenza and RSV were the main circulating respiratory viruses, with SARS-CoV-2 making up only 12.4% (15/121) of the total number of laboratory-confirmed cases.

Figure 1. Swab positivity by week in the English national sentinel surveillance network from March 2022 to January 2023 [4]. hMPV: human metapneumovirus; RSV: respiratory syncytial virus.

In the context of a postpandemic health care service where there are high levels of circulating influenza, accurate, rapid molecular diagnostic test platforms have the potential to (1) improve clinical decision-making regarding the use of antibiotics and antivirals, (2) improve patient outcomes due to the early appropriate use of antivirals, and (3) provide better information to inform sentinel surveillance and clinical research including studies of vaccine effectiveness and real-world trials [5,6].

Specifically, for patients with influenza infection, early diagnosis and administration of antivirals may improve clinical outcomes [7,8]. They may also limit symptom duration and spread to household contacts, and newer antivirals for influenza, such as baloxavir, have been shown to improve the time to resolution of symptoms and reduce complications in high-risk patients [9].

Currently, only a small proportion of patients with respiratory tract infections (RTIs) undergoes diagnostic microbiological testing before receiving treatments in primary care [10], and there is evidence of widespread variations in antimicrobial prescribing practices [11]. This is important, as prescribing in primary care accounts for about 8% of National Health Service (NHS) expenditure, which is equivalent to over £9 billion (US $11.1 billion) per year, with just over £220 million (US $271.5 million) being spent on antimicrobials [12]. Inappropriate prescribing of antimicrobials and unwarranted variation in prescribing can contribute to increase of antimicrobial-resistant strains and patient adverse events in the short and long term [13].

We have previously shown that, in a prepandemic context, it is feasible to undertake point-of-care testing (POCT) for influenza in primary care in the England, with promising impacts on antimicrobial use and estimates of influenza vaccine effectiveness that are comparable with published data [14-16].

XSL•FO
RenderX

However, its impact on more severe outcomes such as hospitalization and mortality following infection has not been reported.

Recent work on in-pandemic prescribing of azithromycin and doxycycline for RTIs across the sentinel network has shown scope for measures to improve antibiotic stewardship in primary care [17].

With the ending of widespread national testing for SARS-CoV-2 and other RTIs in the United Kingdom in March 2022 [18] and with high levels of circulating influenza in a post-COVID-19 health service during the autumn 2022 compared with 2021, there is a need to revisit questions about the feasibility of implementing rapid diagnosis of influenza during the expected peak of viral circulation this winter (2022-2023) season and its impact on clinical management in terms of improved antimicrobial stewardship and severe outcomes (hospitalization and mortality).

Table 1. Swab positivity by week in the English national sentinel surveillance network between September 2022 and November 2022 (n=818).

Week commencing	Swab positivity					
	Adenovirus (n=54)	hMPV[a] (n=85)	Influenza (n=215)	Other coron-aviruses (n=13)	RSV[b] (n=255)	SARS-CoV-2 (n=196)
9/26/2022 (n=26), n (%)	0 (0)	0 (0)	0 (0)	0 (0)	11 (42.3)	15 (57.7)
10/3/2022 (n=54), n (%)	0 (0)	1 (1.9)	20 (37)	0 (0)	6 (11.1)	27 (50)
10/10/2022 (n=52), n (%)	0 (0)	2 (3.8)	14 (26.9)	1 (1.9)	6 (11.5)	29 (55.8)
10/17/2022 (n=70), n (%)	0 (0)	6 (8.6)	19 (27.1	2 (2.9)	17 (24.3	26 (37.1)

[a]hMPV: human metapneumovirus.

[b]RSV: respiratory syncytial virus.

Objectives

This study aims to report the impact of POCT for influenza on antimicrobial prescribing in primary care. We will additionally describe severe outcomes postinfection (hospitalization and mortality) and how POCT is integrated into primary care workflows.

Methods

Study Setting and Population

The impact of POCT for influenza on antimicrobial stewardship (PIAMS) study will take place between December 2022 and May 2023, during the influenza season as defined by the UK Health Security Agency (UKHSA). It is nested within the English national sentinel network managed by the Oxford-Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC) at the Nuffield Department of Primary Care, University of Oxford. This network of over 1800 primary care practices is the primary infectious disease surveillance network for England, which is generally representative of the English population [19]. It has been providing weekly infection data for over 50 years that are used to monitor trends in infectious disease and investigate real-world vaccine and treatment effectiveness [20].

All practices that contribute data to the English national sentinel network will be invited to participate in the PIAMS study, and 10 practices will be selected to take part in the PIAMS study. We will prioritize practices within the network with capacity to undertake influenza POCT and who had previously been involved in SARS-CoV-2 POCT through the RAPTOR-C19 study [21]. Those practices that have a history of less than 80% complete data returns during the previous winter season will be excluded.

Each participant practice will receive training about the study, including hands-on training on how to administer a swab test and how to use the POCT analyzers.

Case Definition of Eligible Patients

All patients registered within the PIAMS study practice who do not have an opt-out code on their medical record and are showing symptoms of influenza-like illness (ILI), acute respiratory illness (ARI), or fever of higher than 37.5 °C will be eligible for the study if they consent to participate. We will use the European Centre for Disease Prevention and Control case definitions of ILI and ARI for this study. We will use the following exclusion criteria: (1) patient has an opt-out code on their medical record or (2) no informed consent.

XSL•FO
RenderX

Face-to-face Recruitment of Eligible Patients and Point-of-care Testing for Influenza

We will undertake opportunistic swab sampling for this study, with potential participants being identified from those registered patients who present to the study practice with respiratory symptoms described in the case definition. No screening nor eligibility assessment will be undertaken. Blinding of participants and researchers will not be undertaken.

Eligible patients or their parent or legal guardian will be approached by a practice general practitioner (GP) or research nurse to explain the study and ask for consent to take part when they present for a face-to-face consultation at the practice.

After obtaining consent, a nasopharyngeal swab will be taken by a suitably qualified and experienced GP or research nurse. For those who do not attend the practice in person, a self-test kit will be sent to their home.

The cobas Liat POCT analyzer, manufactured by Roche Diagnostics International, will be used for this study [22]. This POCT analyzer is an automated multiplex polymerase chain reaction system, with previous studies demonstrating excellent performance comparable with gold standard laboratory assays, with sensitivity and specificity in the region of 100% and 97.1%-100%, respectively, for influenza A and 97.8%-100% and 99.5%-99.7%, respectively, for influenza B when fresh, prospectively collected samples are tested [23,24]. It has CE-marking in the European Union. In the United States, it is Food and Drug Administration–cleared, and it is also Clinical Laboratory Improvement Amendments–waived for use for rapid influenza testing. This study will not assess the accuracy of the POCT analyzer but will use the machine for its approved purpose.

The swab will be inoculated in a test kit and tested on the cobas Liat analyzer as soon as possible after being taken. The results will be available to the clinician in less than 20 minutes.

Antimicrobial prescribing and other study outcomes for those who have been swabbed will be obtained by linking information from the cobas Liat analyzer with data from the patient's computerized medical record in primary care. We will demonstrate the feasibility of reporting antimicrobial stewardship and severe outcomes postinfection. Severe outcomes postinfection such as hospitalization and mortality will be obtained by linking the patient's primary care computerized medical record to secondary care records at the national level including hospitalization and mortality data. A recent study used a linked cohort to study severe outcomes from COVID-19 infection [25].

Virtual Recruitment of Eligible Patients and Home Swabbing of Recruited Patients

We envisage that the majority of eligible patients will be seen face-to-face for this study. Where the eligible patient is not able to attend the practice in person, they will be told about the study remotely, and verbal consent will be taken.

A home swabbing kit will be sent to consented patients who are not able to attend the practice in person. This will include a nasal swab and instructions on how to take a self-test. Further details of our patients self-swabbing at home service have been previously published [26]. Once the nasal swab has been taken, the patient will be asked to place the swab in the included transport container with the manufacturer-approved universal transport media or viral transport media and inform the study practice staff who will arrange collection of the swab sample within 4 hours of being taken for immediate POCT.

Clinical Workflow Integration

Data regarding the utility of the influenza POCT in primary care and the issues and barriers to implementation of influenza POCT in primary care workflows will be collected by ethnographic observation of study practices and by a semistructured survey of clinicians and practice staff at the participating practices. Information will be collected about the following domains previously found to be important to implementation of POCT sampling [27]: usability of the POCT platform, clinical pathways and training, result reporting, clinical governance, costs, monitoring of effectiveness.

The ethnographic observations, semistructured survey, and reported POCT results will be used to assess which practices were more successful at integrating POCTs into their practice processes by comparing business process models of the practices. Business process models are graphical representations of business-oriented processes within an organization. This is helpful to model collaborations and business transactions within health systems. Business processes are typically modeled using Business Process Modeling Notation (BPMN). BPMN can be used to depict the end-to-end flow of a business process. The notation has been specifically designed to coordinate the sequence of processes and the messages that flow between different process participants in a related set of business activities [28,29].

Sample Size Calculation

The primary outcome measure is the proportion of consultations for RTI with all antibiotics prescribed during the winter season. We aim to detect a difference of ≤7% in the proportion of consultations for RTI in which antibiotics were prescribed, which is what we found previously between practices using POCT and the rest of the RCGP network [14,15]. We have assumed that the coefficient of variation between practices within the sentinel network, for the proportion of consultations with antibiotics prescribed, is 0.23 from Ashworth et al [11] with an α of .05 and a power of 80%. To detect a 5% difference in the proportion of consultations at which antibiotics are prescribed, we would need to sample 1023 people with ILI or ARI.

Previous swabbing rates across the network have averaged 6 swabs per practice per week in previous years. Given 10 practices swabbing a maximum of 3 swabs per week for 36 weeks, we would expect to collect up to 1000 face-to-face nasopharyngeal swabs from eligible people with ILI or ARI over the course of the study.

Statistical Methods

We will undertake descriptive analysis of the swabbing rates and swab positivity rates from the study practices. This includes

XSL•FO
RenderX

analysis of the demographic and clinical characteristics of those presenting with RTI symptoms and those with confirmed influenza infections in primary care. We will also report the number of patients who have also undertaken swabbing for reference laboratory analysis in addition to POCT testing in study practices. In those study practices that also take part in virological surveillance, these reference laboratory swabs are reported to the UKHSA as part of national disease surveillance.

To answer our primary objective, we will calculate the crude odds of antimicrobial prescribing (all antibiotics and all antivirals regardless of type), given a POCT diagnosis of influenza is the probability of antimicrobial prescribing given a particular POCT test result. We will record whether the antimicrobials were given within 7 days of the POCT diagnosis or within 30 days of diagnosis. We will calculate the crude odds ratio by dividing the odds of antimicrobial prescribing in people who receive a positive influenza POCT result by the odds in people who receive a negative test result.

We will also calculate the adjusted odds ratio using a logistic regression model. We will use the following set of covariates that are known to be associated with the severity of influenza and are collected from the routine data extracted from the electronic health record: age, sex, ethnicity (reported in 5 categories: White, Asian, Black, other, or mixed; maximized using an ontology [30]), socioeconomic status (measured using the index of multiple deprivation [31], which is a nationally available measure assigned based on post code), any of these chronic underlying conditions (chronic pulmonary disease, cardiovascular disease, diabetes, liver disease, renal disease, neurologic or neuromuscular conditions, treatment-induced immunosuppression, and disease-induced immunosuppression), number of GP visits in the 12 months prior to the study period describing a study participant's health care–seeking behavior, number of hospitalizations in the 12 months prior to the study period (used as proxy for the severity of the chronic conditions), influenza vaccination in previous influenza seasons (at least one), pregnancy, use of influenza antivirals, and pneumococcal and COVID-19 vaccination status.

To answer our secondary objective, we will select a matched set of practices from the rest of the English national sentinel network based on practice size, average age of registered patients, proportion of registered female patients, and number of GPs employed during the study.

The rates of hospital referrals and deaths related to influenza infection within 30 days of diagnosis will be compared between PIAMS study practices and the rest of the network using the ANOVA test.

Ethical Considerations

The study was approved by the English National Research Ethics Committees (Integrated Research Application System reference: 292961; REC reference: 21/YH/0077).

A practice GP or research nurse will undertake informed consent. This person will be suitably qualified and experienced and have been authorized to do so by the principal investigator. Once an eligible patient is identified, they or their parent or legal guardian will be approached by a practice GP or research nurse. Written and verbal versions of the participant information and informed consent will be presented to the patient or their parent or legal guardian detailing no less than the exact nature of the study, what it will involve for the participant, the implications and constraints of the protocol, and the known side effects and any risks involved in taking part. It will also be clearly stated that the participant is free to withdraw from the study at any time for any reason without prejudice to future care, without affecting their legal rights, and with no obligation to give a reason for withdrawal.

The patient will be allowed as much time as wished to consider the information and provided the opportunity to question the investigator, their GP, or other independent parties to decide whether they will participate in the study. Written informed consent will then be obtained by means of a dated signature and the dated signature of the person who presented and obtained the informed consent. A copy of the signed informed consent will be given to the participant. The original signed form will be retained at the study site.

When the eligible patient is not able to attend the practice in person, they will be told about the study remotely by a trained GP or nurse. The trained GP or nurse will go through the remote consent form with the participant over the phone. Once the participant has provided verbal consent to take part in the study, the researcher will sign a copy of the remote consent form and will provide the participant with a copy via a secure method such as NHS email. The patient will then be sent a swab to take at home and return to the practice within 4 hours of being taken for immediate POCT. Collection of the sample will be arranged by study staff.

For the ethnographic observations, we will verbally inform and orally consent the clinicians, a PIAMS researcher will record the consent process by completing a Record of Consent Form and the form will be signed in the presence of the participant to confirm oral consent. We will also provide information about the PIAMS study on practice posters to notify the patients about the observation activities associated with the nested qualitative study. Their consent will be implied by not opting out. A PIAMS researcher will be available to answer any questions they may have about observations undertaken for the nested qualitative study. Both clinicians and patients have the right to withdraw from participation or to decline to participate at any time without reason.

For the semistructured questionnaire, all survey respondents will complete an informed consent question embedded at the beginning of the anonymous questionnaire. If the participants answer "YES" to the first question of the form, this will imply their consent to participate, and the survey will begin. If the participants answer "NO" to the informed consent question, they will directly exit the current page. No participant will be forced to participate in the survey, and their participation will be based on their agreement, which can be withdrawn at any time.

Pseudonymized information about swab samples from consented patients, including participant ID, site ID, and swab result, will be stored in the POCT machines. These data will be extracted weekly from the machines and sent via an encrypted email to

XSL•FO
RenderX

the study team to be stored in the research group's secure network.

Data from study practice medical records will be extracted twice weekly from information systems of the RCGP RSC practices by Apollo, part of Wellbeing Software. These records are pseudonymized as close to the source as possible by Apollo using a nonreversible "hash" algorithm. Patients who decline to share their data are excluded from the extraction process.

Data for the study are held on dedicated secure servers at the RCGP data and analytics hub in the Clinical Informatics and Health Outcomes Research Group, University of Oxford. The research group's secure network is located behind a firewall within the university's network; all in-bounded connections are blocked, but out-bounded connections are allowed. Only staff members or associated members of the research group approved by the head of department can access the data from secure workstations or secure laptops with encrypted drive. All staff members of the research group working within the team base work from secure workstations or secure laptops with encrypted drive within the research group's secure network. The use of personal equipment is not permitted and cannot be connected to the secure network. A risk assessment of the physical security of the research group's offices and server room has been conducted by the building and facilities manager, the faculty information technology (IT) service manager, and the research group's information governance lead.

Survey data for the nested qualitative substudy are securely collected using Jisc (online surveys). The university has a license agreement to use this service and has recommended the service for gathering confidential data. Extraction of the survey data is only available to people with a registered Jisc account, which the university has to approve. Only authorized study researchers will be able to export survey data once logged in to Jisc. Once survey data are extracted, the data will be stored within the secure Oxford-RCGP Clinical Informatics Digital Hub (ORCHID) network. Access to your data is strictly controlled. Only authorized study researchers will have access to only pseudonymized research data from within the aforementioned secure ORCHID network.

The university is compliant with the Data Protection Act and UK GDPR and has systems for technical and organizational controls for information security, including a university-level Information Security and Governance Group chaired by the university senior information risk owner. The research group's private network has its own system-level security policy and is tested for vulnerabilities annually.

Study practices are provided with a fee for participating in this study to cover the costs of training staff and hosting the study. A small remuneration is also provided to practices for each swab taken to cover the additional time taken during each consultation to undertake swabbing for this study. Patients are not remunerated for taking part in this study.

Results

The study started in December 2022, and we expect to complete the final analysis for the study by June 2023.

Baseline Data From the English National Sentinel Surveillance Network

In terms of context for this study, currently, the English national sentinel network had grown from just over 500 practices in 2019 to 1879 practices by October 2021. This represents 28.6% of English primary care practices and 31% of the population (N=17,560,196). The sentinel network's population was found to be broadly representative of the national population in terms of age, gender, ethnicity, NHS Region, socioeconomic status, obesity, and smoking habit [19].

Latest data from across the sentinel network, between October 2020 and October 2021, show that practices have collected >8000 virology swab samples for reference laboratory testing [19]. Figure 1 and Table 1 show the latest virology swab positivity by week in the English national sentinel surveillance network prior to the start of the study.

Protocol Amendments

Important protocol amendments will be referred to the English National Research Ethics Committees for ethical approval. Once approved, changes will be communicated directly with the recruiting study practices. The amended protocol will be shared with all relevant parties (eg, investigators and clinical research networks) in a timely manner.

Discussion

Overview

This study will generate data on the impact of POCT testing for influenza in primary care, especially information on its impact on antimicrobial prescribing. Additionally, the study will describe severe outcomes postinfection (hospitalization and mortality) and how POCT is integrated into primary care workflows.

It will be a chance to revisit questions about the feasibility of implementing rapid diagnosis of influenza following the end of widespread national testing for SARS-CoV-2 and other RTIs in the United Kingdom and previous studies about its promising impacts prepandemic [14-16].

Limitations

The nonrandomized design is a limitation of our study. However, we feel that there is still value in examining the objectives within this study using a mixed methods approach as there are many questions about the challenges and barriers to implementation of rapid diagnostic testing in primary care, including the variability of adoption in different practices that are important to understand [15]. Unpacking these factors using a mixed methods design will be important to design a successful experimental study at scale to answer questions related to health outcomes. Additionally, information about influenza subtype is not available from the POCT machines used in this study and will restrict interpretation of our results, especially for calculating influenza vaccine effectiveness. A possible solution to this would have been to ask study practices to send their swabs to the national reference laboratory for additional analysis. However, this would have introduced a further step in the testing procedure in the clinic, which may have increased the risk of

XSL•FO
RenderX

aerosol generation. Given that the study was originally proposed during the COVID-19 pandemic, we felt it was important to minimize the risk of generating aerosol droplets and thus did not include this in the study.

Strengths

A strength of the study is that it is conducted among practices that are nested in the RCGP RSC English sentinel surveillance network and had also been involved in POCT sampling in previous years. This ensured that practice staff had experience with using rapid diagnostic machines, minimizing the number of spoiled samples. It will also allow comparisons of the performance of practices using POCT for influenza testing with other practices in the sentinel network that participate in the usual virology sampling program conducted by the UKHSA.

Conclusion

Building on previous work showing the promising impacts of rapid, near-patient testing on antimicrobial use in primary care within the context of a prepandemic health service, this study will help inform about the feasibility of incorporating POCT into primary care workflows. It will inform the design of future larger studies about the effectiveness and cost-effectiveness of POCT to improve antimicrobial stewardship and any impact on severe outcomes.

Acknowledgments

We acknowledge Professor Maria Zambon from the UK Health Security Agency for her advice about the use of point-of-care testing in the National Health Service. We also acknowledge the participating practices for sharing data and patients and their parents or carers for volunteering to participate in this study as well as In Practice Systems and Wellbeing for their collaboration with pseudonymized data extraction. We thank Elissa Robbins, Karen Gilliam, Susie Ochoa, and Babar Javed from Roche Diagnostics for the scientific discussions regarding the design of the study protocol and their support in undertaking this study.

This collaborative study is funded by Roche Diagnostics through an investigator-initiated grant. The manuscript was also reviewed by Roche Diagnostics before submission.

The University of Oxford sponsored this study and reviewed and proposed edits to the study protocol and study documents prior to submission for ethics approval. The Nuffield Department of Primary Care Health Sciences, University of Oxford is the coordinating center.

Data Availability

Data cannot be shared publicly because the data are owned by the Oxford Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC) and its participating practices. Data are available from the University of Oxford Institutional Data Access Committee (contact via ku.ca.xo.chp@nanigsuled.nomis) for researchers who meet the criteria for access to confidential data. The data underlying the results presented in the study are available from [32]. Further enquiries about the RCGP RSC network and data requests can be found at [33] or by emailing ku.ca.xo.chp@seiriuqneecitcarp.

Authors' Contributions

UH, AW, JS, CA, EB, JM, ML, CXX, and SdL contributed to the planning of the study. UH, AW, JS, CA, EB, JM, CO, RB, FF, ML, CXX, MJ, GM, TC, and SdL contributed to the reporting of the study protocol and to the conduct of the study to date.

Conflicts of Interest

SdL is director of the Oxford Royal College of General Practitioners Research and Surveillance Centre. Through his university, he has received funding for vaccine-related research from AstraZeneca, GSK, Sanofi, Seqirus, and Takeda; he has been a member of advisory boards for AstraZeneca, Sanofi, and Seqirus. UH has undertaken continuing professional development podcasts funded by Seqirus and has been a member of advisory boards for Janssen. TC has received grant funding and/or equipment and consumables free of charge for the purposes of independent research from BioFire diagnostics, Biomerieux, QIAGEN and Sherlock Biosciences. They have received speaker fees, honoraria and travel re-imbursement from BioFire diagnostics, BioMerieux, QIAGEN and Janssen. TC has also received consultancy fees from BioMerieux, QIAGEN, Cepheid, Roche, Janssen and Synairgen research. TC has been a member of advisory boards for Cepheid, Roche, Janssen, Shiongi, Sanofi and Seqirus and acted as a member of independent data monitoring committees for trials sponsored by Roche and received remuneration at fair market value for these services. TS is also a member of an independent data monitoring committee for a Roche-sponsored study.

Abstract

Background: Between 10% and 20% of people with a COVID-19 infection will develop the so-called *long COVID syndrome*, which is characterized by fluctuating symptoms. Long COVID has a high impact on the quality of life of affected people, who often feel abandoned by the health care system and are demanding new tools to help them manage their symptoms. New digital monitoring solutions could allow them to visualize the evolution of their symptoms and could be tools to communicate with health care professionals (HCPs). The use of voice and vocal biomarkers could facilitate the accurate and objective monitoring of persisting and fluctuating symptoms. However, to assess the needs and ensure acceptance of this innovative approach by its potential users—people with persisting COVID-19–related symptoms, with or without a long COVID diagnosis, and HCPs involved in long COVID care—it is crucial to include them in the entire development process.

Objective: In the UpcomingVoice study, we aimed to define the most relevant aspects of daily life that people with long COVID would like to be improved, assess how the use of voice and vocal biomarkers could be a potential solution to help them, and determine the general specifications and specific items of a digital health solution to monitor long COVID symptoms using vocal biomarkers with its end users.

Methods: UpcomingVoice is a cross-sectional mixed methods study and consists of a quantitative web-based survey followed by a qualitative phase based on semistructured individual interviews and focus groups. People with long COVID and HCPs in charge of patients with long COVID will be invited to participate in this fully web-based study. The quantitative data collected from the survey will be analyzed using descriptive statistics. Qualitative data from the individual interviews and the focus groups will be transcribed and analyzed using a thematic analysis approach.

Results: The study was approved by the National Research Ethics Committee of Luxembourg (number 202208/04) in August 2022 and started in October 2022 with the launch of the web-based survey. Data collection will be completed in September 2023, and the results will be published in 2024.

Conclusions: This mixed methods study will identify the needs of people affected by long COVID in their daily lives and describe the main symptoms or problems that would need to be monitored and improved. We will determine how using voice and vocal biomarkers could meet these needs and codevelop a tailored voice-based digital health solution with its future end

users. This project will contribute to improving the quality of life and care of people with long COVID. The potential transferability to other diseases will be explored, which will contribute to the deployment of vocal biomarkers in general.

Introduction

Context

COVID-19 and Long COVID

The novel SARS-CoV-2 infected >532 million people and caused >6.3 million deaths worldwide as of June 2022 [1].

COVID-19 initial infection can take several forms, from asymptomatic to moderate or severe illness. Common symptoms are fever, cough, dyspnea, fatigue, loss of taste or smell, and gastrointestinal symptoms. Complications include acute respiratory distress syndrome, anemia, or acute cardiac injury [2].

After the acute phase, some people with COVID-19 develop a so-called *long COVID* or *post-COVID condition*. The World Health Organization's definition of this condition is as follows: "Post-COVID-19 condition occurs in individuals with a history of probable or confirmed SARS-CoV-2 infection, usually 3 months from the onset of COVID-19 with symptoms that last for at least 2 months and cannot be explained by an alternative diagnosis. Common symptoms include fatigue, shortness of breath, and cognitive dysfunction but also others that generally have an impact on everyday functioning. Symptoms may be new onset, following initial recovery from an acute COVID-19 episode, or persist from the initial illness. Symptoms may also fluctuate or relapse over time" [3,4].

It has been estimated that a mean of 10% to 20% of patients with COVID-19, representing millions of people worldwide, will have persisting or relapsing symptoms >12 weeks after acute infection [5] with complaints such as tachycardia, extreme fatigue, or dyspnea as observed by Rubin [6]. In Luxembourg, we showed that 59% of COVID-19–infected people included in the Predi-COVID cohort study, who completed a detailed 1-year questionnaire, still declared 1 or more persisting symptoms. The number of persisting symptoms increased with the initial disease severity, and the quality of life of these participants was highly affected by sleep disorders (54%) and altered respiratory quality of life (12.9%) [7].

The COVID-19 pandemic accelerated the use of remote patient monitoring in clinical practice or research for safety and emergency reasons, justifying the need for innovative digital health solutions to monitor key parameters or symptoms related to COVID-19 or long COVID. A panel of experts from the National Institute for Health and Care Excellence recommended the development of telemonitoring and encouraged self-management of acute and long COVID symptoms in a tailored and accessible way for each patient [8].

Although long COVID is now a recognized illness in many countries, few dedicated consultations exist, and the awareness and scientific knowledge of this disease are still poor among not only the general population but also general practitioners. For these reasons, many people experiencing persisting symptoms after a COVID-19 infection (confirmed or not) may feel abandoned by or lost in the health care system, with difficulties in obtaining a long COVID diagnosis or obtaining specific support, and there is a demand among them for new monitoring solutions to objectify the symptom evolution and identify causes of symptom degradation. Moreover, people with long COVID experience difficulties in performing daily physical tasks, and many of them cannot engage in the same levels of activity or work as before [9].

Vocal Biomarkers of COVID-19 Symptoms

Using voice is an interesting approach for telemonitoring, as it is easy to collect, quick, and energy efficient, inducing less fatigue on the patients. Moreover, the use of voice-based technologies is increasing swiftly; in 2019, 31% of smartphone users worldwide used voice technology at least once a week, and 20% of queries on Google's mobile app and Android devices were voice searches [10].

Voice is a rich source of health-related information, as many voice features can be related to symptoms or health status [11-14]. In addition, because voice analysis involves highly complex methods for processing audio features, this kind of development might also be capable of detecting subtle changes associated with COVID-19 symptoms [10].

For example, voice features have previously been associated with a COVID-19 infection or a consequence of COVID-19 infection [15,16]. COVID-19 infection or complications can affect the voice through different mechanisms. Indeed, respiratory insufficiency can lead to reduced airflow and thus to changes in voice parameters. Other studies showed that voice quality was reduced in patients with COVID-19 owing to repeated cough, laryngeal or pharyngeal erythema, or sore throat [17-19].

In Luxembourg, participants from the Predi-COVID hybrid prospective cohort study were invited to perform voice recordings at the same time as they completed web-based questionnaires regarding their symptoms and health status. To date, almost 6000 voice recordings from more than >500 patients with COVID-19 have already been collected in the Predi-COVID study [2]. These voice recordings have been

XSL•FO
RenderX

analyzed, and promising vocal biomarker candidates for fatigue, loss of taste and smell, and symptomatic status in people with a COVID-19 infection have already been identified [20-22].

The question now is to determine how these vocal biomarkers could help and improve the quality of life of people with long COVID and how they could be implemented in a digital health solution such as a smartphone app. For example, people with COVID-19 or long COVID symptoms could record their voice in real-life settings by following basic instructions such as "read a pre-defined text, count from 1 to 20, or say a vowel as long as possible," and the app would analyze voice features and give them back a result for one or several vocal biomarkers. Importantly, to ensure that the developed digital solution using vocal biomarkers is meaningful and useful for the patients, our study involves them at an early stage together with health care professionals (HCPs).

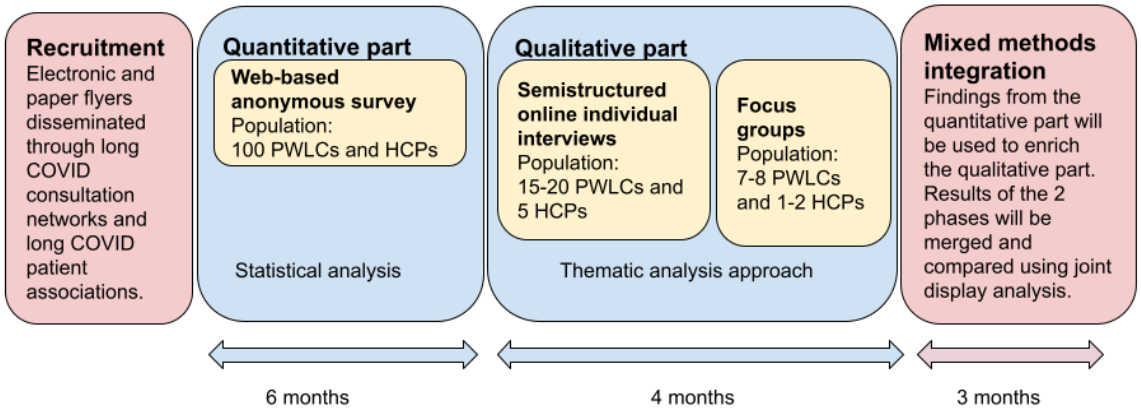
Objectives

The UpcomingVoice project aims to co-design a voice-based digital health solution for screening and self-monitoring of frequently reported COVID-19–related symptoms with its end users, namely, (1) people with persisting COVID-19–related symptoms, with or without a long COVID diagnosis confirmed by an HCP, and (2) HCPs involved in the care of people with long COVID. The goal of this study is to develop a digital health solution that really matters and helps people with long COVID in their daily lives and could be a complementary support in addition to the medical care that they could benefit from.

To achieve this main objective, the UpcomingVoice study will (1) explore the impact of long COVID in the everyday lives of people with long COVID and the needs of people with long COVID to improve their quality of life and manage their symptoms; (2) explore the extent to which the use of voice and, in particular, vocal biomarkers could propose a solution to the patient's needs (ie, we will investigate the expectancies, acceptability, fears, barriers, and leverages regarding using voice to self-monitor or screen for long COVID symptoms); and (3) define the specifications that such a mobile app should meet so that it could be recommended to patients by HCPs and be considered acceptable and useful by its intended users in terms of technological aspects (ie, type of device, type of voice recordings, etc), frequency of use, design, etc.

As a secondary aim, we will also assess the transferability potential of the results of this study in the context of COVID-19 to other diseases (eg, monitoring fatigue could also be used in the context of cancer).

Methods



Study Design

This cross-sectional study is based on a mixed method sequential explanatory design. It consists of 2 successive phases: a quantitative phase (descriptive approach), followed by a qualitative phase (inductive pragmatic approach). The study design is summarized in Figure 1. The research questions addressed in the 2 phases of the study are listed in Table 1.

A conceptual framework of the key areas of daily functioning will be elaborated based on the literature review, the survey, and individual interview results as previously described [23], and the framework will be used to identify the most relevant use cases of the digital health solution. The general design of the digital health solution will be defined using the survey results, and its specific items and response modalities will be further elaborated during the qualitative phase.

To study the transferability potential of the digital health solution that will be developed, we will provide an extensive description of our study population and their daily life concerns to identify other populations, diseases, or conditions with similar characteristics (in terms of impact on quality of life, main symptoms, and intensity of symptoms) that could also benefit from a voice-based technology. Subsequently, we will use the APEASE (Affordability, Practicability, Effectiveness, Acceptability, Side Effects, and Equity) criteria and other relevant checklists previously described for the evaluation of transferability of health technology assessments [24,25] to assess the potential transferability of each use case or the main characteristics of the solution identified in the 2 phases of the study to the other fields.

Phase 1 (Quantitative)

The first phase, the quantitative phase, consists of a web-based anonymous survey.

The objective of this survey is to define the main aspects of daily life impacted by long COVID and the needs of people with long COVID and to assess the acceptability and expectancy toward the use of vocal biomarkers for the symptom monitoring of long COVID. The general outline of the digital health solution based on vocal biomarkers will be defined based on these results.

The following dimensions adapted from the user version of the Mobile Application Rating Scale (uMARS) [26] will be covered by different questions: engagement, functionality, aesthetics, information, and subjective items ("Would you recommend," "Would you be interested in," etc).

People With Long COVID

In addition to the above-mentioned items, the survey for people with long COVID has been designed to further identify the most impairing symptoms for their quality of life, to assess whether the severity of their initial infection or of their long COVID symptoms or their vaccination status has an impact on their opinions and needs regarding a new health technology based on voice, and to assess how the use of vocal biomarkers could be of interest for the management of their symptoms. The detailed questionnaire for people with long COVID is provided in Multimedia Appendix 1.

HCP Survey

The HCP survey is focused on assessing the needs of their patients with long COVID in their daily lives and how they foresee the use of vocal biomarkers of long COVID symptoms in the management of their patients and in the health care system. The detailed HCP questionnaire is provided in Multimedia Appendix 2. Completing the survey will take a maximum of 20 minutes to ensure a high acceptability rate, particularly in people with long COVID who frequently experience fatigue and trouble concentrating. The participants are expected to complete the survey once.

Web-based survey data will be collected and managed using REDCap (Research Electronic Data Capture; Vanderbilt University) tools hosted at the Luxembourg Institute of Health (LIH) [27].

Phase 2 (Qualitative)

The second phase is based on qualitative methods and consists of semistructured individual interviews and focus groups. Participants in this phase will have either participated in the web-based survey or not.

Individual interviews will be conducted to deeply understand the impact of long COVID on daily life, the needs of people with long COVID, and the potential interest in using vocal biomarkers to meet these needs, and define use cases for the digital health solution. The maximum duration for the interview will be 60 minutes.

Following the individual interviews, 2 successive focus groups (maximum duration of 90 minutes) will be organized with a panel comprising people with long COVID and HCPs. During the first focus group, the objective is to present 1 or 2 prototypes of the digital health solution and to collect users' comments and suggestions. The prototype or prototypes will be improved according to the collected comments and validated during the interaction with the second focus group.

The individual interview and focus group guides will be elaborated based on the insights obtained from the survey in phase 1. The questions will be asked in a general manner to ensure the identification of the most relevant aspects for people with long COVID in their daily lives and to minimize the expectancy and confirmatory bias.

Using teleconferencing software, interviews and focus groups will be conducted by a qualified interviewer and a moderator, respectively, both trained in qualitative methods.

Patient Public Involvement

The INVOLVE recommendations [28] will be followed to involve people with long COVID and HCPs in the most efficient way during the entire course of the project. First, we contacted a representative of a long COVID association and an HCP in charge of people with long COVID and presented them with the study aims and the participation procedures. They were then invited to review the study protocol, participant documents, and questionnaires before the study implementation.

Second, we will also follow the framework of core principles for selecting and developing measurements in digital health developed by Manta et al [29]. The 4 levels of this framework to evaluate the meaningfulness of digital biomarkers for patients are the Meaningful Aspect of Health, the Concept of Interest, the Outcome to be measured, and the End point.

In this perspective, the UpcomingVoice study design is a co-design process that will continuously involve patients with long COVID and HCPs.

At each step, the participants will receive feedback on the results from the previous step: during individual interviews, feedback on survey results will be given, and during the first focus group, results from the individual interviews will be provided and discussed.

Finally, participants with long COVID and HCPs willing to be even more deeply involved in our research will be invited to coauthor the scientific articles presenting the results of this research and to promote the results of the study to the lay audience.

XSL•FO
RenderX

Study Participants

Inclusion Criteria

Participation in the study will be proposed to adults (men and women) with persisting COVID-19–related symptoms, with or without a long COVID diagnosis, and to HCPs in charge of patients with long COVID (doctors, nurses, psychologists, physiotherapists, etc).

All participants must be aged >18 years, have a sufficient level of speaking and comprehension in French, and have internet access to participate in the web-based survey and the web-based individual interviews and focus groups.

Seeking a representative sample of people is not part of qualitative research aims [30]; however, to increase the variations in our study population, the inclusions in the qualitative phase will be monitored to obtain an equal representation of different age and gender categories.

Recruitment and Enrollment

Before starting each part of the study, pilot phases will be performed to correct potential technical issues and ensure that the time for the completion of the survey and the interviews and focus groups do not exceed the expected duration (20 minutes for the survey and 60 and 90 minutes for individual interviews and focus groups, respectively).

The recruitment of participants will be based on electronic and paper flyers disseminated via social media, long COVID consultations, and long COVID patient associations in Luxembourg and neighboring countries (eg, France). Participation will also be proposed to participants from the Predi-COVID cohort study [2] who declared persisting symptoms at 1 year.

Flyers present information about the study and contain a direct link to the web-based survey so that interested persons can directly participate. The contact details of the study assistant at the LIH are also provided so that people can contact her directly if they are interested in participating in the qualitative part of the study.

People who expressed their interest in participating in the second part of the study, either after the survey completion or by contacting us directly, will be contacted by the study assistant. The study assistant will provide additional information regarding the second part of the project, and if the person confirms his or her interest in participating, an electronic ethical information notice and consent form will be sent to the participant. After signing the electronic consent form, the participant will be able to download a copy of the document. The study assistant will contact him or her to organize the individual interview. Electronic informed consent will be obtained before any data collection for the second part of the study.

Once the study assistant has received the notification that the participant has a valid signed consent, they will contact her or him to organize the web-based individual interview.

When all the individual interviews are completed, a panel comprising 7 to 8 people with long COVID and 1 to 2 HCPs will be constituted among the participants who expressed their willingness to participate in the focus group sessions.

When all individual interviews and focus groups are conducted, a restitution meeting will be organized. Everyone who has expressed an interest in this project will be invited.

Sample Size Calculation

For the quantitative part of the study, a formal size calculation was not feasible, given the exploratory nature of the study. The quantitative data from the survey will be exclusively used for descriptive purposes and to evaluate the different topics' importance for the participants.

For the qualitative part, no gold standard for the "right" sample size exists and depends closely on the nature and aims of the study [31]. Qualitative studies do not aim to estimate magnitudes or generalize the results to a larger population but evaluate patterns in a data set. Participants will be sampled until data saturation is reached, which can be formalized as the point at which new data repeat what were already collected [32,33]. A recent systematic review showed that data saturation was achieved with a mean of 9 to 17 interviews but with high disparities between studies [34]. The ideal size for focus groups is estimated to be between 6 and 10 persons, particularly when including participants with high knowledge of the problem, which is the case for people with long COVID and HCPs [35].

To achieve data saturation, at least 15 people with long COVID and 5 HCPs involved in the management of patients with long COVID will participate in the individual semistructured interviews. However, these are estimations, and we will recruit participants until data saturation is reached.

A maximum of 7 to 8 people with long COVID and 1 to 2 HCPs will participate in 2 successive focus groups with an iterative co-design objective. Participants in the focus groups may be the same as those in the individual part, but this is not mandatory.

Data Analysis

Phase 1: Quantitative Part

Quantitative data from the web-based survey will be analyzed using descriptive statistics methods. Continuous variables will be presented as means with SDs. Discrete numeric variables and ordinal variables will be presented as medians with IQRs. Nominal and categorical variables will be presented as proportions. Standard statistical methods will be followed.

Phase 2: Qualitative Part

Qualitative data from the semistructured interviews and focus groups will be audio recorded and transcribed verbatim. Transcripts will be checked for accuracy to ensure data quality and analyzed by using the thematic analysis approach [36]. This is the most commonly used method in qualitative research and allows one to identify, analyze, and report patterns within the data through the following five major steps:

1. Compiling: during this step, the recorded interviews are transcribed and organized.

XSL•FO
RenderX

2. Disassembling to allow for the creation of meaningful codes by identifying themes, concepts, or ideas. The coding process will be iterative and based on grounded theory [37].
3. Reassembling to further dive into the themes and creating subthemes. The coding process will be iterative until saturation.
4. Interpreting: thematic maps or code clusters will be created to analyze the relationship between the themes and thus answer the research question.
5. Concluding: conclusions are not generalizable to the population; they are merely an analytical generalization—a guide to assess how the findings can be transferred and applied. Indeed, qualitative research typically aims for in-depth understanding rather than statistical generalizability.

The MAXQDA software (VERBI Software GmbH) will be used for the transcription of the audio files, for coding and qualitative analysis.

Data analysis will be performed by the study investigators. In particular, coding will be performed by 2 researchers, including an experienced qualitative researcher.

On the basis of the data, the codes and the overall coding structure will be created by the researchers themselves, which is justified because the analysis will be based on grounded theory. Common themes and subthemes from the qualitative data will be identified using a thematic analysis. The first step will be performing coding from scratch. To facilitate coding, we will also create memos. We will clearly define each code that both researchers should approve. The 2 researchers will also have regular meetings to decide whether to merge or exclude codes (data reduction). The themes will be created by grouping similar codes. Subsequently, each theme will be revised to ensure a good definition that aligns with the required codes and to avoid redundancy or missing themes. In addition, we will define themes automatically, using nonsupervised machine learning algorithms (natural language processing using topic modelling R package [R Foundation for Statistical Computing]).

We will assess the intercoder reliability by double-blinded coding performed by 2 independent researchers. The Intercoder Agreement function from the MAXQDA software will be used to compare the coding of the 2 researchers involved in the coding process.

Mixed Methods Integration and Analysis

The integration of the quantitative and qualitative data will be done twice. First, in the design of the qualitative phase of the study: the findings from the quantitative phase will be used to develop the semistructured interview guide that is to be used for the qualitative phase. In particular, the most important topics raised by the survey will be addressed first in the discussions.

Second, after the end of the qualitative phase, the results from the 2 phases will be integrated to triangulate the findings.

Ethics Approval, Informed Consent, and Participation

This study was approved by the National Research Ethics Committee of Luxembourg (study number 202208/04) in August 2022. Interested persons can participate either in the 2 parts of the project or only in 1 part.

In the first part (quantitative web-based survey), each person who receives the link can participate. Detailed information on the survey is provided before acceding to the survey. Informed consent is not required, as this part is anonymous.

An extensive electronic information and informed consent form will be sent to people interested in participating in the qualitative part of the study. Electronically signed informed consent will be collected before any data collection for the second part of the study. REDCap will be used to manage the electronic consent forms.

Participants enrolled in the qualitative part may terminate their participation at any time by contacting the study assistant, and they will not be required to provide reasons for the decision. The assistant will complete the withdrawal form for our own records to ensure that the participant has declared whether LIH may continue to use the information that was already collected or if it should be destroyed (if applicable).

Participation in the individual interviews and the focus groups may tire some participants, particularly people with long COVID. To prevent this risk, regular pauses will be proposed during the interviews and focus groups, and the maximum duration of 60 and 90 minutes, respectively, will be strictly respected. The interviewer and the moderator will be the investigators trained in qualitative research methods and confidentiality.

There will be no financial incentive for participation in one or both parts of the study. Participants will be informed that they will not have any direct benefit but will contribute to a research effort that could make an impact not only in the care of patients with long COVID but also that of patients with other chronic diseases in the following years.

Data Management—Confidentiality

The personal data of participants will be protected according to the *Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation)*. The participants will receive detailed information on data privacy and protection in the information sheets from both parts of the study. In particular, they will be informed of how the data will be collected and stored, what security measures will be in place, and who will be authorized to access the data. They will also be asked to give their consent for the potential secondary use of their data for other research projects and will be informed that in case they agree, only their anonymized data will be shared with other researchers. Participants in the anonymous survey will be informed that their data will potentially be used for other research studies and shared with other researchers. The participants will be informed that they can contact the institution's data protection officer if they have questions related to data privacy and protection. The contact details of the data protection officer are provided in the electronic information and consent form.

XSL•FO
RenderX

The survey will be anonymous and accessible by following a direct link to the web-based survey platforms (no application to download).

No account, log-in, or password will have to be created by the participants. There will be no link between the email addresses collected after the survey completion from people interested in the second part of the study and the survey answers.

The data collected from the qualitative part will be pseudonymized. Participants who express their interest in participating in the second part of the project will receive a unique link to access the electronic consent form. After the completion of the electronic consent form, a unique study number will be assigned to them.

Data collected during the individual interviews and focus groups will never be linked to a participant's name or email address. A nickname will be used to refer to each participant during the exchanges. Interviews and focus groups will be recorded and transcribed using a transcription tool. All records will be destroyed directly after the transcription. The interviewer will be responsible for audio transcription and destruction.

The nominative data collected via the consent form will be stored on LIH internal servers, separated from the pseudonymized data from the interviews and focus group notes. All data stored on the LIH servers will be encrypted using the Transport Layer Security (TLS) encryption protocol. Access to the data will be restricted by user accounts and will be provided by the principal investigator of the study to a limited number of people. Access logs will be implemented to control data accesses and ensure high data security.

The contact data (email address and identification data) of the participants will be deleted 2 years after the individual interview. The pseudonymized data will be anonymized after 2 years by deleting the correspondence table and deleted after 10 years according to the LIH standard procedure for archiving.

LIH internal procedures will be followed to ensure data destruction after the retention period ends.

Results

The web-based survey was launched in October 2022. The individual interviews and focus groups will start after the end of the survey in March 2023. The end of data collection is expected in September 2023, and the results will be published at the end of 2023 or in 2024.

Discussion

This paper presents a protocol for a mixed methods study that aims to codevelop a digital health solution based on vocal biomarkers to monitor long COVID symptoms and conditions with its potential end users, namely, people with long COVID and HCPs in charge of patients with long COVID.

Expected Findings

Long COVID is a complex disease with a high impact on the daily life and quality of life of affected people [38,39]. Patients often feel abandoned by the health care system and demand for support and new tools to track their symptoms and relapses. This could be helpful to identify the potential causal factors of symptom exacerbation and relapses to improve pacing and prevention. In particular, postexertional symptom exacerbation is a well-known problem in long COVID and can be defined as the worsening of symptoms following a physical or mental activity [40]. Postexertional symptom exacerbation needs to be carefully monitored, for example, to ensure a safe rehabilitation program or to personalize the daily activities to prevent symptom degradation.

HCPs also recognize that there is a need for more integrated health care structures to manage patients with long COVID. Additional tools to ensure an efficient and safe rehabilitation would also be helpful for both people with long COVID and HCPs, as some patients with long COVID experience postexertional malaise [40] and may need a tailored rehabilitation program. Moreover, with new therapies and drugs currently in development for long COVID treatment, this tool might also be used as a companion tool to monitor the health status of people with long COVID during clinical trials.

The use of vocal biomarkers to monitor long COVID symptoms seems of high interest because voice samples are noninvasively collected and are easy to collect compared with the completion of tedious self-reported questionnaires. They could also objectify a subjective condition such as fatigue or mental health and facilitate the communication between patients and HCPs [10,41]. Moreover, audio recordings may be more adapted and accurate than traditional paper questionnaires for people with neuropsychological disorders or other patients who are chronically ill with reduced functioning [42,43].

Vocal biomarkers of several symptoms related to COVID-19 and long COVID have been identified previously and need to be integrated into a digital health solution before being used in daily life or clinical practice. We recently proposed an optimal pipeline and recommendations to achieve the successful implementation of vocal biomarkers in practice, with their potential benefits and limitations in the context of long COVID [41]. The identification of the problem and the symptoms to be monitored and the involvement of the end users as soon as possible in the development process are key points. The protocol of the study described in this paper is based on these recommendations.

The findings of this study will have several potential implications. First, we will take advantage of combining quantitative and qualitative data in a mixed methods design to describe the needs of people with long COVID in depth and understand how the use of vocal biomarkers in a voice-based digital health solution could solve their problems. The visualization of the results in the digital health solution will also be discussed and tailored to best fit its end users. The tool will be developed with an interoperability objective to ensure its future dissemination to a maximum number of people.

Second, the findings could potentially be transferred to other diseases, and this is of the highest importance for the future of vocal biomarkers and voice-based health technologies to understand the extent of transferability.

XSL•FO
RenderX

Finally, the concrete output of the study will be a voice-based digital health solution that will provide support to people with long COVID in their daily lives and improve their quality of life.

Strengths and Limitations

One of the strengths of this study is that patients with long COVID and HCPs in charge of patients with long COVID have been involved in the study design and will be involved in the entire study course.

The use of a mixed methods design, using quantitative and qualitative approaches, will provide an extensive description of the future user's expectancies, barriers, and leverages regarding the use of vocal biomarkers in a digital health solution and will provide the specifications of a digital health solution optimally designed with and for its end users.

The results will reveal the transferability potential of the use of vocal biomarkers for other diseases and contribute to the expansion of this recent technology.

This study has some limitations. First, the fully web-based format of the study may limit the participation of some population categories (such as people with low eHealth literacy) but by contrast, may also facilitate the participation of people who are geographically distant or experience more impacting symptoms.

Another potential limitation is that even if the chosen sample size should ensure achieving data saturation, it may probably not represent all different subpopulations with long COVID. However, this is not the objective of this mixed methods study. The opinions collected should be varied enough to ensure the development of a digital solution that provides help and support to all patients with long COVID.

Finally, mixing people with long COVID and HCPs in the focus groups may induce conformity, dominance, and shyness biases. However, people with long COVID are highly involved in the management of their disease and generally interact easily with HCPs. The moderator's role will also be crucial in minimizing the risks of bias during focus groups by communicating from the start the objectives of the discussions and by ensuring that each participant receives the same amount of speaking time. The cultural bias will also be reduced by the inclusion of participants from different countries.

Conclusions

This mixed methods study will identify the needs of people affected by long COVID in their daily lives and describe the main symptoms or problems that would need to be monitored and improved. We will determine how the use of vocal biomarkers in a digital health solution could meet these needs and further describe the end user's expectations and barriers regarding the use of this new digital technology to monitor COVID-19–related symptoms. Finally, our study will ensure the development of a digital health solution that will match the actual needs of people with long COVID by involving them in the design process from the beginning. The study will also provide important insights into the transferability of the results to other diseases and contribute to the deployment of vocal biomarkers in general.

Publication Plan

The study results will be disseminated at the end of 2023 in a scientific article submitted to an international peer-reviewed journal, to long COVID patient associations, and through social media communications to the lay audience.

Acknowledgments

This study is funded by the Luxembourg National Research Fund (FNR; Predi-COVID, grant 14716273) and the Luxembourg Institute of Health. The Predi-COVID study was supported by the FNR (Predi-COVID, grant 14716273), the André Losch Foundation, and the European Regional Development Fund (FEDER, convention 2018-04-026-21). The authors are thankful to all the participants of the Predi-COVID study. The authors also acknowledge the involvement of the interdisciplinary and interinstitutional study team that contributed to Predi-COVID. The full list of the Predi-COVID team can be found [44].

Data Availability

The data sets generated during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

AF, GAA, and GF contributed to the study design, literature review, and drafting of the manuscript. PO, LM, and CB contributed to the study design and reviewed the study documents. All authors read and approved the final manuscript.

Abstract

Background: Traditional longitudinal aging research involves studying the same individuals over a long period, with measurement intervals typically several years apart. App-based studies have the potential to provide new insights into life-course aging by improving the accessibility, temporal specificity, and real-world integration of data collection. We developed a new research app for iOS named Labs Without Walls to facilitate the study of life-course aging. Combined with data collected using paired smartwatches, the app collects complex data including data from one-time surveys, daily diary surveys, repeated game-like cognitive and sensory tasks, and passive health and environmental data.

Objective: The aim of this protocol is to describe the research design and methods of the Labs Without Walls study conducted between 2021 and 2023 in Australia.

Methods: Overall, 240 Australian adults will be recruited, stratified by age group (18-25, 26-35, 36-45, 46-55, 56-65, 66-75, and 76-85 years) and sex at birth (male and female). Recruitment procedures include emails to university and community networks, as well as paid and unpaid social media advertisements. Participants will be invited to complete the study onboarding either in person or remotely. Participants who select face-to-face onboarding (n=approximately 40) will be invited to complete traditional in-person cognitive and sensory assessments to be cross-validated against their app-based counterparts. Participants will be sent an Apple Watch and headphones for use during the study period. Participants will provide informed consent within the app and then begin an 8-week study protocol, which includes scheduled surveys, cognitive and sensory tasks, and passive data collection using the app and a paired watch. At the conclusion of the study period, participants will be invited to rate the acceptability and usability of the study app and watch. We hypothesize that participants will be able to successfully provide e-consent, input survey data through the Labs Without Walls app, and have passive data collected over 8 weeks; participants will rate the app and watch as user-friendly and acceptable; the app will allow for the study of daily variability in self-perceptions of age and gender; and data will allow for the cross-validation of app- and laboratory-based cognitive and sensory tasks.

Results: Recruitment began in May 2021, and data collection was completed in February 2023. The publication of preliminary results is anticipated in 2023.

Conclusions: This study will provide evidence regarding the acceptability and usability of the research app and paired watch for studying life-course aging processes on multiple timescales. The feedback obtained will be used to improve future iterations of the app, explore preliminary evidence for intraindividual variability in self-perceptions of aging and gender expression across the life span, and explore the associations between performance on app-based cognitive and sensory tests and that on similar traditional cognitive and sensory tests.

Introduction

Background

Longitudinal aging research involves studying the same individuals over a long period, typically with measurement intervals several years apart. Although this approach can inform long-term developmental processes, it cannot capture processes that fluctuate on multiple—sometimes acute—microlongitudinal timescales. This project aims to contribute to the contemporary theories of life-course aging and gender by establishing a novel methodology for examining their daily experiences, known as the Labs Without Walls research app. We seek to evaluate the feasibility and usability of the app and a paired Apple Watch (Apple Inc) for studying the microlongitudinal processes of aging among a life-course sample of Australian adults. The validity of the app-based administration of common cognitive and sensory tasks will also be explored.

Benefits of App-Based Approaches for Longitudinal Aging Research

Recent data suggest that 91% of Australians aged 18 to 75 years own a smartphone, and 58% use a smartphone or smartwatch device to monitor their health or well-being [1]. The rise in the popularity of smartphone devices has been accompanied by a commensurate rise in app-based studies of health and well-being. However, it is notable that many of these studies are designed for younger cohorts or specific clinical populations [2,3]. Few studies have examined processes that may differ across the life course [4].

App-based approaches to research offer a number of benefits for conducting longitudinal research [5] that may provide new insights into many factors that may be associated with developmental changes across the human life span, which we term *processes of life-course aging*. First and foremost, research apps remove the physical barriers to participation that are a feature of more traditional life-course aging studies. Apps can be accessed from anywhere with an internet connection, and this opens participation opportunities to adults living remotely or experiencing mobility restrictions that would otherwise prevent travel to urban research centers. Apps can be convenient for both participants and researchers, as they can allow participants to configure their testing and alert schedules to times that suit their daily routines and reduce researcher workloads associated with in-person testing sessions. Well-designed apps can also be interactive and engaging. This may be particularly important for studies that require participants to provide regular, intensive data.

Smartphones and paired wearable devices also include a range of sensors that provide new opportunities to noninvasively study complex microlongitudinal processes. For example, mobile apps can be designed to collect high-quality passive data (including physical activity metrics, heart rate, location data, and noise exposure), which can help researchers obtain more accurate and detailed data than possible using other methods. These data can be collected and integrated in real time, which can be useful for studying dynamic or rapidly changing phenomena and improving the ecological validity of research.

Finally, although substantial investment is often required in the development stage of bespoke research apps, app-based research can be a cost-effective option, as they can reduce the need for in-person research sessions and specialized equipment and leverage free-to-use open-source cognitive, sensory, and behavioral testing resources for research, such as those provided by the Apple ResearchKit framework (Apple Inc) [6].

This Study: Capturing Day-to-Day Subjective Experiences of Age and Gender

Age and gender are 2 defining characteristics used in nearly all human studies. The perceptions and expressions of each are influenced by social, biological, and environmental determinants, and people's subjective experiences of age and gender have been vastly understudied. Self-perceptions of aging (SPA) is a multidimensional construct involving the personal evaluation of age-related changes experienced in various life domains, irrespective of chronological age [7]. Subjective age is a form of SPA and refers to how young or old individuals experience themselves to be. SPA is associated with numerous health outcomes, including mortality [8], mental health [9], and functional health [10]. SPA changes over the life course. Previous research has shown that adolescents perceive themselves as older than their chronological age (age in years from the date of birth), potentially reflecting increased perceptions of maturity [11]. This changes in early adulthood, when people usually hold younger subjective ages. The discrepancy between the chronological and subjective age increases across the life span [11,12]. Life-course variability in SPA may reflect psychosocial changes experienced at different life stages; however, there is yet to be a study exploring SPA among a life-course sample. Despite strong evidence of long-term variability in SPA, limited data exist on how SPA fluctuate on microtimescales, that is, hours, days, or weeks. Existing day-to-day variability in measures of subjective age, an area of SPA, suggests fluctuations in multiple domains [13]. The measurement timescale may greatly alter the perceived relationship between variables [14] and could help elucidate intraindividual variability in SPA and the interplay between SPA and other time-varying constructs, such as mood, stress, and physical activity.

XSL•FO
RenderX

Gender, similar to many other social constructs, can change and evolve over time [15]. Gender is often conflated with sex, although they are distinct constructs. *Sex* commonly refers to a person's biological status as male, female, or another variation of sex characteristics. Indicators of biological sex can include sex chromosomes (XX and XY), hormones, internal reproductive organs, and external genitalia [16]. In research practice, sex is usually reported as male or female based on the sex recorded at birth. *Gender* is a dynamic social construct that refers to the psychological, social, and cultural factors that shape attitudes, behaviors, stereotypes, and knowledge. In research practice, gender is typically treated as a fixed, binary variable despite substantial variations in the real world [17]. Such an approach does not take into account the multidimensional nature of gender, which includes gender norms (spoken and unspoken rules within the family, community, institution, or culture), gender relations (power relations between individuals with different gender roles and identities), gender identity (how individuals and groups perceive and present themselves within specific cultures), and gender expression (the outward expression of one's gender identity, including physical and behavioral dimensions) [16], nor does such an approach allow for an understanding of gender as dynamic [15]. Indeed, gender dynamism can be seen in at least 3 aspects: the meaning of gender has changed over time; there are substantial cultural differences in the meaning of gender; and one's own gender and relationship with it can change, evolve, weaken, and galvanize across the lifetime [15]. There is also likely to be heterogeneity in gender dynamism at the individual level and between and within age and sex-at-birth groups, which has not been the subject of study to this point.

Theoretical accounts of socioemotional aging suggest that intraindividual variability in gender expression may be greatest during early adulthood—when broad social networks and diverse social interactions are used to help craft an individual's self-concept—and decrease at older ages when interactions with diverse identities are reduced and one's sense of self is more clearly defined [18]. This study seeks to understand the factors that impact daily variability in gender expression across the life span and how variability may differ between male participants and female participants. Research has not explored the variability in SPA and gender expression and its relationships with both stable and variable personal, social, and environmental factors. Improving the understanding of life-course variability in self-perceptions may help identify complex relationships among self-perceptions, health, and the environment.

Aims of This Study

Technology has enabled vast improvements in app-based research that have yet to be used to study SPA or gender expression across the life course. Therefore, the aim of this study is to evaluate the feasibility and usability of the newly developed Labs Without Walls research app and a paired Apple Watch for studying life-course aging among male and female participants from different age groups. We hope to disentangle processes that may vary across microtimescales, including SPA and gender expression. The study also aims to validate the app-based administration of common cognitive and sensory tasks for use among Australian life-course samples.

Hypotheses

We hypothesize the following:

Hypothesis 1: Participants aged 18 to 85 years will be able to successfully provide e-consent, be able to input survey data through the Labs Without Walls research app, and have passive data collected using an Apple Watch over 8 weeks.

Hypothesis 2: The user experience of the Labs Without Walls research app and Apple Watch will be rated as acceptable by research participants aged 18 to 85 years.

Hypothesis 3: Data collected on multiple timescales using the Labs Without Walls research app will enable the exploration of variability in SPA and how SPA may be affected by personal characteristics, environmental conditions, physical health, resilience, fatigue, stress, and mood.

Hypothesis 4: Data collected using the Labs Without Walls research app will also allow for the exploration of stability and variability in gender expression and how gender expression may be affected by personal characteristics, physical health, resilience, mood, stress, and fatigue.

Hypothesis 5: Cognitive and sensory assessments delivered through the Labs Without Walls research app will be comparable with the traditional face-to-face versions of the assessments.

Methods

Participants

We aim to recruit a total of 240 Australian adults stratified by sex (male and female) and age group (18-25, 26-35, 36-45, 46-55, 56-65, 66-75, and 76-85 years).

Power

Sample size calculations for the full sample and the face-to-face validation subsample were estimated using the following criteria: threshold probability for rejecting the null hypothesis (2-tailed =.05) and the probability of failing to reject the null hypothesis under the alternative hypothesis (=.20). This pilot study is exploratory in nature. However, based on a previous meta-analysis [19], the odds ratio of subjective age impacting overall health is estimated to be 1.57. Using the aforementioned criteria, G*Power [20] was used to calculate the minimum sample size of 129 participants for the full study, which was well below our target. To allow for the addition of multiple covariates in statistical models and potential cases of missing data or attrition across the 8-week study period, we aim to recruit a total sample of 240 participants.

For the face-to-face validation subsample, a minimum sample size of 29 participants is required to detect a moderate correlation of r=0.50 between the performance on app-based cognitive and sensory tasks and that on face-to-face cognitive and sensory tasks, based on α (2-tailed)=.05 and β=.20 [21]. We aim to oversample to a total of 40 participants to account for possible missing data or the withdrawal of consent across the study.

XSL•FO
RenderX

Recruitment

Between May 2021 and January 2023, research volunteers will be recruited from the general Australian population using email, social and professional media call outs, and the Neuroscience Research Australia (NeuRA) Healthy Research Volunteer Registry. Participants will be invited to read the study information on the web via the study website. Web-based recruitment materials include a link to the study website, where those who are interested enter their contact details and preferred method of contact (phone, email, or text) for the research team to conduct eligibility screening.

Eligibility

To be eligible to participate in this study, adult volunteers must be living in Australia, be aged 18 to 85 years, be a current iPhone (Apple Inc) user, be willing to use their iPhone to download free research apps, be proficient in English, be able to access a home Wi-Fi connection for the duration of the study, not be reliant on text-to-speech services to use their iPhone, be willing to wear the Apple Watch during the study period and use headphones to complete hearing tasks, be willing to provide informed consent and comply with the study protocol, and agree to return the loaned study equipment (Apple Watch and headphones) at the end of the study.

As noted earlier, approximately 40 participants who join the study and are located in metropolitan Sydney will be invited to attend a 2-hour onboarding session either at the NeuRA or their homes to complete the traditional face-to-face versions of cognitive and sensory measures to assess validity across face-to-face and app-based administration methods.

Materials and Devices

iPhones

Study participants will use their own iPhones (model 6S or newer, supporting iOS 13 or later) in the study.

Apple Watches

Participants can join the study with their own Apple Watch or can elect for the study team to post them an Apple Watch Series 5 GPS for use during the study period. In this study, Apple Watches will be used to collect a range of health and behavioral data (as outlined in Table 1). In addition, Apple Watches will be used to deliver task reminders to the participants.

XSL•FO
RenderX

Table 1. Brief description of the app- and laboratory-based cognitive and sensory tasks administered in the Labs Without Walls Study.

Format and task name	Source	Expected duration (minutes)	Construct or constructs measured	Description
App-based testing				
Trail Making Task A	[6]	2	Sequencing, visual search, and processing speed	The participant uses their finger to connect a series of labeled circles presented on their phone screen, in order. The circles are labeled with sequential numbers (1, 2, 3, etc).
Trail Making Task B	[6]	2	Cognitive flexibility, alternating attention, sequencing, visual search, and processing speed	The participant uses their finger to connect a series of labeled circles presented on their phone screen, in order. The circles are labeled with alternating numbers and letters (1, a, 2, b, 3, c, etc).
Spatial Memory Task	[6]	2	Visuospatial memory and executive function	The participant is asked to observe and then recall pattern sequences of increasing length in a game-like environment.
Stroop Task	[6]	3	Cognitive flexibility and inhibitory control	The participant is shown a series of words that are displayed in color and must select the first letter of the color's name.
Tapping Speed	[6]	2	Motor function, tapping speed, tapping accuracy, and tapping rhythm	The participant rapidly alternates between tapping 2 targets on the touch screen. The task is repeated for the left and right hands.
Tower of Hanoi	[6]	2	Problem solving	The participant is asked to solve a puzzle in a minimum number of moves. To solve the puzzle, the participant must move the entire stack to the highlighted platform in as few moves as possible.
Reaction Time	[6]	2	Reaction time	The participant shakes their iPhone (Apple Inc) in response to a visual cue on the screen.
9-Hole Peg Test	[6]	2	Hand dexterity	The participant uses 2 fingers to touch on an on-screen peg and drag it into an on-screen hole and across a line. Both hands are tested.
dB HL Tone Audiometry task	[6]	6	Hearing ability	The participant listens through ear pods (provided by the research team) to a series of tones and taps the left or right button on the screen when they hear each tone. These tones are of different audio frequencies and play on different channels (left and right), with the volume being progressively increased until the user taps one of the buttons.
Amsler Grid	[6]	1	Visual problems, such as macular degeneration	The participant observes an on-screen grid while closing 1 eye for any anomalies and marks the areas that appear distorted using their finger.
16-Plate Ishihara Colour Deficiency Test	Adapted for mobile from the original 25-plate Ishihara colour deficiency test [22]	3	Red-green color deficiency	The participant is shown 16 images depicting a circle made of smaller red and green dots. Each circle is presented on a single screen. Within each circle, numbers appear in alternating colors. The participant must enter the number shown within each circle using an on-screen keyboard.
Face-to-face testing				
Trail making task A	[23]	3	Sequencing, visual search, and processing speed	The participant is presented with a sheet of paper that contains numbers randomly scattered throughout. The task is to connect the numbers in sequential order as quickly as possible.
Trail Making Task B	[23]	5	Cognitive flexibility, alternating attention, sequencing, visual search, and processing speed	The participant is presented with a sheet of paper that contains both numbers and letters randomly scattered throughout. The task is to connect the numbers and letters in alternating, sequential order as quickly as possible. For example, the participant would connect 1 to A, then A to 2, then 2 to B, and so on.
WMS-III[a] Spatial Span (forward span)	[24]	5-10	Visuospatial memory	The participant is shown of a series of spatial locations, typically marked by a set of blocks or cubes, arranged in a particular order on a board or table. The examiner then points to each location in sequence, and the participant being tested is required to touch or point to each location in the same order.

XSL•FO
RenderX

Format and task name	Source	Expected duration (minutes)	Construct or constructs measured	Description
Victoria Stroop Task	[25]	5-10	Cognitive flexibility and inhibitory control	The participant is asked to read aloud a list of color names, such as “red,” “green,” and “blue,” as quickly and accurately as possible. The participant is then presented with a list of color words that are printed in an incongruent color, such as the word “red” printed in blue ink and is instructed to name the color of the ink, not the word itself, as quickly and accurately as possible.
SHOEBOX dB HL Tone Audiometry Test	[26]	10-20	Hearing ability	The participant wears headphones. A series of pure tone sounds are presented at different frequencies and loudness levels, and the participant is asked to respond each time they hear the sound. The test typically begins at a frequency of 1000 Hz and progresses to higher and lower frequencies.
25-plate Ishihara Colour Deficiency Test	[22]	5-10	Red-green color deficiency	The participant is shown a series of plates with colored dots or patterns arranged in a specific way to form a number. The participant must identify the number on each plate.

[a]WMS-III: Wechsler Memory Scale-III.

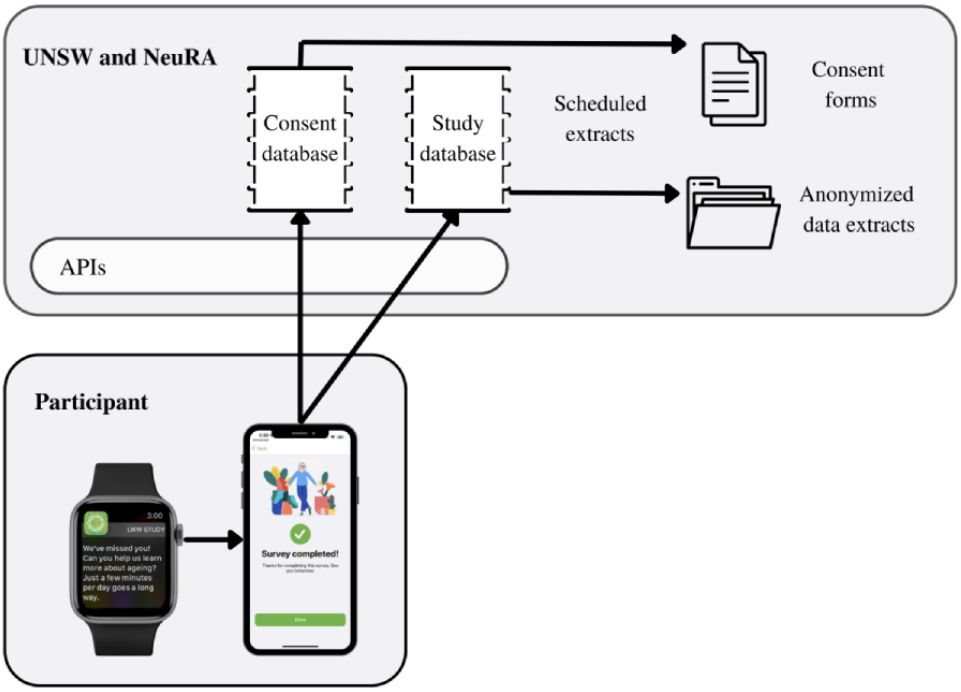
Headphones

Participants will be posted a new pair of Apple in-ear wired EarPods with a lightning connector (model number MMTN2FE/A) for use during hearing tasks.

Labs Without Walls Research App for iOS

Labs Without Walls was developed to provide a means of conducting life-course aging research outside traditional research laboratories. It was conceived and developed by the investigators. The app is primarily built in Swift (Apple Inc), using XCode (Apple Inc) as the development environment. Objective-C (Apple Inc) is used for enhancements to the Apple ResearchKit framework [6]. Apple’s ResearchKit is used to provide functionality, including consent, questionnaires, prebuilt active tasks, and graphs. The app uses read-only access to the local health store on the participant’s iPhone via Apple’s HealthKit interface, subject to the participant’s consent. Data will be collected continuously throughout the study period from both the worn Apple Watch and the participant’s iPhone. The app fully supports light and dark mode presentations throughout.

Backend



A backend, hosted on the Amazon Web Services (AWS) platform, will be used to collect study data securely. The AWS offers a range of security measures to protect data stored in the cloud, including industry-standard encryption algorithms to protect data in transit and at rest. Data cannot be accessed without the appropriate decryption key, and access is restricted to only essential research staff approved by the ethics committee. Two-factor authentication will be implemented, and 6-month audits of data access will be conducted.

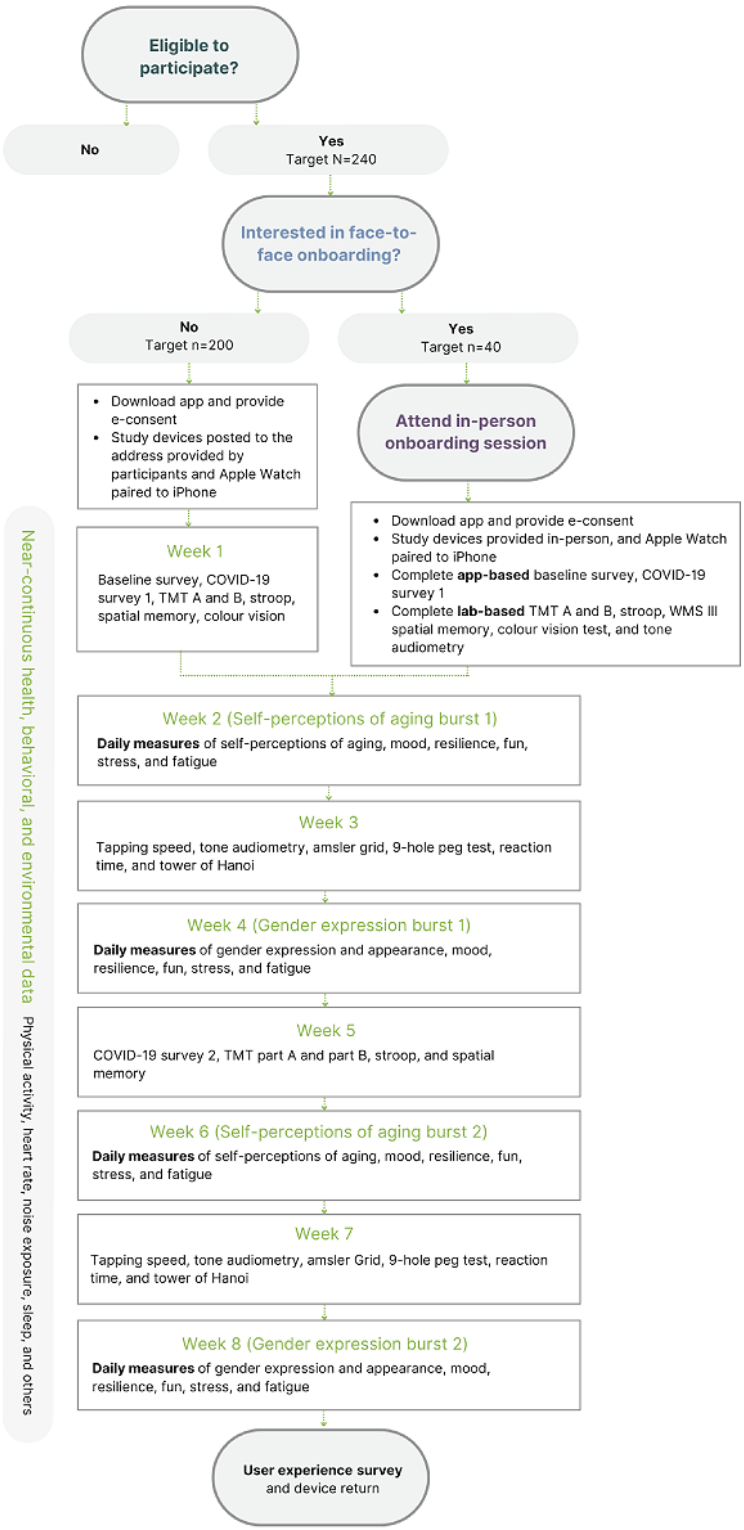
Technical Architecture

The technical architecture of the Labs Without Walls study is summarized in Figure 1.

XSL•FO
RenderX

Figure 1. Technical architecture of the Labs Without Walls research study. API: application programming interface; NeuRA: Neuroscience Research Australia; UNSW: University of New South Wales.

The technical architecture of the app is designed to separate consent forms and other identifiable information from deidentified study data. The consent details provided, including those in the signed e-consent form, will be transmitted by secured application programming interfaces to an AWS backend, where they will be stored in the stand-alone consent database. All other study data collected from participants (including data from questionnaires and cognitive and sensory tasks and health data) will be initially stored on the iPhone and transmitted to the backend when the app is running and has an active internet connection.



Two sets of data extracts will occur on a periodic basis. First, consent forms will be extracted to a secured location (S3 bucket), accessible to a limited number of members of the study team. These will be retained as a record of informed consent. Second, the collected study data will be extracted for analysis. These extracts will be anonymized to remove personally identifying information. These will be extracted to a separate secured location (S3 bucket) and will be accessible only to a limited number of members of the study team. Data extracts will be stored and handled according to an approved University of New South Wales Research Data Management Plan.

Procedure and Study Design

This project uses a multitimescale measurement burst design [27,28] to collect single–time point, near-continuous, and repeated-measure data from participants using the Labs Without Walls research app and an Apple Watch. Participants will complete a total of 31 short surveys and 14 active tasks using the research app. The completion of tasks is staggered across the 8-week period. The study procedure is summarized in Figure 2. The time commitment for each day will not exceed an average of 5 to 10 minutes. At the end of the study, after completing a user satisfaction questionnaire, participants will be asked to return any borrowed devices (Apple Watch and headphones) using a supplied prepaid mailing box. Participants may also choose to leave the study early from within the app and specify whether they consent to the data previously collected from them being used in the study. Participants will not receive payment for joining the study. However, participants who attend the NeuRA for face-to-face cognitive and sensory testing will be offered a voucher worth Aus $20 (US $13) to assist with travel costs.

XSL•FO
RenderX

Figure 2. Flowchart summarizing the Labs Without Walls study procedure from eligibility screening to user experience feedback. TMT: Trail Making Task; WMS-III: Wechsler Memory Scale-III.

Ethics Approval

Ethics approval was obtained from the University of New South Wales Human Research Ethics Committee (HC200792).

Participant App Experience

Joining the Study

Eligible participants will be given a link to download the Labs Without Walls app from the Apple's public App Store and install it onto their existing iPhone. Alternatively, as the app is publicly visible in Australia, participants can search for it using the App Store app on their device. Each participant will be issued a

XSL•FO
RenderX

unique 1-time invitation code to allow them to join the study within the app. Once their invitation code is accepted, the user can proceed to the study consent process within the app.

e-Consent

The e-consent process obtains and records the consent of the participant within the app before they participate in the study.

The Labs Without Walls e-consent flow, summarized in Figure 3, is presented in Textbox 1.

Figure 3. Summary of the Labs Without Walls in-app consent flow.

XSL•FO
RenderX

Textbox 1. Labs Without Walls e-consent flow.

- An introductory page will appear.
- Multiple pages presenting essential study information will appear.
- A consent quiz to check the participant's understanding of key consent concepts will be administered. The participant needs to complete the quiz correctly to proceed (can retry as required).
- A review page with an Agree button, which the participant can tap on to proceed further, will appear.
- When the participant taps on Agree, a confirmation message will be shown.
- If the participant confirms their agreement, then they will be taken to a signature capture page, to obtain their signature.
- A page where the participant can allow access to their health data and choose which measures are to be accessible (refer to the *Health Data Collection* section) will appear.
- Contact information will be collected to allow for device mail-out.
- Pages where the participant can provide optional consent for the use of anonymous data by other approved researchers, contact for further studies, and contact for media events will appear.
- A completion page will appear.

Once consented, participants will be posted an Apple Watch (if not joining with their own device) and Apple EarPods for use during the study. Once participants pair the watch with their phones, they will begin the 8-week study period.

Study Tasks

Task List

At any time, the list of available tasks to complete will be displayed on the home tasks screen. Tasks will remain in the task list for 3 days after the scheduled date, and the date of completion will be recorded in the data file. Tasks beginning the following day will also be shown in the task list, although not accessible until the scheduled date. Tapping on a task will start the task. A task can be a survey, cognitive task, or physical or sensory task. These are described in the subsequent section.

Survey Measures

Much of the study data will be collected from participants in the form of short surveys. The Labs Without Walls research app includes one-off surveys (eg, baseline), surveys administered twice (COVID-19 experiences), and daily diary–style repeated-measure surveys (eg, SPA, gender expression, mood, and resilience). A list of the in-app surveys and their measurement frequencies is provided in Table 2. Composite scores—which can be automatically computed within the app—will be created according to the published guidelines for existing measures. The typical survey flow consists of an introductory page, multiple pages of questions, and a completion page (Figure 4).

XSL•FO
RenderX

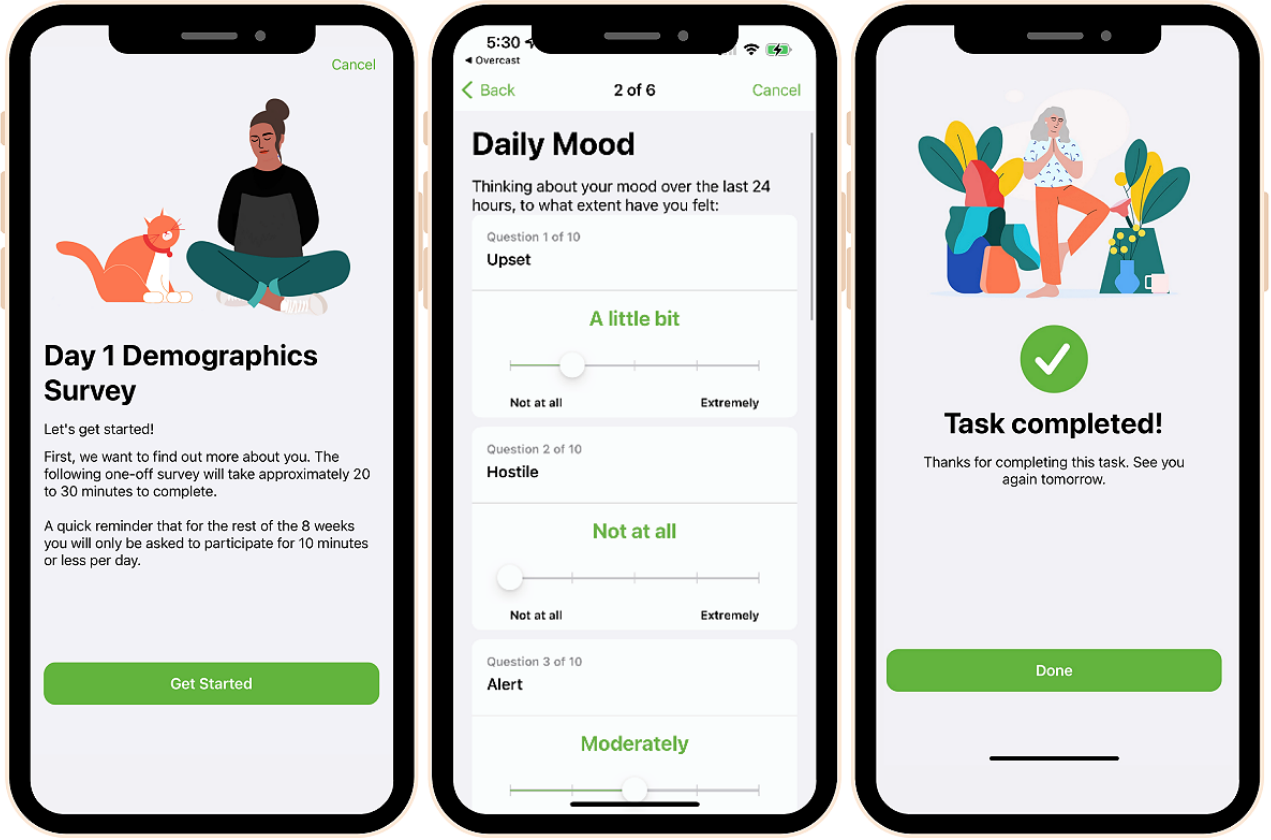


Table 2. Surveys included in the Labs Without Walls research app and their measurement frequencies.

Construct of interest	Measure description	Items, n	Administration day or days
Age	Years	1	1
Ethnicity	Ethnic group or groups identified with	1	1
Relationship status	Married, in a relationship, or single	1	1
Education	Years of education by education stage (primary, secondary, technical college, university, or other)	5	1
Household income	Weekly average household income before tax	1	1
Employment	Employed, unemployed, or retired	1	1
Self-rated health	Physical and mental health measured by the SF-12[a] version 2 [29]	12	1
Sex	Self-reported sex at birth	1	1
Gender identity	Self-reported gender identity	1	1
Childhood gender role nonconformity	Subset of items from the Recalled Childhood Gender Identity and Gender Role Questionnaire [30]	3	1
Genders in childhood home	Balance of genders in childhood home	1	1
Sexuality	Sexual orientation	1	1
Menopause	Self-reported female reproductive status (administered only to those assigned female at birth)	1	1
HRTs[b]	Currently taking HRTs	1	1
Smoking	Currently smoke	1	1
Vaping	Currently vape	1	1
Alcohol	Frequency of consumption and amount per occasion	2	1
Resilience	CD-RISC2[c] [31]	2	1
Chemical intolerance	BREESI[d] [32]	3	1
Perceptions of air quality	Perceived in-home air quality and perceived impact of quality on health	2	1
Future time perspective	Short-form FTP[e] scale [33,34]	5	1
Expectations regarding aging	ERA-12[f] [35]	12	1
Social isolation	UCLA[g] Loneliness Scale [36]	3	1
Digital technology use	Weekday use of digital and internet technologies and impact of use	6	1
COVID-19 experiences	COVID-19 experiences and impact questionnaire	37	4 and 30
Subjective aging (daily)	Felt age, look age, behave age, mental performance age, interests age, and ideal age	6	1, 8-14, and 36-42
Mood (daily)	Adapted 10-item Positive and Negative Affect Scales [37]	10	8-14, 22-28, 36-42, and 50-56
Resilience (daily)	Adapted CD-RISC2	2	8-14, 22-28, 36-42, and 50-56
Fun (daily)	Original items measuring fun, laughter, and excitement in the past 24 hours	3	8-14, 22-28, 36-42, and 50-56
Gender expression (daily)	Gender appearance and expression adapted from the study by Wylie et al [38]	2	22-28, and 50-56
Stress (daily)	Original items measuring daily stress about work, finances, relationships, global events, and COVID-19	5	8-14, 22-28, 36-42, and 50-56
Fatigue and vitality (daily)	SF-36[h] vitality subscale [39]	4	8-14, 22-28, 36-42, and 50-56
User satisfaction	Multifaceted feedback on the app and watch user experience	9	56

Feasibility and Acceptability Data

The feasibility and acceptability of the app and paired Apple Watch will be assessed in a number of ways. First, we will look at the number of successful consents—including successful completion of the 3-item consent quiz—as an indicator that the e-consent process is clear and reliable. The study retention rate will be examined as an indicator of how many participants remained in the study for the entire 56 days. Survey and task completion rates will be examined to look for potentially systematic gaps in the data or frequently incomplete surveys or tasks across participants. Participant-reported acceptability of the app will be assessed using 3 items: "Was the assessment schedule *manageable* in the context of your daily life? (Yes or No)," "How *user-friendly* did you find the mobile technology? (1=Not at all to 5=Extremely)," and "How much did you *enjoy* using the mobile technology? (1=Not at all to 5=Extremely)." Participants will be asked to provide feedback on alert frequency by responding to the item "What do you think about the frequency of alerts?" using a 9-point scale ranging from "too few" (1) to "just right" (5) to "too many" (9). Participant-reported acceptability of the watch as a study device will be assessed using 4 items: "How difficult did you find the watch setup process? (1=Not at all to 5=Extremely)," "How much did you enjoy wearing the watch? (1=Not at all to 5=Extremely)," "How comfortable did you find the Apple watch? (1=Not at all to 5=Extremely)," and "How difficult was it to charge the watch? (1=Not at all to 5=Extremely)." Participants will also be asked the question "What impact do you think the watch had on your physical activity?" to which they can respond using a 5-point scale ranging from "increased activity a lot" to "decreased activity a lot." Participants will also be invited to provide general feedback by responding to the question "Do you have any other feedback on the research app that you would like to share with us?" using free text.

Cognitive Tasks

Several different cognitive tests will be conducted during the study, and in some cases, they will be repeated during the course of the study. App-based measures are a variety of active tasks, including the Trail Making Task (parts A and B), Spatial Memory, Stroop Test, Tapping Speed, Tower of Hanoi, Reaction Time, and 9-Hole Peg sourced from the Apple ResearchKit framework [6]. Laboratory-based cognitive measures include

XSL•FO
RenderX

the Wechsler Memory Scale-III (WMS-III) Spatial Span (forward span) [24], Victoria Stroop Task [25], and the pen and paper version of the Trail Making Task (parts A and B) [23]. More information regarding the cognitive tasks is provided in Table 1.

Sensory Tasks

Several different sensory tests will be conducted during the course of the study, and in some cases, they will be repeated during the course of the study. We will use the dB HL Tone Audiometry task to assess hearing thresholds and the Amsler Grid to detect potential visual problems, sourced from the ResearchKit framework [6]. Our research team also developed an app-based version of the Ishihara Colour Deficiency Test [22]. Laboratory-based sensory tasks include a dB HL Tone Audiometry test administered using SHOEBOX Audiometry software (SHOEBOX Ltd) [26] and the 25-plate Ishihara Colour Deficiency Test. More information regarding the sensory tasks is provided in Table 1.

Alerts and Progress Reminders

As new tasks are available for completion, notifications will be sent to the participant via both the iPhone and Apple Watch (subject to them allowing notifications on their phone). The notification time of day is user configurable in the app. Repeated notifications will be sent if the participant misses completing tasks for 1 day and 3 days, as shown in Figure 5. Tapping on a notification on their iPhone will take the participant to the task list page of the app. The task list page also includes a progress ring that displays the number of days completed and the number left to be completed. A balloon animation will be displayed to participants as they complete the project milestones (eg, week 1 complete and week 2 complete).

Figure 5. Sample task reminder alerts from the Labs Without Walls (LwW) research app on an iPhone and Apple Watch.

Health Data Collection

As noted, a range of health data measures will be collected throughout the study. These will be accessed from the health app on the participant's iPhone, with their explicit on-device consent (see the *e-Consent* section). These data will be collected from the participant's iPhone and a paired Apple Watch as appropriate (if worn). Participants can change their consent at any time using phone settings. Requested health measures are presented in Table 3.

XSL•FO
RenderX

Sleep data will be collected whenever the participant wears an Apple Watch while sleeping. For 1 week during the study, the participant will be asked to do so each night and will receive reminders to charge the watch in advance and put it back on before going to bed.

Table 3. Daily health, behavioral, and environmental data collected during the Labs Without Walls pilot study using an iPhone (Apple Inc) and an Apple Watch (Apple Inc).

Domain and measure	Input device	Are the data visible to participants in the app?
Energy used		
Active energy (kJ)	Apple Watch	Yes
Basal energy (kJ)	Apple Watch	Yes
Activity		
Exercise (minutes)	Apple Watch	Yes
Stand time (minutes)	Apple Watch	Yes
Hours with at least 1 minute standing (number)	Apple Watch	Yes
Step count (number)	Apple Watch	Yes
Walk and run distance (km to 3 decimal places)	Apple Watch	Yes
Flights of stairs climbed (number)	Apple Watch	Yes
Hours the Apple Watch is worn (hour, to nearest quarter hour)	Apple Watch	Yes
Heart rate		
Resting (beats per minute)	Apple Watch	Yes
Walking (beats per minute)	Apple Watch	Yes
Maximum (beats per minute)	Apple Watch	Yes
Variability (SD of the interbeat [RR[a]] interval between normal heart beats)	Apple Watch	No
Mobility		
Walking speed (km per hour)	iPhone and Apple Watch	Yes
Walking step length (cm)	iPhone and Apple Watch	Yes
6-minute walk: meters (to a maximum of 500 m)	iPhone and Apple Watch	No
Stair speed (up and down; km per hour)	iPhone and Apple Watch	No
Gait—double support time (percentage of total walk time)	iPhone and Apple Watch	No
Gait—walking asymmetry (percentage of total walk time)	iPhone and Apple Watch	No
Noise exposure		
Environmental (average and maximum)	Apple Watch	Yes
Headphones (average and maximum)	iPhone	Yes
Sleep		
Hours slept (number)	Apple Watch	Yes

[a]RR communicates the time between 2 successive heartbeats.

Data Analysis Plan

Statistical Models

To answer hypothesis 1, aggregate data and summary statistics will be reported on the number of successful consents, retention rate, survey and task completion rates, app and watch usability, feedback on alert frequency, and hours of watch wear. To answer hypothesis 2, qualitative data on usability will be analyzed using thematic analysis, and quantitative data will be collected via Likert-type scales and analyzed using summary statistics (eg, mean and range). To answer hypotheses 3 and 4, the variability in SPA and gender will be analyzed using multilevel modeling. Random coefficient regression models will be used to analyze time-varying covariates. To answer hypothesis 5, correlation analysis will be used to establish the validity of the app-based versions of cognitive and sensory tests against laboratory-based tests. Log transformations will be used for any nonnormal data needed for parametric testing. In general, categorical variables will be coded numerically from low to high (eg, low=1 and high=5). The threshold probability for rejecting the null hypothesis will be set as (2-tailed)=.05, unless otherwise specified, and 95% CIs will be reported.

XSL•FO
RenderX

Data Exclusion and Missing Data

The data collected from the Apple Watch will be validated against the number of hours it has been worn each day. If the watch has been worn for <10 hours within a 24-hour period, data from that day will be excluded from the analyses. The average time taken to complete the surveys and tasks will also be checked for any outliers using box and whisker plots. Listwise or pairwise deletion or multiple imputation will be used to account for missing data where feasible and depending on what is most appropriate for the variables under consideration.

Results

Recruitment began in May 2022. Data collection was completed in February 2023. The main project outputs will be (1) peer-reviewed publications, (2) conference presentations, and (3) research briefs that explain the study outcomes in a shorter format designed for a general audience. The publication of the preliminary results is anticipated in 2023.

Discussion

Expected Findings

There is a scarcity of studies that have examined the feasibility and acceptability of app- and smartwatch-based research technologies among life-course samples. This study aims to fill this gap by demonstrating the validity of these technologies among adults aged 18 to 85 years recruited from the general population of Australia. On the basis of previous research indicating high ownership and use rates of smartphones and smartwatches in Australia [1], it is expected that Labs Without Walls will prove to be acceptable, usable, and engaging for the life-course sample in this study.

This study aims to provide the first evidence for daily variability in multidimensional SPA from an Australian life-course perspective. SPA has been shown to be associated with mortality, mental health, and functional health [8-10]. Although long-term variability in SPA is well evidenced [11,12], far fewer studies have explored variability in SPA on shorter timescales. The findings of this study could shed light on intraindividual variability in SPA and the interplay between SPA and other time-varying constructs, such as mood, stress, and physical activity.

In addition, this study is expected to be the first to explore stability or variability in gender expression across time, as well as the degree to which gender expression is impacted by other factors such as age and sex at birth. In research practice, gender is typically treated as a fixed, binary variable despite significant variations in the real world [17], where gender dynamism can be seen in at least 3 aspects: the meaning of gender has changed over time; there are significant cultural differences in the meaning of gender; and one's own gender and relationship with it can change, evolve, weaken, and galvanize across the lifetime [15]. This study aims to provide initial evidence exploring the degree of heterogeneity in gender dynamism at the individual level and between and within age and sex-at-birth groups.

The study also seeks to explore the cross-validity of app-based and laboratory-based administrations of common cognitive and sensory tests. Previous research has provided initial support for remote digital cognitive assessments in the context of cognitive aging [40] and psychiatric disorders [41]. The findings could add to the evidence base for remote digital cognitive assessments in the context of cognitive aging and psychiatric disorders.

Overall, the anticipated results of the Labs Without Walls study will inform the development of future iterations of the research app, aiming to answer ambitious questions regarding aging. We are interested in exploring the utility of other yet-to-be-used capabilities of the Apple Watch and iPhone in future studies. For example, GPS data collected using the Apple Watch or Apple smartphone can provide interesting insights into an individual's "life-space," which has been linked to well-being [42], mobility, and health [43,44]. Emerging behavioral and linguistic digital biomarkers of cognitive function are also promising [45,46]. By pilot-testing a Labs Without Walls approach, this study hopes to provide evidence for a platform that drives innovation in life-course aging research in Australia and beyond.

Strengths and Limitations

This study has several limitations. Owing to budget restrictions, the Labs Without Walls app is built only for iPhones and is not available to Android users. Although iPhones are by far the most commonly used smartphones in Australia [47], we acknowledge that there is a selection bias inherent in the restricted availability of the app. We also acknowledge that the pilot version of the Labs Without Walls app does not include the functionality to enable adults with vision impairment to interact with it. In addition, app-based research can raise ethical concerns, such as the potential for privacy violations and the use of sensitive personal data. As detailed earlier, the research team has taken measures to protect the rights of participants, including their data security. Overall, the potential benefits of app-based approaches for conducting more accessible, convenient, and enjoyable research that also deliver more complex longitudinal data warrant dedicated efforts to develop apps that overcome (to the greatest extent possible) potential shortcomings.

Conclusions

App-based studies have the potential to radically improve our understanding of processes that vary over microlongitudinal timescales. This study will provide evidence regarding the feasibility, acceptability, and usability of the Labs Without Walls research app and a paired Apple Watch for conducting research among a life-course sample of Australian adults. The feedback obtained will be used to improve future iterations of the app, explore preliminary evidence for intraindividual variability in SPA and gender expression across the adult life span, and explore the associations between the performance on app-based common cognitive and sensory tests and that on traditional common cognitive and sensory tests.

Acknowledgments

The research team would like to thank the research volunteers who have joined the Labs Without Walls study from around Australia. This project received assistance for the design and setup of the backend data storage architecture from University of New South Wales Sydney Research Technology Services. Research Technology Services also partially supported the cost of hosting the backend storage of the study data via their cloud pilot scheme. Apple Watches were provided by Apple Inc, following a successful application to their Investigator Support Program [48]. Apple is not involved in the conduct of the research. This project is funded by the University of New South Wales Ageing Futures Institute. BB, LZ, and KJA are supported by the Australian Research Council Laureate Fellowship (FL190100011). SZ is supported by an Australian Government Research Training Program scholarship and the Australian Research Council Centre of Excellence in Population Ageing Research (project number CE170100005).

Data Availability

Study data sets and analytic codes will be deposited in publicly available repositories (where available and appropriate), as dictated by our funders, or presented in the main paper or additional supporting files whenever possible.

Authors' Contributions

BB contributed to conceptualization, methodology, software (review), resource accumulation, writing—original draft, writing—review and editing, supervision, and project administration. SZ contributed to methodology, software (review), resources, writing—review and editing, project administration, and data curation. LZ contributed to methodology, software (review), resources, writing—review and editing, and project administration. DA contributed to methodology, software (lead), resources, writing—review and editing, and data curation. RE contributed to writing—review and editing, project administration, and funding acquisition. MHH contributed to methodology and writing—review and editing. KJA contributed to conceptualization, methodology, software (review), resources, writing—review and editing, supervision, project administration, and funding acquisition.

Conflicts of Interest

None declared.

Abstract

Background: Health care services are being challenged by an increasing number of patients and limited resources. Hence, research investigating options to reduce costs and increase effectiveness is warranted. Digital outpatient services can provide flexible and tailored follow-up, improve patients' health literacy, and facilitate the identification of adverse courses of disease. However, previous research largely focused on disease-specific contexts and outcomes. Therefore, research on digital services investigating generic outcomes such as health literacy is warranted.

Objective: This article aims to describe the "digital outpatient service" intervention and present the protocol for an ongoing multicenter, nonrandomized trial evaluating this intervention.

Methods: Based on previous experiences and evidence-based knowledge, we developed this intervention through patient-journey maps in collaboration with each clinical specialty. The patients gain access to a mobile app for self-monitoring and patient-reported outcomes and a chat for contact between the patients and health care workers. The health care workers' dashboard includes a traffic light system to draw attention to the most urgent patient reports. In this multicenter, non–randomized controlled trial, patients are allocated to the control group receiving standard care or the 6-month intervention. Eligible patients are aged 18 years or older who receive outpatient care at the neurology, lung, pain, or cancer departments at 2 university hospitals in Norway. Our evaluation will include patient-reported outcomes, qualitative interviews, and clinical measures. The primary outcome will be health literacy using the Health Literacy Questionnaire. A sample size of 165 participants is split into a 1:2 ratio in favor of the intervention. We will analyze quantitative data in SPSS (IBM Corp) using descriptive statistics and logistic regression, and qualitative data using thematic analysis.

Results: This trial started in September 2021, and the intervention started in January 2022. Recruitment has ended, with 55 patients in the control group and 107 patients in the intervention group. Follow-up is expected to end in July 2023, with results expected to be obtained in December 2023.

XSL•FO
RenderX

Conclusions: This study will evaluate an intervention facilitated by an already certified digital multicomponent solution, with intervention content based on patient-reported outcomes, health literacy, and self-monitoring. The intervention is specifically tailored to each participating center and the needs of their patients using patient journey maps. The comprehensive and generic evaluation of this digital outpatient service intervention is a strength as it targets a heterogeneous sample of patients. Thus, this study will provide important knowledge about the applicability and effects of digital health care services. As a result, patients and health care workers will gain a new, evidence-based understanding of whether and how digital tools may be used in clinical care.

Introduction

While advanced medicine contributes to prolonged life expectancy, the number of patients increases, and health service resources remain limited [1]. The reduction in hospital overnight capacity often increases the number of outpatient consultations. There is a risk of suboptimal resource use in current health services as these do not sufficiently meet individuals' needs for understandable health information [2,3]. Digital health solutions, which have emerged over the last decades, are embraced and called for by health authorities [4,5], and the recent COVID-19 pandemic has led to a fast, large-scale adoption [6]. Systematic reviews provide some evidence about the effects of digital solutions [7-9], but the extent to which digital services can improve patient outcomes or resource use has not been firmly established [10].

Any implementation of digital health solutions requires patients' and health care workers' understanding of why and how the digital possibilities are used [11,12]. Thus, it is necessary to attain a certain level of health literacy, defined as "the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways which promote and maintain good health" [13]. Health literacy is closely related to patients' self-management and decisions related to their health [14], and eHealth literacy is linked to the use of digital solutions for health [12]. Low health literacy is associated with poorer health outcomes [15], lower self-management, and less use of digital health solutions [2,16]. It is reasonable to expect that better health literacy will improve self-management and the ability to benefit from digital health solutions [12]. The paucity of systematic reviews supports research focusing on the possibilities of digital interventions on health literacy [12,16].

Digital health solutions have embraced the use of patient-reported outcome measures (PROMs), allowing patients to subjectively report their health, pain, symptoms, and other relevant parameters [17]. PROMs allow health care workers to individualize patient care, although it has been challenging to demonstrate clinical effects in research [18]. However, effect evaluations should be part of studies on how PROMs are used in a clinical setting, and explanatory factors should be identified [19-21]. When routinely used, PROMs may support self-management and communication between patients and health care workers [17,19].

Allowing patients to digitally engage, self-monitor, and share data with health care workers has some obvious advantages and challenges [16,20,22,23]. From both the patient's and the health care worker's perspectives', digital solutions must be usable, clinically relevant, convenient, and evidence based. Patients rely on health care workers to assess their data; likewise, health care workers depend on patients to report the assigned health parameters without under- or overreporting symptoms [24]. Digital solutions in outpatient care may contribute to the prevention of complications or exacerbations by promoting contacts between patients and health care workers, allowing the latter to intervene earlier and to act according to clinical needs [25]. A recent systematic review found that using digital solutions increased patients' engagement in the technical usability of the solutions that affected their everyday lives [26]. Patients were also found to report more confidence in and knowledge of their own conditions and increased autonomy. These findings support those of earlier research on patients' engagement and the impacts of digital solutions [27].

There is limited research regarding the development and impacts of multicomponent digital solutions that include PROMs, remote monitoring, patient notifications, alerts for health care workers, asynchronous chats, and video consultations. An evaluation of a heterogenous range of digital health interventions found some positive effects on coping, quality of life, and pain in cancer treatment [28], as well as alleviation of both pain and functional disabilities in disorders associated with musculoskeletal pain [29]. Primary research in home monitoring of symptoms enables detection of exacerbations and progression in patients with interstitial lung disease (ILD) [30], but there is a need for evidence to support new ILD interventions [31]. There has been wide adoption and positive effects of mobile apps for patients with epilepsy, although less so in collaboration with health care workers [32]. The need to study homogeneous, static, and standardized interventions with a high level of fidelity [33] might explain why research on digital solutions is rarely conducted despite the frequency of their application in clinical care. Furthermore, clinical challenges remain, particularly regarding the integration of electronic health records into

XSL•FO
RenderX

existing platforms [22]. There is limited knowledge about how digital systems fit current workflows and about how data and PROMs should be standardized to best generate registry data of value for other clinical sites and researchers [16,23]. Altogether, there is a paucity of empirical studies on the implementation and impacts of digital health solutions on outpatient care.

The purposes of this article are to (1) describe the digital outpatient service intervention and how it promotes digital outpatient care, and (2) present a multimethod protocol for a multicenter, nonrandomized trial to evaluate the intervention.

Methods

In the following, the development of the digital outpatient service intervention is presented before the details of the planned trial. The aim of the planned trial is to evaluate whether this intervention can have positive impacts on outcomes, including health literacy, health-related quality of life (HRQL), digital health literacy, satisfaction, and use of health service resources. Qualitative interviews will provide in-depth knowledge about the intervention from the perspectives of patients and health care workers. Furthermore, possible care pathways that ensure the quality of care and efficiency of remote monitoring in digital outpatient care will be investigated. The reporting of the intervention was guided by the Template for Intervention Description and Replication (TiDiER) [34], the protocol is reported according to the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) [35], and the PROMs are reported according to the SPIRIT PRO extension [36].

Development of the Digital Outpatient Service Intervention

Participants in the Development of the Intervention

The intervention was developed through collaboration among researchers from the Oslo University Hospital (OUH) intervention center, product managers at Dignio Connected Care, and health care workers and health care researchers from each participating department. These include the Department of Respiratory Diseases, the Department of Neurology, and the Department of Pain Management at OUH, as well as the Department of Cancer at the University Hospital of North Norway (UNN). To achieve an intervention suitable for patients' needs and available staffing resources, each department tailored the intervention to their patient group and organizational structure.

Patient and Public Involvement

Representatives from the Norwegian Cancer Society contributed to the project's development. Furthermore, the intervention for the neurology department is based on content developed together with patients and stakeholders. Health care workers are included as they constitute significant users in this project. The MyDignio app has been through several patient reviews before the current version.

Essential Elements and Aim of the Intervention

At the core of the intervention in all 4 departments is increased access to outpatient services. On the digital platform, patients can respond to PROMs and self-monitor parameters relevant to their conditions and have asynchronous, easy-access contact with health care workers. Designated health care staff will assess these data and act accordingly. These elements may facilitate flexible patient follow-up, building on a conceptual model that explains associations between health literacy and health outcomes, such as access to services, use of services, interactions between patients and health care workers, and patient self-care [37]. Patients can have an increased influence on their care and their contact with health care services through self-reported subjective experiences related to their care needs and their wishes for follow-up, in combination with their reports of objective measures such as blood pressure or oxygen saturation. This may facilitate timely contacts between patients and health care workers, where patients can receive guidance based on their questions, and likewise enable health care workers to identify patient struggles more accurately.

The Digital Platform for the Intervention: Dignio Connected Care

The platform for the digital outpatient service intervention is Dignio Connected Care [38], consisting of the multicomponent cloud-based system Dignio Prevent for health care workers and the MyDignio patient app. It is CE (Conformité Européenne: French for "European conformity") marked, satisfies all regulatory requirements for privacy and information security, and has been used in various clinical settings in Norway [39-41], the United Kingdom [42], and China [38]. The digital platform can be tailored to the needs of individual patients in consultation with their health care workers. Components can be added to individualize follow-ups (Tables 1 and 2) and will vary depending on the treatment at any given time. Examples of the interface are given in the Multimedia Appendices 1 and 2.

XSL•FO
RenderX

Table 1. Patient-reported components used in the digital outpatient service.

Dignio component	Short description	Center using the component in its intervention
Patient-reported outcome measures (PROMs)	Standardized and individualized PROMs with numerical scales, single and multiple-choice answers, and free text.	• Cancer: Edmonton Symptom Assessment System (ESAS-r) [43], Eastern Cooperative Oncology Group (ECOG) scale assessing functional level [44], PROM version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE) [45] and items on side effects of chemotherapy. The frequency of administration is per individual needs. • Lung: King's Brief Interstitial Lung Disease questionnaire (K-BILD) [46] assessing self-reported health every 12th week, and items on side effects (vomiting, rash, dizziness, abdominal pain, or diarrhea), administered every 4th week. • Neuro: PRO-EPI: A multidimensional epilepsy PROM with items on seizures, medication, living with epilepsy, and need for health services developed by clinicians and the Norwegian Epilepsy Network for health care workers [47,48], administered every 11th week. • Pain: Items on pain on a visual analog scale, intensity, location, side effects (constipation, sweat, anxiety, etc), compliance with current treatment and need for health services, administered per medication plan when changes to this plan are made.
Physiologic measures		
Blood pressure	Bluetooth devices or BYOD[a]	• Cancer, on clinical indication
Body temperature	Bluetooth devices or BYOD	• Cancer, on clinical indication
Body weight	Bluetooth devices or BYOD	• Lung, weekly
Spirometry values	Bluetooth device	• Lung, weekly
Oxygen saturation	Bluetooth device	• Lung, weekly
Pulse	Bluetooth devices or BYOD	• Lung, weekly

[a]BYOD: bring your own device.

XSL•FO
RenderX

Table 2. Functionality for remote monitoring and communication.

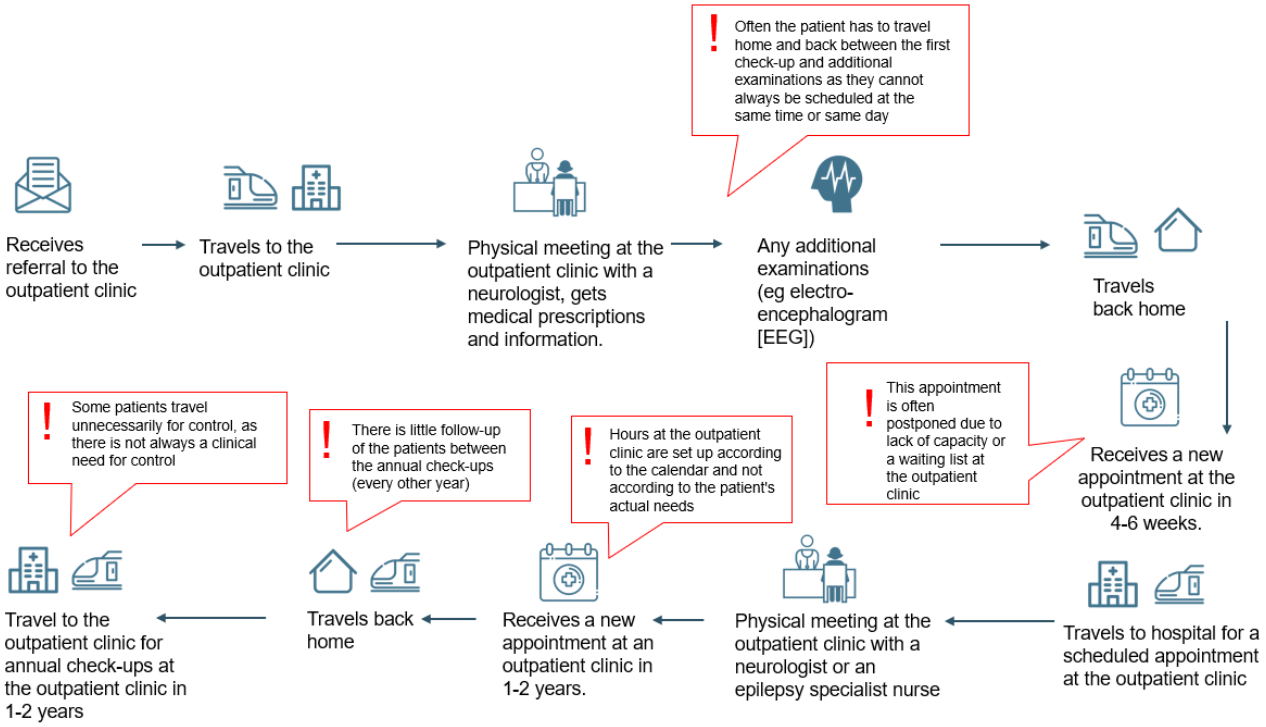
Dignio component	Brief description
Tasks	• Health care workers can specify tasks for patients, such as performing daily activities, registering measures taken with the patients' own devices, or watching patient videos.
Thresholds	• Health care workers can define thresholds. The limit values are set, based on each patient's baseline, and follows the traffic light model, with green, yellow, and red alerts.
Notifications and triage	• When measures are outside defined thresholds, health care workers are notified. Deviating values, responses, and unanswered messages from patients are captured by an overview of patients in Dignio Prevent, where they are sorted by degree of urgency or severity (traffic light model). If the patient does not perform the defined tasks at the specified time, a warning is triggered. This can admittedly be turned off if desired.
Reminders	• Reminders can be sent to the patients as push-notifications in MyDignio, through email or SMS texts. When the task or measure is done, the reminders stop.
Messages or chat	• Patients and health care workers can send messages to each other and have an asynchronous dialogue when it is best for both parties. • Lung: patients are asked to upload photos of the results of any laboratory tests conducted and the results of a 6-minute walking test conducted at their local hospital every 12th week. • Neuro: patients are allowed to upload photos of seizures whenever relevant.
Video consultations	• A video consultation can be arranged if needed. A video room is created with an encrypted connection where the patient and health care worker can meet.
Information pages	• MyDignio has an information page that can be updated by health care workers from the web portal Dignio Prevent. It is possible to create an individual information page, create templates, and send updates to several patients.
Efficacy tools (templates)	
Templates for patient care	• Templates can be developed to facilitate a standardized follow-up at given times, allowing health care workers to monitor any changes in a timely manner.

Patient Journey Maps

In collaboration with each department, patient journey maps have been drawn [49] to target the potential for a digital outpatient service and assess how the use of digital tools may affect patient outcomes, patient flow, and health care workflow. Common challenges, visualized through the red exclamation marks (Figures 1 and 2), include limited health care worker resources, an overwhelming number of patients, time-consuming telephone calls, and the challenge of contacting patients at risk (see Multimedia Appendix 3 for further examples). Patients may have a limited overview of their parameters, including PROMs and clinical data, compromising their health literacy and self-monitoring.

XSL•FO
RenderX

Figure 1. Patient journey map from the neurology department: as-is.



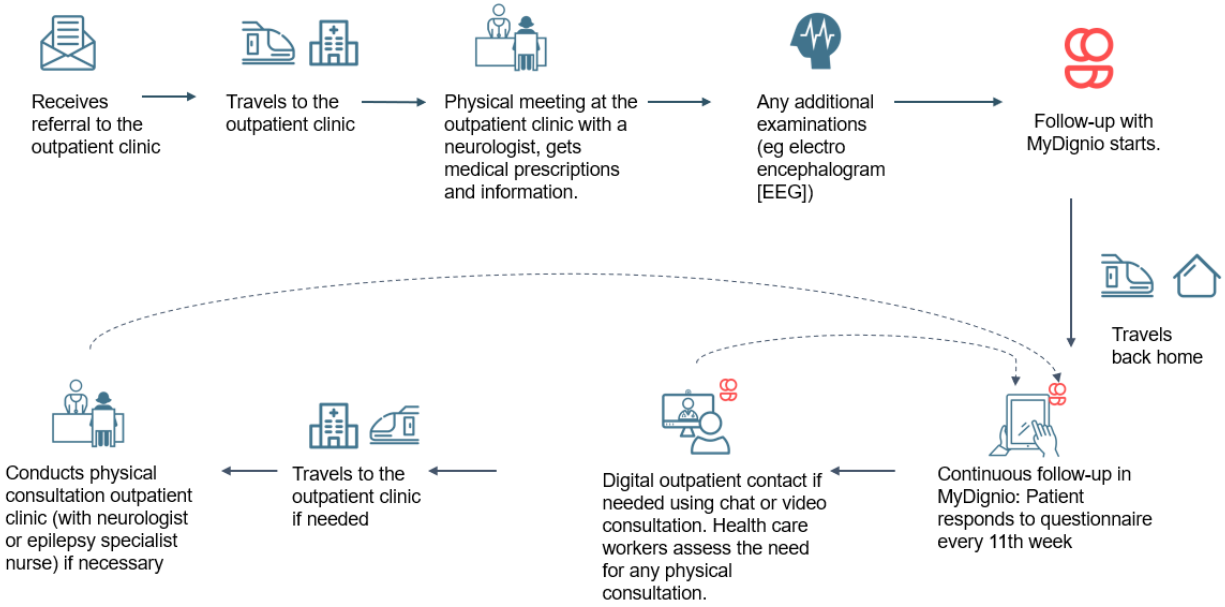


Figure 2. Patient journey map from the neurology department: to-be.

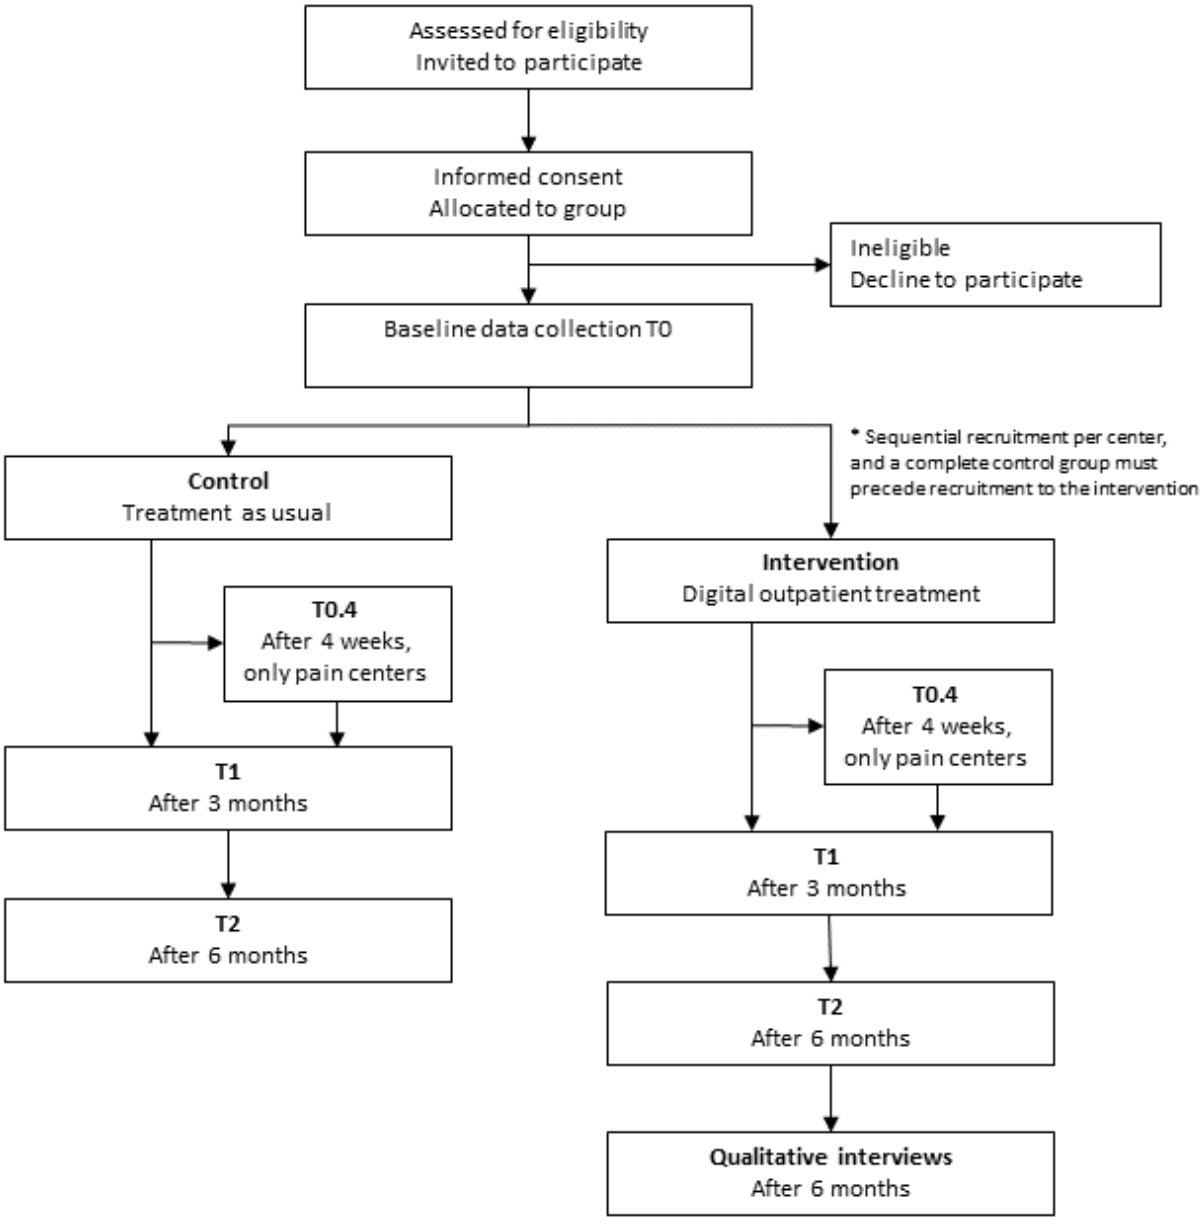
Information and Training

The patients receive a brief introduction and digital user manuals for the app. Patients using technical equipment such as spirometers are instructed to ensure correct technique and synchronization with MyDignio. Patients in the intervention group can contact their health care worker or a researcher for technical inquiries.

Most of the health care workers are familiar with the platform as they are involved in the development of the individual interventions at each center. All new health care workers receive training by the Dignio personnel or the assigned administrator at their center, and the training will be repeated upon request.

Training in interpreting scores reported by the patients is provided within each department based on the needs of the health care workers. For the majority of the involved health care personnel, the PROMs applied are already used paper-based in the clinics; thus, a dialogue between the programmers from Dignio Connected Care and the health care workers has facilitated the use of already standardized cutoffs.

Implementation is secured through the involvement of dedicated health care workers within each department that contributed to the development of the intervention, the summarizing of the "as-is," and the potential and suggestions of the "to-be" that had received training in the digital platform. In addition,



XSL•FO
RenderX

designated health care workers were compensated for 10%-20% of their time to contribute to the intervention.

Study Design for the Planned Trial to Evaluate the Intervention

The study is a multicenter, non–randomized controlled trial with 2 treatment arms and a 6-month follow-up (Figure 3). The comprehensive evaluation is based on the method for assessment of telemedicine (MAST) [50], including elements regarding the purpose and maturity of the technology, how the health problems align with the technology, safety, clinical effectiveness, patient perspectives, economic aspects, organizational, and sociocultural, ethical, and legal aspects, followed by an assessment of cross border between countries, transferability, and generalizability to other contexts. The relevance of MAST lies in its thorough assessment of the preceding conditions and its multidisciplinary assessments. Patients are currently allocated to 1 of the 2 arms. At each department, recruitment to the control arm will be completed before inclusion in the intervention arm. The control arm will receive follow-up *per the* routines at each department, largely as described in the patient journey maps labeled "as-is" (Figures 1 and 2, and Multimedia Appendix 3). The intervention arm will receive our digital outpatient service. Quantitative measures are collected longitudinally, and qualitative interviews are conducted postintervention.

Figure 3. Flowchart of the multicenter non–randomized controlled trial.

Patient Participants and Recruitment

Patients at the Department of Respiratory Diseases, the Department of Neurology, and the Department of Pain Management at OUH, as well as the Department of Cancer at UNN, are eligible for participation in the study if they are 18 years of age or older, home-based, and able to fill out Norwegian questionnaires (Table 3). Both newly diagnosed or newly referred patients, those with a diagnostic history, and those already in outpatient care are eligible for inclusion.

XSL•FO
RenderX

Eligible patients are identified through an outpatient consultation or through patient lists. All patients receive written and oral information about the project from a nurse or physician before giving their consent. The patients are not regarded as consenting participants until they have signed the consent form and filled out the baseline questionnaire. To reduce contamination in the intervention arm, patients must consent and fill out the baseline questionnaire before accessing the digital intervention.

The recruitment of patients to the qualitative interviews after the intervention is based on their consent to receive information regarding the interviews. Purposive sampling is applied to reach a heterogeneous sample with a balanced diversity in age, gender, and use of the intervention. Thus, in-depth knowledge can be obtained from both high and low users.

Table 3. Eligibility criteria for patients.

Patient groups	Inclusion criteria	Exclusion criteria
Patients with cancer	• Cancer • Receiving active treatment	• Life expectancy: less than 6 months • Expected need for follow-up: less than 6 months
Patients with interstitial lung disease (ILD)	• ILD	• Very low degree of function with risk of cognitive influence
Patients with epilepsy	• Epilepsy	• Complex causes of epilepsy • Severe comorbidity • Other planned or ongoing assessment and treatment, including assessment of unexplained illness or testing of medication
Patients with long-term, complex pain	• Drug testing, adjustment, and dose reduction • Self-administering medication	• Comorbidity that directly affects the drug adjustment • Interference with other ongoing treatment • Cognitive impairment • Not living at home

Health Care Personnel Participants

Health care workers in the hospital departments are eligible for the qualitative interviews if they are affiliated with the included departments and have had a role in this project. This group includes leaders and health care workers, such as nurses and physicians, with hands-on management of patient follow-up through the intervention.

Randomization and Blinding

This is a non–randomized controlled trial without blinding. Both patients and health care workers are familiar with the treatment arm to which the participants belong during the study.

Outcomes to be Measured

Overview

The study will consider the elements affected by both external factors in the health care services and internal factors held by the patient. Patients will self-report on the questionnaires (Tables 4 and 5). Clinical parameters and information on the use of resources will be collected from electronic medical records. The primary outcome is the health literacy questionnaire (HLQ) domain 9 “understanding health information well enough to know what to do” [51]. This domain encompasses health actions relevant for a digital service, such as basic reading and understanding of health information, following instructions from health care workers, and the ability to fill out forms correctly. The secondary outcomes are health literacy, eHealth literacy, HRQL, and acceptability of the digital intervention (Table 4).

XSL•FO
RenderX

Table 4. Outcome measures for health literacy, health-related quality of life, digital health literacy, satisfaction, and COVID-19.

Measures, domains, and variables	Response options	Scale	Interpretation	Time point		
				T0	T1	T2
Health literacy						
Health literacy questionnaire (HLQ) (5 of 9 domains)						
• Feeling understood and supported by health care providers (4 items) • Having sufficient information to manage my own health (4 items) • Actively managing my own health (5 items)	All items have the same response options: strongly disagree, disagree, agree, or strongly agree	1-4	A higher score indicates a higher level of health literacy	✓	✓	✓
• Ability to actively engage with health care providers (5 items) • Understanding health information well enough to know what to do (5 items)	All items have the same response options: cannot do or always difficult, usually difficult, sometimes difficult, usually easy, or always easy	1-5	A higher score indicates a higher level of health literacy	✓	✓	✓
eHealth literacy						
eHealth literacy questionnaire (eHLQ; 7 of 7 domains)						
• Using technology to process health information (5 items) • Understanding health concepts and language (5 items) • Ability to actively engage with digital services (5 items) • Feel safe and in control (5 items) • Motivated to engage with digital services (5 items) • Access to digital services that work (6 items) • Digital services that suit individual needs (4 items)	All items have the same response options: strongly disagree, disagree, agree, or strongly agree	1-4	A higher score indicates a higher level of eHealth literacy	✓	✓	✓
Health-related quality of life (HRQL)						
RAND 12 (2 of 2 domains)						
• Physical health composite (6 items)	All items have their individual scoring, and the physical composite score is based on the following 6 items: • General health (excellent, very good, good, fair, or poor) • Moderate activities, and • Climb several flights of stairs, are scored on: limited a lot, limited a little, or not limited at all • Accomplished less (physical), and 5. Limited in any kind of work, are scored on yes or no • Pain interference (not at all, a little bit, moderately, quite a bit, or extremely)	0-100	A higher score reflects good physical health.	✓	✓	✓

XSL•FO
RenderX

Measures, domains, and variables	Response options	Scale	Interpretation	Time point		
				T0	T1	T2
• Mental health composite-12 (6 items)	• Accomplished less (emotional) (yes or no) • The following items have the same scoring: (all of time, most of the time, a good bit of the time, some of the time, a little of the time, or none of the time) • Did work less careful • Calm and peaceful • Energy • Downhearted and blue • Social limitations (time)	0-100	A higher score reflects good mental health.	✓	✓	✓
Service User Technology Acceptability Questionnaire (SUTAQ; intervention arm only)						
SUTAQ (5 of 5 domains)						
• Perceived benefit (9 items) • Kit as a substitute (3 items) • Satisfaction (3 items)	• All items have the same response options: completely agree, moderately agree, mildly agree, mildly disagree, moderately disagree, or strongly disagree	1-6	A higher score reflects higher satisfaction.		✓	✓
• Privacy and discomfort (4 items) • Care personnel concerns (3 items)	• All items have the same response options: completely agree, moderately agree, mildly agree, mildly disagree, moderately disagree, or strongly disagree	1-6	Reversed scale, thus higher score reflects a higher concern.		✓	✓
Satisfaction in general						
• Satisfaction with the outpatient service in general (3 items)	All items have their individual scoring. • Satisfaction with treatment (very satisfied, satisfied, neither satisfied nor dissatisfied, dissatisfied, or very dissatisfied) • 2. Benefit from treatment (much better, somewhat better, stayed the same, somewhat worse, or much worse)	1-6	A higher score reflects higher satisfaction.	✓	✓	✓
• Satisfaction with the outpatient service in general (3 items)	• Safer with digital outpatient services (Yes; Feel free to elaborate/ No; Feel free to elaborate)	Y/N	Yes–safer	✓	✓	✓
COVID-19						
• Perceived safety related to the COVID-19 pandemic (2 items)	• Previously infected (yes or no)	Y/N	Yes–previously infected	✓	✓	✓
• Perceived safety related to the COVID-19 pandemic (2 items)	• Fear of COVID-19 (never, seldom, sometimes, often, or almost always)	1-5	A higher score reflects more fear	✓	✓	✓

XSL•FO

Comorbidities	Number of comorbidities	✓		
Use of health care resources (from the medical record)				
Contact with the outpatient clinic	Contact type (physical consultation, video consultation, telephone call, or other), planned or acute, and number of each			✓
Use of the digital service (dose of intervention)	Contact type (PROM[a] response, task, chat, video, or other) and the number of each			✓

[a]PROM: patient-reported outcome measure.

Health Literacy

The HLQ is a multidimensional measure of health literacy, with 44 questions across 9 domains. The HLQ is validated for adults using various modes of administration, including computer-based [51,52]. The HLQ was developed in Australia, translated into Norwegian, and used in studies on chronic diseases [51,52]. To reduce overlap with the domains of the eHealth literacy questionnaire (eHLQ), 5 of the HLQ domains (domain 1,2,3,6, and 9) that represent all 3 levels of the Nutbeam model have been included in this study [14]. Domains 2 and 9 are at the basic level; domains 1, 3, and 6 are at the communicative level, while domain 3 is at the critical level of health literacy [51].

eHealth Literacy

The eHLQ is multidimensional with the same origin as the HLQ, assessing people's interactions with digital services based on the eHealth literacy framework [53]. The eHLQ contains 35 questions over 7 domains, and the full questionnaire is applied in this study. Although the eHLQ is translated into Norwegian and used in Norway, it is not yet validated. Validation in Denmark shows good psychometric properties [53].

HRQL

To assess HRQL, the patients fill out the RAND-12 [54,55], an abbreviated version of its predecessor, the SF-36. The 12 items are summarized into 1 physical and 1 mental health composite. The RAND-12 is validated in Norwegian [56].

Acceptability of the Digital Intervention

To assess acceptability among the participants assigned to the intervention arm, the patients fill out the service user technology acceptability questionnaire (SUTAQ). Acceptability refers to whether a system is good enough to satisfy users' needs and requirements. The SUTAQ also assesses the importance of having contact with health care workers and whether this may affect patients' acceptance [57,58]. The SUTAQ has 22 items across 5 domains. The participants are instructed to keep the digital outpatient service intervention in mind when responding. The SUTAQ has been translated into Norwegian, psychometrically tested [58], and is used in Norway for patients with type 1 and type 2 diabetes.

Qualitative Evaluation Measures

Individual qualitative interviews will be conducted following the same structure for patients in the intervention group and the health care workers. The interviews will explore the

XSL•FO
RenderX

interviewees' perceived satisfaction with the digital outpatient service, and security in and beyond pandemic situations. The semistructured guide has been developed by the research team, inspired by topics on innovation assessment [59] and is added as a Multimedia Appendix 4. The aim of the qualitative interviews is to gain in-depth knowledge about the components of the intervention, how they are used, and whether and how they are perceived as useful. The interviews are also intended to obtain in-depth knowledge about how the digital intervention differs from traditional consultations and how these differences are perceived. In line with the primary outcome of health literacy obtained from the quantitative measures, any experiences of improved or otherwise affected health literacy will be investigated. Accordingly, the same guide will be applied to health care workers, tailored to their profession.

Sample Size

An *a priori* sample size calculation was conducted to estimate the number of patients from all departments necessary to recruit based on changes from the baseline to the 6-month follow-up in the generic primary outcome "understanding health information well enough to know what to do" (HLQ domain 9) [51]. Previous research was summarized to find the most fitting SD. No similar studies were identified. Thus, an SD of 0.6 was applied in this study's calculations based on 3 identified studies: one study on patients with epilepsy, reporting an SD of 0.77 after 18 months of follow-up [60], and studies reporting an SD of 0.42 in patients after kidney transplant [61] and an SD of 0.025 in the Danish norm data [62]. With no previous description of a minimally important difference for this exact domain, a 10% change on this scale of 1-5 was calculated, ending in a 0.5-unit difference between the groups. The analysis was based on a power of 0.90, an SD of 0.6 from the outcome measure, and a 2-sided significance test. The effect size was a 0.5-unit difference between the groups on a scale of 1-5, with a 20% dropout and an opportunity to perform controlled analyses. With a 1:2 recruitment ratio, this study must have a minimum of 55 participants in the control group and 110 participants in the intervention group. This is equivalent to a total sample size of 165 participants. When divided among the 5 departments, each department must recruit 33 participants. However, the total sample size is a shared goal. The intention was a 1:1 allocation of participants; however, to provide a more efficient recruitment when recruitment was slow, a statistician was consulted, suggesting an alternation in the allocation to ensure a sufficient sample size in favor of both groups.

For the qualitative interviews, this study needs a sample of 12-15 patients from the intervention group [63] and 12-15 health care workers or stakeholders that have experience with the tailoring of, or patient follow-up, using the digital outpatient intervention.

Analysis

Statistical Analysis

The baseline and follow-up variables will be presented descriptively. Continuous variables will be analyzed using the mean and the SD for normally distributed data and the median and the range if the data are skewed. Categorical data will be presented as counts and percentages. The mean change will be estimated by subtracting the baseline score from the follow-up score, both at 3 months and 6 months. Differences in mean changes in short-term and long-term variables will be modeled using a one-way ANOVA. To adjust for possible confounders, logistic regression models will include age, gender, education, and hospital department. Missing data will be handled according to the syntax and protocol of the standardized instruments, such as HLQ, eHLQ, SUTAQ, and RAND-12. The missing data in terms of dropout has been accounted for in the power analysis.

Qualitative Analysis

Individual interviews with patients and health care workers will be audio-recorded, transcribed verbatim, and analyzed using thematic analysis [64], with the following steps: (1) familiarize with the data; (2) generate initial codes; (3) search for themes; (4) review themes; (5) define and name the themes; and (6) produce the report. Examples of data extracts and codes will be presented alongside the final thematic analysis results. Patient interviews will be analyzed by 2 researchers (HH and EF), while health care worker interviews will be analyzed by HH, EF, and an associated member of the research team. Any conflicts during the analysis will be resolved through discussion as a natural part of the analysis process. Preliminary findings will be presented to the project group to add reflections and nuances not already addressed.

Data Security

Digital consent and digital responses to the questionnaires are collected using a service for sensitive data developed at the University of Oslo. The service for sensitive data is designed for storing and processing sensitive data in compliance with the Norwegian "Personal Data Act" and "Health Research Act." The questionnaires are sent to the participants through the pretty good privacy-encrypted version of the University of Oslo web-questionnaire service "Nettskjema" which demands a governmental ID portal for login and allows secure data harvesting. A personal, secure link to the follow-up questionnaires is sent to the participants' email or mobile phone, with 1 reminder after 6-7 days in the case of unanswered questionnaires, followed by a phone call if they still have not filled out the pending questionnaire after 1 more week.

Ethics Approval

The regional ethical committee (REC) in Norway prereviewed the protocol and judged the project as outside its mandate according to the Norwegian Health Research Act (REC south-east reference number 252051). The project was reviewed by the institutional data protection officer at UNN regarding the cancer department (reference number 2021/4942) and the data protection officer at OUH regarding the remaining departments (reference number 21/06826); both granted approval.

Results

Trial Status

Recruitment started in September 2021, and as of December 14, 2022, a total of 55 patients had been enrolled in the control

XSL•FO
RenderX

group, and 101 patients had been enrolled in the intervention group. It is expected that the recruitment will be completed by the end of December 2022 and that the 6-month follow-up for all participants will end by June 2023. Qualitative interviews will be conducted successively as the participants complete their 6-month assessments. All study results are expected to be ready by the end of 2023.

Deviations From the First Registration in Clinical Trials

Initially, this study was a 2-arm trial with a 1:1 recruitment ratio. Recruitment was planned in 4 departments, and the department of pain management aimed at recruiting both patients with chronic pain as well as acute postoperative pain. However, due to unforeseen challenges, the recruitment of patients with postoperative pain was terminated in March 2022. Thus, a new power analysis was performed with reduced heterogeneity. Additionally, the follow-up period was shortened from 12 months to 6 months due to the lengthy process of the risk and vulnerability assessment before the use of the digital outpatient service in the hospital setting, which had not been done before this study.

Discussion

Evidence regarding the need for multicomponent digital outpatient services and their possible effects on outcomes in a real-life setting remains scarce [12,16]. Therefore, this study will likely provide valuable knowledge as it aims to assess the impact and acceptability of digital outpatient services and their effects on health literacy, HRQL, and the acceptability of the digital intervention. The analyses will also address how the digital outpatient intervention is used. In-depth perspectives gathered from the qualitative interviews with patients and health care workers will add value to the qualitative findings. This study will provide important knowledge about the applicability and effects of digital health care services. As a result, patients and health care workers will gain a new, evidence-based understanding of whether and how digital tools may be used in clinical care.

The described intervention will be delivered through a multicomponent digital platform (Dignio) that has been implemented and studied in various health care settings in recent years. This way, digital usability is considered ready for evaluation on a larger scale in specialized outpatient care services. By collaborating with the clinical environment and the patient's journey to identify the best potential for the digital intervention, the relevance of the intervention is increased. Likewise, complementing the digital platform with PROMs and clinical measures based on the expected needs according to the patient's diagnosis will likely facilitate use among patients and health care workers. Together, these will add value to this study's evaluation of health literacy, HRQL, and the acceptability of the intervention.

This intervention will support and enhance patients' understanding of health information well enough to know what to do, make them feel understood and supported by health care workers, ensure that they have sufficient health information, support their feeling of actively managing their health, and improve their ability to interact with health care workers. These actions are directly transferable to the HLQ and this study's outcome domains [51]. Additionally, the intervention will support patients' use and understanding of digital solutions for health and thus their engagement, as well as ensure their access to digital solutions that work, suit their needs, and keep their health data secure, all of which are transferable to digital health literacy [12,53]. Altogether, this intervention will target and measure the domains of health literacy skills at the basic, communicative, and critical levels [14]. This study will also consider factors that are affected by external factors in health care services and the internal factors held by the patient. As this intervention will be individualized according to each patient's needs, it can facilitate health actions and lead to an increase in health literacy.

This study describes how the digital outpatient service intervention will be explored in a multicenter, nonrandomized controlled trial with 2 treatment arms and a 6-month follow-up. The strengths of the current trial include its focus on patient-reported health literacy in a digital health intervention that targets a diverse sample of outpatients. Previous interventions have tended to focus on a single component, target a very specific sample, and primarily use clinical end points. Whether or not a patient chooses to use a digital intervention perhaps relies more on their health literacy and motivation to self-monitor, and a positive change in clinical end points may primarily be perceived as a potential result of their health literacy levels and self-monitoring. Moreover, the multimethod design inspired by the MAST [50] will provide quantitative data on the effects of the intervention on health literacy and in-depth qualitative knowledge on the acceptability of the intervention among patients and health care workers. Overall, the proposed trial will evaluate the effects while providing an understanding that can facilitate lasting changes in how outpatient specialty health services use digital solutions.

The proposed trial is designed as a nonrandomized trial, which inherently includes some risk of bias. Thus, differences may occur between the control group and the intervention group. The groups will therefore be compared at baseline to detect any imbalances that would need handling in the statistical analysis. Changes in outcome measures will be calculated based on the change from baseline to follow-up, thus handling the fact that individuals might have a different baseline score. Further, we did not pilot the intervention within each group before the full trial, which could have revealed weaknesses relevant to the full trial. Lastly, the outcomes measured by standardized questionnaires have not been used to screen for any need for a more tailored intervention. That is, it could have been relevant to tailor the intervention based on the participants' scores in health literacy or digital health literacy. Individual health care workers have individualized patient follow-up based on the patients' needs, but not through systematic screening. Also, we do not have data on the occurrence of any comorbidities in the sample, which could have been a relevant confounder added to the already described ones. No patients were specifically involved in the development of this intervention or the design of this trial. However, the intervention toward patients with

XSL•FO
RenderX

epilepsy was developed alongside user representatives before this study.

Acknowledgments

The authors would like to thank all the participating patients, all the health care workers participating in the development and patient follow-up in this study, particularly Saida Alfrida Martinez Overgaard, Monica Mellegård, Anne-Maria Johanna Tanskanen, Erik Taubøll, Merete Lyngstad, Markus Sonnenberg, Kristin Iren Jensen, Magnar Johansen, Audun Stubhaug, Unni Halvorsen, and Karl Arne Johannessen, and our project team at Dignio Connected Care for facilitating the digital platform. Furthermore, we would like to thank the statistician Ragnhild Falk Sørum, who provided valuable guidance in the power analysis. And, lastly, we would like to thank the staff at Dignio for their valuable insight and practical tailoring of their platform and for a good collaboration, particularly with Anna Hurrød, Meetali Kakad, and Andreas Norling.

This work was supported by the Research Council of Norway (grant 316244), internal funding from Oslo University Hospital and University Hospital of North Norway to secure staff, and funding from Dignio Connected Care to finance user licenses on the digital platform. The Research Council of Norway and Dignio Connected Care had no role in preparing this manuscript.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study. Future data collected as part of the study described in this protocol will be made available from the corresponding author upon reasonable request.

Authors' Contributions

All authors had a substantial contribution in the development of the intervention. HH drafted and revised the manuscript and has the responsibility for data collection in the ongoing trial. HH wrote the PRO specific content of the protocol. CE, AMH, TKK, and LSL are responsible for local recruitment and intervention. CE, LPG, AMH, TKK, LSL, TML, and EF commented and revised on versions of the draft, and all approved the final manuscript. The funding proposal was written by EF, TKK, Dignio, and other partners.

Abstract

Background: There is a growing body of academic literature focusing on the significant financial burdens placed on people living with cancer, but little evidence exists on the impact of rising costs of care in other vulnerable populations. This financial strain, also known as financial toxicity, can impact behavioral, psychosocial, and material domains of life for people diagnosed with chronic conditions and their care partners. New evidence suggests that populations experiencing health disparities, including those with dementia, face limited access to health care, employment discrimination, income inequality, higher burdens of disease, and exacerbating financial toxicity.

Objective: The three study aims are to (1) adapt a survey to capture financial toxicity in people living with dementia and their care partners; (2) characterize the degree and magnitude of different components of financial toxicity in this population; and (3) empower the voice of this population through imagery and critical reflection on their perceptions and experiences relating to financial toxicity.

Methods: This study uses a mixed methods approach to comprehensively characterize financial toxicity among people living with dementia and their care partners. To address aim 1, we will adapt elements from previously validated and reliable instruments, including the Comprehensive Score for Financial Toxicity and Patient-Reported Outcomes Measurement Information System, to develop a financial toxicity survey specific to dyads of people living with dementia and their care partners. A total of 100 dyads will complete the survey, and data will be analyzed using descriptive statistics and regression models to address aim 2. Aim 3 will be addressed using the process of "photovoice," which is a qualitative, participatory research method that combines photography, verbal narratives, and critical reflection by groups of individuals to capture aspects of their environment and experiences with a certain topic. Quantitative results and qualitative findings will be integrated using a validated, joint display table mixed methods approach called the pillar integration process.

Results: This study is ongoing, with quantitative findings and qualitative results anticipated by December 2023. Integrated findings will enhance the understanding of financial toxicity in individuals living with dementia and their care partners by providing a comprehensive baseline assessment.

XSL•FO
RenderX

Conclusions: As one of the first studies on financial toxicity related to dementia care, findings from our mixed methods approach will support the development of new strategies for improving the costs of care. While this work focuses on those living with dementia, this protocol could be replicated for people living with other diseases and serve as a blueprint for future research efforts in this space.

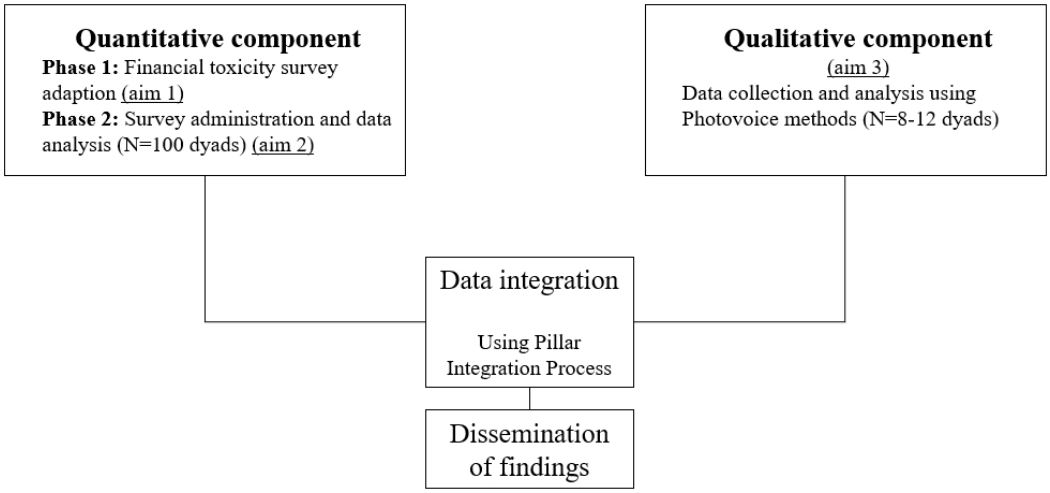
Introduction

There are significant financial burdens placed on people living with chronic, complex medical conditions and their care partners. The growing body of evidence primarily focuses on people with cancer and the subsequent adverse effects of financial hardship due to the unchecked rising costs of cancer care [1,2]. This treatment-related financial strain of cancer care for people diagnosed and their family members has been coined financial toxicity. Financial toxicity can impact multiple domains of life, including behavioral (eg, rationing medications or medical care due to costs), psychosocial (eg, depression associated with medical costs), and material (eg, bankruptcy, loss of income, and debt) [3-5]. It can take the form of both direct costs (eg, copays for appointments and medication) and indirect costs (eg, lost income from a patient or care partner's inability to work).

There is mounting evidence that people living with dementia and their care partners face limited access to health care, employment discrimination, income inequality, and higher burdens of disease [6]; however, the majority of evidence surrounding financial toxicity has focused on the population with cancer [7]. Previous research highlights the high cumulative financial burden of dementia (particularly in the final years of life) [8-10]. Other studies have quantitatively examined the relationship between financial difficulty and care partner mental health [11]. Yet few studies have combined qualitative and quantitative methods to examine the complex behavioral, psychosocial, and material impacts of dementia and dementia-related care costs. There remains limited knowledge surrounding how these domains of financial toxicity are experienced by people living with dementia and their families, this knowledge is essential to inform system-level solutions. The Comprehensive Score for Financial Toxicity (COST) measure is a reliable screening tool within the cancer space, but a similar metric does not exist within the dementia space [12].

The purpose of this study is to comprehensively characterize the financial burdens experienced by people living with dementia and their care partners using a mixed methods approach. This study is guided by the following aims: (1) adapt a survey to capture financial toxicity in dyads of people living with dementia and their care partners, (2) characterize the degree and magnitude of different components of financial toxicity among people living with dementia and their care partners (eg, out of pocket expenses, financial stress, and retirement savings), and (3) empower the voice of people living with dementia and their care partners through images and critical reflections of their perceptions and experiences related to financial well-being and hardship due to dementia using "photovoice," a creative, qualitative method. Results of this study will support the identification of primary drivers of financial toxicity for potential system-level solutions to mitigate patient burden.



Methods

Study Design

This study will use a convergent mixed methods design to comprehensively characterize financial toxicity among people living with dementia and their care partners. Quantitative methods include survey adaptation (aim 1) and administration and analysis (aim 2). Qualitative photovoice methods will be used to address aim 3. Quantitative and qualitative data will be collected concurrently within a similar time frame, analyzed independently, and then integrated using a validated, joint display table approach called the pillar integration process (PIP) [13]. (See Figure 1 for an overview visualization of quantitative and qualitive component data integration)

XSL•FO
RenderX

Figure 1. Quantitative and qualitative components and data integration overview.

Quantitative Methods

A financial toxicity survey will be adapted to capture sociodemographic data, out-of-pocket expenses, and cost-coping strategies of the people living with dementia and their primary care partners. Adapted elements from validated instruments include the Patient-Reported Outcomes Measurement Information System (PROMIS) [14], COST [12], the Institute for Medical Technology Assessment Productivity Cost Questionnaire (iPCQ) [15], and the Cost of Care Index [16]. (See Table 1 for adapted elements from validated instruments included in the survey)

The survey will then be administered to 100 participant dyads of people living with dementia and their care partners. The study includes a projected sample size of 100 dyads (200 total participants). We chose a sample size of 200 for our survey study based on a power analysis conducted to detect even a small effect size (Cohen *d*=0.2) with low to moderate variability of SD 0.5-1.0. The power analysis indicated that a sample size of 200 would be sufficient to detect this small effect size with 80% power at a significance level of .05 (See Table 2 for power analysis and sample size calculations).

Table 1. Concepts, measurement instruments, psychometric properties, and references.

Concept and measurement instruments	Psychometric properties	References
• General health of person living with dementia and care partner: Perceived General Health (Likert scale; 1 item) • Mental health of person living with dementia and care partner: Perceived Mental Health (Likert scale; 1 item)	• Internal consistency: Cronbach α of .73-.81 have been reported for physical and mental health reporting items [17] • Test-retest reliability: ICCs[a] were greater than 0.85 for physical and mental health scores [18]. • Construct validity: physical function measures have high correlations with conceptually related measures ranging from 0.43 to 0.82, demonstrating strong convergent validity [19]. • Discriminant validity: Patient-Reported Outcomes Measurement Information System physical function measures show weak correlations with dissimilar domains, indicating good discriminant validity. [20]	Patient-Reported Outcomes Measurement Information System Questionnaire [14]
• Financial toxicity for dyad: Perceived Likelihood of Various Financial Costs (Likert scale; 5 items)	• Internal consistency: Cronbach α of .73-.86 have been reported for general financial situation and impact of illness on financial situation items [21] • Test-retest reliability: cost measures have been reported to have ICC of 0.80 [12] • Construct validity: the Comprehensive Score for Financial Toxicity measures of financial toxicity are shown to have good predictive validity and be multidimensional in a sample of individuals with chronic conditions [22] • Discriminant validity: discriminant validity has been reported as acceptable when compared to the Financial Index of Toxicity and Breast Cancer Finances Survey Inventory [23]	Comprehensive Score for Financial Toxicity tool [12]
• Amount of missed work for the person living with dementia and for the care partner: Perceived Missed Work (Likert scale; 1 item)	• Internal consistency: interitem correlation has been reported to range from 0.42 to 0.62 for productivity cost items, including absenteeism [24]. • Test-retest reliability: ICCs for absenteeism have been reported as greater than 0.88, indicating overall good reliability [24]. • Construct validity: confirmatory factor analysis found a 3-component solution accounting for 82% of the total variance, similar to the original study of the Institute for Medical Technology Assessment Productivity Cost Questionnaire [24] • Discriminant validity: discriminant validity has been reported as acceptable when included in a comprehensive questionnaire [25]	Institute for Medical Technology Assessment Productivity Cost Questionnaire [15]
• Financial toxicity of dementia care for dyad: Perceived Likelihood of Various Financial Costs (Likert scale; 5 items)	• As the Cost of Care Index is not a specific instrument, it does not have standardized psychometric properties such as reliability or validity. It is primarily used to compare the relative cost of living and health care expenses in different geographies.	Cost of Care Index [16]

[a]ICC: intraclass correlation coefficient.

Table 2. Power analysis and sample size calculations.

	Low variability (SD 0.5)	Moderate variability (SD 1.0)	High variability (SD 1.5)
Small (Cohen *d*=0.2)	125	252	405
Medium (Cohen *d*=0.5)	32	64	102
Large (Cohen *d*=0.8)	14	28	43

Eligible participants with dementia will (1) be at least 40 years old and (2) have a diagnosis of dementia of any type (determined by self- or proxy-report by caregiver). The age range of 40 years and older was chosen, as it provides a more inclusive view of the population with dementia and has been shown to be a critical, but less understood time period in dementia-related pathology [26,27]. Eligible care partners must (1) be at least 21 years old; (2) identify as the primary care partner of the person with dementia; and (3) be able to read and speak English. Dyads must live together in the same household and will be excluded if they reside in an assisted living home, nursing home, or other long-term care setting. The survey can be completed by the dyad together or by the caregiver on behalf of the family unit.

Dyads will be recruited through several local, regional, and national dementia- and caregiver-specific community support organizations, including the Duke Dementia Family Support Program, Dementia Inclusive Durham, Durham Center for Senior Life, Family Caregiver Alliance, and the National Council of Dementia Minds. Study information and flyers will be shared through web-based and in-person events offered by these organizations. Study information will also be shared

XSL•FO
RenderX

through a national social media campaign using Facebook and Reddit. Interested individuals will be able to access the eligibility screening electronically using a link or QR code or contact the study team directly to determine eligibility. Our social marketing plan was developed with guidance and support from the Duke Clinical and Translational Science Institute Recruitment Innovations Center. We will use an adaptive recruitment method and review recruitment and enrollment every week through weekly team meetings. Changes will be made to recruitment strategies as necessary to reach our projected samples.

If eligible, participants will complete the survey electronically through REDCap's survey distribution platform or by hardcopy depending on their preference. Participant responses will auto-populate to the study's REDCap database. All participants will review a study informed consent form embedded in the electronic survey, or as a hardcopy. Completion of the survey will be considered implied consent to participate in the study.

Data Analysis

The data analysis for this survey will involve both descriptive and inferential statistical analysis. Descriptive statistics will be used to summarize the background demographics and qualitative responses about financial hardship. Inferential statistics, such as the Wilcoxon rank-sum test, logistic regression, and correlation analyses will be used to examine the relationships between financial health, demographic variables, and additional survey elements. Results will be reported with appropriate measures of central tendency and dispersion, and statistical significance will be determined at an α level of .05. Stata (StataCorp) will be used to manage, analyze, and create graphical presentations of data.

Qualitative Methods

Photovoice is a highly creative, participatory research method that involves photography, reflection, and in-depth discussion to capture the lived experience and empower the voice of participants [28]. Photovoice methods were selected for this study as reflection on photos and photo-elicitation is an important approach to more actively engage people living with dementia by allowing them more opportunities to share their lived experiences using verbal communication, as well as visual cues [29,30].

The qualitative component of this study will engage 8-12 dyads of people living with dementia and their care partners recruited through the same channels as the quantitative component. The same eligibility criteria will be used for the qualitative component as is used for the quantitative survey with two additions: (1) participants with dementia in the qualitative component must also be able to express themselves verbally in English and (2) dyads must have access and ability to use a phone or internet. Dyads who complete the quantitative survey can also participate in the qualitative component, provided they meet the eligibility criteria. A study informed consent form will be sent to all participants and verbal consent will be obtained by telephone from all dyads before data collection.

All consenting dyads will attend a series of 6-8 group discussion sessions using the photovoice participatory research approach. The photovoice methodology includes taking photos, discussing these photos with a group, selecting photos to caption, and grouping photos and captions thematically (Table 3) [31,32]. Photovoice was chosen as the preferred qualitative research method because people living with dementia may be limited in their ability to engage verbally, and photos can allow them to communicate aspects about their self and daily living [33]. Given that financial changes can be mundane and ingrained into everyday life, photos may be well-positioned to capture the topic of financial toxicity. Furthermore, photo elicitation also has been shown to enable caregivers of individuals living with dementia to share a more nuanced look into their own experience [34]. Participants will be encouraged to use their own cell phones or digital cameras to take photos. Disposable cameras will be provided to participants without phones or cameras. No photos will be kept by the study team without written permission from participants. Ownership and copyright of the photos will remain with the participants, and media release forms will be obtained as needed for the dissemination of findings. Qualitative analysis occurs through interactive and iterative group discussions throughout the photovoice process. Data analysis will occur in the following ways:

- Coding selected photographs and calculating a summary frequency count by theme.
- Visual analysis of selected photographs, involving (1) descriptions of photo production techniques, for example, spontaneous or planned photography, existing photos, and photos taken by someone other than the participant; (2) thematic analysis of how the subject matter, caption content, or photo group themes relate to the broader topic [35]; and (3) structural narrative analysis of the photo and caption together to understand how participants make sense of their realities and experiences through photography [35].

XSL•FO
RenderX

Table 3. Overview of photovoice sessions and procedures. Procedures achieved through each session may vary depending on the group's process. This table is meant to provide an overview and preliminary plan but may be adapted throughout the study.

Photovoice group sessions	Description
1	The research team will introduce participants to the overall photovoice process and the group will broadly discuss the meaning of financial health and well-being.
2	The research team will introduce the ethics of photo taking for research purposes and basic photography skills. As a group, participants and the research team will brainstorm ideas for photos that participants could take in their daily lives to capture financial well-being and hardship.
Between sessions 2 and 3	People living with dementia and care partners will take photographs between sessions to document their own experiences with financial well-being and financial hardship. From the photos taken, dyads will select 3-5 for group discussion.
3 and 4	People living with dementia and care partners will be asked to share and discuss their photos. They will be asked to describe how each photo relates to financial well-being and hardship, what it was like to take each photo, and what it feels like to reflect on the photo through group discussion. Sharing and discussion of photos will occur 1-on-1 with a study team member, in small groups, or with the larger group. A trained research team member will take detailed notes on these discussions. Post-group summaries will be prepared after each group by a trained research team member.
5	Participants will work with the research team to write or dictate narrative captions and titles for each photo they shared.
6 and 7	As a group, participants and research team members will group photos into themes that cluster together conceptually. The team will analyze photos, titles, captions, previous session notes, and postgroup summaries to identify emergent themes. Consensus on final themes and theme titles will be achieved through in-depth discussion.
7 and 8	Participants and research team members will work together to prepare materials to present photovoice findings through a public exhibit of photographs and captions. This exhibit will be designed to engage broad audiences to encourage dialogue among people living with dementia and their families, researchers, community leaders, health care professionals, policymakers, decision-makers, and others.

Data Integration Process

Quantitative and qualitative data will be analyzed independently and then integrated using a validated mixed method, joint display table approach called PIP. The PIP includes 4 stages to integrate mixed methods data after it has been analyzed independently (See Table 4, Table 5, and Textbox 1 for stage descriptions, exemplar, and emergent pillar themes) [13]. The PIP is designed to not only verify or illustrate discrepancies between quantitative results and qualitative findings, but also expand findings through identification of emergent pillar themes. Pillar themes emerge by rigorously comparing and contrasting quantitative results and qualitative findings.

Table 4. Pillar integration process stages.

Pillar integration process stages	Description
Stage 1: Listing	Raw data and coded or grouped data are listed in a joint display table (Table 5) in the quantitative data and categories columns, or the qualitative codes and qualitative categories columns.
Stage 2: Matching	Quant data and qualitative codes that reflect similar content, patterns, or qualities are horizontally aligned to match quantitative results to qualitative findings.
Stage 3: Checking	Data cross-checked for completeness and appropriate matching.
Stage 4: Pillar building	Findings in the quantitative and qualitative columns are compared and contrasted, and gaps are identified to analyze patterns, insights, and emergent findings to build inferences from the findings as a whole, then added to the pillar building themes column.

Table 5. Pillar integration process exemplar table. Concept: health-related financial hardship among people living with dementia and their care partners; goal: illustrate points of convergence in quantitative results with qualitative findings, identify discrepancies and gaps, and expand findings to elucidate potential strategies to reduce financial hardship among dyads living with dementia

Quantitative data	Quantitative categories	Pillar building themes	Qualitative categories	Qualitative codes
Raw data (percentages, frequencies, means, cross-tabulations)	Coded or grouped data abstracted from raw data (categories abstracted from raw data)	Integrated themes identified through the pillar building process	Coded or grouped data (themes and categories)	Raw data (narratives, captions, individual photographs, notes)

XSL•FO
RenderX

Textbox 1. Pillar integration process data and emergent pillar themes.

Hypothesized example of PIP data and emergent pillar theme

- 30% of lower-income dyads report that they do not have enough money in savings, retirement, or assets to cover the costs of the partner living with dementia care, compared to 10% of higher-income dyads.
- Higher use of savings to pay for care for lower-income dyads.
- Targeted strategies are needed that include alternatives to using savings to pay for dementia related-care for families in lower income brackets.
- Unanticipated use of savings.
- Caption of a photo taken by photovoice participant with dementia of a hospital bill: "Not my plan for retirement savings."

Dissemination of Findings

Findings will be disseminated through scholarly outlets (eg, abstracts, manuscripts, symposiums, and presentations), as well as to the broader public through news and social media. A web-based or in-person photovoice exhibit will be held to raise awareness of financial toxicity in this population. The exhibit's intent will be to inspire discussion and actionable solutions to improve the lived experiences of people living with dementia and their care partners. Further brainstorming sessions may be planned, depending on the interest of attendees.

Ethics Approval

This study protocol was reviewed and approved by the Duke Health Institutional Review Board (PRO00111170).

Consenting Procedures

Quantitative Component

In place of written or verbal consent, participants will be asked to review a study information sheet embedded at the beginning of the survey. The study information sheet indicates participation is voluntary and that participants can stop the survey for any reason at any time. Completion of the survey implies voluntary consent. The study information sheet will include contact information that participants can use to contact the study team with any additional questions.

Qualitative Component

All participants will provide their consent verbally to participate in the photovoice project. Potential participants will review a study consent form with a research team member by phone who will assess participants' understanding of participation and answer any questions that participants have regarding the study. After reviewing the consent form, participants will be asked verbally if they wish to participate in the study. Both members of the dyad must provide verbal consent. Date of verbal consent and staff member who received consent will be documented. The research team member obtaining consent will let participants know that they can ask questions regarding consent or withdraw participation at any time throughout the study.

Understanding of Participation

To demonstrate a sufficient understanding of study participation, a trained research team member designated to obtain consent will use the teach-back method [36], where they will ask potential participants to recall or explain topics that were discussed in the study information sheet, using their own words. These questions are meant to prompt a discussion [36]. The designated research team member will ask the following questions to assess comprehension of informed consent: (1) "This is a research study, do you have to participate?" (2) "What would you do if you change your mind about participating in the study?" (3) "There are some risks involved in this study. Can you tell me about the risks discussed?" (If they do not remember, they are prompted to review them again), and (4) "Do you still want to participate after hearing all the details?" If the person living with dementia or the care partner participant cannot demonstrate comprehension of study participation or necessary cognitive ability for study participation or both as assessed by the research team member, the dyad will not be included in the study.

Confidentiality

To protect participants' confidentiality, we will limit the amount of protected health information and identifiable information that is collected. Data management will strictly adhere to the Duke University Health System Institutional Review Board guidelines and federal privacy regulations. All participant data (eg, questionnaires, photos, captions, discussion notes, themes, and categories) will be deidentified, where each participant will receive a 3-digit identification number that will be used to label their data materials. Only the study principal investigators will have access to the key linking identification numbers to participants' names. No identifiers will be used in reports, materials, or presentations that originate from this study. For publication purposes, only group data will be published. All data will be stored in a secure Duke University manner (secure drives, identifiers separate). More specifically, all recorded information will be documented in an electronic format. All electronic data files will be stored only on a password-protected secure file server (located behind a firewall) using a Duke University secure file server, or on a secure REDCap study database. Nonelectronic files will be immediately entered into the study database upon receipt, then shredded.

Compensation

Dyads that complete the survey will be able to follow a separate link at the end of the survey to provide their contact information to receive a US $25 gift card as compensation. These responses will not be linked to the finance survey responses. Participant dyads in the photovoice component will receive a US $100 check for compensation.

XSL•FO
RenderX

Results

Quantitative Component

This study is ongoing with survey data collection anticipated to be completed by December 2023. Quantitative results from survey analysis are expected to describe the extent to which dyads experience financial toxicity and correlation across sociodemographic identities, out-of-pocket expenses, and cost-coping strategies.

Qualitative Component

The study team anticipates a comprehensive collection of photographs and narrative captions from each photovoice session, compiled into a poster for exhibition. Anticipated results from the data integration process are emergent themes pertaining to potential strategies to reduce financial hardship among dyads living with dementia (see Table 5) [13]. Emergent themes will be highlighted in the photovoice exhibit and used to spark discussion among the research team and attendees.

Discussion

Overview

Financial toxicity has garnered more of the limelight in recent years; however, the academic and policy focus has centered on people diagnosed with cancer. While rising financial costs and associated financial burden on health systems are frequently studied, there remains a dearth of evidence on the impact these costs might have on the individual level. Longitudinal and chronic diseases have rarely found a place in the academic literature, especially with regard to the financial impact on the patient and their family. Dementia is one particularly important chronic disease process with an estimated prevalence of 7 million people living with dementia in the United States, and the number is projected to rise to 12 million by 2040 [37]. Our study would be one of the first to use a mixed methods approach to characterize financial toxicity in individuals living with dementia and their care partners.

This study must be considered in the context of its potential strengths and limitations. The strengths of this study center on its novel methodological approach of integrating both qualitative and quantitative methods. In particular, the use of photovoice allows us to richly capture the “patient voice,” which is frequently missing in financial studies that use retrospective, claims-based, and even validated financial questionnaires. Potential limitations include difficulty ascertaining individual insurance plans which impact out of pocket health care expenditures and therefore the degree of financial toxicity. Because recruitment for this study was primarily through partner organizations and social media campaigns, additional limitations may include a bias toward participants of higher socioeconomic positions.

The results of this study have important implications for health care professionals, policymakers, and leaders going forward. Policymakers, including the Center for Medicare and Medicaid Services and Center for Medicare and Medicaid Innovation, have emphasized a focus on addressing affordability of care for people in their strategic vision [38]. However, a major roadblock in developing new care models or policies to improve affordability is robust financial data for people with chronic diseases like dementia. Our study would provide a baseline assessment of the financial well-being of people living with dementia and their care partners to support the development of new strategies for improving costs of care. Furthermore, as new treatments and high-cost drugs are potentially incorporated into the care pathways for those with dementia, this financial baseline will become increasingly important to understand the financial impact these medications and treatments could have. Importantly, understanding financial health at the individual level provides an important foundation for improving health equity. While this work will start with those living with dementia, this protocol could potentially be replicated for people living with other diseases as well and serve as a blueprint for future research efforts in this space. Insights gleaned from this study can also support education and training materials for health care professionals regarding financial resources available for people living with dementia. Gaining a better understanding of the financial challenges that people living with dementia and their caregivers face can inform the creation of pathways to assist families in navigating the financial journey after diagnosis.

Conclusions

The issue of financial toxicity is an increasingly prevalent problem for people living with chronic conditions and their care partners. Despite considerable evidence for the financial burdens of cancer care, there is little known about financial toxicity’s impact on people living with dementia and their families. This study will use an adapted survey and photovoice interviews as quantitative and qualitative methods to comprehensively characterize financial toxicity in dementia dyads. Study results will enhance the understanding of financial toxicity in individuals living with dementia, provide insights into the primary drivers of financial burden, and explore potential solutions to mitigate this issue. Findings from this study can be used to inform payment reform efforts, lead to improved health outcomes for people living with dementia and increase support for their families.

Abstract

Background: The national Omaolo digital social welfare and health care service of Finland provides a symptom checker, Omaolo, which is a medical device (based on Duodecim Clinical Decision Support EBMEDS software) with a CE marking (risk class IIa), manufactured by the government-owned DigiFinland Oy. Users of this service can perform their triage by using the questions in the symptom checker. By completing the symptom checker, the user receives a recommendation for action and a service assessment with appropriate guidance regarding their health problems on the basis of a selected specific symptom in the symptom checker. This allows users to be provided with appropriate health care services, regardless of time and place.

Objective: This study describes the protocol for the mixed methods validation process of the symptom checker available in Omaolo digital services.

Methods: This is a mixed methods study using quantitative and qualitative methods, which will be part of the clinical validation process that takes place in primary health care centers in Finland. Each organization provides a space where the study and the nurse triage can be done in order to include an unscreened target population of users. The primary health care units provide walk-in model services, where no prior phone call or contact is required. For the validation of the Omaolo symptom checker, case vignettes will be incorporated to supplement the triage accuracy of rare and acute cases that cannot be tested extensively in real-life settings. Vignettes are produced from a variety of clinical sources, and they test the symptom checker in different triage levels by using 1 standardized patient case example.

Results: This study plan underwent an ethics review by the regional permission, which was requested from each organization participating in the research, and an ethics committee statement was requested and granted from Pirkanmaa hospital district's ethics committee, which is in accordance with the University of Tampere's regulations. Of 964 clinical user–filled symptom checker assessments, 877 cases were fully completed with a triage result, and therefore, they met the requirements for clinical validation studies. The goal for sufficient data has been reached for most of the chief symptoms. Data collection was completed in September 2019, and the first feasibility and patient experience results were published by the end of 2020. Case vignettes have been identified and are to be completed before further testing the symptom checker. The analysis and reporting are estimated to be finalized in 2024.

Conclusions: The primary goals of this multimethod electronic symptom checker study are to assess safety and to provide crucial information regarding the accuracy and usability of the Omaolo electronic symptom checker. To our knowledge, this will be the first study to include real-life clinical cases along with case vignettes.

Introduction

Background

Seeking information online regarding medical symptoms is a common and well-known phenomenon worldwide [1-4]. According to a study in the United States, more than one-third of the surveyed adults regularly used the internet for self-diagnosis [5]. In another study, on average, 15% of the people queried on general-purpose search engines about symptoms associated with their conditions before receiving a proper medical diagnosis [6]. However, self-diagnostic web-based sources may be of varying quality, with misleading information and possibly false advertising [7,8].

To address these problems, health care digital applications have been introduced online, including self-diagnosing tools and symptom checkers. Based on users' input of their symptoms, applications such as Babylon GP at Hand, K Health, Isabel, Symcat, Everyday Health, Ada, and WebMD use algorithms to help identify the relevant medical condition. An evaluation study of GP at Hand found that healthier individuals use e-services more than others [9]. Studies have also found that younger, highly educated people, and those with a higher socioeconomic status use eHealth services more actively [10-12]. Evidence on user behavior when using symptom checkers indicates that 3 in 4 users in a sample of nearly 500 users comply and follow electronic symptom checker recommendations, regardless of the urgency level [13]. One study [14] found that users are overcautious in deciding whether they require medical care at all and they miss identifying a considerable portion of emergencies. Further, women may be more risk averse than men in both types of decisions. However, users have mostly been satisfied with the electronic symptom checkers they use [10,15-18].

As with clinical decision-making in general, symptom checker questionnaires and algorithms used are based on research evidence, probabilities, and expert opinions as to whether the condition described is mild and self-limiting or whether it requires the intervention of a health care professional. In terms of urgency, an assessment is made on how soon the condition would worsen without treatment. For an accurate diagnosis, the user provides information that is required, complemented by clinical examinations, various diagnostic tests, and potential consultations with other medical personnel [19,20].

Previous studies have evaluated the accuracy of electronic symptom checkers for diagnosis and triage by using clinical case vignettes [21-30]. Vignettes appear to be a valid and comprehensive method that directly focuses on the process of care provided in actual clinical practice [31]. Under experimental conditions, the diagnostic accuracy of clinicians has been shown to be superior to that of electronic symptom checker tools in both primary and specialized health care [21-23].

Studies have shown that there are risks and room for error in digital triage. Users diagnosed with electronic symptom checkers may be referred to self-care even if they need professional help, and users for whom self-care would be sufficient are referred to professionals [21-23]. Specifically, self-care guidance should be limited to situations where it is safe and appropriate. A study to the point used data on more than 150,000 patient interactions with a web-based triage tool and found that the urgency of patients' intended level of care decreased in more than 1 in 4 of the cases and increased in 1 in 20 cases, with the remaining patients remaining at the same level [32].

When comparing physicians' and computers' diagnostic accuracy by using case vignettes, physicians listed the correct diagnosis first more often than symptom checkers (72.1% vs 34%, respectively) [22]. There is limited evidence of patient safety hazards associated with the use of electronic symptom checkers [10,22,23,33]. However, a study comparing artificial intelligence and human doctors for the purpose of triage and diagnosis found that the artificial intelligence system was able to provide users triage and diagnostic information with a level of clinical accuracy and safety comparable to that of human comparators [34,35]. Electronic symptom checkers are, on average, more sensitive at recommending more urgent care than is actually needed [21,23,29,36]. Triage performance of symptom checkers has, on average, not improved over the course of 5 years [30].

In clinical practice, triage assessment and guidance are usually performed by health care professionals either during telephone contact or face-to-face, for example, at a health care center. In England, there were 1,678,880 calls made to National Health Service 111 in March 2021. Out of these calls triaged, 12% were referred to ambulance service, 11% to accident and emergency, 54% were recommended primary care, 8% advised to attend another service, and 14% were deemed not to need another service, that is, suitable for self-care [37].

Triage takes a lot of professional time and is of varying quality. In health care organizations, therefore, the goal is to unify triage and digitalize it with the help of symptom checkers. This is expected to increase service uniformity and efficiency as well as free up working hours [10,38].

Study Objectives and Outcomes

The goal of this study was to ensure that the symptom checker is sensitive enough to recommend urgent care when it is needed and that it is specific enough to avoid unnecessary use of health care services. This is a mixed methods validation study of the Omaolo symptom checker (Table 1, Table 2, and Textbox 1). The focus of this study is on the usability of this tool, reliability of the assessments, and user safety [37-41]. The first part consists of comparing the Omaolo symptom checker assessment with an assessment made by an experienced primary care triage nurse to see how well they match. The second part complements

XSL•FO
RenderX

the first by using patient case vignettes for the validation of the Omaolo symptom checker.

Table 1. Overview of the Omaolo symptom checker studies.

Characteristics	Substudy 1	Substudy 2
Study type	Quantitative clinical validation study	Validation with case vignettes study
Study objectives	Differences and similarities between the nurse's and symptom checker's (n=15) triage in real-life settings	To test if recommendations are safe on rare and acute cases, which could not be tested extensively in a real-life setting Case vignette accuracy is determined by comparing case vignette–filled symptom checker surveys with expert panel's assessment (gold standard)
Study design and setting	Comparison of nurse's triage to symptom checker's triage	Comparison of symptom checker's triage to triage nurse, general practitioner, and gold standard
Outcome	Triage frequencies, proportions of matches, symptom checker safety, specificity, and sensitivity	Case vignettes to complement the real-life assessment of the symptom checker

Table 2. Research questions for the clinical and case vignettes validation study.

Substudy	Research question
Clinical validation study: differences between the nurse's and symptom checker's triage in real-life settings	• Are the recommendations of the symptom checker safe to use? • In what proportion (% and 95% CIs for an estimate) of the assessments do the experienced nurse's triage and the recommendation of action given by the symptom checker correspond or differ before the nurse has seen the recommendation of action given by the symptom checker? • Are the recommendations of the symptom checker specific and sensitive enough to prevent unnecessary use of primary health care services? • Does an experienced nurse change his or her assessment after seeing the recommendation for action by the symptom checker? • What are the key factors that lead an experienced nurse's triage to differ from the symptom checker's recommendation? • How many cases are there and to which symptom checker do they relate to wherein a triage nurse would refer the user to a heavier service than that recommended by the symptom checker (2 levels lighter is considered as unsafe recommendation for a symptom checker)? • How many assessments can be found and to which symptom checker they relate to wherein the triage nurse would refer the user to a lighter service than that recommended by the symptom checker (2 levels heavier is considered as overconservative recommendation for a symptom checker)? • Analysis of the content for the reasons given by the participants that influenced their triage when the individual assessments differed
Validation with case vignettes study: performance between nurses' and symptom checker's triage in case vignettes compared to expert panel assessment (gold standard)	• In what proportion (% and 95% CIs for an estimate) of the assessments do the experienced nurse's triage and the recommendation of action given by the symptom checker correspond to or differ from case vignette's predetermined (assesses by expert panel) triage? • Does an experienced nurse change his or her assessment after seeing the recommendation for action by the symptom checker? • How many cases are there and to which symptom checker do they relate to wherein a triage nurse would refer the user to a heavier service than that recommended by the symptom checker (2 levels lighter is considered as unsafe recommendation for a symptom checker)? • How many assessments can be found and to which symptom checker they relate to wherein the triage nurse would refer the user to a lighter service than that recommended by the symptom checker (2 levels heavier is considered as overconservative recommendation for a symptom checker)? • Analysis of the content for the reasons given by the participants that influenced their triage when the individual assessments differed • Sensitivity, specificity, positive and negative predictive values of the symptom checker and nurse assessments compared to expert panel assessments

Textbox 1. Questions presented in the research forms specifically for triage nurses.

Questions

- How old are you?
- How much work experience do you have in assessing the need for care (triage) ? ____ years
- How did the user arrive at the reception? (walk-in or via telephone contact)
- Did you consult a doctor to assess the user's need for treatment (triage)?
- Choose where the user should be referred according to the terms of the electronic symptom recommendation action guide (based on your own evaluation, triage)
- What was the most significant thing (observation, symptom, or discovery) that influenced your decision-making?
- Do you feel the need to change your assessment of need for treatment (triage) after seeing the responses and recommendation in the electronic symptom checker? (Yes/No)
- If yes, then why did you change the assessment of the need for treatment (triage) after seeing the responses and recommendation in the electronic symptom checker?
- If you feel it is necessary to change your triage assessment, reselect where the user should be referred to according to the classification terms of the electronic symptom checker's recommendation.

Intervention

Development of the Omaolo Symptom Checker

The clinical validation process of the Omaolo symptom checker proceeded at a national level and it complies with the European Union and Finnish medical device requirements with a CE marking (risk class: IIa) [42-45]. The Omaolo management team selected the topics to be included in the symptom checker on the basis of the most popular searches made on the evidence-based medicine guidelines (decision support for health care professionals by Duodecim Medical Publications Ltd), considering the most common reasons for visiting health centers and joint emergency services [46]. The Omaolo symptom checker is intended for users older than 15 years. There is no upper age limit, except for the symptom checker for urinary tract infections, which is intended for women aged 18-65 years.

The reasoning of each symptom assessment consists of 1 algorithm, which uses a common function library as an aid. All traffic goes through the engine of the evidence-based medicine decision support device, the application programming interface and related filters and conversions, and data processing. However, the algorithm that has the most central effect on reasoning can be separated from each individual symptom assessment within the symptom checker.

Description of the Omaolo Symptom Checker

Omaolo is a national web-based service for social welfare and health care. The purpose of Omaolo is to promote the health and well-being of citizens. Omaolo supports self-care and helps people to contact public health care professionals, if necessary. Omaolo is a medical device with a CE marking, manufactured by government-owned DigiFinland Oy founded in the year 2017. Omaolo meets the requirements set for medical devices.

The aim of the Omaolo symptom checker (Textbox 2) is to identify, based on the assessment of alarm symptoms and other pre-existing conditions, situations that require immediate or urgent assessment and to conduct follow-up examinations and treatment without delay in situations where conservative treatment may lead to complications. Both the questionnaire for the user and the algorithm that the symptom checker uses are based on research evidence (Multimedia Appendix 1), especially on the need to treat different combinations of symptoms and in other respects on medical experience (Textbox 2) [42-50].

Textbox 2. List of symptoms selected for the Omaolo symptom checker (n=15) and sources of medical knowledge and regulations applied in creating them [42-50] (full detailed references are listed in Multimedia Appendix 1).

Omaolo symptom checker

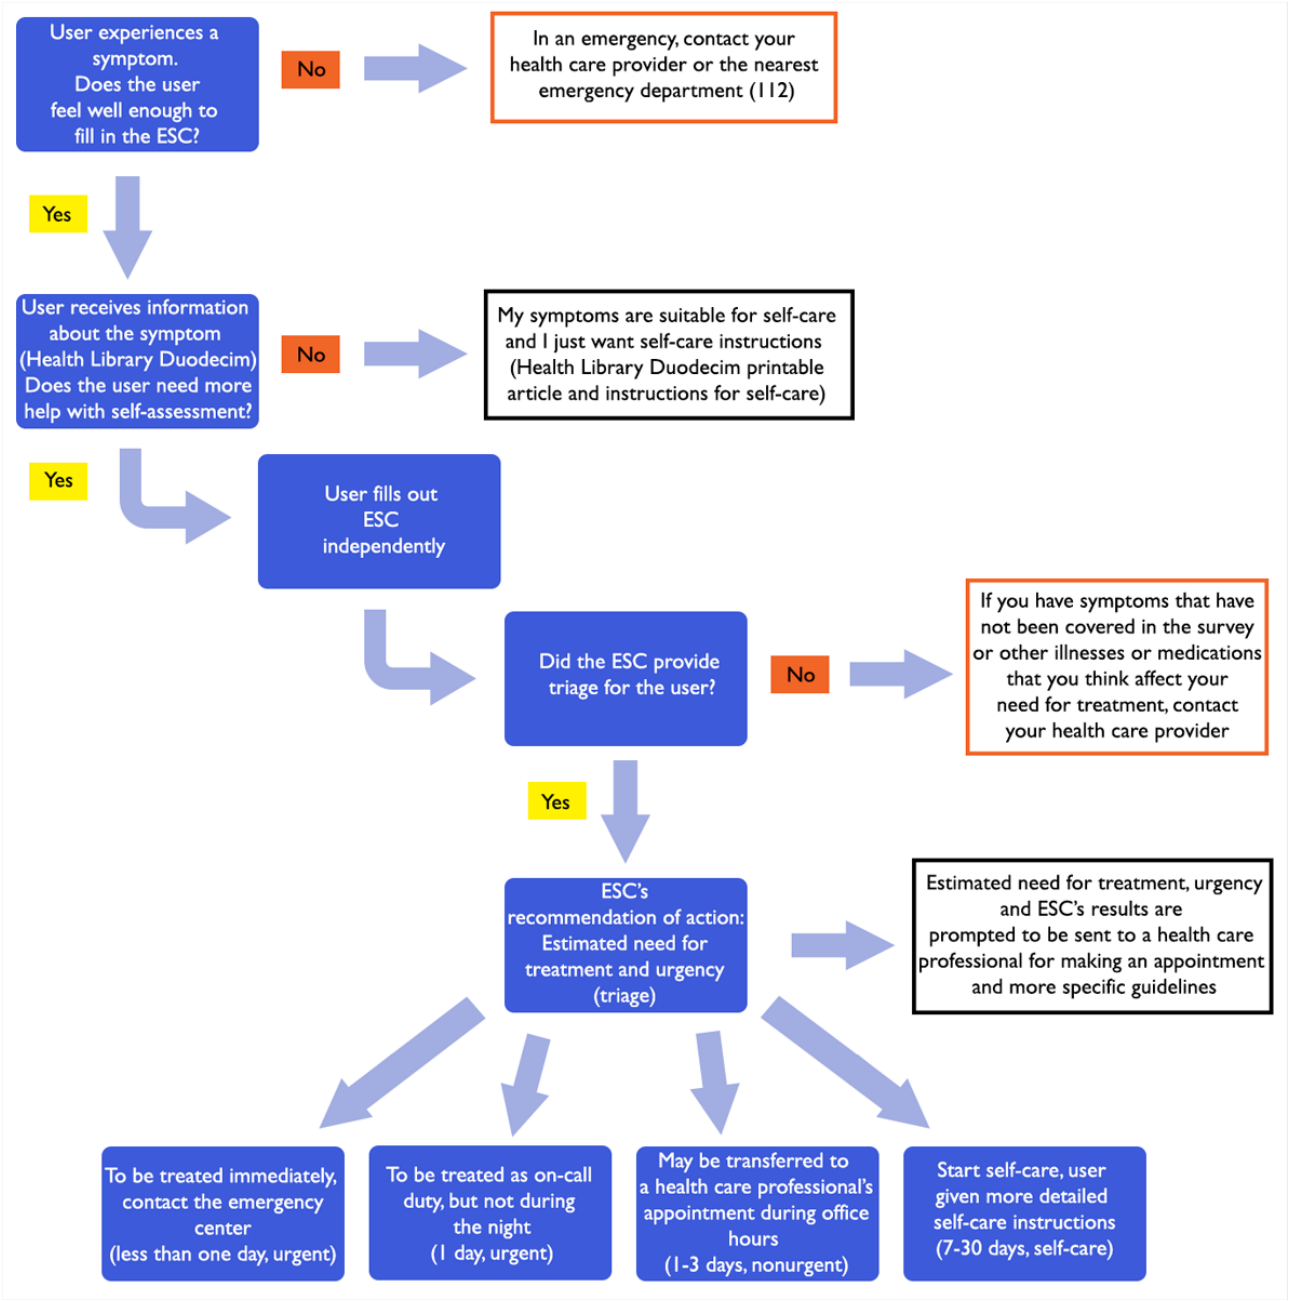
- Anal region symptom
- Cough
- Diarrhea
- Discharge from the eye, watery or reddish eye
- Headache
- Heartburn
- Knee symptom or injury
- Lower back pain or injury
- Oral health
- Painful or blocked ear
- Respiratory tract infection
- Sexually transmitted disease
- Shoulder pain, stiffness, or injury
- Sore throat or throat symptom
- Urinary tract infection

Regulations

- Regulation (European Union) 2017/745 of the European Parliament and of the Council of April 5, 2017, on medical devices [42]
- Finnish Health Care Equipment and Supplies Act [43]
- New requirements and operational implications of medical devices (Finnish) [44]

Sources of medical knowledge

- Cochrane Database of Systematic Reviews [45]
- Articles in the DynaMed Plus; database produced by the EBSCO (Elton B Stephens CO) community [46]
- Finnish administrative sector of the Ministry of Social Affairs and Health publication “Basics of Emergency Care” [47]
- Finnish Current Care Guidelines [48]
- Evidence-Based Medicine Guidelines (Duodecim Medical Publications Ltd) [49]
- City of Helsinki Assessment of the Need for Urgent Care in Adult Patients (2014) [50]
- Preliminary studies investigating the likelihood of different combinations of symptoms and associated conditions requiring treatment



The symptom checker can only assess symptoms based on the information provided by the user. As with clinical decision-making in general, assessments of the need for treatment are based on the likelihood that the condition described is mild and self-limiting or that action by a professionally trained health professional is likely to be required to treat or prevent its worsening. In terms of urgency, the available information is used to assess whether and how quickly the condition is likely to worsen without treatment.

The symptom checker makes a general assessment and then recommends a course of action based on medical knowledge. It gives the user an idea of the quality and urgency of the treatment (triage) likely required. The user will be recommended to either treat their symptoms and their health problems themselves or be prompted to contact a health care professional who can provide a professional assessment of the situation and appropriate treatment, if necessary [39-41].

The use of the Omaolo symptom checker is intended to be as simple as possible (Figure 1): the user initially receives reliable information about the symptom (articles in the Health Library Duodecim) with a short summary, helping the user in assessing their condition. If, however, the user is still unable to decide on the treatment, they can next answer the relevant symptom checker questions. These will, in turn, result in a recommendation by the checker on course of action and urgency. The checker does not result in a diagnosis.

XSL•FO
RenderX

Figure 1. Flowchart for using Omaolo services and the decision tree of the symptom checker. ESC: electronic symptom checker.

The first priority of the symptom checker is to seek to identify any alarming symptoms that should prompt immediate contact to an emergency department. The aim is then to identify situations where a professional assessment is necessary and to determine the urgency of the assessment. For example, these include situations where antibiotic treatment may be necessary or situations where the symptom of the infection can be associated with an exacerbation of another disease. The combinations of symptoms are used to draw conclusions about the likely nature of the situation and to provide an appropriate recommendation. The successfully answered questions are saved, and the user can have it sent to a health care professional through the Omaolo symptom checker [39-41].

The user is encouraged to access the Duodecim Medical Library articles on the subject, which open as links in the questionnaire introductory text and feedback, since not all possible real-life situations can be covered. The user is also encouraged to consider whether they have other symptoms not covered by the questions of the information provided. To help with this, the following is displayed to the user at the end of the query: "If you have symptoms that have not been covered in the survey or other illnesses or medications that you think affect your need for treatment, contact your health care provider or, in an emergency, the nearest emergency department" [39-41].

Methods

Inclusion Criteria

To be eligible for the study, users had to be older than 18 years and experience some of the symptoms listed in the Omaolo symptom checker when participating. There is no upper age limit, except for the symptom checker of urinary tract infection,

XSL•FO
RenderX

which is intended for women aged 18-65 years. The experienced nurses had to have at least 2 years of triage experience.

Exclusion Criteria

The only exclusion criterion was refusal of the user to participate in this study.

Pilot Study

The purpose of this pilot study was to examine the functionality of the study design of the symptom checker validation. The pilot was conducted at the Espoonlahti Health Center in July 2018. The pilot complied with the research plan and was performed to test the feasibility of the study design and the questionnaires. The pilot was conducted by collecting symptom checker assessments of 50 users with several symptoms at the same time. More than 200 users (Table 3) were interviewed to participate in this study, but only 50 symptom checker assessments were completed. The pilot caused minor changes mainly to question the formulations of the data collection documents and details of collecting the data.

Table 3. Reported reasons for users not taking part in the pilot study.

Reason for not participating in the study	Users (n=234)
Skeptical toward digitalization and e-services	33
Polite refusal without further explanation	76
Already has a reserved appointment time	41
On a matter regarding a family member's well-being	10
Severity of symptoms hinders participation	29
User's experienced symptoms are not found in the symptom checker	35
Fear of losing their place when waiting in the queue to meet the nurse	10

Study Design and Setting

The study setting is Finnish Primary Health Care, with 13 participating health care organizations nationwide. Each participating organization provided the study space where it is practically possible for the users to complete Omaolo symptom checker and triage by an experienced nurse. The organization also ensures that the target population of the study remains unscreened. Study users are recruited in units that use the walk-in model in primary health care settings, where clients come to a health center without prior contact (Figure 2).

The validation with case vignettes (virtual clinical patient cases) will be used to complement the assessment of triage accuracy of some of the questions of the Omaolo symptom checker (Figure 3). Vignettes are either obtained from previous studies or produced for this study from a variety of clinical sources, including material used in medical education examinations. For example, an outcome that has been reached in a patient case in the educational environment is considered when creating a virtual patient case vignette [21-24]. Patient case vignettes are also produced from standardized clinical patient cases and panel-decided materials [22]. Panel-decided patient case vignettes and standardized patient case vignettes are a common method for developing and training health care professionals in their diagnostic ability to make treatment decisions [21].

The panel in our study aims to consist of 3-5 independent clinician general practitioners (GPs) and another 3-5 triage nurses. We will apply a modified Delphi procedure [51]. For the creation of clinical vignettes, the GPs are required to have over 5 years of primary care and emergency department experience. These GPs are not to be directly involved with Omaolo creation. In case of the vignette validation process, the panel first assesses the triage for case vignettes (gold standard). Second, the panel-decided triage is then compared with the nurse's and GP's triage and the symptom checker's recommendation of action (this is possible in simulated cases where conditions are constant) (Figure 2). Case vignettes test the symptom checker and compare their performance with other providers in different triage levels by using standardized patient case examples [21-24]. Individual patient case vignettes are formed according to urgency classifications. Case vignettes also include common and rare diseases. The focus of this study will be on rare and acute cases, which cannot be tested extensively in real-life settings, for example, the number of cases collected for diarrhea and heartburn symptom checker is small (Table 4). Some of the vignettes will be derived from established sources [22].

Table 4. Data of the collected clinical user cases across the symptom checker.

Symptoms in Omaolo symptom checker	Approved assessments for clinical validation (n=877), n	Approved assessments for usability study (n=964), n
Anal region symptom	41	39
Cough	71	87
Diarrhea	21	23
Discharge from the eye, watery or reddish eye	65	64
Headache	41	45
Heartburn	24	19
Knee symptom or injury	55	56
Lower back pain or injury	65	69
Oral health	62	69
Painful or blocked ear	81	83
Respiratory tract infection	104	121
Sexually transmitted disease	39	30
Shoulder pain, stiffness, or injury	47	50
Sore throat or throat symptom	101	117
Urinary tract infection	60	60

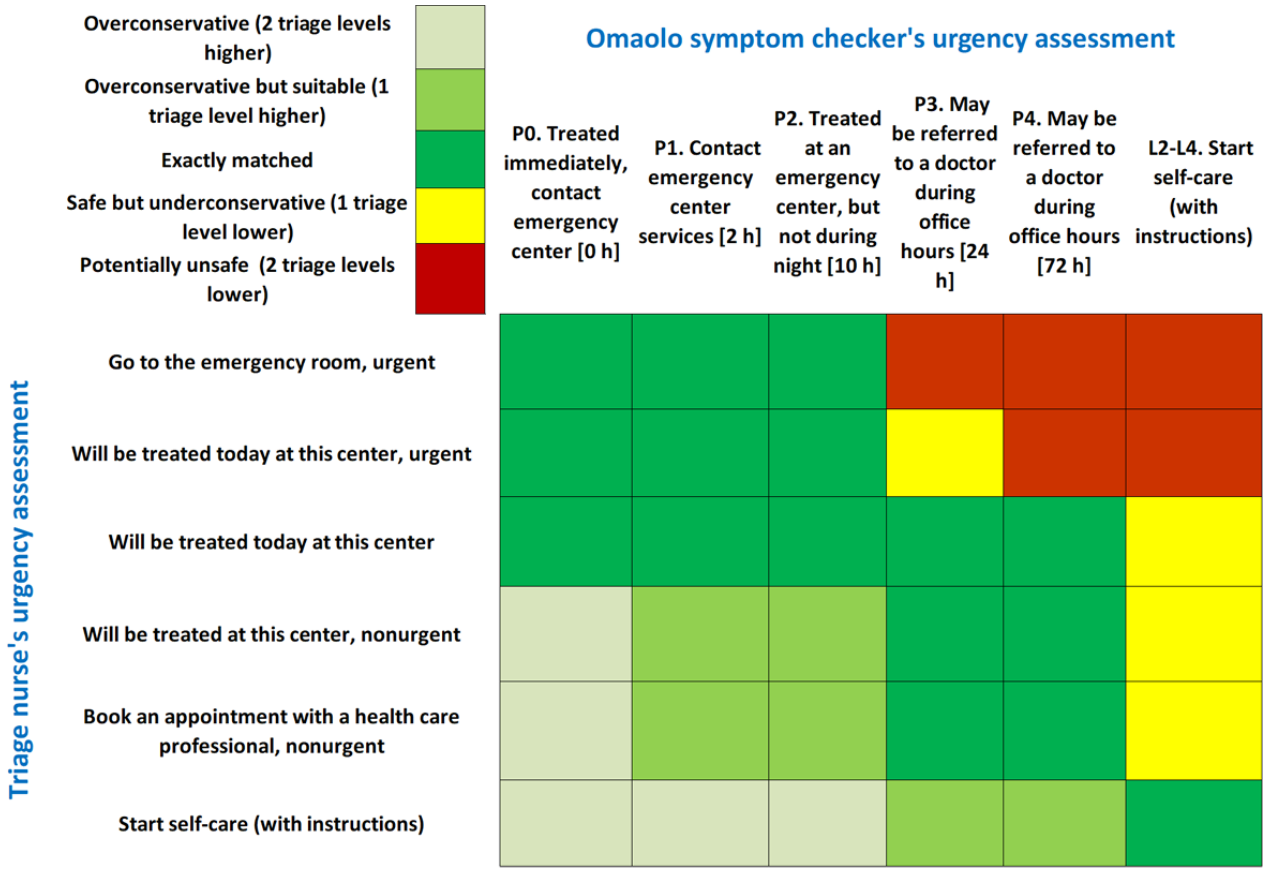
Sample Size Calculations

In a study performed by Gilbert et al [22], triage levels of 7 different symptom checker apps were tested and the mean percentage of safe advice provided by the apps was found to be 90.1% (SD 7.4%). Furthermore, a symptom checker app was found and defined to be safe to use if the particular app had safe advice performance within 1 SD compared to the GP's (mean) percentage of given safe advice. The GP's percentage of safe advice was 97% (SD 2.5%) [22]. For our study, hypothesis 1 (α) is that the Omaolo symptom checker is safe to use in the defined study settings (Table 1).

For the study group in the clinical validation study, we accept a safe performance of 97% when directly comparing symptom checker's recommendation of action to nurse's triage of the same user that has filled in the symptom checker successfully. We estimate the required sample size by assuming the given range of safe advice at 97% and by using a 95% confidence level, and we compute the confidence interval estimate for the true proportion of safe-filled symptom checker assessments (Figure 2). For each symptom, we aim to collect as many completed symptom assessments as possible.

For the study in validation with the case vignettes study, we assume that the Omaolo symptom checkers' performance is similar to that of symptom checker apps defined as safe as described by Gilbert et al [22]. This includes that the suggested safe advice performance marginal and size of the difference between the study groups is acceptable (Figure 3).

Data Analysis



The qualitative assessment of the study data from the open-ended questions of the survey was analyzed by qualitative inductive content analysis [52]. In this approach, the codes and themes derived from the data were suggested by the data rather than by a theoretical framework. The steps that we used for our analysis were iterative processes to familiarize ourselves with the qualitative data and to identify quotations with common concepts, code formation, grouping of codes into subthemes and themes, and creation of an explanatory thematic summary.

The quantitative analysis in the clinical and vignette validation studies includes the results and findings of individual users, nurses, and study assistants being analyzed based on individually completed study forms. The results of the electronic symptom assessments compared to the assessment of an experienced nurse and case vignettes will be presented regarding each symptom checker individually. Possible differences in triage levels, including "overconservative," "overconservative but suitable," "exactly matched," "safe but underconservative," and "potentially unsafe," for all symptom estimates will be reported (Figure 4) [22]. We will calculate the percentages of matches for each individual symptom checker and the 95% CIs.

A case is to be defined as safe if the conflict condition is not met and the recommendation for action given by the symptom assessment is at most 1 degree of urgency less urgent than the triage assessment of the same case. The definition of a conflict is as follows: cases assessed by the nurse as urgent/on-call duty but assessed by the electronic symptom checker as nonurgent/self-care.

XSL•FO
RenderX

Figure 4. An example of a triage comparison chart with matched color coding differences in triage levels. Matching rows (triage nurse) to their respective columns (symptom checker) results in a safety assessment. Ethics Approval

This study plan underwent an ethics review by the regional permission, which was requested from each organization participating in the research, and in addition to this, an ethics committee statement was requested and granted from Pirkanmaa hospital district's ethics committee (ETL-Code:R18126), which is in accordance with the University of Tampere's regulations. When recruiting participants for this study, the research assistant informs the user about the study, distributes the study information sheet, and then asks if the user is willing to participate in the study. If, after being informed, the user is willing to participate in the study, they are asked to sign a consent form in which the user acknowledges that they have received sufficient information about the study and agree to participate in it. The user is given an information sheet about the study, which contains information about the study and contact information in case the user wants to ask more about the study. The user was paid no amount of compensation. The user's consent form is not connected to the response form with a personal identification code, that is, the users are anonymized. No medical record data are collected or combined with research forms. The users can withdraw their consent to the study at any time, but the completed forms cannot be destroyed after the data collection, because the consent form, which contains personal data, does not have an identification code that could be used to link the consent to other study forms. The most significant ethical issue related to the research setting is that the user's participation in the research does not affect their chances of receiving timely treatment. In connection with the research protocol, all users who fill out the symptom checker will be forwarded to an appointment with an experienced nurse. Denial of treatment for users who refuse to participate in the study is strictly prohibited.

Results

Data (Table 4) for this study were collected between June 1, 2018, and December 31, 2020, when users filled in electronic symptom checker questionnaires on arrival at the health centers (they also signed an informed consent form). The version of the Omaolo.fi symptom checker of 2019 was used. Few user cases were collected for diarrhea and heartburn in the clinical validation part of the study. In the supplementary case vignette validation study, the use of virtual clinical patients will be used to support the triage accuracy of chief symptom assessments with a small number of approved assessments for clinical validation (heartburn, diarrhea) in the Omaolo symptom checker. The focus will be on rare and acute cases, which cannot be tested extensively enough in real-life settings. Data collection was completed in September 2019, and the first feasibility and patient experience results were published by the end of 2020 [33]. Further results and publications are expected in 2023-2024. It is estimated that the analysis and reporting will be finalized during 2024.

Discussion

Principal Findings

This multidimensional study will be the first to assess both the usability and safety of the Omaolo symptom checker in the Finnish primary health care context. In addition, this research might provide information to help evaluate the reliability and possible shortcomings of this service. This information can then be used to support the further development of the service entity and thus improve the usability of the Omaolo service. The real benefit and safety of this service can be gauged from the written feedback of users who use the symptom checker in real clinical trial environments [53].

Strengths and Weaknesses

The real-life setting is both a strength and a potential weakness of this study. A strength of this study is the large number of real-life users with real-life symptoms and real-life triage performed by a nurse. The first potential concern is the selection bias of the symptoms experienced when users fill the symptom checker questionnaires in health center waiting rooms, while in real-life settings, the symptom checker questionnaire is filled at home. The Omaolo symptom checker is designed for users older than 15 years, but in this study setting, only users older than 18 years are recruited. Second, the potential selection bias results from excluding users who are not able to complete the symptom checker questionnaire independently (inability to use the provided computer mouse or tablet devices). Further, users presenting with symptoms at the extremes of the spectrum may be problematic. Cases of mild self-care symptoms may be excluded, and users with serious acute symptoms may be rare in this setting. The symptom checker service does prompt users to contact health care services urgently when unable to fill in the questionnaire due to severe symptoms. The lack of urgent cases for some symptoms (eg, heartburn, diarrhea) in real-life settings is considered to be supplemented by virtual user cases, that is, case vignettes. The focus of validation with the case vignette study will be on rare and acute cases, which cannot be tested extensively enough in real-life settings. More common and less urgent situations can be covered even with the vignette study. Finally, although the production of research data was slowed down by the COVID-19 pandemic [54,55], the number of individual users of mobile medical apps and Omaolo.fi grew exponentially during the pandemic [56-58].

Acknowledgments

This research was carried out in addition to the work of primary health care centers, municipalities, health care district–based health care organizations nationwide, Omaolo project employees, and Finnish Medical Society Duodecim employees.

Data Availability

The forms concerning individual users in the database are anonymized and cannot be combined with the user's identification code to personal data. The information in the questionnaires is coded electronically and transferred to an electronic folder. The names or personal information of the users are not shown in this electronic file but only the user's identification code. Paper forms with identification codes are stored in a locked cabinet. The consent form containing the user's name and signature is kept in a separate locked cabinet. All paper forms are stored in the University of Tampere. The forms are disposed of with a shredder 10 years after the end of the study. The electronic data sets generated during and analyzed in this study are available from the corresponding author on reasonable request.

Conflicts of Interest

MK is the President of Finnish Medical Society Duodecim. THK has worked as a salaried part-time editor for Duodecim Medical publications up to year 2018.

Abstract

Background: Obsessive compulsive disorder (OCD) in youth is characterized by behaviors, emotions, physiological reactions, and family interaction patterns. An essential component of therapy involves increasing awareness of the links among thoughts, emotions, behaviors, bodily sensations, and family interactions. An automatic assessment tool using physiological signals from a wearable biosensor may enable continuous symptom monitoring inside and outside of the clinic and support cognitive behavioral therapy for OCD.

Objective: The primary aim of this study is to evaluate the feasibility and acceptability of using a wearable biosensor to monitor OCD symptoms. The secondary aim is to explore the feasibility of developing clinical and research tools that can detect and predict OCD-relevant internal states and interpersonal processes with the use of speech and behavioral signals.

Methods: Eligibility criteria for the study include children and adolescents between 8 and 17 years of age diagnosed with OCD, controls with no psychiatric diagnoses, and one parent of the participating youths. Youths and parents wear biosensors on their wrists that measure pulse, electrodermal activity, skin temperature, and acceleration. Patients and their parents mark OCD episodes, while control youths and their parents mark youth fear episodes. Continuous, in-the-wild data collection will last for 8 weeks. Controlled experiments designed to link physiological, speech, behavioral, and biochemical signals to mental states are performed at baseline and after 8 weeks. Interpersonal interactions in the experiments are filmed and coded for behavior. The films are also processed with computer vision and for speech signals. Participants complete clinical interviews and questionnaires at baseline, and at weeks 4, 7, and 8. Feasibility criteria were set for recruitment, retention, biosensor functionality and acceptability, adherence to wearing the biosensor, and safety related to the biosensor. As a first step in learning the associations between signals and OCD-related parameters, we will use paired *t* tests and mixed effects models with repeated measures to assess associations between oxytocin, individual biosignal features, and outcomes such as stress-rest and case-control comparisons.

Results: The first participant was enrolled on December 3, 2021, and recruitment closed on December 31, 2022. Nine patient dyads and nine control dyads were recruited. Sixteen participating dyads completed follow-up assessments.

Conclusions: The results of this study will provide preliminary evidence for the extent to which a wearable biosensor that collects physiological signals can be used to monitor OCD severity and events in youths. If we find the study to be feasible, further studies will be conducted to integrate biosensor signals output into machine learning algorithms that can provide patients, parents, and therapists with actionable insights into OCD symptoms and treatment progress. Future definitive studies will be tasked with testing the accuracy of machine learning models to detect and predict OCD episodes and classify clinical severity.

Introduction

Background

Up to 3% of children and adolescents suffer from obsessive compulsive disorder (OCD) [1], which is characterized by repetitive, intrusive thoughts about threats of contamination, harm to self or others, loss of esteem, and committing moral transgressions, accompanied by repetitive or ritualized behaviors that can be time consuming, such as cleaning, checking, and ordering [2]. These obsessive thoughts and compulsive behaviors lead to marked distress, avoidance, and negative emotion (eg, anxiety and disgust) [2]. To regulate OCD-related distress, youths (individuals below the age of 18 years) may avoid situations that trigger obsessions and compulsions, perform rituals to neutralize feelings of incompleteness or magically remove the threat, or seek reassurance and help from others such as parents [3]. Parents are biologically primed to be sensitive to distress signals from their children [4,5]. Thus, parents may become distressed when their children are distressed. Interactions between parents and youths with OCD can be conflictual when parents refuse to accommodate their children's symptoms [6]. Youths may coerce or use verbal and physical aggression to elicit accommodation or parents may voluntarily provide family accommodation to regulate their own or their children's distress [7]. Family accommodation refers to ways in which parents help their children with OCD perform rituals, avoid stimuli that trigger symptoms, and change their own routines because of their children's OCD symptoms [8]. This reciprocal coordination of parent-child behavior is reflected in the parent's and child's physiology and may in part be facilitated by the oxytocin system [9]. In short, OCD is characterized by distress, negative emotions, and behavioral repertoires in individual youths and their parents that can be directly observed or indirectly detected in behavior, facial expressions, speech patterns, and physiological signals.

Automatic, continuous detection of these OCD signals would facilitate close monitoring of patient treatment progress and allow for more targeted interventions. The first-line treatment for OCD is cognitive behavioral therapy with exposure and response prevention (ERP) [10,11]. Continuous monitoring of distress levels and the function of distress during the treatment is essential for optimizing ERP [12]. Currently, patients are asked to rate their level of distress throughout an ERP task. Machine learning (ML) models that detect distress levels would automate distress monitoring and enable passive collection of objective measures allowing therapists to adjust exposures accordingly. Automatic, continuous distress detection may also facilitate the monitoring of treatment response across therapy sessions as well as monitoring disorder progression in individuals with subclinical symptoms. Finally, an important part of therapy is increasing awareness of the connections between thoughts, emotions, behaviors, and bodily sensations [13]. ML models that detect changes in mental states would facilitate increasing awareness of these connections.

Previous studies have demonstrated that ML models can detect physiological, behavioral, and speech signals that may be relevant to youth with OCD and thus aid in developing objective, intelligent monitoring tools that will enable timely actionable insights and interventions supporting psychotherapy in and outside of the clinic. A previous study demonstrated that ML models using 3 minutes of physiological data from a wearable biosensor worn by 20 youths could predict aggressive behaviors in youths with autism spectrum disorders 1 minute prior to their occurrence with relatively high accuracy [14]. Another study linked behavioral synchrony between 15 fathers and their 2-5–year-old children with Down syndrome to synchrony in the dyads' electrodermal activity (EDA) measured with wearable biosensors during a play session [15]. Using speech features as input, ML models have classified the severity of depression [16] and differentiated between children with and without internalizing disorders [17]. ML models that use speech features as input have also been utilized to gauge the quality of interpersonal interactions in a psychotherapy setting [18]. Finally, ML models (ie, computer vision models) are also capable of analyzing data from videos to track movement; infer emotion from facial expressions; and estimate visual attention, engagement, and interpersonal interaction from gaze-tracking information [19,20]. A systematic review showed that computer vision studies have sample sizes as low as 2 participants, often in the range of 10-20 and with more than 50 participants in rare cases, to demonstrate the capabilities of computer vision as a clinical tool [19]. To date, no artificial intelligence (AI) tools for monitoring clinically relevant parameters of OCD in youth are available and validated. Thus, Wrist Angel aims to develop AI tools capable of predicting OCD episodes, related (mal)adaptive parent behavior, and continuously monitoring OCD-related distress in youths and parents.

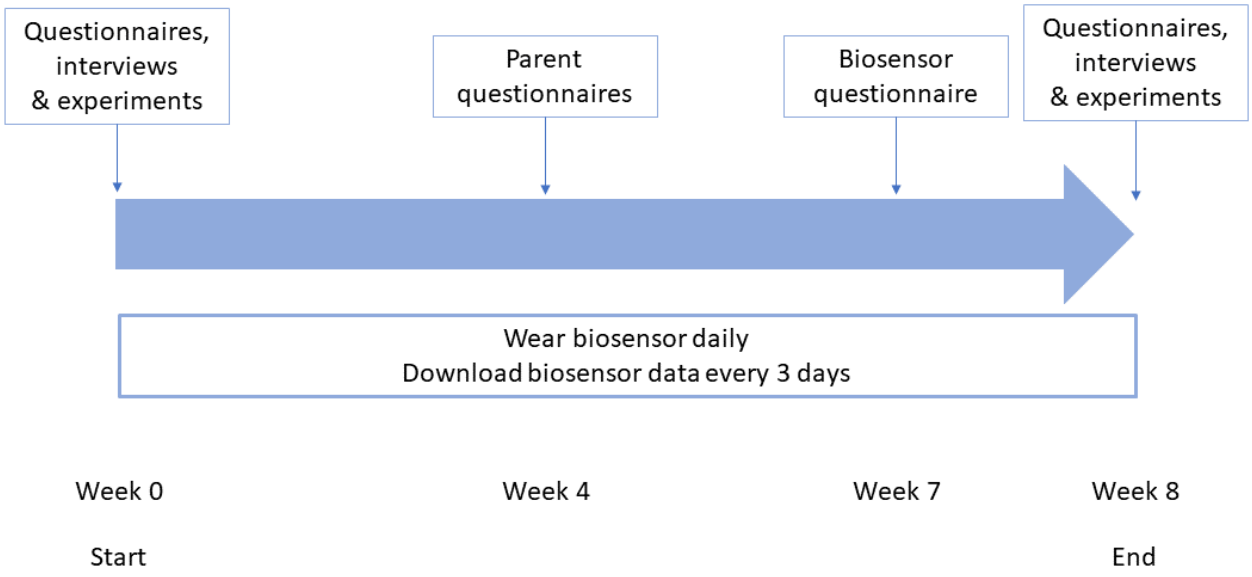
Goal of This Study

The purpose of this protocol is to provide a detailed account of our study design and methods for data collection. The primary aim of the Wrist Angel pilot study is to test the feasibility of using a wearable biosensor to detect OCD-related events and monitor clinical severity in children and adolescents. Ultimately, we aim to develop algorithms for detecting OCD-relevant parameters using physiological, audio, and visual signals as input and assess their accuracy. Thus, important information from the pilot study will be whether it is feasible to collect enough data to develop such algorithms. Specifically, we will test the feasibility of recruiting and retaining participants for brief experiments in the clinic and an 8-week observational

XSL•FO
RenderX

study during which youths and parents wear a biosensor in their everyday lives. Feasibility will also be assessed in terms of biosensor safety and functionality, participant acceptance of the biosensor, and participant adherence to wearing the biosensor. We also explore methods for collecting ecological momentary assessments (EMAs) for labeling data collected in the 8-week observational study, including a mobile app for data collection. Our primary hypothesis is that the study protocol will demonstrate sufficient feasibility to support subsequent larger studies.

Biosensors are worn by youths and one of their parents, as OCD causes distress in youths with the diagnosis as well as their parents. Furthermore, efficacious psychotherapy approaches for OCD in youth intervene by working either exclusively with the child [13] or the parent [21]. We also include measurements of oxytocin levels and response in youths and parents, as oxytocin may hold important information about how family dynamics interact with OCD symptoms and the optimal type of psychotherapy to address these interactions [22].



Methods

Design

The reporting of this protocol follows the recommendations for reporting protocols of pilot and feasibility trials [23]. We used the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 checklist for interventional trials [24] ignoring nonapplicable items, supplementing with relevant items from the CONSORT (Consolidated Standards of Reporting Trials) extension to pilot trials [25] and making relevant modifications according to the guidelines for reporting nonrandomized pilot and feasibility studies [26] (see Multimedia Appendix 1).

This is a nonrandomized, longitudinal pilot study, which includes a case-control comparison and repeated experiments. Youths and their participating parent are asked to wear a biosensor daily during waking hours for 8 weeks. In comparison, previous studies have collected data from 7 hours to 10 days [14]. To better understand these *in-the-wild* signals, we collect physiological signals and additional audio and visual signals under controlled conditions in the clinic. Figure 1 depicts the study design.

Figure 1. Design of the Wrist Angel pilot study. Lab visits were performed at week 0, or the start of the study (baseline), and at week 8. Participants completed self-rated questionnaires at weeks 0, 4, 7, and 8. Participants wore the biosensor for up to 8 weeks.

Setting

This pilot study is being conducted at a public child and adolescent mental health center within a psychiatry department of a university hospital in Denmark, covering the geographical area of the Capital Region.

Participants

We aim to enroll 10 patient-parent dyads and 10 healthy control-parent dyads. A small sample size was chosen for practical and economic reasons to establish proof of concept. We aim to collect a larger number of observations for each individual (8 weeks) compared to previous studies (less than 2 weeks) to assess feasibility within subjects in contrast to across subjects. The inclusion and exclusion criteria are summarized in Textbox 1.

XSL•FO
RenderX

Textbox 1. Participant inclusion and exclusion criteria.

Patient inclusion criteria

- 8 to 17 years old (both inclusive)
- Primary or secondary diagnosis of obsessive compulsive disorder (OCD; International Classification of Diseases [ICD]-10 F42) [27] as set by a child and adolescent psychiatric team
- Primary psychiatric diagnosis that a psychiatrist determined is eligible for care within psychiatry
- Children's Yale-Brown Obsessive-Compulsive Scale (CY-BOCS) [28] entry total score >7 points
- Normal intellectual functioning as indicated by parent or youth report, clinical observation, and/or the appropriate full-scale Wechsler Intelligence Scale (for Children-Fifth Edition or Wechsler Adult Intelligence Scale-Fourth Edition) [29,30] (Intelligence Quotient>70)
- Signed informed consent from legal guardian(s)

Patient exclusion criteria

- Disorders that contraindicate study participation, including substance dependence syndrome (ICD-10 F1x.2), schizophrenia/paranoid psychosis (ICD-10 F20-25 and F28-29), mania or bipolar disorder (ICD-10 F30 and F31), depressive psychotic disorders (ICD-10 F32.3 and F33.3), intellectual disorder (ICD-10 F70-79), pervasive developmental disorder (ICD-10 F84.0-84.4 and F84.8-84.9), not including Asperger syndrome [27]
- Any condition (eg, allergies, eczema, hypersensitivity associated with Asperger syndrome) that would prevent the child or parent from wearing a wristband biosensor
- Current participation in other OCD trials

Control participant inclusion criteria

- 8 to 17 years old (both inclusive)
- Lives in the catchment area of the study site during the study
- Normal intellectual functioning as indicated by parent or youth report, clinical observation, and/or the appropriate full-scale Wechsler Intelligence Scale (for Children-Fifth Edition or Wechsler Adult Intelligence Scale-Fourth Edition) [29,30] (Intelligence Quotient>70)
- Signed informed consent from legal guardian(s)

Control exclusion criteria

- Any current or previous psychiatric or intellectual disorders according to ICD-10 criteria, as assessed by Schedule for Affective Disorders and Schizophrenia for School-Age Children-Present and Lifetime Version (K-SADS-PL) [31] at the time of screening
- Current participation in other OCD trials
- Any condition (eg, allergies, eczema) that would prevent the youth from wearing a biosensor on the wrist

Parent inclusion criteria

- Has a child participating in the current study
- Signed informed consent

Parent exclusion criteria

- Any condition (eg, allergies, eczema) that would prevent them from wearing a biosensor on the wrist

Concomitant Care

There are no prohibited forms of care or interventions. Patients could be on wait lists, in any form of psychotherapy, or taking any form of pharmacological treatment.

Recruitment

Patient participants are recruited from patients referred to the child and adolescent mental health center with probable OCD symptoms or a set OCD diagnosis. Potential patient participants' journals are first screened for eligibility. Case workers then ask patient families if our research group may contact them about our research project. The control group is recruited from the control group of the Treatment Effects of family based Cognitive Therapy in children and adolescents with Obsessive compulsive disorder (TECTO) trial [32] and schools in the catchment area. After obtaining permission from the school administration, flyers are posted in the school or the school intranet.

Psychologists, medical doctors, and masters-level medical and psychology students screen and assess potential participants. For previous TECTO participants, we use their clinical information from the TECTO trial to determine eligibility. Potential control participants who contact us are screened for intellectual disability and psychiatric diagnoses using the Schedule for Affective Disorders and Schizophrenia for School-Age Children-Present and Lifetime Version (K-SADS-PL) criteria [31].

XSL•FO
RenderX

The recruitment period ranged from September 15, 2021, until December 31, 2022.

Ethical Considerations

Approval and Consent

The Ethics Committee of the Capital Region of Denmark approved this study on June 17, 2021 (H-18010607-79689). This study is registered at ClinicalTrials.gov (NCT05064527; October 1, 2021). The interdisciplinary team of principal investigators (the authors) are responsible for the design and conduct of the study and preparation of the protocol and revisions. The principal investigators at the hospital are responsible for recruitment and monitoring participants. Any major modifications or protocol deviations are discussed with the other principal investigators during weekly meetings. Any major protocol modifications are reported to the Ethics Committee and amended on ClinicalTrials.gov.

After families assent, we inform the families about the project verbally, in person or over the telephone, and send written participant information via secure email. After receiving verbal and written information about the study, youth and parents are given 24 hours to deliberate. A psychologist or medical doctor obtains signed consent forms from legal guardians of youth and their participating parent along with assent from participants before participating in the study. A model consent form is available in Multimedia Appendix 2.

Safety

We are not aware of any major risks or safety issues associated with participation. Adverse reactions to the biosensor are monitored throughout the study (see Multimedia Appendix 1). Any serious adverse events will be reported to the sponsor and The Ethics Committee of the Capital Region of Denmark. Participants have the right to submit complaints and seek compensation for injuries or unsatisfactory treatment related to the study.

Compensation

Child and parent participants receive a DKK 600 (~US $90) gift card upon completion of their participation and return of the biosensor.

Withdrawal/Discontinuation From the Study

A participant who no longer wishes to participate in the study can withdraw their informed consent at any time without explanation nor consequences for their treatment. Consent can be withdrawn from parts of the study. For example, participants can consent to biosensor data collection and withdraw their consent for video data. Participants are also allowed to withdraw from parts of the pilot study such as the experiments, the 8-week observation period, and completion of measurements. We withdraw participants if they experience an untenable adverse reaction related to the biosensor or data collection procedures, they consistently do not attend data download meetings, the child participant receives a diagnosis included in our exclusion criteria, or we otherwise deem continued participation to be unsafe. We modify measurement requirements in the case of nonserious adverse events (eg, skin irritation at the site of the biosensor) and reduce burden of measurements if they are too frequent for the participant or found to be incomprehensible to the participant.

Data Management

Data collection, storage, and security adhere to the regulations set by The Knowledge Centre on Data Protection Compliance in The Capital Region of Denmark and follow the General Data Protection Regulation of the European Union. Signed data processing agreements between The Capital Region of Denmark and the Technical University of Denmark allow our interinstitutional research team to share data for analysis. Participating child-parent dyads are identified using a unique identification number with each dyad's data linked to the unique identifier.

Original electronic, paper, and relevant medical records are source documents. The research team will ensure that all data entered in the central database represent a true record of events. Study data are collected and managed using Research Electronic Data Capture (REDCap) electronic data capture tools hosted at The Capital Region of Denmark [33,34]. REDCap is a secure, web-based software platform designed to support data capture for research studies, providing (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources.

Empatica, the manufacturer of the E4 biosensor, is also a data processor. Physiological signals recorded by the E4 biosensor are stored on a central database managed by Empatica. Anonymized biosensor data, which can only be traced to our research group, are transferred to Empatica's E4 Connect via a secure Amazon Web Service server. E4 Connect stores physiological signals under unique device identifiers. Our research group then downloads and stores physiological signal data on a logged drive of The Capital Region of Denmark where the data are connected to the unique participant identification number.

Wearable Biosensor

Prior to the experiments at baseline, we instruct participants on how to use and care for the biosensor, which the youth and parent then place on their nondominant hand. Following the manufacturer's manual, we inform the participants that they should not look directly at the light-emitting diode lights, that the biosensor tolerates splashes of water during handwashing and rain but not submersion, and that the biosensor should be stored at room temperature and out of direct sunlight. Participants are asked to charge the biosensor at night. We demonstrate how to put on the wristband, how to turn it off and on, how to tag events, and how to click the charging cradle on and off the wristband. All participants received an abridged user manual that we translated into Danish.

The E4 (Empatica, Milan, Italy) wristband is a US Food and Drug Administration (FDA)-approved Class II device for adults and children (FDA 2018, 2019) and a European Union Class IIa device denoting that it is a noninvasive monitoring device [35]. The E4 battery can last over 48 hours and can store up to

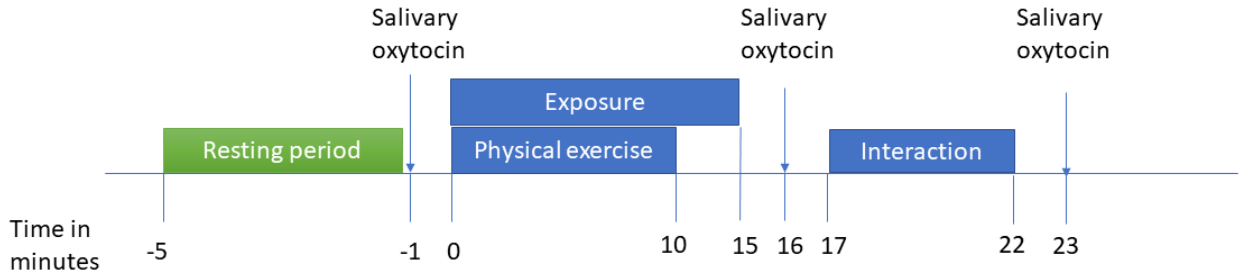
XSL•FO
RenderX

60 hours of data. The E4 wristband contains a photoplethysmographic (PPG) sensor, an EDA sensor, a 3-axis accelerometer, and an optical thermometer. PPG uses infrared light to measure changes in blood volume (ie, blood volume pulse) calculated by an algorithm that uses light signals during red and green exposure, sampled 64 times per second, as input [36]. The interbeat interval timings and heart rate are computed using the blood volume pulse signal as input to algorithms [36]. Under conditions of slight movement (<30% of the time), it is possible to use the interbeat interval to compute heart rate variability. The EDA sensor measures skin conductance sampled 4 times per second [37]. The accelerometer measures movement on three axes at a sampling rate of 32 times per second. The optical thermometer measures skin temperature at a sampling rate of 4 times per second [37].

Data Collection

Assessments

The assessment time of each measure is outlined in Multimedia Appendix 3.



After recruitment (baseline assessment), we obtain information about mental health treatment history for the patients by asking the youths and parents and checking the youths' medical journals. Medical journals are also used to obtain patient multiaxial diagnoses. During baseline testing, we ask participating parents to report probable or confirmed psychiatric diagnoses in the youths' first-degree relatives, and we ask youths about their current stage of puberty using the Tanner stages [38]. After baseline testing, participating families are asked to complete a set of questionnaires online to provide demographic information and baseline measures of youth quality of life, family dynamics, and parent symptoms of affective disorders. The demographic questionnaire includes questions about age, sex, and country of origin for the youths and parents as well as parents' highest attained level of education. Youths and parents also complete a questionnaire that includes questions about menstruation, hormone medication use, pregnancy, and breastfeeding. Information about hormones and puberty are collected as these are factors that may influence salivary oxytocin levels. Parents are also asked to complete the KIDSCREEN-52 [39], Parental Stress Scale (PSS) [40], Depression, Anxiety and Stress Scale (DASS) [41], and the Family Environment Scale [42]. Youths receive the KIDSCREEN-52 [39]. Parents of patients are also asked to complete a modified version of the Family Accommodation Scale–Parent Rated (FAS-PR) [43,44].

At the 8-week follow-up, patients' OCD severity is assessed with the Children's Yale-Brown Obsessive Compulsive Scale (CY-BOCS) before the experiments. After the experiments, all youth-parent dyads are interviewed for a maximum of 30 minutes about their experiences with the biosensor and their opinions about potentially using an app for data collection. Patient interviews are video- and audio-recorded. All participant answers are paraphrased and recorded in the REDCap database during the interview.

Experiments

Before the experiments at the beginning (week 0) and end (week 8) of the study, a researcher interviews patients about their current OCD symptoms using the symptom checklist from the CY-BOCS and the distress level associated with each endorsed symptom on a scale from 0 to 10. The timeline for the experiments is depicted in Figure 2.

Figure 2. Experiment design. Participants complete experiments during lab visits at week 0 and 8. Before providing the first saliva sample, participants rest for 5 minutes. Afterward, patients complete an exposure task for up to 15 minutes and controls are physically active for about 10 minutes. All participants complete a parent-child interaction task that lasts for 5 minutes. Saliva samples are collected again, before and after the interaction task.

The experiment starts with a 5-minute resting period, in which the youth and parent are left in a room and are asked to relax and refrain from speaking and touching each other for 5 minutes. Patients complete an exposure task for up to 15 minutes led by a mental health professional in the research team in the presence of the parent unless the patient prefers to complete the exposure without the parent. The preparation and delivery of the exposure exercise were inspired by a treatment manual for youth with OCD [45] (page 73). The clinical researcher delivering the exposure provides psychoeducation about OCD and explains the procedure and rationale behind the exposure. During this ERP preparation phase, patients are asked to report their expectation for what will happen to their distress level during ERP with a multiple-choice question: (1) distress will increase until it is unbearable, (2) distress will remain the same, (3) distress will decrease over time. Throughout the exposure, patients are asked to report their level of distress.

Control dyads complete a physical activity task, in which they are shown an exercise dance video lasting approximately 10 minutes. The participants are not required to follow the video, but are asked to move their bodies in a way that increases their heart rate for the duration of the task. The physical activity task allows us to examine the performance of the biosensor under

XSL•FO

intense movement and measure salivary oxytocin reactivity following physical stress. In the final controlled condition, patient and control dyads complete a parent-child interaction task, in which they are asked to plan their best warm-weather (baseline) and cold-weather (follow-up) vacation together, inspired by previous work [46,47]. Saliva samples are collected from the youth and the parent after the resting period, exposure task, physical activity, and the parent-child interaction task.

For behavioral coding, the exposure and parent-child interaction tasks are video- and audio-recorded. Human coders will code the videos for interlocutor positive and negative affect, anxiety, arousal, affective touch, and synchrony, as well as parent sensitivity and youth engagement using the Coding Interactive Behavior manual [48].

Exposure sessions will also be coded for youth distress, avoidant/approach behavior, reassurance and proximity seeking, as well as parent accommodating behavior and discouraging avoidance, using items from the Exposure Rating Scale for Exposure and Response Prevention [49] and the Exposure Process Coding System [12,50]. Parent acceptance statements and confidence statements will be coded based on definitions in a treatment manual for OCD and anxiety disorders in youth targeting parents [51].

Observation Period (Weeks 1-8)

We ask participating youths and parents to wear the biosensor during their daily routines for 8 weeks from the time they wake up until the time they go to sleep.

Patients are asked to push the event tag button every time they feel stressed by their OCD symptoms. Their parents are asked to tag every time they notice their child is distressed by their OCD symptoms. Control youths are asked to push the button when they feel very scared. Control parents are asked to push the button when they notice that their child feels very scared. Researchers meet with participants up to twice a week during the 8 weeks of continuous data collection to exchange biosensors full of data with empty biosensors. A byproduct of having up to two weekly in-person meetings with participants to download biosensor data securely throughout the observation period is an implicit reminder to wear the biosensor.

Ecological Momentary Assessment

We are developing mobile apps for EMAs of child and parent emotional states to produce more data labels during the observation period. The Copenhagen Center for Health Technology Research Platform, on which the apps are built, is a research tool for data collection [52]. The child and parent apps contain information about the study and versions of the Positive and Negative Affect Questionnaire [53,54] that are triggered at random times during the day to offset the potential negative focus on OCD and anxiety symptoms from tagging these emotional events on the biosensor. In addition to reporting their emotional state, children and parents report whether they are in the company of the other, other family members, or friends to establish the context of EMA data, similar to previous studies [55]. The patient app also includes daily guided exposure tasks to help patients practice ERP outside of the clinic and a weekly form for reporting OCD symptoms and their severity.

Study End Points

Defining Feasibility

The following study-specific feasibility criteria were developed: recruitment; retention rate; biosensor functionality; acceptability of the biosensor; compliance with wearing the biosensor; safety related to the biosensor; and physiological, audio, and visual markers of OCD. These are defined in Table 1.

Table 1. Operationalized feasibility success criteria.

Feasibility indicator	Criteria for success
Recruitment: consenting invited families (%)	>30% of invited families consent
Retention rate (%)	>80% retention
Biosensor functionality: unfixable malfunctions (N)	<10% irreparable malfunctions
Acceptability of biosensor: user experience questionnaire	>85% positive attitudes
Compliance	
Days participants wear biosensor (N)	Biosensor worn >30% of days in study
Tagged events, falsely tagged events, missed events (N)	False events identified; >70% accurately tagged events
Safety: adverse reactions to biosensor[a]	No major injuries or worsening of symptoms reported
Comparison of physiological signals as measured by the wearable biosensor; audio or visual signals; and reported, observed, or biochemical endpoints as markers of clinically relevant obsessive compulsive disorder parameters	>70% accuracy or high correlation with relevant endpoint

[a]Adverse reactions are defined as any negative effects of the biosensor. Investigators monitor adverse reactions at in-person visits, and they can be reported by parents, youths, or case workers.

Biosensor Experience

Children's and parents' level of physical (dis)comfort of wearing the biosensor, degree of satisfaction with the design, concerns of stigmatization, and data security as well as usability are assessed with a questionnaire in week 7. There are 13 multiple-choice questions answered on a 4-point scale (0=disagree a lot to 3=agree a lot) and one open-ended question. The English versions of the patient questionnaire and experience

XSL•FO
RenderX

of biosensor questionnaire are provided in Multimedia Appendix 4.

Participants and parents are interviewed together after the experiments in week 8 about their experiences with the biosensor. They are also asked about their thoughts on the convenience and data security of using a mobile app for data collection (see Multimedia Appendix 4). At the end of the interview, participants are also asked whether they have any feedback about any aspect of their participation in the study.

Biosensor Compliance
