Abstract

Background: Dental fear and anxiety (DFA) is a condition that affects approximately one-quarter of children and adolescents. It is a significant cause for pediatric patients to avoid dental care later in adulthood. Lack of patient cooperation due to DFA can create an environment of stress, often obligating dentists to end appointments prematurely and consider alternative pharmacological treatment options. Virtual reality (VR) use during dental care, providing an immersive experience through sensory stimuli, is potentially an additional nonpharmacologic tool to better manage DFA in children with special health care needs (SHCN) undergoing dental procedures.

Objective: This pilot study aims to assess the feasibility and acceptability of VR immersion as a tool to reduce DFA in pediatric special needs patients undergoing dental procedures. The study also aims to gain insight on parent and health care provider perspectives on the use of VR during dental appointments.

Methods: This pilot randomized controlled trial study will follow a parallel design including 2 groups: a control group (clinic's standard care using a wall TV) and an experimental group (using a VR game). We will randomize 20 participants to either group. Recruitment will be carried out at the dental clinic of the Centre Hospitalier Universitaire Sainte-Justine, a tertiary-quaternary care center that mostly serves pediatric patients with SHCN. The primary outcome will be patient recruitment rates and completion rates of planned procedures. DFA in children will be assessed using both an observation-based proxy assessment with the Venham Anxiety and Behavior Rating Scale and physiological assessments using parameters such as change in heart rate and levels of salivary alpha-amylase as a stress biomarker before and 10 minutes after the procedure. Sociodemographic characteristics, measures of the levels of parent and health care professional satisfaction, occurrence of side effects, and any deviation from normal procedure length will also be collected. Descriptive statistics, nonparametric tests, and effect sizes will be used for demographic and clinical variables and to present parent and health care professional satisfaction levels as well as procedural time.

XSL•FO
RenderX

Results: This study will be conducted from May 2023 to May 2024, with results expected to be available in December 2024.

Conclusions: The pilot study will provide insight on the feasibility and acceptability of VR use in clinical dentistry to reduce DFA for pediatric patients with SHCN. This study will guide future research on VR use in pediatric dentistry and can serve as a framework for a larger randomized clinical trial.

Introduction

Dental fear and anxiety (DFA) is a condition that affects approximately 13.3% to 29.3% of children and adolescents and is a significant cause of patients avoiding dental care [1,2]. In children, DFA is also associated with a lower oral health–related quality of life [3]. Although the etiology of DFA is multifactorial, often stemming from both exogenous and endogenous sources, a previous traumatic dental experience is the most predictive factor for DFA [4,5]. A study by Ten Berge et al [6] stated that the majority of DFA experienced by adults stems from poor dental experiences as children. These findings highlight the importance of keeping each dental experience a positive one for pediatric patients. Short-term distress during appointments that is not managed properly can accumulate into poor dental experiences and, in turn, reinforce DFA into adulthood [7]. The long-term effects of these poor dental experiences as children can lead patients to avoid seeking proper dental care in the future [8].

Dental patients with special health care needs (SHCN) are defined as patients requiring additional time and special consideration when receiving treatment due to medical, physical, cognitive, or developmental conditions [9]. The population includes children with behavior (eg, autism spectrum, anxiety, attention deficit hyperactivity disorder), congenital (eg, trisomy 21, congenital heart disease), developmental (eg, cerebral palsy), systemic (eg, childhood cancer, sickle cell disease), or cognitive disorders (eg, intellectual disability) [9]. Children with SHCN face more barriers to dental care than the overall population [9]. Barriers include external factors (transportation, cost, inadequate dental facilities) and internal factors (fear and poor tolerance) [9,10]. Many children with SHCN are cared for by dentists in the community or, more often, in hospital dental clinic settings [9]. They experience more DFA, which can result in more difficult dental visits [9]. The importance of providing well-rounded care and making each dental visit a positive one for pediatric patients with SHCN is crucial for promoting a good oral health routine, as well as improving their oral health transitioning into adulthood [9].

Understanding and assessing DFA in children are important for delivering successful dental care with high satisfaction in this age group. Among the vast number of assessment method options available today, self-report assessment, parental proxy assessment, observation-based assessment, and physiological assessment are the 4 major types for DFA in children [11]. In the recent literature, salivary alpha-amylase, an enzyme correlated with both adrenaline and noradrenaline, has also been used as a marker for autonomic nervous system activity and stress [12].

Factors in the dental setting that trigger DFA include the loud sounds of dental instruments, presence of strangers examining the oral cavity, and the fear of pain [13]. Of these, the biggest trigger of DFA is the anticipation and use of local anesthesia injections [5,13]. Although necessary to provide adequate pain control during certain treatments, local anesthesia injections are understandably uncomfortable [5]. For children, the initial injection combined with the feeling of numbness during the procedure is especially distressing [5]. Pharmacological agents, combined with light to moderate sedation, or general anesthesia can also be considered for noncooperative patients; these options are often time-consuming and confer a higher cost as well as health risk [1]. In the current literature, audiovisual distractions such as tablets or TV screens have been used as additional distraction techniques rather than just traditional tell-show-do distraction, with overall positive results [14]. However, there is a lack of interactivity with these techniques, and as a result, they produce less immersive environments with distraction for the children [15]. Lack of patient cooperation due to DFA often obliges dentists treating pediatric populations to end appointments prematurely and sometimes without completing the planned procedure. Treating an anxious and fearful patient can create an environment of stress for the clinician and associated dental team [1].

Particularly when treating children with SHCN, extra time and tools are needed to provide comfortable dental care. Depending on the child's diagnosis, some have hypersensitivity to external stimuli such as loud noises, aversion to specific tastes, and difficultly straying from usual daily routines [16]. A study by Pagano et al [16] showed that the use of augmented reality was well suited for patients with autism spectrum disorder in preparation for their dental visits. Additionally, a systematic review by Cunningham et al [17] concluded that virtual reality (VR) is a promising tool in dentistry, especially for the population of children with autism spectrum disorder or other special needs.

VR is defined as an artificial environment that is experienced through sensory stimuli [18]. It is a modern tool that can immerse patients in a "game" or "world." Commonly used in

XSL•FO
RenderX

the medical field to help distract patients during unpleasant procedures such as vaccination, cast removal, and short bedside interventions, it has proven to be effective at decreasing procedural anxiety and providing a more positive experience for patients [19]. Among the limited existing literature, the use of VR to manage anxiety during dental procedures has shown positive results. A recent clinical trial by Alshatrat et al [15] concluded that VR is an effective tool for reducing anxiety in young children during dental procedures. Moreover, a previous study by Ram et al [20] showed that both parent and clinician satisfaction was high using audiovisual glasses as distraction for children during dental treatments. However, clinical VR research in pediatric dentistry is limited, especially with special needs populations. VR use in pediatric dentistry offers the potential to add a nonpharmacologic tool to a clinician's toolbox. A clinical study on the use of VR during dental appointments with pediatric patients with SHCN would allow a better understanding of the effect of VR on DFA in this population and possibly facilitate dental procedures.

Aims of the Study

The aims of the study are twofold: (1) assess the feasibility and acceptability of VR immersion as a tool to reduce DFA in pediatric patients with SHCN undergoing dental procedures and (2) gain insight on parent and health care provider perspectives on the use of VR during dental appointments.

Objectives

The primary research objectives are to determine (1) the feasibility and acceptability of VR distraction for children with special needs requiring dental procedures, (2) compare parent and health care professional satisfaction levels between the VR distraction group and the clinic's standard mounted TV showing cartoons, and (3) observe the preliminary effects of VR distraction on reducing patient anxiety during dental procedures compared with standard nonpharmacological behavior management.

The secondary objectives of this study are to compare the following between the VR distraction group and the clinic's standard mounted TV showing cartoons: (1) physiological parameters (pulse and oxygen saturation), (2) the occurrence of side effects, (3) dental procedure length, (4) the number of retakes of dental procedures due to DFA, and (5) salivary amylase levels.

Methods

Design

This randomized controlled trial pilot study will follow a parallel design including 2 groups: a control group (mounted wall TV playing cartoons) and an experimental group (VR intervention during the dental procedure).

Sample and Setting

This pilot will include 20 participants, totalling 10% of the expected 200 children to be included in the final study. All participants in this pilot study will be allocated in an equal ratio of 10 per group. Recruitment will be carried out at the dental clinic of the Centre Hospitalier Universitaire Sainte-Justine, a pediatric hospital in Montreal, Canada. This clinic mostly serves patients with SHCN such as craniofacial abnormalities, autism spectrum disorder, cancer, and others. Pediatric patients with SHCN represent around 80% of the total clientele of this clinic, while the rest is comprised of otherwise healthy patients with dental traumas and other dental emergencies.

Inclusion Criteria

Children participating in this study will have to meet the following criteria: (1) aged 6 years to 17 years; (2) recommended by the dentist to participate; (3) required to undergo any dental procedure; and (4) accompanied by a parent or a legal guardian who can understand, read, and write in either French or English.

Exclusion Criteria

Participants will be excluded from this study if they meet the following criterion: have epilepsy or any other conditions preventing them from using VR. Non-SHCN patients will not be excluded from the study, but this information will be collected. Patients with a strong history of motion sickness will not be excluded from this study, but this information will be collected and additional monitoring will be provided. The use of medication (opioid and non-opioid analgesic, antiemetic, anxiolytic, or any other drugs) prior to the procedure within the last 4 hours will not exclude participants from this study, but this information will be collected during the pre-intervention questionnaire. Patients having undergone previous dental procedures in the past will not be excluded.

Randomization and Allocation

Randomization will be done through the electronic REDCap (Vanderbilt University) system. Allocation to either intervention will be randomized by an independent biostatistician from the Applied Clinical Research Unit (URCA). To equalize participants in both arms, permuted block randomization with a randomly selected block size design will be used to randomize participants to the intervention [21]. Access to the randomization list will only be granted to the biostatistician, and allocation will be concealed using REDCap to reduce selection bias.

Interventions

Control Treatment

The control group will only receive a care-as-usual approach. This includes a television mounted on the wall showing cartoons and the use of pharmaceutical treatment during the procedure such as the use of injected local anesthesia. In the event of noncooperation during the appointment, any retakes or rescheduling of appointments will be compiled by the resident dentist. One parent will be permitted to be present in the room during the procedure as part of the clinic's usual protocol, and their presence will be recorded. Children allocated to the control group will be offered the possibility to try the VR game after the study period if they choose to do so.

Experimental Treatment

The experimental group will be provided the VR video game "Dental Dream" designed specifically for this study. Pharmaceutical treatment, such as the use of injected local

XSL•FO
RenderX

anesthesia, during the procedure will be used if the procedure requires it. Children will be able to play for the entire duration of the dental procedure. “Dental Dream” aims to reduce anxiety in children aged 6 years to 17 years old by means of immersive distraction. The VR headset offers children the ability of viewing the game they are playing in real time while simultaneously obstructing the partial view they would normally have of the procedure. In the event of noncooperation during the appointment, any retakes or rescheduling of appointments will be compiled by the resident dentist. One parent will be allowed in the room during the dental procedure, and their presence will be recorded.

Developed by Paperplane Therapeutics, “Dental Dream” is an easy-to-play, immersive VR video game tailored for the pediatric population and approved by a team of health care professionals in pediatric care. The simplified no-success game allows it to be enjoyable no matter the child’s video game experience, and its point-and-shoot arcade style also allows for easy understanding and fast immersion in the game. Positioning is normally a challenge for VR as it is very position-specific, needing a semi-fowler's angle of 30°-45° to function properly. “Dental Dream” was designed specifically for this study with the specific horizontal position needed for dental procedures in mind. “Dental Dream” is designed to be supported by the Pico Neo 4 VR headset.

Children playing the game will be immersed through a virtual environment where they will be able to use a remote in one hand to target floating and static objects in the VR game. The objective of the game is to throw balls at targets such as balloons, trolls, and diamonds to gain points. The “Dental Dream” game uses an on-rail feature guiding the child through space with a new eye tracking technology developed within the headset in order to help the child navigate the same way head movement normally would in classic VR, making it easier for dental procedures where head movement is restricted. These features also aim to reduce cybersickness.

The preliminary version of the VR headset has been tested in clinic on staff—the size and volume of the Pico Neo 4 headset do not hinder delivery of dental care as it is smaller than usual VR headsets.

Study Time Points

Sociodemographic data will be assessed before the intervention at baseline (T0) to establish a baseline using a simple questionnaire completed by the parent or legal guardian present while sitting in the waiting room. Salivary alpha-amylase samples will be collected at T0 and after the intervention/procedure (T2; Multimedia Appendix 1). Measures of specific dental procedure–related anxiety and uncooperative behavior will be assessed at T0, during the procedure (10 minutes from the start; T1), and immediately after the end of the procedure (T2). Physiological parameters will be measured at T0, during the intervention (T1), and T2. Data on occurrence of side effects will be assessed and monitored at all times for the duration of this study. All clinical monitoring will be performed by the dental resident on site. Measures of parent or legal guardian and health care professional satisfaction will be assessed at T2.

Measures and Outcomes

Sociodemographic Characteristics

Sociodemographic characteristics will be provided by the parent or legal guardian in the waiting room prior to the intervention and will include information such as age, sex, ethnicity, and the procedure needed. Other information will also include any medication taken within the last 24 hours (name, class, and posology) that could have an impact on the conclusions of this study.

Primary Outcomes

To measure feasibility and patient acceptability, we will record patient recruitment rates, completion rates of planned procedures, and satisfaction. As this is a population of children with SHCN, we estimate 50% of patients will agree to participate during recruitment, and we expect a completion rate of planned procedures of 75%.

Measures of Primary Outcomes

Parent or legal guardian satisfaction with the intervention will be assessed using a visual analog scale (VAS; 0-10, where 0 is very dissatisfied and 10 is very satisfied) and the question recommended by the Pediatric Initiatives on Methods, Measurement and Pain Assessment in Clinical Trials (PedIMMPACT): “Considering anxiety relief, side effects and emotional recovery, how satisfied were you with the intervention used to manage DFA experienced by your child?” [22] (Multimedia Appendix 2). The parent or legal guardian will respond according to their satisfaction level.

Health care professional satisfaction with the intervention will be assessed using a VAS (ranked from 0-10, where 0 is very dissatisfied and 10 is very satisfied) as well as a 6-question satisfaction questionnaire (each answer will be given a score of 1, 2, 3, or 4 based on the choice of answer: Fortement en désaccord, En désaccord, En accord, Fortement en accord, respectively) and will result in a final score between 6 and 24 (Multimedia Appendix 3).

DFA scores will be evaluated using the Venham Anxiety and Behavioral Rating Scale [23]. It is an observation-based assessment by proxy for DFA and is among the most frequent behavior scoring models for DFA [23] (Multimedia Appendix 4). It is composed of 2 scales used to assess the anxiety and uncooperative behavior of children in the dental setting. The scale is also found under the name Clinical Anxiety Scale/Uncooperative Behaviour Rating Scale or Venham Clinical Cooperation Scale and Venham Clinical Anxiety Scale and has been used as an anxiety rating scale in other studies that have evaluated the efficacy of VR distraction for the management of DFA [11,24,25]. Both consist of a 6-point scale, with 6 defined behavioral levels that range from 0 to 5. The highest score defines the highest anxiety level or lack of cooperation [23]. A high degree of reliability has been observed for both scales, even for an untrained observer [23,26]. The scale points are measured by proxy and anchored in objective, specific, and readily observable behavior. The research assistant indicates the participant’s behavior by picking a number from 0 to 5 according to the scale; thus, for each participant, 2 scores

XSL•FO
RenderX

on the levels of anxiety and cooperation with the dental procedure will be obtained at T0, T1, and T2. Venham et al [27] reported that the scale is a reliable and valid scale and provides an interval-level measurement. The scale has been a useful instrument for assessing a child's response to dental stress. The anxiety score and uncooperative score will both be evaluated at T0 (baseline), during the procedure at 10 minutes after the beginning of the procedure (T1), and after the completion of the procedure (T2). The videos will be reviewed by 2 independent evaluators who will provide a score for the anxiety of each child during the procedure. Scores will be compared afterwards. The same scales will be used during observation of the child's behavior using the video recordings by a separate member of the team. Both evaluations (when available depending on consent) will allow for inter-rater agreement to be calculated.

Secondary Outcomes

The secondary outcomes will be (1) changes in physiological parameters (such as heart rate and pulse oximetry) during and after the intervention compared with baseline, (2) occurrence of side effects, (3) deviation from the normal procedure length, (4) rescheduling of procedures in the event cooperation is impossible, and (5) salivary amylase levels.

Measures of Secondary Outcomes

The secondary outcomes will be measured as described here. Physiological parameters will be continuously measured using the Nellcor pulse oxygen saturation meter (Covidien), an approved and validated device. The occurrence of side effects will be collected from arrival on site to discharge from the study using a checklist of common side effects experienced while using VR and also related to dental medication. The length of the procedure will be measured and collected for every participant and will be compared with the average duration for a similar procedure that will have been measured prior to the study by the clinic's personnel. Rescheduling of procedures in the event that cooperation is impossible will be noted. Salivary amylase levels, as a stress biomarker, will be measured before and after the dental procedure as described in the following section.

Measurement of Salivary Amylase

Saliva samples will be collected from all children in this study at 2 different study time periods: before (T0) and after (T2) the intervention. Salivary alpha-amylase has been recognized and validated as a reliable and specific marker for autonomic nervous system activity and has been proposed as an alternative biomarker for stress [12]. Alpha-amylase sampling has been performed in previous studies to evaluate DFA for children undergoing dental procedures [28-30]. Alpha-amylase, as a salivary biomarker, can be considered an important and noninvasive tool for assessment of anxiety-related events, such as dental extraction and other treatment, for children [28,31].

Salivary samples will be collected using a sterile dental cotton swab from under the tongue 10 minutes before and 10 minutes after the procedure and stored immediately within a sterile vile in a research-specific on-site freezer. Samples will be collected by the dental resident and taken to the laboratory. Results will be entered in REDCap for analysis after the study.

Table 1 provides an overview of which questionnaires will be answered by which respondents during the study.

Table 1. Questionnaires and corresponding respondents.

Questionnaires	Respondents
Parent or legal guardian satisfaction	Parents or legal guardians
Health care professional satisfaction	Health care professional
Anxiety score, physiological parameters	By proxy through research assistants

Study Proceedings Including Data Collection

Participants will be identified by the resident dentist through the appointment scheduling system as requiring any dental procedure. Since DFA can arise from multiple different procedures such as simple cleaning to teeth extraction, dentists at the clinic will identify possible participants to include based on their cooperation, personality, and fears. An individual independent to the study will review consent with participants and parents. Written consent by the parents or legal guardian—including the child's assent—will be obtained on arrival at the clinic the day of the procedure while completing the preprocedural questionnaire.

After verifying that the participant meets all the inclusion and exclusion criteria, the dental resident will log into REDCap only 10 minutes before the start of the intervention to minimize the risk of bias toward the intervention and to obtain the group allocation and announce it to the participant. Because of the nature of VR, no blinding of staff, participants, and parents or legal guardians will be possible. Baseline data collection prior to the dental procedure, including the sociodemographic questionnaire, recording of physiological parameters, and salivary alpha-amylase sampling, will take approximately 15 minutes to complete. The VR headset will be adjusted for the child's size, and approximately 5 minutes will be allotted for children to familiarize themselves with the room, equipment, and game before the start of the procedure.

The intervention will last the entire time of the dental procedure, and the duration will be recorded for every patient. DFA assessment by proxy using the Venham Anxiety and Behavioral Rating Scale will be performed on site by the dental resident present and will also be filmed (if consent was given) to be evaluated by another member of the team at a later date.

As per the clinic's protocol, if a child becomes restless and cooperation is impossible, the child will be held by his or her parents for the remaining duration of the procedure if it cannot be safely stopped at that time or if the procedure is considered

XSL•FO
RenderX

an emergency. If the procedure can be safely stopped, rescheduling will be discussed with the parents including the possible need for sedation. The involvement of parents will be recorded as well as any other distractions used during treatment such as the use of stickers, teddy bears, or music.

All side effects and medication used will be recorded. The former will be transmitted to the ethics committee if needed. As VR has the potential to cause nausea, dizziness, and motion sickness, should participants experience any of these, they will be dealt with according to the clinic's protocols. If participants experience adverse side effects and the attending dentist and dental assistant have been informed, the treatment will be safely discontinued. All instruments in the mouth will be removed. The VR device will be removed from the participant. The dental chair will be placed in a comfortable position, and the patient will rest until they feel comfortable and recovered. The option of continuing the treatment (without the VR headset) or postponing the treatment to another day will be discussed. Postprocedure salivary alpha-amylase sampling and completion of questionnaires regarding parent and health care professional satisfaction levels after the dental procedure will take approximately 20 minutes. Equipment used by children will be disinfected before the next participant arrives.

Statistical Analysis

Analysis will be conducted using the SAS (SAS Institute) statistical analysis software (version 9.4). Descriptive statistics, by treatment, will be conducted for demographic and clinical variables and will be used to present sociodemographic and clinical data, parent and health care professional satisfaction levels, and procedural time. Due to a small sample size, we will also assess effect sizes.

For the pilot project, we plan to perform descriptive analyses of the sample as well as comparative analyses between the 2 groups. Nonparametric tests for procedural type, age, parental presence, parental and health care satisfaction levels, and baseline (T0) anxiety score measurement will be used to assess the composite outcome for mean salivary cortisol level and mean difference in anxiety score (using the Venham Clinical Cooperation Scale and Venham Clinical Anxiety Scale) between the experimental and control groups at T2. Analyses will be carried out according to the intention-to-treat principle, with a significance level (α) of .025, considering Bonferroni's correction.

For secondary outcome analyses, nonparametric tests adjusted for procedural type, age, and parental presence will be used to assess the mean procedural length at T2 using the VAS and 6-item tailored questionnaire, respectively. Comparison of dichotomous variables including the necessity for procedural retakes, use of other nonpharmacological interventions, and the occurrence of side effects will be assessed using the Cochran-Mantel-Haenszel test.

The study data will be recorded in the REDCap system belonging to URCA. The data manager associated with URCA and independent of the study will be responsible for the storage of the recorded data. However, a URCA biostatistician independent of the study will be responsible for the data analysis. The data analysis plan will be discussed with the principal investigator (SLM). Interjudge correlations will be conducted for the video tape analysis. Two judges will independently rate the anxiety measure on the videotapes. Subsequently, we will conduct intraclass correlation coefficient analyses to compare the scores for each of the recruited patients between the 2 judges.

Ethical Considerations

Approval by the Ste-Justine Hospital research board of ethics (#2023-4985) was obtained in March 2023. An individual independent to the study will review consent with participants and parents. The information and consent form will be signed by one of the parents on the day of the visit. Upon enrollment, children are assigned codes used on all data collection forms to protect their confidentiality. Only the dental resident and the principal investigator will have access to the log that links the study codes to the participants. Patient-identifying information is kept separate from the case reports and is linked to study enrollment by a study ID number. The consent form also identifies all the information that may be collected during this study and details the use of videos that may be needed for further behavior evaluation using proxy scales with the possibility to opt out. All data collected by paper forms the day of the intervention will subsequently be transferred into REDCap. No recording of the child's screen nor their game inputs will be collected. The intervention will be filmed and recorded, as the use of proxy scales will need further evaluation of the child's behavior. As per usual, all information such as links between patient identifiers to study ID and paper copies of forms and questionnaires will be kept stored and double locked for 7 years (starting from the end of trial) at the principal investigator's office at the research center.

Results

This study will be conducted from May 2023 to May 2024, with results expected to be available in December 2024. The findings of the study will be disseminated through peer-reviewed publications.

Discussion

The results of the study will allow us to gain insight on the feasibility and acceptability of the intervention and on the satisfaction of parents and health care professionals regarding the use of VR as a tool to reduce anxiety in pediatric dentistry, especially in children with SHCN. Due to the limited clinical studies about VR and pediatric SHCN populations in dentistry, this pilot study will guide potential future, larger, clinical trials.

Challenges and Limitations

Individual experience with VR varies immensely, as some children may love to have an active distraction during dental treatment, while others may prefer to be present in the moment. As such, we acknowledge that the acceptance of VR use during dental treatment is a tool that may be useful for a certain population within a patient pool. Like all other distraction tools used in the dental setting, proper screening and patient selection are crucial during treatment planning. Moreover, the game

XSL•FO
RenderX

design used during the study was created specifically for our study, so the results of our study may not be able to be extrapolated to a different setting with a different game design.

Conclusion

The results of the study could be used to help us to better understand how VR distraction can reduce DFA in children with special needs and the acceptability of its use by parents, patients, and health care professionals during dental procedures. The results can be used as preliminary data for a future clinical trial on the use of VR in dentistry with special needs patients. In addition, this study will possibly allow for more comfortable and less traumatic dental care for pediatric patients. By exploring new avenues for behavior and anxiety management tools for pediatric dentistry, this study and its results will provide improved patient-centered care.

Data Availability

Once the pilot study is completed, the authors confirm that the data supporting the findings of this study will be available through the clinicaltrials.gov repository. In addition, data will be available within a future publication and its supplementary materials.

Abstract

Background: The increasing burden of depression and noncommunicable disease (NCD) is a global challenge, especially in low- and middle-income countries, considering the resource constraints and lack of trained human resources in these settings. Effective treatment of depression in people with NCDs has the potential to enhance both the mental and physical well-being of this population. It will also result in the effective use of the available health care resources. Brief psychological therapies, such as behavioral activation (BA), are effective for the treatment of depression. BA has not been adapted in the community health care services of India, and the feasibility of using BA as an intervention for depression in NCD and its effectiveness in these settings have not been systematically evaluated.

Objective: Our objective is to adapt BA for the Indian NCD context and test the acceptability, feasibility, and implementation of the adapted BA intervention (BEACON intervention package [BIP]). Additionally, we aim to test the feasibility of a randomized controlled trial evaluation of BIP for the treatment of depression compared with enhanced usual care.

Methods: Following well-established frameworks for intervention adaptation, we first adapted BA (to fit the linguistic, cultural, and resource context) for delivery in India. The intervention was also adapted for potential remote delivery by telephone. In a randomized controlled trial, we will be testing the acceptability, feasibility, and implementation of the adapted BA intervention (BIP). We shall also test if a randomized controlled feasibility trial can be delivered effectively and estimate important parameters (eg, recruitment and retention rates and completeness of follow-up) needed to design a future definitive trial.

Results: Following the receipt of approval from all the relevant agencies, the development of the BIP was started on November 28, 2020, and completed on August 18, 2021, and the quantitative data collection was started on August 23, 2021, and completed

XSL•FO
RenderX

on December 10, 2021. Process evaluation (qualitative data) collection is ongoing. Both the qualitative and quantitative data analyses are ongoing.

Conclusions: This study may offer insights that could help in closing the gap in the treatment of common mental illness, particularly in nations with limited resources, infrastructure, and systems such as India. To close this gap, BEACON tries to provide BA for depression in NCDs through qualified NCD (BA) counselors integrated within the state-run NCD clinics. The results of this study may aid in understanding whether BA as an intervention is acceptable for the population and how feasible it will be to deliver such interventions for depression in NCD in South Asian countries such as India. The BIP may also be used in the future by Indian community clinics as a brief intervention program.

Introduction

Noncommunicable diseases (NCDs), also known as chronic diseases, tend to be of long duration and are the result of a combination of genetic, physiological, environmental, and behavioral factors. NCDs are the leading cause of mortality in the world, much of which is premature and avoidable [1,2]. The largest population-based study conducted in India on the prevalence of depression found that 15.1% of urban South Indians were depressed. The most frequent symptom was a depressed mood (30.8%), followed by fatigue (30%), whereas less frequently occurring symptoms included suicidal thoughts (12.4%) and speech and motor retardation (12.4%) [3]. Another study conducted in South India shows patients with ischemic heart disease and hypertension were more likely to exhibit somatization and depression symptoms, whereas patients with diabetes mellitus, those with hypertension, and those with ischemic heart disease were more likely to exhibit anxiety symptoms [4]. According to a study on comorbid depression in NCDs among older patients conducted in Punjab, India, 58.1% of study participants had depression, of which 34.1% had severe depression. Generalized anxiety disorder (GAD) was found to be present in 38.7% of cases, with 19.7% falling into the severe category. In 37.8%, GAD and depression were both identified [5]. There is increasing evidence that comorbid mental health conditions, such as depression, can greatly affect people with physical health conditions [6]. For example, people with NCDs are 2-3 times more likely to experience depression [2]. As the population grows in number and becomes older, more people with physical and mental illnesses are living longer. These persistent disorders are closely related. Several key modifiable risk factors for NCD, such as a poor diet, inactivity, smoking, and hazardous alcohol use, are made worse by poor mental health. A person is more likely to have one or more chronic illnesses if they have a mental illness, which is a risk factor for NCD [3].

The presence of depression worsens NCD symptoms, adversely impacts the quality of life, and increases the financial burden for patients and their families [2]. Therefore, it is important to recognize and treat depression to improve the overall management of NCDs and improve health, quality of life, and economic outcomes for these patients.

There is an identified need to integrate mental health care in NCD care settings to help address the high burden of comorbid depression with NCDs. However, there is a notable gap worldwide between the number of people in need of mental health care and those who receive treatment. This “treatment gap” is especially high in low- and middle-income countries (LMICs) [7,8]. It is recognized that depression management is not standardized across services and is often not available at all.

Another reason for this treatment gap would be that in developing nations, stigma is a significant barrier to people seeking care for mental health issues. Those who are stigmatized may expect to be treated unfairly and with contempt by others, which may encourage them to use unhealthy coping techniques such as withdrawal or secrecy. This tendency has been noted in research conducted in LMICs, such as Ethiopia and India. One option would be to incorporate areas of mental health treatment that influence the development of stigma, such as successful task-shifting programs, peer and health worker-delivered therapy, and case management [9]. Task shifting is a strategy that has been shown to be successful in helping to address this shortage of specialists, whereby nonspecialist health workers are trained to deliver interventions that would usually be provided by specialists [10]. This approach is supported by the World Health Organization’s (WHO’s) Mental Health Gap Action Program (mhGAP) [11].

Behavioral activation (BA) is an evidence-based, simple, structured psychotherapy for the treatment of depression, initially developed in the 1970s. BA aims to break the negative cycle of aversive behaviors and low mood by increasing engagement in activities that are associated with positive reinforcement. BA therapy is delivered by a trained practitioner, usually over a series of face-to-face therapy sessions, with “homework” tasks that are agreed upon with the person with depression to be undertaken between sessions. BA can be delivered through a number of sessions over digital and telephone platforms as well as in person [2,12,13].

XSL•FO
RenderX

Although there is interest in using BA for depression in people with NCDs, evidence for the effectiveness of this approach has not been clearly established. A systematic review conducted in 2011 found only 8 randomized controlled trials of BA in long-term conditions (with study sample sizes ranging from 20 to 105) [14]. A total of 3 trials targeted stroke; another 2 were in dementia and 1 in breast cancer. The remaining 2 included studies targeting older residents in nursing homes but did not specify the comorbid physical conditions. Since the publication of that review, the "Integrating Depression and Diabetes Treatment" (INDEPENDENT) study, a randomized controlled trial of BA delivered through a multicomponent care model in India, has shown effectiveness and cost-effectiveness for the treatment of depression in people with diabetes. However, the study intervention was complex and multifaceted, combining collaborative care, decision support, and population health management. It remains uncertain whether a briefer intervention like BA is effective for the treatment of depression in NCDs in LMICs [15].

This study aims to address this evidence gap by (1) adapting BA for the Indian NCD context; (2) testing the acceptability, feasibility, and implementation of the adapted BA intervention (BEACON intervention package [BIP]); and (3) testing the feasibility of a randomized controlled trial evaluation of BIP for the treatment of depression compared with an enhanced usual care (EUC) package.

Methods

Intervention Adaptation

The purpose of this step was to ensure the BA intervention content and delivery were appropriate for the Indian NCD's cultural, linguistic, and resource context. The initial content was based on treatment manuals and workbooks from previous adaptations of BA for multimorbidity and delivery by lay counselors in the United Kingdom [16] and India [17]. The research team also looked at training packages from the WHO mhGAP [11] relevant to the delivery of BA and formative research exploring the implementation of BA in similar settings in South Asia [18].

Following adaptation frameworks, including cultural adaptation [19,20], and taking this information into account and in discussion with experts within the National Institute of Mental Health and Neuro Sciences (NIMHANS) and the wider BEACON team, the materials, plans for delivery, and training package were adapted. Revisions to the package were made through expert panel reviews, co-design workshops with NCD counselors, and feedback sessions from NCD patients and caregivers. Major revisions included modification of the workbook as a flipbook with less text and more pictures, simplification of the BA counselor's manual, and preparation of a separate session log instead of homework tasks in between session follow-ups. The training package for the BA counselors was modified in collaboration with a BA expert from the United Kingdom.

The finalized BIP comprised a BA counselor's manual, a session log, and a flipbook for the patient participants. The intervention could be delivered remotely by telephone over 6 sessions lasting approximately 30-40 minutes each. The training of the BA counselors focused on developing skills in communication, establishing therapeutic relationships, and using the manual and materials to deliver therapy sessions. The task of adapting BA for the Indian NCD context has already been completed.

Feasibility Trial

Objectives

The objectives of the feasibility trial are to (1) test the acceptability, feasibility, and implementation of the adapted BA intervention (BIP) and (2) test if a randomized controlled feasibility trial can be delivered effectively and estimate important parameters needed to design a future definitive trial.

This will be achieved by answering the following research questions (RQs): (1) what are the recruitment and retention rates for participants in the trial? (2) What is the feasibility and acceptability of the proposed randomization and data collection procedures? (3) To what degree can the BIP be implemented as planned? (4) What is the acceptability of the BIP from the perspective of study participants and BA counselors?

Design

A randomized controlled feasibility trial with the nested process and economic evaluations was conducted over 12 months. The Gantt chart can be found in Multimedia Appendix 1.

The 2 trial arms are the intervention arm (BIP) and the control arm (EUC).

Setting

In 2010, the Ministry of Health and Family Welfare, Government of India, launched the National Programme for Prevention and Control of Cancer, Diabetes, Cardiovascular Diseases, and Stroke (NPCDCS). This includes the prevention and management of NCDs at district and subdistrict-level facilities. These facilities provide services for screening, treatment, or referral of patients with NCD but do not, at present, include the integrated detection and management of mental disorders. They do not yet cover all districts in the country [21].

The setting for the BEACON study is a district in Kolar, Karnataka, South India, where it was possible to explore the integration of mental and physical health care based on several pragmatic considerations, including the availability of NCD services that are part of the government health system and the engagement of key stakeholders. Therefore, to better understand the health system at the study site, a survey of the organizational capacity in the study area was conducted, along with interviews with the NCD counselors and the patients who visit the health facility. Following this, the selection of health care facilities was based on (1) the provision of NCD services, (2) the availability of health care staff such as NCD counselors and nurses to identify the patient participants for the study (by administering the Patient Health Questionnaire [PHQ-2]) [22], a screening tool to identify those who need further assessment for depression), (3) the engagement and support of senior managers, and (4) a sufficient number of patients with NCD attending the facility. Facilities were part of

XSL•FO
RenderX

government-supported health services and were within a reasonable travel distance of the research team's base to make the study feasible.

Since most NCD services are limited to providing care for cardiovascular and chronic lung diseases and diabetes (excluding cancer), the study focused on these disorders. Finally, a total of 6 NCD clinics were chosen for data collection.

Eligibility Criteria for Trial Participants

The eligibility criteria for this study are given in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for the study.

Inclusion criteria

- Aged 18 years or older.
- Diagnosed with cardiovascular disease, chronic respiratory disease, or diabetes (type 1 or 2).
- Current diagnosis of depression (confirmed with a Patient Health Questionnaire [PHQ-9] [23] score of ≥10).
- Willing to participate and able to attend therapy sessions in person or by telephone.
- Other mental or physical illness comorbidities will not be a reason to exclude unless the patient is judged to be too unwell to participate.

Exclusion criteria

- Already receiving psychotherapy for depression. Being on antidepressant medication will not, however, be a reason to exclude.
- Lacking the capacity to provide informed consent.
- Unable to take part in therapy because of cognitive impairment or the severity of a mental or physical illness.

Intervention Arm

Participants in the intervention arm will receive the BIP, delivered by trained nonmental health specialists (BA counselors) who will be specifically recruited for the study. BA counselors will be supervised by a mental health specialist.

The BIP will be delivered over 6 sessions lasting 30-40 minutes over a period of 6-12 weeks, with a minimum of one week between sessions. All sessions will be delivered remotely, by telephone. An alternate telephone number will be collected at the time of recruitment to ensure the unhindered delivery of BA sessions to the client.

The components of BIP include structured sessions where participants, with the BA counselors, plan and identify 3 types of activities. The first one includes routine and necessary activities that are done either regularly or on a daily basis, for example, getting fresh, taking a bath, cooking, doing household chores, etc. Second, social activities involve interacting with other people, for example, meeting or chatting with people from the neighborhood, etc. And third, pleasurable activities include activities that one enjoys and has fun with. For example, reading a newspaper or book, watching television (serials and movies), etc. The BA counselor and the participant will both have a flipbook for guidance and a better understanding of the activities during the session, as it contains a pictorial representation of each type of activity. The BA counselor will follow a manual and maintain the session logs of the participants. The BA counselor in the session log will not only maintain the session details but also keep a record of the daily activities done by the participants and the mood associated with doing these activities through telephonic follow-up in between the sessions. Another reason this is done is to check if the participants are doing the activities or if they are facing any challenges while doing them.

Control Arm

Participants in the control arm will receive an EUC leaflet describing depression and its treatment and signposting, including providing contact details (addresses and telephone numbers) to help access usual care for depression. They will also be provided with 1-time brief advice on the same from the research assistants (RAs) remotely.

Outcomes

The outcomes for the feasibility trial relate to (1) the acceptability and feasibility of recruitment and data collection and (2) the acceptability, feasibility, and implementation of the BIP.

Outcomes relating to the feasibility and acceptability of recruitment and data collection are (1) the rates of recruitment into the trial and retention at 3 months (RQ1), (2) the proportion of participants recruited who are randomized (RQ2), and (3) the completeness of data collection (percentage of planned measures completed) (RQ2) at:

- Baseline: demographic data, depression symptoms—PHQ-9 [23], negative emotional state of depression—depression subscale of Depression Anxiety and Stress Scale (DASS-21) [24], GAD-7 [25], health-related quality of life (EQ-5D-5L) [26], measures of potential mediators, for example, knowledge, intention, beliefs of 3 activities (routine and necessary, social, and pleasurable activities), and questions on how doing these activities will affect their NCDs, Premium Accredited Activation Scale (PAAS) [27], and adverse events.
- 3 months: depression symptoms—PHQ-9 [23], negative emotional state of depression—depression subscale of DASS-21, GAD-7 [25], health-related quality of life (Euroqol-EQ-5D-5L) [26], measures of potential mediators, for example, knowledge, intention, and beliefs of 3 activities (routine and necessary, social, and pleasurable activities),

XSL•FO
RenderX

and questions on how doing these activities affected their NCDs, PAAS [27], and adverse events.

Outcomes relating to the acceptability, feasibility, and implementation of the BIP are described below in the process evaluation.

Trial Sample Size

The sample size is set to enable reliable estimation of recruitment and retention rates and to adequately explore the feasibility of data collection and intervention delivery in this feasibility trial. A total of 56 participants will be recruited for this study. This should be adequate to estimate a participation rate of 20% and a follow-up rate of 80% to within a 95% CI (with SD of 5% and 10%, respectively).

Trial Recruitment and Consent Procedures

The BEACON study flowchart can be found in Multimedia Appendix 2.

Participating sites were asked to implement depression screening by NCD health care staff, such as NCD counselors and nurses, using the PHQ-2 [22], as part of routine clinical practice. The PHQ-2 is a simple screening tool with minimal training and time requirements. The training was provided by the study team, and staff were asked to use the PHQ-2 with every patient attending the NCD service.

Staff (NCD counselors and nurses) will be asked to give information about the study and screen the patients for PHQ-2 [22] after obtaining their written consent. The participants who scored ≥3 will be qualified for the next level of screening. Those who indicated they were interested in participating in the feasibility trial were approached by RAs for the next level of screening by administering the PHQ-9 [23].

Recruitment of the willing participants by RAs was done remotely by telephone, mobile phone, internet, or video calling, as was convenient for the participant. Accordingly, verbal informed consent will be obtained before administering the PHQ-9, along with consent for participation in the feasibility trial. Those screening positive for depression on PHQ-9 (score ≥10) were invited to participate in the feasibility trial and provided detailed information about the purpose of the study and trial procedures either face-to-face or remotely. Furthermore, a suicide risk assessment was conducted at this point, where the participant was asked whether they have had thoughts of harming themselves or wished they were dead in the past week. If they say no, then the recruitment process will continue. Final verbal consent for participating in the trial will be obtained. The BEACON patient information sheet and consent forms can be found in Multimedia Appendix 3.

But if the answer is yes to the question of whether they have had thoughts of harming themselves or wished they were dead in the past week, then further questions on plans, actions, and prevention are to be asked, and based on the responses, the participants will be categorized into level A (mild), level B (moderate), and level C (severe). Three-week follow-ups by the RAs will be done, and then the decision on whether to recruit the patient or not will be made by the research team. The details about the safety considerations followed in the trial can be found in Multimedia Appendix 4.

Participants were free to withdraw consent and leave the trial at any time without giving a reason. They were able to withdraw by letting any member of the research team know that they wished to do so. If a participant withdrew consent to participate, no further data were collected from them. However, data collected up to the point of withdrawal were retained and used in the analysis, except where withdrawal of consent for the use of this data is explicit, in which case all data will be destroyed.

Randomization

Once consent has been secured, eligible participants complete a baseline questionnaire and are then randomized (BIP or EUC) by the trial manager or research fellow who will be based at the central office. Participants will be allocated in a 1:1 ratio using simple randomization without stratification. Treatment allocation was concealed from the study team at the point of recruitment using an automated computer data entry system, administered remotely by York Trials Unit, and using a computer-generated randomization sequence generated by an independent statistician (using Stata; version 16 or later; StataCorp).

Quantitative Data collection

Baseline and 3-month follow-up data were collected by RAs. The SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) schedule of enrollment, interventions, and assessments can be found in Multimedia Appendix 5. Quantitative data were collected with predesigned and tested data collection forms, using tablets to improve efficiency and minimize the risk of errors in data entry. Data will be anonymized, replacing identifiable personal data with unique study participant identification numbers, with the key only available to the local research team, principal investigator, and manager. Data will be secured and transferred safely, in line with the University of York data management policies and procedures. The completed SPIRIT checklist can be found in Multimedia Appendix 6.

Quantitative Data Analysis

Analyses will be conducted using Stata software. The number of participants who were screened, randomized, treated, and followed up for the primary outcome (PHQ-9) [23] will be reported in a CONSORT (Consolidated Standards of Reporting Trials)-style flowchart [28]. The number of study completers, by trial arm, will be calculated as a proportion of the number randomized at baseline.

The proportion of baseline and outcome measures completed out of those planned and presented by the treatment allocation arm will also be calculated. The normality of the data will be assessed, and based on that, an independent *t* test or Mann-Whitney *U* test will be used to compare the intervention and the EUC arm.

Process Evaluation

The 3 key functions of a process evaluation (mechanisms of impact, context, and implementation) will underpin our approach for the feasibility trial [29]. The qualitative inquiry will be used

XSL•FO
RenderX

in combination with quantitative data to gain a more complete picture.

Survey (Implementation and Mechanisms of Impact)

To capture the views and experiences of participants, all participants will complete a brief quantitative survey at a 3-month follow-up. Participants in the intervention arm will be asked about their engagement with and acceptability of BIP, views on remote delivery, as well as the perceived impact on their depression symptoms. Control arm participants will answer these questions in relation to the EUC leaflet. Participants in both trial arms will also complete some questions to assess the acceptability of trial processes.

Potential mediators of intervention impact will be measured at baseline and 3 months: intentions, beliefs about capabilities, and beliefs about outcomes. These have been selected to reflect the hypothesized mechanisms of action of BA [30].

Qualitative Data Collection: Interviews (Implementation, Mechanisms of Impact, and Context)

A subsample of 16 participants will be interviewed. We will purposively sample to ensure a mix of participants (intervention and control arms, men and women, aged 60 years or younger and aged 60 years or older, and completed or dropped out of BIP). The interviews will seek in-depth feedback on the topics explored in the brief survey as well as explore individual and context barriers and drivers to performing the 3 types of activities (routine and necessary, social, and pleasurable).

Once delivery of the BIP is completed, a group interview will be conducted with the 4 BA counselors to explore their experiences, including the acceptability of the interventions and the barriers and drivers to delivery, including contextual factors such as remote delivery.

All interviews will be conducted in the local language, face-to-face using topic guides, and digitally audio-recorded. A hermeneutics approach, which encourages participants to discuss features of the intervention to elicit data on their experience and evaluation of its delivery or receipt, will be used with trial participants, family members, and health care staff [31].

Trial participants will provide written informed consent for these interviews within their trial consent.

Fidelity Index (Implementation)

Fidelity in delivering BIP will be assessed using a fidelity index. This index consists of 2 subindices, namely, the adherence index, which assesses adherence to delivering the content of the 6 BIP sessions, and the interaction index, which assesses the level of counselor-participant with which the intervention was delivered. Both indices are scored on a 3-point Likert scale (0=not implemented, 1=partially implemented, and 2=fully implemented).

All BIP sessions will be audio-recorded. We will then perform the fidelity checks by reviewing the audio recording of a subsample (n=18) of sessions. These sessions will be purposefully selected to include a mix of sessions 1-6, delivered by all BA counselors early and late in the feasibility trial.

Fidelity Data Analysis

The quantitative data from the fidelity index and questionnaire will be analyzed using descriptive statistics, including means and SD for continuous variables and absolute and relative frequencies for categorical variables.

Qualitative Data Analysis

Interviews will be transcribed verbatim, translated into English, and analyzed using the Framework Approach [32], which is particularly useful for understanding and improving programs and policies and when multiple researchers are working with the data [33]. Excel (Microsoft Corp) software will aid in data handling.

Integration of interview findings with respective questionnaire data will be done using a “triangulation protocol” [34]. Methodological triangulation, where more than one research method or data collection technique is used [35], will be used in this study.

Economic Evaluation

The feasibility of undertaking a full cost-effectiveness analysis will be assessed. This will primarily investigate the acceptability and resource use associated with capturing data for a cost-effectiveness evaluation in the full trial.

The team will capture costs associated with depression in NCD, such as delivery or receipt of the BIP. Costs will include the time to deliver the BIP and the cost of the materials used. And the costs of training the BA counselors to deliver the BIP will be calculated. Training requires the “staff time” of the trainer plus staff travel costs. Staff time is based on the salary of the trainer and allocated on a cost-per-minute basis, plus costs of materials.

Diaries to capture resource use, to be completed by patients and BA counselors, will be developed by the research team. Participants will be asked to complete these on a monthly basis for 3 months.

A pro forma to capture the costs of delivering the BIP incurred by the host organization will be completed by service managers, including staff salaries, time, and costs of estates and materials. An average cost per case per trial arm for treatment and the control group will be calculated.

Health service use will be assessed by asking pretested questions on contacts with doctors and nurses, hospital admissions, pharmacy visits, drug use, etc.

Quality of life will be assessed using a quality of life questionnaire (EQ-5D-5L) at baseline and 3 months. This information can be used as a quantitative measure of health outcomes as judged by the individual respondents. A higher score represents a better-perceived health state. The data will be checked for completeness.

Data Management

The following data will be collected from feasibility trial participants (at baseline and 3-month follow-up): demographic data and validated instrument measurements of mental and physical health. The process evaluation of the feasibility trial

XSL•FO
RenderX

will collect data from interviews with trial participants and BA counselors, a sample of audio-recorded BIP sessions, and drop-out data. Health economic data will be collected to provide evidence of the costs of providing the BIP in the host institution.

All study data will be stored in accordance with the General Data Protection Regulation and the University of York data management policies. Electronic data will be password-protected and stored on secure servers at the country's partner institutions and the University of York.

Unique study identification (ID) numbers, allocated by the research team, will be used to anonymize data on electronic documents containing data from the trial and interviews. Paper-based documents, for example, consent forms and hard copies of transcripts, as well as any research participant personal data collected, will be stored in locked filing cabinets at the partner institutions.

Study documents (paper and electronic) at the research sites will be retained in a secure (locked when not in use) location during and after the study finishes. Interview recordings will be transferred from the digital recorder to a secure server as soon as possible after the interview has taken place. Once the transferred recording has been checked to ensure audibility, the original will be deleted from the digital recorder. All essential documents, including source documents (eg, transcripts), will be retained for a minimum period of 10 years after study completion, in accordance with the University of York Research Data Management Policy. This is deemed to be sufficient time for any queries arising from the findings to be answered, for example, queries arising from the publication of the findings. They will be retained in secure locations (locked when not in use) at the University of York and at the partner institutions.

The Department of Health Sciences at the University of York has a backup procedure approved by auditors for disaster recovery. There will be a separate archive of electronic data performed at the end of the study to safeguard the data and comply with regulatory requirements. The access, use, and storage of sensitive or confidential data will be conducted in accordance with the University of York Data Security Policy and Handling Sensitive Data Guidance. All sensitive or confidential data used for BEACON will be encrypted.

Data Monitoring

Data will be monitored for quality and completeness by the delegated researchers at the study site, followed by a second check by researchers at the University of York using verification, validation and checking processes. Missing data will be pursued until the study's end unless it causes any distress to the participant contacted. Data will be reported to the Health Ministry Screening Committee and Ethics Committee as required.

Adverse Events

Working with a potentially vulnerable group of participants has many ethical implications. We have addressed them in our ethics application. The main adverse events anticipated in this study, both during the recruitment phase and during the delivery of the BIP, are self-harm and suicide risk. Therefore, standard operating procedures to address these adverse events will be adapted by the study team.

Informed Consent

As the recruitment is done at 2 levels, written consent will be obtained at first-level screening using PHQ-2 [22] by the staff (NCD counselors and nurses) and verbal consent for the next level screening using PHQ-9 [23] by the RAs.

Privacy and Confidentiality

Data will be anonymized, replacing identifiable personal data with unique study participant identification numbers, with the key only available to the local research team and the principal investigator.

Community Engagement

A community advisory panel will provide community engagement and involvement for the duration of the study. This panel consists of patient and family representatives and community and voluntary sector advocates interested in improving the care of common mental disorders and NCDs. The panel has already given feedback on:

- The accessibility and feasibility for patients of the proposed BIP intervention, including remote delivery.
- Delivery of BA counseling by the NCD counselors.
- The acceptability of proposed methods for the feasibility trial.

The feedback and suggestions were incorporated into the intervention development and delivery plans of the study. The panel will continue to provide feedback, providing an important perspective on the delivery of the study and its findings.

Dissemination

Feasibility study results will be disseminated by engaging end users of our research, including policy makers and commissioners, by holding knowledge transfer and dissemination events at key stages. Lay summaries and fact sheets of findings are distributed using social media, newspapers, and a project website, alongside publications in academic journals, to reach a range of audiences.

Ethical Considerations

Ethics and other relevant approvals on the protocol have been secured from the University of York Health Sciences Research Governance Committee (HSRGC/2020/418/B; November 27, 2020); the Health Ministry Screening Committee, India (2020-9330; June 12, 2020); and the ethics committee, NIMHANS's Behavioral Sciences Division (NIMHANS/EC [BEH. SC.DIV.] 22nd MEETING/2OI9; February 3, 2020). The trial is also registered under the Clinical Trial Registry of India (CTRI/2020/05/025048; May 6, 2020).

Approvals for necessary amendments adjusting to the COVID-19 pandemic situation have been provided by the institutional ethics committee, Behavioral Sciences Division, NIMHANS.

The following amendments are made to the protocol:

XSL•FO
RenderX

- In the first amendment to the protocol dated September 25, 2020, the focus group discussions and interviews as part of the survey of organizational capacity were shifted from face-to-face to telephonic mode.
- In the second amendment to the protocol dated May 15, 2021, the recruitment process was shifted from face-to-face to telephonic mode, and NCD counselors were involved in preliminary screening. A total of 4 BA counselors of the same cadre as the NCD counselors were recruited into the study to deliver the BA sessions.
- In the third amendment to the protocol dated January 27, 2022, process evaluation interviews are to be conducted at 8 weeks instead of 12 weeks, that is, immediately after the participants in the intervention group complete their 6 BA sessions and in the control group at 8 weeks after the participants receive their brief advice from the RAs postbaseline assessment.

Participants in the intervention group will receive INR 250 (US $3.01) per session, and participants in the EUC group will receive INR 250 (US $3.01) for attending the one-time brief advice.

Results

The BIP was developed beginning on November 28, 2020, and it was finished on August 18, 2021. The quantitative data-gathering process began on August 23, 2021, and was finished on December 10, 2021, following the acquisition of approval from all pertinent agencies. Process evaluation (qualitative data) collection is ongoing. Both the qualitative and quantitative data analyses are ongoing.

Discussion

Overview

This research study overall aims to address the evidence gap regarding the use of BA for depression in people with NCDs by adapting BA interventions to the Indian context, testing the acceptability, feasibility, and implementation of adapted BA intervention, and testing the feasibility of a randomized controlled trial evaluation of BIP for the treatment of depression compared with EUC.

Effective treatment of depression in NCDs offers the potential to improve mental and physical outcomes for this population and, additionally, maximize the efficient use of health care resources. To bridge the treatment gap globally, psychological therapies must be scaled up, which necessitates their effective use in many cultural contexts. An increasing number of studies have examined the degree to which cultural adaptation enhances the acceptability and effectiveness of psychological therapies among populations from various cultural backgrounds. The data are still unclear at this stage because there are not enough studies that analyze the many types of changes involved in cultural adaptation [36]. If shown to be effective, the approach of integrating treatment for a mental disorder within NCD care will also provide the opportunity to harness physical health resources to reduce the large mental health treatment gap, reduce stigma for people with mental illness, and add to the data on cultural adaptation of interventions such as BA.

Several of the issues with conventional psychological therapy may be resolved through remote therapy. Because of their accessibility and simplicity, telephone-based therapies are a popular research topic in the field of therapeutic communication and may provide important advantages. Data suggests that a therapeutic connection and successful treatment outcomes may not require the colocation of a patient and therapist. Nonetheless, the evidence is scant in both amount and quality [37]. Therefore, this study might provide evidence of how well BA can be delivered remotely and whether this approach can be further scaled up.

If the feasibility trial demonstrates that the BIP is feasible and potentially beneficial, we will be able to make further adaptations to the BIP and test the intervention in a full trial.

Limitations

Given the COVID-19 situation, BA counselors of the same cadre as the NCD counselors were recruited into the study to deliver the BA sessions, which can be a drawback as there is no sense of familiarity, which might affect intervention delivery.

Future Directions

This work will support a future definitive trial evaluation of BA for depression in NCD in India.

Conclusions

This study has the potential to provide evidence that would be useful to bridge the treatment gap for mental disorders, especially in resource-, infrastructure-, and system-constraint countries such as India. BEACON attempts to deliver BA for depression in NCDs through trained NCD (BA) counselors integrated within the NCD clinics to reduce this gap. The findings from this study will help understand the impact of the BA intervention for depression in NCD in countries such as India. Also, the BIP may serve as a culturally validated intervention package for the Indian population for future use.

Acknowledgments

The authors would like to thank the members of the community advisory panel and the expert panel for their input and suggestions for the research. We would also like to thank the study participants for their participation in the study.

This research was funded by the National Institute for Health and Care Research (NIHR) (17/63/130) using UK aid from the UK Government to support global health research. The views expressed in this publication are those of the authors and not necessarily those of the NIHR or the UK Department of Health and Social Care. The funders had no role in study design, data collection and analysis, the decision to publish, or the preparation of the manuscript.

Data Availability

All data generated or analyzed during this study are included in this study and its Multimedia Appendices.

Authors' Contributions

NS is responsible for the conceptualization of the study. DE, AK, PM, CEH, GN, GNR, PM, and KC planned the phase I research, whereas the methodology for phase II research was planned by NS, AK, PM, CEH, CJ, and HJ. AK is the principal investigator. The investigation was done by AK, RZ, NAB, and CVD. Manuscript writing was undertaken by RZ, AK, HJ, and CJ. All authors reviewed and approved the manuscript.

Abstract

Background: Depression is a serious, prevalent, recurrent, and undertreated disorder in adolescents. Low levels of treatment seeking and treatment adherence in this age group, combined with a growing national crisis in access to mental health care, have increased efforts to identify effective treatment alternatives for this demographic. Digital health interventions for mental illness can provide cost-effective, engaging, and accessible means of delivering psychotherapy to adolescents.

Objective: This protocol describes a virtual randomized controlled trial designed to evaluate the efficacy and safety of a self-guided, mobile app–based implementation of behavioral activation therapy, SparkRx, for the adjunct treatment of symptoms of depression in adolescents.

Methods: Participants are recruited directly through web-based and print advertisements. Following eligibility screening and consenting, participants are randomly assigned to a treatment arm (SparkRx) or a control arm (assessment-enhanced usual care) for 5 weeks. The primary efficacy outcome, total score on the 8-item Patient Health Questionnaire (PHQ-8), is assessed at the end of the 5-week intervention period. Additional participant-reported outcomes are assessed at baseline, the postintervention time point, and 1-month follow-up. The safety of the intervention is assessed by participant report (and legal guardian report, if the participant is younger than 18 years) and by patterns of symptom deterioration on the PHQ-8, as part of a larger clinical safety monitoring protocol. The primary efficacy outcome, total PHQ-8 score at the postintervention time point, will be compared between SparkRx and enhanced usual care arms using mixed effect modeling, with baseline PHQ-8 and current antidepressant medication status included as covariates. Secondary efficacy outcomes, including the proportion of participants exhibiting treatment response, remission, and minimal clinically significant improvement (all derived from total PHQ-8 scores), will be compared between groups using chi-square tests. Symptom severity at 1-month follow-up will also be compared between arms. Planned subgroup analyses will examine the robustness of treatment effects to differences in baseline symptom severity (PHQ-8 score <15 or ≥ 15) and age (younger than 18 years and older than 18 years). The primary safety outcome, the number of psychiatric serious adverse events, will be compared between trial arms using the Fisher exact test. All other adverse events will be presented descriptively.

Results: As of May 2023, enrollment into the study has concluded; 223 participants were randomized. The analysis of the efficacy and safety data is expected to be completed by Fall 2023.

Conclusions: We hypothesize that the results of this trial will support the efficacy and safety of SparkRx in attenuating symptoms of depression in adolescents. Positive results would more broadly support the prospect of using accessible, scientifically validated, digital therapeutics in the adjunct treatment of mental health disorders in this age range.

Introduction

Depression is among the most prevalent mental health disorders in adolescents and young adults [1,2], with global rates rising sharply in the past decade [3]. Symptoms of the disorder can contribute in significant ways to the disruption of social and familial relationships, decreased quality of life and physical health, poor academic and occupational outcomes, and increased risk of substance abuse and self-harm [4-11]. Alarmingly, suicide is now among the leading causes of death in this age group [12-14], highlighting a critical need for the development and deployment of effective and accessible treatments to affected individuals.

Despite the high rate of depression among adolescents, levels of treatment seeking and adherence are low for both psychotherapy and pharmaceutical treatment [15-17], likely due in part to concerns over privacy or stigma [18,19] and side effects [20,21], respectively. Simultaneously, access to effective mental health care is often limited [22-24], with a documented shortage of mental health providers [25-27], long waitlists [28-33], and prohibitive treatment costs [34,35]. For young patients, logistical barriers may also exist for seeking or accessing traditional forms of care, such as limited caregiver time, and conflicting responsibilities, such as school and other activities. An evidence-based self-guided psychotherapy program delivered via personal mobile device may be a promising and scalable option as an adjunct to the standard of care; such a program, if effective, would be expected to overcome many of the existing limitations in access to mental health care, adherence, and safety. As with other digital health interventions, such a program could be less stigmatizing, leading to higher rates of engagement and self-disclosure [36-39].

Cognitive behavioral therapy (CBT), a recommended form of treatment for adolescent depression by the American Academy of Pediatrics, has been shown to be effective when implemented in a digital format [40-42]. Behavioral activation, a key component of CBT, may be particularly well suited for deployment as a digital therapeutic, as it is fundamentally individualized, self-driven, and self-monitored. Specifically, behavioral activation emphasizes engagement in adaptive and personally meaningful activities to increase feelings of reward, mastery, or goal advancement; additional components focus on techniques for reducing harmful or avoidance behaviors commonly associated with depression [43-46]. Importantly, evidence supports behavioral activation therapy on its own as efficacious in the treatment of depression [47]. SparkRx (Limbix Health, Inc), an investigational mobile app–based digital therapeutic, was developed to deliver behavioral activation programming and psychoeducation to adolescents with symptoms of depression as an adjunct to usual care.

This randomized controlled trial (RCT) is designed to test the efficacy and safety of SparkRx. To test the efficacy of the intervention, we will compare self-reported symptom severity (total score 8-item Patient Health Questionnaire [PHQ-8] [48]) between adolescents who receive SparkRx and adolescents who continue their usual care for symptoms of depression. We hypothesize that the SparkRx group will exhibit (1) lower PHQ-8 scores at the postintervention time point, (2) higher rates of treatment response defined as a 10-point decrease in PHQ-8 score from baseline, (3) higher rates of remission defined as a postintervention PHQ-8 score less than 5, (4) lower PHQ-8 scores at 1-month follow-up, and (5) higher rates of clinically meaningful reduction in symptom severity, defined as a 5-point or greater reduction in PHQ-8 score from baseline to postintervention. We also hypothesize that SparkRx users will, on average, demonstrate a minimal clinically important difference at the postintervention time point, defined as a 5-point reduction from baseline. To test the safety of SparkRx, the number of serious adverse events (SAEs) reported during the intervention period will be compared between treatment groups. We hypothesize that participants who receive SparkRx will report no more of these events than those who continue their usual care for symptoms of depression.

Methods

Study Overview

This parallel-group, superiority, and single-blind (investigator) RCT compares the efficacy and safety of an investigational digital therapeutic (SparkRx) with assessment-enhanced usual care (eUC) for symptoms of depression in adolescents (13-21 years). Participants are randomly assigned to receive 5 weeks of access to either SparkRx or a control app with no therapeutic content in addition to continuing their usual care for symptoms of depression. Participant-reported efficacy outcomes are obtained at baseline, weekly during the intervention period, at the postintervention time point, and at 1-month follow-up. Safety is monitored throughout study participation using a combination of explicit assessment of symptom deterioration and side effects and triage of other incoming information for potential clinical concerns. The RCT is conducted entirely virtually. Study procedures were preregistered on ClinicalTrials.gov (NCT05462652). The study is overseen by an independent Data and Safety Monitoring Board.

Ethics Approval

Study procedures were approved by the Advarra institutional review board prior to participant enrollment (Pro00061682).

Sample Size

G*Power [49] was used to calculate the estimated sample size based on the primary outcome—total PHQ-8 score at postintervention. Using a 2-sample *t* test approach and assuming

XSL•FO
RenderX

a 2-tailed α set at .05, a total of 200 participants (100 in each study arm) was estimated to provide 80% power to detect a moderate effect size of at least *d*=0.4. Given an anticipated 10% rate of attrition, the target sample size was determined to be 220 (110 randomized to each trial arm).

Participants

The inclusion criteria are assessed via self-report and legal guardian report (if applicable, ie, participant is under the age of 18 years) and include (1) aged 13-21 years; (2) PHQ-8 score ≥5 at eligibility screening; (3) English fluency and literacy; (4) access to a compatible smartphone (or other device) and operating system (ie, capable of installing the app from the Google Play or Apple App Store) and regular internet access (most app content is usable offline, but internet access is required to submit weekly check-in PHQ-8 and safety data); (5) willing and able to provide informed consent or assent and, if required, have a legal guardian willing and able to provide informed consent; (6) under the care of a US-based licensed health care provider and willing and able to provide contact information for the provider and sign a Health Insurance Portability and Accountability Act (HIPAA) release that allows Limbix to contact provider; (7) willing and able to provide the information required for study enrollment (eg, all responses to initial PHQ-8 assessment and current antidepressant medication status); and (8) located in the continental United States, Hawaii, or Alaska and not planning to leave the United States during the study period (through 1-month follow-up assessments, up to 11 weeks after eligibility screening).

The exclusion criteria are assessed via self-report and legal guardian report (if applicable) and include (1) a diagnosis of (or treatment for) bipolar disorder, posttraumatic stress disorder, psychotic disorder, substance use disorder, or eating disorder within the 12 months prior to eligibility screening; (2) recent change in psychotropic medication (past 30 days) or plans to change psychotropic medication or other treatment for a mental health disorder during the 5-week intervention period; (3) recent participation (past 60 days) in or plans to initiate participation in any other mental health intervention research during the intervention period; (4) suicide attempt within the past year; (5) active suicidal ideation with intent; (6) having a sibling in the study; (7) previous participation in user testing or clinical testing of SparkRx; and (8) any other condition, comorbidity, or event that may prevent the potential participant from adhering to the protocol or benefitting from the intervention (eg, coercion or low level of cognitive functioning) or will prevent investigators from being able to ensure safety.

Recruitment, Consent, and Screening

Recruitment is conducted through direct advertisement, including web-based and print media advertisements, flyers, word of mouth, and health care provider referrals. Potential participants (and legal guardians, if applicable) are directed to a study website where they can evaluate their preliminary eligibility to participate and sign up for a videoconferencing-based consent and onboarding session if they are preliminarily eligible to participate. During the session, potential participants and legal guardians (if required) provide informed consent or assent. The consent form provides information about the potential uses and disclosures of participant data, as well as the security practices for maintaining data. Specifically, the consent form provides a description of the parties who may gain access to participant data (eg, Data and Safety Monitoring Board, US Food and Drug Administration, and third-party vendors required for the operation of the study app and web platform). Third-party vendors are required by contract to maintain the confidentiality of participant data and to follow applicable data protection laws. Participants are informed that study staff will protect information from disclosure to others to the extent required by law but are obliged to share information under certain circumstances, such as in cases of suspected abuse, or indications of imminent harm to self or others. The consent form also discusses the risk of a loss of confidentiality and describes a few of the security features in place to reduce the likelihood of such a breach, including firewalls and end-to-end data encryption. Following consenting procedures, participants complete a screening/baseline PHQ-8 assessment and are screened for all remaining eligibility criteria. For potential participants younger than 18 years, self-report confirmation of eligibility is conducted privately with the minors and again with their legal guardians to increase the likelihood that sensitive information relevant to determining ineligibility (eg, active suicidal ideation with intent) is disclosed. Research coordinators confirm the licensure of participants' health care providers in the National Provider Identifier registry and inform providers of their patients' participation in the study via phone message. Eligible participants are enrolled into the study, complete baseline assessments, and receive instructions for downloading their assigned study app onto their mobile device. Participants are also provided with a safety plan template [50] and instructions for use as a personal resource.

Randomization With Stratification

A permuted block randomization schedule is used to randomly assign participants in a 1:1 ratio to either the treatment arm or the control arm. Stratification factors for randomization include baseline total PHQ-8 score (<15 or ≥15) and current antidepressant medication use (yes or no).

Intervention Arms

Overview

Participants are randomized to receive either the treatment app (SparkRx) or a control app (eUC). Both apps deliver weekly questionnaires for participants to complete. User guides for each app include instructions on app usage, study team contact information, crisis resources, and troubleshooting help.

Treatment Arm: SparkRx (Investigational)

SparkRx is a 5-week, self-guided multilevel program based on clinically validated behavioral activation protocols [44,45] to treat adolescent symptoms of depression (see Multimedia Appendix 1). In the first level, participants learn about the deleterious cycle of negative mood triggers and behavioral avoidance patterns in depression and practice identifying their negative mood-behavior patterns by tracking their mood in the app. In the second level, participants learn to distinguish between "Up" and "Down" activities and value-based activity scheduling

XSL•FO
RenderX

is introduced. In the third level, participants practice scheduling activities to perform outside of the app. Push notifications remind and encourage participants to log their moods, complete their scheduled activities, and review each activity and their mood after scheduled activity times have elapsed. Participants engage in guided problem-solving to overcome challenges in the completion of their scheduled activities. In levels 4 and 5, participants learn mindfulness techniques to combat avoidance patterns and develop an action plan to maintain gains after SparkRx program completion. Levels and tasks within each level progress in a linear fashion (ie, each task or level must be completed to progress to the next task or level). Participants are encouraged to complete 1 level per week, though they are at liberty to complete the levels at their own pace without penalty. Certain on-demand resources can be accessed in the app at any time, including crisis resources.

Control Arm: eUC

Usual care is broadly defined as any of the existing treatment options for symptoms of depression, including active monitoring of depressive symptoms and suicidality, supportive counseling by a health care provider, psychosocial support interventions, collaborative care (eg, facilitation of parental and patient self-management, referral for peer support or other community, or school-based behavioral health programs), psychoeducation, complementary and alternative medicine approaches, psychotherapy (eg, behavioral treatment, interpersonal therapy, or CBT), pharmacotherapy for mood problems, visit to a primary care provider, behavioral or mental health specialist or therapist, counselor or coach for a mood disorder. It also includes the option of obtaining no treatment for symptoms of depression. For purposes of this study, usual care is considered enhanced (eUC) by prompting participants to complete a weekly PHQ-8 assessment and side effect screen (Participant Symptom Check) in the control mobile app, providing a safety plan template, and clinician-based safety monitoring (with corresponding clinical reach out, as needed).

Blinding (Investigator)

Study staff and investigators are not directly involved in the collection of any efficacy outcome data. These data are collected directly from participants through the study app and a secure web portal. The proprietary electronic data collection system used in this trial (Limbix Synapse) enables selective blinding or unblinding of designated individuals; thus, study staff who enroll participants, monitor assessment completion and send reminders to complete assessments, and directly correspond with participants about technical difficulties are not exposed to any data fields that contain implicitly or explicitly unblinding information.

Randomization is performed automatically upon entry of relevant data fields into Synapse during enrollment, and the deployment of assigned interventions takes place without the need for study staff involvement and without exposure of treatment assignments to study staff. Specifically, all participants download a single study app onto their mobile devices. Content specific to a participant's assigned treatment arm is displayed only after they log in to the app for the first time and confirm that study staff are unable to see their mobile device screen. Participants are asked not to reveal their assigned treatment arm in communications with study staff.

Study coordinators and clinicians involved in safety monitoring are unblinded to treatment assignment by necessity, as monitoring includes a review of freeform text entered into only the SparkRx app, clinical reach out in response to identified safety concerns, and the identification and categorization of adverse device effects (see the *Safety Monitoring* section for details). Unblinded study staff are instructed not to discuss treatment allocation or any potentially unblinding information with blinded study team members.

Assessments

Overview

Assessments take place at baseline, weekly during the intervention period, at the postintervention time point, and at 1-month follow-up (see Table 1 for the schedule of assessments). Baseline assessments are completed during the consent and onboarding session prior to mobile app download. Participants complete weekly assessments during the intervention period in their assigned mobile app. In-app push notifications and text messages are sent to remind participants to complete these assessments within a 4-day response window. Participants in the treatment arm are unable to continue engaging with content in the app until they have completed (or actively skipped) the weekly assessment or until their response window for a given week has closed. Legal guardians (if applicable) complete weekly proxy assessments in a secure web portal and receive reminders to do so. At the postintervention time point (immediately following the intervention period) and again at 1-month follow-up, participants (and legal guardians, if applicable) complete assessments in a secure web portal. The window for completion of postintervention and 1-month follow-up assessments is 2 weeks. Participants who do not complete 1-month follow-up assessments within the 2-week window are considered lost to follow-up. No collateral reports are obtained for participants older than 18 years.

[a]A legal guardian proxy is additionally administered when participants are younger than 18 years.

[b]A single Patient Health Questionnaire–8 is administered to participants at the consent and onboarding session for purposes of both eligibility screening and baseline assessment.

Primary Outcome

The primary outcome is depressive symptom severity as measured by the PHQ-8, an 8-item participant-reported measure used to screen for depression and to establish depression severity [48]. The PHQ-8 was selected as the primary end point to align closely with a tool used for initial screening (and severity assessment) of depressive symptoms in clinical practice. Whereas the 9-item Patient Health Questionnaire is often used in clinical settings, the PHQ-8 (which drops an item related to suicidality) is commonly used in research contexts that are not geared toward clinically responding to reports of suicidality [48].

The total score ranges from 0 to 24, with a higher score indicating greater depression symptom severity. Scores of 5, 10, 15, and 20 represent thresholds for mild, moderate, moderately severe, and severe symptom severity, respectively; here, we define the minimal clinically important difference to be a 5-point reduction in total score from baseline [51,52].

Secondary Outcomes

The total PHQ-8 score will also be used to compute the trial's secondary outcomes, which include the (1) proportion of participants meeting criteria for intervention response, defined as a 50% reduction in symptoms from baseline to postintervention [47,53-56]; (2) proportion of participants meeting criteria for remission, defined as a score less than 5 at the postintervention time point [53,57]; (3) depressive symptom severity at 1-month follow-up; and (4) proportion of participants meeting criteria for a clinically meaningful reduction in symptom severity, defined as a 5-point or greater reduction in PHQ-8 score from baseline to the postintervention time point.

Tertiary and Exploratory Outcomes

As described below, a series of additional participant- and legal guardian–reported assessments are collected to investigate the potential effects of the SparkRx digital therapeutic on other clinical and functional domains, as well as its perceived usability and degree of engagement.

Anxiety symptoms are assessed with the Generalized Anxiety Disorder–7 (GAD-7) scale. The GAD-7 is a validated 7-item participant-reported assessment for generalized anxiety disorder [58]. The total score ranges from 0 to 21, with a higher score indicating greater anxiety symptom severity.

Quality of life will be assessed with the Pediatric Quality of Life Enjoyment and Satisfaction Questionnaire (PQ-LES-Q), a 15-item participant-reported self-administered questionnaire that captures life satisfaction over the past week [59]. Each question is rated on a 5-point scale from 1 (very poor) to 5 (very good). The first 14 items are summed to form a total score, with higher scores indicating higher quality of life. The 15th item ("Overall, how has your life been?") is a stand-alone item. For participants younger than 18 years, a legal guardian proxy version of the PQ-LES-Q is administered to legal guardians.

Depression-associated behavior is assessed with the Behavioral Activation for Depression Scale-Short Form (BADS-SF). The BADS-SF [60] consists of 9 participant-reported questions assessing behavioral activation and avoidance over the previous week, each rated on a 7-point scale ranging from 0 (not at all) to 6 (completely). This form can be used to track changes in behaviors that are targeted by behavioral activation therapy. It examines changes in areas such as activation, avoidance or rumination, work or school impairment, and social impairment.

XSL•FO
RenderX

The total score ranges from 0 to 54, with higher scores indicating higher activation.

The usability of the mobile app is assessed with the participant-reported System Usability Scale (SUS) [61]. The SUS consists of a 10-item questionnaire with 5 response options for respondents, ranging from strongly agree to strongly disagree. User engagement is assessed with the User Engagement Scale–Short Form [62], a participant-reported, statistically reliable measure that is tailored to the specific device being tested (ie, the study app). The form has 12 items and uses a 5-point Likert scale to evaluate domains such as aesthetic appeal, focused attention, perceived usability, and reward. Each subscale score ranges from 1 to 5, with higher scores indicating higher levels of each scale. The total score also ranges from 1 to 5, with higher scores indicating more engagement.

Absenteeism is assessed with study-specific adaptations of the absenteeism and presenteeism questions of the World Health Organization's Health and Work Performance Questionnaire [63] that solicit information from participants (and legal guardians, if applicable) about missed time at work or school attributable to the participant's mental health condition over the past 4 weeks.

Finally, the use of health care resources is evaluated with a brief questionnaire assessing the use of health care resources such as hospital visits and medical appointments over the past 4 weeks.

Treatment Compliance Outcomes

Treatment compliance for those assigned to use SparkRx is assessed descriptively by examining the rates of module and program completion, as well as the amount of time spent in the app over the course of 5 weeks and the number of participants who engaged with the app on each day of the intervention period.

Safety Monitoring and Safety Outcomes

Safety Monitoring

Safety is monitored during consent and onboarding sessions and throughout study participation. In this trial, clinical concerns are defined as any negative experiences or symptoms reported by a participant or a legal guardian, whether or not they are thought to be associated with participation in the study. Examples of clinical concerns include past or current suicidal ideation, self-harm, worsening of depression symptoms, new symptoms, changes in medication or treatment status, or hospitalizations. Sources for potential clinical concerns include (1) freeform text input into the SparkRx app or study questionnaires; (2) communication from participants or legal guardians to study staff during the consent and onboarding session or study participation; (3) patterns of responses to PHQ-8 assessments, as defined below; and (4) responses to the Participant Symptom Check that is deployed to participants (and legal guardians, if appropriate) weekly during the intervention period, at the postintervention time point, and at 1-month follow-up. Responses to PHQ-8 assessments are considered to be clinical concerns if they suggest (1) temporary clinical deterioration, defined as a PHQ-8 score >15 that reflects a 5-point or more increase from baseline, or (2) sustained elevated symptom severity, defined as a total PHQ-8 score greater than 20 for 2 or more consecutive weeks. In addition, a built-in algorithm in the SparkRx app compares all freeform text input into the app to a defined list of risk words and phrases. When a match occurs, the participant receives a pop-up alert directing them to the crisis resources page; study staff are automatically notified about potential clinical concerns involving the use of risk words or phrases. All identified clinical concerns are logged by a study staff member and reviewed by a study clinician daily. If clinical involvement for a logged clinical concern is indicated for the purpose of clinical safety management or to investigate the presence of a possible adverse event (AE), the study clinician contacts the participant and legal guardian (if applicable) to further evaluate clinical status and make determinations regarding continued participation in the study.

AE Classification

AEs, per the US Food and Drug Administration's guidance [64], are identified from logged clinical concerns during regular reviews by the study clinician. Each AE is then preliminarily categorized by expectedness, seriousness, and the likelihood of relatedness to the SparkRx app ("not possible," "possible," "probable," or "definite"), as well as whether it constitutes a psychiatric or nonpsychiatric occurrence.

Given the trial population, the following AEs are classified as "expected": (1) passive or active suicidal ideation, with or without intent to act; (2) clinically significant deterioration in depressive symptoms, including temporary clinical deterioration as defined in the *Safety Monitoring* section; (3) nonsuicidal self-injury ideation; and (4) nonsuicidal self-injury not resulting in the need for medical care or intervention. All other types of AEs are classified as "unexpected."

Definitions of AE seriousness and adverse device effects follow the guidance provided by the International Organization for Standardization 14155:2020. "Psychiatric" AEs constitute experiences that are related to the presence of a mental disorder, symptom of a disorder, or issue, as defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) [65].

Following preliminary categorization by a study clinician, a second independent clinician, not otherwise associated with the study, completes the final categorization of all AEs.

Statistical Analysis

Overview

Efficacy and safety analyses will be conducted by an independent statistician external to the sponsor organization who is otherwise not involved in the design or conduct of the trial. A statistical analysis plan, finalized prior to the conclusion of data collection, will be followed that includes detailed provisions for the handling of missing data. The plan will be made public as part of results reporting on ClinicalTrials.gov (NCT05462652).

XSL•FO
RenderX

Populations

The primary population for all analyses is defined according to the intention-to-treat (ITT) principle, whereby all participants will be included according to their assigned study arm at baseline, regardless of adherence to study protocol.

Secondary analyses of the primary and secondary outcomes will be conducted with the following additional populations: (1) a modified ITT population will exclude from analysis participants who were found to not meet eligibility criteria after randomization and individuals without any postrandomization data. This population is included to ensure that effects are observed with the appropriate intended sample. In addition, this population allows for the handling of missing data without the need to impute values based solely on baseline data. (2) A per-protocol population will include individuals who complete, at minimum, the postintervention PHQ-8 assessment and, for participants in the SparkRx arm, meet a minimum engagement threshold of completing 2 app modules. This population is intended to estimate treatment effects in participants who adhere to the study and treatment protocol. (3) A moderate-severe population will include participants from the ITT population whose baseline PHQ-8 score was 10 or greater. This population is intended to ensure that efficacy outcomes are not masked by floor effects.

Analysis of Primary and Secondary Outcomes

A mixed effect model with an appropriate correlation matrix will be implemented to evaluate the effect of treatment on PHQ-8 scores at the postintervention time point. Time point, treatment arm, time point by treatment interaction, baseline PHQ-8 score, and antidepressant medication status will be included in the model as fixed effects. For analysis of the ITT population, missing PHQ-8 total scores will be imputed with multiple imputation within treatment arm under the assumption that data are missing at random; 20 imputed data sets will be analyzed independently and then combined [66]. As a sensitivity analysis, this model will be repeated without imputation using the modified ITT population, which includes only participants with at least 1 postbaseline data point.

For descriptive purposes, the mean change from baseline (and 95% CIs) in the SparkRx arm will be estimated to determine whether the change in this group meets or exceeds criteria for minimal clinically important difference (a 5-point improvement) and whether a 5-point change was contained or surpassed by 95% CI.

To analyze the secondary outcomes, we will compute the number and proportion of participants meeting the criteria for intervention response, remission, and clinically meaningful reduction in severity at postintervention and compare the rates between treatment arms using chi-square tests. If counts are low, Fisher exact tests will be used. As above, the 20 imputed data sets will be analyzed independently and combined. All tests will be 2-tailed.

Control of Type I Error in Primary and Secondary Outcome Analyses

The primary outcome analysis, conducted with the ITT population, will be tested with a 2-tailed α set at .05. To control for multiple comparisons, a serial gatekeeping approach will be applied, whereby the secondary outcomes will be tested only upon obtaining a significant primary outcome test and in the order in which they are listed in the Secondary Outcome section (see above). All subsequent outcomes will be considered to be nonsignificant following the first *P* value greater than α=.05.

Additional Planned Analyses of the Primary and Secondary Outcomes

Analyses will be repeated within the 4 subgroups: aged <18 years at enrollment, aged ≥18 years at enrollment, baseline PHQ-8 score <15, and baseline PHQ-8 score ≥15. *P* values will be reported; however, because the protocol was not powered for comparisons within such subgroups, they should be considered purely descriptive.

Analyses of Tertiary and Exploratory Outcomes

Appropriate models (eg, analyses of covariance) will be used to compare continuous clinical outcomes (eg, GAD-7, BADS-SF, PQ-LES-Q, and legal guardian PHQ-8 proxy) at the postintervention time point between treatment arms. Baseline scores will be included in models as appropriate. Changes in health care utilization and absenteeism from baseline to postintervention will be examined descriptively.

Moderation analyses will test whether demographic and other participant features (eg, baseline PHQ-8 score, antidepressant medication use, sex or gender, and age) influence the effects of treatment on PHQ-8 outcomes. Mediation analyses will be used to determine whether the degree to which participants engaged with SparkRx (eg, module completion rate) explains its effect on PHQ-8 scores. The usability and engagement of the SparkRx app (SUS and User Engagement Scale–Short Form) will be examined descriptively.

Analysis of Safety Outcomes

The rate of psychiatric SAEs (irrespective of device relatedness) derived from the Participant Symptom Check (side effect screen) and PHQ-8–based deteriorations will be compared between SparkRx and eUC groups using the Fisher exact test. For purposes of this comparison, psychiatric SAEs reported via app freeform text will be excluded, as freeform text is unique to the SparkRx arm.

Control of Bias

As Limbix Health Inc is the sponsor-investigator of this trial, there is a risk of bias due to study staff's conflicts of interest. This risk is mitigated in a number of ways. First, the efficacy end points are participant reported and digitally input by the participant directly into a password-protected, web-based assessment portal or into their study app. After the baseline session, data are not collected in the presence of study staff members. Thus, study staff members will not be directly involved in the capture of efficacy data. Except in cases of clinical reach out to ensure participant safety, all communication with study participants will be conducted by study staff blinded

XSL•FO
RenderX

to treatment assignments to prevent bias. Second, to reduce bias related to the collection of safety outcomes, an independent clinician with no other role in the study nor conflict of interest will review all AEs and provide final classifications of AE seriousness and device relatedness for use in data analysis. Third, an independent statistician will conduct statistical analyses for the study based on a Statistical Analysis Plan to be finalized prior to data transfer.

Results

As of May 2023, enrollment into the study has concluded; 223 were participants randomized. The analysis of the efficacy and safety data is expected to be completed by Fall 2023.

Discussion

Expected Findings

While SparkRx is based on well-validated therapeutic behavioral activation protocols for depression, this RCT represents one of the first assessments of their efficacy in treating symptoms of depression as deployed to adolescents via a self-guided mobile app. For our primary outcome, we hypothesize that participants assigned to the SparkRx arm will report lower total PHQ-8 scores at postintervention compared to those in the eUC arm. For our secondary outcomes, we hypothesize that there will be higher rates of intervention response, remission, and clinically meaningful reduction in severity in the SparkRx arm than in the eUC arm. In addition, we expect to observe a durable effect of SparkRx as indicated by significantly lower PHQ-8 scores at 1-month follow-up in participants who received the SparkRx app compared to those who did not. Similarly, we hypothesize that participants in the treatment arm will report experiencing fewer symptoms of anxiety, greater quality of life, and higher levels of behavioral activation (lower levels of behavioral avoidance) at the postintervention time point than participants in the control arm. Finally, we anticipate that there will be statistically no more psychiatric SAEs in the SparkRx arm than in the eUC arm, supporting the overall safety of the SparkRx intervention.

Potential Problems

Poor adherence and low levels of engagement are common challenges with self-guided digital therapies [67]. As such, user engagement was a primary goal in the development of the SparkRx intervention [68]; the app was co-designed with a teen advisory council and iterated through rounds of user research and diary studies among adolescents with and without depression symptoms. For this trial, a few additional strategies are being implemented to encourage adherence to the study protocol. In addition to SparkRx push notifications that encourage engagement with the app and scheduled activities, both automatic and manual text messages are sent to remind participants to complete assessments. Adherence is also incentivized by compensation that is tied to discrete study components (attending the onboarding session and completing each set of questionnaires).

Dissemination

The primary results of this trial will be submitted to a peer-reviewed journal, irrespective of magnitude or direction of effect, and findings will be presented at scientific conferences. A lay report of findings will also be prepared for dissemination to trial participants (upon request) and to broader audiences.

Conclusions

During this mental health crisis, adolescents are in urgent need of accessible and quality care. Digital therapeutics, such as SparkRx, can bring such care to those who might otherwise have to wait months to see a provider or who face barriers to receiving care, such as high costs or stigma against traditional mental health treatment. To our knowledge, this is the first digital therapeutic offering CBT-based content specifically designed for adolescents with symptoms of depression, and this RCT is the first fully powered test of the efficacy of SparkRx. Support for our hypotheses would increase not only the scientific evidence base for SparkRx specifically but also more broadly for the model of using self-guided, adjunct digital therapeutics in the treatment of mental health disorders in adolescents.

Acknowledgments

Limbix Health, Inc developed SparkRx and funded this work. Employees of Limbix Health, Inc developed the study protocol, conducted the clinical trial, and reviewed or approved this manuscript for publication.

Conflicts of Interest

All authors are employed by the sponsor, Limbix Health, Inc, and have a financial stake in the company.

Abstract

Background: The integration of artificial intelligence (AI) into health sciences students' education holds significant importance. The rapid advancement of AI has opened new horizons in scientific writing and has the potential to reshape human-technology interactions. AI in education may impact critical thinking, leading to unintended consequences that need to be addressed. Understanding the implications of AI adoption in education is essential for ensuring its responsible and effective use, empowering health sciences students to navigate AI-driven technologies' evolving field with essential knowledge and skills.

Objective: This study aims to provide details on the study protocol and the methods used to investigate the usability and efficacy of ChatGPT, a large language model. The primary focus is on assessing its role as a supplementary learning tool for improving learning processes and outcomes among undergraduate health sciences students, with a specific emphasis on chronic diseases.

Methods: This single-blinded, crossover, randomized, controlled trial is part of a broader mixed methods study, and the primary emphasis of this paper is on the quantitative component of the overall research. A total of 50 students will be recruited for this study. The alternative hypothesis posits that there will be a significant difference in learning outcomes and technology usability between students using ChatGPT (group A) and those using standard web-based tools (group B) to access resources and complete assignments. Participants will be allocated to sequence AB or BA in a 1:1 ratio using computer-generated randomization. Both arms include students' participation in a writing assignment intervention, with a washout period of 21 days between interventions. The primary outcome is the measure of the technology usability and effectiveness of ChatGPT, whereas the secondary outcome is the measure of students' perceptions and experiences with ChatGPT as a learning tool. Outcome data will be collected up to 24 hours after the interventions.

Results: This study aims to understand the potential benefits and challenges of incorporating AI as an educational tool, particularly in the context of student learning. The findings are expected to identify critical areas that need attention and help educators develop a deeper understanding of AI's impact on the educational field. By exploring the differences in the usability and efficacy between

XSL•FO
RenderX

ChatGPT and conventional web-based tools, this study seeks to inform educators and students on the responsible integration of AI into academic settings, with a specific focus on health sciences education.

Conclusions: By exploring the usability and efficacy of ChatGPT compared with conventional web-based tools, this study seeks to inform educators and students about the responsible integration of AI into academic settings.

artificial intelligence; AI; health sciences; usability; learning outcomes; perceptions; OpenAI; ChatGPT; education; randomized controlled trial; RCT; crossover RCT

Introduction

Background

The integration of artificial intelligence (AI) into the education field has led to many possibilities, benefiting both educators and students [1]. AI takes on various roles as an intelligent tutor, a collaborative learning partner, a valuable tool, and even an adviser in influencing educational policies [2,3]. The multidimensional role of AI in education, as demonstrated by the potential for dynamic and adaptive learning experiences, aligns with ChatGPT's capacity to operate as a valuable educational tool. ChatGPT is a generative AI that can generate complex answers to questions asked by the user. It has been described as a tool offering numerous benefits in the field of education [4]. It serves as a platform for enhancing students' writing skills through features such as text completion, translation, and summarization tools. Educators can integrate ChatGPT into their courses to customize the learning journey for their students by considering their preferred learning methods and existing proficiency levels [4].

An exploratory survey examining the use of ChatGPT in various domains, including education, health care, and research, revealed both positive and negative impacts [5]. On the positive side, ChatGPT was found to level the playing field for students facing language challenges, enhance comprehension by providing additional details, and offer valuable assistance in crafting writing assignments. However, the study also uncovered negative consequences, such as the potential for inaccuracies, concerns about replacing hard work with automated solutions, and the possible discouragement of critical thinking skills. In addition, questions remained regarding academic integrity and students' willingness to disclose their use of ChatGPT. These findings emphasize the need for careful consideration and guidance when integrating AI technologies such as ChatGPT into various fields [5].

It is crucial to acknowledge that integrating AI into education can result in unintended consequences [6]. The use of ChatGPT, while presenting remarkable potential, has sparked discussions regarding its potential negative implications. Concerns have been raised regarding its potential to promote academic dishonesty, stifle creativity, and diminish critical thinking abilities [7]. Numerous legitimate concerns encompass a spectrum of challenges. These include the potential for generating inaccurate content and ethical dilemmas such as the imminent risk of bias, instances of plagiarism, and complex copyright matters [8]. The findings of a systematic review exploring the application of ChatGPT in health care education, research, and practice revealed that ethical concerns were prevalent in 33 out of 60 records. These concerns, particularly the risk of bias and plagiarism, often revolved around data privacy and security issues [8]. This underscores the significance of investigating students' perceptions of ethics and accountability concerning the use of ChatGPT in health sciences.

Within the health sciences domain, the successful use of AI relies on several key factors. First, usability is paramount. For example, chatbots and AI programs designed to simulate conversations with human users must be user-friendly, ensuring that students, health care professionals, and patients can interact effortlessly. Second, efficiency is critical because these chatbots should streamline processes, reduce workload, and provide rapid and accurate responses [9]. Finally, the overall effectiveness of these chatbots plays a pivotal role, as they need to deliver tangible benefits such as improved patient care, enhanced diagnostic accuracy, and increased efficiency in health care operations. Consequently, the usability, efficiency, and overall effectiveness of chatbots in health sciences are vital aspects that warrant careful consideration and optimization for their successful integration into the field [8].

In this study, the term *usability* is defined as "a quality attribute that assesses how easy user interfaces are to use." The word *usability* also refers to "methods for improving ease-of-use during the design process" [10]. The 5 components of usability are learnability (how easy is it for users to accomplish basic tasks the first time they encounter the design?); efficiency (once users have learned the design, how quickly can they perform the tasks?); memorability (when users return to the design after a period of not using it, how easily can they reestablish proficiency?); errors (how many errors do users make, how severe are these, and how easily can they recover from them?); and satisfaction (how pleasant is it to use the design?) [10]. The evaluation of ChatGPT's usability will be conducted in health sciences students, as assessing the usability of this AI holds significance due to the potential impact on adopting this technology in the training of these students.

Over the past few years, extensive research has investigated the usability of ChatGPT across various domains. A study assessing ChatGPT's usability in formal English language learning revealed promising outcomes. The findings showed that

XSL•FO
RenderX

ChatGPT is an effective tool for formal English language education, excelling in various learning tasks encompassing conversation, writing, grammar, and vocabulary enhancement [11]. A systematic mapping study examining the usability of chatbots and human-computer interaction systems examined the field exhaustively, drawing on numerous references. Of the 170 studies that met the inclusion criteria, 21 were primary studies. The authors' conclusions highlighted the emerging nature of chatbot usability research, which mainly comprises surveys, informal experimental studies, and usability tests. They emphasized the need for more formal experiments to rigorously gauge the user experience, leveraging these findings to design guidelines that prioritize usability [12]. To our knowledge, no randomized controlled trial (RCT) has assessed the usability and students' perceptions of ChatGPT use within the health sciences.

Study Objectives

Primary Objectives

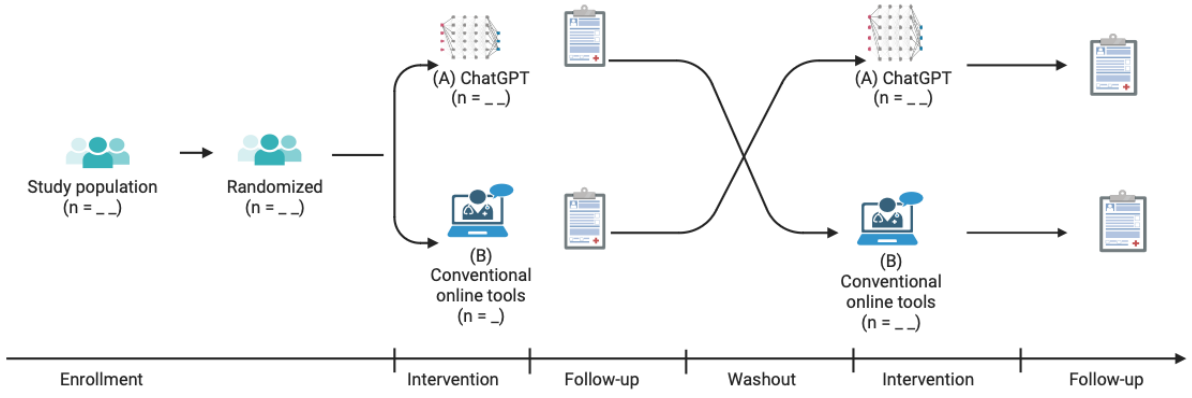
We aim to explore the usability and effectiveness of ChatGPT compared with conventional web-based tools as a supplementary assistance tool to enhance undergraduate health sciences students' learning experiences and outcomes.

Secondary Objectives

Our secondary objectives are to (1) explore students' perceptions and experiences with ChatGPT as a learning tool; (2) explore the potential benefits of or barriers to using ChatGPT to improve students' writing abilities in the health sciences; and (3) investigate students' perceptions of accountability, ethical considerations, and equity concerns related to the use of AI in education.

Study Hypotheses

The study's hypotheses are as follows:



- *Null hypothesis:* there is no significant difference in technology usability and learning outcomes between students who use ChatGPT (group A) and those who use conventional web-based tools (group B) for accessing resources and completing assignments.
- *Alternative hypothesis:* there is a significant difference in technology usability between students who use ChatGPT (group A) and those who use conventional web-based tools (group B) for accessing resources and completing assignments.
- *Exploratory hypothesis:* the learning outcomes of students who use ChatGPT (group A) will significantly differ from those of students who use conventional web-based tools (group B) for completing their assignments. This hypothesis proposes that the choice of intervention (ChatGPT or conventional web-based tools) may influence the learning outcomes and explore the interaction between usability and learning outcomes.

Methods

Study Design

We will use a randomized crossover design to ensure equity in the learning experience for all students. This involves assigning students to use ChatGPT (group A) or conventional web-based learning tools (group B) to access resources and assist them in completing their assignments (Figure 1). To address the potential biases associated with the reporting of results using RCT design, we will adhere to 2 specific guidelines: the CONSORT (Consolidated Standards of Reporting Trials) and its extensions. The CONSORT statement was introduced in 1996 to enhance the quality of clinical trial reporting [13]. However, critics observe that the reporting of crossover trials has been inconsistent and incomplete. To address this issue, the CONSORT 2010 statement was extended to provide recommendations for reporting randomized crossover trials, including a specific checklist [14]. This CONSORT extension for crossover trials includes 14 additional items aimed at improving the reporting of such trials. Furthermore, our report will also draw upon the CONSORT-AI, an extension of the CONSORT 2010 statement published in 2020, which focuses on the evaluation of RCTs involving AI [15].

Figure 1. Crossover randomized controlled trial study design on the usability and efficacy of ChatGPT for health sciences students.

Setting

This crossover RCT will be conducted on the web and will include health sciences students who are registered in a course on chronic diseases and disability, a third-year undergraduate course at Carleton University in Ottawa, Canada.

Eligible participants will receive comprehensive information about the trial, including the study's purpose and procedure,

XSL•FO
RenderX

through both verbal communication and written materials. To address ethical concerns regarding power dynamics between those responsible for the study and those who may be involved in student teaching and assessment (ie, professors) and students, we opted to involve an individual who is independent of the research team in the recruitment process (ie, a teaching assistant [TA] not involved in other aspects of the study). This decision aims to minimize any potential bias or influence that could arise from direct professor involvement in the recruitment and research. By introducing a TA to be involved in recruitment, we strive to create a more equitable research environment and mitigate any power imbalances that may exist between professors and students. This approach helps ensure that the study is conducted fairly and unbiasedly, fostering a research environment that prioritizes equal opportunities for all participants. Both groups will simultaneously work on an assignment.

Participants

Inclusion Criteria

The inclusion criteria consist of health sciences undergraduate students who are aged ≥18 years and of any gender identity at Carleton University, Canada. They must be registered in a course on chronic diseases and disability during fall of 2023.

Students who responded to the advertisements and consented to participate in the study will be included. Participant recruitment will involve the TA who is not associated with the research project and does not hold any power or authority over the students. The research assistant (RA) will be responsible for overseeing the consent process. They will ensure that informed consent is obtained from the students voluntarily and without undue influence.

Exclusion Criteria

Students who do not provide informed consent are not included in the study.

Recruitment

Recruitment will be conducted in September 2023, followed by interventions and assessments in October and November 2023. All students registered in the course will participate in the learning activities (ie, course assignments) included in this study, as these activities are mandatory for completing the course. They will be asked to give their informed consent for the data generated by their participation in the course assignments to be used for the purposes of the study and for web-based questionnaires to be sent to them to gather information about their learning experience while performing the assignments.

The students will be identified from the class list in Brightspace (Desire2Learn; the digital learning environment of the course), and all students who express their consent will be eligible for inclusion. Upon providing consent, the students will receive an invitation email containing instructions to access and complete the web-based questionnaires through the Qualtrics platform (Qualtrics International Inc). If there is no response within 2 weeks of the initial invitation, a follow-up reminder email will be sent to nonresponding students.

Sample Size

Recently, Luna et al [16] evaluated the performance of an AI compared with that of a group of physiotherapists in a squat exercise–related quiz and found that the AI demonstrated a sensitivity of 84% in providing correct responses. Assuming a minimum sensitivity of 50% as the null hypothesis, we estimated that 45 participants need to be evaluated to obtain a sample that represents the alternative hypothesis of this study with 90% power and 95% confidence (Fleiss method with continuity correction). Considering the possibility of sample loss from the first to the second intervention, we added an additional 10% added to this sample, totaling 50 students. The sample size was calculated using OpenEpi (version 3.01) [17].

Randomization and Allocation Concealment

The participants will be allocated randomly to one of the 2 sequences: ChatGPT (A), followed by conventional web-based tools (B), or conventional web-based tools (B), followed by ChatGPT (A). The allocation of participants into sequences (AB or BA) will be determined through computer-generated randomization in an allocation ratio of 1:1. The research team responsible for analyzing the data will be kept blind to the participants' group assignments. The research team will generate the allocation sequence, and the TA will enroll the participants and assign them to the intervention. The trial will adhere to established procedures to maintain separation between staff that take outcome measurements and staff that deliver the intervention [13,14].

Intervention and Measurement

During the initial phase of the study, participants assigned to sequence AB will use ChatGPT (experimental intervention: group A) to complete their assignments, while participants assigned to sequence BA will use conventional web-based tools (control intervention: group B) and serve as a control group. In the subsequent period, the interventions will switch between the 2 groups. Students will not know which one is the "intervention of interest" and which one will be the "comparator." As mentioned above, the learning activity to be assessed in this project is part of the mandatory course activities. This means that all students will receive a grade for this assignment. Therefore, the instructor will not be able to determine which students have or have not participated in the study. Students' acceptance to participate in this study only gives permission to the research team to use their data for research purposes, but all students will be assessed for this work as part of the course. The course instructor will not be responsible for grading the assignments associated with the intervention. The TA will be responsible for grading assignments and assigning a unique number code to each participating student, which will be linked to their names. This coded information will be sent to the RA to preserve anonymity throughout the process. The RA will receive the graded assignments, the student names, and their respective codes from the TA. The RA will collect the grades of the student participants and submit them to the research team members responsible for the analysis. It is important to note that the research team, which includes the course instructor, will not have access to the participants' names. Only the grades and the

XSL•FO
RenderX

participant codes will be accessible for analysis. The research team, including the course instructor, will perform the data analysis based solely on the provided grades and participant codes, without access to any identifiable information. This further ensures that anonymity is strictly maintained throughout the analysis phase.

Experimental Intervention

In this study, the intervention of interest is the use of ChatGPT by students to complete their assignments. As part of this intervention, students will be given a period of 6 days to use it for assignment completion. Along with the assignment instructions, participants will receive an ethical guideline and specific guidelines on how to use ChatGPT effectively (Multimedia Appendices 1 and 2) [18-23].

Control Intervention

In this study, the control intervention is the use of conventional web-based tools by students to complete the assignment. In this intervention, they will receive instructions on how to complete the assignment using conventional web-based tools available on the internet, without the use of ChatGPT or other generative AI platforms “and” or “or” tools. They will have a timeframe of 6 days to complete the assignment using these conventional web-based tools. Similar to the participants in the experimental intervention, they will also be required to fill out a survey on technology usability, providing feedback on their experience with the web-based tools.

Washout Period

The purpose of the 21-day washout period is to mitigate or minimize any potential carryover effects from the intervention. The term *carryover effect* refers to the persistence of the previous intervention’s effect or the impact of the initial intervention that extends beyond its duration and influences the subsequent intervention’s effect. By incorporating a washout period, we aim to ensure a clearer distinction between the effects of each intervention and minimize any potential interference or bias [24].

The available evidence on determining the appropriate washout period to eliminate the carryover effect effectively is limited. The conventional approach for determining the washout period is often based on the concept of 5 half-lives of the specific drug involved [25]. To address the carryover effect in this study, we used 2 strategies. First, we implemented a washout period of 21 days between interventions. This time gap was intended to allow for a sufficient delay to minimize the memory of the previous intervention and any lingering effects from the previous intervention. In addition, for the second intervention, the investigators carefully selected a different topic from the assignment to ensure that students would not easily recall specific details from the previous intervention. Furthermore, the research team ensured that the assignment content for the second intervention had similar complexities and requirements to maintain consistency across the study.

Outcomes and Measurements

The outcome measures will be (1) the usability of the technological tools (ChatGPT or conventional) for completing the assignments (primary outcome), (2) the participants’ perception of these tools as support for learning, and (3) the learning outcomes (secondary outcomes). Outcomes and measurements will be collected at 2 points: at the first follow-up, that is, after the first intervention (experimental or control) in the initial phase, and at the second follow-up, that is, after the second intervention (experimental or control) in the final phase (Figure 1).

Usability

Participants in the experimental intervention (AI-ChatGPT intervention) will also be asked to fill out a survey regarding their perception of using generative AI as an assistance tool to complete their assignments. This survey aims to gather insights into their thoughts, opinions, and attitudes toward using AI in their learning experiences. Participants will have the opportunity to share their feedback on the effectiveness, benefits, challenges, and overall satisfaction while using AI for assignment completion. Their responses will provide valuable information on AI technology’s perceived value and acceptance in enhancing their learning experience. Participants in the control intervention (conventional tools) will complete the same survey, but regarding the usability of the conventional tools.

The System Usability Scale (SUS) will assess the participants’ perceptions of usability. The SUS is a valid questionnaire [26] and will be administered at the end of the interventions and when participants cross over to the other assistance tool (AI-ChatGPT or conventional web-based tools without AI). The SUS is commonly used in numerous studies to assess the effectiveness and usability of new technologies, including in the education field [27-29]. A recent systematic review of home-based telerehabilitation software systems for remote supervision revealed that the SUS tool was the most frequently used measure or tool across the studies examined [28]. This scale has been translated into several languages, including the American Sign Language [30-32]. The SUS questionnaire was originally developed as a “quick and dirty” tool, with the goal of providing a fast and nonintrusive assessment experience for participants [26]. The SUS consists of 10 items formulated as affirmative statements, for which users indicate their level of agreement or disagreement on a 5-point Likert scale (1=strongly disagree; 5=strongly agree). For the odd answers (1, 3, and 5), we will subtract 1 from the score that the user answered; for the even answers (2 and 4), the score will be subtracted from 5. The values of the 10 questions will be added and multiplied by 2.5. The final score can range from 0 to 100. Internal consistency will be calculated using Cronbach α per item and overall. This scale allows for the assessment of outcomes and comparisons within and between the 2 interventions (Table 1).

XSL•FO
RenderX

Table 1. Overview of outcome measures.

Outcome measure	Variable or scale	Measure	Analysis method
Primary			
Usability (SUS[a])	Continuous, nominal, ordinal, and 5-point Likert-type scale[b]	• 0-100 (SUS score: >68=above average and <68=below average) • The individual scores of the participants for each question are transformed into a new number, which is then aggregated and multiplied by 2.5 to convert the initial range of scores from 0-40 to a new range of 0-100.	The frequencies, means, and SD of each item of the SUS scale will be calculated and compared using the McNemar or chi-square and Wilcoxon tests, respectively. In addition, each group's usability scores and grades will be correlated using Spearman correlation.
Secondary			
Perception of AI[c]	Continuous, nominal, ordinal, and 5-point Likert-type scale	• The questionnaire consists of four sections: (1) sociodemographic information; (2) AI literacy exploration of positive learning experiences with AI; (3) examination of negative experiences associated with AI use; and (4) an assessment of the potential for discussing accountability, fostering student leadership, and addressing ethical and equity concerns pertaining to the use of AI.	Fisher exact or Pearson chi-square test will investigate the associations between the categorized scales and sociodemographic characteristics.
Learning outcomes	Continuous	• Students' grades on both interventions. Score range (0-100)	Mean, SD

[a]SUS: System Usability Scale.

[b]5=Strongly agree, 4=agree, 3=neither agree nor disagree, 2=disagree, and 1=strongly disagree.

[c]AI: artificial intelligence.

Perception of Ethics and Accountability

After the intervention with ChatGPT, the students will be asked to fill out a web-based survey about their perception of their AI experience. The survey will use multiple-choice questions, short open questions and a 5-point Likert scale, using closed-ended response options. This response format ensures enhanced objectivity and enables appropriate discrimination to address the research objectives effectively. A closed-ended Likert scale also promotes the participants' comprehension and active engagement with the study. The questionnaire consists of four sections: (1) a sociodemographic information; (2) AI literacy exploration of positive learning experiences with AI; (3) an examination of negative experiences associated with AI use; and (4) an assessment of the potential for discussing accountability, fostering student leadership, and addressing ethical and equity concerns pertaining to the use of AI. One question of this survey was taken from a Swedish questionnaire about the use and views among university students about chatbots and other AI for learning. Qualtrics software will be used for survey design and data collection, as this software passed a security assessment of Carleton University, and its server is located in Montreal, Quebec, Canada.

The SUS survey is expected to take approximately 2 minutes to complete, whereas the perception survey is anticipated to be completed in approximately 10 minutes. By collecting data at multiple points in the study (2 points), we can evaluate the effects of each intervention and any potential carryover effects during the crossover period. In addition, it provides an opportunity to measure changes in outcomes within individual participants as they switch from one intervention to another.

Data Analysis

This study aims to compare the 2 interventions in terms of usability, student perception, and learning outcomes. The crossover design allows for within-group and between-group comparisons, enabling a comprehensive analysis of students' perceptions of the use of the intervention and its impact on their learning, as well as the effects of the intervention on their learning outcomes.

The use of an identification code will anonymize data. The data set will be exported from the datasheet and imported into the SPSS software (version 28.0; IBM Corp) for Mac, where the data will be subjected to analysis with a confidence level of 95%. Descriptive statistics, including the calculation of frequencies, will be performed on the sociodemographic variables of the students. The usability scale and grades at each assessment time will be summarized using mean and SD. The nonparametric Wilcoxon test will be used to compare the differences between these variables.

The frequencies, means, and SDs of each item of the SUS scale will be calculated and compared using the McNemar or chi-square and Wilcoxon tests, respectively. In addition, the usability scores and the grades of each group will be correlated using Spearman correlation.

For the analysis of perception and usability outcomes, we will use the Spearman correlation coefficient to assess the relationship between the 2 scales. This statistical approach was chosen to measure the strength and direction of the associations between variables when the data may not conform to a linear pattern. Using the Spearman correlation coefficient, we aim to better understand how perceptions and usability factors are

XSL•FO
RenderX

interrelated, providing a robust basis for our research findings and conclusions. To assess the internal consistency of the scales, Cronbach α coefficient will be calculated for both constructs and for each individual item.

To categorize the students into groups of low and high performance (using a cut-off value of 80) and classify the SUS scale into high and low usability groups (with a cut-off value of 50), appropriate statistical tests will be applied. Specifically, Fisher exact test or Pearson chi-square test will investigate the associations between the categorized scales and sociodemographic characteristics.

Ethical Considerations

This study has obtained ethical approval from Carleton University Research Ethics Board-B, ethics clearance ID: 119784, ensuring strict adherence to participant confidentiality, anonymity, informed consent procedures, and data protection, in compliance with applicable institutional and ethical guidelines. No identifiable data will be included in any part of the research. Participants will be given the opportunity to enter a drawing for gift cards valued at US $25 each, specifically for completing the surveys.

Results

Data collection took place in October and November 2023; the anticipated results are scheduled for publication in 2024. We anticipate several key findings. First, randomization is expected to have groups with closely matched demographic characteristics, ensuring a balanced starting point for our analysis. Second, we anticipate that usability will be significantly higher for the ChatGPT intervention than for conventional methods, reflecting the potential benefits of AI-assisted learning. In addition, regarding ChatGPT's use in assignments, we expect to observe students expressing concerns about data privacy and plagiarism, consistent with prior literature findings on these issues. The potential correlation between usability and learning outcomes is a significant aspect to consider in our study. Understanding how usability impacts learning outcomes not only is critical for this study but also lays the foundation for future investigations. By quantifying the effect sizes of both the learning and usability effects in this study, we can better inform the calculation of sample sizes for larger RCTs on this topic. These data will be invaluable for designing robust experiments and ensuring that our research can provide meaningful insights into the relationship between usability and educational outcomes.

Furthermore, it is our anticipation that despite these concerns, learning outcomes will remain consistent across both interventions. We expect to observe that while these concerns may be raised, the overall effectiveness and educational benefits of ChatGPT are not compromised. Our study seeks to determine whether these anticipated results are confirmed. These data will contribute to a better understanding of the potential impacts of integrating AI into health sciences education.

This study is expected to contribute to the identification of key areas and challenges concerning the use of AI as an educational tool, specifically examining its benefits and challenges for students. By doing so, it aims to facilitate the establishment of comparable frameworks for future academic endeavors. In addition, the findings will enlighten educators about the potential advantages and barriers associated with integrating AI into educational activities for university students.

We expect this study's findings to be disseminated through multiple channels. The study will undergo a rigorous peer review process for publication in a reputable, peer-reviewed journal. Subsequently, the results will be initially shared with the community in the health sciences department, ensuring timely access for the scientific community. Furthermore, we intend to submit the results of this study to relevant national conferences to provide a platform for knowledge exchange and engagement with a broader audience.

Discussion

Overview

This study will compare the use of ChatGPT and web-based conventional tools in terms of usability, student perception, and learning outcomes. ChatGPT is expected to be perceived as more usable than conventional tools. However, we anticipate that both groups will achieve similar learning outcomes. Furthermore, our findings may align with those of previous studies that underscore the significance of AI in education, albeit with concerns related to data privacy, as students increasingly recognize the importance of AI in their learning experiences.

This study is expected to provide details on students' perceptions of using AI to perform their learning assignments. The results of this study will be compared with those of the literature. In recent years, there has been a growing body of research on AI, focusing on its applications in various fields, including medical education, health care, radiography, and ophthalmology [5,33,34]. Many of these studies use cross-sectional and qualitative research methods to explore the perspectives and attitudes of professionals and students [33,35,36]. Despite variations in the specific field of study, some common themes emerge from this research. These themes include a generally positive attitude toward AI's potential benefits, a widespread lack of formal AI education among participants, concerns about data privacy and ethical implications, and a clear and urgent need for structured AI education to be integrated into relevant curricula [33,35]. These studies collectively underscore the importance of preparing individuals in these fields for the increasing role of AI in their respective domains.

A study focused on assessing medical students' knowledge, attitudes, and perceptions of AI chatbots in health care revealed that while medical students generally held positive attitudes toward AI, they also had data protection and monitoring concerns. Students expressed a desire for more comprehensive AI education integrated into their medical curriculum, emphasizing the importance of preparing them for AI's role in health care [35]. A systematic review of the utility of ChatGPT, an AI-based conversational large language model, in health care education, research, and practice highlighted numerous benefits and emphasized the need for a code of ethics and responsible use guidelines for AI chatbots, such as ChatGPT in health care

XSL•FO
RenderX

and academia, to maximize their potential while addressing limitations and risks [8]. A Canadian study explored how undergraduate medical students in Canada perceive AI in medical education. The survey conducted with 486 students from all 17 Canadian medical schools revealed that while there was a consensus that AI will be important in future medicine and should be formally taught, many students believed that there are currently insufficient educational opportunities related to AI. Interviews with students echoed these concerns, emphasizing the need for AI integration into the medical curriculum to better prepare future physicians for the changing health care landscape [33].

These studies have provided valuable insights into students' and professionals' knowledge, attitudes, and perceptions regarding AI and AI chatbots in health care and related fields. They generally indicate positive attitudes toward AI's potential benefits, along with concerns about data privacy and the need for structured AI education. However, it is essential to acknowledge that these studies have limitations, including potential biases inherent to their study designs. Therefore, further research is needed to delve deeper into the utility and students' perceptions of AI chatbots, such as ChatGPT, in health care and academia. To address these gaps and gain a more comprehensive understanding, we plan to conduct a crossover RCT. This proposed study will enable us to systematically investigate the effectiveness and user perceptions of ChatGPT in specific health sciences and educational contexts while controlling for potential biases and limitations observed in previous studies.

Limitations and Strengths

Although this study possesses several strengths, it anticipates limitations. First, the sample size may restrict the generalizability of the findings to a broader population of health sciences students. However, this constraint is balanced by the advantages of a focused investigation within a specific academic institution, allowing for in-depth exploration. Second, the relatively short intervention period may limit the ability to capture long-term effects or changes in participants' perceptions over time. Nevertheless, this controlled timeframe allows for a rigorous assessment of immediate impacts. Moreover, although the study specifically examines the use of ChatGPT, acknowledging the limitation of generalizability to other AI tools, it contributes to the existing body of knowledge in this field. Finally, participants' self-reported data, including their perceptions and experiences, may introduce response bias. However, this method aligns with the quantitative nature of the research and provides rich insights into participants' perspectives. Despite these anticipated limitations, this study's strengths lie in its focused investigation, controlled timeframe, and quantitative approach, all of which contribute valuable insights into the usability, perceptions, and potential benefits of using AI in health sciences education.

It is important to note that the next phase of this study, which involves subsequent qualitative data collection and analysis, is strategically designed to address some of these limitations. By investigating participants' experiences and perceptions through focus groups, the next phase of the study aims to provide a more comprehensive understanding of the long-term effects, nuanced challenges, and potential benefits associated with AI use in health sciences education. This approach complements the quantitative phase of the study presented in this protocol and enhances the overall robustness of the study's findings, thereby mitigating some of the anticipated limitations.

Acknowledgments

This project was funded by the Scholarship of Teaching and Learning Grant from Carleton University.

Data Availability

The data sets used and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

MV, DK, and J-OD conceptualized this study. MV drafted the protocol, with critical inputs from J-OD, DK, MR, PGBS, and DR. All authors contributed to the study design and manuscript drafting. MV drafted the first and last versions of the manuscript. All authors have read and approved the final manuscript.

Abstract

Background: Uncontrolled hypertension is a leading risk factor for cardiovascular diseases. In Uganda, such diseases account for approximately 10% of all deaths, with 1 in 5 adults having hypertension (>90% of the hypertensive cases are uncontrolled). Although basic health care in the country is available free of cost at government facilities, regularly accessing medication to control hypertension is difficult because supply chain challenges impede availability. Clients therefore frequently suspend treatment or buy medication individually at private facilities or pharmacies (incurring significant costs). In recent years, mobile health (mHealth) interventions have shown increasing potential in addressing health system challenges in sub-Saharan Africa, but the acceptability, feasibility, and uptake conditions of mobile money approaches to chronic disease management remain understudied.

Objective: This study aims to design and pilot-test a mobile money–based intervention to increase the availability of antihypertensive medication and lower clients' out-of-pocket payments. We will build on existing local approaches and assess the acceptability, feasibility, and uptake of the designed intervention. Furthermore, rather than entering the study setting with a ready-made intervention, this research will place emphasis on gathering applied ethnographic insights early, which can then inform the parameters of the intervention prototype and concurrent trial.

Methods: We will conduct a mixed methods study following a human-centered design approach. We will begin by conducting extensive qualitative research with a range of stakeholders (clients; health care providers; religious, cultural, and community leaders; academics; and policy makers at district and national levels) on their perceptions of hypertension management,

XSL•FO
RenderX

money-saving systems, and mobile money in the context of health care. Our results will inform the design, iterative adaptation, and implementation of an mHealth-facilitated pooled financing intervention prototype. At study conclusion, the finalized prototype will be evaluated quantitatively via a randomized controlled trial.

Results: As of August 2023, qualitative data collection, which started in November 2022, is ongoing, with data analysis of the first qualitative interviews underway to inform platform and implementation design. Recruitment for the quantitative part of this study began in August 2023.

Conclusions: Our results aim to inform the ongoing discourse on novel and sustainable pathways to facilitate access to medication for the management of hypertension in resource-constrained settings.

Introduction

Background

Globally, noncommunicable diseases (NCDs) are becoming the leading cause of death [1]. Further exacerbated by aging populations, NCD-associated mortality is expected to exceed infectious and respiratory causes of death by 2030 [2]. Cardiovascular diseases (CVDs) make up 13% of the mortality rate in sub-Saharan Africa (SSA) and account for the largest proportion (37%) of deaths caused by NCDs [3], adding to a double burden of communicable diseases and NCDs. Although the age-adjusted CVD mortality rates are lower in SSA than in high-income countries, the absolute number of CVD-related deaths in SSA has increased significantly in the past three decades, largely due to rapid urbanization, population growth, aging, dietary and lifestyle changes [4,5].

The successful management of CVDs requires controlling common risk factors (such as hypertension and diabetes) and ensuring that access to required medications is stable. The latter point is particularly challenging in settings marked by scarcity. In Uganda, an estimated 26.4% of adults have high blood pressure, and another estimated 36.9% of the country's population are estimated to be prehypertensive (with a blood pressure reading of >120/80 mm Hg) [6]. Among those who are prehypertensive, approximately one third could become hypertensive within 4 years [7]. Although basic health care is meant to be available free of cost at government facilities across the country, the availability of essential medicines for conditions requiring long-term management, including hypertension, is generally low [8-10]. Clients who do not receive treatment at government facilities must buy prescribed medicines at private health facilities or pharmacies, where prices tend to be 3 to 4 times higher than at public facilities [11]. Out-of-pocket payments represent 39% of the total health care expenditures in Uganda [12], often exceeding the resources of many households and causing noncompliance with prescribed regimens [13-15]. The resulting regular disruptions in long-term medication schedules can result in uncontrolled blood pressure associated with a high CVD risk.

However, uncertainty remains in terms of potential interventions to sustainably address gaps in NCD care in SSA in general and Uganda in particular. Several novel approaches have been recently trialed, including community health worker (CHW) mobilization in South Africa [16] and medication adherence clubs in Kenya [17]. Other novel approaches have explored mobile health (mHealth) to target medication adherence (eg, SMS text message reminders for tuberculosis medication [18] or an electronic app for self-monitoring in Uganda [19]). Dialogue within our team (comprising anthropologists, epidemiologists, clinicians, nurses, community outreach workers, community leaders, and policy makers) therefore guided us toward mHealth solutions with a particular focus on mobile money, given that medication adherence is greatly affected by financial resources [20].

Mobile money, which refers to payments made via a digital wallet on a mobile device, has been evaluated in several studies for health interventions in SSA to address health system challenges in agile ways, including mobile money transfers to pay transportation costs for patients with cancer in Malawi [21] or to facilitate health insurance uptake in Kenya [22]. In Uganda, mobile money programs across the country have provided a savings mechanism to many people who were previously unable to access formal bank accounts; in 2021, approximately 71% of individuals were registered for a mobile money account [23] (compared with 29% of individuals having access to a formal bank account [24]). However, although a range of sectors have used mobile money approaches to facilitate payment for, among others, school fees, bills, water or food [25,26], application in the context of health interventions in Uganda has so far been limited.

To the best of our knowledge, no interventions have yet explored the potential of mobile money approaches in alleviating financial difficulties for hypertension treatment. Although the interest in mHealth interventions in general is rising, and the potential of mobile money for economic equality in particular is high [27], their application might be associated with implementation challenges, with scholars highlighting the complexity of mHealth interventions, particularly in relation to accessibility [28]. However, person-based development strategies have shown

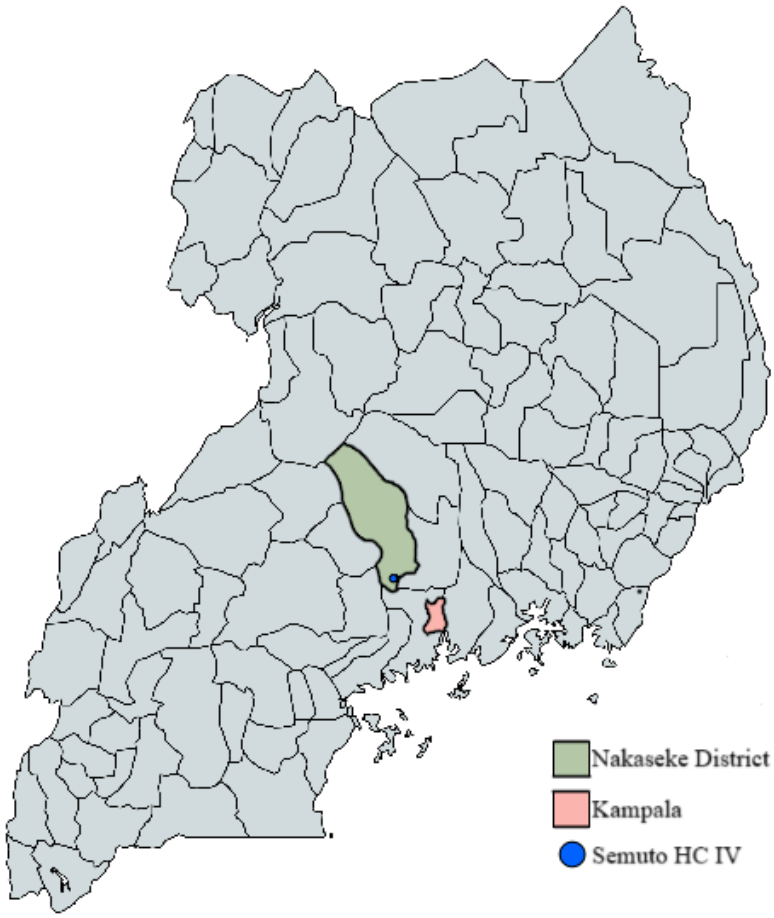
XSL•FO
RenderX

promising results in terms of increasing the interventions' acceptability and feasibility [29,30], but these strategies remain underused when exploring the potential of mobile money approaches to chronic disease care. This study seeks to fill this gap in the literature by applying human-centered design (HCD) to co-design and test an mHealth blood pressure management intervention in rural Uganda, assessing the design process as well as intervention uptake and viability.

Study Objectives

This study aims to codevelop (with end users and implementers) an integrated mobile money–based solution for antihypertensive medication delivery and to assess the platform's feasibility, acceptability, and effectiveness.

The specific study objectives are as follows:



1. Understanding client, provider, and intervention implementer perspectives on financing schemes and mHealth interventions that are meant to increase medication availability and uptake among clients with NCDs (work package [WP] 1a).
2. Developing together with end users a prototype for a mobile phone–based solution to increase the availability and uptake of antihypertensive medication and assessing the development and design process (WP 1b and WP 2).
3. Testing the prototype and evaluating end users' and health providers' experiences with 2 versions of the prototype, including how users make and evaluate payment management decisions (WP 3) and whether 1 version is more effective than the other.

Methods

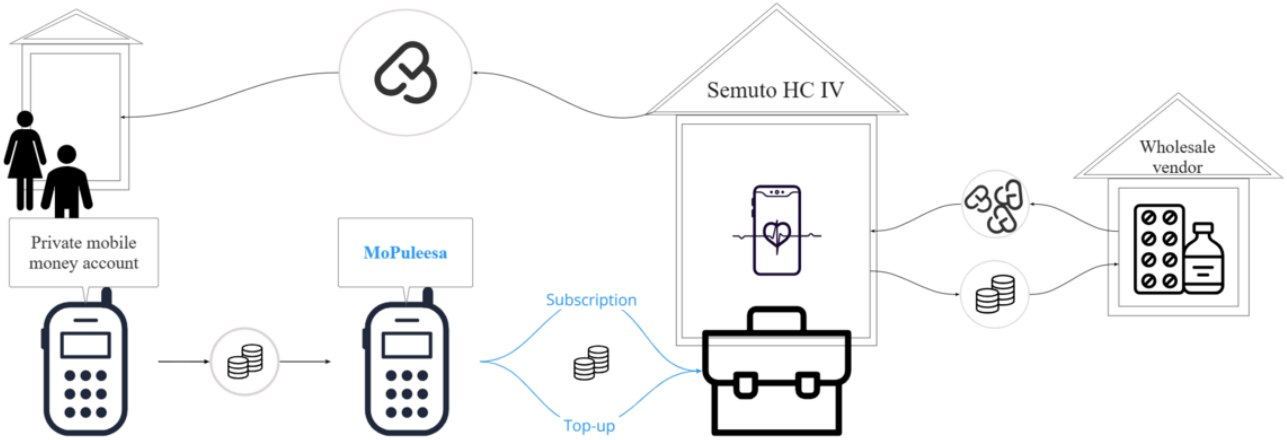
Study Setting

This design research study will take place in rural Nakaseke district, Uganda, with a population of 29,400 [31] (Figure 1). Nakaseke administratively belongs to the central region of Uganda, where an estimated 28.5% of the population are hypertensive [6]. Our study will focus on clients within Semuto Health Center IV, chosen during an early formative phase of research because the center has initiated an alternative, promising approach to manage blood pressure, which is described in the following subsection.

Figure 1. Map of Uganda highlighting the location of our study setting: Nakaseke district and Semuto Health Center (HC) IV.

Semuto Health Center IV's Alternative Approach: A Community-Led Pooling Strategy

Recognizing the challenges of medication supply, the clients and staff of a designated NCD treatment unit at Semuto Health Center IV collectively initiated a client self-help financing scheme wherein clients living with hypertension were invited to pay 2000 Ugandan shillings (US $0.54) per clinic visit, and clients living with diabetes were invited to pay 7000 Ugandan shillings (US $1.87) per clinic visit. These funds were then pooled to purchase medication. This initiative sought to increase medication availability by buying in bulk via a wholesale



XSL•FO
RenderX

vendor, which is a more cost-effective approach than purchasing medication from a retail vendor. Payment was voluntary; those who contributed to the pool could draw on the additional allotment, whereas those who did not contribute could access government-supplied medication. Beyond purchasing blood pressure medication, excess funds were also used to purchase equipment such as batteries or glucose strips. The scheme, although promising, was not reliably generating sufficient funds to ensure a continued supply of medications and proved challenging in terms of paperwork, accounting, and management. A nurse was assigned the task of purchasing medication from a central pharmacy in the capital, Kampala, but real-time knowledge regarding the amount of funding available complicated her purchasing trips. Furthermore, the clinic staff struggled to track who had made or not made payments, which would affect who could draw from the specially purchased pool of medication.

Semuto Health Center IV Approach 2.0: The MoPuleesa Intervention

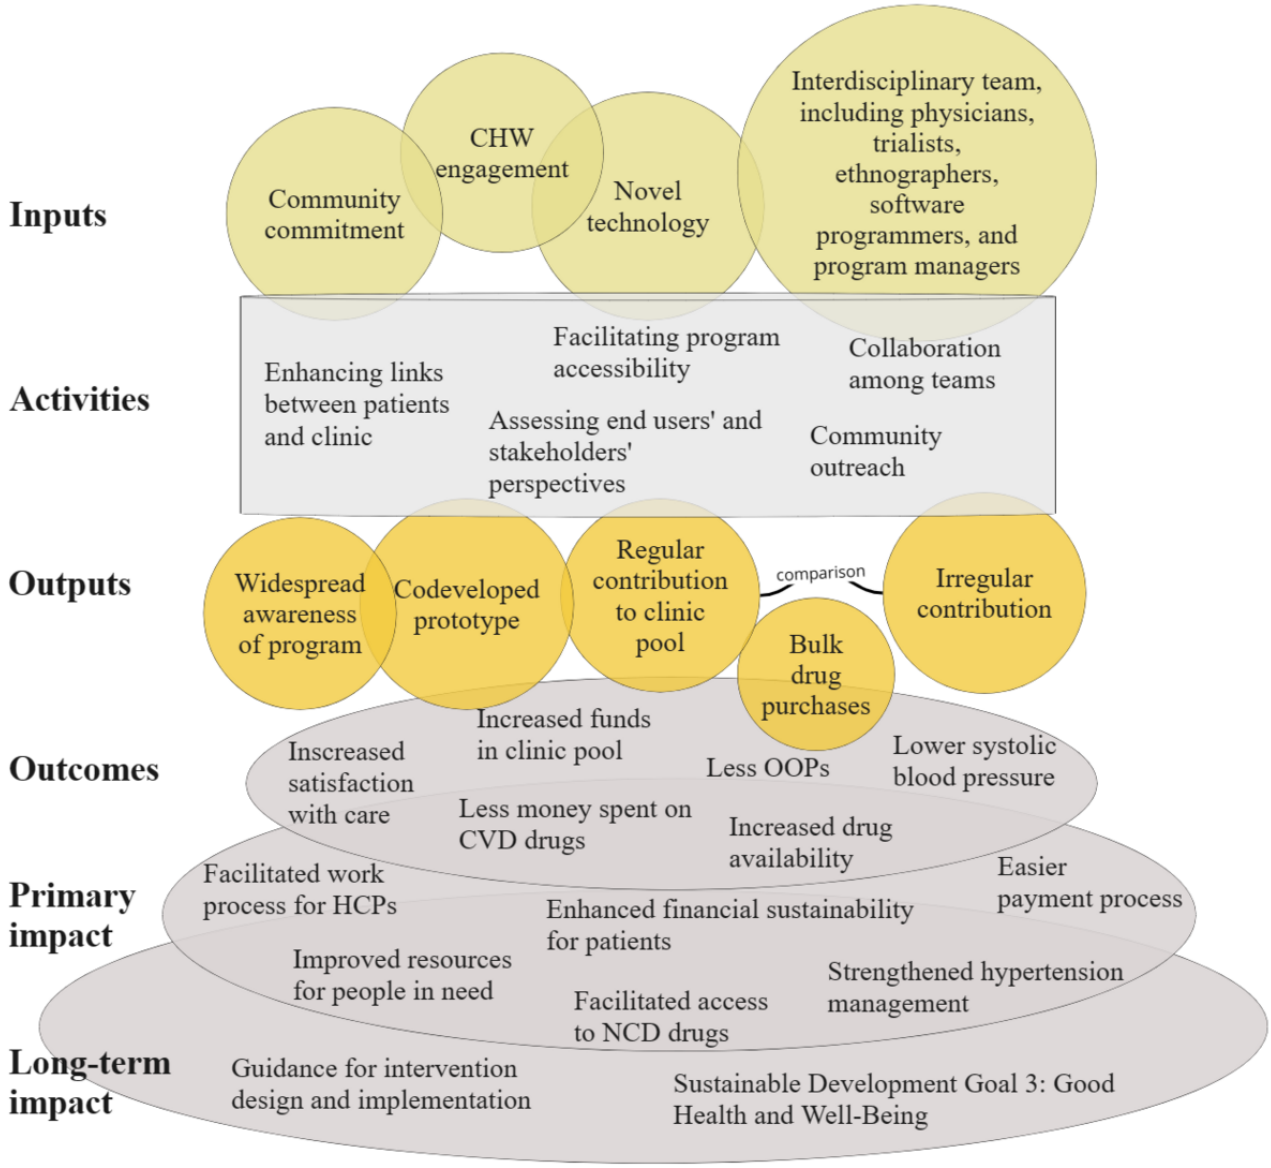
Building on the paper-based approach of Semuto Health Center IV, we will digitize and expand the existing system, drawing on insights from community members, software programmers, anthropologists, social scientists, health care providers (HCPs), mHealth implementers, policy makers, and local leaders with an aim to create a continual flow of money to secure medication availability. The proposed money flow is illustrated in Figure 2.

Figure 2. Flow of money from the client via their mobile health wallet to the Health Center (HC) and medication flow back to the client.

The central component of the co-designed intervention will be the mHealth wallet (illustrated as the *MoPuleesa feature phone* in Figure 2 [*puleesa* means "pressure" in the Luganda language]), which will allow clients to deposit the money they wish to save for their health care expenses via their private mobile money accounts. Others (eg, family members) who are themselves not users of the system can also remotely contribute to a client's mHealth wallet. Clients will be prompted to transfer money from their account to the clinic pool to facilitate bulk medication purchasing via 1 of 2 ways: either allowing for a specific amount of money to be automatically transferred from a marked savings account via direct deposit at predetermined and fixed intervals (the *subscription approach*) or independently transferring amounts of their own choosing at any time within a 1-month period (the *top-up approach*), shown by the corresponding arrows in Figure 2. Clients using the subscription approach who want to change the subscription amount or frequency can approach the designated clinic staff in person at the health center. For the top-up approach, clients can choose the timing themselves but can only contribute the exact amount needed to avail drug coverage each month; excess contributions will not be transferred to the following months. Core principles guiding our design and implementation efforts are the engagement of CHWs for community commitment, the use of mHealth technologies not requiring costly infrastructure at an individual level, and the integration of the designed intervention into existing clinic structures via a multidisciplinary team.

To facilitate end-user buy-in, we will work with CHWs, who are volunteers serving as intermediaries and communication links between clients and medical facilities within their own communities, which often imbues them with considerable trust, experience, and communicational skills [32,33]. In our study, we will include CHWs not only for outreach and recruitment purposes but also as key informants who can provide valuable insights on setting and intervention design, supporting a sustainable outreach that in turn might enhance the engagement of the community with the intervention and assist regular contributions.

For the integration of a novel technology, we acknowledge the need for easy accessibility by all members of the community; therefore, the platform does not rely on users having their own smartphone or an internet connection. Instead, following successful examples [34,35], all system functions will be accessible from feature phones via unstructured supplementary service data (USSD) menus, which operate via service and control commands in a mobile network. To access the USSD menu, users will be able to either register their own mobile phone number or receive a new SIM card in their name upon study enrollment (with which they can access their personal account via the mobile phones of CHWs, other clients, or any friend or family member). For validation purposes, the study team will routinely conduct on-site user research with stakeholders and end users to ensure that the envisioned flows and developed prototypes fit the needs of end users. Following



XSL•FO
RenderX

the tenets of HCD, this validation process is directly integrated into the prototype codevelopment and product design.

Theory of Change

Building on the envisioned MoPuleesa intervention approach, Figure 3 summarizes key inputs, activities, and causal pathways that underpin our design and implementation work, serving as a guide to understand how the intervention will lead to the desired outcomes and impact.

Figure 3. Theory of change illustrating inputs and activities, with expected outputs, outcomes, and impact. CHW: community health worker; CVD: cardiovascular disease; HCP: health care provider; NCD: noncommunicable disease; OOP: out-of-pocket payment.

We theorize that the mHealth platform will foster a regular influx of money into the pooled system, which will allow the clinic to purchase antihypertensive medication in bulk via designated channels (medication purchase by the health center directly from wholesale vendors shown in Figure 2), thereby reducing costs for individual clients (compared with out-of-pocket purchasing of medication at pharmacies) and facilitating a sustainable, stable supply of medication. Considering a possible scale-up of this intervention and learning from our design and implementation process, we envision a long-term impact (shown in the increasingly larger circles in the lower part of Figure 3) on the well-being of patients with hypertension and on scientific intervention design efforts. Our envisioned methodological approaches to achieve this goal and the overarching study objectives are outlined in detail in the following subsections.

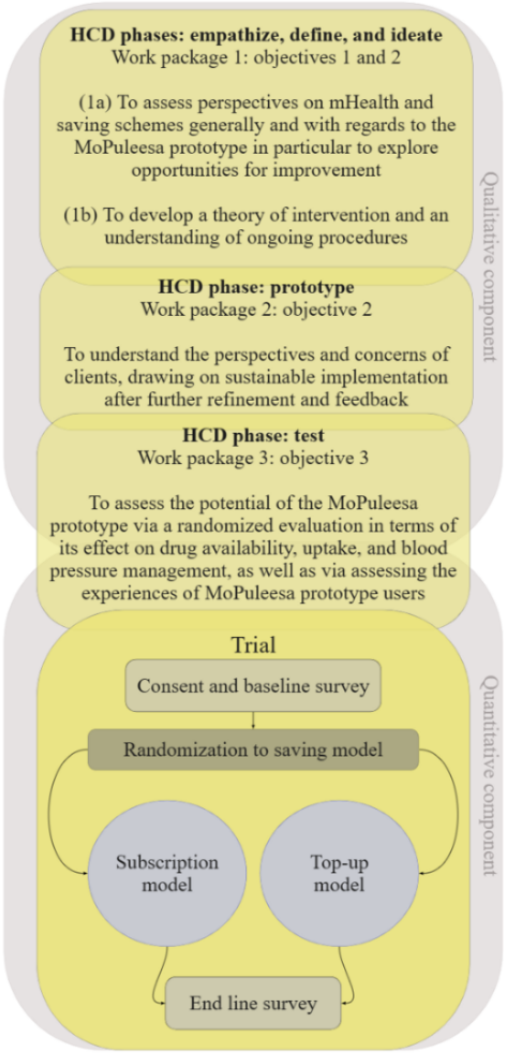
Methodology

Originating in computer science, artificial intelligence, and ergonomics, HCD has more recently begun to inform how public health actors design and implement health interventions [36]. In the HCD approach, end users are involved in all stages of the design process and have influence on the final product of the intervention, with the implicit rationale that engaging users facilitates implementation success [37]. HCD begins with developing a thorough understanding of the status quo in

XSL•FO
RenderX

question to define an issue that will be addressed. On the basis of this understanding, researchers and end users together develop an idea for a potential product or intervention (empathize, define, and ideate). As this process continues, researchers elicit feedback to iteratively adapt the envisioned solution to end users' needs and expectations to maximize the fit of the developed prototype to the setting at hand (prototype). Finally, the developed product is pilot-tested (test).

As a design-driven study, this research did not begin with a predetermined intervention in mind; instead, we sought to capture the nature of the challenge and potential solutions, identified as promising, in similar settings. We use the HCD approach to identify product priorities and intervention approaches and to codevelop product prototypes together with end users. Once a final product is identified, it will be evaluated quantitatively for efficacy, usability, and desirability.



To provide maximum experience and expertise, we will leverage the multidisciplinarity of our team throughout the project with a focus on trust, communication, and team identification within the team to facilitate collaborative work [38]. Our team includes ethnographers and social scientists who will ensure context sensitivity and qualitative insight into end users' and stakeholders' experiences, preferences, and perspectives; local clinical research leaders who will tap into context expertise and communication channels; medical professionals, including biomedically trained clinicians, who will assess the medical aspects and health benefits of the intervention and gain insight into the local health system; NCD-focused trialists who can meaningfully incorporate quantitative results that can guide further research directions; and, finally, software programmers and experts in the technical aspects of the project who will guide successful implementation, identify opportunities, and make the intervention as up to date and innovative as possible.

Research Design

This study will follow a mixed methods exploratory sequential design [39] in line with established recommendations for HCD studies [40,41]. In a first step, the design approach will allow us to qualitatively explore stakeholder perceptions, experiences, and recommendations in the setting at hand, informing key design decisions in accordance with specific study objectives 1 and 2. Although formative research revealed the essential challenge of accessing drugs in the study setting and recognized mobile money as a potential solution, qualitative data are needed to inform the design and operationalization of the platform, anticipate potential difficulties and facilitators, and assess clients' willingness to accept the approach. Building on these qualitative results, while maintaining core trial design and rationale, we will refine and finalize the concluding quantitative component aimed at pilot-testing the intervention in the form of a randomized controlled trial (study objective 3). Sequentially combined, these methods will allow us to ideate and design an intervention adapted to the specific study context, as well as allow for evidence-based conclusions regarding the prototype's potential in facilitating sustainable hypertension care. Figure 4 highlights the overlap of research activities and WPs across the HCD phases.

XSL•FO
RenderX

Figure 4. Summary of all study phases and methods (including trial details) corresponding to specific study objectives. HCD: human-centered design; mHealth: mobile health.

HCD Phases

Empathize, Define, and Ideate: WP 1

WP 1 is divided into 2 phases, both informed by the tenets of HCD. In the first phase (WP 1a), we will conduct in-depth interviews (IDIs) and focus group discussions (FGDs). The IDIs will facilitate the capture of clients' personal perspectives on, and experiences with, blood pressure management and hypertension, mHealth, savings schemes, and the existing paper-based scheme that inspired this work. We will explicitly probe on more nuanced facets such as trust and transparency. In addition to IDIs, we will conduct FGDs to determine how groups such as HCPs, clients, and CHWs negotiate the trade-offs and opportunities of different approaches to hypertension management and care, including the proposed intervention. Within the FGDs, the envisioned platform use process will be explained to participants step by step, and feedback will be gathered. We will collectively determine intervention facets, such as how the intervention should be explained or presented within a community, who should be responsible for enrolling clients and troubleshooting challenges, what foreseeable challenges respondents see with the intervention, and how these should be circumnavigated or addressed. Finally, within WP 1a, we will examine field notes from the previous phases of formative research, where we collected information on CVD management in Nakaseke region from NCD clients and HCPs; these notes will bolster our own recall of the system in place at Semuto Health Center IV and its development, which can inform how we can build a meaningful product.

In a second phase (WP 1b), we will conduct nonparticipant semistructured observations of client-provider interactions and clinic processes, as well as IDIs with higher-level stakeholders. The observations will be conducted by research team members working in Nakaseke district who will already have interacted with clients and providers on site; this will allow us to understand actual behaviors and current workflows regarding hypertension management and care in the study setting (including, eg, how client-provider interactions and medication procurement or delivery currently take place). Using an observation checklist, we will examine how health services related to blood pressure management are currently provided and how clients are handled at Semuto Health Center IV. In addition, we will gather information on the locations and processes of medication prescription, storage, and delivery. In the stakeholder IDIs, we will capture insights from policy makers, academics, and public health actors at community and

XSL•FO
RenderX

national levels to determine the feasibility, opportunities, and potential pitfalls of our proposed intervention, both with regard to our target setting and when considering how to scale-up our intervention. Table 1 summarizes the individual activities conducted in WP 1a and WP 1b.

Table 1. Methods used in work package (WP) 1: in-depth interviews, focus group discussions, and document analysis.

Activities	Participants	Themes	Purpose
WP 1a			
IDIs[a] (n=20-40)	Clients visiting the NCD[b] clinic at Semuto Health Center IV	• Hypertension management and care • Mobile health • Money-saving schemes • Feedback on early concepts for the intervention	To identify essential facets to include in the prototype
FGDs[c] (n=5)	Clients and CHWs[d]	• Perspectives on planned intervention • Communities' hypertension experiences and perspectives	To identify possible facilitators and barriers to intervention implementation
Document analysis	Field notes	• Field notes from formative research phase	To gather information on what has informed the existing approaches and identify key stakeholders
WP 1b			
Semistructured observations (n=3-5 clinic days)	HCPs[e], clients, and staff at the health center	• Client-provider interaction (n=10) • Clinic processes • Medical examination • Medication procurement and delivery • Locations of medication supplies, output, or storage	To understand current workflows regarding NCD management and care
IDIs (n=10-20)	Academics, implementers working on CVDs[f] or mHealth[g] interventions, and policy makers	• Development and implementation of mHealth interventions • Research on NCD management • Current health care services	To develop a theory of intervention for implementation and scale-up

[a]IDI: in-depth interview.

[b]NCD: noncommunicable disease.

[c]FGD: focus group discussion.

[d]CHW: community health worker.

[e]HCP: health care provider.

[f]CVD: cardiovascular disease.

[g]mHealth: mobile health.

Prototype: WP 2

WP 2 (Table 2) aims at finalizing the design prototype and preparing for pilot testing. To collect detailed feedback from end users and ensure that the final product aligns with their expectations, we will present a first MoPuleesa prototype on mobile devices to the end users. Luganda-speaking research team members on site will conduct think-aloud exercises, which will allow a much more targeted refinement of the prototype to address emerging barriers or challenges [42]. Think-aloud exercises are used to track a participant's thoughts while using a platform and to capture their problem-solving process [43]. After a short practice phase, participants are asked to comment on each step they take while using the platform and to say out loud what thoughts come to mind [42]. To minimize potential biases, data collectors will be asked to not interrupt the exercise and not interact with participants during the exercise unless they stop speaking (whereupon participants will be encouraged to continue speaking). Furthermore, we will capture local policy makers' and local leaders' feedback on the prototype and envisioned implementation processes via IDIs to further refine the prototype and identify potential difficulties and facilitators for rollout.

XSL•FO
RenderX

Table 2. Methods used in work package 2: think-aloud exercises and in-depth interviews.

Activities	Participants	Themes	Purpose
Think-aloud exercises (n≤40)	Clients, HCPs[a], CHWs[b] (who have or have not used a version of the prototype before)	• Interaction with latest prototyped platform • Usability of platform features	To refine the prototype to address emerging barriers or challenges
IDIs[c] (n≤20)	Key stakeholders (policy makers and local leaders)	• Latest prototype version • Benefits and barriers • Implementation process	To incorporate further concerns and perspectives

[a]HCP: health care provider.

[b]CHW: community health worker.

[c]IDI: in-depth interview.

Test: WP 3

In WP 3 (Table 3), we will pilot-test the final prototype. For the qualitative component of this WP, we will conduct IDIs with clients who were particularly engaged in previous interviews or who suggest during trial administration that they would like to expand on their responses in more detail to get a full understanding of their perspectives on the design and implementation process. In addition, to provide guidance on best practice approaches to co-designing mHealth interventions with end users, we will conduct IDIs with key stakeholders involved in this process, including health center staff, software developers, and members of the study team.

Quantitatively, we will assess differences between the top-up and subscription contribution options, as well as the impact of the intervention on service use, user satisfaction, intervention uptake and funds contributed, and clients' blood pressure readings, in a 2-arm between-participants parallel randomized controlled trial.

Participants will be randomized to 1 of the following 2 intervention arms (for the randomization plan, refer to the *Sample, Sampling, and Data Collection* subsection):

Table 3. Methods used in work package 3: in-depth interviews and randomized controlled trial.

Exercise	Participants	Themes	Purpose
Qualitative			
IDIs[a] (n=5-7)	Clients (particularly engaged in previous interviews or suggested during survey administration that they would like to expand on their responses in more detail)	• Expectations toward the prototype • Perception of implementation process	To assess experiences with the finalized prototype
IDIs (n=10-15)	Key stakeholders involved in the implementation process (health center staff, software developers, and members of the study team)	• Team communication • Implementation process • Problem-solving	To provide guidance on best practice approaches to co-designing mHealth[b] interventions with end users
Quantitative			
Trial (sample size: 250-350 clients)	All clients who have given consent to participate in the trial and take up a money-saving model	• Baseline and follow-up survey • Kano questionnaire [44] • Aggregation of clinic data	To gather information on trial participants

[a]IDI: in-depth interview.

[b]mHealth: mobile health.

Arm 1: subscription-based model, where individuals will be given the opportunity to enroll in a medication-specific mobile money savings account where they can deposit money over the course of the month. If clients reach the minimum amount needed to purchase medications for the following visit, the money will be automatically debited from their savings account at the end of each month.

Arm 2: top-up payment model, where clients can actively make mobile money transfers to the health facility throughout the month for the purchase of medication in the subsequent month without the option to make marked contributions for several months in advance.

Main Hypothesis

For the comparison between these 2 subscription approaches (specifically study objective 3), we draw on ongoing discourses in the literature regarding the chances and challenges of monetary contribution approaches for various purposes. Our considerations included findings regarding the differences between restrained commitment accounts and flexible liquid accounts that suggest greater willingness to save with less account flexibility in cases where clients self-report awareness of their own limited saving discipline [45]. In addition, several scholars have suggested that marked savings accounts, similar to our proposed subscription-based model where clients can

XSL•FO
RenderX

save money to cover automatically deducted monthly medication costs, increase utility costs for the later repurposing of already made marked savings and thereby can increase overall savings made for the intended purpose [46,47]. Furthermore, Fisher and Anong [48] have found that long-term saving motives as well as low risk tolerance might add to regular savings. Transferred to the setting at hand, this suggests that marked savings combined with regular and automated contributions might be preferred to ensure sustainable contribution and treatment.

When testing the developed prototype, our main hypothesis therefore is that the subscription model, combining benefits from committed, semiliquid, and long-term savings possibilities, will lead to more clinic visits, more intervention take up, and greater funds contributed to the health facility for the purpose of purchasing essential medications. We argue that, thanks to the ability to save dedicated funds in small increments for the explicit purpose of accessing a guaranteed medication stock, individuals in the subscription arm will be more likely to contribute to, and pick up, antihypertensive medications than individuals in the top-up payment arm. We will test whether this will lead to monetary savings (eg, individuals receive their medications through the public facility at a lower total cost than when purchasing out of pocket from a private pharmacy) and improved health (eg, individuals will be more consistent with picking up their medication and thus have improved blood pressure). We will evaluate the effect of the subscription model compared with that of the top-up payment model based on the outcomes listed in Table 4.

Table 4. Outcomes.

Category	Outcome	Measurement
Primary outcome	• Number of NCD[a] clinic visits as well as number of medication pickups	Health facility records
Implementation and medication outcomes	• Percentage of people who take up funding models • Total amount contributed to the clinic funds	Directly from MoPuleesa platform
Long-term health outcome	• Systolic and diastolic blood pressure readings	Collected through CHWs[b] and health facility records
User experience outcome	• User satisfaction	Questions on user satisfaction in baseline and follow-up surveys

[a]NCD: noncommunicable disease.

[b]CHW: community health worker.

Participants will be asked to fill out a questionnaire at baseline and after 6 months that will address care-seeking behavior, the consistency of medication pickups, health-related money-saving routines, and the perceptions of care quality. At baseline, the questionnaire will also include sociodemographic characteristics. At 6 months, the questionnaire will further include questions about the feasibility and acceptability of the intervention, as well as a short series of platform attribute or Kano-style questions (the Kano model describes the relationship between product attributes and user satisfaction or disapproval to determine the relative importance of product features [44]). In addition, we will use data routinely collected at clinic level (demographic data, blood pressure readings, and height and weight measurements) and via the MoPuleesa prototype (money contributed and medication ordered) as detailed in Table 4.

Participants and Inclusion Criteria

Across all WPs, the respondent groups include HCPs at facility and community levels (medical doctors and clinic staff), CHWs working in the community, community members and key stakeholders (religious and local leaders, members of pooled financing schemes, and academics), clients (diagnosed with hypertension and living within the catchment area of Semuto Health Center IV), and decision makers (policy makers and ministry of health representatives). In the final WP, we also include study team members involved in intervention design, implementation, and evaluation processes as respondents.

Ethnicity, race, political orientation, religion, and class are not criteria for inclusion or exclusion in this study. Respondents must be aged ≥18 years to participate. Persons who are incapacitated (mentally challenged or physical disability: hearing and speech impaired) are excluded from this study. Textbox 1 summarizes the inclusion and exclusion criteria for this study.

XSL•FO
RenderX

Textbox 1. Study inclusion and exclusion criteria.

Inclusion criteria (aged ≥18 y and having given informed consent)

- Health care providers: community health workers, medical doctors, clinic staff working at Semuto Health Center IV or in community outreach in Nakaseke district, etc
- Local key stakeholders: religious and local leaders, members of financing schemes, academics, etc
- Clients: clients who have been diagnosed with hypertension and are registered at Semuto Health Center IV
- Decision makers: policy makers, ministry of health representatives, health insurance representatives, district administrators, etc
- Study team members: individuals involved in the intervention design, implementation, and evaluation

Exclusion criteria

- Refusing or withdrawing informed consent
- Not responding to invitations to participate
- Persons who are incapacitated (mentally challenged or physical disability: hearing and speech impaired)

Sample, Sampling, and Data Collection

Qualitative Components

For the qualitative components of this study, we expect to recruit a maximum of 160 individuals. In line with the tenets of saturation (new data cease to provide fundamentally novel insights) [49] and information power [50], our sample size will be determined as data are collected. The aforementioned estimate is based on experience and an effort to achieve a justifiable trade-off between collecting high-quality data and minimizing strain on the target populations (eg, individuals to be interviewed) [51].

We will use purposive sampling [52] for WP 1 and WP 2 to gain a range of perspectives. Local leaders, policy makers, and academics will be contacted and recruited through the official communication channels for the respective health facility or office or via the established channels of African Community Center for Social Sustainability (ACCESS) Uganda. Health care professionals will be contacted through the respective clinics or when conducting structured observations once the clinics have agreed to participate. We will use snowball sampling [53] as necessary to contact additional participants.

For clients, convenience sampling [52] will be used. Clients will be approached during structured observations in the clinic areas where they await NCD care (waiting time: minimum 30 min). As clinic days for NCD care are conducted once a week at the health facility, clients will additionally be purposively recruited via local HCPs guiding the study team toward a range of clients who represent different types of background characteristics using the sampling criteria: age group (those aged >50 y and those aged <50 y), gender (male and female), and condition (hypertension, diabetes, or both). The study will be briefly introduced using an information sheet. If clients signal interest to participate, contact information will be exchanged to schedule an IDI. All IDIs and FGDs will take approximately 60 minutes and will be conducted by researchers and research assistants, including CHWs who work in the area but not in the study setting. All research assistants will have gone through a 5-day training program in qualitative research and interviewing and will work together as teams of 2 people representing a moderator and a notetaker. Research assistants will be provided with interview guides that will be refined in group sessions during the 5-day training period and pilot-tested on 2 days with participants within the study setting.

Quantitative Component

For the quantitative component, we anticipate enrolling between 200 and 350 clients. Client recruitment will follow the same procedures as those outlined in the previous subsection. This number was not the result of a detailed power calculation; rather, it was determined and constrained by the total client population from which we can recruit. Specifically, based on our discussion with the administrators of the NCD study clinic at Semuto Health Center IV, the clinic currently serves approximately 380 clients who meet the aforementioned inclusion criteria. Thus, we realistically expect to enroll 200 to 350 clients based on exact attendance during the study period and refusal rates.

Sample Size Estimation

On the basis of the range of recruited participants, we estimate the following minimal detectable effects (Table 5). For these calculations, our primary outcome is the number of clinic visits for medication pickups. On the basis of the 6-month study duration, this can range from 0 to 5 visits (individuals are asked to come once a month), which we will analyze as a count variable using Poisson regression. We additionally set an α of 5% and a power of 80%, with a 2-tailed *t* test for all estimates, and show the minimal detectable effects across a range of possible control counts (the number of visits for pickups among the voluntary contribution group in a range from 1 to 5) and sample sizes (ranging between 200 and 350). The minimum detectable effect is expressed as a rate ratio and measures the percentage increase in mean visits for the subscription contribution (intervention 1) compared with those for the voluntary contribution (intervention 2) over the 6-month study period.

XSL•FO
RenderX

Table 5. Minimum detectable effect size across sample sizes and base rates.

Mean number of visits in the voluntary contribution (intervention 2) group	Minimum detectable effect size			
	200[a]	250[a]	300[a]	350[a]
1	1.44	1.39	1.35	1.32
2	1.30	1.27	1.24	1.22
3	1.24	1.22	1.20	1.18
4	1.21	1.19	1.17	1.16
5	1.19	1.16	1.15	1.14

[a]Total sample size (50% intervention 1 and 50% intervention 2).

Randomization

Participants will be randomized to be offered either the subscription model or the top-up contribution payment model and assigned to the different models by study team members after the initial recruitment at the facility and upon providing informed consent. The allocation sequence for the random assignment of the intervention was developed by an independent statistician. Individuals are randomly assigned in a 1:1 ratio. We use stratified randomization by sex and day of recruitment, with participants randomized in blocks of 4 to maximize balance between treatment and control. The allocation is concealed because assignment is based on a random draw from a box such that an individual's assignment is only revealed after they physically draw a slip.

Randomization Implementation

The quantitative research team developed the allocation sequence, and the research assistants enroll participants into the study. After enrollment into the study, each participant will be assigned to a particular arm by drawing concealed slips labeled either direct payment or savings from a box on the day of their recruitment into the study.

Blinding

The allocation sequence of assigning the intervention will be concealed from the research team until the moment of assignment. This will prevent selection bias when assigning participants to study arms. However, because of the nature of this intervention, blinding of neither the research team nor the participants will be possible once the program has started.

Data Management

The research study data manager will guide the data management responsibilities for this study. This study's quantitative data will be collected using both paper and electronic case report forms, whereas qualitative data will be collected using audio recorders. Transcripts and field notes from the qualitative work as well as the paper case report forms will be kept under lock and key and will be overseen by the principal investigators. The transfer of participant-related data, if any, will be carried out in pseudonymized form; third parties will not have access to original data. REDCap (Research Electronic Data Capture; Vanderbilt University) will be used to enter, store, and manage quantitative data. To ensure that quality data are collected, the REDCap platform will provide an interface for data entry (an audit trail to track all changes within the database). In addition, automated validation checks will be embedded within the study database. The study data manager will share data queries generated from the accruing data with the research team on a biweekly basis.

Data Analysis

Qualitative Data Analysis

Data generated from the qualitative interviews will be transcribed verbatim and analyzed using NVivo software version 14 (Lumivero) following a five-step framework approach: (1) *familiarization with the data*, (2) *identifying a thematic framework*, (3) *indexing*, (4) *charting*, and (5) *mapping and interpretation* [54]. This will help us generate an understanding of stakeholders' experiences with the prototype. After the completion of the intervention prototype, a detailed analysis plan for this study will be developed. To adapt and inform our design and implementation processes, we will conduct systematic debriefings after each day of qualitative data collection. In weekly team meetings, we will share the first findings from these debriefings with all team members to adjust platform features to end users' needs and facilitate implementation steps within the community.

Quantitative Data Analysis

We will summarize participant demographic characteristics and assess baseline balance between those randomized to the top-up and subscription arms. We will then assess the effect of offering the subscription model on the number of clinic visits with medication pickups (the main outcome) by comparing differences between those *offered* (including those who were offered and did not take up) the subscription model and those *offered* the top-up contribution model. As not all individuals will take up the offer, this will represent the intention-to-treat effect. We will estimate this effect using Poisson regression models. Next, we will assess the effect of the amount of money an individual contributed on the number of visits they attend. We will do this using a Poisson instrumental variable regression approach, where we use the random assignment as an instrument for the amount of money contributed. Finally, we will assess the effect of the random assignment to the different contribution arms on the proportion of individuals who take up the contribution model (the implementation outcome) using linear probability models and the effect on systolic and diastolic blood pressure readings using linear regression models.

XSL•FO
RenderX

Statistical Analysis

The baseline characteristics of participants will be compared between the 2 arms using medians and IQRs for continuous variables and proportions for categorical variables. Outcomes will be analyzed by both the intention-to-treat and per-protocol analysis methods using mixed effects Poisson regression methods for the primary outcomes. We will adjust for baseline imbalances for both the primary and secondary analyses, and both unadjusted and adjusted analyses will be presented. All our regression models will additionally control for baseline patient characteristics such as age, sex, and income to increase the precision of the treatment effects. We will not only conduct a complete case analysis but also present the results using multiple imputation as sensitivity analyses. Missing data on outcomes and key covariates will be assessed before analyses. Where applicable (missingness >10%), we will implement multiple imputation methods appropriate for random effects models. Two-tailed *P* values of ≤.05 will be considered to indicate statistical significance. Analysis will be performed with Stata software (version 17; StataCorp LLC). We will not conduct any interim analysis for this study.

Ethical Considerations

The study protocol was approved by the institutional review board of the Medical Faculty, Heidelberg University, Heidelberg, Germany (S-299/2022) and the Makerere University School of Biomedical Sciences Research and Ethics Committee (SBS-2022-175), Kampala, Uganda. The study has been registered at the Uganda National Council for Science and Technology (HS2445ES). Protocol modifications will be communicated to both ethics committees, the Uganda National Council for Science and Technology, and the German Clinical Trials Register. All participants will provide written informed consent before their enrollment in the study. Consent will be obtained by the study research team.

Dissemination of Findings

We will disseminate the findings from all study phases via established academic channels (eg, peer-reviewed publications and conference contributions). Furthermore, we will hold dissemination workshops with local stakeholders and policy makers to ensure transparent communication; to discuss the impact the intervention has had on local medication availability, purchase, and distribution; and, in the case of proof of concept, to explore the potential for scaling up and replicating our intervention.

Results

This study was granted funding by the German Federal Ministry of Education and Research via the German Alliance for Global Health Research in April 2021 for a duration of 24 months, with an extension of 8 months until December 2023. The funders have no role in study design or analysis. As of August 2023, the first part of qualitative data collection had been finalized (with 55 IDIs and 4 FGDs conducted with clients, HCPs, CHWs, local leaders, and policy makers), and qualitative data analysis is underway. The results from the ongoing qualitative phase have informed platform design and implementation in accordance with the HCD principles outlined previously. In addition, the results are providing insights into current practices and understandings in the target population regarding topics such as NCDs, community-led health financing, and mHealth approaches. The findings are expected to be published in early 2024.

The randomized controlled trial for pilot-testing the final intervention prototype was registered in December 2022, paving the way for recruitment, which started in August 2023 and is ongoing. The results from the quantitative trial are expected to be published in summer 2024.

Discussion

Expected Observations

Hypertension is a key risk factor for CVDs and significantly contributes to morbidity and mortality across the globe, but accessing the required long-term care remains challenging, especially in low-resource settings. In this study protocol, we outlined how we will work with clients, providers, and other key stakeholders in a rural Ugandan setting to build on a community-led self-help financing scheme for facilitating access to antihypertensive medication. Following the tenets of HCD, we will rapidly iterate and refine an mHealth platform to incorporate end-user feedback across all stages of the design process.

Efforts to bolster sustainability and fairness in access to health care have a long history in global health. The large-scale multisectoral declaration of Alma Ata in 1978, aiming at adequate health care provision for everyone by 2000, has been criticized for the lack of follow-up on implemented goals and its selectiveness in the addressed diseases [55]. Placing a larger emphasis on the principle of strengthening primary health care, the Bamako Initiative of 1987 aimed at the integration of communities in attempts to facilitate health care financing. However, this initiative is widely considered to have failed, and it has been criticized for its top-down approach or in some instances increasing financial burden on some of the populations classified as the most disadvantaged [56]. In the aftermath of these large-scale efforts, researchers and implementers have highlighted still-open questions regarding pathways to avoid selectiveness in primary health care, to prevent shifts toward the private sector when client charges are introduced, and to meaningfully engage communities in implementation and follow-up [57]. In our study, we will contribute to providing answers to these questions, combining qualitative and quantitative approaches in the HCD design to gain insights into the perspectives and experiences of local stakeholders and end users.

In response to the lessons learned in the context of the previous efforts highlighted in this paper, we aim to build on a system initiated locally with already existing stakeholder buy-in, rather than implementing a new intervention created outside the study setting. We focus on a bottom-up approach to work with local realities and learn from clients' and providers' past experiences, and we have conducted extensive formative research in the study setting to inform the research and implementation

XSL•FO
RenderX

activities presented in this protocol. The results of this study may inform future research on the potential of design research as a means to build on locally sourced approaches with high existing stakeholder buy-in.

Addressing Reported Challenges

mHealth approaches in resource-constrained settings are often accompanied by many difficulties that could hinder their acceptance and uptake (eg, incomplete mobile phone access owing to lack of a personal mobile phone, charging challenges, or theft) [58]. Some studies report difficulties for mHealth interventions that rely on a stable network connection or complex digital software [28,59,60]. To facilitate accessibility and overcome the challenges reported by fellow researchers, the MoPuleesa platform is based on a simple USSD menu that can be operated from any feature phone without internet access. It is also linked to a SIM card that can be accessed via different devices and can be locked in case of theft. This way, we hope to contribute to the potential of digital technologies for health care to reach resource-limited areas. Furthermore, research has shown that trust and risk assessment play a crucial part in enhancing the uptake of mHealth interventions and mobile money acceptance [61]. Moreover, service quality and confirmed expectations in turn seem to increase confidence in an intervention [62]. We want to investigate these components within our quantitative evaluation to provide thorough feedback on the variables for intervention uptake and use.

Community financing approaches should consider mandatory contributions to facilitate sustainability [63]. However, end users and implementers in the context of our formative research have voiced concerns that in our setting, mandatory contributions might result in a decrease of community engagement and continual intervention uptake. Similar findings have been reported from research conducted in Nigeria [64]. As health care should be available free of cost at government facilities in Uganda, mandatory contributions might be perceived as unfair and an additional, often prohibitive burden. Instead, formative research in our setting has shown that a financing scheme led by the community can spark substantially more trust and willingness to participate if it is an optional addition to governmental health coverage. Despite the potential of such community-driven efforts, a tension remains between creating a program that is flexible in terms of contribution (as desired by clients who are contending with seasonal harvests and uneven employment) and building a program that is rigid in its contribution requirements (as desired by health providers who are trying to forecast bulk purchasing needs). To strike a balance between maintaining acceptability of the community-initiated financing program and facilitating a sustainable influx of funds, our comparators for pilot-testing the developed intervention will be based on 2 voluntary contribution approaches that differ in their rigidity.

To further facilitate a sustainable influx of money, previous studies have highlighted the importance of affordability and the amount of trust placed in the operating administrators [65]. In addition, both previous studies and our formative research have found that the acceptability of financing schemes might increase if contributors are closely involved in the creation and the management of a scheme [66]. Therefore, in our study, we aim to bolster trust by engaging CHWs, HCPs, and other local stakeholders throughout intervention design and rollout, and suggested contribution amounts will be determined based on conversations with both clients and providers.

Finally, the success of pooled financing approaches strongly depends on the number of regular contributors [67]. After proof of concept of our intervention, 1 key challenge to achieve long-term sustainability will therefore be to scale platform integration and participation to maintain the constant influx of money required for bulk medication purchasing. To explore options for scale-up at clinic level, we will continually engage stakeholders to discuss possibilities in the case of proof of concept to expand platform integration to include other NCDs requiring long-term management (eg, diabetes) according to local priorities. As a first step toward informing policies and the potential scale-up of our intervention in the Ugandan setting, we will engage local policy makers in qualitative interviews to discuss the wide-range potential and adaptability of our program. We plan for further engagement of these key stakeholders through dissemination workshops at the conclusion of data collection to ideate on how to further develop and grow our program.

Limitations

With this study being a design study, the available sample size and limited generalizability owing to the specificity of patients with hypertension at 1 health facility might prove not to be sufficient to establish large-scale statements regarding intervention efficacy. Therefore, in the case of proof of concept, we encourage further randomized testing of the developed intervention with representative populations to allow for more robust interpretation and recommendations. Although the specific setting of an established dedicated NCD clinic and a patient-initiated money-saving program is one of our study's' key strengths, it could also prove to be a potential limitation in terms of transferability to settings with less ideal conditions. Although restricted, recent project development addressing NCDs in this region has emphasized the potential of HCD, mHealth, and community-led intervention to guide future policy decisions [68]. We will therefore refrain from making sweeping statements across settings but encourage further research on these topics in other contexts.

Conclusions

Our study will contribute to filling a gap in the literature by investigating the design and implementation of an mHealth intervention based on an existing community-led financing scheme. We hope to spark discourse and inform future research on the potential of design research in exploring novel approaches to facilitate sustainable access to medication in resource-constrained settings. We also aim to broaden the scope of established practices for community involvement in the design and implementation of interventions by focusing on their potential for expanding end user–driven solutions already established in the field.

RenderX

Acknowledgments

The authors highly appreciate the feedback from clients and health care providers at Semuto Health Center IV that has led the formative research phases of this study and already paved the way toward a structured design process. The authors furthermore acknowledge the support of the clients and health care providers with recruitment and logistical organization for the start of their qualitative data collection. In addition, the authors are very grateful for the inputs provided by their research assistant team during the first phase of qualitative data collection.

Data Availability

All data collected in the context of this study will be managed at the African Community Center for Social Sustainability (ACCESS) research facility in Nakaseke, Uganda. Data sharing will take place in compliance with the ACCESS data sharing policy and established procedures. Third-party researchers who are interested in the data must complete and sign data sharing agreements. Decisions on data sharing will be made on a case-by-case basis by the investigators upon reasonable request. Individuals granted database access will be expected to use the data to answer the questions clearly outlined in the data sharing agreement.

Authors' Contributions

JVE, TB, FK, SK, RK, and SM conceived of the study. JS, J Wachinger, RM, MN, J Wafula, RI, IW, JC, IS, JVE, TB, FK, SK, NS, CKN, RK, and SM conceptualized the study. JS and J Wachinger led the ethical and administrative approval processes in Germany. RM, J Wafula, and IW led the ethical and administrative approval processes in Uganda. JS, MN, and CKN prepared data collection plans and conducted data collection training. JS led manuscript writing and prepared the first draft. J Wachinger and SM supported and supervised manuscript writing. RM, MN, RI, IW, JC, IS, JVE, TB, FK, SK, NS, CKN, and RK provided feedback on the manuscript and study design. All authors have read and approved the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Treatment-resistant depression (TRD) is the inability of a patient with major depressive disorder (MDD) to accomplish or achieve remission after an adequate trial of antidepressant treatments. Several combinations and augmentation treatment strategies for TRD exist, including the use of repetitive transcranial magnetic stimulation (rTMS), and new therapeutic options are being introduced. Text4Support, a text message–based form of cognitive behavioral therapy that allows patients with MDD to receive daily supportive text messages for correcting or altering negative thought patterns through positive reinforcement, may be a useful augmentation treatment strategy for patients with TRD. It is however currently unknown if adding the Text4Support intervention will enhance the response of patients with TRD to rTMS treatment.

Objective: This study aims to assess the initial comparative clinical effectiveness of rTMS with and without the Text4Support program as an innovative patient-centered intervention for the management of patients diagnosed with TRD.

Methods: This study is a multicenter, prospective, parallel-design, 2-arm, rater-blinded randomized controlled pilot trial. The recruitment process is scheduled to last 12 months. It will involve active treatment for 6 weeks, observation, and a follow-up period of 6 months for participants in the study arms. In total, 200 participants diagnosed with TRD at rTMS care clinics in Edmonton, Alberta, and rTMS clinics in Halifax, Nova Scotia will be randomized to 1 of 2 treatment arms (rTMS sessions alone or rTMS sessions plus Text4Support intervention). Participants in each group will be made to complete evaluation measures at baseline, and 1, 3, and 6 months. The primary outcome measure will be the mean change in the scores of the Patient Health Questionnaire-9 (PHQ-9). The secondary outcome measures will involve the scores of the 7-item Generalized Anxiety Disorders Scale (GAD-7), Columbia-Suicide Severity Rating Scale (CSSRS), and World Health Organization-Five Well-Being Index (WHO-5). Patient data will be analyzed with descriptive statistics, repeated measures, and correlational analyses. Qualitative data will be analyzed using the thematic analysis framework.

XSL•FO
RenderX

Results: The results of the study are expected to be available 18 months from the start of recruitment. We hypothesize that participants enrolled in the rTMS plus Text4Support intervention treatment arm of the study will achieve superior outcomes compared with the outcomes of participants enrolled in the rTMS alone arm.

Conclusions: The application of the combination of rTMS and Text4Support has not been investigated previously. Therefore, we hope that this study will provide a concrete base of data to evaluate the practical application and efficacy of using the novel combination of these 2 treatment modalities.

Introduction

Background

Major depressive disorder (MDD) is one of the most prevailing mental health conditions, which affects about 300 million people globally [1]. MDD is considered the second leading cause of years lived with disability, and it was associated with an estimated worldwide loss of over 63 million healthy years in 2010 [2,3]. The lifetime prevalence of MDD stands at 15% [4], with a substantial socioeconomic impact and an estimated annual cost of about US $236 billion and €91 billion (US $96 billion) in the United States and Europe, respectively [5,6]. The lifetime prevalence of MDD within the Canadian population stands at 9.9% [7], with an estimated annual economic cost of about US $12 billion [8]. Data demonstrate that among MDD patients who receive first-line treatment, about 50% fail to achieve remission, with two-thirds requiring further treatment trials before they can reach the state of remission [9,10].

Most MDD patients may respond to treatment modalities, which include conventional psychopharmacology, psychotherapy, and electroconvulsive therapy. However, about one-third of patients fail to respond to these treatment modalities and hence are diagnosed with treatment-resistant depression (TRD) [11,12]. Owing to the heterogeneity of MDD and the absence of clear biological predictors of what constitutes a response to a specific treatment agent, there is a high chance of any patient with treatment failure being classified as treatment resistant [13,14].

The concept of TRD spans over decades [15]. While many definitions of TRD have been proposed in the literature, the consensus appears to center on the failure of an MDD patient to respond to 2 adequate trials of recommended antidepressant pharmacotherapy [16]. However, the term “adequate response” may be in contention regarding the precise meaning of what constitutes “adequate.” Generally, it has been argued that “TRD” may not be the best term to describe the nonresponse to therapeutic modalities in patients with MDD [16]. Instead, the term “difficult-to-treat depression” has been proposed in the literature. It has the added benefit of preventing MDD patients from feeling that their condition is impossible to treat with the recommended treatment modalities [17]. In Canada, TRD is diagnosed based on nonresponse to at least two antidepressant medications from different classes [18].

Data in the literature suggest that TRD is characterized by a disproportional socioeconomic burden for affected individuals, their relatives, and the health care system in general [19]. TRD presents with a higher direct and indirect medical cost than MDD, which is responsive to therapeutic interventions. This medical cost increases with the severity of TRD [20-23]. Compared with other depressive conditions, TRD leads to at least about 12% more outpatient attendance, is associated with about twice the chances of hospitalization, and is associated with the use of up to about 3 times more psychopharmacological medications [22]. Evidence in the literature suggests that the overall medical cost for hospitalization among patients with TRD is about 6 times greater compared to that among patients without TRD [22]. Similarly, the total cost of a TRD episode among patients with TRD is about 2.7 to 5.8 times higher compared to that among patients without TRD. This difference in cost is due to a longer duration of TRD episodes coupled with a greater rate of usage and a higher cost per treatment visit among patients with TRD [23]. Furthermore, the overall depression-related cost among patients with TRD is estimated to be about 19 times greater compared to that among patients with other depressive conditions [22]. Data suggest that up to about 47% of depression-related costs are attributed to TRD in the United States alone [21,24].

TRD is associated with several risk factors, which include physical or psychiatric conditions, such as anxiety disorders, personality disorders, and hypothyroidism; drug interactions; sociodemographic risk factors, such as individual education attainment and gender; and other external issues affecting ill health [21,25-27]. Furthermore, bipolarity is considered a major factor in TRD based on the inadequate management of bipolar diathesis in MDD, which is diagnosed as unipolar [26,28,29]. Again, TRD is characterized by a greater risk of comorbidities of both psychiatric and medical conditions, an increased risk of suicides, and impairment in normal functioning such as impaired quality of life and social functioning [20,30-32]. Due to its recurrent nature, an estimated 80% of patients with TRD relapse within 1 year after remission of their symptoms [30].

The prevalence of TRD varies significantly across the literature (12%-55%) [21,33-35]. In the United States alone, the estimated annual prevalence of medication-treated MDD was 8.9 million adults, of which 2.8 million (30.9%) had TRD [24]. A study that evaluated the prevalence and burden of TRD among patients with MDD in 4 Latin American countries (Argentina, Mexico,

XSL•FO
RenderX

Colombia, and Brazil) revealed that 29% of the study participants with MDD were resistant to medication. The results demonstrated a TRD prevalence of 33% in Argentina, 21% in Mexico, 32% in Colombia, and 40% in Brazil [19]. In Europe, data from a multicenter study of patients with TRD suggested a prevalence rate of 41% among patients with MDD, while in the United Kingdom, a study conducted on patients treated for MDD in a primary care setting demonstrated that 55% of the patients had TRD [36,37]. In Canada, the prevalence of TRD is about 21.7%. However, there were no differences in prevalence between men and women or among ethnic groups [18]. The wide variation in prevalence estimates is not unconnected with the variation in the definition and criteria for classifying TRD in the literature.

Treatment Options for TRD

Since the idea of TRD was established in 1974 [38,39], there has not been any straightforward standardized technique made available for the management of TRD; however, several studies have been conducted to evaluate the optimum treatment modalities for the same [40,41]. Many different psychopharmacological and nonpharmacological agents have been proposed and considered for the management of TRD. These treatment strategies may consist of psychopharmacological options, such as switching, augmentation, combination, and optimization of antidepressant medications [42]. Other comprehensive strategies include electroconvulsive therapy [43], psychotherapy [44], exercise [45], deep brain stimulation [43], light-based therapy [45], yoga [45], and transcranial magnetic stimulation (TMS) [43].

Use of Repetitive TMS in the Treatment of TRD

TMS was developed in the late 1980s [46]. Subsequently, researchers came up with newer techniques to deliver multiple pulses of TMS in shorter intervals referred to as repetitive TMS (rTMS) [47]. Thereafter, several studies were conducted to evaluate the efficacy of rTMS for the management of MDD [48] and other psychiatric conditions. rTMS is effective in the management of TRD, with response rates ranging from 30.6% to 64.7% [49-54]. In 2002, the application of rTMS for the management of TRD was approved by Health Canada [16].

rTMS is a noninvasive brain stimulation treatment modality that is deemed to be a valuable and promising treatment technique for TRD [55]. Two main protocols of rTMS are mostly used in the management of TRD: low-frequency (≤1 Hz) rTMS targeting the right dorsolateral prefrontal cortex and high-frequency (5-20 Hz) rTMS targeting the left dorsolateral prefrontal cortex [56]. Studies have argued that there is no significant difference in the efficacy of low-frequency rTMS and high-frequency rTMS in the management of patients with MDD. However, high-frequency rTMS seems better suited in clinical practice owing to the placebo effect [57,58]. The rTMS protocol of choice commonly used in suicide interventions (a common feature of TRD) is high-frequency rTMS [59,60]. The evidence in the literature in support of rTMS as a suicide reduction treatment intervention is modest and yet promising. Although there have been variations in the rTMS protocol among studies, several studies have demonstrated reductions in the rates of suicidality, with remission rates ranging from 40% to 65% in patients diagnosed with depressive disorders [59-63].

A standard session of rTMS for the management of TRD may consist of 20 to 30 daily treatment sessions for 4 to 6 weeks [64]. The administration of rTMS does not require an anesthetic agent and hospitalization, and thus, it is more accessible compared to electroconvulsive therapy in the management of TRD. Furthermore, rTMS application is deemed safe and tolerable, with no serious adverse effects among users [65].

Digital Technology Used in the Treatment of TRD

Though many treatment interventions for depressive conditions have been proposed in the literature, it is quite obvious that the traditional face-to-face means of delivering mental health care alone will not be enough to meet the demands for health care services, given the high prevalence of MDD and TRD, without any hope or likelihood of a decrease any time soon [66]. According to the 2012 Canadian Community Health Survey on Mental Health, about 2.3 million Canadians mentioned among other things that the barriers hindering them from accessing quality mental health care include a lack of a readily available care system, stigma, and high cost of health care services [67,68]. There has been a significant advancement in the development of digital technologies for the provision of health care in recent decades [69]. In particular, mobile digital information and communication technologies continue to advance at an exponential rate, making it possible to communicate, obtain information, and access care services with ease.

There is evidence in the literature in support of the therapeutic efficacy and cost-effectiveness of these digital technologies, such as tele-mental and e-mental health services, with the potential of enhancing easy access to health care and thereby helping to reduce the decades-old problem of unmet treatment needs and the wide treatment gap for mental conditions, particularly TRD [70,71]. These useful technological methods of health care delivery include smartphone apps, text messages, and email messaging [71,72]. In 2019 alone, about 97% of the world's population lived in communities with coverage of mobile cellular signals [73]. This exponential growth of mobile networks and phones has greatly opened new opportunities for health care delivery and health promotion, with a significant improvement in mobile health within recent years [74]. A global survey conducted in 2015 demonstrated that Canada, among Western countries, is in the high internet use group, with about 90% of Canadians using internet services and 67% owning a smartphone [75]. In 2022, internet usage among individuals aged 15 years or above in Canada increased to 95% from 92% in 2020. Notably, there was a significant rise in usage among those aged 75 years or older, with an increase from 62% in 2020 to 72% in 2022 [76].

Technology-enabled cognitive behavioral therapy–based programs have been increasingly acknowledged as innovative, accessible, cost-effective, and acceptable ways of delivering psychological treatments to patients and the general public with mental health problems [77]. An estimated 99% of all messages received on mobile phones are opened, and about 90% of all text messages end up being read within 1 to 3 minutes of

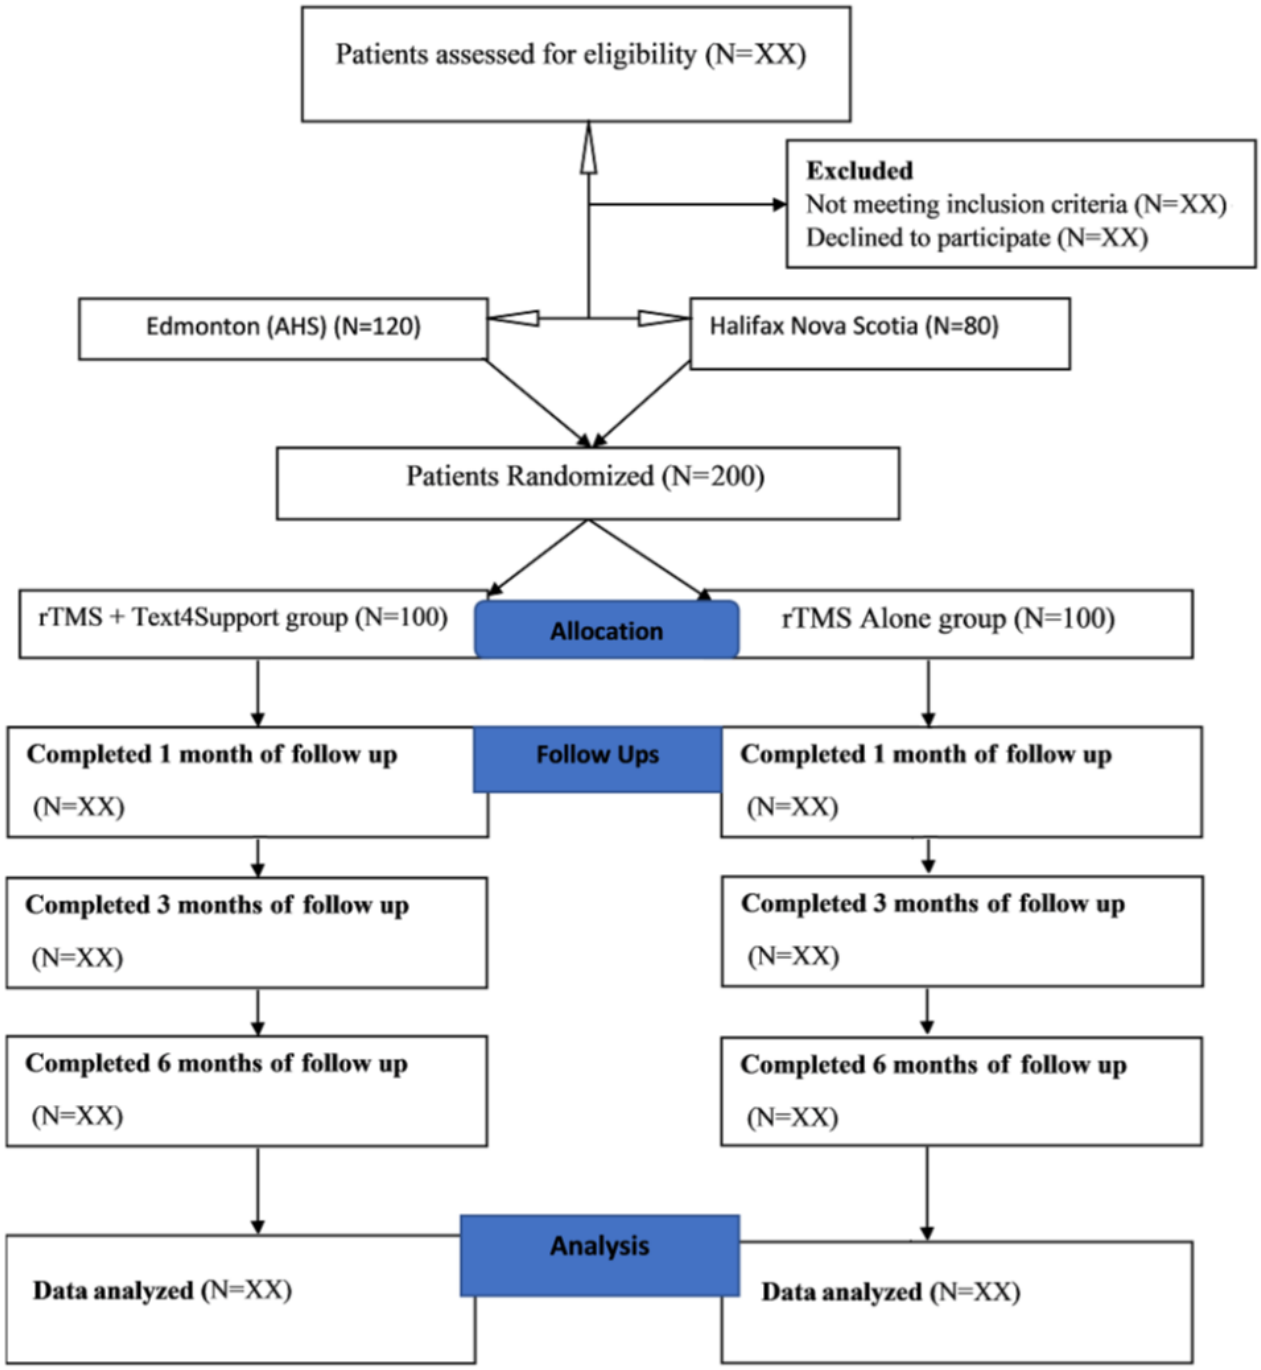
XSL•FO
RenderX

reception [78]. Thus, providing an affordable means of accessing care could help close the psychological treatment gap for patients with TRD [79].

Text4Support is one of the supportive text messaging programs in the ResilienceNHope [80] suite delivered by the Global Psychological eHealth Foundation [81]. The program allows users to receive daily supportive text messages, which have been written by a team of cognitive behavioral therapists and mental health professionals in collaboration with users of mental health services. The aim of this Text4Support depression program is to positively enhance the mood of patients with clinical depression. The program operates using positive reinforcement to correct distorted or negative thought patterns.

Evidence in support of the therapeutic efficacy of supportive text messaging exists from randomized controlled trials (RCTs) on supportive text messaging for the management of MDD conducted in Canada [82] and Ireland [83]. In these trials, patients with MDD were offered twice daily supportive text messages in addition to their usual care. Overall, there were significantly greater reductions in the symptoms of MDD among patients in the intervention group than among those in the control group receiving only usual care. After 3 months, the study in Canada demonstrated a statistically significant difference in the mean Beck Depression Inventory-II (BDI-II) score between the intervention group and the control group (mean change of −7.6, 95% CI −13.2 to −1.9; Cohen *d*=0.67) in favor of the intervention group [82]. Similarly, the RCT conducted in Ireland demonstrated a statistically significant difference in the BDI-II score between the intervention group and the treatment as usual group (mean change of −7.9, 95% CI −13.06 to −2.76; Cohen *d*=0.85) in favor of the intervention group [83]. User satisfaction with the Text4Support intervention and related programs has been assessed and reported in several other studies [79,84]. About 83% of users of the Text4Mood program reported an overall improvement in their mental health conditions, which they attributed to receiving daily supportive messages [79].

This study seeks to investigate the combined effect of an rTMS intervention with and without a text message–based cognitive behavioral therapy program (Text4Support) in patients diagnosed with TRD. The study also aims to generate effect size data for these interventions, which will help inform sample size and power calculations for a full-scale randomized clinical trial.



Methods

Study Design and Setting

This study is a multicenter, prospective, parallel design, 2-arm, rater-blinded randomized controlled pilot trial. Participants will be randomly assigned to 1 of 2 treatment conditions. The first condition includes rTMS sessions combined with Text4Support. The second condition includes treatment as usual (rTMS sessions alone). The recruitment process is scheduled to last 12 months. It will involve active treatment for 6 weeks and follow-up with observation periods of 6 weeks, and 3 and 6 months for participants in both arms of the study. Figure 1 presents the CONSORT (Consolidated Standards of Reporting Trials) flowchart for the project. Participants will be recruited from 4 different centers for this project. Two centers (the Addiction and Mental Health Clinic and the Alberta Day Hospital) are from the large sociodemographically diverse city of Edmonton in Alberta, Western Canada. The remaining 2 centers are in Halifax and Annapolis Valley in Nova Scotia, Canada. Table 1 presents the proposed timelines for this project.

4.2. Data analysis		✓	✓	✓	✓	✓
4.3. Preparation of reports, publications, and presentations						✓

[a]rTMS: repetitive transcranial magnetic stimulation.

Participants

We aim to randomize 200 patients (Edmonton/AB=120 and Halifax/NS=80) in this study.

Inclusion Criteria

The inclusion criteria are as follows: (1) Age 18 years or above; (2) Diagnosis of MDD based on the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition criteria, and failure of at least two standard antidepressant treatments during the current episode; (3) Good understanding of the English language; (4) Possession of a smartphone, and ability to receive and read text messages; and (5) Ability to consent, and willingness to provide written informed consent.

Exclusion Criteria

The exclusion criteria are as follows: (1) Age less than 18 years; (2) Diagnosis (current unless otherwise stated) of a neurological disorder (including a history of seizures), a primary or secondary tumor in the central nervous system, cerebrovascular disease, stroke, cerebral aneurysm, or movement disorder; (3) Diagnosis of a current psychotic disorder, such as substance-induced psychosis, psychotic disorder due to a medical condition, or MDD with psychotic features at the time of screening; (4) Diagnosis of a current personality disorder that may hinder participation in this research or may have the potential of affecting cognition and the ability to fully participate in the study; (5) Presence of a learning disability as identified through medical history or by the investigator during the assessment process; (6) Involvement in any drug or device clinical trial within the last 6 weeks before the screening visit or involvement in another clinical trial for the duration of this study; and (7) Identification of or the sudden appearance of any condition identified by the investigators to have the potential to hinder the progress and completion of the trial, or be a confounding factor for the outcome assessment.

Sample Size Calculation

This study is a pilot study with no standardized data documented on the effect size, which could aid in power and sample size calculations. We will therefore use data that can be generated from the study participants recruited within the existing protocol. This approach is accepted for pilot studies that consist of novel interventions, such as this, and this method has been described by Haynes et al [85] as using “the participants I can get.” In this regard, the study will be limited to a sample size of about 200 (120 from Edmonton and 80 from Halifax), with 100 participants recruited in each of the study arms. Since TRD is characterized by periods of relapses and depressive attacks, we anticipate a certain number of eligible patients to decline to enroll in the study or even drop out before the completion of the study.

Recruitment Process

Participant eligibility will be determined by the rTMS specialist team within the various centers. If found eligible for inclusion in the rTMS program, the patient will be approached by a member of the study team to introduce the study. A copy of the information leaflet will be provided to patients to have a detailed insight into the study processes. Once the patients agree to take part in the study, they will be asked to sign a consent form. The signing of the consent form and recruitment process will be conducted face-to-face at the various study sites during the week of the rTMS eligibility assessment of the participants, which usually occurs 1 week before the rTMS sessions begin. Participation in the study is by choice, and a participant can decide to withdraw at any time without providing a reason. To withdraw from the study, participants can contact the research coordinator to communicate their decision to discontinue their

XSL•FO
RenderX

participation in the study. Once withdrawn, the study will not collect any new information about them, and if deemed fit, the said participants may approach the research team to withdraw all data collected on them before the study data are analyzed or disseminated.

Randomization and Blinding

A simple randomization technique will be employed using a single sequence of random assignments. The simple randomization will be performed using a computer-generated Excel sheet (Microsoft Corp). To ensure balance (1:1), the randomization will be stratified by using permuted blocks. The codes generated will then be transmitted via text message by an independent statistician directly to a blinded researcher's password-protected phone line with a secure online backup. This process will occur for enrollment as each participant signs the consent form.

Since blinding of participants in this study is impossible, their treatment allocation will be made known to them right after the randomization process. Primary outcome assessors will not be granted access to the database that contains the randomization codes, and they will not be involved with all discussions concerning the study participants and may be blinded to the treatment arm allocations. The data that would be generated from the study will undergo a blind review for the reason of finishing the planned analysis.

Interventions

Study participants will be randomized to 1 of 2 treatment interventions (rTMS alone or rTMS plus Text4Support). During the introductory visit to the study sites, participants in both arms of the study will be given a detailed orientation about the rTMS application, and all procedures and activities within each visit will be explained to them. As part of their participation in the rTMS program, all patients will be made to complete some standard measures. Participants will be invited to the various rTMS clinics a week before the commencement of the rTMS sessions to enable them to undergo motor threshold (MT) assessment. MT assessment is essential in that it aids in the selection of the required stimulation intensity for each patient for inclusion in the treatment. It is a measure of the minimum intensity of TMS output needed to elicit a motor response in the participating TRD patients in at least 50% of all attempts.

All MT assessments will be conducted by the rTMS team of experts within the rTMS clinics in the various treatment centers, and the team may involve psychiatrists, nurses, and other health care professionals with the requisite training to perform the assessments. Each TMS assessment session will take about 3 to 5 minutes, and the total time will be within 35 to 45 minutes. This visit timeline will be the same for all study participants. Overall, all study participants will be scheduled to receive 30 sessions of rTMS treatment for 6 weeks according to the schedule pre-established by the Alberta Health Services' Strategic Clinical Network for Addiction and Mental Health and Nova Scotia Health. The rTMS protocol includes low-frequency (1 Hz) inhibitory stimulation targeting the right dorsolateral prefrontal cortex at 120% MT, with 20 trains (60 pulses/train at 60 s) and a total pulse of 1200 for 20 minutes, and high-frequency (10 Hz) excitatory stimulation targeting the left dorsolateral prefrontal cortex at 120% MT, with 75 trains (intertrain interval of 11 s) and a total pulse of 3000 for 19 minutes. The study will use the MagVenture rTMS machine with a figure-of-8 coil. The angle between the coil and the head will be measured at 45 degrees. The cortex area will be targeted by using the 5-cm technique. The prefrontal cortex stimulation site will be determined as 5 cm anterior further ahead of the motor strip in the parasagittal line. Regarding the issue of adherence to the treatment protocol, the rTMS team of experts will contact each patient to remind them of their sessions whenever they default in order to ensure adherence to the treatment. The patients will be continuously monitored, and an attending nurse will remain with each patient during the whole session, checking on any expected side effects. Complete treatment will be considered as attending at least 25 out of 30 sessions.

Additionally, participants in the rTMS plus Text4Support group of the study will be assisted by a study team member to register into the Text4Support program. The process will require all participants in this arm of the study to input their phone numbers into the Text4Support platform, which will be used to deliver daily messages. Starting a day after enrollment, participants will receive daily supportive text messages designed by mental health therapists, clinical psychologists, psychiatrists, and mental health service users. These messages will be based on cognitive behavior therapy principles crafted to positively enhance the mood of users with depressive symptoms and other related mental health problems of concern. The messages will be preprogrammed into a software program that will deliver the messages automatically to the participants' mobile phones at 10 AM (Mountain Time) and 12 PM (Atlantic Time), and each participant will receive these messages continuously for 6 weeks.

Hypothesis

We hypothesize that participants enrolled in the rTMS plus Text4Support treatment arm of the study will achieve superior outcomes compared with the outcomes of participants enrolled in the rTMS treatment alone arm of the study in terms of all outcome measures that will be assessed.

Data Collection and Follow-Up Assessment

All study participants who provide informed written consent and agree to participate in the study will be asked to complete a baseline assessment questionnaire that captures both demographic and clinical information. Study participants will also be asked to complete various follow-up assessments related to primary and secondary outcome measures at 6 weeks, and 3 and 6 months from enrollment. All self-completed surveys will be completed online on tablets or on participants' cell phones. Clinician-rated scales will be completed either face-to-face at the study sites or over the phone/video conference with the help of a blinded researcher. All follow-up survey links will be delivered to participants' cell phones at the designated time points. Two reminder text messages will be sent a day apart to encourage participants to complete the follow-up surveys. Participants who do not complete the online surveys despite receipt of 2 reminder text messages will be contacted by a research team member to ascertain if there are any barriers to

XSL•FO
RenderX

survey completion and if any assistance is needed. Qualitative data collection will be in the form of a patient experience questionnaire and a key informant interview via telephone, which will be conducted at 3 and 6 months. Data related to participants' clinic or program attendance rates and use of health services will be compiled from administrative records by a blinded researcher at 6 months.

Outcome Measures

The primary outcome measure for the study will be changes in the mean score of the Patient Health Questionnaire-9 (PHQ-9) [86] from baseline to the specified time points for the intervention and control groups. With 9 items, the PHQ-9 is half the length of many other depression measures, has comparable sensitivity and specificity, and is made up of the actual 9 criteria upon which the diagnosis of depressive disorders is based according to the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition. This instrument has the potential to establish major depressive disorder diagnosis, as well as grade the severity of depressive symptoms [86]. The PHQ-9 has good psychometric qualities with high internal consistency, and Cronbach α values of .86 and .89 were obtained in a study that included 2 separate patient populations [87]. The secondary outcome measure will include the 7-item Generalized Anxiety Disorders Scale (GAD-7) [88]. The GAD-7 score is calculated by assigning scores of 0, 1, 2, and 3 to response categories. The GAD-7 total score for the 7 items ranges from 0 to 21, with a score of 0-4 indicating minimal anxiety, 5-9 indicating mild anxiety, 10-14 indicating moderate anxiety, and 15-21 indicating severe anxiety. The GAD-7 has excellent internal consistency (Cronbach α=.92) and test-retest reliability (intraclass correlation=0.83) [88]. The screen version of the Columbia-Suicide Severity Rating Scale (CSSRS) [89] will be included to measure the suicidal ideation of participants. The CSSRS is made up of 6 questions. Users are required to respond "Yes" or "No" to whether they have thought about suicide, have acted or plan to act, or have attempted or plan to attempt suicide. Each of the 6 questions evaluates a different component of the respondent's suicidal ideation severity and behavior. This measuring tool is scored as low, moderate, or high risk, depending on positive answers (Yes) to the various questions. If a respondent answers positively (Yes) to question 2, the respondent is instructed to respond to questions 3-5. If a respondent answers "No" to question 2, the respondent may skip to question 6. Responding "Yes" to any of the 6 items may imply a need for referral to a mental health care professional, but responding "Yes" to question 4, 5, or 6 indicates a high risk. The CSSRS intensity of ideation subscale has good internal consistency, with Cronbach α values ranging between .73 and .93 [89]. Additionally, the World Health Organization-Five Well-Being Index (WHO-5) [90] will be employed to measure the quality of life of participants. The WHO-5 is a psychometrically robust questionnaire with high internal consistency (Cronbach α=.923) [91]. The WHO-5 is a short questionnaire made up of 5 simple and noninvasive questions, which assess the subjective well-being of respondents. A respondent is asked to rate how well each of the 5 statements applies to them within the last 14 days. Each of the 5 items is scored from 5 (all of the time) to 0 (none of the time). The raw score therefore theoretically ranges from 0 (absence of well-being) to 25 (maximal well-being). To translate the scores to percentages (from 0 [absent] to 100 [maximal]) as required by scales measuring health-related quality of life, the raw score is multiplied 4. The outcome measures and time points for the study are demonstrated in Table 2.

Table 2. Client-oriented outcome measures and time points.

Variable type and construct	Tool	Rater	Time points assessed			
			Baseline	1 month	3 months	6 months

Suicidal ideation	Columbia-Suicide Severity Rating Scale (CSSRS)	Clinician	✓	✓	✓	✓
Functional variables						
Quality of life	World Health Organization-Five Well-Being Index (WHO-5)	Client	✓	✓	✓	✓

Data Analysis

SPSS Version 26 (IBM Corp) will be used to analyze all quantitative data in accordance with the CONSORT guidelines [92]. Following an intention-to-treat approach, data will be analyzed with descriptive statistics, repeated measures, and correlational analyses. Descriptive data for baseline parameters will be presented using frequencies and percentages among the 2 intervention groups and compared using the chi-square test for categorical variables and the independent sample *t* test for continuous variables. The type of intervention (rTMS alone and rTMS plus Text4Support) will be considered the independent variable, while the scores of the various scales at each time point (6 weeks, and 3 and 6 months) will be considered the dependent variables for each of the analyses. Baseline scores of the respective scales will be used as covariates in the analyses.

To compare the effectiveness of the treatment interventions for the management of TRD among participants, the 1-way between-group analysis of covariance (ANCOVA) comparing changes in the mean scores from baseline to 6 weeks, and 3 and 6 months for all measures will be employed. Preliminary checks will be conducted to ensure there is no violation of the assumption of normality, linearity, homogeneity of variance,

XSL•FO
RenderX

homogeneity of regression slopes, or reliable measurement of the variate before ANCOVA is conducted. For participants with missing data, the last observation will be imputed before performing sensitivity analyses of covariance to explore the impact of the imputation of data loss on the PHQ-9 and the secondary measures at each time point.

The chi-square test or Fisher exact test will be employed to compare the prevalence of depression symptoms using the PHQ-9, the prevalence of anxiety symptoms using the GAD-7, suicidal ideations using the CSSRS, and quality of life using the WHO-5 between the 2 intervention groups at all time points in the overall sample.

Furthermore, a paired *t* test will be used to examine the changes in the mean scores of the PHQ-9, GAD-7, CSSRS, and WHO-5 at baseline and 6 weeks for participants who complete the instruments at both time points. Frequencies and percentages will be used to report categorical variables, while mean scores, confidence intervals, and effect sizes will be used to report continuous variables. The 2-tailed α-level criterion for statistical significance will be set at $P \leq .05$.

Qualitative data obtained through audio recordings from participant focus group discussion sessions will be transcribed and analyzed using thematic analysis aided by NVIVO software [93]. Data analysis will be both deductive and inductive. After familiarization with the transcripts obtained, 2 researchers will independently conduct the initial coding, and subsequently, the final coding criteria will be agreed by the 2 researchers. This will be followed by an iterative review of emerging themes as informed by the research questions. The final sets of themes and subthemes in relation to the overall study aims will be reported and supported with verbatim quotes.

Ethical Considerations

The study will be conducted according to the Declaration of Helsinki (Hong Kong Amendment) [94]. The study participants will be made to provide informed consent before their inclusion in the study. The research team will strictly adhere to the protection of participants' health information according to the structure laid down by the 2 major health institutions (Alberta Health Services and Nova Scotia Health Authority). An independent monitor will be assigned by the research team to monitor the progress of the research, ensure the completeness of informed consent and data safety, and liaise with the ethics committee. Although not anticipated, serious adverse events will be reported to the Research Ethics Committee. The study has received ethical clearance from the Health Ethics Research Board of the University of Alberta (Pro000122696) and the Nova Scotia Health Research Ethics Board (REB File #: 1028488).

Results

The study is registered at ClinicalTrials.gov (registration number: NCT05570344). The study is yet to commence recruitment of participants. The study results are envisioned to be available 18 months from the start of recruitment. The results are expected to be disseminated at different levels, including practitioners, health care organizations, and academics/researchers. Before the study ends, the team of investigators will organize an engagement plan to discuss the practicability and effectiveness of the study.

Discussion

Overview

The findings from the study will provide the data needed to assess the initial effectiveness of rTMS plus Text4Support for individuals diagnosed with TRD. Though there are several pieces of evidence in the literature in support of the effectiveness of rTMS in TRD, the data generated regarding rTMS application are relevant only when it is used as a single treatment modality. However, the concomitant application of psychotherapy with rTMS is limited. Therefore, we hope that this novel project will provide a concrete base of data to enable the evaluation of the wider-scale practical application and efficacy of the combination of rTMS and Text4Support. To the best of our knowledge, this study will be the first clinical trial to investigate the combined effect of these 2 interventions. Owing to the limited availability of data regarding this specific area of treatment, another objective will be to generate effect size information for these interventions to aid future power and sample size calculations for a full-scale RCT.

Strengths of This Study

This study has several strengths. First, since this RCT will be conducted in a naturalistic clinical care setting, translation of the results to clinical practice will be easier. Regardless of the outcome of this trial, the findings can inform clinical decision-making and aid in choosing the right treatment for a patient with TRD. Second, this study will have a longer follow-up duration than other rTMS trials. Since data up to 6 months from the start of the study will be available, the durability of the treatment effects of rTMS in the longer term can be evaluated. Third, randomizing participants will ensure that participants in the 2 treatment arms have similar psychiatric morbidity at baseline. Moreover, the blinding of all primary outcome assessors to the primary outcome measures will ensure the elimination of rater bias in the outcome measures.

Limitations

As eligible patients will ultimately decide on whether they want to join the study, a major limitation may be selection bias, which will potentially result in the selection of highly motivated patients. This may affect the ability to achieve a good study sample size and power. Another limitation may be associated with possible variabilities in illness duration and concomitant treatments being received by patients outside the rTMS treatment, which could have confounding effects on the outcomes of our interventions.

Abstract

Background: Total knee arthroplasty (TKA) is currently the main treatment for end-stage knee disease. The number of cases of TKA in China increased from 53,880 in 2011 to 374,833 in 2019, representing a 5.9-fold increase. Moderate to severe pain often occurs after TKA, which seriously affects postoperative rehabilitation, patient satisfaction, and overall outcome. Multimodal analgesia is considered the ideal solution. Adequate postoperative analgesia can not only reduce pain, opioid consumption, and, consequently, opioid-related adverse events, but can also reduce the length of hospital stay and costs and improve rehabilitation and patient satisfaction.

Objective: Effective multimodal pain management in the early postoperative period is essential for anesthesiologists. Additional studies have demonstrated that a low-dose intravenous infusion of ketamine can be administered as an adjuvant drug to alleviate acute postoperative pain. Therefore, we aim to appraise the efficacy and safety of intraoperative intravenous injection of S(+)-ketamine to relieve acute pain after TKA in older patients.

Methods: This is a protocol for a randomized, placebo-controlled trial. A total of 144 participants aged 65 years and older undergoing TKA will be randomly allocated into the S(+)-ketamine and placebo groups in a 1:1 ratio. S(+)-ketamine or the placebo will be intravenously administered at 0.3 mg/kg/h during the operation by anesthesiologists. Blinded evaluation by trained investigators will be completed at 2 hours, 24 hours, and 48 hours after surgery. The primary outcome measure will be the numeric rating scale score at rest and movement at 24 hours after surgery. The secondary outcomes will include the numeric rating scale scores at rest and movement at 2 hours and 48 hours after surgery, the number of patients who require additional analgesics during the first 48 hours after operation, the total consumption of opioids or nonsteroid anti-inflammatory drugs during the first 48 hours after operation, and adverse events at 2, 24, and 48 hours after operation.

Results: The protocol was registered at Clinical Trials.gov on February 26, 2022. It was performed in accordance with the approved guidelines and regulations of the participating institutions. Recruitment began in April 2022. Data collection is expected to conclude in September 2024. Study completion is expected in December 2024.

Conclusions: A randomized, controlled, clinical study was designed to observe the analgesic effect of intraoperative intravenous administration of a lower dose of S(+)-ketamine (0.3 mg/kg/h) in older patients after TKA surgery. The protocol will appraise the efficacy and safety of intraoperative intravenous injection of S(+)-ketamine to relieve acute pain after TKA in older patients who may benefit from the administration of S(+)-ketamine.

KEYWORDS

analgesic; S(+)-ketamine; total knee arthroplasty surgery; older patients, multimodal pain management

Introduction

Total knee arthroplasty (TKA) is currently the main treatment for end-stage knee disease. The number of cases of TKA in China increased from 53,880 in 2011 to 374,833 in 2019, representing a 5.9-fold increase [1]. Moderate to severe pain often occurs after TKA [2], which seriously affects postoperative rehabilitation, patient satisfaction, and overall outcomes [3,4]. Multimodal analgesia is considered the ideal solution. Adequate postoperative analgesia can not only reduce pain, opioid consumption, and, consequently, opioid-related adverse events, but can also reduce the length of hospital stay and costs and improve rehabilitation and patient satisfaction [5].

Opioids are effective for acute postoperative pain, but they have numerous adverse effects (eg, respiratory depression and nausea), especially in older patients. In addition, the use of excessive opioids may pose a risk of opioid addiction [6]. Despite encouraging results and rapid recovery after the use of perioperative local infiltration analgesia and nerve block agents, pain management can be further optimized [7]. Therefore, effective multimodal pain management in the early postoperative period is essential for anesthesiologists.

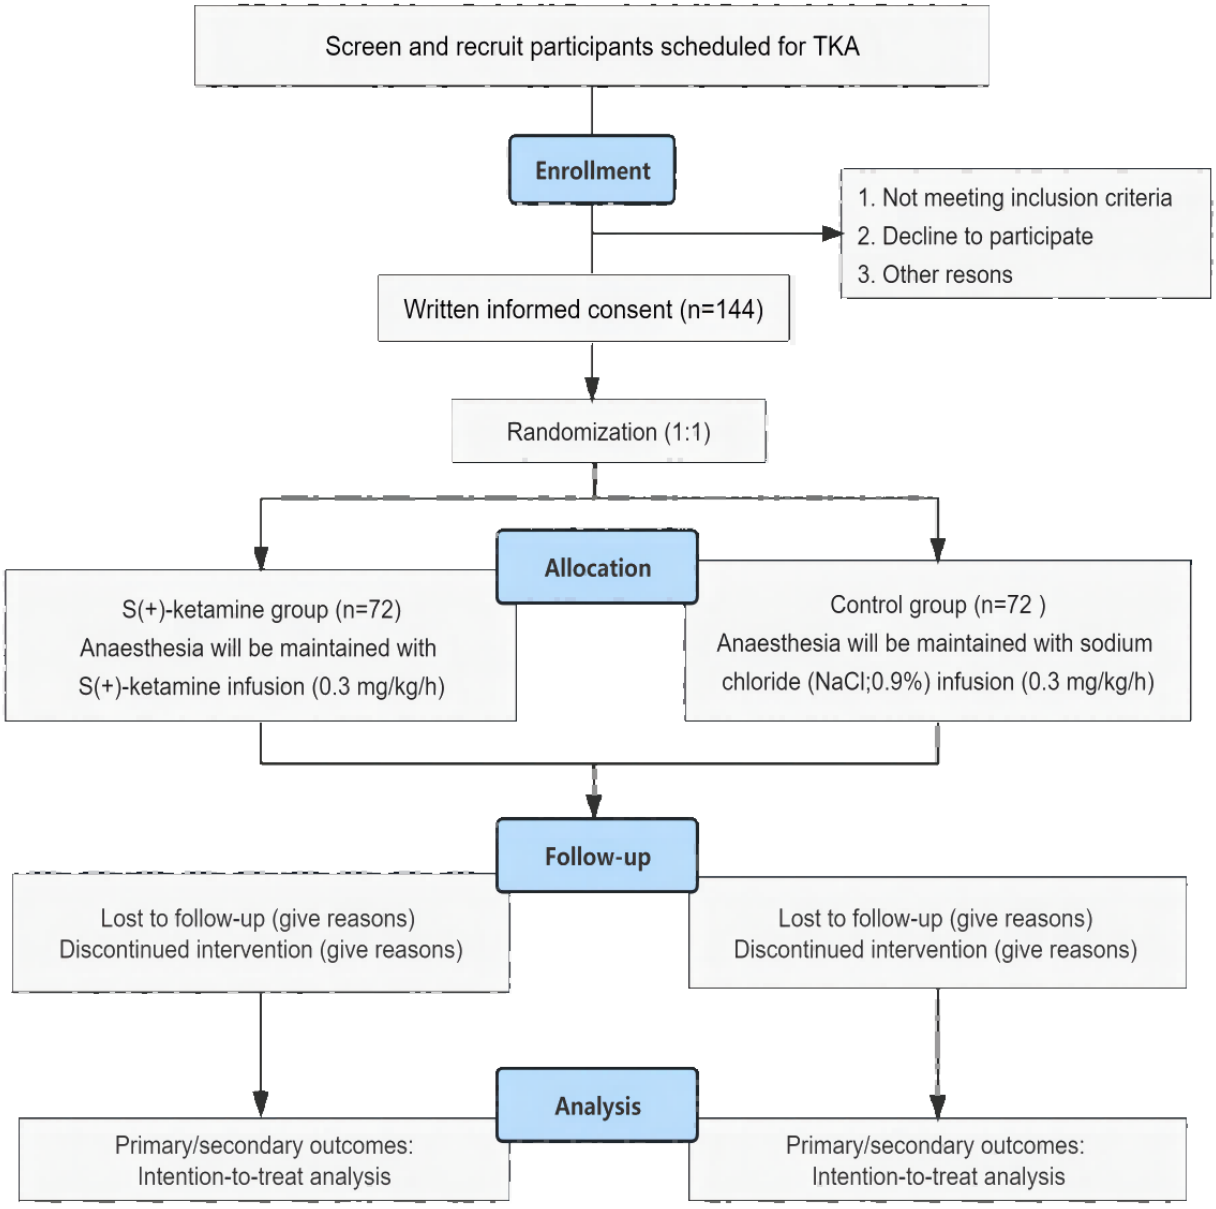
Ketamine has been widely used in anesthesia to relieve postoperative pain. It mainly acts on the N-methyl-D-aspartate (NMDA) receptor to produce sedative, analgesic, and anesthetic effects [8,9]. S(+)-ketamine is an effective S-enantiomer of racemic ketamine with a greater affinity than ketamine (approximately 2- to 4-fold) for NMDA receptors, thereby producing stronger sedative and analgesic effects and fewer adverse events, and it has been used to prevent central sensitization [10-13]. Opioids, such as remifentanil, may lead to hyperalgesia and more analgesic requirements. A clinical study showed that IV ketamine improved the analgesic effect of fentanyl and lessened hyperalgesia [14].

Aggressive management of TKA pain has multiple benefits, such as shortening the length of hospital stay, preventing postoperative complications, and accelerating patient recovery [15]. Therefore, S(+)-ketamine requires further investigation, and the following questions must be addressed: What is the ideal dosage of S(+)-ketamine infusion for the prevention of postoperative acute pain? Can older patients experience a beneficial effect after surgery? To answer these questions, a randomized, controlled, clinical study was designed to observe the analgesic effect of intraoperative intravenous administration of a lower dose of S(+)-ketamine (0.3 mg/kg/h) in older patients after TKA surgery.

Methods

Objective and Trial Design

This clinical study was designed to observe the analgesic effect of a lower intravenous dose of S(+)-ketamine (0.3 mg/kg/h) in patients after TKA surgery.



This is a single-center, randomized, single-blind, controlled, clinical trial in older patients undergoing TKA under general anesthesia. Eligible patients will be randomized to receive S(+)-ketamine (n=72) or a placebo equivalent, 0.9% sodium chloride (n=72), in a ratio of 1:1. Patients will be randomized using a computer-generated list. The anesthetist nurse and the pharmacist will not be blinded and will not partake in the following research, but the follow-up evaluators will be blinded in the trial.

Recruitment and Study Setting

A researcher with a detailed understanding of the study protocol (ie, study objective, inclusion and exclusion criteria, and benefits and risks for patients) will present the protocol to the patients and answer any questions in a concise and comprehensive manner. All patients are required to provide written consent before surgery (Figure 1).

XSL•FO
RenderX

Figure 1. Consolidated standards of reporting trials flow diagram describing patient progress throughout the study. TKA: total knee arthroplasty.

Inclusion Criteria

The inclusion criteria include patients who have an American Society of Anesthesiologists physical status of I-III; understand the study in detail and voluntarily sign the informed consent form; are to be treated with TKA surgery under general anesthesia; are 65 years or older, regardless of sex; can communicate normally; have no contraindications to drugs, such as midazolam, fentanyl, and S(+)-ketamine; and have a body mass index between 18 kg/m^2 and 30 kg/m^2.

Exclusion Criteria

The exclusion criteria include patients who have increased intracranial or intraocular pressure, severe hypertension, severe psychiatric disease and mental system diseases, severe respiratory diseases, hyperthyroidism, liver or kidney dysfunction, or an allergy to midazolam, fentanyl, or S(+)-ketamine; are unwilling to participate in the study; or misuse alcohol or drugs.

Intervention

Preanesthetic Preparation

An experienced anesthesiologist will participate in the management of the entire perioperative period. Patients will be randomly assigned to the intravenous S(+)-ketamine intervention group or placebo equivalent (0.9% sodium chloride) control group. All patients will be continuously monitored with pulse oximetry, noninvasive blood pressure, and electrocardiogram. General anesthesia induction will be provided after saphenous nerve block is performed with 0.375% ropivacaine (20 ml) by ultrasound guidance.

XSL•FO
RenderX

Induction and Maintenance of Anesthesia

All patients will undergo anesthetic induction administered by an experienced anesthesiologist per the protocol using dexamethasone (10 mg), midazolam (0.01-0.05 mg/kg), sufentanil (0.2-0.4 μg/kg), etomidate (0.15-0.3 mg/kg), and atracurium (0.3-0.6 mg/kg). A laryngeal mask airway will be inserted followed by muscle effective relaxation. Patients in both groups will be given ondansetron hydrochloride (8 mg) intravenously during anesthesia induction to prevent postoperative nausea and vomiting.

For patients in the S(+)-ketamine group, anesthesia will be maintained with S(+)-ketamine infusion (0.3 mg/kg/h), sedation will be maintained with propofol infusion (4-12 mg/kg/h), and analgesia will be maintained with remifentanil (0.15-0.3 μg/kg/min). The sufentanil dose at induction and the rate of intraoperative remifentanil and propofol infusions are at the discretion of the anesthesiologist in charge of the patient. The assessment of the depth of anesthesia will be based on clinical evaluation. S(+)-ketamine infusion will be stopped 15 minutes before the end of surgery. Propofol and remifentanil infusion will be stopped at the end of surgery. For the control group, other procedures will be consistent; however, S(+)-ketamine (0.3 mg/kg/h) will be replaced by intravenous sodium chloride (0.9%) infusion (0.3 mg/kg/h).

Intraoperative Management

Hypertension will be defined as an intraoperative systolic blood pressure exceeding 20% from the baseline value, and hypotension will be defined as 20% of the baseline value. Norepinephrine should be administered if the patient has hypotension and a heart rate (HR) >90 beats per minute; dopamine should be administered when the patient has hypotension and an HR <50 beats per minute; urapidil hydrochloride should be administered if the patient has hypertension and their HR is normal; and atropine should be administered if the patient has normal blood pressure and a HR <50 beats per minute. The dosages are to be determined by the patient's sensitivity to drugs to maintain stable circulation.

Outcome Measures

Primary Outcome Measure

The primary outcome is the numeric rating scale (NRS) score at rest and during movement 24 hours after surgery in the surgical ward. The NRS is widely used to assess pain intensity after surgery. The NRS is evaluated on an 11-point scale (no pain: NRS=0; mild pain: 0<NRS<4; moderate pain: 4≤NRS<7; severe pain: 7≤NRS<10; worst pain imaginable: NRS=10).

Secondary Outcome Measures

The secondary outcomes are as follows:

1. The NRS score at rest and during movement at 2 hours after surgery.

2. The NRS score at rest and during movement at 48 hours after surgery.

3. The cumulative consumption of opioids, such as pethidine, sufentanil, and morphine, during the first 48 hours after the operation.

4. The number of patients who required additional analgesics, such as opioids (pethidine, sufentanil, or morphine) or nonsteroid anti-inflammatory drugs (acetaminophen or diclofenac) during the first 48 hours after the operation.

5. The total consumption of opioids (pethidine, sufentanil, and morphine) or nonsteroid anti-inflammatory drugs (acetaminophen and diclofenac) during the first 48 hours after the operation.

6. The incidence of nausea and vomiting and adverse central nervous system events at 2, 24, and 48 hours after the operation.

The use of rescue analgesic drugs (types, administration times, and doses) and any adverse side effects (yes or no) will be recorded.

Participant Timeline

The participant timeline is shown in Table 1.

[c]Opioids included pethidine, sufentanil, or morphine.

Safety

The main adverse effects of S(+)-ketamine alone are neuropsychiatric symptoms, such as dizziness. Therefore, S(+)-ketamine is usually used with midazolam and propofol to decrease its psychoactive effects. All adverse events related to this research will be investigated and recorded by research personnel from the time patients sign the informed consent to the end of follow-up. The investigator will decide whether to continue the study according to the status of the patient. Any serious adverse events will be treated with appropriate interventions and submitted to the principal researcher and the Medical Ethics Committee within 24 hours.

Ethical Considerations

This study has been approved by the Medical Ethics Committee of the First Affiliated Hospital of Shandong First Medical University under approval number YXLL-KY-2021 (077) and will be performed in accordance with the approved guidelines and regulations of the participating institutions. The study was registered at ClinicalTrials.gov (NCT05289050) on February 26, 2022. Informed written consent will be obtained from all patients before inclusion in the study. Because the involvement of the patients is voluntary, the study can be stopped at any time.

Data Management

The basic information of the patients before surgery and the dosage of drugs used during the operation will be collected by the anesthesiologists participating in surgical anesthesia, and the follow-up data after surgery will be provided by independent researchers. Each data point related to the study will be entered into the case report form to improve data completeness and accuracy, and electronic data will be collected and analyzed by statisticians. All the clinical trial materials will be stored securely.

Statistics

The SD will be described for measurement data that follow a normal distribution, and the median (IQR) will be described for measurement data that do not conform to a normal distribution. The student *t* test will be used to compare continuous and normally distributed variables, and the Mann-Whitney U test will be used to compare nonnormally distributed variables. Counts (percentages) will be described for categorical variables using χ^2 analysis or Fisher exact tests for compilation.

Both primary and secondary outcomes will be based on an intention to treat analysis. SPSS 22.0 software (IBM) will be used for statistical analysis, and a P value of <.05 will be considered to be statistically significant.

XSL•FO
RenderX

Sample Size

The minimum clinically important difference (MCID) can be used to guide the noninferiority margin for clinical trials and to determine the sample size in a clinical trial [16,17]. The NRS pain score ranges from 0 (no pain) to 10 (worst pain imaginable). The MCID for the NRS that was used for the calculation of the study sample size was 1.3; however, some studies suggest that an MCID of 1.5 or 2 is appropriate [18-20]. The sample size would have been too small if we choose an MCID of 2. Considering a 10% withdrawal or dropout rate, a sample size of 72 patients per group was calculated, with a power of 80%. The MCID determined 1.5 as statistically significant, with an SD of 3 at the 5% bilateral significance level.

Results

The protocol was registered at ClinicalTrials.gov (NCT05289050) on February 26, 2022. It was performed in accordance with the approved guidelines and regulations of the participating institutions. Recruitment began in April 2022. Data collection is expected to conclude in September 2024. Study completion is expected in December 2024. As of December 2023, we have enrolled 132 patients.

Discussion

TKA is increasingly performed in geriatric patients to cure pain, deformation, and the inability to walk normally caused by knee arthritis. The total number of TKA procedures may increase by 401% in 2040 compared to that in 2014 [21]. Poor management of acute pain after TKA increases the risk of complications, such as venous thrombosis, an inability to exercise effectively, and pneumonia. Currently, there is a consensus that inadequate postoperative pain control measures are being implemented, especially in older patients. Opioids are the main treatment for relieving TKA postoperative pain [22]. Considering the side effects of opioids, appropriate multimodal medication projects are required to decrease postoperative opioid use and improve effects with decreasing pain levels in geriatric patients. Ketamine can suppress the pathway of central sensitization and secondary postoperative hyperalgesia and has been proposed as a component of multimodal analgesia for various surgical procedures [23]. Ketamine in subanaesthetic doses is available as an adjuvant to the standard regimen of opioids, presenting prominent analgesic and opioid-sparing effects without adverse effects [24]. Some studies have shown that low-doses of S(+)-ketamine can reduce the incidence of side effects (eg, the induction of hypotension) and high doses of opioids through its sympathetic stimulation, analgesia, and antagonism of the NMDA receptor [25,26]. Similarly, a meta-analysis demonstrated that the administration of low-dose ketamine can decrease total opioid use and pain scores over 2 days and may also reduce postoperative nausea and vomiting. This has been attributed to reductions in total opioid administration, leading to decreased opioid-associated nausea and vomiting [27,28]. Another meta-analysis demonstrated that perioperative intravenous ketamine reduced postoperative opioid consumption by 8 mg morphine equivalents per day [29].

Additional studies have demonstrated that a low-dose intravenous infusion of ketamine can be administered as an adjuvant drug to alleviate acute postoperative pain, while the guidelines for ketamine for postoperative acute pain have found grade B evidence to advocate perioperative ketamine as an adjuvant [15,30].

Although low-dose S(+)-ketamine has been shown to be beneficial in pain management after various surgeries, there is no consensus regarding the effectiveness of an S(+)-ketamine analgesic combined with opioids in older patients with knee arthroplasty. In addition, the appropriate administration duration and dose of S(+)-ketamine to achieve pain relief in older patients are unknown. A randomized controlled trial will be conducted to assess the efficacy and safety of an intraoperative intravenous low-dose of S(+)-ketamine for pain management in older patients undergoing TKA.

The design of our protocol has several limitations. First, this is a single-center study with a relatively small sample size, and only older patients undergoing TKA will be enrolled, which limits the generalizability of our outcomes. Second, the end of our follow-up is 48 hours postoperatively. A longer follow-up is necessary to demonstrate the long-term effects and safety of S(+)-ketamine.

In conclusion, we will appraise the efficacy and safety of the intraoperative intravenous injection of S(+)-ketamine to relieve acute pain after TKA in older patients who may benefit from the administration of S(+)-ketamine.

Acknowledgments

The authors thank the staff of the Department of Anesthesiology, The First Affiliated Hospital of Shandong First Medical University for their support in this study. The trial was initiated and planned by the researchers and funded by the 2021 Shandong Medical Association Comfort Medical Treatment anesthesia optimization special fund.

Data Availability

The data sets used or analyzed during the trial will be made available from the corresponding author on reasonable request.

Abstract

Background: Chronic insomnia (CI) is a mind-body disease that is commonly defined as a state of having disturbed daytime activities due to poor nighttime sleep quality. Baduanjin qigong (BDJQG) is widely used for CI in China. However, there is little scientific evidence to evaluate its effects on the hyperarousal state, which is closely associated with improved sleep quality.

Objective: The objective of the trial is to assess the therapeutic effects of BDJQG on sleep quality in patients with CI.

Methods: A randomized controlled trial will be conducted on 86 patients, who will be divided into a BDJQG group and a cognitive behavioral therapy for insomnia group at a ratio of 1:1. Interventions in both groups will be given to the participants 7 times a week for 8 weeks, and the participants will be followed up for 4 weeks. The primary outcome is the change in the Pittsburgh Sleep Quality Index from baseline to week 8. The secondary outcomes are the changes in the Hyperarousal Scale, Insomnia Severity Index, Fatigue Scale-14, wrist actigraphy, salivary cortisol level, and functional magnetic resonance imaging from baseline to week 8. All main analyses will be carried out on the basis of the intention-to-treat principle.

Results: This study was funded from January 2023. As of the submission of the manuscript, there were 86 participants. Data collection began in April 2023 and will end in January 2024. Data analysis is expected to begin in January 2024, with the publication of results expected in February 2024.

Conclusions: This study will present data concerning the clinical effects of BDJQG on CI. The results will help to demonstrate whether BDJQG is an effective therapy for improving sleep quality in association with a decreased hyperarousal level as a possible underlying mechanism. This study will provide much-needed knowledge for complementary and alternative therapy for patients with CI.

Introduction

Chronic insomnia (CI) is the most common clinical sleep disorder. It is characterized by persistent challenges in initiating or maintaining sleep; suboptimal sleep quality; and impairments in daytime functioning, including fatigue, attention deficit, and emotional instability [1]. The prevalence of CI in the general population varies between 9% and 12%, with transient insomnia symptoms reported by 22% to 35% of individuals [2]. The widely recognized classification framework for sleep disorders, the *International Classification of Sleep Disorders, Third Edition*, stipulates specific criteria for diagnosing CI. Specifically, the diagnosis of CI necessitates the presence of insomnia symptoms for a minimum duration of 3 months, with no fewer than 3 associated symptoms, which may encompass manifestations such as fatigue, irritability, and compromised work, school, or social performance [3]. While CI is classified as a sleep disorder, its pathophysiological underpinnings suggest a prevailing state of hyperarousal during both sleep and wakefulness phases [4]. Evidence of the hyperarousal phenomenon in individuals with insomnia encompasses elevated levels of cortisol and adrenocorticotropic hormone during the initial stages of sleep and discernible thalamic responses determined through functional magnetic resonance imaging (fMRI) [5].

Several pharmaceutical agents, including benzodiazepines, benzodiazepine agonists, and certain antidepressants, have demonstrated efficacy in the short-term management of insomnia [6]. However, these pharmacological interventions carry inherent risks related to the sedative properties. The risks encompass an elevated propensity for falls; cognitive confusion; and the potential for the development of tolerance, dependence, and withdrawal effects when used for extended periods [7]. Cognitive behavioral therapy for insomnia (CBTI), regarded as the first-line treatment for insomnia, has proven its effectiveness in addressing CI in adults. It consistently ameliorates clinical symptoms associated with insomnia, producing clinically meaningful effects [8]. Nevertheless, the accessibility of CBTI remains challenging for patients, primarily due to the limited availability of specialized practitioners, which hinders its ability to adequately meet clinical demands [9]. Several complementary and alternative medicine modalities, including traditional Chinese herbal medicine [10], acupuncture [11], and qigong, have exhibited efficacy in the treatment and prevention of insomnia, effectively mitigating symptoms such as fatigue and depression.

Qigong is a component of traditional Chinese medicine characterized by its integrated approach, involving breath control, physical movement, and meditation techniques. Notably, extant research has furnished evidence supporting the beneficial effect of qigong on various facets of health among individuals with insomnia, including the enhancement of sleep quality [12,13], alleviation of symptoms related to anxiety and depression [14,15], and modification of sleep-wake patterns as corroborated by actigraphy assessments [16].

The nomenclature “Baduanjin qigong” (BDJQG) was first documented in *Yi Jian Zhi* by Hong Mai during the Northern Song Dynasty, indicating that this mind-body practice has a history spanning over 800 years [17]. This modality is renowned for its holistic approach, characterized by facilitating overall coordination, unblocking meridians, harmonizing the mind and body, and assisting the body in achieving a relative equilibrium between the yin and yang elements. The safety and efficacy of BDJQG have garnered empirical support through numerous clinical trials, rendering it a widely embraced therapeutic approach for diverse chronic ailments [18-20]. For example, an illustrative meta-analysis has indicated that BDJQG, particularly when integrated with mindfulness techniques, is effective in alleviating musculoskeletal pain and enhancing the overall sleep quality in individuals with chronic conditions [21]. Furthermore, BDJQG comprises 8 distinct movements that are easy to learn. If its efficacy is proven, its wider use could be promoted.

Previous investigations into insomnia treatment have primarily centered on enhancing sleep quality but have often overlooked the assessment of daytime functioning. In contrast, our previous research findings suggested that qigong exhibits efficacy both in ameliorating sleep quality and in enhancing daytime functioning [22].

Remarkably, assessments of the hyperarousal state have been conspicuously scarce in previous trials. In this study, we intend to comprehensively evaluate hyperarousal from a multidimensional perspective, encompassing cognitive functions (evaluated through the Hyperarousal Scale [HAS]), cortical activities (scrutinized through fMRI), and hypothalamic-pituitary-adrenocortical (HPA) axis functioning. Salivary cortisol level (SCL), known to correlate with various sleep parameters [23], will be measured, given that hyperarousal in insomnia is associated with heightened cortisol secretion. Previous empirical evidence has directly indicated that BDJQG may induce changes such as increased melatonin levels and decreased cortisol levels, which are indicative of reduced wakefulness-related factors [24]. These physiological markers will be meticulously monitored as potential indicators of BDJQG’s effect on the HPA axis.

Building upon the insights gleaned from previous research and considering the plausible role of BDJQG in attenuating hyperarousal, we have formulated a randomized, open-label, parallel-controlled trial to systematically investigate the therapeutic efficacy of BDJQG concerning both sleep quality and hyperarousal state in individuals with CI.

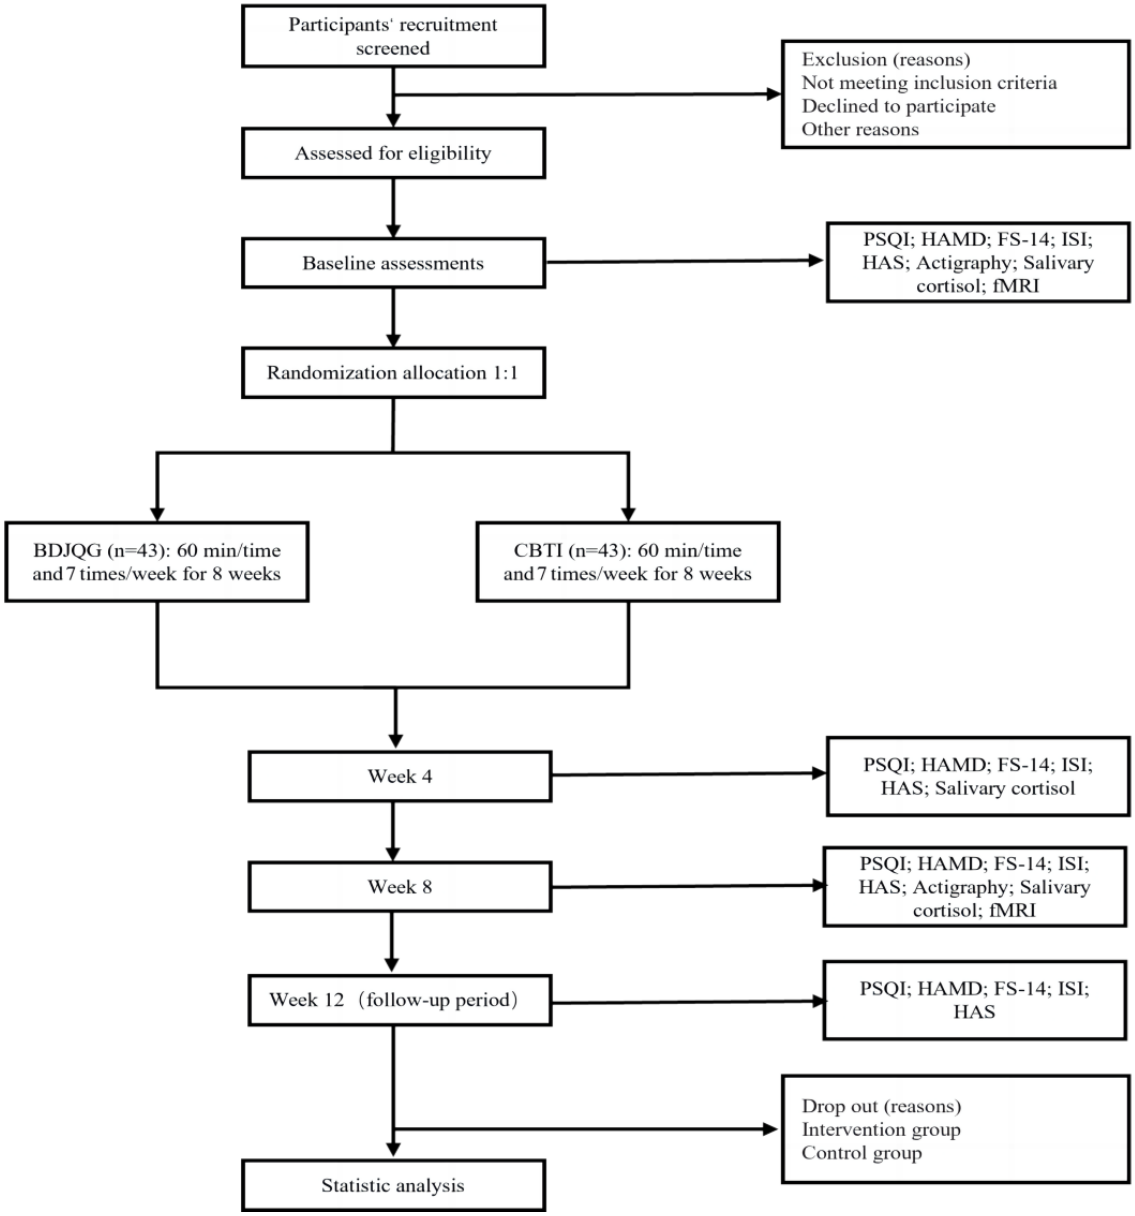
Methods

Aims and Study Design

The primary objectives of this open-label, parallel, noninferiority randomized controlled trial (RCT) will be 2-fold:

1. To ascertain whether BDJQG can yield improvements in the primary outcome, which is sleep quality, and the secondary outcomes, encompassing an array of measures spanning various domains, including hyperarousal state, severity of insomnia, and levels of fatigue. These improvements will be evaluated in comparison to CBTI.
2. To explore the potential efficacy of BDJQG as a therapeutic intervention for CI and its potential association with a

XSL•FO
RenderX



reduction in hyperarousal levels, which may serve as an underlying mechanistic pathway. This exploration will be facilitated through correlation analyses.

Study Setting

Participants will be recruited from the Shanghai Municipal Hospital of Traditional Chinese Medicine. Eligibility for inclusion will be determined by 2 orthopedic surgeons based on predefined inclusion and exclusion criteria. Participants who are determined to be eligible and provide written informed consent will be randomly allocated to either the BDJQG group or the CBTI group in a 1:1 ratio. The BDJQG group will undergo BDJQG treatment, while the CBTI group will receive cognitive behavioral therapy for insomnia. Both groups will undergo an 8-week-long treatment program, consisting of 1 supervised session per week at Shanghai University of Traditional Chinese Medicine and the remaining 6 days of the week completed at home. The study will span a total of 13 weeks, comprising a 1-week-long screening period, an 8-week-long treatment phase, and a subsequent 4-week-long follow-up period.

Assessments using various scales will be conducted at baseline, the 4-week intervention mark, the 8-week intervention mark, and the 4-week follow-up. SCL will be measured at baseline, the 4-week intervention mark, and the 8-week intervention mark. Actigraphy and fMRI assessments will be administered at baseline and the 8-week intervention mark. Figure 1 gives a visual representation of the research process, and Table 1 shows an overview of the study's time points.

Participants' Eligibility Criteria

Textbox 1 shows the inclusion, exclusion, and withdrawal criteria.

XSL•FO
RenderX

Textbox 1. Inclusion, exclusion, and withdrawal criteria.

Inclusion criteria

Participants meeting the following criteria will be included:

- Chronic insomnia based on established diagnostic criteria (*International Classification of Sleep Disorders, Third Edition*), including a report of sleep initiation or maintenance problems, adequate opportunity and circumstances to sleep, daytime consequences, and duration of at least 3 months, with a frequency of at least 3 times per week
- Insomnia Severity Index score between 8 and 21
- Age between 20 and 55 years and male or female sex
- Hamilton Depression Scale score ≤14
- No treatments for insomnia, including medication and acupuncture, received during the past month
- Right-handedness
- Understanding the process of this study and agreeing to participate and sign the consent form

Exclusion criteria

Participants meeting any of the following criteria will be excluded:

- Severe pain or systemic diseases (endocrine system diseases, motor system diseases, autoimmune diseases, infectious diseases, and metabolic diseases such as diabetes mellitus) that affect sleep
- History of metal, head surgery, and implantation of any metal or other contraindications for functional magnetic resonance imaging
- Insufficient language skills and mobility to perform Baduanjin qigong
- Major depressive disorder, anxiety disorder, panic disorder, or other mental disorders, and alcohol or caffeine addiction
- Pregnancy, breastfeeding, or planning to become pregnant

Withdrawal criteria

Participants meeting the following criteria will be excluded after the start of the trial:

- Occurrence of an adverse event related to the research
- Participant's personal request

Interventions

The two arms of the trial are (1) the intervention arm (BDJQG) and (2) the control arm (CBTI).

Intervention Arm (BDJQG Group)

BDJQG consists of 8 forms, which are shown in Multimedia Appendix 1. A qigong teacher from Shanghai University of Traditional Chinese Medicine, who has been involved in qigong education for at least 5 years, will be in charge of the concentrated supervision of the exercise and correction of the exercise posture for 1 hour every Sunday throughout the intervention period. The teacher will first lead a 5-minute stretching and relaxation exercise session to be done before the qigong exercise; and they will then introduce and demonstrate each movement, explain precautions, and answer the participants' questions for 5 minutes. Then, the teacher will give individual guidance to each participant by correcting their movements. This will last for 30 minutes. Finally, all participants will be told to practice qigong together for 20 minutes. The participants will be asked to practice at home for 30 minutes on the remaining 6 days of the week, to practice on WeChat (Tencent) cluster video at 6 PM daily, and to practice under video supervision. Private video surveillance will be carried out if this is deemed appropriate by an individual participant. A "practice log" will be distributed, to be filled in after each exercise. The entire treatment will last for 8 weeks. The BDJQG intervention will be in line with the descriptions provided in the study by Xie et al [25].

Control Arm (CBTI Group)

The CBTI protocols used in this study are based on the comprehensive guide titled *Cognitive Behavioral Treatment of Insomnia: A Session-by-Session Guide* [26]. The participants assigned to the CBTI group will undergo an 8-week-long cognitive behavioral therapy program for insomnia, guided by an experienced psychotherapist, with each session spanning 1 hour and occurring weekly. Additionally, the participants will be provided with a "practice log" to document their activities and progress after each video session.

Follow-Up Period

An 8-week-long follow-up will be conducted subsequent to the conclusion of the trial, during which the participants will resume their regular lifestyles. However, it is imperative that all of the participants maintain a record of their daily exercise or study activities. To facilitate this, WeChat will be used as a platform for the participants to periodically capture and share photos, providing the researchers with a comprehensive account of their daily exercise or study routines. Upon the culmination of the follow-up period, a reassessment of several metrics, including the Pittsburgh Sleep Quality Index (PSQI), Insomnia Severity

XSL•FO
RenderX

Index (ISI), HAS, and Fatigue Scale-14 (FS-14), will be conducted. The objective of this follow-up assessment is to evaluate the enduring or long-term effects of BDJQG on individuals with insomnia, as elucidated in a study conducted by Guan et al [27].

Quality Control

The specific movements and the corresponding intensity levels used in the BDJQG regimen will be meticulously tailored to individual prescriptions, with variations designed to minimize disparities. Preceding the commencement of the experimental phase, each participant will undergo a structured training program spanning 3 days, administered by a traditional Chinese medicine practitioner with a minimum of 5 years of clinical experience. This training regimen is intended to impart standardized BDJQG movements to ensure uniformity and precision among the participants.

Outcomes

Primary Outcome (PSQI)

The primary outcome is the change in PSQI from baseline to week 8. The PSQI is a comprehensive self-report instrument comprising 19 items aimed at evaluating sleep quality and disturbances experienced within a 1-month time frame. These items collectively contribute to the generation of 7 distinct "component" scores, encompassing assessments of subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medication, and daytime dysfunction. The sum of the scores derived from these 7 components yields a singular global score. The total global score spans a range from 0 to 21, with a lower global score indicative of a higher quality of sleep [28].

Secondary Outcomes

The secondary outcomes include the changes in ISI, HAS, FS-14, actigraphy, SCL, and fMRI from baseline to week 8.

ISI Instrument

The ISI is a self-report instrument encompassing 7 items intended to assess various aspects of insomnia, including the challenges associated with falling asleep and maintaining sleep, overall sleep satisfaction, daytime functioning, impaired attention attributable to sleep disturbances, the degree of distress caused by insomnia-related symptoms, and the level of preoccupation with insomnia-related concerns. Each of these aspects is evaluated on a 5-point scale. The cumulative ISI score ranges from 0 to 28 points and is categorized as follows: 0-7=absence of insomnia; 8-14=mild insomnia; 15-21=moderate insomnia; and 22-28=severe insomnia [29].

HAS Instrument

The HAS comprises 26 self-report items designed to gauge a range of cognitive and behavioral factors associated with heightened information processing, propensity for introspection, tendencies to engage in deep emotional reflection, and heightened responsiveness to unforeseen stimuli, all of which are postulated to be indicative of cortical arousal [30]. Elevated scores on this scale are suggestive of an increased state of arousal. Consequently, the HAS serves as a valuable tool for assessing the effect of interventions on cognitive and somatic hyperarousal levels [31].

FS-14 Instrument

Fatigue is a prominent consequence of CI, as consistently documented in previous research studies [32,33]. The FS-14 is a self-report assessment tool comprising 14 items designed to capture both physical and mental aspects of fatigue. On this scale, a higher score is indicative of a more pronounced and debilitating level of fatigue.

Actigraphy

The ActiGraph GT9X Link (Actigraphy LLC) will be worn on the participants' wrists to record sleep quality by noting sleep awakenings, total sleep time, sleep onset, sleep latency, and efficiency of sleep. Subsequent analysis of sleep conditions and sleep quality will be executed using the ActiLife6 software (version 6.8.1; Actigraphy LLC) [34]. The participants will be instructed to wear the device continuously for 3 consecutive days, both before and after the 8-week-long intervention period.

SCL Measurement

SCL will be quantified using the enzyme-linked immunosorbent assay (ELISA) methodology. Sampling will be conducted at 4 distinct time points during the day, namely upon awakening [35], 30 minutes after awakening [36], before sleep (30 minutes before bedtime) [37], and immediately before bedtime [38] (with the timing adjusted to fall within the range of 9 PM to 1 AM, contingent on each participant's self-selected bedtime). This collection process will be carried out during 3 distinct cycles, namely at baseline, 4 weeks, and 8 weeks.

Saliva samples will be gathered using a Salivette collection system (hygienic saliva collection; Sarstedt) [36] and stored in a –20 °C freezer until they undergo analysis using the General Cortisol ELISA Kit (RK00639; ABclonal) [39]. The participants will be provided with specific instructions not to engage in eating, drinking, toothbrushing, or strenuous physical activity within the 30-minute interval preceding each saliva sampling session.

fMRI Examination Procedure

fMRI data will be acquired from all of the participants using a 3.0-T Trio Siemens System (SIEMENS AG) at the Yueyang Hospital of Integrated Traditional Chinese and Western Medicine affiliated with the Shanghai University of Traditional Chinese Medicine, Shanghai, China. A total of 30 participants will be scanned under the following conditions: repetition time=1900 ms; effective echo times=2.93 ms; sagittal slices=188; thickness/skip=1.2/0.6 mm; field of view=256 × 256 mm^2; matrix=240 × 256 mm^2; voxel size=1.0 × 1.0 × 1.0; phase encoding direction=A >> P; and flip angle=90°. The participants will be requested to rest for 10 minutes with their eyes closed, and they will be requested not to think about anything before the scan. They will be asked not to move the head during data acquisition. We will acquire 242 3D image volumes with the following parameters: repetition time=2000 ms; effective echo times=30 ms; section thickness=1 mm; sagittal slices=32; field of view=256 × 256 mm^2; matrix=64 ×

XSL•FO
RenderX

64 mm^2; and flip angle=90°. Both groups of participants will be examined before and after treatment.

Sample Size

The following 2 hypotheses are related to the differences between the 2 groups:

- Hypothesis 1: $\mu_1 = \mu_2$
- Hypothesis 2: $\mu_1 \neq \mu_2$,

where μ_1 is the PSQI mean score of the 8-week treatment in the BDJQG group, and μ_2 is the PSQI mean score of the 8-week treatment in the CBTI group.

The required sample size has been calculated using an estimation formula based on the difference between 2 sample means and SDs (PSQI, which is assessed using composite points of sleep quality). Therefore, in a study with this sample size, the difference between the BDJQG group and the CBTI group will be considered, and the conservative comparison method by Bonferroni will be adopted. In this study, it is expected that the BDJQG group will be 1.78 points better than the CBTI group in the PSQI scale mean score. The final calculated difference and SD of the 2 groups of the PSQI mean scores were calculated [40]. On the basis of 0.9 power to detect a significant difference (α=.025; 1-sided), 34 participants will be required for each group.

The following formula was used to calculate the sample size in this trial:

Given that an attrition rate of ~20% is anticipated, our target enrollment will be 43. Therefore, a total of 86 participants should be recruited for this RCT.

Recruitment

To attain the requisite participant enrollment necessary to achieve our predetermined target sample size, recruitment will be conducted within the Shanghai area. These endeavors will encompass the dissemination of recruitment materials through posters, promotion through WeChat public accounts, engagement with individuals attending outpatient clinics, and outreach to those using medical examination centers.

Randomization and Blinding

Following a postbaseline assessment, the eligible participants will be randomly allocated to the BDJQG group and the CBTI group, adhering to a 1:1 equal proportion allocation. A randomization list will be meticulously generated by a skilled statistician using a computer program (Strategic Applications Software, version 9.1.3; SAS Institute Inc). The generated random sequences will be sequentially numbered by the statistician, who serves as the architect of the randomization sequence. Subsequently, the sequences will be placed within opaque envelopes by a designated project manager, uninvolved in the recruitment process. These sealed envelopes will ultimately be delivered to the research team.

Before implementing the random assignment procedure, the research team will diligently record the particulars of each participant at the clinical center. These records will encompass the participant's information, such as name, date of birth, participant and center codes, and the inclusion date. Following a meticulous review of the participant's information by the research team to ascertain eligibility, a sequence will be randomly drawn from the envelope. The selected sequence will be applied to label the participant's data, designating the participant's assignment to one of the study groups. This information will then be conveyed to the respective participants.

It is noteworthy that, due to the specific nature of the intervention approach, this study is an open trial, with only the statistical analysis experts being kept blinded, as delineated in the research conducted by Cheng et al [41].

Adverse Events and Assessment of Safety

Adverse events (AEs) encompass any untoward and nonsignificant occurrences, namely abnormal experimental findings, symptoms, or illnesses that transpire during the course of the study, irrespective of their causal relation to the intervention. It is important to note that numerous authors have attested to the relative safety of qigong as an approach to addressing various health conditions, including hypertension, with no records of severe AEs. In the event of any unexpected AEs, categorized as functional abnormalities brought about by the intervention, such as symptoms like headache, dizziness, vertigo, head distension, tinnitus, chest tightness, aggravated shortness of breath, heart palpitations, muscular soreness or pain, profuse cold perspiration, irritability, neurasthenia, hallucinations, paranoia, or psychological stress—regardless of their treatment association—prompt notification will be made to the nearest affiliated Shuguang Hospital physician. The physician will then conduct an assessment and initiate appropriate medical intervention.

In instances where serious AEs are encountered, the investigator will promptly report the incident to the primary investigator and the ethics committee to collectively determine whether the affected participant should be withdrawn from the study and the associated treatment. The investigator will earnestly strive to avert and manage any potential harm that may arise during the course of the study. If, following the assessment by the expert committee, the AE is determined to be linked to the qigong treatment, the research team will assume responsibility for covering the cost of treatment and providing appropriate financial compensation for any damage arising from the trial. This comprehensive approach to describing AEs and ensuring the assessment of safety closely adheres to the framework delineated in the study conducted by Guan et al [27].

Data Management and Monitoring

Upon recruitment, the participants' identities will be replaced with numerical codes to safeguard their privacy. Data collection will be conducted at baseline, week 4, and week 8. This process will entail the involvement of 2 proficient data specialists who will be responsible for transcribing the paper-based records into a unified database while meticulously verifying the accuracy of the entered data. Ultimately, both the paper records and encrypted electronic files will be securely stored and redundantly backed up by the research leader. These records will be retained

XSL•FO
RenderX

in storage for a period of 3 years following the conclusion of the study.

The oversight of the study will be carried out under the purview of the ethics committee of the Shanghai Municipal Hospital of Traditional Chinese Medicine. Importantly, the members of this committee have been carefully vetted to ensure they possess no conflicts of interest pertaining to this study. The principal investigators will retain unfettered access to all study results and will have the final authority to decide on the termination of the study. Furthermore, they will extend the privilege to project team members to disseminate the trial's findings through the publication of research papers.

Statistical Analysis

The collected data will meticulously be entered into Microsoft Excel (Microsoft Corporation), and subsequent statistical analysis will be conducted using SPSS software (version 18.0; SPSS Inc). Continuous variables will be summarized using the mean value and SD, with the median and IQR used for variables exhibiting nonnormal distributions. Categorical variables will be presented as frequencies or percentages.

For within-group comparisons, paired 2-tailed *t* tests will be used. Between-group differences will be analyzed through 2-sample, independent-sample *t* tests, with effect sizes computed using Cohen *d* statistics. Furthermore, demographic characteristics, baseline measurements, and changes in measurements from baseline to study completion between the 2 groups will be analyzed using 2-sample, independent-sample *t* tests. In cases where baseline measurements exhibit disparities, analysis of covariance will be implemented to account for these variations when comparing the 2 groups.

The clinical overall efficacy evaluation will be based on a nonparametric test for 2 independent samples. In instances of limited participant numbers within a specific subject or in the presence of missing data, the Mann-Whitney *U* test will be used to assess differences between the groups. A statistical significance level of $P<.05$ will be used, signifying statistical significance when this threshold is met.

Ethical Considerations

This study will adhere to the principles outlined in the Declaration of Helsinki, ensuring that no additional harm or risks are imposed on the participants. The study has been meticulously designed in compliance with the Standardized Protocol Items, encompassing the recommendations for interventional trials (SPIRIT [Standard Protocol Items: Recommendations for Interventional Trials]) checklist, and has received approval from the ethics committee of Shanghai Municipal Hospital of Traditional Chinese Medicine (2023SHL-KY-17-01). Furthermore, the study has been duly registered in the Chinese Clinical Trials Registry in 2023 (ChiCTR2300069241). The information presented in this report is derived from protocol version 1.0. Before the commencement of the trial, the participants will undergo a comprehensive orientation session regarding the study protocol and their associated responsibilities. This briefing will encompass a detailed explanation of the required physical examinations and relevant precautions. Of paramount importance, the participants will be unequivocally apprised that their engagement in the study is entirely voluntary, and they retain the prerogative to decline participation or withdraw at any juncture without any impact on their medical care or other associated benefits. Notably, if a participant opts to withdraw from the study, any previously collected data will remain intact and be incorporated into the final analysis. To initiate any study-related interventions, explicit written informed consent will be diligently obtained from each participant. A designated research assistant will be entrusted with the responsibility of securing informed consent from all participants. Separate informed consent forms have been developed for the collection of magnetic resonance imaging and saliva samples. Furthermore, all participants will be asked for their consent for the potential publication of identifying information or images within an internet-based open publication, in accordance with established ethical guidelines. The study data will be anonymous or deidentified. Upon the conclusion of the study, the patients will be extended an invitation to continue their 4-week follow-up period at the Shanghai University of Traditional Chinese Medicine, located in Shanghai, China. The 8-week BDJQG program is an enduring initiative, and the participants will maintain their eligibility to engage in this program. Should they desire to do so, the participants can opt to attend BDJQG or CBTI classes free of charge following the culmination of their participation in the study. As an additional incentive to bolster follow-up participation, the participants will be furnished with a large gift pack that will include specialized topical pain patches, a wellness pot, and ¥300 (US $41.98) at the conclusion of the follow-up evaluation. This provision is aimed at enhancing their enthusiasm for continued participation in the follow-up phase.

Results

This study was funded from January 2023. As of the submission of the manuscript, there were 86 participants. Data collection began in April 2023 and will end in January 2024. Data analysis is expected to begin in January 2024, with the publication of results expected in February 2024.

Discussion

Overview

The impact of insomnia extends beyond individual challenges, significantly affecting both personal and societal domains, encompassing physical and mental health, social progress, and economic facets. Regrettably, despite its considerable debilitating effects, effective treatments for insomnia have remained elusive. Moreover, there is limited application of evidence-based interventions aimed at alleviating symptoms and enhancing patients' overall functioning. Therefore, the quest for a cost-effective and efficacious insomnia remedy is of paramount importance. Numerous studies have underscored the effectiveness of qigong and related therapies in ameliorating insomnia, although these investigations have primarily centered on efficacy and largely overlooked the underlying mechanisms. Furthermore, there is a scarcity of rigorous studies to affirm the clinical effects of BDJQG exercises on insomnia-induced hyperarousal.

XSL•FO
RenderX

The primary objective of this trial is to probe the efficacy of BDJQG in addressing sleep quality and hyperarousal state associated with CI. The trial's efficacy indicators will encompass both subjective and objective aspects, such as sleep duration and quality as evaluated by the PSQI and wrist actigraphy, daytime functioning as assessed by the FS-14, physiological changes linked to the HPA axis determined through cortisol level measurements, and cortical activities monitored through fMRI. This study aims to establish a connection between the effect of BDJQG on CI and its potential impact on hyperarousal state, measured across multiple dimensions. A diagram to illustrate the mechanism of change before and after the intervention is shown in Multimedia Appendix 2. This novel approach marks the first endeavor in a clinical trial of CI to explore both the clinical effects and the plausible underlying mechanisms associated with BDJQG.

fMRI serves as a vital tool to assess changes in cortical hyperarousal, a phenomenon observed in individuals with insomnia. The thalamus is the switch that controls wakefulness [42]. Patients with insomnia disorder demonstrate decreased thalamic connectivity with the left amygdala, parahippocampal gyrus, putamen, pallidum, and hippocampus across wakefulness [43]. Previous studies have shown that qigong can affect the brain response [22,44-46]. This trial strives to bridge the existing knowledge gap by combining fMRI, which investigates arousal responses spatially within the brain, with wrist actigraphy, enabling the temporal monitoring of arousal status. This combined approach will enhance our ability to comprehensively elucidate the shifts in arousal experienced by individuals with insomnia.

The strengths of this protocol are manifold. First, it represents the inaugural RCT delving into the effects of qigong, specifically BDJQG, on hyperarousal among individuals with insomnia. The findings emerging from this trial will enrich the existing body of research on qigong for the management of insomnia. Second, BDJQG's accessibility and versatility, enabling indoor or outdoor practice by individuals or groups without necessitating specialized sports facilities or equipment, make it an appealing intervention. Third, BDJQG's dual benefits of physical and mental conditioning render it suitable for individuals across diverse age groups.

Nonetheless, this study exhibits certain limitations. First, the challenge of achieving blinding in nonpharmaceutical trials, wherein participants are aware of the treatment they receive, could potentially introduce bias into the results. However, rigorous measures have been implemented to ensure that laboratory technicians, data managers, and statisticians remain detached from the recruitment and participant processing phases. Furthermore, recent meta-epidemiological research has indicated no substantial differences in estimated treatment effects between trials with and without patient blinding. Second, the recruitment criteria limit participants to those aged between 20 and 55 years without severe CI, possibly limiting the generalizability of the results to other age groups. Third, as this is a single-center study, it will not recruit participants from diverse regions. Nevertheless, recruitment strategies will encompass community outreach and internet-based channels to diversify the participant pool and minimize regional bias. Therefore, we are prepared to follow up with a multicenter study to provide more adequate evidence.

Conclusion

This study is poised to provide valuable data regarding the treatment of CI through BDJQG. Its outcomes will help elucidate whether BDJQG is an efficacious approach for enhancing sleep quality and explore its potential mechanistic associations. We will scrutinize the hypothesis that BDJQG's effect on insomnia may be linked to its capacity to mitigate hyperarousal states. The findings of this trial hold the potential to guide more informed and selective use of BDJQG as an insomnia treatment modality in the future.

Acknowledgments

We thank Rui-ping Wang and Guan-wu Li for their contributions to the development of this protocol. This study is funded by the Young Gifu Scholars Support Program and the National Natural Science Foundation of China (grants 82105038 and 82374610). It is important to note that the funding body has no involvement in the design of the study, data collection, analysis, interpretation of results, manuscript preparation, or the decision to submit the report for publication. FY and YLY are co-corresponding authors on this article.

Data Availability

The data sets analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

CQX reviewed the literature and wrote the manuscript. FFX and JWM wrote and revised the manuscript. HYY revised the manuscript. FY and YLY designed and revised the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Adherence to oral anticancer treatments is critical in the disease trajectory of patients with breast cancer. Given the impact of nonadherence on clinical outcomes and the associated economic burden for the health care system, finding ways to increase treatment adherence is particularly relevant.

Objective: The primary end point is to evaluate the effectiveness of a decision support system (DSS) and a machine learning web application in promoting adherence to oral anticancer treatments among patients with metastatic breast cancer. The secondary end point is to collect a set of new physical, psychological, social, behavioral, and quality of life predictive variables that could be used to refine the preliminary version of the machine learning model to predict patients' adherence behavior.

Methods: This prospective, randomized controlled study is nested in a large-scale international project named "Enhancing therapy adherence among metastatic breast cancer patients" (Pfizer 65080791), aimed to develop a predictive model of nonadherence and associated DSS and guidelines to foster patients' engagement and therapy adherence. A web-based DSS named TREAT (treatment adherence support) was developed using a patient-driven approach, with 4 sections, that is, Section A: Metastatic Breast Cancer; Section B: Adherence to Cancer Therapies; Section C: Promoting Adherence; and Section D: My Adherence Diary. Moreover, a machine learning–based web application was developed to predict patients' risk factors of adherence to anticancer treatment, specifically pertaining to physical status and comorbid conditions, as well as short and long-term side effects. Overall, 100 patients consecutively admitted at the European Institute of Oncology (IEO) at the Division of Medical Senology will be enrolled; 50 patients with metastatic breast cancer will be exposed to the DSS and machine learning web application for 3 months (experimental group), and 50 patients will not be exposed to the intervention (control group). Each participant will fill a weekly medication diary and a set of standardized self-reports evaluating psychological and quality of life variables (Adherence Attitude Inventory, Beck Depression Inventory-II, Brief Pain Inventory, 13-item Sense of Coherence scale, Brief Italian version of Cancer Behavior Inventory, European Organization for Research and Treatment of Cancer Quality of Life 23-item Breast

XSL•FO
RenderX

Cancer-specific Questionnaire, European Organization for Research and Treatment of Cancer Quality of Life Questionnaire, 8-item Morisky Medication Adherence Scale, State-Trait Anxiety Inventory forms I and II, Big Five Inventory, and visual analogue scales evaluating risk perception). The 3 assessment time points are T0 (baseline), T1 (1 month), T2 (2 months), and T3 (3 months). This study was approved by the IEO ethics committee (R1786/22-IEO 1907).

Results: The recruitment process started in May 2023 and is expected to conclude on December 2023.

Conclusions: The contribution of machine learning techniques through risk-predictive models integrated into DSS will enable medication adherence by patients with cancer.

Introduction

Adherence to Oral Anticancer Treatments

Metastatic breast cancer (MBC) is an incurable disease, wherein the available medications are primarily focused on deferring disease progression and symptom mitigation, thereby prolonging survival rate as well as preserving the quality of life (QoL) and psychological well-being [1,2]. The clinical advancements achieved in anticancer treatments have increased the survival rates of patients with MBC. The 5-year survival rate of patients with MBC is around 38% [2]. Notwithstanding, several studies [3-6] have shown that adherence to anticancer treatments is a critical issue in the disease trajectory of patients with breast cancer, especially regarding oral anticancer treatments (OATs), which are intensely demanding because patients are responsible for assuming medications according to the medical prescriptions, thereby increasing the risk of not appropriately taking the therapy [7].

From a theoretical perspective and according to the World Health Organization's recommendations [8], medication adherence might be explained by a set of mutual and interconnected determinants incorporating (1) sociodemographic (eg, age, gender, socioeconomic status), psychocognitive, and social variables (eg, psychological well-being, social support); (2) disease and treatment-related characteristics (eg, cancer stage, prognosis, dosage, side effects); (3) attitudes, beliefs, and values; (4) health literacy and knowledge; and finally (5) health care system–related factors [7,9,10]. Accruing evidence have highlighted that patients with advanced cancer might report significant levels of nonadherence because in case of some cancers such as MBC, the patients have to change the type of treatments or dosage frequently and they experience a high level of fear of cancer spread [3]. For example, Yerrapragada and colleagues [6] reported nonadherence to tamoxifen in patients with MBC, ranging between 30% and 85% and further reducing over time. In addition, patients with MBC reported several barriers to the daily management of OAT, such as emotional (eg, worry, depression) and physical distress related to the side effects (eg, fatigue, weakness, sleep disturbance, emotional burden, pain) and lack of knowledge about their disease. Further, patients might experience a lack of control and a lack of perceived benefits during the disease pathway, and they may experience difficulty in managing therapy [3,6]. Other studies have shown that patients with MBC experience modest QoL due to the related treatment side effects, financial burden affecting therapy discontinuation, and a significant level of nonadherence [4,7]. Marshall and colleagues [4] observed that patients with MBC who frequently report treatment concerns rather than treatment benefits are less likely to be adherent to prescriptions, as well as patients who experience a more significant number and severity of side effects tend to have more medication worries that could negatively impact adherence.

Risk-Predictive Models and Decision Support Systems

Given the impact of nonadherence on clinical outcomes and the associated economic burden on the health care system [11,12], finding effective ways to increase treatment adherence is particularly relevant. Patients who adopt nonadherent behaviors need support in managing oral therapies and in overcoming individual and systemic barriers and roadblocks [5]. Notwithstanding, the dynamics influencing adherence to OATs are understudied in the cancer field [13], and a comprehensive model of the risk determinants of nonadherence is not currently available, particularly for targeted therapies and novel generations of hormonal therapy [14]. Besides, a shared definition of medication adherence and satisfactory assessment tools is not acknowledged, which vary in terms of accuracy and reliability [14-17], even in the explicit case of the equivalent treatment protocol and diagnosis [13,18]. Because of the direct costs of nonadherence (eg, survival rate, health-related QoL for patients with MBC) and the indirect costs for the health care system (eg, economic burden), it is mandatory to identify potential risk factors of nonadherence to OATs and to define personalized interventions supporting adherence during the clinical pathway in patients with MBC.

Consistently, defining, measuring, and developing a comprehensive model of medication adherence based on real-world data predictive models is a crucial clinical, psychological, social, and economic challenge. Machine learning has become an integral part of the health care industry—from biomedical research to the delivery of health care services. Compared to traditional statistical methods, machine learning provides numerous advantages such as increased flexibility,

XSL•FO
RenderX

prediction accuracy, possibility of automation, and processing of big data. Prediction models for adherence have already been developed and tested in various scenarios [19-22]. If adequately reported, these models can help guide treatment decision-making, improve patient outcomes, and streamline perioperative health care management. Considering the complexity of medication nonadherence in patients with MBC, it is critical to identify patients at risk of nonadherence and carry out timely, precise, and tailored interventions to improve their adherence. Through machine learning models, it is possible to provide personalized prediction on medication adherence for a given patient, supporting adherence and performing a specific intervention [22,23].

A growing body of studies have underlined that eHealth technologies (eg, mobile apps, web-based solutions, wearables) might be helpful tools to foster patient management and engagement in clinical decisions during the cancer pathway [24]. Different web-based solutions based on educational and behavioral interventions have been developed for patients with breast cancer to foster medication adherence [25,26]. For example, the Multinational Association for Supportive Care in Cancer has developed an educational and teaching tool for patients with cancer receiving OATs that is composed of different educational sections aimed at assessing general patient knowledge about their treatment protocol and drug information (eg, side effects), skills in the management of therapy, possible strategies to manage nonadherence occurrences, and a specific questionnaire section to evaluate patient comprehension [26]. Moreover, Omaki and colleagues [27] have developed a patient decision aid named "My Healthy Choices" to foster adherence to pain treatments, assessing the environmental and personal risks and setting patient treatment priorities.

Nevertheless, no study has been conducted on patients with MBC to foster medication adherence to OATs through the clinical care pathway based on designing and developing a decision support system (DSS), integrating risk predictive models and educational and training tools. The information embedded in a DSS solution designed and developed according to the needs of patients with MBC might enable users to be better informed, develop more accurate expectations of the benefits and harms, and increase participation in the decision-making processes and medication adherence [28]. Evidence shows that, when implemented on web or mobile apps, DSS may support patients and physicians by improving adherence to medical treatments [27,29,30].

The Pfizer Project (65080791)

Drawing from the theoretical framework described above, we present and explain the study protocol of a prospective, randomized controlled study that is nested in a large-scale international project named "Enhancing Therapy Adherence Among Metastatic Breast Cancer Patients" (Pfizer 65080791) aimed to develop a predictive model of nonadherence and an associated DSS and guidelines to foster patients' engagement and therapy adherence among patients with MBC concerning oral chemotherapy, endocrine therapy, supportive care, and the treatment of comorbidities. Consistently, the Pfizer Project (65080791) has been organized into 2 different studies to achieve the key goal. A retrospective study has been designed and a model has been developed to predict adherence to OATs, which use existing physiological, clinical, and QoL data available in the European Institute of Oncology (IEO; Milan, Italy). More in-detail, multimodal retrospective data have been retrieved from patient electronic health records by using natural language processing in a sample of 2750 patients with MBC (from 2010 to 2020). Data included in the analysis have been sociodemographic variables, diagnosis, biochemical and medical tests, procedures and medical history, treatment programs, treatment side effects, comorbidities, and familiarities. Concerning adherence to the treatment protocols, data included the following dimensions: initiation of the treatment, interruption of treatment, and skipped treatment doses. Furthermore, a prospective study is designed to assess the effectiveness of a DSS web-based solution and to enrich the predictive power of the machine learning model to forecast adherence behavior in patients with MBC. The tuning of the model permits adding additional predictors (personality traits, self-efficacy for coping with cancer, sense of coherence, pain, anxiety, depression, risk perception, and QoL) known to influence medication adherence behavior and that are not available retrospectively [10]. These data are used to improve the predictive power of the machine learning model and its capacity to profile patients' adherence behaviors and to provide an individual risk value of nonadherence.

Methods

Primary End Point Analysis

The primary end point was to assess the effectiveness of the DSS web-based solution and the machine learning web application in promoting adherence to OATs in a sample of 100 patients with MBC at 3 months. The adherence is evaluated using the number of pills taken divided by the number of pills prescribed. Further, the adherence is assessed using behavioral measures: the 8-item Morisky Medication Adherence Scale (MMAS-8) [31] and Adherence Attitude Inventory (AAI) [32].

Secondary End Point Analysis

The secondary end points were to identify clinical (comorbidities, presence of pain, tumor type, type of treatment), psychological (personality traits, anxiety, depression, self-efficacy for coping with cancer, sense of coherence, and risk perception), and QoL variables predicting patients' adherence to OATs. These variables are used as predictors for evaluating nonadherence to OATs among patients with MBC and for enriching the preliminary version of a machine learning model developed in the retrospective study. Our initial machine learning models that are evaluated as an intervention in this study were built based on variables extracted from clinical notes by using natural language processing. Once the data collection for this study is complete, we will also use the data collected to improve our initial machine learning models. Data for the secondary end points are collected using the European Organization for Research and Treatment of Cancer QoL Questionnaire Core 30 (EORTC-QLQ-C30) [33,34], European Organization for Research and Treatment of Cancer QoL 23-item Breast Cancer-specific Questionnaire

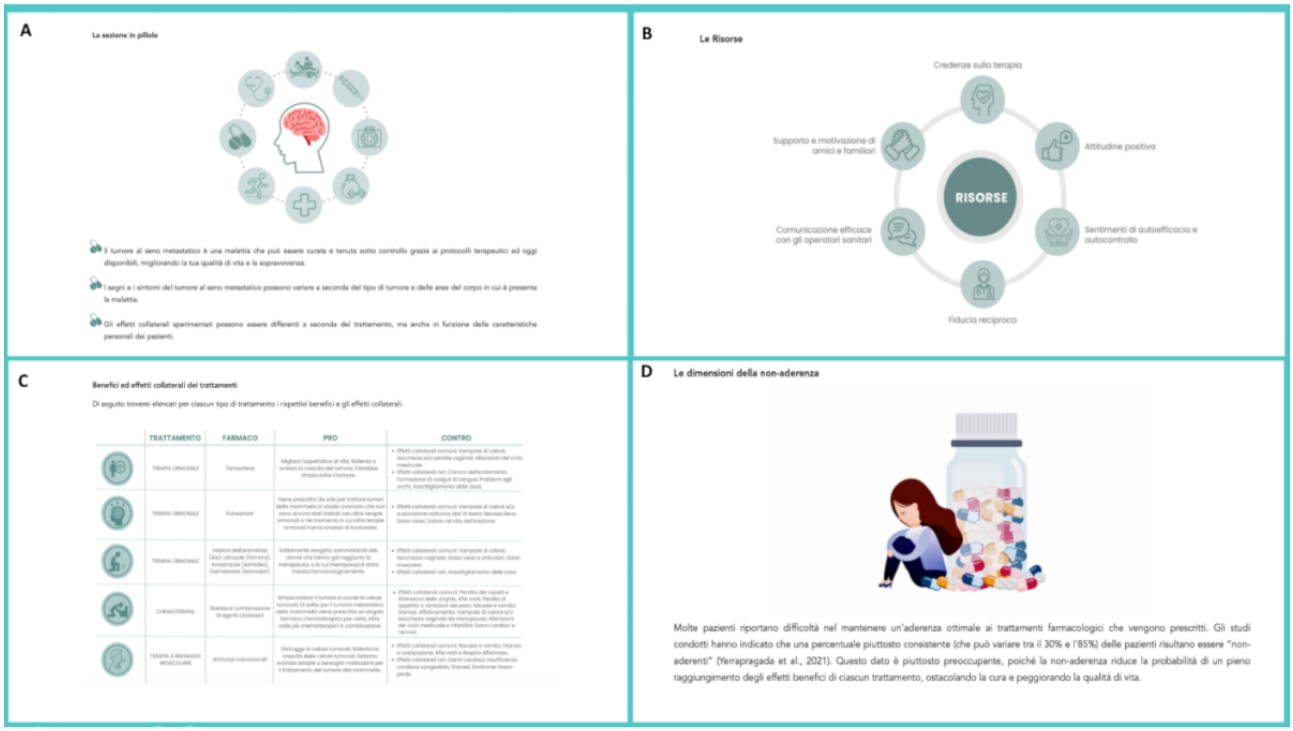
XSL•FO
RenderX

(EORTC-QLQ-BR23) [35], and the Brief Pain Inventory (BPI) [36]. To evaluate psychological variables, we used the State-Trait Anxiety Inventory (STAI-Y) [37,38], Beck Depression Inventory-II (BDI-II) [39,40], Big Five Inventory (BFI) [41], Brief Italian version of Cancer Behavior Inventory (CBI-B/I) [42,43], 13-item Sense of Coherence scale (SOC-13) [44], and risk perception (using 2 visual analogue scales) [45,46].

Study Design

Treatment Adherence DSS

The first version of the web-based DSS, namely, TREAT (treatment adherence support) was designed and developed in the first year of the Pfizer Project (65080791) by using a patient-driven approach. The development phase was systematized in 5 steps. First, a systematic review of the literature was conducted to explore the main issues related to the interventions fostering adherence in patients with breast cancer [47]. Second, 4 focus group studies with 19 patients with MBC (mean age [years] 55.95, SD 6.87; range 46-70) with different metastasis localizations were implemented in order to explore patients' unmet needs related to the MBC disease and knowledge about the adherence, barriers, roadblocks, and resources related to OATs and to examine the role of technologies and decision support as aids fostering adherence behaviors during the care pathway [45]. The first and second steps informed the third step in which a preliminary set of mock-ups of TREAT using Wikimedia technology was shaped. TREAT was developed as a web-based application accessible by patients through a web link, without personal registration, and in Italian according to the patient's user approach. The information contained in TREAT was constructed using the international guidelines for patients with MBC (eg, European School of Oncology-European Society for Medical Oncology 2nd international consensus guidelines for advanced breast cancer) [1,46]. Further, the information was organized using different setups (written text, figures, flowcharts, graphs, and tables). In the fourth step, this preliminary version was revised by an internal and multidisciplinary review group (oncologists, psychologists, technicians, and patients). Finally, the TREAT's revised version was translated and published.



Currently, TREAT is organized into 4 key sections. Section A on metastatic breast cancer provides information on MBC disease (eg, definition, clinical management), physical consequences (eg, pain, weight loss, lack of energy), psychological consequences (eg, anxiety, depression, fatigue), anticancer treatments and the associated side effects, and benefits that can be experienced during the care pathway. Section B on adherence to cancer therapies discusses the meaning of nonadherence and its consequences, incidence in the population with cancer, and determinants of medication adherence according to the World Health Organization's approach. Section C on promoting adherence provides information about the resources (eg, personal beliefs, social support, trust in the health care providers), barriers (eg, distress, inadequate knowledge) of medication adherence, and the different available interventions (eg, educational, affective, behavioral) to promote patients' adherence. Further, TREAT delivers specific self-managed suggestions to mitigate potential risk factors associated with nonadherence and an example of a specific training based on a goal-setting approach. In Section D, that is, My Adherence Diary, patients are invited to write a free-text diary reporting doubts, concerns, thoughts, and behaviors related to their disease and therapies, sharing this information with their oncologists in the following clinical consultation (Figures 1-2).

Figure 1. The 4 main sections of the decision support system in Italian. Section A: metastatic breast cancer; Section B: adherence to cancer therapies; Section C: promoting adherence; Section D: my adherence diary. The screenshot with the decision support system, namely, "TREAT - Supporting Therapy Adherence" is shown in the center.

XSL•FO
RenderX

Figure 2. Screenshots of the decision support system, exemplifying some examples of the information nested in different sections of the system (A, B, C, D). A. "The Section on Pills" refers to a short summary enclosed at the end of each section of the decision support system reporting the key themes (renamed pills) discussed in the section. B. "Resources" is a flowchart on the main resources that can improve medication adherence. C. "Benefits and side effects of the treatments" is a table that shows the action of each anticancer treatment, type of drug, expected benefits, and side effects. D. "The adherence dimension" is a written text that informs about the dimension of nonadherence in the population with cancer.

We also developed a machine learning application, which will be tested with the DSS. This application focuses on models to predict adherence risk factors and used data extracted from the electronic health records of the IEO. Specifically, the machine learning models focused on 2 outcomes: short-term and long-term side effects as well as physical status and comorbid conditions. We evaluated the models predicting performance by utilizing metrics such as area under the curve, precision, recall, sensitivity, specificity, κ, and positive and negative predictive values. Based on these criteria, we identified the top performing models, which were integrated into a web application built using the Shiny open source framework for the R statistical language (R Core Team) [48]. We designed this application for shared decision-making sessions between patients and oncologists. It also uses the Shapley interpretable machine learning algorithm, which offers insights into the specific risk factors that played a role in predicting outcomes for individual patients.

Participants

A sample of 100 patients enrolled consecutively in May 2023 in the IEO at the Division of Medical Senology with an MBC diagnosis. The enrollment started in May. Specifically, the observed outcomes of 50 patients with MBC exposed to the DSS (experimental group) and 50 patients with MBC not exposed to the intervention (control group) are evaluated.

Inclusion and Exclusion Criteria

The inclusion criteria were female patients with MBC, 18 years of age and older, with a prescription of oral treatment (eg, oral chemotherapy, endocrine therapy, cyclin-dependent kinase 4/6 inhibitors), having internet access and a personal smartphone or tablet, and ability to read and sign informed consent. The exclusion criteria were the presence of any primary psychiatric or neurological conditions.

Procedure

Randomization

Patients who signed the informed consent are given a unique identifier and assigned to either the control or intervention arm in a 1:1 ratio. First, the system asks to confirm all the inclusion and exclusion criteria. Then, an independent researcher generates a random sequence using the statistical language R (R Core Team 2020). Our randomization schedule involves an undisclosed blocking size that the data science team calculates without stratification. A patient is considered randomized when the randomization system assigns the patient an identification number according to a pre-established randomization list. We have created 2 different groups: the experimental group (n=50), in which each participant receives the link for the DSS and is trained to use the DSS for 3 months; and the control group (n=50), in which each patient receives standard care and suggestions bolstering adherence. Among all participants, the personal nonadherence risk is calculated through the preliminary version of the machine learning model to predict patients' nonadherence behavior.

Recruitment and Follow-Up

Patients admitted to the Division of Medical Senology of the IEO are enrolled by the oncologist during the formal clinical consultation. Patients are enrolled even if they already had oral treatments in the past and they are switching to a new one. The patients who show interest in this research have a phone call

XSL•FO
RenderX

with a trained psychologist to receive further information about the Pfizer study. If patients decide to participate in this study, the psychologist plans a consultation to receive informed consent and a preliminary assessment. Patients are informed that TREAT will not replace the clinical consultation. However, it should help manage oral treatment and improve adherence through education using evidence-based information. Patients may decide to discontinue their participation in the trial without any penalties. Patients who refuse to participate in this study are asked to complete a short refusal survey regarding the main reasons for not participating and their demographic information in order to assess the potential differences among the participants. Furthermore, patients have to contact the pertaining division for any necessity. Data are collected by the REDCap (research electronic data capture) platform and stored centrally by the IEO.

Measures

Assessment of Nonadherence to OATs

This study uses the operational definition of adherence provided by the International Society for Pharmacoeconomics and Outcomes Research Medication Compliance and Persistence Work Group, which defines adherence as "the extent to which a patient acts in accordance with the prescribed interval and dose of a dosing regimen" [49]. Coherently, the nonadherence to OATs is evaluated using a prospective method [15] by weekly medication diaries and 2 self-reported measures.

Adherence Medication Diary

A weekly paper diary is given to patients to monitor their medication intake. The diary will assess if medications are taken as prescribed and the possible reasons for not taking pills (eg, side effects, forgetfulness, no pill refill). The data collected refer to the number of pills not taken per week and the number of pills established according to the patient medical prescription protocol per week as well as planned interruptions. Further, the diary evaluates and monitors the side effects, their intensity (from 0 to 10) associated with the therapy intake, and their emotions, thoughts, behaviors, and consequences.

MMAS-8 Self-Report Questionnaire (© 2006 Donald E Morisky)

The MMAS-8 scale [31,50,51] is an 8-item self-report questionnaire evaluating treatment adherence (forgetfulness, medication-taking behavior, adverse effects, and problems) (Cronbach α=.83). The first 7 items have dichotomous responses (0=Yes, 1=No), and the last includes a 5-point Likert scale response [52].

AAI Self-Report Questionnaire

The AAI is a 28-item self-report questionnaire on a 5-point Likert scale response (from "does not fit" to "perfect fit") evaluating treatment adherence (Cronbach α=.80) [32]. The AAI is organized into 4 subscales: cognitive functioning (evaluating the ability to remember issues and tasks related to adherence in the short and long term), patient-provider communication (evaluating thoughts, attitudes, feelings, and ideas related to adherence between patient and medical provider), self-efficacy (evaluating the belief in one's ability to adhere to medication and a history of similar success), and commitment to adherence (evaluating the determination to overcome obstacles to achieve adherence).

Demographic, Clinical, Emotional, and QoL Assessments

Considering that adherence to OATs is explained by a set of mutual and interconnected determinants, a comprehensive pool of self-reported measures is administered to identify the psychological predictors of nonadherence in patients with MBC.

Patient Demographic and Clinical Variables

Age, gender, education, marital status, cancer diagnosis and staging, oncological treatments, BMI, alcohol and smoking habits, and comorbid medical disorders are collected through electronic medical records.

STAI-Y Self-Report Questionnaire

The STAI-Y is a 40-item self-report questionnaire on a 4-point Likert scale (Cronbach α=.89). The STAI-Y evaluates both trait anxiety (20 items) and state anxiety (20 items) [37,38].

BDI-II Self-Report Questionnaire

The BDI-II is a 21-item self-report questionnaire on a 4-point Likert scale response evaluating depression (Cronbach α=.89). The BDI can be administered to adults and adolescents aged 13 years and older [39,40].

CBI-B/I Self-Report Questionnaire

The CBI-B/I is a 12-item self-report questionnaire on a 7-point Likert scale response (from not all confident to totally confident) evaluating self-efficacy for coping in patients with cancer (Cronbach α=.84). The CBI-B/I is composed of 4 subscales: coping and stress management, maintaining independence, managing affect, and participating in medical care [42,43].

SOC-13 Self-Report Questionnaire

The SOC-13 is a 13-item self-report questionnaire on a 7-point Likert scale response (Cronbach α=.76). The SOC-13 is composed of 3 subscales: comprehensibility, manageability, and meaningfulness [44].

BPI Self-Report Questionnaire

The BPI is a 9-item self-report questionnaire evaluating pain intensity during the past 24 hours (Cronbach α=.91) [36].

EORTC-QLQ-C30 Self-Report Questionnaire

The EORTC-QLQ-C30 is a self-report questionnaire composed of 28 items on a 4-point Likert-type scale (ranging from not at all to very much) and 2 items, that is, general global health status and QoL on a 7-point Likert-type scale (ranging from very poor to excellent) [33,34]. The EORTC-QLQ-C30 provides information on 3 areas: functional (physical, role, cognitive, emotional, and social), symptoms (appetite loss, fatigue, pain, nausea, constipation-diarrhea, dyspnea, and insomnia), and global health status or QoL (Cronbach α=.85) [32,33]. Further, the EORTC-QLQ-B R23 for patients with breast cancer has been used previously (Cronbach α=.87) [34,35].

XSL•FO
RenderX

BFI Self-Report Questionnaire

The BFI is a 44-item self-report questionnaire on a 5-point scale (from disagree strongly to strongly agree) that assesses 5 dimensions of personality: openness to experience (Cronbach α=.78), conscientiousness (Cronbach α=.81), extraversion (Cronbach α=.87), agreeableness (Cronbach α=.81), and neuroticism (Cronbach α=.82) [41].

Risk Perception

Risk perception is evaluated using 2 visual analogue scales (from 0 to 100): one for the objective and one for the subjective risk perception. These items were developed using the Weinstein approach [45,46].

Timeline

There are 3 assessment time points. At the baseline (T0), all patients fill a set of validated measures (MMAS-8, AAI, STAI-Y forms I and II, BDI-II, CBI-B/I, SOC-13, BPI, EORTC-QLQ-C30, EORTC-QLQ-BR23, BFI, and visual analogue scale). The expected time to complete all the given questionnaires at baseline is approximately 40 minutes. Access to DSS is given to the experimental group for 3 months. At T1 and T2, the following questionnaires are filled: MMAS-8, AAI, STAI-Y form I, BDI-II, CBI-B/I, EORTC-QLQ-C30, and EORTC-QLQ-BR23. Further, all patients have to fill a weekly adherence medication diary for 3 months. Variables that are not sensitive to change, for example, personality (BFI) and anxiety traits (STAI-Y form II) are collected only at T0. Each month, all participants receive a brief telephone interview in which they are monitored for adherence to the research protocol. Two psychologists perform the monthly telephone interview to monitor the filling out of the questionnaires and the medication adherence diary supporting patients with MBC in this task, barriers, and concerns related to the study participation. At T3 (3 months), all behavioral and psychological measures are filled, and an interview (online or vis-à-vis) is performed.

Calculation of Sample Size

The sample size calculation was based on estimates for the effectiveness of TREAT as the primary outcome, assuming that the final analysis would be performed with a 2-sample 2-sided *t* test, a power of 96.4%, an α of .05, a standard deviation of 1.2, and a minimal difference in outcomes of 0.51 (effect size of 0.42) based on the patients' self-reported satisfaction with the treatment decision [53]. Under these considerations, the final sample size was calculated to be 100 patients with MBC, with 50 individuals per group (50 patients with MBC exposed to DSS and 50 patients with MBC not exposed to the intervention). This sample size is expanded to 120 when a 20% attrition rate is used.

Statistical Considerations

Exploratory Analysis

Our exploratory analysis will start with a visual exploration of all variables to evaluate the frequency, percentage, and near-zero variance for categorical variables (eg, gender, cancer stage); distribution for numeric variables (eg, age); and their corresponding missing value patterns [54]. Near-zero variance is found when a categorical variable has a small percentage of a given category and will be addressed by recategorization. We will consider variable transformations such as logarithmic, Box-Cox, or categorization of numeric variables that do not present a normal distribution. Missing values will be handled through imputation algorithms followed by sensitivity analyses to verify whether our results are stable with and without imputation [53]. Comparisons for the exploratory analysis will be conducted through analysis of variance (2-sided *t* tests being a category of analysis of variance) and chi-square tests (Fisher exact test when any cell presented a frequency below 5).

Propensity Score

For residual confounding after randomization, we will use propensity scores based on inverse probability of treatment weighting [55]. We will first assess the covariate balance between control and intervention groups through standardized mean differences and differences in proportion. Covariates will include the patient demographic and clinical variables. Values greater than 0.1 will signal an imbalance in covariates. Next, we will use inverse probability of treatment weighting generated through logistic regression to balance the covariates [56]. Once we achieve covariate balance, we will estimate the effect for each outcome by using a double robust approach.

Generalized Linear Models

Additional analyses will be run using generalized linear models with a Gaussian distribution family (multiple linear regression) being adjusted for randomization baseline imbalances. These models will evaluate the association between all previously reported outcomes (the number of pills taken during the prescribed interval, MMAS-8, AAI, STAI-Y, BDI-II, CBI-B/I, SOC-13, BPI, EORTC-QLQ-C30, EORTC-QLQ-BR23, BFI, and risk perception) and the intervention (TREAT and machine learning web application), accounting for the baseline differences. We will build one model for each combination of predictor and outcome, where the outcome will be the dependent variable (Y) and the predictor will be the independent variable (X), adjusted for the covariates unbalanced at baseline. We will also evaluate models with a Poisson or negative binomial distribution for non–normally distributed outcomes. Results will be reported as predicted means along with 95% CIs.

Ethics Approval

This study is compliant with the recommendations outlined in the Helsinki Declaration [57] and the Council for International Organizations of Medical Sciences guidelines [58], as well as with the principles of biomedical ethics reported in the Belmont report [59]. This study presents a fair balance between risks and benefits for study participants and future patients affected by the same condition. No physical risks directly related to participation in the research are expected. Although psychological risks are not expected, in case these raised from participation, psychologists responsible for the study will promptly intervene and take care of the patient. Regarding the benefits, given the impact of nonadherence on clinical outcomes, finding effective ways to increase treatment adherence is particularly relevant for the community of patients with MBC, thus playing a role in the improvement of the patient's general well-being. The principle of self-determination is also respected.

XSL•FO
RenderX

A devoted informed consent form is signed by participants before participation. Signing the informed consent form is preceded by a dialogic consent process necessary to ensure informed, voluntary, and awareness of participation in research. Regarding the respect for privacy, this study is performed according to the General Data Protection Regulation (Regulation EU, 2016/679) [60]. All data are collected in a pseudoanonymized form. Data are treated confidentially and used only by the collaborators in this study for scientific purposes related to what is stated in the research protocol. The retrospective study was approved by the IEO ethics committee (R1595/21-IEO 1704). The prospective study was approved by the IEO ethics committee (R1786/22-IEO 1907).

Results

The recruitment process started in May 2023 and is expected to be concluded on December 2023. Data analysis will be performed between 2023 and 2024. This project has been funded by a Pfizer grant: Enhancing therapy adherence among patients with metastatic breast cancer (65080791).

Discussion

Expected Findings

Adherence to anticancer treatment is fundamental in the clinical management of patients with MBC, as adherence can lead to a series of crucial clinical outcomes (eg, prolonged survival time, better monitoring and management of side effects, improvement of QoL) [1-6]. Studies on implementing machine learning to foster medication adherence as well as the development of shared DSSs are quite recent [23].

We believe that our study might achieve 3 milestones in the clinical care of patients with MBC with regard to adherence to OATs. Concerning the primary end point, implementing a shared and integrated DSS web-based solution might be an essential strategy for patients with MBC to enhance their health knowledge and understanding of medication nonadherence issues and to learn behavioral strategies to overcome individual, disease-related, and organizational barriers impacting adherence behaviors. This expected result is coherent with the results of other studies on patient decision tools, highlighting that such engines might improve patients' participation and health knowledge in the care pathway [61]. Regarding the secondary end point, this prospective study will contribute to refining the initial risk-predictive model of adherence attained from the retrospective study, informing about specific (inner and external) predictors of adherence behavior during the MBC care pathway that were not considered in the preliminary version of the model. This should provide a more comprehensive and systematic definition of medication adherence for OATs in patients with MBC, defining an interrelated and evidence-based list of predictors. Data will define a final risk-predictive model of adherence and enable the identification of specific patient populations at risk of nonadherence. The earlier identification of patients with poor adherence using our machine learning web application will permit the development of tailored psychological and behavioral interventions to foster adherence by dealing with individual barriers and needs according to the risk profile. Finally, the information retrieved by the risk-predictive models might support oncologists' treatment decisions, allowing them to better understand the hindered reasons behind a complex adherence trajectory.

Limitations of This Trial

Despite the key contributions of this study in the field of the medication adherence to OATs among patients with MBC, some limitations have to be acknowledged. First, the questionnaires used to refine our risk-predictive model might cause cognitive burden and general fatigue among participants. However, a monthly telephone interview has been introduced as a mitigation risk strategy. The interview is aimed to support participants in filling out the questionnaires and medication adherence diary and to manage barriers and concerns related to this study. Related to this aspect, the second limitation concerns the recall bias that might be generated using self-report measures. Further, self-report measures might overvalue adherence compared to the other prospective methods such as the Medication Event Monitoring System. However, the weekly medication diary method, in which patients have to report a detailed and systematic description of pill counts, side effects, and barriers related to the management of the therapy and missed doses, can aid in providing a more comprehensive picture of medication adherence. Moreover, as highlighted by Shah and colleagues [15], the diary has a higher accuracy and minor recall bias and permits the evaluation of subjective information (eg, emotions, thoughts, worries, behaviors, expectations) related to the medication coherently with the processual model of the adherence used in this research protocol [8]. Third, a monthly follow-up and a 3-month end point have been established, considering the type of diagnosis, high variation in the prognosis, and shifting in the lines of treatment due to cancer progression or declining physical functioning. This short end point might affect a deep understanding of the efficacy of our DSS in the long term. However, previous studies have used correspondent follow-ups and end points [13]. Fourth, as observed by other studies on patients with MBC [14], an additional risk that should be considered is related to the overestimated adherence rate. Patients participating in clinical trials are highly motivated, possibly leading to greater adherence to the OATs prescribed. Fifth, the initial version of the machine learning web application was not able to directly predict patient adherence. Instead, it predicted adherence risk factors, including short-term and long-term side effects, as well as physical status and comorbid conditions. This is a limitation of the data we used to build this initial version of the model, as it was not possible to reliably identify adherence patterns. However, predicting adherence risk factors can still provide insights that can assist in improving OAT adherence during shared decision-making sessions between physicians and patients.

Conclusions

Considering the poor evidence on OATs and the need to develop validated instruments to evaluate medication adherence to improve patient clinical outcomes [14,16], the development of integrated and shared DSSs able to foster adherence behaviors and to profile patient adherence risks might have key impacts on clinical practice and patient health-related QoL, thereby

XSL•FO

enabling the early identification of high-risk populations and enriching knowledge about the implementation of machine learning models in clinical practice.

Abstract

Background: Children living in low and middle-income countries (LMICs) are at greater risk for experiencing adversities that can undermine their health and early development. Recently launched digital early childhood development (ECD) programs attempt to support families with young children in their home environments using digital technologies. However, relatively little is known regarding the effectiveness of these new technologies.

Objective: The goal of this study is to rigorously assess the reach, effectiveness, and cost-effectiveness of a newly developed digital ECD platform called Afini. The Afini platform was designed to support parents of young children in low-resource settings to improve ECD and interact with caregivers through messenger services and a chatbot.

Methods: This is a 3-arm cluster randomized controlled trial. In total, 2471 caregivers and their 3- to 9-month-old children were enrolled in the study across 164 study clusters in the San Marcos, Cajabamba, and Cajamarca provinces of Peru. Clusters of participants were randomly assigned to 1 of 3 groups: a control group (72 community clusters and 980 caregiver-child dyads), a home visit intervention group (20 community clusters and 316 caregiver-child dyads), and an Afini intervention group (72 community clusters and 1175 caregiver-child dyads). Families in the control group receive no focused ECD intervention. The home visit group is receiving biweekly home visits by a trained field staff following the national ECD program (*Programa Nacional Cuna Más*) curriculum and training guidelines. Caregivers in the Afini group are receiving ECD activities and advice through the digital platform. The primary study outcome is children's overall development at the age of 2.5 years, using the internationally validated long form of the Global Scales for Early Development. Secondary outcomes include caregiver engagement; caregiver mental health; screen time; as well as caregiver reports of children's motor, cognitive, language, and socioemotional development measured through locally piloted and validated tools.

Results: Enrollment started in September 2021 and ended in March 2023. Endline assessments will take place between August 2023 and September 2024.

Conclusions: This study is, to our knowledge, the first to rigorously assess the effectiveness and cost-effectiveness of digital ECD technologies in LMICs. Given the large number of children in LMICs currently receiving only limited external support, the evaluated platform has the potential to improve the short- and long-term well-being of millions of children and their parents globally.

Introduction

According to the World Health Organization, early life adversity affects more than 250 million children younger than 5 years, making it more difficult for them to reach their developmental potential [1,2]. Chronic poverty, malnutrition, and high exposure to infectious diseases undermine children's development in their early years [1] and limit their physical and cognitive development over time. The most recent estimates suggest that 30% of children younger than 5 years in low and middle-income countries (LMICs) are stunted [3], and 37% of children aged 3-4 years display deficits in their cognitive or socioemotional development [4]. Interventions targeted at this early life stage are crucial for creating environments that support healthy development [5-8] and ensuring children's long-term economic and overall well-being [9].

Home visiting programs have emerged as one of the most promising and popular approaches for improving child health and well-being in both high- and low-income settings [10], with successful implementation in Bangladesh [11], Brazil [12], Colombia [13], Jamaica [14,15], Pakistan [16], Peru [17], and South Africa [18]. These programs involve training community agents on child development and having them meet with mothers or parents weekly, biweekly, or monthly to discuss their children's overall well-being. They provide practical guidance to caregivers on creating a healthy and developmentally stimulating environment in the home. Home visiting programs usually have a structured curriculum containing essential child health and development topics that are covered during each home visit. Despite consistently positive impacts on maternal [19,20] and child well-being [21,22], most countries have not adopted home visiting programs at scale due to the high cost and logistical efforts associated with them. In Peru, the state-run national early childhood development (ECD) program (*Programa Nacional Cuna Más* [PNCM]) provides a crèche-based intervention in urban and periurban settings and traditional home visits by trained agents in rural settings [17,23,24].

The rapid rise in cell phone coverage globally [25] and the introduction of mobile computing devices such as smartphones and tablets have created new opportunities for health and social systems to engage with patients and parents at scale [26-28], resulting in a rapid growth in the development of software apps for these platforms [29-34]. Additionally, new mobile phone contracts that offer low-income families access to basic messaging software (such as WhatsApp and Facebook messengers) without formal data contracts have also contributed to the expansion. Such light messenger-only data plans allow users to share information, pictures, and videos on messaging platforms without incurring any cost per message or upload. In our pilot study, 84.4% (152/180) of families owned a smartphone and 94% (169/180) had internet connectivity at home [35]. In this setting, new artificial intelligence (AI)–based ECD technologies using automated chatbots to interact with caregivers of young children seem to be a potentially attractive new option to support parents and their children.

In this project, we will test whether one of these newly developed digital platforms, called Afini [36], can be effective at improving children's development in a remote population in high-altitude rural Andean Peru. Through this study, we wish to assess the reach, impact, and scalability of the newly developed Afini platform as a tool for improving children's early development; the subaims are to (1) improve the functionality and usefulness of the Afini platform through qualitative and quantitative feedback and to integrate of state-of-the-art machine learning algorithms, (2) assess the cost and cost-effectiveness of Afini platform as a tool, and (3) disseminate the findings to our targeted population and reach out to the policy makers for further scalability of digital platform initiatives on ECD.

Methods

Study Setting

The study is conducted in 3 provinces of the Cajamarca region (San Marcos, Cajabamba, and Cajamarca) in the Northern Andes of Peru. The altitude in the study area ranges between 1900 and 3900 m above sea level. The region is predominantly rural and has a large share of low-resource and remote households engaged in farming, making it representative of many rural and periurban settings in Andean South America. The majority (80%) have regular access to social media platforms [35]. Communities were classified in accordance with the Peruvian National Institute of Statistics and Informatics as urban (communities with >2000 inhabitants with contiguous and grouped homes forming streets) or rural (scattered or grouped houses of up to 2000 inhabitants per community [37]). The study area is partially covered by PNCM.

Study Design

The study was designed and adapted based on a field-testing phase completed over a period of 5 months from February to July 2021. During the test phase, we conducted a mixed method feasibility pilot to test the reach, reception, and use of the Afini parenting platform. Specifically, we (1) systematically assessed internet connectivity in the greater study region, (2) conducted focus groups and in-depth interviews to adapt Afini to the local cultural context, and (3) assessed use over time and satisfaction

XSL•FO
RenderX

with Afini in a sample of 280 mothers with children up to 2 years of age and smartphone access [35].

The study was designed as a 3-arm parallel cluster randomized controlled trial to assess the Afini platform's effectiveness in improving ECD outcomes relative to a control group receiving no additional intervention as well as relative to a home visit group receiving an ECD home stimulation intervention (gold standard). The trial enrolled 2471 caregivers and their 3- to 9-month-old children across 164 community clusters from September 2021 to March 2023. As described above, communities were randomly assigned to the three study groups: (1) a control group receiving no additional ECD support (72 community clusters and 980 caregiver-child dyads), (2) a home visit intervention group receiving a biweekly home visit by a trained field staff following the national ECD program PNCM curriculum and training guidelines (20 community clusters and 316 caregiver-child dyads), and (3) the Afini intervention group receiving ECD activities and advice through the digital Afini platform (72 community clusters and 1175 caregiver-child dyads).

Description of the Study Groups and Intervention

Control Group

The control group comprises families that receive the regular level of mother and newborn child health care in the region. They have not been benefitting from any ECD program or intervention, but they may have sought assistance regarding parenting from within their network. This study group is only visited once at the beginning (baseline survey) and once at the end of the study (endline survey and assessment).

Home Visit Intervention Group

Home visits are considered the gold standard for enhancing child health and development in LMICs [21]. Families in the home visit intervention group (home visit group) receive support through biweekly home visits following the nationally developed and validated curriculum of the national ECD program PNCM. The PNCM program offers home visits to low-income families residing in rural areas (*Servicio de Acompañamiento a Familias*) and daycare services in urban settings (*Servicio de Cuidado Diurno*) [23]. Specifically, all families in the home visit group are receiving biweekly home visits by our trained field staff from when their children turn 6 months until endline assessments at approximately 2.5 years of age. Trained staff members visit families at home every 2 weeks. During these visits, they follow a structured (age-specific) curriculum to educate parents on engaging in educational activities and games for daily interaction with their children, actively play with the child, and provide parents with a set of age-appropriate toys every 3 months. The toys and activities were designed in Peru to promote their children's psychomotor, cognitive, language, and socioemotional development.

Afini Intervention Group

Caregivers in the Afini intervention group (Afini group) were introduced to the Afini digital system on Facebook Messenger during the study baseline visit. During the initial setup, families registered the child's day of birth and other demographics for Afini to recommend a first educational activity.

After this initial visit, caregivers received automated weekly alerts with personalized content from Afini over Facebook Messenger. Specifically, the Afini system sent weekly reminders to engage in age-specific, health- and development-promoting activities as well as general information on child development and the child's progress. Afini was available for families 24/7, and families could request up to 4 personalized educational activities for their child, ask for advice, or ask any questions related to child development to the Afini chatbot system at any time. The personalization of content works based on the child's age, initial child development assessment on the platform, and user preferences (ratings) for each educational content.

After approximately 1 year, caregivers in the Afini group will receive a short home visit to ensure they can still connect to the system. Caregivers continue to use Afini independently until they are visited at the end of the study (endline survey and assessment).

The Afini platform is a digital parental support platform for children younger than 5 years in LMIC settings. The platform can be accessed via Facebook Messenger, WhatsApp, or an independent Afini app. Once connected, the Afini content recommender system uses AI to learn about individual children's needs and recommends content or ideas for activities that caregivers can practice at home together with their child. The platform tracks child development and caregivers can contact the assistant chatbots at any time to receive general advice on child development and parenting. Afini offers over 1500 age-specific, health- and development-promoting activities, articles, and tips to caregivers. Afini's educational activities, tips, and content are designed in a fun, simple way and with materials that are commonly found at home. All Afini contents offered to caregivers in the Afini group were developed by early development experts and revised by local experts in Cajamarca [35].

Ancillary Studies

In order to assess whether the usage and impact of Afini can be improved through incentives, a total of 20 study clusters among the 72 Afini intervention clusters were randomly selected for additional top-up intervention. Within these 20 clusters, all caregivers with a prepaid phone plan with either Claro or Bite phone operators were eligible to receive small biweekly data credit transfers with a value of between US $0.8 and US $2. The credit transfers can be used for unlimited access to WhatsApp and Facebook Messenger for 1-3 days, depending on the provider; the monetary value of US $2 corresponds to half a kilo of chicken at a local market. We will assess the marginal impact on the use and development of these incentives as well as their relative cost-effectiveness.

In addition, and to increase the generalizability across the country, we added a comparison group composed of families participating in the existing governmental PNCM program. These families were screened during the enrollment of the main trial and excluded due to their participation in another ECD program; they became eligible for the ancillary study. This

XSL•FO
RenderX

PNCM comparison group comprises 237 caregiver-child dyads and is treated the same as a natural control group without intervention. This group was not randomly selected or assigned and will thus mostly be used for descriptive purposes and to provide further context for this study. In summary, the project thus included 2471 trial participants and 237 comparison group participants, totaling 2708 project participants.

Sample Size Calculations

The study is powered to detect a 0.25 SD difference in normalized child development *z* scores (mean 0, SD 1) at the age 2 years between the Afini group and the control group and a difference of 0.5 SD in *z* scores between the home visit group and the control group. These calculations are based on the following assumptions: (1) an average of 15 (SD 5) children per village or study cluster, (2) an intraclass correlation of 0.12, (3) α=.05, and (4) an attrition rate of 15%. The estimated normalized effect size of 0.5 SD was based on 2 recent reviews of ECD home visiting programs [10,16]. We conservatively anticipate the Afini platform to only reach about half the target population and, thus expect an intention-to-treat effect size of 0.25 SD. Our assumptions regarding intraclass correlations, number of children per cluster, and attrition rates are based on a recently completed ECD-focused study in the same area [17].

Recruitment

Recruitment occurred continuously over 18 months with a target to enroll 2460 caregiver-child dyads. To identify potential children, the local health facilities' birth registries from San Marcos, Cajamarca, and Cajabamba were used. All children between 3 and 9 months of age identified during the recruitment period in the study catchment area were eligible. All families that complied with the eligibility criteria were visited in person by study staff and invited to participate. The only reasons for exclusion were if the (1) caregiver and child intended to migrate outside the study area within the next 12 months, (2) child had a diagnosis of congenital abnormalities or a disability such as deafness or blindness (as reported by the caregiver), and (3) child already participated in the national PNCM program and did not belong to the PNCM comparison group. The study was built on a long-standing relationship of the research team with the regional and local health centers that facilitated recruitment.

Randomization Process

Stratified constrained randomization was used to ensure both spatial and covariate balance across groups. As study strata, 3 study provinces (Cajamarca, Cajabamba, and San Marcos) were used. Within each stratum, communities were allocated with ratios 3.6:1:3.6 for the control group, home visit group, and the Afini group, resulting in a final sample of 72 clusters in both the control group and Afini group and 20 clusters in the home visit group. A total of 1000 potential cluster allocations were randomly drawn using the Stata SE (version 16.0; Stata Corp) software package. We then chose the allocation minimizing mean differences across the 3 arms concerning variables such as cluster population size, cluster number of births, cluster altitude, household cell phone ownership, education of caregiver, and household wealth. Information on these covariates was obtained from governmental sources and validated by our field staff.

Primary and Secondary Outcome Measures

The primary study outcome will be children's overall development at the age of 2.5 years. Children's development will be assessed using the long form of the Global Scales for Early Development (GSED) [38]. The GSED is a new global open access tool designed to provide a standardized method for measuring the development of children up to 36 months of age in low-resource settings. We will use the long form of the GSED tool, which allows for a direct assessment of children's development through trained assessors.

Secondary outcomes include (1) caregiver-reported early child development in motor, cognitive, language, and socio-emotional domains; (2) quality of a caregiver-child relationship; (3) screen time with and without a child being present; (4) primary female caregiver's parenting behaviors; (5) parenting attitudes; and (6) mental health. Table 1 summarizes the measures to be collected at baseline and endline—all measures will be applied to the full sample, that is, to all participants independent of their random group assignment. Given that children were very young at baseline (6 months on average), detailed assessments of child development and caregiver-child interactions seemed unlikely to yield much insight at baseline. For overall child development, we used a caregiver report (Caregiver Reported Early Development Instruments [39]) at baseline and will use a more detailed direct observation tool (GSED) at endline. Sociodemographic factors collected at baseline will be used as controls in the final analysis.

Data Collection

Baseline Assessments

Upon caregivers' consent, all caregivers completed a baseline survey, including household demographics, household structure, household poverty and income, educational attainment, child assets, household member interactions with the child, caregiver mental health, social support, and digital literacy. The baseline survey also collected data on the child's age, sex, twin status, gestational length, birthweight, and attendance of daycare or other child- and household-supporting services as well as children's early development using the Caregiver Reported Early Development Instruments tool [39].

End-of-Study Assessments

The endline surveys will occur when children reach 2.5 years of age, which will begin in September 2023. Table 2 shows an overview of the study timeline.

Table 2. Study timeline and project activities.

Time period	Description of project activities
July 2020 to January 2021	Study setup, software development, and ethics board approval
February to July 2021	Field testing and finalizing tool development and high-frequency feedback to the programming team
September 2021 to March 2023	Enrollment and baseline survey of 2471 small children and their caregivers in the main trial plus 237 small children and their caregivers in the comparison group (total 2708 project participants)
September 2021 to August 2024	Parenting interventions
August 2023 to September 2024	Endline survey and assessments
October 2024 to February 2025	Data analysis
March 2025	Study dissemination event

The end-of-study assessment will involve gathering information on child development, maternal mental health, mother-child interactions, and parenting attitudes toward the child. To measure the primary outcome, we will use the GSED assessment tool [38]. Secondary outcomes include (1) caregiver-reported early child development in motor, cognitive, language, and socioemotional domains; (2) the quality of a caregiver-child relationship; (3) screen time with and without the child being present; (4) primary female caregiver's parenting behaviors; (5) parenting attitudes; and (6) mental health. Table 1 provides details on the instruments used.

Additional Data Collection

To monitor and ensure the quality of the Afini platform, we collect data on users' platform usage and interactions with the system for the Afini group. These data include activities dispatched to the users, users' ratings, and feedback on the activities and questions asked. This data access is restricted to the service developers and maintainers and associated with an anonymized internal ID. Through these data, we identify users that have been "recently active" in the platform, which we define as having interacted with the service in any way in the past 15 days. A randomly selected subset of households in the Afini group, qualifying as "recently active," receives a small biweekly data credit transfer (US $0.8 to US $2.0) to evaluate a potential increase in the use of the platform through small rewards. The data transfer cost and value depend on the service provider (Claro and Bitel) and the aggregator used to perform the credit transfer (Reloadly and DTOne), with these costs increasing within that range from the start of the reward program.

Home Visits

For each home visit, a short visit form was completed to document the time and date, topics covered, and toys delivered. Additionally, we collected information about the play environment, the toys available, and the interactions between the caregiver and the child at the time of the visit.

Table 3 provides an overview of all study activities. Recruitment and baseline surveys started in the third quarter of 2021. Given the prerandomization of clusters to treatment, interventions were initiated directly after baseline in September 2021, gradually increasing sample sizes in all arms. Recruitment was completed in January 2021, and the first households were scheduled to complete the endline assessment (and exit the study) in September 2023. Interventions will continue (with a steadily decreasing number of households) until the last household completes the endline survey and exits the study in late 2024.

[a]Summarizes data collection and intervention activities. Each cell corresponds to a quarter in the 2021-2024 period. Active data collection periods and active intervention periods are marked with a ✓.

Statistical Analysis

After confirming the psychometric reliability and validity of our key variables, we will perform a descriptive analysis (means and percentages) for the main characteristics and calculate prevalence and proportions for the primary outcomes. We will use standard linear regression models to assess the impact of the 2 intervention arms on child development. The primary outcome variable will be overall development as measured by the GSED, normalized to a developmental *z* score with a mean (0, SD 1) in the global reference population. Our primary empirical approach will be intent-to-treat, that is, comparing average outcomes across the 3 arms (independent of intervention compliance) with average outcomes in the control group. We will also conduct additional per-protocol analyses measuring mean differences between compliant children in the intervention arms with compliant children in the control group. For the home visit group, compliance will be defined as receiving at least 18 out of the 36 anticipated visits over the 18-month intervention period. Compliance with the Afini intervention will be defined as having interacted with the system at least once per month for at least 6 months in the observation period. Cluster-robust standard errors will be used to account for the cluster-level randomization of the intervention. Separate models will be estimated with and without baseline covariates.

Specifically, we will assess and control for household factors, caregiver factors, and child factors. Structural equation modeling will be used to test subgroup and mediation effects.

We will calculate the intervention's cost-effectiveness by comparing the developmental outcomes observed in the 2 intervention arms to the average developmental levels in the control arm to the costs of the 2 interventions per child.

Ethical Considerations

The study was approved by the University Peruana Cayetano Heredia institutional review board in Lima, Peru (SIDISI: 202522-Ref 030-03-21) and the Ethics Commission for Northwest and Central Switzerland (EKNZ: AO_2021-00002). All participants signed an informed consent before participating in any project-related activity. Verbal consent was asked for key informant interviews and focus group discussions during the pilot phase. The nature of the study was thoroughly explained to all participants, and all questions were answered before obtaining informed consent. Community leaders and local authorities are aware of the study.

Results

As shown in Table 2, enrollment and baseline data collection were completed in March 2023, and endline assessments were launched in September 2023. Table 4 shows descriptive statistics for the baseline sample by study arm. On average, children were 5 months old at baseline, 49.9% (1223/2452) were female, 8.1% (199/2452) had low birthweight (<2500 g at birth), and 97.5% (2391/2452) of children had a child health card. On average, mothers were 28 years old and considered literate. Fathers were slightly older, with an average age of 31.5 years at baseline, and had slightly higher education levels than mothers. The average household consisted of 2.5 adults and 1 additional child (sibling).

[a]CREDI: Caregiver Reported Early Development Instruments.

[b]SES: socioeconomic status.

We anticipate completing the endline assessments in September 2024 and presenting final trial results to the local and national governments in Peru in early 2025.

Discussion

Principal Findings

In this study, we present the design and setup of a cluster randomized trial to evaluate the effectiveness and cost-effectiveness of Afini, a digital platform that provides digital support to children from 0 to 7 years of age. The trial compares the developmental improvement achievable through the Afini platform to developmental improvements achievable through home visits, which currently are considered the gold standard in this field. While home visits offer the advantage of personal interactions with caregivers, the main benefits of new technologies, such as Afini, lie in their flexibility. Using a chatbot and AI system, Afini efficiently and automatically takes into account the caregiver's and child's preferences. It then offers age-specific recommendations for development-promoting activities that parents can undertake with their children whenever they have the time for such interactions. The platform also provides advice on early child development, well-being, and health similar to the contents typically delivered through ECD home visits.

The proposed trial is innovative and timely for several reasons. Due to the rapid global increase in cell phone coverage [25], there are now unprecedented opportunities for health and education systems to interact with patients and families and intervene at scale effectively and efficiently [31,33,34]. These advances have paved the way for the development and use of parenting support platforms as a means of engagement [26,30,43,45,46]. However, several key questions must be addressed before such platforms can be used in remote and resource-constrained settings. These include understanding their reach and actual impact on child development. Additionally, it remains unclear whether these technologies can be scaled to populations with limited digital literacy.

Understanding the extent to which digital platforms can reach low-income communities and families is crucial for understanding the feasibility and effectiveness of digital platforms in addressing the needs of vulnerable populations. During our formative research, we were particularly concerned about the challenges related to technology access, internet connectivity, and affordability. However, our early findings indicated that the large majority of mothers with young children had internet and smartphone access. Furthermore, 2 months after baseline, 84% of mothers reported using the platform at least once, and 87% rated it as useful [35]. Similar studies conducted in LMICs have also reported high acceptance of digital parenting interventions [47,48] and good reach for mobile health interventions to improve maternal and child health [31,34]. However, the majority of existing data on digital parenting support interventions during early childhood has been collected in high-income countries [27,30,33,43]. While those studies show promise in parenting outcomes and engagement, such as enhancing parental self-efficacy [49,50], data from LMIC contexts are largely missing. Furthermore, to date, limited data exist on digital parenting interventions' impact on child development, with few randomized controlled trials [51], and many studies still in the piloting stages, with small samples, or in ongoing data collection [52-54].

Our second question revolves around the impact of digital platforms on caregiver-child interactions and child development in low-resource communities. Caregiver-child interactions are

XSL•FO
RenderX

vital for a child's early development, and it is important for a digital platform targeting households in low-resource communities to facilitate positive and developmentally appropriate caregiver-child interactions. A study conducted in the United States examined the availability and quality of the apps in app stores and found very few apps offering tailored materials to parents instead of promoting generic guidance that may have limited usefulness in certain contexts [55]. However, several pilot studies demonstrated that digital interventions are feasible, engaging, and cost-effective ways for delivering developmental education to families, particularly in enhancing language-promoting behaviors [56,57]. A recent review highlighted the potential of mobile health and apps to promote early language development as well, although it raised concerns about the frequency and consistency with which parents will access and use digital interventions in their daily lives [58].

From a policy perspective, scalability is maybe the most critical aspect to consider when evaluating a digital platform. It is important to assess whether the platform can be successfully extended to other settings and populations beyond the initial study in the rural Andes. This becomes especially relevant when there is a possibility of limiting access for subsets of the population with varying levels of digital literacy, particularly in the absence of guidelines or follow-up assistance. Initial data collected in the study area showed that smartphone access and connectivity are almost universal [35]. While there have been limited studies demonstrating scalability thus far, it is essential to identify any unanticipated limitations or challenges that may arise during implementation and adherence, particularly in populations with diverse levels of digital literacy.

The proposed study has some limitations. First, while all intervention content was carefully adapted and is thus optimized for the local context studied, the materials used (and results obtained) may not directly work and translate to other settings. Second, our study is only able to follow-up children for about 2.5 years and can thus only give short-term treatment effects that may not fully capture long-term gains for treated children. Third, our intervention focused primarily on a broad measure of child development and did not offer specific insights into more narrow areas of early childhood health such as nutrition or emotional development. Future studies will be needed to address these issues.

Conclusions

This trial will provide valuable insights into the impact and scalability of tailored digital ECD platforms, particularly in reaching remote and vulnerable populations in low- to middle-income settings, and address challenges faced by home visiting models, such as cost and sustainability. We wish to demonstrate the platform's effectiveness, especially among diverse population groups with varying levels of digital literacy. This is crucial for designing effective future interventions.

Acknowledgments

We would like to thank the Botnar Research Center for Child Health for providing funding support for this project and all the mothers and children participating in the trial for their engagement and willingness to participate in this study. We also thank the project's field team for their relentless efforts to interact with the mothers and children obtaining the data.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request. All trial data will be made publicly available upon completion of the trial and analysis.

Conflicts of Interest

None declared.

Abstract

Background: Community service providers (CSPs) play an integral role in the health care of low-income Hispanic or Latinx (HL) communities. CSPs have high-stress frontline jobs and share the high-risk demographics of their communities. Relational savoring (RS) has been associated with lower cardiovascular reactivity and psychosocial benefits, with particular promise among HL participants. In this study, we aim to identify RS's potential in promoting CSPs' cardiometabolic health and, in so doing, having broader impacts on the community they serve.

Objective: This randomized controlled waitlist study aims to examine the effect of an RS intervention on (1) CSPs' cardiometabolic health (cardiometabolic risk factors and outcomes) and (2) CSPs' threats to leaving the workforce.

Methods: We will recruit a sample of 80 CSPs from community health agencies serving low-income HL populations. Participating CSPs will be randomized into an experimental or a waitlist control. Participants will complete 1 or 2 baseline assessment batteries (before the intervention), depending on the assigned group, and then complete 2 more assessment batteries following the 4-week RS intervention (after the intervention and at a 3-mo follow-up). The RS intervention consists of guided reflections on positive moments of connection with others. Electrocardiogram data will be obtained from a wearable device (Polar Verity Sense or Movisens) to measure heart rate variability. The primary outcome is cardiometabolic health, consisting of cardiometabolic risk (obtained from heart rate variability) and cardiometabolic health behaviors. The secondary outcomes include CSPs' threats to leaving the workforce (assessed via psychological well-being), intervention acceptability, and CSPs' delivery of cardiometabolic health programming to the community (exploratory). Analyses of covariance will be used to examine the effects of RS on cardiometabolic health and on CSPs' threats to leaving the workforce, comparing outcomes at baseline, postintervention, and at follow-up across participants in the experimental versus waitlist group.

Results: The study has been approved by the University of California, Irvine, Institutional Review Board and is currently in the data collection phase. By May 2023, 37 HL CSPs have been recruited: 34 have completed the baseline assessment, 28 have completed the 4 intervention sessions, 27 have completed the posttreatment assessment, and 10 have completed all assessments (including the 3-mo follow-up).

Conclusions: This study will provide valuable information on the potential of RS to support cardiometabolic health in HL CSPs and, indirectly, in the communities they serve.

Introduction

Background

Ethnic and racial disparities in cardiometabolic health within the United States have been widely documented [1-5]. Racial-ethnic minoritized and historically underrepresented groups, including Hispanic or Latinx (HL) Americans, face higher cardiometabolic risks, such as obesity, diabetes, hypertension, and dyslipidemia, than non-HL White Americans [6,7]. According to data obtained from the National Health Interview Survey of 2018, HL adults are 1.3 times more likely to die from diabetes and 70% more likely to be diagnosed with diabetes by a physician than non-Hispanic White (NHW) adults [8]. Similarly, HL Americans are 1.2 times more likely to be obese than NHW Americans, whereas HL women are 20% more likely to be overweight than their NHW counterparts [9]. The etiology of cardiometabolic risk disparities in racial-ethnic minoritized communities, including low-income HL communities, is multifactorial and includes socioeconomic, behavioral, and environmental factors. Cultural and language barriers, lack of health care access, and differences in education and employment opportunities contribute to these disparities [1,5,10]. Community service providers (CSPs), also called *promotores de salud*, are members of the community who provide culturally appropriate health education and information, offer support and care, and advocate for the community's health needs [11]. These roles empower HL CSPs to help community members overcome or withstand the barriers that contribute to health inequalities.

Through culturally accessible programming, CSPs help prevent and manage chronic diseases, including cardiometabolic diseases, in the communities they serve. Indeed, CSPs play a significant role in reducing health risks and disease burden as well as in the management of various health problems, including hypertension, diabetes, HIV infection, cancer, and cardiovascular disease [12-16]. Community interventions led by CSPs have been proven to effectively lower cardiometabolic risk factors in HL communities while being affordable and well received by community members [12-16]. These include, among others, prevention programs targeting diabetes and obesity, which effectively impact risk factors such as blood pressure, low-density lipoprotein cholesterol, triglycerides, insulin, sedentary behaviors, and one's weight [12-16]. There are many advantages to CSPs belonging to the same communities they serve, including cultural and linguistic understanding, trust, credibility, and rapport. All of this contributes to community members' engagement and retention in interventions that improve health outcomes and provide long-term support. However, sharing the same demographic characteristics also means that HL CSPs face the same high cardiometabolic risks as the community members they serve. In fact, it is often the case that CSPs are individuals who themselves have experienced health challenges and have learned to manage their conditions (eg, diabetes, HIV). In addition to providing support to others, as they have been trained to, their own health concerns might still require monitoring and self-management. Furthermore, the high-stress nature of their occupations may further amplify health risks. This is especially true when considering the extensive stress that the COVID-19 pandemic brought to frontline health care workers, including CSPs. In support of this assertion, a qualitative analysis found that the pandemic affected CSPs' work and daily life, leading to psychological and social stress [17].

CSPs, along with all frontline health care professionals (HCPs) during the pandemic, experienced acute psychological distress and associated effects [17]. A study analyzing the role of CSPs in the COVID-19 pandemic response reports that CSPs faced significant exposure to stress and grief, among other difficulties [18]. In addition, HL communities, as well as other minoritized communities, were more likely to be exposed to the SARS-CoV-2 virus, to experience severe forms of COVID-19, and to face higher mortality rates [19,20]. Understandably, this led to catastrophic financial and social consequences in low-income HL communities. Owing to the comprehensive support that CSPs provide to community members, which addresses not only physical health but also various financial and social needs (eg, unemployment, housing insecurity, food insecurity, domestic violence, and language barriers to navigate legal paperwork), CSPs carried a significant burden [17]. Considering the fact that they are at higher risk for negative health outcomes (eg, diabetes, high blood pressure, and overweight) based on demographics alone and the role they played during the pandemic, which led to heavy workloads and high stress, CSPs may face substantial risk for cardiometabolic disease. Nevertheless, to the best of our knowledge, there have been no interventions aimed at protecting cardiometabolic health specifically in CSPs.

By placing enormous demands on CSPs, the aftereffects of COVID-19 have placed CSPs at risk of professional burnout, endangering their abilities to deliver this care [17,21]. CSPs play a crucial role in the health of underserved communities, but to carry out their greatly needed service, there must be a system that promotes and protects their health and well-being. Supporting CSPs is a matter of equity; in response to the health care system failure to adequately support medically underserved communities, the CSP model represents these communities' efforts to promote health and build resilience. Although no previous studies have specifically examined how CSPs' physical and psychological well-being relates to the quality and reach of their services, researchers have investigated how burnout in other HCPs affects the quality and safety of the care they provide [22,23]. In line with theory, a meta-analysis comprising 210,669 HCPs concluded that burnout (depersonalization, emotional exhaustion, and reduced personal accomplishment) is negatively associated with quality (perceived quality and patient satisfaction) and safety of care [22]. Similarly, in a systematic literature review, burnout among physicians was associated with decreased productivity, as evidenced by the number of sick days, hours worked, number of patients seen, and intent to leave the profession [23]. Considering these relationships between

XSL•FO
RenderX

HCPs' burnout and reduced productivity, impaired quality of care, and reduced safety of the care provided, it is reasonable to expect similar associations between CSPs' well-being and the reach and quality of the services delivered to the community. As such, interventions designed to promote CSPs' well-being and prevent their burnout are a necessity.

Relational Savoring: A Culturally Congruent Approach

Relational savoring (RS), based on positive psychology and attachment theory, is a brief intervention in which one deeply reflects on a positive emotional experience involving a moment of connection with another person [24]. The underlying premise is that focusing on a memory of positive connection will augment the meaning and positive emotion associated with this interpersonal experience [24]. Through this process, one's sense of psychological agency, fulfillment, and satisfaction are enhanced [24]. Similarly, per attachment theory, experiences of felt security such as *safe haven* (a time when an attachment figure provided care of comfort) and *secure base* (a time when the support provided by an attachment figure allows one to take a risk one would not have taken otherwise) in our early relationships constitute the basis of later socioemotional health [25]. As such, moments of closeness recalled in an RS intervention include times when one supported (secure base) or comforted (safe haven) another person and felt deep positive emotions such as joy, peace, satisfaction, or love [24]. For CSPs, experiencing interpersonal connectedness when helping members of their community is a common occurrence [26], thereby underscoring the cultural congruence of this intervention. RS has the potential to prolong and enhance the attention given to these moments, helping CSPs lower stress and motivating them to continue engaging in their meaningful and necessary work.

Although RS has not previously been tested with CSPs or HCPs, other interventions rooted in positive psychology, such as the Web-based Implementation for the Science of Enhancing Resilience (WISER) intervention, have been found to decrease burnout and depression and support work-life integration in neonatal intensive care unit HCPs [27]. The WISER intervention includes 6 modules, 2 of which are titled "Three Good Things" and "Relationship Resilience" and refer to reflecting on 3 positive moments that occurred that day and reflecting on positive interactions, respectively. Considering RS's focus on reflecting and enhancing positive emotions linked to a relational memory, there are considerable similarities with these 2 modules of WISER. Likewise, support for the RS intervention exists in its prior findings with other samples. Findings across studies with parent-child dyads, long-distance couples, older adults, and male adolescents in residential treatment have shown that RS can improve emotional states, psychological agency, relational schemas, and relationship satisfaction compared with control conditions [28-32]. Likewise, the RS intervention shows promise in affecting physical health by impacting health behaviors and lowering heart rate [29,31]. In addition, previous studies report that RS might be especially effective in HL populations because of its compatibility with cultural values [28]. Considering the potential of RS in positively impacting psychological and physical health in different populations, as well as evidence suggesting cultural computability, it is worth exploring its effect among HL CSPs.

In this study as well as in previous studies [26,28-32], while maintaining its core characteristics, the RS intervention is tailored to our priority population of HL-serving CSPs. This was done based on discussions held between the investigative team and the CSPs regarding what brings them meaning in relation to the job. Furthermore, the results of a qualitative study of *promotores'* experiences during the pandemic revealed important insights regarding the meaning derived from work as well as the unique challenges posed by working during the pandemic [17]. The challenges reported included enduring their own and their community's losses, which placed them at risk of compassion fatigue or vicarious traumatization, along with feelings of grief and anxiety [17]. However, by being able to provide help to the community during difficult times, their work also provided a source of agency and meaning [17]. Therefore, in this investigation, RS focuses on assisting CSPs' recall moments of connection with community members while doing their work and engaging with the community.

Finally, the participants in this study are all CSPs who serve the HL community, with most of them being HL themselves. Although we recognize that *Hispanic* and *Latinx* refers to individuals with origins in different countries, racial backgrounds, and levels of acculturation, there are cultural values that seem to be shared across communities of Latin American origin. Shared values include, among others, *simpatía*, the inclination toward emotional positivity or warmth and the avoidance of negativity or conflict with others, and *familismo*, valuing close family connections above the individual or self [33,34]. Considering that RS focuses on finding and reflecting on moments of warmth and connection, this intervention is culturally compatible with HL populations without the need for substantial tailoring [24]. In agreement, a previous study reported that HL mothers, but not non-HL mothers, showed a greater response to an RS intervention than to a personal savoring intervention [24]. Likewise, besides cultural congruence, HL CSPs share the fact that their job is caring for and supporting community members. In other words, CSPs' day-to-day interactions with members of their communities may lead to various moments of connection that can be used throughout the RS intervention [26]. As such, the characteristics of their job may facilitate engagement with RS.

CSPs are required to support low-income HL communities' health. If their physical and psychological well-being are at risk, their ability to reach community members through their programming is compromised. Considering the challenges endured in the pandemic and the risk factors associated with both their demographic characteristics and their job responsibilities, there is a need for interventions that support HL CSPs' well-being. Bearing in mind this intervention's compatibility with CSPs' occupation and cultural background, RS holds immense potential.

Objectives

This study aims to analyze the effects of an RS intervention on (1) HL CSPs' cardiometabolic health (cardiometabolic risk and health behaviors) and (2) the risks of CSPs leaving the

XSL•FO
RenderX

workforce. We hypothesize that compared with participants assigned to the waitlist control condition, those in the RS condition will exhibit the following health improvements:

- 1a. Exhibit lower cardiometabolic risk (lower heart rate variability [HRV]) during a discrimination stressor task
- 1b. Report more favorable cardiometabolic health behaviors pertaining to sleep, exercise, and diet
- 2a. Show reduced threats to CSPs leaving the workforce (greater work satisfaction and psychological agency and lower burnout)
- 2b. Exploratory hypothesis: That introduction of the RS intervention into agencies will result in greater engagement, as evidenced by the following: agencies will show increases in their demonstrated reach to community members through their health programing (ie, fewer absent days, more health-related events offered, larger community attendance at their events, and larger retention of community members in their programs) during the period following the introduction of RS as compared with the 6 months preceding the introduction of RS

Methods

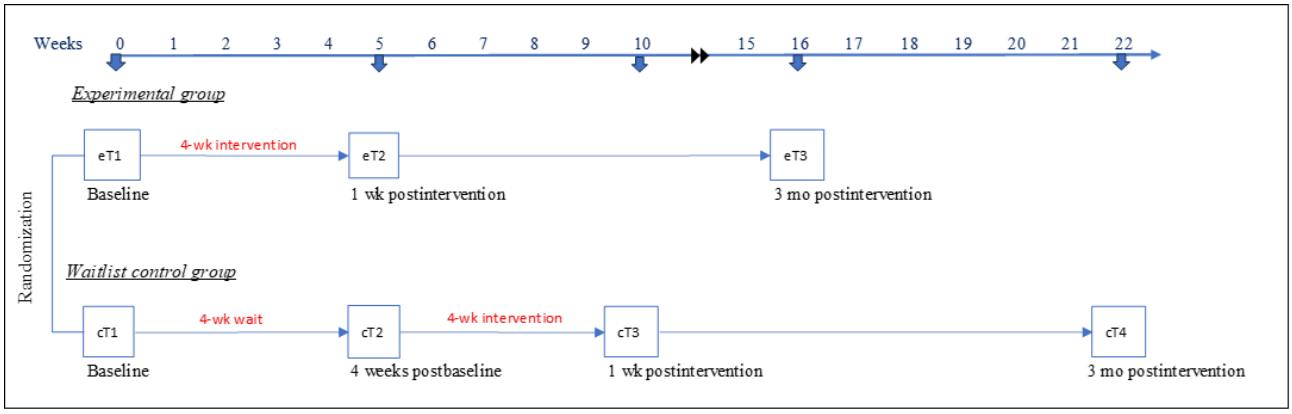
Ethical Considerations

In conducting this study, careful attention was given to the ethical considerations that guide the treatment of research participants, ensuring the protection of their rights, privacy, and well-being throughout the study.

1. The study was conducted in accordance with the Declaration of Helsinki, and the protocol was approved by the University of California, Irvine, Institutional Review Board (UCI IRB #1596).
2. Informed consent: All participants gave their informed consent for inclusion before they participated in the study.
3. Privacy and confidentiality protection: All identifiable data collected were removed and replaced with a code. A securely maintained list links this code to the identifiable information, and is kept separately from the research data. All research data are maintained in a secure location at the University of California, Irvine, to which only authorized individuals have access. The data are stored electronically on a cloud and an external drive in an encrypted, password-protected file. Video or audio recordings are stored in a secure location; these data are transcribed and deidentified before analyses.
4. Compensation: The CSPs are compensated for their participation in the study, with compensation broken down as follows: US $30 for baseline visit 1, US $40 for baseline visit 2 (waitlist control group only), US $25 for each intervention session (total US $100), US $40 for posttreatment session, and US $50 for the follow-up visit. Overall, participants can earn US $220 or US $260 depending on the assigned group (experimental vs control). Participants can choose to receive the compensation via Venmo (PayPal, Inc) or as a physical or web-based gift card.

Eligibility Criteria and Recruitment

All participants will be CSPs employed at partner community health agencies, including Latino Health Access (LHA), Dignity Health, and other agencies, to be recruited throughout our enrollment period. Participating agencies and CSPs will serve HL communities and will be located throughout the United States. Inclusion criteria include being aged ≥18 years and working (for payment or as a volunteer) as a CSP serving low-income HL families. Given that this pilot study is intended to test RS on a new population, we identified a sample size (n=80) that would allow us to identify a signal but not a statistically significant ($P<.05$) effect. This study aimed to generate a pilot study that could be used to support an adequately powered randomized controlled trial.



Participants will be recruited both offline and via email through their agencies, which will post advertisements in English and Spanish at their facilities, announce the opportunity in staff meetings and via email, and facilitate introductions between the research team and the CSPs. Interested participants will contact research personnel.

Randomization and Overview

In this randomized controlled waitlist design (ClinicalTrial.gov identifier NCT05560893), the CSPs will be randomly assigned to an experimental group or a waitlist group. Both groups will complete an identical assessment battery (assessing health behaviors and psychological well-being) and complete stressor tasks (assessing cardiometabolic risk) before the intervention, after the intervention, and at a 3-month follow-up. The experimental group will receive the RS intervention (4 sessions, 1/wk) 1 week after the baseline assessment (Figure 1). The waitlist group will complete the baseline assessment, wait 4 weeks, complete a second baseline assessment, and 1 week later receive the RS intervention. After completing the RS intervention, the participants in both the experimental and waitlist groups will complete the postintervention assessment 1 week later and a follow-up 3 months later.

XSL•FO
RenderX

Figure 1. Randomization and timeline.

Measures

Primary Outcomes

All the constructs and measures assessed are summarized in Table 1.

All assessments are available in both English and Spanish. Cardiometabolic health, as indicated by cardiometabolic risk and cardiometabolic health behaviors, will be the primary outcome and will be measured before the intervention, after the intervention, and at the 3-month follow-up. Cardiometabolic risk will be measured via HRV in response to a stressor task. The stressor task will consist of a discrimination stream-of-consciousness (SOC) task [35,36], where participants will talk for 4 minutes about an occasion where they felt discriminated against. Before completing the SOC task, participants will complete a questionnaire [36] that will provide them with a list of commonly occurring discrimination events from which they can select an event that has occurred to them. Vagally mediated HRV will be calculated from the variability of the interbeat intervals obtained from electrocardiogram (ECG) data. ECG data will be recorded using a Polar Verity Sense heart rate monitor or Movisens device, small wearable devices that the participants will place in their arm or chest, respectively, during the stressor task and at rest (before and after the stressor task baseline measures). Favorable cardiometabolic health behaviors include behaviors pertaining to sleep, exercise, and diet and will be assessed using the Pittsburgh Sleep Quality Index [37], the International Physical Activity Questionnaire–Short Form [38], the Food Behavior Checklist [39], the 36-Item Short Form Health Survey [40], and 2 self-developed scales (subjective assessment of overall health and impairment owing to overall health).

The measures and tasks used to assess the primary outcome, cardiometabolic health, are described in the following sentences:

1. Everyday Discrimination Scale: the participants will complete a Spanish version of the Everyday Discrimination Scale [36], a 9-item scale that assesses the frequency and the attribution of discrimination experiences (eg, In your day-to-day life, how often are you treated with less respect than other people are?) to assist them in identifying a discrimination experience to speak about in the SOC task. Items are rated on a scale of 0 (never) to 5 (almost every day), with higher scores indicating a higher frequency of discrimination experience. Previous studies have demonstrated good reliability and validity in HL samples [41].

2. SOC task: after a 2-minute baseline task (sitting with no stimuli), the participants will be asked to select an experience of discrimination to focus on for a SOC task. To help them do this, the participants will complete a brief questionnaire of common discrimination experiences, followed by a 5-minute interview to help them select among the experiences reported on the questionnaire. This cardiovascular reactivity task is modeled after a SOC task previously used in our laboratory [35], modified to be ecologically relevant to this population. The SOC task will ask the participants to speak for 4 minutes about the discrimination experience, focusing on the thoughts and feelings they had. The participants will then complete a 2-minute resting-recovery task wherein they will speak about a positive memory. The prompt for the SOC task is as follows (prompt translated to Spanish and available in English and Spanish, based on participant's preference):

> *For the next four minutes, I would like for you to please discuss in detail your experience during this time that you have identified when you felt [insert discrimination experience here]. Please discuss your thoughts, feelings, hopes, and concerns about the experience. Remember, there are no right or wrong answers, so please say whatever comes to mind. Your job is to talk continuously about anything that comes to mind about this experience for the 4-minute period. We will record your responses because how you are thinking and feeling about this experience is very important to us.*

3. Pittsburgh Sleep Quality Index: the participants will report on their sleep quality using the Spanish version of the Pittsburgh Sleep Quality Index [42], a 10-item measure that assesses sleep quality and duration. Items (eg, How many hours of actual sleep do you get at night—this may be different than the number of hours you spend in bed?) are rated on a scale of 0 to 3, whereby higher scores reflect more sleep disruption. Previous studies have demonstrated good reliability and validity in HL samples [43].

4. Food Behavior Checklist: the participants will report on their diet using the Food Behavior Checklist for Spanish speakers [39], a 16-item questionnaire that measures basic dietary behaviors, including the frequency of fruit, vegetables, juice,

XSL•FO
RenderX

and low-fat dairy consumption; food insecurity; shopping; and cooking techniques. Previous studies have demonstrated good reliability and validity in HL samples [44].

5. Thirty six-Item Short Form Health Survey: the participants will report on their overall health using a Spanish version of the 36-Item Short Form Health Survey [40], a 36-item quality of life measurement that assesses 8 health-related domains, including physical functioning, role limitations because of physical problems, bodily pains, general health perceptions, vitality, social functioning, role limitations because of emotional problems, and perceived mental health. Previous studies have demonstrated good reliability and validity in HL samples [45].

6. Subjective assessment of overall health: the participants will report on their subjective assessment of their overall health by answering a 2-item scale designed for this study. Items assess perceptions of health (eg, Compared with men or women of your age, how would you define your health?) and are rated on a scale of 0 (bad) to 5 (excellent).

7. Impairment owing to overall health: the participants will report on impairments owing to their overall health by answering a 2-item scale designed for this study. Items assess behaviors related to health (eg, During the past 3 months, how many times have you missed school or work for physical or health problems?) and are rated on a scale from 0 (never) to 5 (>10 times).

8. International Physical Activity Questionnaire—Short Form: the participants will report on their exercise habits using a Spanish version of the International Physical Activity Questionnaire–Short Form [38], a 7-item scale that assesses the duration and intensity of physical activities undertaken over the previous 7 days, including the number of hours engaged in physical activity at different intensities, including walking, moderate-intensity activities, and vigorous-intensity activities.

Table 1. Outcomes: constructs and measures assessed.

Outcomes and constructs	Measures assessed
Primary outcome: cardiometabolic health	
Cardiometabolic risk	
Stressor-level heart rate variability	• Everyday Discrimination Scale • SOC[a] task
Cardiometabolic health behaviors	
Sleep quality	• Pittsburg Sleep Quality Index
Diet	• Food Behavior Checklist
Overall health	• 36-Item Short Form Health Survey
Subjective assessment of overall health	• Self-Developed Scale
Impairment due to overall health	• Self-Developed Scale
Exercise	• International Physical Activity Questionnaire–Short Form
Secondary outcomes	
CSPs'[b] threat to leaving the workforce (psychological well-being)	
Psychological well-being	• Brief Symptom Inventory
Emotion	• Self-Assessment Manikin
Closeness to community	• Inclusion of Other in the Self Scale–Community Version
Trauma history	• Traumatic Life Events Questionnaire
Burnout	• The COVID-19 Burnout Scale • Maslach Burnout Inventory
Job satisfaction	• Job Satisfaction Survey
Psychological agency	• Coder-rated measures based on SOC
Reflective functioning	• Coder-rated measures based on SOC
Intervention acceptability	
Savoring uptake	• Self-developed questionnaires
Intervention acceptability	• Self-developed questionnaires
Community reach	
Number of days CSPs worked	• Information obtained from agency
Number of health-related events offered	• Information obtained from agency
Retention of community members in programs	• Information obtained from agency
Community attendance at events	• Information obtained from agency

[a]SOC: stream-of-consciousness.

[b]CSP: community service provider.

XSL•FO
RenderX

Secondary Outcomes

Secondary outcomes include threats to CSPs leaving the workforce, which will be assessed via psychological well-being (ie, agency, burnout, and job satisfaction) and intervention acceptability. For these secondary outcomes, we will use the Brief Symptom Inventory-18 [46], the Self-Assessment Manikin [47], the Inclusion of Other in the Self Scale–Community Version (IOS-C) [48], the COVID-19 Burnout Scale [49], the Maslach Burnout Inventory [50], the Traumatic Life Events Questionnaire [51], and the Job Satisfaction Survey [52]. RS intervention acceptability and savoring uptake will be assessed via self-developed questionnaires. All these will be assessed before the intervention, after the intervention, and at the 3-month follow-up.

Finally, the CSPs' delivery of cardiometabolic health programming to the community will be measured in an exploratory manner. This will be assessed via the number of days the CSPs worked, the number of health-related events offered, the retention of community members in the programs offered by the CSPs, and the number of community members attending the events. Data from the time following the introduction of RS will be compared with those from the 6 months preceding the introduction of RS. This information will be obtained from the health agencies' institutional data. It is worth mentioning that these measures are not a reflection of the CSPs' effectiveness, given that the CSPs may meet with fewer community members at any given time yet effectively support them in improving their health outcomes. Likewise, given different structures or job tasks across agencies (eg, leading groups, doing outreach, and follow-ups), there might be differences in how these measures are analyzed in the future. The collection of these data will not enable us to detect differences between the intervention and waitlist control groups. We intend to collect these data on the CSP's delivery of health programming to lay the groundwork for a more in-depth future investigation of the impact of RS.

The measures and tasks used to assess the secondary outcomes are described in the following sentences:

1. Brief Symptom Inventory: the participants will report on their psychological well-being using the Spanish version of the Brief Symptom Inventory-18 [46], an 18-item measure assessing depression (eg, During the past week including today, how much were you distressed by feelings of worthlessness?), anxiety (eg, During the past week including today, how much were you distressed by nervousness or shakiness inside?), and somatization. Items are rated on a 5-point scale ranging from 0 (not at all) to 4 (extremely). Previous studies have demonstrated good reliability and validity in HL samples [53].
2. Self-Assessment Manikin: the participants will report on their emotions using the Self-Assessment Manikin [47], a widely recognized nonverbal pictorial measure that assesses emotional states, valence, and arousal levels using pictures to represent how a participant is feeling in response to stimuli.
3. IOS-C: the participants will report on closeness to the community using IOS-C [48]. This single-item pictorial measure uses Venn‐like diagrams—each diagram represents different degrees of overlap of 2 circles, progressing through 7 equal steps, representing lower and higher levels of closeness as the circles overlap more and more. The Inclusion of Other in the Self Scale has good test-retest reliability and convergent validity and has been used in samples with a large percentage of HL participants [54].
4. Traumatic Life Events Questionnaire: the participants will report their trauma history using the Spanish version of the Traumatic Life Events Questionnaire [51], a 23-item scale measuring whether an individual has experienced a wide range of traumatic events, including sexual assault, exposure to combat, or the unexpected death of a loved one, on a scale ranging from 0 (never) to 4 (≥5). Previous studies have demonstrated good reliability and validity in HL samples [55].
5. The COVID-19 Burnout Scale: the participants will report on their COVID-19 related burnout using the COVID-19 Burnout Scale [49], a 10-item scale that measures burnout feelings related to the pandemic. Items (eg, When you think about COVID-19 overall, how often do you feel hopeless?) are scored on a scale ranging from 0 (never) to 6 (all the time).
6. Maslach Burnout Inventory: the participants will report on their occupational burnout using a Spanish version of the Maslach Burnout Inventory [50], a 22-item scale that measures occupational exhaustion, depersonalization, and level of personal accomplishment related to work. Items (eg, I have become more callous to people since I have started doing this job) are scored on a scale ranging from 0 (never) to 6 (every day). Previous studies have demonstrated good reliability and validity in HL samples [56].
7. Job Satisfaction Survey: the participants will report on their job satisfaction using the Spanish version of the Job Satisfaction Survey [52], a 36-item assessment measuring attitudes related to the job and aspects of the job. Items (eg, I feel I am being paid a fair amount for the work I do) are scored on a scale ranging from 1 (disagree very much) to 6 (agree very much). Previous studies have demonstrated good reliability and validity in HL samples [57].
8. Savoring uptake: after completing the intervention, the participants will reflect on the savoring experience using the savoring uptake questionnaire that was developed for this study. The 6-item questionnaire measures the frequency at which participants have engaged in savoring since their last session, how useful they found savoring, how valuable they found savoring, whether they would recommend the program to others, and whether they would like to continue savoring on their own time. Items are scored on a scale ranging from 1 (not at all likely, useful, or valuable) to 5 (extremely likely, useful, or valuable).
9. Intervention acceptability: the participants will report on the acceptability of the RS intervention by completing the Relational Savoring Acceptability Questionnaire, a 14-item assessment created for this study to capture how participants feel before they begin the program (eg, I expect the program will improve my feelings about my work) and how they

XSL•FO
RenderX

feel after they complete the program (eg, The program improved my health and well-being) on a scale ranging from 1 (strongly disagree) to 5 (strongly agree).

Intervention

Consistent with prior work, the RS intervention will involve 4 weekly sessions, each lasting approximately 30 minutes, consisting of 2 phases: memory selection and memory reflection (Textbox 1).

Textbox 1. Relational savoring: intervention phases.

Phases and steps

- Memory selection
  - Recall a few memories of positive connectedness or attachment content when helping community members.
  - Participants describe these memories and interveners ask follow-up questions designed to reveal the level of specificity, positivity, connectedness, and potential for spoiling in the memories.
  - Interveners select one specific memory with the best content for the next phase.
- Memory reflection (5-step guided reflection)
  - Sensory reflection (eg, Where were you? What did your surroundings look like? What could you hear?)
  - Emotion reflection (eg, What did you feel?)
  - Meaning making (eg, What did you think?)
  - Future-oriented reflection (eg, What do you think will happen in the future thanks to this connection?)
  - Mind-wandering reflection (eg, What else comes to mind?)

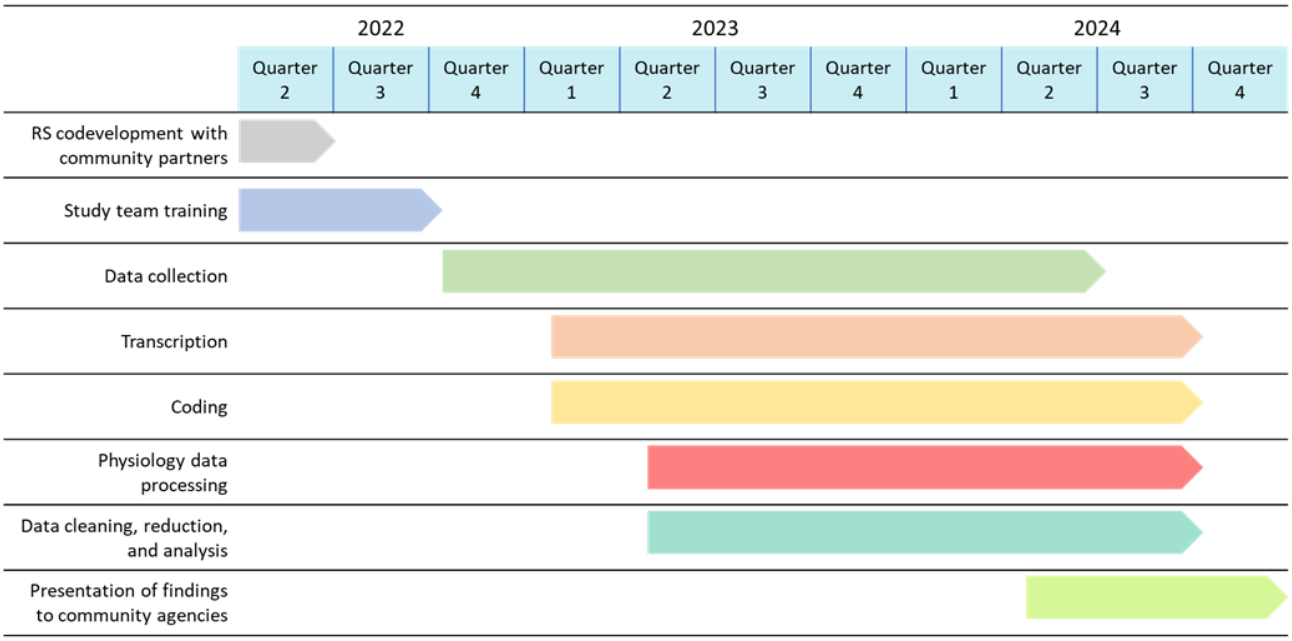
RS is a manualized intervention that has been adapted to allow CSPs the opportunity to savor memories of providing care to community members to enhance their sense of connectedness to the community [24,28]. In this study, as in previous studies, the intervention will be delivered by paraprofessionals (eg, undergraduate and postbaccalaureate students) [28]. Previous studies have shown that the intervention can be administered with high fidelity by paraprofessionals with a low level of clinical training (4 h of didactic training plus approximately 4 h of practice-based training) [28].

At the beginning of RS, the CSPs will complete a 1-minute mindfulness exercise, which is consistent with prior studies [28,29]. Next, during the first phase of the RS intervention (*memory selection*), the CSPs will be guided to generate memories of the times when they felt closeness, connection, or joy when they were able to support, encourage, or protect community members. The participant will be guided to select a memory with substantial attachment content (ie, secure base and safe haven memories). Alternatively, if the participant is unable to produce a memory explicitly related to safe haven or secure base content, they may select a memory involving a moment of positive connectedness or togetherness [28]. Then, during the second phase (*memory reflection*), the CSPs will engage in a 5-step guided process, where they will reflect on sensations, emotions, and cognitions associated with the selected moment. Sessions will be conducted via Zoom (Zoom Video Communications, Inc) by trained bilingual and bicultural research assistants in the participant's language of choice (Spanish or English). The RS sessions will be recorded and transcribed to assess themes that emerge during the savoring sessions and to analyze therapist fidelity and therapist-client relationship quality. In addition, immediately before and after each intervention session, the participant will complete a 2-question survey assessing the participant's mood (Self-Assessment Manikin) and perceived closeness to the community (IOS-C) [47,48].

Data Analytic Plan

Descriptive statistics will be used to analyze the demographic characteristics of our sample population. A series of analyses of covariance will be conducted to examine the effects of RS on HRV, health behavior, psychological well-being, threats to CSPs leaving the workforce, and the reach of CSPs' cardiometabolic health programming. We will compare outcomes at baseline, immediately postintervention, and at the 3-month follow-up across participants in the experimental versus waitlist group. HRV at baseline will be included as a covariate in analyses examining HRV, and all analyses will examine a range of potentially confounding covariates for potential use in analyses (eg, age, BMI, and socioeconomic status; those that are significantly associated with key study variables will be included as covariates in hypothesis testing). Effect sizes will be examined in all analyses. With a sample size of 80, it will be possible to detect small-to-moderate effects (yielding an effect size d=0.24) of RS on the CSPs' cardiometabolic health, threats of CSPs leaving the workforce, and the delivery of cardiometabolic health programming. As stated in the *Eligibility Criteria and Recruitment* section, our goal is not to detect statistically significant effects but rather to look for effect sizes to inform future studies.

Results



We expect that 80 CSPs will complete this study. The study was approved by the institutional review board in July 2022. CSPs from community agencies began participating in the study in October 2022, with 79 CSPs enrolled by November 2023.

XSL•FO
RenderX

The data collection process is expected to continue until May 2024 and will include participants from LHA, Dignity Health, Green Madison Park, Orange County Health Promoters, and potentially from additional partner community agencies serving low-income HL communities. Transcription; coding; physiological data processing; and data cleaning, reduction, and analysis will occur throughout the following months and after the completion of data collection (Figure 2). We expect to publish our findings during the fourth quarter of 2024.

We will answer our central research questions using statistical analyses. In addition to these central analyses, we anticipate using qualitative methods to examine savoring sessions and discrimination SOC recordings for the themes that emerge (eg, nature of work, sources of strength or stress, and recurring topics). These qualitative analyses have the potential to reveal important information about HL CSPs, an understudied and important population.

Figure 2. Study timeline. RS: relational savoring.

Discussion

Expected Findings

This study will provide valuable information on the potential of RS to positively impact cardiometabolic health in HL CSPs and, indirectly, in the communities they serve. By improving cardiometabolic health behavior and lowering HRV, RS can reduce the risk of cardiovascular disease in CSPs. Simultaneously, supporting CSPs' well-being and engagement can improve the community's cardiometabolic health. Theoretically, if CSPs are healthy both psychologically and physically, their risk of leaving the workforce is reduced, and more community members will be reached and impacted by CSPs' cardiometabolic health programming. This is particularly important in the context of communities' recovery following the COVID-19 pandemic and considering the unique ability of CSPs to reach community members in ways that the health care system is unable to do. Therefore, RS interventions aimed at CSPs have the potential to influence well-being and cardiometabolic health at both individual and community levels.

Importantly, RS appears to be compatible with both HL CSPs' cultural background and the characteristics of their job. This is evidenced by previous studies reporting greater benefits of RS in HL (vs non-HL) participants [28]. Likewise, CSPs are in constant interaction with community members, mostly in the context of CSPs providing some sort of support (eg, information, resources, and socioemotional support) [17,26]. This may facilitate engagement with the memories preferred for the RS intervention: moments where the participant helped or comforted others (safe haven) or when the participant provided support or encouragement (secure base) [24]. Congruence with both culture and occupation makes RS a particularly promising approach to support this population, especially when considering additional factors pertaining to the delivery of the intervention.

The use of culturally centered language is an important aspect to be considered in the delivery of psychosocial interventions [58]. As previously mentioned, the prompts generated for the RS intervention in this study were conducted in collaboration with our partner community health agency, LHA, to ensure culturally and linguistically appropriate wording. Relatedly, authors have contended that bilingual clinicians, rather than interpreters, are preferred to achieve optimal outcomes [58]. In this study, all participating CSPs are given the option of completing the intervention either in English or Spanish. Accordingly, RS is delivered by bilingual and bicultural trained paraprofessional interviewers, which may facilitate the use of culturally centered language throughout the interventions.

As previously mentioned, in this study, RS is delivered by paraprofessionals. Data from past studies have shown that RS can be administered at high fidelity by interveners who have had a low level of clinical training [28], such as interveners who are undergraduate college students and interveners who are

XSL•FO
RenderX

promotores (trained community workers without formal education in mental health). This suggests that RS could be effectively implemented in settings without the need of professional health personnel, suggesting great promise as a highly scalable intervention. The data from this study will provide an opportunity to further examine RS intervener training, which could have important implications pertaining to this intervention's potential for dissemination. The fact that we are delivering RS via telehealth further facilitates the interventions' reach and potential impact. The flexibility offered by the remote setup reduces participant burden by avoiding a commute to and from a specific location, while broadening the timeframe in which the intervention can take place throughout the day both for participants and interviewers [59]. Likewise, this allows for participation throughout the country.

If RS is shown to be effective in supporting HL CSPs' cardiometabolic health and psychological well-being, it could be implemented within the broader context of HL community health agencies' personnel (employed and volunteer). In a more encompassing sense, once the CSPs have completed the intervention, they could potentially be trained as facilitators and conduct the intervention with community members. Although the cultural congruence between RS and HL values may boost its efficacy in our priority population, RS has the potential to support CSPs from other non-HL low-income communities. Medically underserved communities that rely heavily on community health agencies, such as those served by the CSPs participating in this study, may be particularly benefited by interventions such as RS that show great portability.

Limitations

We anticipate that our study has limitations, some associated with the fact that the study will be conducted virtually, with participants usually at home or at their job location. Although remote sessions have advantages, it has been reported that it may be necessary to contact additional participants to reach enrollment and compliance goals in remote (vs in-laboratory) studies [60]. This is in addition to the fact that overall research recruitment has been affected since the pandemic. Likewise, the technology (devices, programs, and internet connection) needed to conduct remote studies can be unreliable, as has been found in previous studies [60]. Regarding the cardiovascular data, technical difficulties with the wearable devices and logistical issues in their delivery might result in missing ECG data, particularly given that the participants themselves will be tasked with deploying the devices. Given that one of the broader goals of the project is to provide information regarding the feasibility of the approach, any information yielded through this effort will be useful. However, missing data will preclude us from being able to understand the impact of RS on cardiometabolic health. Finally, we recognize that the planned analyses may be considered simple, yet this is what the sample size will afford. Furthermore, the data we can collect is limited to that which is feasible for the community agencies with whom we collaborate. These compromises accompany community-engaged work.

Conclusions

Although considerable efforts are being made to expand the CSP model, it is necessary to ensure that the CSP workforce is adequately supported. The RS intervention holds immense potential in supporting HL CSPs' overall health, specifically in lowering cardiometabolic risk. As such, RS could be used as a tool to promote resilience and support health in the growing number of CSPs. By supporting CSPs' individual well-being, community health is strengthened. Our study will provide important contributions regarding the therapeutic effects of this psychosocial intervention in HL CSPs, who are particularly susceptible to cardiometabolic risks because of the COVID-19 pandemic, and consequently, on the communities they serve.

Acknowledgments

The authors thank their lead partner community health agency, Latino Health Access, for their contributions as well as other community health agencies that they will partner with in the future. This work was supported by a University of California END DISPARITIES pilot award through the National Institute of Health or National Institute on Minority Health and Health Disparities grant #P50-MD017366, National Institute of Health or National Center for Advancing Translational Sciences UC Irvine Institute for Clinical and Translational Science grant #UL1 TR001414.

Data Availability

As data collection for this project is still ongoing, the complete data sets pertaining to this study are not yet available. Once the study is finalized, the data sets generated during this study will be available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Adolescents living with type 1 diabetes (T1D) often experience diabetes distress (DD), a construct distinct from depression or anxiety that refers to the negative emotions that arise from living with and managing diabetes. Self-compassion, which involves being open to one’s own suffering and treating oneself with the same care one would show to loved ones, is associated with better psychological and clinical outcomes among individuals with T1D. Self-compassion is a skill that can be taught and therefore represents an opportunity for intervention.

Objective: The overall aim of this study is to assess the effectiveness of a web-based mindful self-compassion for teens (MSC-T) intervention on improving DD, anxiety, depression, diabetes-related disordered eating, and suicidal ideation experienced by youth with T1D (aged between 12 and 17 years) compared with a waitlist control group (standard of care). We will also explore (1) if the effect of the MSC-T intervention changes over time, (2) if the MSC-T intervention has a positive impact on measures of glycemic control, and (3) if the effect of the MSC-T intervention differs based on self-reported gender.

Methods: We will conduct a single-center, parallel-group randomized controlled trial of 140 adolescents with T1D followed for 12 months. Participants will be randomly allocated (using hidden allocation) in a 1:1 ratio to either the MSC-T intervention or the waitlist control group. Our primary outcome is DD, as measured by the Problem Areas in Diabetes-Teen (PAID-T) version at 3 months. Secondary outcomes, assessed at 3 and 12 months, include anxiety (Generalized Anxiety Disorder 7-item [GAD-7]

XSL•FO
RenderX

scale), depression (Patient Health Questionnaire-9 [PHQ-9]), diabetes-related disordered eating (Diabetes Eating Problem Survey-Revised [DEPS-R] version), and suicidal ideation (using 1 question from the PHQ-9).

Results: Study recruitment began in October 2022 and was completed in March 2023, with a total of 141 participants enrolling. Data collection will be ongoing until March 2024. The first results are expected in June 2024.

Conclusions: This study will be the first randomized trial to assess the effectiveness of the web-based MSC-T intervention on adolescents with T1D. Given that adolescence is a period where individuals are typically required to assume more responsibility for their diabetes care, providing adolescents with the tools they need to better manage the stress that often accompanies T1D management is paramount.

Introduction

Background and Rationale

Adolescence constitutes a critical developmental period during which youth establish their autonomy while grappling with the social, emotional, and physical challenges of becoming young adults. This period represents a time of tremendous vulnerability, during which psychiatric and mood disorders often manifest [1]. Adolescence is even more challenging for youth with type 1 diabetes (T1D), as they contend with the daily challenges of disease management in addition to the developmental challenges inherent to this phase of development.

Diabetes distress (DD) is an emotional construct that refers to the negative emotions that arise from living with and managing diabetes. The majority of youth with T1D experience some level of DD [2,3], with adolescent females experiencing greater DD than males [4-6]. More than one-third of youth with T1D suffer from substantial DD [7]. DD is apparent in youth for many reasons, including fear of stigma from peers [8], feeling overwhelmed by their diabetes regimen [9], and worry of hypoglycemia and long-term complications of a potentially fatal condition [9].

Self-compassion, a positive psychological construct, involves being open to one's own suffering and treating oneself with the same care one would show to loved ones [10]. Youth can have varying degrees of innate self-compassion [11]. Higher levels of self-compassion are associated with lower levels of distress in youth with other chronic medical conditions [12], and it is a psychological characteristic that correlates with favorable outcomes, including psychological well-being, self-care, and hemoglobin A_{1c} (HbA_{1c}) among individuals with diabetes [13].

Among adults with diabetes, an intervention to increase self-compassion resulted in reductions in DD [14]. However, this relationship has yet to be shown in youth with T1D. Self-compassion interventions lead to better psychological well-being and decreased psychopathology in healthy adolescents and those with some chronic conditions [15,16]. Since self-compassion is a modifiable behavior on which one can be trained [17,18], we have a largely untapped opportunity for intervention among youth with T1D.

Mindfulness-based therapy has led to short-term improvements in self-reported stress among adults and emerging adults with T1D [19]. However, a sole focus on mindfulness is not sufficient, as it does not provide enough training around active self-comforting in suffering. Mindfulness also does not provide the aptitude to address the feelings of failure and self-blame that are common among youth with T1D [20]. Therefore, our goal is to study the effects of a psychological intervention combining mindfulness and self-compassion (mindful self-compassion for teens [MSC-T]) on DD among youth with T1D.

Objectives

Our primary objective is to compare DD at 3 months among youth with T1D who participated in the MSC-T intervention to those in a waitlist control group. Our secondary objectives are to (1) compare anxiety, depression, diabetes-related disordered eating, and suicidal ideation at 3 months among youth with T1D who participated in the MSC-T intervention with those in the waitlist control group; and (2) compare DD, anxiety, depression, diabetes-related disordered eating, and suicidal ideation at 12 months among youth with T1D who participated in the MSC-T intervention with those in the waitlist control group. Finally, our exploratory objectives are to (1) explore if the effect of the MSC-T intervention changes over time throughout the 12-month follow-up period, (2) compare glycemic control (HbA_{1c} and time in range) among adolescents with T1D who participated in the MSC-T intervention to those in the waitlist control group, and (3) explore if the effect of the web-based MSC-T intervention on DD differs based on self-reported gender.

Hypotheses

We hypothesize that adolescents who participate in the MSC-T intervention will report lower DD, anxiety, depression, diabetes-related disordered eating, and suicidal ideation at 3 months compared with the waitlist control group.

Methods

Ethical Considerations

This study was reviewed and approved by the local Research Ethics Board at the Children's Hospital of Eastern Ontario (CHEO; protocol 22/09E, approved July 17, 2022). Following an introduction from a member of the participant's circle of care, in line with requirements outlined in the Personal Health Information Protection Act, a member of the research team will obtain written informed consent, either in person or remotely, using our REDCap (Research Electronic Data Capture; Vanderbilt University) system [21,22]. Participants will consent on their own behalf and will be compensated with gift cards for completing the study questionnaires (US $15 for baseline, US $20 for week 8, US $30 for month 3, US $30 for month 6, and US $35 for month 12) and up to 15 volunteer hours.

Study Design

We will conduct a single-center, parallel-group randomized controlled trial assessing the effect of a web-based MSC-T intervention on DD in adolescents with T1D followed for 12 months, compared with a waitlist control group (standard of care).

Participants and Recruitment

We will recruit 140 adolescents with T1D, aged between 12 and 17 years, from the Diabetes Clinic at CHEO in Ottawa, Ontario, Canada.

Inclusion and Exclusion Criteria

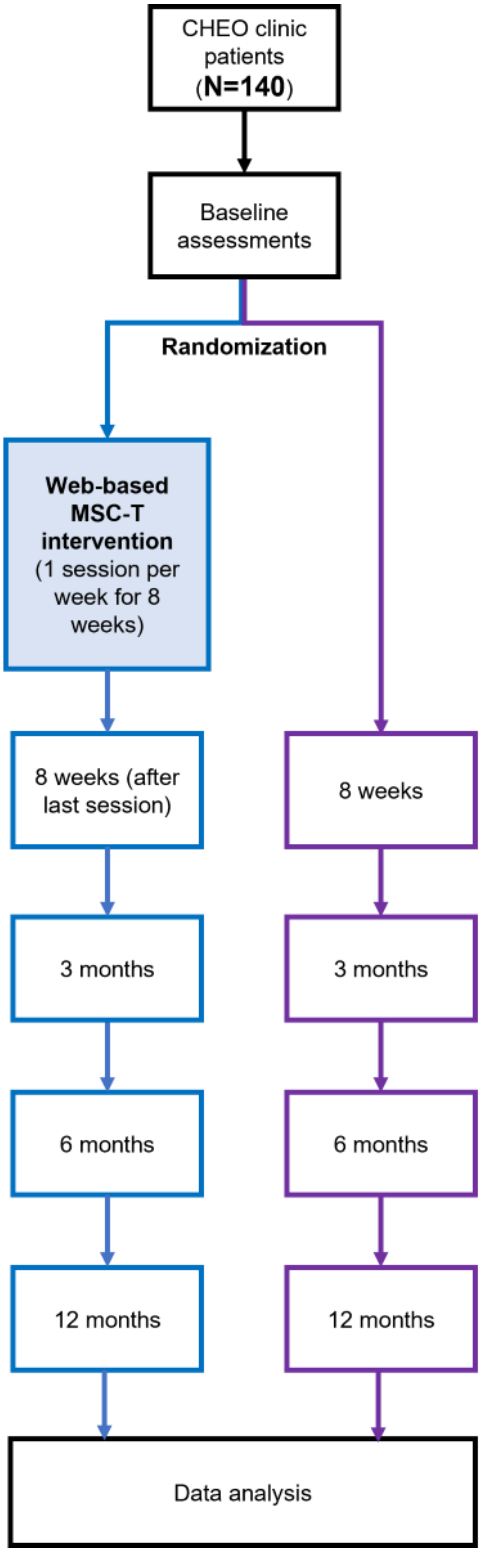
The inclusion criteria and exclusion criteria for this study are presented in Textbox 1.

Textbox 1. The inclusion and exclusion criteria.

Inclusion criteria

- Aged between 12 and 17 years.
- Diagnosed with type 1 diabetes (T1D) ≥6 months before enrollment.
- Ability to provide informed consent.

Exclusion criteria



- Inability or unwillingness to provide informed consent.
- Inability to speak English with enough fluency to complete all study-related tasks.
- Presence of an intellectual disability that would preclude participation in the mindful self-compassion for teens (MSC-T) intervention, as assessed by the treating physician.
- A lifetime diagnosis of a psychotic or bipolar disorder given by a clinician (these often involve intensive treatments with psychological and pharmacologic implications, which may confound our results).
- Presence of acute suicidality at the time of enrollment.
- Active participation in another mental health intervention trial.

Trial Intervention

As shown in Figure 1, participants from the diabetes clinic at CHEO will be randomized to the MSC-T intervention group or the waitlist control group (standard of care).

XSL•FO
RenderX

Figure 1. Schematic overview of the study. CHEO: Children's Hospital of Eastern Ontario; MSC-T: mindful self-compassion for teens.

Intervention Group

The MSC-T intervention (Textbox 2) teaches the participants to be open to, rather than disconnected from, their own suffering and treat themselves with the same care they would show to a friend [10]. The program consists of 8 weekly interactive sessions, each lasting 1.5 hours (a total of 12 hours). The program will be led by our collaborators (KB and AL), who are trained, experienced MSC-T instructors. Each session will begin with a brief mindful art activity, which provides a transition to the class. Classes include developmentally appropriate hands-on exercises, videos, games, mindful movement, music meditation, and between-class practice assignments to solidify practices. The session content and structure were reviewed by our people with lived experience collaborators (SH and OI).

MSC-T program fidelity will be determined by (1) assessing the change in self-compassion between baseline and 8 weeks and (2) assessing if the required topics for each MSC-T session

XSL•FO
RenderX

were covered and activities performed. Self-compassion will be assessed using the Self-Compassion Scale for Youth, a psychometrically valid and reliable measure of self-compassion for adolescents [23]. To ensure the respective topics are appropriately covered in the MSC-T sessions, a member of the study team will complete a fidelity assessment during each session.

Participants' satisfaction and acceptability of the intervention will be evaluated using an intervention satisfaction survey, similar to what has been previously used to determine satisfaction with the web-based MSC-T program [18].

Textbox 2. Program summary (sessions and topics) for mindful self-compassion for teens (MSC-T) intervention.

Week 1

- Discovering mindful self-compassion: introduction to concepts of mindfulness and self-compassion; safety measures for class established; and both informal and formal practices are introduced.

Week 2

- Paying attention on purpose: concepts of mindfulness, wandering mind, and default mode network are discussed; mindful eating, "soles of the feet," and "palm of the hand" meditations are presented.

Week 3

- Lovingkindness: "lovingkindness" is defined and lovingkindness practice is introduced; participants create their own lovingkindness phrases; adolescent brain development is discussed.

Week 4

- Self-compassion: this exercise encourages teenagers to turn from the "inner critic" toward the "compassionate voice," and music meditation is introduced.

Week 5

- Self-compassion versus self-esteem: the difference between these 2 is elucidated, and the perils of social comparison are discussed.

Week 6

- Living deeply: core values exercise; "giving and receiving" meditation is introduced.

Week 7

- Managing difficult emotions: "soften, soothe, and allow" practice is introduced; tools to contend with anger and unmet needs are practiced; and 2 developing systems of the adolescent brain are explained.

Week 8

- Embracing your life with gratitude: gratitude and self-appreciation practices are presented, and the wrap-up of the course takes place through writing a letter to oneself.

Waitlist Control Group

Participants in the wait-list control group will receive standard-of-care treatment as usual. Following the conclusion of the experimental protocol, participants in this group will be given the opportunity to complete the 8-week web-based MSC-T program.

Randomization Procedures

We will use the randomization module in REDCap [21,22] to allocate participants to their group. The randomization table will be created by a study team member who is not directly involved in patient recruitment or data collection using R (R Core Team) [24]. The trial coordinator will generate the allocation for each participant following obtaining informed consent and completion of the baseline assessments (ie, there will be hidden allocation).

Participants will be randomly allocated to either the MSC-T intervention group or the waitlist control group using a 1:1 ratio block randomization. We will stratify each block by age group (12-14 years [early adolescence] or 15-17 years [middle adolescence]). The cohort will be divided by these age groups to deliver the intervention with the goal of fostering a developmentally appropriate and open environment. Stratification by age group is therefore necessary to ensure an equal age distribution between the treatment groups, since the developmental age of a participant could impact their response to the intervention [25]. We will also randomly vary the block size, with blocks of either 6 or 8, to prevent prediction of group allocation as participants are accrued [26].

Data and Outcome Measures

We will collect the following demographic information at baseline: age, postal code (to determine socioeconomic status using neighborhood-level material and social deprivation indices [27,28]), optional self-reporting of gender identity (participants will be presented with a range of options [29,30]; Table 1), race or ethnicity, and indigeneity [31] (Table 2), and participant's

XSL•FO
RenderX

social context (living arrangements, etc). Medical history will be collected at baseline, and at intervals, it will be reviewed at each follow-up visit to determine if participants have been newly diagnosed with a serious mental illness (exclusion or withdrawal criteria).

Table 1. Gender reporting options to be presented to participants. The presented gender reporting options are in line with accepted standards for determining gender identity in research [29,30]. Participants will be informed that the provision of this information is voluntary and that they will be allowed to select more than one.

Self-reported option	Analysis group
Male	Male
Female	Female
Transgender	Will depend on if another option is selected
Transgender boy or transgender male	Male
Transgender girl or transgender female	Female
Genderqueer	Gender diverse
Gender expansive	Gender diverse
Androgynous	Gender diverse
Nonbinary	Gender diverse
Two-spirited	Gender diverse
Third gender	Gender diverse
Agender	Gender diverse
Not sure or questioning	Gender diverse
Other	Will depend on free text
Prefer not to say	Will be excluded from gender analysis

Table 2. Ethnicity and Indigenous identity questions and responses to be presented to participants. The categories are in line with accepted standards for reporting ethnicity from the Canadian Institute for Health Information [31]. Participants will be informed that the provision of this information is voluntary and that they will be allowed to select more than one. Participants will be asked to answer the following question: "In our society, people are often described by their race or racial background. These are not based in science, but our race may influence the way we are treated by individuals and institutions, and this may affect our health and health outcomes related to diabetes. Which category or categories best describe you? Check all that apply."

Response category	Examples
Black	African, African Canadian, and Afro-Caribbean descent
East Asian	Chinese, Japanese, Korean, and Taiwanese descent
Indigenous (First Nations, Inuk/Inuit, Métis)	First Nations, Inuk or Inuit, and Métis descent
Latin American	Hispanic or Latin American descent
Middle Eastern	Arab, Persian, and West Asian descent (eg, Afghan, Egyptian, Iranian, Kurdish, Lebanese, and Turkish)
South Asian	South Asian descent (eg, Bangladeshi, Indian, Indo-Caribbean, Pakistani, and Sri Lankan)
Southeast Asian	Cambodian, Filipino, Indonesian, Thai, Vietnamese, or other Southeast Asian descent
White	European descent
Other category	Includes options not described above
Do not know	N/A[a]
Prefer not to answer	N/A

[a]N/A: not applicable.

Our primary outcome, DD, has been shown to be the psychological construct most related to metabolic outcomes in adolescents with T1D [3]. DD will be measured using the Problem Areas in Diabetes-Teens (PAID-T) version [32], a validated measure to evaluate diabetes-specific emotional distress in adolescents with high internal consistency (Cronbach α=.96) [32]. It consists of 26 items, each scored on a 6-point ordinal scale, allowing for the calculation of an overall distress score of 26-156, with scores of <70, 70-90, and >90 representing none-to-mild, moderate, and severe DD, respectively [33]. The

XSL•FO
RenderX

PAID-T has excellent psychometric properties [34], is sensitive to change from behavioral intervention [35], and is a commonly used measure to assess DD in adolescents [7,36].

Our secondary outcomes are anxiety, depression, diabetes-related disordered eating, and suicidal ideation. Symptoms of anxiety will be measured using the Generalized Anxiety Disorder 7-item (GAD-7) scale, a self-report tool to detect clinically significant anxiety symptoms. The GAD-7 is scored from 0-21, with 0-4, 5-9, 10-14, and 15-21 indicating minimal, mild, moderate, and severe anxiety symptoms, respectively [37]. It has been validated in adolescents [38] and has previously been used to assess adolescents with T1D [39,40].

Symptoms of depression will be measured using the Patient Health Questionnaire-9 (PHQ-9) by self-report [41]. The PHQ-9 is a valid and reliable screening tool for identifying adolescents meeting the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) criteria for major depression [41]. Scores range from 0-27, and in adolescents, scores of 0-4, 5-10, 11-14, 15-19, and ≥20 indicate absence of, mild, moderate, moderately severe, and severe depression, respectively [41].

Symptoms of diabetes-related disordered eating will be measured using the Diabetes Eating Problem Survey-Revised (DEPS-R) version [42], a diabetes-specific measure of disordered eating symptoms that is valid for use in adolescents with T1D [42]. The DEPS-R is scored from 0-80, with higher scores indicating more disordered eating behaviors, and a score of ≥20 is suggestive of disordered eating behaviors [42]. The use of a diabetes-specific tool to measure disordered eating is important, as generic measures may overestimate the prevalence of disordered eating symptoms given that diabetes management involves an emphasis on food intake and carbohydrate counting and that insulin restriction is not captured in generic measures [43].

Suicidal ideation will be assessed using 1 question on the PHQ-9, which asks the respondent if they have had thoughts that they would be better off dead or of hurting themselves in the previous 2 weeks. This question is scored on a scale from 0 (not at all) to 3 (nearly every day). In line with previous use of the PHQ-9 [44], we will consider any score of >0 to be indicative that suicidal ideation is present.

Our exploratory outcomes are the effects of time, HbA_{1c}, time in range, and effect of gender. We will assess whether the effect of the MSC-T intervention on DD changes over time by exploring the interaction of time (ie, study time point) with DD. We will assess both HbA_{1c} and time in range, as not all our clinic patients wear a continuous glucose monitor (CGM), which is necessary to calculate time in range (>70% of our clinic patients wear a CGM).

HbA_{1c} is a measure of the average blood glucose levels over the previous 3 months and is a routinely followed biochemical marker used to gauge metabolic control in individuals with T1D. We will explore changes in HbA_{1c} over the duration of our trial, as mental health morbidity has been associated with higher HbA_{1c} levels [45,46]. Time in range is a metric that denotes the proportion of time that a person's glucose level is within a desired target range, calculated using a CGM. A total of 14 days of data from CGM provides a good approximation of glucose data [47]; time in range will allow us to evaluate the glucose control at the various time points. We will collect CGM data at all study visits. Given the web-based nature of the trial combined with the high proportion of our clinic population that uses CGM, which is a more reliable measure of metabolic control [48], we will minimize additional blood collection by recording results from clinically collected HbA_{1c} at baseline and 1 year.

Safety Parameters and Description of Risk

All the mental health outcomes being assessed are self-reported by participants directly into the study database. The principal investigator or delegate and study coordinator will be immediately alerted through an automated REDCap algorithm when (1) an individual self-reports as having suicidal ideation >0 on question 9 of the PHQ-9 or (2) an individual intentionally does not fill out the suicidality question on the PHQ-9. The principal investigator, delegate, or study coordinator will contact the participant's endocrinologist or the endocrinologist on call, who will conduct a same-day risk assessment using the Ask Suicide-Screening Questionnaire (ASQ) [49]. If the participant is judged to have acute suicidality or suicidal ideation as per the ASQ, the assessor will either suggest a referral to the emergency department or contact the psychiatrist on call, who will suggest clinical follow-up as appropriate. The assessor will report the results of the ASQ screening back to the study coordinator within 1 day. Participants with acute suicidality as per the ASQ will then be excluded or withdrawn from the study.

Trial Management

To foster an environment where the participants feel comfortable, the web-based MSC-T intervention will be conducted with groups of 12-18 participants of the same age group [18]. To ensure that there is no exclusion of youth based on socioeconomic status or access to technology, participants who do not have a computer, laptop, tablet, or webcam to attend the web-based sessions will be loaned a study tablet, and mobile internet devices will be provided to those who do not have high-speed internet at home. All participants will receive a subsidy to offset the cost of increased home internet use for the duration of the study. To maximize participant engagement, the trial coordinator will provide weekly reminders for the duration of the program through SMS text messages or email, depending on the participant's preference.

At each follow-up visit (Table 3), the study coordinator will review the interim medical history using a study case report form and have the participants complete the study questionnaires.

[a]The intervention satisfaction survey will be given to the participants in the mindful self-compassion for teens (MSC-T) intervention group only.

Engagement of People With Lived Experience of T1D

To ensure that this study is feasible, interesting, and relevant to youth with T1D, we have engaged and plan to continue to engage with people with lived experience throughout all stages of the study. We have 2 people with lived experience as collaborators (SH and OI), both of whom are former patients of the CHEO diabetes clinic, who will help spearhead engagement strategies. Multimedia Appendix 1 provides more information about our people with lived experience engagement activities.

Equity, Diversity, and Inclusion Considerations

We have considered gender and diversity in all aspects of this study, from recruitment through to knowledge translation. Multimedia Appendix 2 [4-6,50-52] provides more information about our equity, diversity, and inclusion considerations.

Statistical Plan

Sample Size

Our target sample size is 70 participants per group (140 participants total). This sample size achieves 80% power to detect group differences of 12 points or more [53] using a 2-sided significance level of 5% [26]. In this calculation, we assumed a mean PAID-T score of 73 in the waitlist control group with a SD of 26 [54]. A 30% attrition rate, based on previous relevant trials [55], was also considered.

Statistical Analysis

For the MSC-T and waitlist control groups, the following will be summarized using descriptive statistics: participant baseline characteristics, mental health outcome measures, and self-compassion score responses from each study time point, and for the MSC-T group, we will summarize the results of the intervention satisfaction survey and session attendance.

Our main analyses will be performed based on the intention-to-treat principle. We will also complete per-protocol analyses where we will exclude participants based on nonadherence to the intervention (defined as attending fewer than 6 out of 8 MSC-T sessions, in line with previous work done using MSC-T [56]).

Primary Analysis for the Primary Outcome

The primary outcome will be analyzed using a linear regression model adjusted for age and baseline DD to assess the effect of the MSC-T intervention on DD at the 3-month time point. We will adjust for age to account for the variability in the developmental stage of each participant, which may impact their response to the mindful self-compassion (MSC) program. We will also account for baseline levels of DD as we are assessing the change in DD from baseline to 3 months.

Secondary Bayesian Analysis for the Primary Outcome

Although our trial is powered to detect a moderate effect size of 12 points on the PAID-T, we acknowledge that a smaller effect size is still clinically meaningful. Bayesian methods focus on providing plausible values for the intervention effect that are compatible with both the observed data and previous knowledge and beliefs. Bayesian analysis enables the use of both noninformative priors that minimize the influence of priors on the statistical inference and informative priors that are guided by existing evidence or a range of collective expertise from investigators regarding the belief or skepticism of the intervention's efficacy. Thus, a secondary Bayesian analysis will complement our frequentist analysis in the interpretation of our randomized trial results [57]. Following existing Bayesian analysis reporting guidelines [58], we will conduct a prespecified Bayesian linear regression analysis to examine the probability that the MSC-T intervention reduces DD in a clinically meaningful way compared with the control group based on the trial results.

The main objective of the Bayesian analysis is to determine the posterior probability (also known as an updated probabilistic belief) that the MSC-T intervention (1) affects PAID-T scores

XSL•FO
RenderX

and (2) reduces DD by between-group differences on the PAID-T of 7-15 points (eg, effect size of 0.27-0.5), given the prior distributions of the treatment effect and the observed data from the trial. We considered an effect size of 0.27 as the minimum threshold for potential clinical relevance, given the strong relationship between DD and clinical outcomes [3], and based on the expert opinions of our team of experienced diabetologists.

To reflect our uncertainty around the effect of the MSC-T intervention, we will use a range of priors representing varying degrees of enthusiasm and skepticism (Multimedia Appendix 3). In the Bayesian regression analysis, noninformative priors will be used for nuisance parameters, including the regression intercept terms and the parameters that do not quantify the MSC intervention effectiveness. The convergence of Bayesian estimation will be examined using trace plots and the R^ convergence index with a cut-off of 1.01 [59]. With the trial data, we will estimate the 95% credible intervals using Markov chain Monte Carlo (MCMC) sampling techniques with at least 2 parallel chains [58] and report the estimated posterior probabilities for different magnitudes of treatment effects as specified in Multimedia Appendix 3. The analysis will be conducted in R statistical software [24], and Bayesian analysis will be performed using Stan MCMC (Stan Development Team) [60].

Analyses for Secondary Outcomes

Linear regression models and generalized linear regression models (for binary or categorical secondary outcomes), adjusting the same covariates as the primary analysis, will be used to assess the effect of the MSC-T intervention on our secondary outcomes of (1) depression, anxiety, disordered eating symptoms, and suicidal ideation at 3 months; and (2) DD, depression, anxiety, disordered eating symptoms, and suicidal ideation at 12 months.

Analyses for Exploratory Outcomes

To explore the effect of the MSC-T program on DD over time, we will use the 3-, 6-, and 12-month data to fit a linear mixed effects model, adjusted for time, age, baseline DD, an interaction term for time and group, and a random intercept (to account for repeated measures).

Exploratory outcome HbA_{1c} at 12 months will be modeled in a linear regression adjusted for age and baseline HbA_{1c}. Linear mixed effects models, adjusted for age, baseline time in range, and a random intercept, will be used to assess the effect of the MSC-T intervention on the repeated measure time in range. Interaction terms between group and gender will be included in a separate model to investigate how the MSC-T intervention differs based on self-reported gender (collapsed to male, female, and gender-diverse for the purposes of analysis) at the primary end point.

Sensitivity Analysis on Missing Data

Differences in characteristics between participants with no recorded outcome measurements and those with at least 1 recorded follow-up measurement will be assessed. For participants with at least 1 available data point, we will input missing outcome data following best-case and worst-case scenarios, where best-case is defined as successfully achieving clinically meaningful improvement in PAID-T scores and worst-case is defined as failure to achieve clinically meaningful improvement in PAID-T scores.

Results

Study recruitment began in October 2022 and was completed in March 2023, with 141 participants enrolling in the trial. Data collection will be ongoing until March 2024. The first results are expected in June 2024.

Discussion

Expected Findings

In this study, we will evaluate MSC-T as a way to improve DD and mental health outcomes among adolescents with T1D. We will also explore the impact of the MSC-T intervention on glycemic control. In adolescents with T1D, psychological interventions have largely targeted improvement in diet and insulin regimen adherence and strategies to cope with specific stressors [61]. While some approaches, including cognitive behavioral therapy (CBT), have shown promise for improving diabetes management, there is limited evidence that these traditional approaches translate to improved coping with distress [61]. A recent review [62] on the use of CBT for stress and coping in youth with T1D showed conflicting results, with a number of studies showing no improvement in stress [63] or DD [64]. CBT may also highlight potential causes of distress related to diabetes that the teenager has not yet considered without providing adequate skills and practices to manage these emotions [64].

We hypothesize that the combination of mindfulness and self-compassion practices in the MSC-T program will result in improved DD and mental health outcomes for adolescents enrolled in the program. We also anticipate that these improvements may translate to improved clinical outcomes through glycemic control.

Strengths and Limitations

To our knowledge, this is the first randomized controlled trial using the MSC-T intervention to address DD in adolescents with T1D. One of our instructors (KB) is a person with lived experience of T1D; having an instructor who is also a person with lived experience of the condition has been identified as a key component in previous studies using MSC interventions [56]. The longer-term follow-up of 12 months is also a clear strength. Throughout adolescence, youth are typically required to become more independent with their diabetes self-management while receiving diminished support from their caregivers. Mental health morbidity, including DD, is associated with poor glycemic control, diabetic ketoacidosis, and hypoglycemia in youth with T1D [7,65,66]. The MSC-T program will help adolescents with T1D develop skills to better cope with their emotions around managing their diabetes.

There are, however, some potential limitations to this study. The trial is single-blind; participants and the trial coordinator

XSL•FO
RenderX

are not blinded to their assignment group. However, the statistician conducting the primary analysis will be blinded to participant allocation to the MSC-T intervention or waitlist control group. Given that the intervention is web-based, it does require the use of high-speed internet and a device that has webcam functionality, which may make it difficult for some youth to attend should these items be lacking. However, in Canada and the United States, over 96% [67] and 95% [68] of youth and emerging adults own smartphones, respectively, suggesting that if the program were to be scaled nationally or internationally, attending such a program would be feasible for the majority of North Americans.

Conclusions

Our proposed research has the potential to lower DD among youth with T1D by increasing their mindfulness-based self-compassion. We expect that our work will enhance the psychological well-being of youth with T1D, providing them with self-compassion skills to face adversity as they develop into young adults, ultimately leading them to live happier and healthier lives. If effective, further research should be done toward the implementation of MSC-T into standard clinical care for youth with T1D through partnerships with diabetes organizations.

Acknowledgments

This study is supported by the Juvenile Diabetes Research Foundation (JDRF; grant 2-SRA-2022-1191-S-N) Canada and the Brain Canada Foundation. The funders had no role in the design of the study and will have no role in the management, analysis, or interpretation of the data.

Authors' Contributions

M-ER and SD designed the trial, and together with AA, BMF, EBG, GSG, KK, YO, SL, JS, NS, and CZ, they contributed to the recruitment plan, selection of outcome measures, safety plan, trial management plan, and data analysis plan. KB developed the intervention and, together with AL, administered it. CP attended all intervention sessions to ensure participant safety in her capacity as a licensed psychologist. SH and OI reviewed all aspects of the protocol through their lens as people with lived experience. All authors read and approved the final manuscript and have agreed to be accountable for all aspects of the work.

Conflicts of Interest

KB is a cocreator of Mindful Self-Compassion for Teens. CZ reports grants to the institution from Tandem Diabetes Care and Advisory Board membership for Dexcom. M-ER reports grants to the institution from Ascendis Biopharma, Ipsen Biopharmaceuticals, and QED Therapeutics, Inc. The remaining authors have nothing to disclose.

Abstract

Background: Patients with chronic inflammatory joint diseases such as axial spondyloarthritis have traditionally received regular follow-up in specialist health care to maintain low disease activity. The follow-up has been organized as prescheduled face-to-face visits, which are time-consuming for both patients and health care professionals. Technology has enabled the remote monitoring of disease activity, allowing patients to self-monitor their disease and contact health care professionals when needed. Remote monitoring or self-monitoring may provide a more personalized follow-up, but there is limited research on how these follow-up strategies perform in maintaining low disease activity, patient satisfaction, safety, and cost-effectiveness.

Objective: The Remote Monitoring in Axial Spondyloarthritis (ReMonit) study aimed to assess the effectiveness of digital remote monitoring and self-monitoring in maintaining low disease activity in patients with axial spondyloarthritis.

Methods: The ReMonit study is a 3-armed, single-site, randomized, controlled, open-label noninferiority trial including patients with axial spondyloarthritis with low disease activity (Ankylosing Spondylitis Disease Activity Score <2.1) and on stable treatment with a tumor necrosis factor inhibitor. Participants were randomized 1:1:1 to arm A (usual care, face-to-face visits every sixth month), arm B (remote monitoring, monthly digital registration of patient-reported outcomes), or arm C (patient-initiated care, self-monitoring, no planned visits during the study period). The primary end point was disease activity measured with the

XSL•FO
RenderX

Ankylosing Spondylitis Disease Activity Score, evaluated at 6, 12, and 18 months. We aimed to include 240 patients, 80 in each arm. Secondary end points included other measures of disease activity, patient satisfaction, safety, and cost-effectiveness.

Results: The project is funded by the South-Eastern Norway Regional Health Authority and Centre for the treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Norway. Enrollment started in September 2021 and was completed with 242 patients by June 2022. The data collection will be completed in December 2023.

Conclusions: To our knowledge, this trial will be among the first to evaluate the effectiveness, safety, and cost-effectiveness of remote digital monitoring and self-monitoring of patients with axial spondyloarthritis compared with usual care. Hence, the ReMonit study will contribute important knowledge to personalized follow-up strategies for patients with axial spondyloarthritis. These results may also be relevant for other patient groups with inflammatory joint diseases.

Introduction

Background

Chronic inflammatory joint diseases (IJDs), including axial spondyloarthritis (axSpA), rheumatoid arthritis (RA), and psoriatic arthritis (PsA), often affect young patients. Most patients are treated with disease-modifying antirheumatic drugs (DMARDs). These patients are scheduled for regular follow-up visits in specialist health care, which can be time-consuming, especially for those active in the workforce. Patients have also reported that in this mode of regular follow-up the health care professionals (HPs) only see a narrow timeframe of their disease course, with important changes often taking place between visits [1].

Details on axSpA

The primary effects of axSpA occur in the sacroiliac joints and the spine, where the main concerns are back pain and spinal stiffness. Some patients experience arthritis and enthesitis and may also have extramusculoskeletal manifestations, such as uveitis, psoriasis, and inflammatory bowel disease [2]. The prevalence of axSpA is 0.3% to 1.4%, and the onset is typically in the third decade of life, with an equal gender distribution [3]. As a consequence of spinal inflammation, structural damage may occur, resulting in limited spinal mobility [3]. Furthermore, high disease activity may affect health-related quality of life with work impairment and a substantial socioeconomic load [4].

The treatment of axSpA is individualized according to the patient's needs, disease manifestations, and level of inflammation. The treatment goals include symptomatic relief, maintaining flexibility of the spine, maintaining or improving function and work ability, and preventing disease-related complications [2,5]. First-line treatment consists of exercises and the use of nonsteroidal anti-inflammatory drugs (NSAIDs). Regular exercises and physical activity are recommended for symptom relief and reduced disease activity [5,6]. A recent study demonstrated that patient-reported flares are associated with impaired physical activity [7]. NSAIDs also reduce pain and stiffness, with doses adjusted to symptom severity [2,5]. Second-line treatment includes the use of DMARDs, usually tumor necrosis factor inhibitors (TNFis) [5], which in most patients leads to a rapid, substantial, and sustained improvement of symptoms, inflammation, and physical function [2], enabling participation in the workforce and in daily activities [4,5].

Follow-up of patients with axSpA treated with TNFi includes long-term monitoring of disease activity, clinical findings, and laboratory tests, with a treat-to-target strategy usually aimed at inactive disease or low disease activity as measured by the Ankylosing Spondylitis Disease Activity Score (ASDAS) <2.1 [5,8,9]. Patients are reviewed regularly during face-to-face visits by a rheumatologist or a rheumatology nurse in specialist health care. The frequency of monitoring is individualized depending on the disease severity. At most clinics, the patients can request extra visits when they experience increased disease activity (flares).

In recent years, technology has opened up for remote monitoring through the digital collection of patient-reported outcomes (PROs) and the use of tools for supporting medical decisions. Patients may receive remote care or self-monitor their disease and receive remote support from HPs when needed [10]. Together with treat-to-target strategies, remote care may improve clinical outcomes [11]. The timing of face-to-face or digital visits may be individualized [11], which may increase patient satisfaction. Patients living in both rural and urban areas with limited access to health care services may experience increased access to health care services if they are offered digital follow-up [12,13]. Remote monitoring and self-monitoring may be a step toward more personalized and potentially better follow-up of patients with axSpA. Remote care may reduce the need for visits to specialist health care and thus be cost-effective.

Prior Work

The effect, user satisfaction, and resource use of new follow-up regimens should be evaluated before their implementation in usual clinical care. Previous studies on remote monitoring in patients with other chronic diseases, such as cardiovascular disease, lung disease, and diabetes mellitus, have shown

XSL•FO
RenderX

beneficial results on clinical outcomes [14]. However, a recent systematic review found little or no effect of resource use in specialist health care services [15].

There is limited research on the remote follow-up of IJDs [16-18]. A few studies on patients with RA and PsA in low disease activity or remission found similar disease activity in patients followed by remote monitoring and usual care [10,19], and patient satisfaction with remote care was high [1,20]. Furthermore, patients have reported that self-monitoring of the disease enables them to see the connection between behavioral factors (eg, taking medications and lifestyle choices) and disease concerns [1]. However, a survey regarding the use of digital technology during the COVID-19 pandemic revealed that HPs considered remote care inferior to face-to-face visits [21]. In a recent study, both patients and HPs considered remote care inferior to face-to-face visits, but remote care was convenient for patients in relation to reduced traveling and waiting times [22]. In studies on patients with RA and PsA, the relative cost-effectiveness has shown conflicting results [23,24]. There is limited research on the sustainability of remote follow-up and self-monitoring in patients with axSpA.

Aim of This Study

The primary aim of the Remote Monitoring in Axial Spondyloarthritis (ReMonit; Multimedia Appendix 1) study is to determine whether 2 new follow-up strategies for patients with axSpA—remote monitoring or patient self-monitoring—are noninferior to the conventional follow-up strategy with regular prescheduled face-to-face visits to maintain low disease activity over time. Second, we aim to evaluate patient satisfaction, HP satisfaction, safety, and cost-effectiveness of the 3 follow-up strategies (Figure 1). Our hypothesis is that remote monitoring and patient self-monitoring are noninferior to traditional follow-up with regular face-to-face visits in maintaining low disease activity and that these new follow-ups are associated with patient and HP satisfaction, safety, and cost-effectiveness.

Figure 1. Logo of the Remote Monitoring in Axial Spondyloarthritis (ReMonit) study.

Comprehensive data collection allows for analyses of willingness to use, adherence to remote care among patients, fluctuations in disease activity, and associations between disease activity and physical activity.

Methods

Study Design

The ReMonit study is a 3-armed, single-center, parallel-group, noninferiority randomized controlled trial (RCT) designed to investigate whether 2 new follow-up strategies for patients with axSpA are noninferior to conventional follow-up for maintaining stable low disease activity (NCT05031767; registered on September 2, 2021).

Study Settings, Population, and Recruitment

Patients were recruited between September 2021 and June 2022 from the outpatient clinic at the Division of Rheumatology and Research, Diakonhjemmet Hospital, Oslo, Norway. Eligible patients (axSpA with stable treatment with TNFi and low disease activity [ASDAS <2.1]) were identified from the waiting list for regular follow-up visits and were sent information about the ReMonit study and a consent form, along with an invitation to a visit with a rheumatologist. At the visit, patients willing to participate were screened according to the inclusion and exclusion criteria (Textbox 1).

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Participants were eligible to be included in the study only if all the following criteria applied
  - Male or female aged >18 years of age at screening
  - Diagnosis of axial spondyloarthritis (axSpA) according to the Assessment of Spondyloarthritis International Society classification criteria for axSpA [25]
  - Stable medical treatment with tumor necrosis factor inhibitors for the last 6 months
  - Inactive disease or low disease activity (Ankylosing Spondylitis Disease Activity Score <2.1) at inclusion
  - Capable of understanding the Norwegian language and of providing informed consent.

Exclusion criteria

- Medical conditions
  - Major comorbidities, such as severe malignancies, severe diabetes mellitus, severe infections, uncontrollable hypertension, severe cardiovascular disease (New York Heart Association class III or IV), severe respiratory diseases, or cirrhosis
  - Indications of active tuberculosis
  - Pregnant or nursing
- Diagnostic assessments
  - Abnormal renal function, defined as serum creatinine >142 µmol/L in female participants and >168 µmol/L in male participants or glomerular filtration rate <40 mL/min/1.73 m2
  - Abnormal liver function (defined as alanine transaminase >3 times the upper normal limit) and active or recent hepatitis
  - Leukopenia, thrombocytopenia, or both
- Other
  - Severe psychiatric or mental disorders, alcohol abuse or other substance abuse, language barriers or other factors which makes adherence to the study protocol impossible.

Ethical Considerations

This study was approved by the Norwegian Regional Committee for Medical and Health Research Ethics (229187) as well as the data protection official (DS-00372) and the local research committee at Diakonhjemmet Hospital. The ReMonit study was conducted according to the Declaration of Helsinki. The Norwegian Regional Committee for Medical and Health Research Ethics approved the collection of data (age, gender, diagnosis, comorbidities, medication, disease activity, laboratory measurement, level of education, work status, and smoking habits) from nonparticipating patients attending a screening visit, both screening failures, and patients unwilling to participate in the RCT, if the patients gave their informed consent. These data will be used to evaluate potential selection bias in patient recruitment.

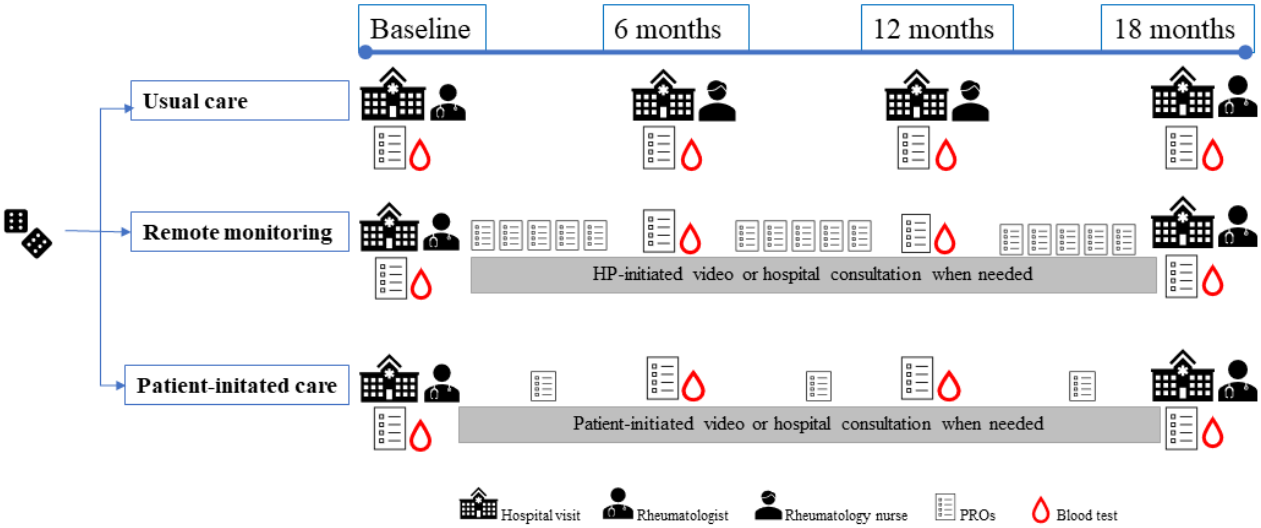
Randomization and Blinding

The included patients were allocated in a 1:1:1 ratio among the 3 study arms (Textbox 2). A statistician and a secretary, not involved in patient screening or enrollment, provided a computer-generated block randomization list (random block size of 6, 9, or 12 patients) and prepared sealed, opaque envelopes containing information on study arm assignment. Participants and treating clinicians are not blinded to the group allocation, but the statistician that will perform the primary outcome analyses is blinded.

Textbox 2. Study arms.

Arm A (usual care): conventional follow-up strategy with prescheduled face-to-face visits at the hospital every 6 months, with an assessment of blood tests, patient-reported outcomes (PROs), and joint examination

Arm B (remote monitoring): hospital health care professionals (HPs) perform remote monitoring of PROs, the HP contacts patients if the PRO score indicates disease flare or if the patient requests an appointment with HPs



Arm C (patient-initiated care): self-monitoring by the patients with no prescheduled visits or remote monitoring, the HP contacts the patient if the patient requests an appointment with HPs

XSL•FO
RenderX

Intervention and Follow-Up

The follow-up for arms A, B, and C lasts for 18 months with data collection at baseline and 6, 12, and 18 months (Figure 2).

Figure 2. Illustration of the Remote Monitoring in Axial Spondyloarthritis (ReMonit) study design. CRP: c-reactive protein; HP: health care professional; PRO: patient-reported outcome.

Digital Monitoring: MyDignio App and Dignio Prevent Platform

Dignio AS offers digital solutions for remote care in the health care system, is certified according to international standards of information security, and has approval for communication of health data in Norwegian health care services [26]. All communication through the software is encrypted and in compliance with the current legislation.

The patients download the MyDignio app on their smartphone or tablet and can report on PROs and manually report data, such as laboratory measurements, in the app. Several instruments can be integrated into the Dignio system, including measurements of physical activity. The HPs can monitor the patient-reported data and measurements on the web-based Dignio Prevent platform, and PROs and measurements can be displayed as graphs or histograms. The MyDignio app and the Dignio Prevent platform also provides the possibility of asynchronous chats between patients and HPs and synchronous communication with video consultations.

In this study, the patients use MyDignio for reporting PROs in the intervention arms B and C and HPs use Dignio Prevent for monitoring PROs in arm B, as described in detail in subsequent sections. Physical activity registered as steps and heart rate is recorded by a smartwatch connected via Bluetooth to a smartphone or tablet that synchronizes data via MyDignio. We also used Dignio for short communication for the patients in arms B and C, such as to send messages reminding patients on completing regularly reported PROs (arms B and C), regular blood sampling, and a link to a questionnaire every 6 months.

Description of the Study Arms

Usual Care: Arm A

Patients underwent conventional prescheduled face-to-face visits with an experienced rheumatology nurse at 6 and 12 months and with a rheumatologist at 18 months (study end), with a review of disease-related concerns, blood test results, joint examination as well as recording medication use, and adverse events. Patients who are unable to attend to a visit are offered a rescheduled visit. Patients can call the study nurse if they experience significant symptom worsening or adverse events.

Remote Monitoring: Arm B

No visits are prescheduled between the baseline visit and study-end visit. Patients download the MyDignio app on their smartphone or tablet and receive a brief introduction from the study coordinator. For monitoring, the patients receive a monthly SMS text message reminder for reporting PROs, which includes the Patient Global Assessment (PGA) and whether they experience a flare (significant worsening of disease-related symptoms). If the PGA is scored ≥3 or they answer “yes” or “uncertain” on the flare question, they are asked to report disease activity using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) [27]. These PRO reports are monitored daily (Monday to Friday) by a study nurse via Dignio Prevent, where patients that need attention are highlighted based on predefined values for the outcomes (Table 1). If patients do not report the PROs, Dignio Prevent alerts the study coordinator who sends a reminder using Dignio. Patients can send messages to the HPs through the app or call the study nurse if they experience significant symptom worsening or adverse events.

XSL•FO
RenderX

Table 1. Indication for the health care professionals (HPs) to contact a patient in the remote monitoring study arm.

Indication	Definition	Action
Significant worsening	• Yellow flag: BASDAI[a] ≥4 in the monthly PRO[b] reporting • Red flag: BASDAI ≥8 in the monthly PRO reporting	The study nurse contacts the patient to evaluate if a visit is needed
The patient has requested to be contacted by the HP	• The patient sends a message in MyDignio app asking to be contacted by HP	The study nurse contacts the patient to evaluate if a visit is needed

[a]BASDAI: Bath Ankylosing Spondylitis Disease Activity Index.

[b]PRO: patient-reported outcomes.

Patient-Initiated Care: Arm C

No visits are scheduled between the baseline visit and study-end visit. Patients in arm C download the MyDignio app on their smartphone or tablet and receive a brief introduction from the study coordinator. The patients receive an SMS text message reminder for reporting PROs every third month (PGA and patient-reported flare, the same as that reported monthly in arm B), but the PROs are not monitored by HPs. If patients do not report the PROs, Dignio Prevent alerts the study coordinator who sends a reminder using Dignio. Patients can send messages to HPs through the app or call the study nurse if they experience significant symptom worsening or adverse events.

Medical Treatment

At inclusion, all eligible patients were on stable medical treatment with TNFi for the last 6 months, and TNFi were continued for patients in all 3 study arms. If, during the study, patients experience a minor worsening of disease-related symptoms, they can initiate or intensify treatment with NSAIDs. Patients experiencing a significant worsening of the disease (identified either at a visit with a nurse in arm A, registered by digital monitoring in arm B, or by the patient contacting the study nurse in either of the arms) are offered a face-to-face visit with a rheumatologist within 2 weeks to evaluate the treatment regimen. The dose of TNFi may be adjusted or if TNFi therapy fails, switching to another TNFi (or an interleukin-17 inhibitor) is considered. In the case of switching treatment, the patient is offered a face-to-face follow-up visit 3 months later to ensure the effectiveness and tolerability of the new medication.

Study Assessments Schedule

Research data are collected throughout the study, separately from the remote monitoring data collected with the My Dignio app in study arm B. The main data collection time points are at baseline and at 6, 12, and 18 months (study end) for all patients (Table 2). Data are collected through interviews by a rheumatologist and a study nurse, self-reports by patients in digital questionnaires, physical examinations by a rheumatologist or a study nurse, laboratory assessments or blood samples, and a physical activity tracker or smartwatch. A qualitative substudy with individual interviews will be conducted after the end of the study.

[a]ASAS: Assessment of Spondyloarthritis International Society.

[b]Measured at baseline and every 3 months throughout the study as recommended due to treatment with tumor necrosis factor inhibitors. Blood samples are analyzed by the patient's general practitioner or at the Diakonhjemmet Hospital, whatever is the most convenient for the patients. The following blood samples will be analyzed: hemoglobin, red blood cells, white blood cells with differential count, platelets, creatinine, and alanine transaminase.

[c]CRP: c-reactive protein.

[d]ESR: erythrocyte sedimentation rate.

[e]Only the subgroup (n=12) in the remote monitoring arm (arm B) that received a home-based C-reactive protein instrument.

[f]At 6 and 12 months, only in the usual care arm (arm A).

[g]Patients in the remote monitoring arm (arm B) will complete a brief questionnaire each month, and patients in the "patient-initiated care" arm (arm C) will complete a brief questionnaire only every 3 months.

[h]Only patients in the remote monitoring arm (arm B) and patient-initiated care arm (arm C) from inclusion or randomization until 12 months.

[i]Only at the early discontinuation visit.

Interview With a Rheumatologist and a Study Nurse

Information on medical history and fulfillment of the Assessment of Spondyloarthritis International Society classification criteria is obtained at baseline by a rheumatologist. Information on medication is recorded at baseline, extra visits, study end, and early discontinuation in all groups as well as at the 6- and 12-month visits in arm A. The dosage and frequency of TNFi and concomitant medication is recorded. The use of NSAIDs, oral or injected glucocorticoids, and analgesics for residual pain (paracetamol or opioids) has received particular attention. Adverse events are reported at all follow-up visits. At the end of the study, the patients will be asked about their preference for future follow-up strategies.

Digital Questionnaires

All patients completed digital questionnaires at baseline and 6, 12, and 18 months and at extra visits and early discontinuation. Data collections were handled by questionnaires created with Nettskjema, a survey solution developed and hosted by the

XSL•FO
RenderX

University of Oslo. At baseline, patients reported demographic data, lifestyle factors (smoking and physical activity), educational level, work status, travel distance, travel time, and way of transport to the hospital. The patients also responded to questions regarding experience with digital technology and eHealth literacy through 20 items from 4 domains of the eHealth Literacy Questionnaire; domain 1, using technology to process health information; domain 3, the ability to actively engage in digital services; domain 4, feel safe and in control; and domain 5, motivated to engage with digital services (response options ranged from 1—strongly disagree, to 4—strongly agree) [28].

Several PROs on disease activity, functional status, sleep quality, health-related quality of life, and patient satisfaction with care and physical activity are reported at baseline and 6, 12, and 18 months; extra visits; and early discontinuation (Table 3). The patients also report, in line with the Assessment of Spondyloarthritis International Society recommendations [29], on the use of medication for spondyloarthritis (TNFi, NSAIDs, and steroids) and if TNFi has been taken as recommended.

Table 3. Patient-reported secondary outcomes at baseline and 6-, 12- and 18-month data collection time points, at extra visits, and at early discontinuation.

Patient-reported outcome	Measurement scale
PGA[a]	• NRS[b] 0-10
Pain assessment	• NRS 0-10
Joint pain assessment	• NRS 0-10
BASDAI[c] [27]	• 6 items, NRS 0-10
BASFI[d] [30]	• 10 items, NRS 0-10
Flare[e]	• Yes, no, or uncertain • If yes or uncertain, which date the flare occurred and number of days it lasted
Change in disease activity last 6 months[e]	• 7-point scale ranging from “much worse” to “much better”
Change in activity impairment last 6 months[e]	• 7-point scale ranging from “more activity impairment” to “improved ability to performed daily activities”
WPAI[f] item no. 6: activity impairment last week [31]	• 1 item, NRS 0-10
Pittsburgh Sleep Quality Index: sleep disturbances due to pain [32]	• 1 item • 4-point scale from “not during the past month” to “3 or more times a week”
EQ-5D-5L [33,34]	• 5 items • 5-point scale • + Health index, VAS[g] 0-100
The patients’ satisfaction with care [35]	• 1 item • 5-point response options ranging from “very satisfied” to “very dissatisfied”
Patient-reported physical activity [36]	• 3 items • Frequency (never, less than once, once, 2 to 3 times, or ≥4 times per week) • Duration (less than 15, 15-30, 31-60, or ≥60 min) • Intensity (no sweat, sweat, or exhausted)

[a]PGA: Patient Global Assessment.

[b]NRS: numeric rating scale.

[c]BASDAI: Bath Ankylosing Spondylitis Disease Activity Index.

[d]BASFI: Bath Ankylosing Spondylitis Functional Index.

[e]Not reported at baseline.

[f]WPAI: Work Productivity and Activity Impairment questionnaire.

[g]VAS: visual analog scale.

In arm A, patients receive a link to the digital questionnaires by SMS text messages a few days ahead of the 6-, 12-, and 18-month visits. Participants in arms B and C receive a digital reminder through the MyDignio app at the time of data collection at 6 and 12 months, with a link to the digital questionnaire, but the link is sent by SMS text messages for the 18-month visit. The study personnel carefully monitor the data collection to ensure completeness and contact nonresponders by SMS text messages or phone calls.

XSL•FO
RenderX

Physical Examinations

Vital signs are examined at baseline (Table 2). A joint examination is performed at baseline, extra visits, study end, and early discontinuation in all arms and at 6- and 12-month visits in arm A.

Laboratory Assessments

Standard care blood samples (Table 2; hemoglobin, red blood cells, white blood cells with differential count, platelets, creatinine, and alanine transaminase) are analyzed as a safety procedure when using TNFi. Patients in arms B and C are asked to report the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) values at 6 and 12 months if measurements are performed by their general practitioner. A subgroup of 12 patients in arm B are asked to perform home-based measurements of CRP each month, in connection with the monthly reporting of PROs. The CRP level is measured using the QuikRead go instrument [37], and the patients register the CRP value in the MyDignio app.

Registration of Physical Activity

The patients in arms B and C are asked to wear a water-resistant smartwatch (Garmin Vivosmart 4) for physical activity monitoring, for example, the number of steps and heart rate during daytime, and data are transferred to Dignio. They are instructed to wear this smartwatch for at least 10 hours during the day, but they can wear it all day and night should they want to. Patients who do not want to wear this smartwatch can still participate in the study in the allocated arm.

Qualitative Substudy

A qualitative substudy with observations and individual semistructured interviews will be conducted after the study ends to gain in-depth insight from patients and HPs on their experiences with remote monitoring. We are planning to conduct interviews with 15 to 20 patients and 5 to 8 HPs. The interview will be recorded through Nettskjema and sent encrypted to Services for Sensitive Data at the University of Oslo.

Outcomes

Primary Outcome

The primary outcome of the study is low disease activity, defined as ASDAS <2.1, and will be evaluated by point prevalence across the 6-, 12-, and 18-month data collection time points. ASDAS is calculated from 4 PROs on patients' experience of back pain, joint pain or swelling, duration of morning stiffness, and PGA during the last week (reported on a visual analog scale, 0-100, 0 being best and 100 being worst) and CRP or ESR, where $ASDAS_{CRP}$ is the preferred measure.

The formula for $ASDAS_{CRP}$ is as follows: 0.12 × back pain + 0.06 × duration of morning stiffness + 0.11 × patient global + 0.07 × peripheral pain or swelling + 0.58×Ln(CRP + 1)). The formula for $ASDAS_{ESR}$ = 0.08 × back pain + 0.07 × duration of morning stiffness + 0.11 × patient global + 0.09 × peripheral pain or swelling + 0.29 × $\sqrt{}$(ESR) [38,39]. In this study, we will calculate $ASDAS_{CRP}$; however, if CRP is missing and we have the value for ESR, $ASDAS_{ESR}$ will be used.

Secondary Outcomes

Secondary outcomes include other measurements of disease activity (eg, ESR, CRP, BASDAI, PGA, change in PGA, pain and joint pain assessment, flare, swollen and tender joint count, presence of heel enthesitis, extramusculoskeletal manifestations, and use of medication), functional status (Bath Ankylosing Spondylitis Functional Index, change in activity impairment, and work productivity and activity impairment item no 6), and sleep quality (Pittsburgh Sleep Quality Index: sleep disturbances due to pain). Furthermore, patient satisfaction with care will be evaluated.

Rates and types of adverse events and serious adverse events are recorded throughout the study at all follow-up visits, extra visits, early discontinuation, and study-end visits by structured interviews and reported in the electronic case report form (eCRF). If an adverse event is considered to be related to the treatment of the patient, the patient's medical treatment is evaluated by a rheumatologist and changed if needed or recommended. Recording adverse events, use of medications such as painkillers, and possible use of antibiotics can provide information on the safety of the 3 follow-up arms.

Substudies

Assessment of the EQ-5D-5L, time for patient being absent from work and potential travel costs related to consultations, time and costs related to patient monitoring (phone calls from patients to nurse or rheumatologist, telephone consultations, video consultations, and face-to-face visits), and health care use (in primary and secondary health care) will provide information on health care use and will allow for evaluation of cost-effectiveness.

All patients will at baseline self-report their experience with digital technology and eHealth literacy. Patients will report on satisfaction with care (Table 3), and patients in arm B will also report on their experiences on reporting monthly disease activity at the 18-month follow-up [40,41].

This qualitative substudy with observations and individual semistructured interviews will provide in-depth insight from patients and HPs on their experiences with remote monitoring.

The close measurement of disease activity by PGA and the monthly CRP for the subgroup in arm B will allow for analyses of fluctuations in disease activity over time. Self-reported physical activity (Table 3) and the measurement of physical activity with smartwatches in arms B and C will provide data to analyze the potential associations between disease activity and physical activity.

Linkage to Registers

The ReMonit project has approval to link data with several national registers in Norway: KUHR (register of national financing support for patients in health services in Norway by Norwegian Directorate of Health), FD-trygd (register of work status, sick leave, and disability pension by Statistics Norway), NPR (register on health information on patients having received treatment or waiting for treatment in specialist health care in Norway by Norwegian Directorate of Health), and NorPD (register of prescription of drugs dispensed from pharmacies,

XSL•FO
RenderX

Norwegian Prescription Database by Norwegian Institute of Public Health). These data can provide information for the cost-effectiveness analyses.

Statistics

Sample Size and Power Considerations

On the basis of data from the NOR-DMARD database (an ongoing longitudinal observational study of the effectiveness of treatment of IJDs with biological disease-modifying antirheumatic drugs in clinical practice, ClinicalTrials.gov NCT01581294) [42], we expect approximately 88% of the usual care patients to have low disease activity at the end of the study. We estimate that 74 patients in each arm will give a power of 80% to conclude that at least one of the alternative follow-up strategies is noninferior to usual care. This assumes a noninferiority margin of 15%, no actual difference between the groups, and an analysis based only on one time point. By collecting the primary end point at 3 time points (and not only at the end of study) for each participant, the power will increase, and a group size of 80 participants should have sufficient power, even with 15% dropout or missing data.

Statistical Analyses

This study will compare the point prevalence of low disease activity (ASDAS <2.1) in the remote monitoring (arm B) and patient-initiated care (arm C) arms to that of usual care (arm A). A monitoring regime will be deemed noninferior to usual care if it can be shown that its low disease activity prevalence is no more than 15 percentage points below that of usual care. In addition, we will test the noninferiority of patient-initiated care to remote monitoring using the same 15% margin. This test will be done only if patient-initiated care is shown to be noninferior to conventional care (a hierarchical test) and thus will not inflate the 5% false positive rate.

The statistical analysis plan will be finalized, signed, and dated before data locking. Demographics, baseline characteristics, efficacy, and safety variables will be summarized using descriptive statistics. Efficacy (both primary and secondary endpoints) and safety analyses will include data from all randomized patients who started the allocated intervention by completing at least one questionnaire and blood test results after randomization, the full analyses set. Robustness analyses will be performed in the per-protocol set, which includes all randomized patients meeting the study entry criteria who followed the study protocol (meeting appointments and reporting data as described in the follow-up regimen of arms A, B, and C).

Primary Analyses

The primary end point, the point prevalence of ASDAS <2.1, will be analyzed by mixed effect logistic regression. The analysis will be based on follow-up data from 6-, 12-, and 18-month data collection time points and will include the randomization group as the main covariate. Sensitivity analyses will include additional covariates such as age, gender, and disease characteristics. The estimates of between-group differences in point prevalence will be based on adjusted risk differences [43]. The noninferiority of remote monitoring to usual care will be evaluated by the CI for the between-group difference in low disease activity (point) prevalence, with a similar approach for patient-initiated care versus usual care [44].

Secondary Analyses

Analyses of secondary effectiveness end points will be presented using point estimates of between-group differences along with their 95% CIs. Continuous and binary outcomes will be analyzed using mixed effects linear and logistic regression, respectively. Cost-effectiveness of the 2 new follow-up strategies will be evaluated primarily with a health care perspective. If the new follow-up strategies are considered noninferior to usual care, cost-minimization analyses may be relevant. Otherwise, calculations of quality-adjusted life-years, determination of the incremental or decremental cost-effectiveness ratio, and the assessment of cost-effectiveness using the cost-effectiveness acceptability curve may be considered. Details of the analyses will be described in the statistical analyses plan.

Missing Data

In the ReMonit study, the primary end point will be collected at 3 time points for each patient, and only patients with at least 1 assessment of the primary end point will be included in the final analyses (the full analyses set). For the main analysis, missing values of the primary end point will not be imputed, as the mixed effect analysis provides unbiased effect estimates, provided the missing data are missing-at-random. Alternative treatments for missing values of the primary end point will be entertained as sensitivity analyses.

Data Registration, Monitoring, and Storage

Data are reported in the eCRF and stored safely at Services for Sensitive Data provided by the University of Oslo [45]. Guidance on the completion of eCRFs is provided in the investigator brochure and eCRF. The regular self-reported disease activity in arms B and C, the CRP measurements performed by the subgroup of patients, and the data on physical activity from the smartwatch are reported in the MyDignio app.

The investigator must permit study-related monitoring and regulatory reviews, audits, and inspections. The investigators will monitor the data collection to ensure completeness. The study personnel will be closely monitoring the data collection needed for the primary outcome, ASDAS (PROs and CRP), at 6, 12, and 18 months. If data are not reported, the patients will be reminded at least 3 times, either through the MyDignio app, an SMS text message, or a phone call.

Study Termination

The end of the study was the completion of the 18-month visit. However, patients may withdraw from the study at any time point. Patients with early termination are asked to participate in a study-end visit—a face-to-face visit or a telephone or video consultation. They are then offered regular follow-up at the outpatient clinic as before inclusion in the ReMonit study.

Results

The project is funded by the Norwegian South-Eastern Regional Health Authority and the Centre for Treatment of Rheumatic

XSL•FO
RenderX

and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Norway.

Patient screening and recruitment began in September 2021, and inclusion was completed in June 2022. The last 18-month study-end visit will be conducted in December 2023. At present, all included patients were followed up according to the outlined schedule.

Discussion

Principal Findings

Patients with IJDs are often followed up in specialist health care for many years. Alternative follow-up strategies with either digital remote monitoring or self-monitoring may be a step toward a more personalized follow-up. By eliminating the need for patients to travel to visits, the ReMonit study aims to enhance accessibility to health care and save valuable time for participants. Furthermore, alternative follow-up strategies may reduce the demands on the health care services [46]. There are few studies evaluating digital follow-up in IJDs [18], and to our knowledge, this trial is among the first to evaluate the effectiveness, satisfaction, safety, and cost-effectiveness of remote digital monitoring and self-monitoring of patient with axSpA.

Patients

Among the IJDs, we considered patients with axSpA to be the most suitable for remote follow-up and self-monitoring, as disease activity is measured by ASDAS, which is based on PROs together with CRP and not based on a clinical examination. Moreover, treatment is focused on alleviating symptoms. We decided to include only patients treated with TNFi because these patients require follow-up in specialist health care. Furthermore, many patients with axSpA are relatively young, usually without comorbidities, and often experience few side effects of TNFi, which minimizes safety issues. Most patients with axSpA are young and participate in the workforce, making remote follow-up especially attractive in this patient group.

Single-Center Study

The ReMonit study is a single-center study conducted at the Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway. This department is responsible for the largest number of patients with IJDs in Norway. The greater Oslo area is the most densely populated area in Norway. Most patients have short to moderate travel distances to the outpatient clinic. Hence, being allocated to either of the study arms, with face-to-face visits (controls) or remote follow-up (intervention), would be acceptable for most of the screened patients and minimize selection bias at inclusion. The potential benefits of saved costs related to fewer face-to-face visits (transport costs, time use, and absenteeism from work) will probably be greater elsewhere in Norway than in this study.

Randomization and Blinding

Treating clinicians are not blinded to group allocation. It could have been possible, by having 2 separate HP teams, but would be challenging in terms of study logistics as well as very resource demanding and regarded unfeasible. Blinding of the patients is not possible because the patients need to know the allocated follow-up strategy. However, the patients will not be informed of the primary outcome measures to minimize their influence on the primary outcome. Furthermore, treating clinicians will not know the ASDAS (primary outcome) of the patients during follow-up.

Study Design

The noninferiority design was chosen because the new follow-up strategies are likely to be less resource demanding (both for patients and HPs) but not be superior to conventional follow-up in maintaining low disease activity. The included patients are well treated with TNFi with an ASDAS <2.1 at inclusion. We cannot expect improvement of disease activity in either of the study arms, and it is unlikely to obtain superiority of the point prevalence of ASDAS <2.1 in the intervention groups. This assumption is based on data from the NOR-DMARD database [42], which showed that 88% of patients with axSpA using TNFi with ASDAS <2.1, remained at ASDAS <2.1 2 years later without change of medication in traditional face-to-face follow-up.

Primary Outcome

Our main goal is to assess whether these new follow-up strategies are associated with low disease activity over time; hence, it is meaningful to assess the primary outcome, ASDAS, at several time points. There are 2 validated measurements of disease activity of patients with axSpA: ASDAS and BASDAI [27,38]. The ASDAS is the newest and is based on both PROs and objective measurements of inflammation (CRP or ESR) and is the recommended instrument for assessing disease activity when monitoring patients [5,47,48]. Thus, ASDAS was chosen as the primary outcome measure and BASDAI as a secondary outcome measure. Other measures of disease activity are included as secondary objectives together with the measure of functional status measured by the Bath Ankylosing Spondylitis Functional Index, which will provide more comprehensive information about disease activity.

Secondary Outcomes

We believe that the evaluation of secondary end points in the ReMonit study is important with regard to the clinical implications of the study results. Even if this study shows noninferiority of the primary outcome with the 2 new follow-up strategies, the success of the follow-up strategies is also dependent on patient satisfaction and safety issues, such as adverse events or the use of painkillers. Follow-up with remote monitoring or self-monitoring may not be relevant to implement if there are increased negative effects compared with usual care.

Selection of Participants

On the basis of prior research and also from clinical experience, where patients at the outpatient clinic often ask for an alternative follow-up rather than face-to-face visits, we hypothesize that patient satisfaction will be high in the remote monitoring and self-monitoring groups [1]. At recruitment, we motivated all patients fulfilling the screening criteria to participate (also patients not interested in digital follow-up) to obtain a representative study sample and avoid selection bias by only

XSL•FO
RenderX

recruiting patients especially interested in digital follow-up. It was underscored that patients in all the study arms can ask for a face-to-face visit with a rheumatologist when they need it.

Safety and Adverse Events

Some patients may experience increased pain or disease activity and a reduced effect of TNFi, and in this case, the patients are instructed to ask for an extra visit. It is possible that some patients in the intervention arms will not ask for an extra visit even when experiencing worsening of the disease and instead increase the use of painkillers. We will register the use of NSAIDs and other painkillers to detect increased use, and we will consider this as a possible adverse event of the intervention. A consequence of increased pain may be reduced sleep quality that will be captured from the reported PROs. The linkage to the Norwegian Prescription Database will provide information on the use of sleeping pills.

Substudies

Another consequence of not detecting increased disease activity might be increased sick leave. Linkage to FD-trygd (register of work status, sick leave, and disability pension) and patient reports will provide information about possible differences in sick leave between the study arms. As all patients use TNFi, an immunosuppressant, they are at increased risk of infection. We will collect information on the use of antibiotics through patient reports and receive information from the Norwegian Prescription Database to assess whether there are differences in the use of antibiotics between the intervention and control groups.

We hypothesize that patients with remote follow-up and self-monitoring will spend less time on disease-related follow-up. However, there is a possibility that patients need closer follow-up in primary health care when follow-up in specialist health care is less close. Furthermore, fewer prescheduled visits may result in more unscheduled telephone or face-to-face visits. Thus, it is important to analyze the cost-effectiveness of the different follow-up regimen when designing future sustainable follow-up strategies.

Data collection will also provide the opportunity to perform other analyses. Before the implementation of digital follow-up, it is important to explore eHealth literacy and the attitude toward digital follow-up [46]. This will provide important information on facilitators and barriers to remote care and may explain why digital health service implementations work or fail. The qualitative substudy with individual interviews will be conducted after the RCT to gain in-depth insights from patients and HPs on their experiences with remote monitoring. Interviews will explore potential implications for patients' empowerment, acceptability of remote monitoring, and patients' views on the frequency and content of remote monitoring. Observations will provide insight into the interaction and communication between patients and HPs with remote follow-up and face-to-face visits.

In arm B, remote monitoring, the patients will self-report on disease activity once a month, and a subgroup will also measure CRP monthly. These data will provide valuable information about how disease activity and inflammation vary over time. The frequent reporting of PROs will provide an opportunity to investigate the optimal frequency of collecting PROs, which is important when designing future follow-up strategies. Frequent registration of disease activity and the tracking of physical activity and heart rate allow for evaluating fluctuations in disease activity and physical activity over time and if flares can be predicted based on changes in monitored physical activity level.

Conclusions

In conclusion, the ReMonit study will evaluate whether remote digital monitoring or self-monitoring is a clinically effective, safe, and sustainable future follow-up strategy for patients with axSpA. The ReMonit study will contribute to the current knowledge on new follow-up strategies, which may result in improved and more personalized follow-up strategies for patients with axSpA, and potentially lead to reduced costs for the patients and the society.

Acknowledgments

The ReMonit study and the qualitative substudy received funding from the South-Eastern Norway Regional Health Authority (funding number 2021062) and the Centre for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Norway (funding number 328657).

Abstract

Background: In preclinical studies, FLASH therapy, in which radiation delivered at ultrahigh dose rates of ≥40 Gy per second, has been shown to cause less injury to normal tissues than radiotherapy delivered at conventional dose rates. This paper describes the protocol for the first-in-human clinical investigation of proton FLASH therapy.

Objective: FAST-01 is a prospective, single-center trial designed to assess the workflow feasibility, toxicity, and efficacy of FLASH therapy for the treatment of painful bone metastases in the extremities.

Methods: Following informed consent, 10 subjects aged ≥18 years with up to 3 painful bone metastases in the extremities (excluding the feet, hands, and wrists) will be enrolled. A treatment field selected from a predefined library of plans with fixed field sizes (from 7.5 cm × 7.5 cm up to 7.5 cm × 20 cm) will be used for treatment. Subjects will receive 8 Gy of radiation in a single fraction—a well-established palliative regimen evaluated in prior investigations using conventional dose rate photon radiotherapy. A FLASH-enabled Varian ProBeam proton therapy unit will be used to deliver treatment to the target volume at a dose rate of ≥40 Gy per second, using the plateau (transmission) portion of the proton beam. After treatment, subjects will be assessed for pain response as well as any adverse effects of FLASH radiation. The primary end points include assessing the workflow feasibility and toxicity of FLASH treatment. The secondary end point is pain response at the treated site(s), as measured by patient-reported pain scores, the use of pain medication, and any flare in bone pain after treatment. The results will be compared to those reported historically for conventional dose rate photon radiotherapy, using the same radiation dose and fractionation.

Results: FAST-01 opened to enrollment on November 3, 2020. Initial results are expected to be published in 2022.

Conclusions: The results of this investigation will contribute to further developing and optimizing the FLASH-enabled ProBeam proton therapy system workflow. The pain response and toxicity data acquired in our study will provide a greater understanding of FLASH treatment effects on tumor responses and normal tissue toxicities, and they will inform future FLASH trial designs.

Introduction

Background

FLASH is an emerging radiation treatment modality that has shown promise for improving the therapeutic ratio by potentially reducing normal tissue toxicity when compared to conventional radiotherapy. FLASH treatment is delivered at ultrahigh dose rates of at least 40 Gy per second, which is approximately 1000 times the dose rate of conventional radiotherapy. In our study—the first clinical trial of FLASH—10 subjects will undergo FLASH treatment for painful bone metastases in the extremities, using a proton radiotherapy system.

The bone, liver, and lungs are the most common sites of metastases from cancer [1]. The pain caused by bone metastases can be severe and debilitating and compromises the quality of life of patients [2,3]. A multimodal approach is often required to adequately manage bone metastases [3], and this does not always adequately control pain.

Subjects with painful bone metastases benefit from radiation therapy [3-8]. Radiotherapy palliation for bone metastasis pain can reduce the use of analgesics [9], enhance mobility, and improve quality of life [10-12]. For painful bone metastases, a standard-of-care radiotherapy regimen is 8 Gy of radiation delivered in 1 fraction (a single treatment) via a medical linear accelerator [4]. Because of the toxicities inherent with ionizing radiation, achieving a favorable therapeutic ratio (balancing radiation-induced damage to the tumor while sparing normal tissue) is a key goal of radiotherapy prescriptions and planning for both radical treatment and palliative treatment.

Study Intervention

Multiple preclinical models have shown that FLASH therapy, when compared to conventional radiotherapy, results in the increased protection of healthy tissue and cells and has equal or greater tumor cell kill rates [13-17]. Research is ongoing to understand the mechanisms underlying the observed benefits of FLASH. Data suggest that the lower levels of toxic oxygen reactive species in normal tissues may explain why less side effects may be produced by FLASH than by conventional radiotherapy [18]. The normal tissue–sparing effects of FLASH have been observed in several tissues and animal models, including mouse intestines [19], mouse skin [20], mouse lungs [21], mouse brains [18], and cat and pig skin [22].

Irradiating mouse lungs in vivo, Favaudon et al [21] found that a higher FLASH dose was required to induce radiation pneumonitis and fibrosis than the dose required for conventional radiotherapy (30 Gy for FLASH vs 17 Gy for conventional radiotherapy). Furthermore, tumor control was more easily achieved with FLASH. The tumor control rates were 70% at 27 Gy in FLASH and 20% at 15 Gy in conventional radiotherapy. At 27 Gy in FLASH, no pneumonitis was observed, whereas significant pneumonitis was observed at 15 Gy in conventional radiotherapy [21]. Similarly, Montay-Gruel et al [18] treated mouse brains in vivo. Subsequent follow-ups revealed that neurocognitive impairment developed in the 10-Gy conventional radiotherapy group but not in the 10-Gy FLASH group. Similarly, Cunningham et al [23] demonstrated that FLASH proton pencil beam scanning irradiation minimized radiation-induced leg contracture and skin toxicity in mice.

To our knowledge, there is only 1 peer-reviewed report [24] on the use of FLASH in humans—a case report of a single subject with cutaneous T-cell lymphoma who underwent extensive prior skin radiotherapy. This individual was treated with a single 15-Gy dose of FLASH, using electrons for a recurrent cutaneous lymphoma lesion. The lesion had a complete response to treatment, with minimal toxicity to the surrounding skin.

A standard of care for the radiotherapy palliation of painful bone metastases is 8 Gy of photon radiation delivered by a medical linear accelerator. Although there is no commercially available medical linear accelerator capable of delivering FLASH dose rates, some cyclotrons, which generate proton radiation for medical treatments, are capable of FLASH dose rates when operated in research mode. Our study will be carried out in a proton treatment facility delivering FLASH dose rate treatment to subjects with painful bone metastases in the extremities.

Rationale and Risk Benefit

The implementation data acquired in this first-in-human investigation will contribute to developing the clinical workflow for FLASH and making this technology routinely available to radiation oncologists and their patients.

The prescription dose and fractionation in this study are the same as those in the standard of care for the palliation of bone metastases—8 Gy of radiation delivered in a single treatment [4]. A single radiotherapy fraction of 8 Gy was also used to administer conventional radiotherapy in prior clinical studies [25,26]. Based on the early data indicating that FLASH may be capable of controlling tumors as effectively as conventional radiotherapy [25,26], it is expected that the subjects with painful bone metastases treated using this study protocol will receive the same pain control benefit as that received by patients treated with conventional radiotherapy.

The subjects' experience of treatment and the follow-up schedule were designed to be very similar to those of standard-of-care conventional radiotherapy. Some of the study activities will occur during regular visits that the subjects will have as part of their oncologic care. Thus, the time and social burden imposed by study participation will be minimal. FLASH will only be delivered to targets in the extremities, which are distant from visceral organs at higher risk of radiation toxicity. In this study, normal tissue toxicity due to FLASH is expected

XSL•FO
RenderX

to be no more than (and potentially less than [21]) that historically observed with conventional radiotherapy. Toxicities of conventional radiotherapy have been evaluated in a prior benchmark multi-institutional prospective randomized clinical trial [9], in which a cohort of 455 patients (433 and 354 patients analyzed for acute and late toxicities, respectively) was treated with 8-Gy, single-fraction conventional radiotherapy for the palliation of painful bone metastases. Toxicities were scored using the Radiation Therapy Oncology Group (RTOG) acute and late morbidity Criteria [27]. Late toxicity (occurring >90 days after radiotherapy) was "rare (4%)," and no patients in the cited study had any grade 4 to 5 acute or late toxicities. The most common toxicity was gastrointestinal. Gastrointestinal toxicity should not be relevant to our feasibility study because radiotherapy will be delivered to the extremities, and no portion of the gastrointestinal tract will be in the radiation field. The acute toxicity that is most likely to occur in this study is radiation dermatitis within the irradiated field. In the prior cited study, of the 433 patients, there were 15 (3%) grade 1, 1 (<1%) grade 2, and no grade 3 acute skin toxicities. Hematologic and "other" (not specified in the prior studies) acute toxicities also occurred in the cited trial.

Methods

Trial Design

This clinical trial is a first-in-human feasibility study of proton FLASH (trial registration number: NCT04592887). Up to 10 adult subjects will undergo FLASH on a proton therapy system operated in research mode. Each subject will undergo FLASH treatment for up to 3 painful bone metastasis sites in the extremities. The feasibility of the clinical workflow will be evaluated. A combination of physician-reported and patient-reported outcomes will be used to assess toxicities and pain relief at scheduled time points throughout the study for the duration of the study participants' lifetime or until they are lost to follow-up.

Objectives

The primary objectives are to assess the workflow feasibility of FLASH therapy in a clinical setting and the toxicities of treatment. The secondary objective is to assess pain relief at the treated site(s).

Setting

This clinical trial will be conducted at the Cincinnati Children's/University of Cincinnati Health Proton Therapy Center—an academic hospital in Cincinnati, Ohio.

Oversight and Compliance

The protocol was reviewed and approved by the US Food and Drug Administration (FDA) prior to participation by any subjects. This research will be conducted on a modified proton therapy device under an investigational device exemption (IDE) approved by the FDA.

Ethics Approval

The FAST-01 protocol was reviewed and approved by the Cincinnati Children's Hospital Institutional Review Board (reference ID: 2020-0030) prior to participation by any subjects.

Recruitment

Patients presenting for palliative radiotherapy to bone metastases will be screened for potential inclusion. In addition, copies of a flier (Multimedia Appendix 1) inviting patients to inquire about the study will be posted.

The radiation oncologists and their staff involved in the study will administer the informed consent procedures for the patients.

Enrollment and Replacement

Enrollment for the study is expected to take 12 months.

All inclusion criteria must be met, and none of the exclusion criteria may be present for a patient to be eligible for the study (Textbox 1). After patients consent to participate in the trial (Multimedia Appendix 2), the investigator will determine whether the patient meets the eligibility criteria, and the results of the screening process will be compiled at the investigational site. No eligibility exceptions will be considered. All patients will be considered regardless of race or gender.

Eligible patients can have 1 to 3 painful bone metastases of the extremities, excluding metastases involving the feet, hands, and wrists. Other bone metastases may be treated with conventional radiotherapy while the patient is participating in the study. Patients who have more than 3 painful bone metastases of the limb bones that require treatment are more likely to have generalized pain, which could confound the measurement of pain relief (ie, the response to treatment).

Patients may continue to take steroids during their participation in the clinical trial, if prescribed by their physician. Steroid medication is optional and at the discretion of the prescribing physician.

Because proton range and dosimetry are less certain in the presence of metal, patients with bone fractures or metal implants in the treatment field will be excluded from this study. Patients who will receive cytotoxic chemotherapy within 1 week prior to or 1 week following their planned radiation treatment will also be excluded because concurrent cytotoxic chemotherapy could affect the tissue response to radiation.

Patients interested in participating in the study will be asked to read, understand, and sign the informed consent document, consistent with institutional practices. Patients who meet all eligibility criteria and sign the consent document may proceed onto the study.

If the subject leaves the study for any reason before the next scheduled follow-up visit is completed, the investigator will document the reason(s). In addition, the investigator will attempt to record the overall score of patient-reported pain and scores for pain specifically in treated site(s), use of pain medications, and adverse events (AEs).

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Inclusion criteria

- Patient age ≥18 years
- Life expectancy of >2 months (per the judgement of the investigator)
- ≤3 painful bone metastases that are in the extremities but are not in the feet, hands, or wrists
- Bone metastases that can be treated using predefined treatment field sizes (7.5 cm × 7.5 cm, 7.5 cm × 10 cm, 7.5 cm × 12 cm, 7.5 cm × 14 cm, 7.5 cm × 16 cm, 7.5 cm × 18 cm, and 7.5 cm × 20 cm), without overlap of radiation fields
- Patients who are able to comply with the protocol
- Provision of signed and dated informed consent form

Exclusion criteria

- Patients who are pregnant or nursing
- Prior radiotherapy to the treatment site(s)
- Patients whose painful bone metastasis sites requiring treatment are all in ineligible treatment sites for FLASH, such as lesions of the feet, hands, or wrists or lesions that are not in the extremities
- More than 3 painful bone metastases of the limbs requiring palliative radiotherapy
- Tumor lysis of >50% of the circumferential bone cortex or other factors considered to place the subject at significant risk of pathologic fracture
- Patients with bone fractures
- Patients with metal implants in the treatment field
- Patients who will receive cytotoxic chemotherapy within 1 week prior to or 1 week following their planned radiation treatment
- Prior local therapy modality to the treatment site(s) within 2 weeks of study enrollment
- Patients with pacemakers or other implanted devices at risk of malfunction during radiotherapy
- Patients at known risk of enhanced normal tissue sensitivity to radiotherapy due to inherited predisposition or documented comorbidity that might lead to hypersensitivity to ionizing radiation
- Patients with any other medical condition or laboratory value that would, at the discretion of the investigator, preclude the patient from participation in this clinical investigation
- Patients enrolled in any other clinical studies that the investigator believes to be in conflict with this clinical investigation

An investigator may withdraw a subject's participation in the study because of the following reasons: patients meeting an exclusion criterion (either newly developed or not previously recognized) that precludes further study participation; significant noncompliance with the study procedure; and the occurrence of an AE, a laboratory abnormality, or any other medical condition or situation such that continued participation in the study would not be in the best interest of the subject.

Subjects who sign the informed consent form and subsequently withdraw or are withdrawn from the study prior to receiving FLASH therapy will not be counted toward the study participant limit and will be replaced. Subjects who sign the informed consent form, receive FLASH therapy, and subsequently withdraw or are withdrawn from the study will be counted toward the study participant limit and will not be replaced.

Imaging and Treatment Plan Selection

Each subject will undergo computed tomography (CT) simulation imaging for the area(s) encompassing the treatment targets. Prior to the acquisition of the CT simulation image, the subject will be fitted with an immobilization device, such as a Vac-Lok bag (MED-TEC Inc); this will be used at simulation and for reproducing the subject's positioning at the time of treatment.

The CT simulation images will be transferred to the Eclipse treatment planning workstation (Varian). The target site(s) will be delineated on the transferred images by one of the radiation oncologist investigators. An expansion (margin) of ≥5 mm will be added to the target to create a planning target volume (PTV).

For each of the FLASH treatment sites, plans will be chosen from a predefined library of single-field, 250-MeV transmission beam plans for different field sizes. The largest treatment field available for this study is 7.5 cm × 20 cm. If it is determined at the time of CT simulation or during treatment planning that the target would be inadequately encompassed by the available fields, then the subject no longer meets the eligibility criteria for the study (Textbox 1) and should be removed from the study and replaced.

The predefined plans are designed to deliver a radiation prescription of 8 Gy in a single fraction at a dose rate of ≥40 Gy per second to the PTV. The volume of the PTV receiving 90% of the prescribed dose shall be ≥90%, and the dose to 10% of the PTV will not exceed 110% of the prescription dose. Because a transmission beam is being used, a relative biological effectiveness of 1.0 will be used for the dose calculation, as there is no Bragg peak within the body.

XSL•FO
RenderX

FLASH Treatment

The treatment plan will be transferred from the ARIA Oncology Information System (Varian) to the proton therapy system console for patient-specific quality assurance (QA) and FLASH radiotherapy delivery. Treatment will be carried out on a ProBeam proton therapy system (Varian). This FDA-cleared proton therapy system will be modified under an IDE to deliver the transmission-beam proton radiation at a FLASH dose rate.

Clinical site staff with appropriate qualifications will be trained on device usage and clinical study operations. The FLASH delivery will be performed in accordance with written instructions and training. QA procedures will be completed to verify that the dose delivered is as prescribed. On each day of treatment, but prior to the subjects' treatments, QA procedures for the radiotherapy system (machine QA) will be performed to confirm the FLASH dose and the dose rate constancy of the proton delivery system [28]. Additionally, patient-specific QA will be performed per institutional practices for all subjects, using, for example, standard film and ion chamber dosimetry procedures.

At the time of treatment, subjects will be positioned on the treatment couch as planned at the time of their simulation visit. Image guidance will be used to verify that the target is in the correct position for treatment.

Assessments

Overview of Assessments

The following assessments will be conducted over the course of the study and according to the schedule of activities (Table 1). The choice of follow-up visit time points was informed by the study designs of Chow et al [29] and Hartsell et al [9]. Questionnaires will be completed as permitted by the subjects' clinical status.

Table 1. Schedule of assessments during the study.

Steps	Enrollment and baseline[a]	FLASH treatment (day 1)[b]			Post-FLASH treatment follow-up		Follow-up
		Before FLASH	FLASH	After FLASH	Day 2[c]	Days 2-11[c]	Each visit[d]
Patient screening	✓						
Informed consent	✓						
Computed tomography simulation	✓						
Eligibility determination	✓						
Subject and tumor characteristics	✓						
Subject evaluation	✓	✓					✓
Pain flare questionnaire		✓			✓	✓	
Pain response questionnaire		✓					✓
FLASH workflow			✓				
Adverse events				✓	✓		✓

[a]Approximately 1 to 2 weeks before computed tomography simulation.

[b]≤7 days after computed tomography simulation.

[c]The assessments associated with these visits will be completed remotely.

[d]After FLASH treatment (day 1), follow-up visits will occur on day 15 (±2 business days), month 1 (±5 business days), month 2 (±10 business days), month 3 (±10 business days), and every 2 months (±10 business days) thereafter until subject death or loss to follow-up.

FLASH Assessment

The following will be documented for each treatment: time that the subject is on the treatment table, any delays in study treatment related to the investigational device (excluding delays due to subject or facility factors not related to study treatment), and any device deficiency.

For each subject, workflow feasibility will be judged as not successful if the total treatment time, measured as subjects' time on the treatment table, is >1 hour or there is a delay related to the investigational device (excluding delays due to subject or facility factors that are not related to the study treatment) of more than 7 business days from simulation to study treatment.

For this study, a *device deficiency* is defined as an inadequacy of a medical device with respect to its identity, quality, durability, reliability, safety, or performance. Device deficiencies include malfunctions, use errors, and inadequate labeling [30].

In the event of interruption to treatment during FLASH, the remaining portion of the treatment should resume, as the system will correctly execute the remainder of the plan such that the full dose of 8 Gy will be delivered to the target volume. Based on reliability testing, treatment interruption is unlikely to occur.

Baseline Characteristics

Baseline characteristics will be assessed before the subjects' simulation CT and include subject and tumor characteristics.

XSL•FO
RenderX

The subjects' characteristics are age, gender, performance status, history of medical comorbidities or autoimmune disorders, diagnosis date, and prior cancer-directed treatments.

The tumor characteristics are histology, anatomic location of the original primary tumor, anatomic location of the treatment site(s), target lesion size, target lesion extent of bone circumferential involvement (if available), and metastasis type (ie, lytic, blastic, or mixed).

Pain Flare

Transient flare in bone pain at a site treated by radiotherapy is a known acute toxicity of palliative radiotherapy for painful bone metastases in some patients [31,32].

Per the methodology of Chow et al [29], flares in bone pain due to radiation will be assessed by using the Pain Flare Questionnaire (Multimedia Appendix 3), which will be administered on day 1 to day 11. *Pain flare* is defined as either of the following: a minimum of a 2-point increase in the worst pain score for the treated site without a reduction in analgesic intake or a ≥25% increase in analgesic intake based on daily oral morphine equivalence without a reduction in the worst pain score. If the worst pain score before treatment was 9 or 10, the criteria for pain flare are met if the follow-up worst pain score is 10 and reported as worse than the worst pain before treatment with no decrease in analgesic intake. To distinguish pain flare from progression of pain, the worst pain score and analgesic intake have to return to baseline levels during the 11-day (day 1 to day 11) period. The incidence of pain flare will be determined both as the percentage of patients and as the percentage of metastatic treatment sites. Consistent with the Chow et al [29] study, we will document the use of steroid medication.

Data on use of pain medication will be collected, and changes in pain medication use will be evaluated at baseline, during each of the first 10 days after treatment, and during follow-up visits (day 15, month 1, month 2, month 3, and long-term). The percentage of subjects requiring narcotics, nonnarcotic analgesics, and no pain medications will be assessed and compared to literature values from prior clinical trials.

Pain Response

Patient-reported pain scores (overall) at baseline and posttreatment (day 15, month 1, month 2, month 3, and long-term) will be assessed, using the Brief Pain Inventory (BPI) Short Form questionnaire (Multimedia Appendix 4). Patient-reported pain scores for each treated site will be assessed using the Treated Sites Pain questionnaire (Multimedia Appendix 5).

The BPI Short Form questionnaire was selected to permit the results of this study to be compared with prior published results that were obtained by using this instrument [9]. Per the methodology of Hartsell et al [9], the worst pain scores in the BPI Short Form and the Treated Sites Pain questionnaire will be used to assess treatment response.

A *complete response* will be defined as having no pain at 3 months after radiation therapy, a *partial response* will be defined as a pain score that is at least 2 points lower than the initial response, a *stable response* will be defined as a 1-point change in pain score in either direction, and a *progressive response* will be defined as a pain score that is at least 2 points higher than the initial score [9].

The percentage of patients and the percentage of metastatic treatment sites having complete, stable, and progressive responses will be determined.

Subject Evaluations

Study personnel will review pain medications (including steroid medications), performance status, and findings of physical examinations involving the skin or other normal tissues at the planned treatment site(s) during subject evaluations. The physical evaluation will include photographs of skin at the entry and exit sites of the beam. These should include an image that encompasses the entire anatomic region treated (upper leg, lower leg, upper arm, and lower arm), with close-up photographs of the skin at each treated area(s) if the treated area(s) can be readily identified.

The investigator or a delegate who is a study physician, nurse, physician assistant, or advanced registered nurse practitioner will evaluate and manage AEs. All AEs, regardless of severity or attribution, from the time of treatment and throughout the subjects' participation in the trial will be captured in the study data. It is expected that most AEs in the study population will be due to underlying cancer and non-FLASH treatments, which will be managed by nonstudy personnel. The investigator (or the person to whom the task is delegated by the investigator) will grade each AE and determine whether the AE is serious per the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. The investigator will document whether the AE is attributable to FLASH radiotherapy delivery.

The anticipated AEs for this study are the previously documented AEs [9] associated with the treatment of bone metastases via 8 Gy of radiation in 1 fraction at a standard dose rate. It is expected that most frequently seen study-related toxicities will be associated with the skin. Radiation dermatitis will be managed at the study site through outpatient treatment by the investigators or their designees, using an appropriate combination of topical emollients, topical steroids, topical antibiotics, and dressings as deemed necessary by the investigator or designee. For other AEs that might occur, such as the pathologic fracture of the treated bone (a known complication of the disease process), patients will be referred to the appropriate specialist for management.

It is desirable to have in-person follow-up visits. However, in the event of a subject's inability or reluctance to travel (given the COVID-19 pandemic), it is acceptable to carry out remote follow-up visits. In these circumstances, subject evaluation may be carried out by using remote visits, record reviews, or a combination thereof. Photographs of the treatment site may be taken at home by caregivers, and physical evaluations will be carried out to the extent that is feasible via telehealth.

Toxicities that are rated by the investigator as possibly, probably, or definitely related to FLASH radiotherapy will be used for assessing the toxicity of the FLASH treatment. A *dose-limiting toxicity* (DLT) is defined as a toxicity grade of $^{3}3$ that is

XSL•FO
RenderX

possibly, probably, or definitely related to FLASH radiotherapy. The number of DLTs will be monitored throughout the duration of the study.

End of Study

At the end of a subject's participation in the study, the investigator will document the reason for the end of the study and will attempt to record patient-reported scores for overall pain and for the pain specifically in the treated site(s), the use of pain medications (including steroid medications), and AEs (including skin and other normal tissue toxicities).

Statistical Analysis

Owing to the small planned sample size, no formal statistical calculations will be performed. The sample size of 10 subjects was determined in consultation with regulatory authorities. Where appropriate, descriptive statistics will be used to analyze the results.

Privacy and Confidentiality

All efforts will be made to remove patient-identifying information and deidentify the data. Only the minimum necessary information regarding the patients' health records and treatment while participating in this study will be collected. All reasonable efforts will be made to protect the privacy of the patients.

Data Collection, Management, and Monitoring

Standardized electronic case report forms and case report form completion guidelines will be created for the collection of study data. These case report forms will include fields for documenting unintended effects of trial interventions or trial conduct, such as AEs, device issues, and protocol deviations.

The study data will be entered into a commercial electronic data capture system designed for clinical research. Automated edit checks, queries, and audit trails are built into the system to ensure accurate data collection. A secure, central storage site provided by the sponsor will be used to collect study DICOM data and photographs.

Data will be transmitted from the study site to the electronic data capture system via a secure internet connection and by using industry-standard encryption modalities. Data access will be password protected.

All data will be reviewed by a clinical monitor from the sponsor or a representative of the sponsor to ensure acceptable accuracy and completeness. The principal investigator will maintain adequate and accurate records to enable the conduct of the study to be fully documented and the study data to be subsequently verified. After study closure, the investigator will maintain all source documents and study-related documents.

Stopping Rules

Enrollment will cease and the study data will be reviewed by the study committee (principal investigator and coinvestigators) and by the Cincinnati Cancer and Blood Disease Institute Data Safety Monitoring Board (DSMB) if any of the following occurs: 3 subjects experience a DLT, 3 subjects are on the treatment table for more than 1 hour, 3 subjects have a delay in study treatment related to the investigational device (excluding delays due to subject or facility factors not related to the study treatment) of more than 7 business days from simulation to treatment, or a major device malfunction in dose delivery (as indicated by the dose monitoring system) occurs. The DSMB is independent of the sponsor.

Results

FAST-01 opened to enrollment on November 3, 2020, and the final patient signed the informed consent document on October 1, 2021.

Data collection will continue for the lifetime of the study participants or when they withdraw from follow-up. Interim results, including the conclusions of the workflow feasibility analysis, are expected to be published in 2022. The final study results will be published upon completion of the study, which may run from 1.5 years to several years, depending on the duration of subject participation.

Discussion

This first-in-human study investigates the use of ultrahigh dose rate proton FLASH therapy for the single-fraction treatment of painful bone metastases in the extremities in a routine clinical setting. Numerous preclinical studies have shown that FLASH therapy reduces radiation-related toxicities when compared to conventional radiotherapy. In this trial, we anticipate that the feasibility of FLASH therapy in a clinical setting will be demonstrated. Additionally, we hypothesize that radiation-induced toxicity will be limited and that pain relief will be similar to historical comparators.

The sample size of 10 subjects in this clinical trial is common in first-in-human device studies, and it was the sample size agreed upon with the US FDA as part of an IDE approval.

This study will use single-fraction treatment delivered at a dose rate of ≥40 Gy per second for the enrolled subjects. Single-fraction radiotherapy for the treatment of bone metastases has been shown to be effective in prior investigations. In 2005, a prospective, phase 3, randomized RTOG study compared the efficacy of multiple-fraction radiotherapy (300 cGy/fraction × 10 fractions) with single-fraction radiotherapy (800 cGy/fraction × 1 fraction) for the treatment of painful bone metastases. The results indicated comparable efficacy for the two fractionation schedules [9]. Based on ongoing reviews of the clinical evidence [4,9,33], single-fraction, 8-Gy radiotherapy remains a standard of care for the palliation of bone metastasis, and it was therefore selected as an appropriate course of treatment for an initial clinical trial of FLASH. The use of this fractionation for the FLASH treatment enables comparison with the data from prior investigations that used photon radiation and conventional dose rates.

AEs attributed to FLASH will be compared with those observed in the prior RTOG randomized trial [9]. In that study, toxicities were scored by using the RTOG acute and late morbidity criteria. That grading system has since been supplanted by the CTCAE system. For skin toxicities, which are expected to be

XSL•FO
RenderX

the most common treatment-related toxicity in our clinical study, the RTOG skin and CTCAE radiation dermatitis scoring systems are very similar, and direct toxicity comparisons can be made between our study and historical studies.

The BPI questionnaire (both the long and the short form questionnaires) was originally developed for patients with cancer and consists of a set of standardized questions for describing pain, pain medication use, and the interference of pain in the patients' lives. The BPI has been recommended as an appropriate tool for measuring pain from metastatic bone disease [34], and using it makes it possible to consider the data from this study in the context of historical data. Similarly, the pain flare questionnaire chosen for use in this evaluation is the same instrument used by Chow et al [29] in a prior study evaluating the use of steroids in combination with radiotherapy for the palliation of bone metastases.

FAST-01 is designed as a first-in-human trial involving 10 patients requiring palliative radiotherapy to the extremities. This low-risk clinical setting is ideal for the initial evaluation of this new technology. Favorable results would support the further investigation of FLASH therapy for other clinical indications. Future research could include treating lesions nearer to sensitive normal tissues and evaluating curative dose regimens.

Acknowledgments

This study is sponsored by Varian, a Siemens Healthineers Company. For more information, contact LL (lisa.levine@varian.com).

Joseph Speth (University of Cincinnati and Cincinnati Children's Hospital, Cincinnati) contributed to the protocol development. Sponsor employees Heike S Hausen and Kathleen T Campbell (Varian) contributed to manuscript development, and Vidhya Krishnamurthi, Aaron Marshall, Adam Harrington, and Michael Folkerts (Varian) contributed to the technical development and discussions that made the proton FLASH treatment possible. The Cincinnati investigators had final authority on journal selection and the content for publication and provided final approval of the versions for submission and publication.

Data Availability

Data sharing is not applicable to this manuscript, as no data sets were generated or analyzed during the development of the protocol described herein. Once data collection begins, all investigators will have access to anonymized patient-level data.

Conflicts of Interest

ECD has received small honoraria from Varian Speakers Bureau for a February 2022 virtual talk. ZX is a principal investigator of a preclinical research grant from Varian, a Siemens Healthineers company. The grant goes to the author's institution. MS is a private investigator on a pre-clinical research grant from Varian, a Siemens Healthineers company; the grant goes to the author's institution. JW, CMC, KR, LL, RS and DK are employees of Varian, and CBS is a Varian Medical Systems consultant. JP is the principal investigator of a multi-investigator research program contract between his institution and Varian Medical Systems; the funding goes to the author's institution. JP's institution also receives funding for the execution of FLASH clinical trials. JP does not receive honoraria or other forms of payment from Varian Medical Systems, and the author follows their institutional policy toward conflicts of interest in this consultant role. JB is a principal investigator of a research grant from Varian Medical Systems; the grant funding goes to the author's institution. JB is also a consultant for Varian, involved in its application to the Food and Drug Administration for FLASH radiotherapy. The author follows the policy of his institute in terms of the conflicts of interest in this consultant role. The remaining authors have no conflicts of interest to declare.

Abstract

Background: Suicide is among the top 10 leading causes of death worldwide. Of people who died by suicide, the majority are diagnosed with depression. It is estimated that 25%-60% of people with bipolar depression (BD) will attempt suicide at least once, and 10%-15% will die by suicide. Several treatments, such as lithium, clozapine, electroconvulsive therapy, and cognitive behavioral therapy, have been shown to be effective in treating suicidality. However, these treatments can be difficult to tolerate or may take months to take effect. Ketamine, a glutamate N-methyl-D-aspartate antagonist, has been shown to have rapid antisuicidal effect and antidepressant qualities, and is thus a promising intervention to target acute suicidality in patients with BD. However, the biological mechanism underlying its therapeutic action remains poorly understood. Enhancing our understanding of underlying mechanisms of action for ketamine's effectiveness in reducing suicidality is critical to establishing biological markers of treatment response and developing tailored, personalized interventions for patients with BD.

Objective: This is an open-label clinical trial to test the safety and feasibility of repeated ketamine infusions to treat acute suicidality. The primary objective is to test the safety and feasibility of ketamine intervention. The secondary objective is to examine ketamine's potential neurophysiological mechanisms of action by assessing cortical excitation and inhibition to determine potential biomarkers of clinical response. Other objectives are to evaluate the effect of ketamine on acute suicidality and other clinical outcomes, such as depressive symptoms and quality of life, to inform a future larger trial.

Methods: This open-label clinical trial aims to test the safety and feasibility of repeated ketamine infusions in patients with BD for suicidality and to assess ketamine's neurophysiological effects. A sterile form of racemic ketamine hydrochloride will be administered over a 40-minute intravenous infusion 2 times per week on nonconsecutive days for 4 weeks (8 sessions). We will recruit 30 adults (24-65 year olds) over 2 years from an academic psychiatric hospital in Toronto, Canada.

Results: This study is currently ongoing and actively recruiting participants. So far, 5 participants have completed the trial, 1 is currently in active treatment, and 8 participants are on the waitlist to be screened. We anticipate initial results being available in the fall of 2023. This proposal was presented as a poster presentation at the Research to Reality Global Summit on Psychedelic-Assisted Therapies and Medicine, held in May 2022 in Toronto, Canada.

Conclusions: Developing effective interventions for acute suicidality in high-risk populations such as those with BD remains a major therapeutic challenge. Ketamine is a promising treatment due to its rapid antidepressant and antisuicidal effects, but its underlying neurophysiological mechanisms of action remain unknown.

KEYWORDS

bipolar depression; suicidality; ketamine intervention; neurophysiological markers of response

Introduction

Background and Rationale

Suicide is among the top 10 leading causes of death, with progressively increasing rates and is a critical public health issue [1]. Bipolar depression (BD) is a serious psychiatric condition with a high mortality rate due to suicide [2]. Between 25% and 60% of those with BD will attempt suicide at least once, and 10%-15% will die by suicide [3-5]. Several interventions, such as lithium, clozapine, electroconvulsive therapy, and cognitive behavioral therapy, have demonstrated antisuicidal properties [4,5]. However, as polypharmacy is common in patients with bipolar illness [6], adding another treatment can be difficult to tolerate, or new treatments may take months to take effect. Therefore, there is an urgent need to develop robust interventions to treat suicidality in patients with BD rapidly. In addition, establishing biological markers of treatment response is critical in developing personalized, tailored treatment interventions.

A paradigm shift from a monoamine hypothesis to a plasticity-based hypothesis of depression represents a substantial advancement, where accumulating evidence suggests that glutamatergic or excitatory neurotransmission system dysfunction plays a pivotal role in depression [7-9]. There are 3 classes of glutamate-gated ion channels such as α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid, and kainite and *N*-methyl-d-aspartate (NMDA) receptors that transduce the postsynaptic signal [7]. NMDA receptors are distributed throughout the brain and are fundamental to excitatory neurotransmission and the normal functioning of the central nervous system (CNS) [7,8]. Ketamine is the first clinically used NMDA receptor antagonist with a primary mechanism of action closely linked to the blockade of the NMDA receptor at the phencyclidine site, which mediates excitatory synaptic transmission through the CNS [8-10].

Developing effective interventions for acute suicidality in high-risk populations, such as BD, remains a major therapeutic challenge. Ketamine is a promising treatment modality due to its rapid antisuicidal [11,12] and antidepressant [13] effects, with numerous studies demonstrating its safety and efficacy in subanesthetic doses administered over 40-minute intravenous (IV) infusions [11-13]. Despite growing interest in ketamine interventions in depressive disorders, our understanding of ketamine's underlying neurophysiological mechanisms of action, especially concerning suicidality, remains very limited.

Noninvasive brain stimulation neurophysiological tools, such as transcranial magnetic stimulation (TMS), offer an opportunity to study human brain cortical physiology mechanisms in vivo with high temporal resolution [14]. The combination of TMS with a CNS pharmacological agent, such as ketamine, will provide a platform to explore the neurophysiological basis of the impact of ketamine on brain physiology, an important piece of work toward identifying neurobiomarkers of treatment response. Until present, only some studies have attempted to examine the excitatory and inhibitory circuits by using a range of TMS protocols during infusion of incremental doses of ketamine [15-17], primarily using very low ketamine doses or single doses in healthy volunteers. Currently, the prediction of the therapeutic response in those with mood disorders as measured by changes in cortical excitability continues to be in very early stages and has not been systematically tested, making this proposal uniquely positioned among other neurophysiological studies on ketamine and TMS. Our group has previously demonstrated impaired GABA (gamma-aminobutyric acid) inhibition from the motor cortex in patients with depression, a finding that was most pronounced in patients with treatment-resistant depression [16,18,19]. In addition, Croarkin et al [19] demonstrated impaired NMDA receptor–mediated excitation in depression.

Objectives

The primary objective of this open-label pilot clinical trial is to examine the safety and feasibility of repeated subanesthetic doses (0.5-0.8 mg/kg) of ketamine administered over 40-minute IV infusions in patients with BD to treat acute suicidality. The secondary objective is to analyze the potential impact of ketamine on neurophysiological markers associated with cortical excitation and inhibition as a proxy of NMDA receptor activity in the cortex. Our scientific group has successfully applied TMS-electromyography (EMG) and TMS-electroencephalogram (TMS-EEG) paradigms to assess cortical activities in patients with psychiatric issues [15,18]. Thus, we will use these paradigms to investigate the impact of ketamine on cortical activities in patients with BD and suicidality. We have previously reported that intracortical facilitation is abnormal in depression [14,18] and is closely associated with NMDA receptor–mediated neurotransmission [9,18]. This study will evaluate cortical excitation and inhibition pre- and postketamine course in patients with BD and suicidality to determine a biological target of ketamine treatment response. We will use a TMS-EMG paradigm to investigate the impact of ketamine on cortical excitation via intracortical facilitation and cortical inhibition via short-interval cortical inhibition paradigms [19-21]. Next, we will compare the effect of ketamine on resting-state cortical oscillation via EEG. These results will provide important evidence for the role of NMDA receptors in cortical physiology, which may serve as a ketamine biomarker and would be a crucial breakthrough in determining potential predictors of clinical response for suicidality in patients with BD.

Trial Design

The DEEPP (Anti-suicidal Response to Ketamine in Treatment-Resistant Bipolar Depression) study is designed as an open-label pilot clinical trial to assess (1) the feasibility of a series of IV ketamine infusions to treat suicidality in patients

XSL•FO
RenderX

with BD and (2) ketamine's neurophysiological markers associated with cortical excitation and inhibition.

Methods

Study Setting

Potential participants will be recruited from 1 site, specifically the Centre for Addictions and Mental Health, a large academic center located in Toronto, Ontario, Canada, over 2 years.

Eligibility Criteria

Inclusion criteria are patients who (1) meet criteria for bipolar disorder according to DSM-V (Diagnostic and Statistical Manual of Mental Disorders, 5th edition) criteria as confirmed by the Mini-International Neuropsychiatric Interview (MINI) [22]; (2) meet criteria for a current depressive episode, confirmed with the 24-item Hamilton Rating Scale for Depression (HRSD-24) score of 14 and above [23]; (3) experiencing suicidal ideation as defined by a score of 9 or higher on the Scale for Suicide Ideation (SSI) [24,25]; (4) capable of providing consent; (5) outpatients; (6) able to speak and understand English; and (7) aged 24-65 years, inclusive.

Exclusion criteria are patients who (1) have a history of a substance use disorder within the past month or a lifetime history of ketamine substance use disorder, as confirmed by the MINI; (2) concomitant major unstable medical illness (eg, poorly controlled hypertension, enlarged prostate, renal- or urinary-related issues, the presence of cardiac decompensation/heart failure, results of liver function tests [alanine transaminase and aspartate transaminase] are 3 times or greater than the upper limit of normal readings); (3) pregnancy or the intention to become pregnant or breastfeeding during the study as confirmed by self-report. Female participants of reproductive potential must be willing to use a medically acceptable method of birth control which includes highly effective (eg, approved hormonal contraceptives, intrauterine device, tubal ligation) or double barrier (eg, male condom with a diaphragm, male condom with cervical cap) methods of contraception or abstinence if that is the usual and preferred lifestyle of the participant; (4) DSM-V diagnosis of any primary psychotic disorder, obsessive-compulsive disorder, posttraumatic stress disorder (current), unipolar depression, other subtypes of depressive disorders, or current psychotic symptoms as confirmed by the MINI; (5) current episode meeting criteria for mania/hypomania or mixed episode as per DSM-V criteria on the MINI or as determined by the study team; (6) primary diagnosis of severe personality disorder as assessed during the initial consultation with a study psychiatrist prior to study entry; (7) any significant neurological disorder (eg, a space occupying brain lesion, a history of stroke, a cerebral aneurysm, a seizure disorder, Parkinson disease, Huntington chorea, multiple sclerosis) as assessed through medical history review during the initial consultation with a study physician prior to study entry; (8) requiring a benzodiazepine with a dose equivalent to lorazepam 2 mg/day or higher; (9) being on any anticonvulsant (eg, lamotrigine, topiramate, carbamazepine) or opioid medication due to the potential of these medications to limit the efficacy of ketamine; (10) cognitive or physical impairment that may potentially interfere with IV ketamine administration or participants' ability to stay in the same place for a 2-hour monitoring supervision as assessed through medical history review during the initial consultation with a study physician prior to study entry; (11) any intracranial implant (eg, aneurysm clips, shunts, cochlear implants) or any other metal object within or near the head, excluding the mouth, that cannot be safely removed given that we will be using TMS-EMG/EEG; (12) inability to secure escort to accompany them back home after ketamine sessions; or (13) any known allergy to ketamine or any component or ingredient of the ketamine preparation.

Discontinuation Criteria

Participants will be discontinued from the study if they cannot safely continue the study based on any of the following criteria: (1) experience clinically significant worsening of depressive symptoms (50% increase in HRSD-24 scores from baseline on 2 consecutive ratings); (2) require in-patient hospitalization due to the presence of clinically significant suicidal ideation with imminent intent or attempted suicide; (3) develop clinically significant worsening of mood or physical symptoms (assessed by a study physician); (4) miss over 2 consecutive treatments during the study without the cause; (5) develop any medical illness that may be unstable; (6) experience a seizure; (7) become pregnant, or (8) withdraw consent.

Intervention

Drug Characteristics, Distribution, and Storing

A sterile form of racemic ketamine hydrochloride (DIN: 02246795, 02246796) will be dispensed through the Centre for Addiction and Mental Health (CAMH) pharmacy. Ketamine will be administered intravenously over a 40-minute infusion using a Baxter FA-2021-056 pump. The CAMH research pharmacy will order the investigational product from the supplier (Sandoz Canada Inc) on behalf of the research team with the study investigator's authorization and will be responsible for the receipt and responsible destruction of the investigational product. As per the manufacturer's recommendation, the investigational product will be stored between 15°C and 30°C, protected from light and heat, and discarded within 28 days of initial use. Only dedicated medical personnel will have access to the investigational product and pick it up from the locked and password-protected storage on the day of the treatment. All treatment sessions will be delivered at CAMH's Temerty Centre for Therapeutic Brain Intervention, a dedicated clinic providing electroconvulsive therapy to patients and thus equipped with a highly trained medical team.

Drug Administration and Scheduling

Ketamine will be administered 2 times per week for 4 weeks (a total of 8 treatment sessions). The dosing schedule will be determined based on the patient's weight, clinical response, and tolerability (Table 1). The first treatment session dose will be calculated based on 0.5 mg/kg. Doses in this trial will range between 0.5 and 0.8 mg/kg.

XSL•FO
RenderX

Table 1. Intervention schedule.

Week	Session, intervention, and dosing
1	• Start-up (first) dose to assess tolerability; 0.5 mg/kg intravenous infusion over 40 minutes
	• Second infusion session (dose adjustment, if needed, 0.5-0.8 mg/kg)
2	• Third infusion session (40 minutes; dose adjustment, if needed, 0.5-0.8 mg/kg)
	• Forth infusion session (40 minutes; dose adjustment, if needed, 0.5-0.8 mg/kg)
3	• Fifth infusion session (40 minutes; dose adjustment, if needed, 0.5-0.8 mg/kg)
	• Sixth infusion session (40 minutes; dose adjustment, if needed, 0.5-0.8 mg/kg)
4	• Seventh infusion session (40 minutes; dose adjustment, if needed, 0.5-0.8 mg/kg)
	• Eighth infusion session (40 minutes; dose adjustment, if needed, 0.5-0.8 mg/kg)

Dose Adjustment

If the first session is tolerated well and the patient has no side effects, the dose can be further increased up to (but not exceeding) 0.8 mg/kg. Participants will have a weekly follow-up with the study's physician. The study physician will determine the exact doses on a case-by-case basis based on treatment tolerability, safety, and clinical response. From principal investigator's (PI) previous clinical experience treating patients with ketamine, dose adjustment occurs within the first 1-3 sessions, and patients continue with stable doses following sessions 2 and 3. However, dose adjustment can also occur after session 3 if the participant experiences side effects with repeated infusions. The procedure around dose adjustment is a part of this trial's feasibility; this information will be collected by the study physician during weekly follow-ups and incorporated into the research protocol for further studies in the future.

Monitoring Schedule

All patients will stay on-site for the administration and monitoring period, calculated as 2 hours from the start of IV infusion per consensus guidelines in ketamine administration. Patients will stay in a separate private space and be provided with noise-cancellation headphones and an eye mask to minimize environmental disruptions. Patients will be closely monitored by available trained personnel, with a medical doctor present on-site for the entire supervision period. Specifically, IV induction will be performed under the direct supervision of an anesthesiologist or delegate and psychiatrist, who will remain present on-site for the entire duration of the 40-minute ketamine infusion. Trained personnel are available on-site to closely monitor the postinfusion period, where vital signs (ie, heart rate, blood pressure, oxygen saturation level) will be monitored every 30 minutes. Each patient will be closely monitored for the entire IV infusion duration and the postinfusion period for at least 2 hours. The overall time per treatment session is at least 2 hours starting from the time of infusion initiation. This includes the 40-minute infusion period and 80 minutes for postinfusion monitoring. Any adverse events will be managed by the medical team administering the treatment. If required, appropriate medications will be provided to manage treatment-related side effects and any adverse events as defined by clinical site policies and regulations. Clinical and neurophysiological assessments will be administered according to the trained research personnel's schedule for study visits. There is a total of 16 study visits in this trial, which includes treatment sessions and follow-ups.

Potential Risks and Mitigation Strategies

Given the potential risks described below, trained medical personnel will be present during the administration and for the entire duration of the 2-hour monitoring period.

Ketamine is classified as a schedule I controlled substance due to its potential for abuse and addiction and can be abused in a number of ways, including via injection, snorting, or orally. Ketamine can produce vivid dreams and a feeling that the mind is separated from the body, referred to as "dissociation." Regular users of ketamine can become tolerant to the dissociative effects of the drug, meaning an increasing amount is needed to achieve the same effect. Drug-related risks include (1) psychiatric symptoms such as fatigue, dizziness, anxiety, visual and auditory disturbances, panic attacks, increased irritability, and changes in mood and behavior; (2) medical symptoms such as transient increases in blood pressure and heart rate, an increase in the need to urinate, headaches, vision changes, chest pain, shortness of breath, confusion, memory impairment, anaphylaxis; and (3) a rare risk of dependency. To address these risks, in this trial, ketamine will be dispensed by the research pharmacy and administered by a trained medical professional, and the patient will receive close supervision and monitoring. Doses are individually calculated, and treatment sessions are structured to prevent tolerance building. Patients will be strongly discouraged from using ketamine outside of the context of this trial and will be informed that they can be discussed with the study physician if they have questions.

IV route–associated risks are infiltration, hematoma, air embolism, phlebitis, extravascular drug administration, and intraarterial injection. Most of these complications are transient and resolve with conservative monitoring. An intraarterial injection is rare but as threatening. An anesthesiologist is present

XSL•FO
RenderX

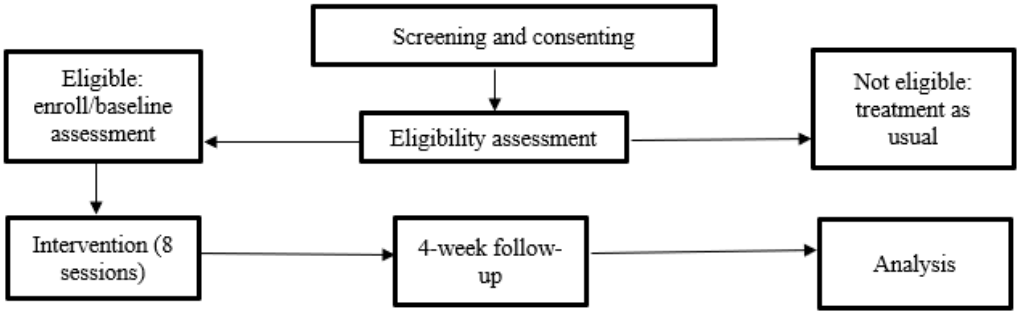
on-site for the IV infusion and will attend if needed, per site rules and regulations.

Clinical Assessment Risks

Answering multiple questions at times can be distressing. These adverse reactions are mostly brief, transient, and rarely have long-term implications.

TMS-EMG/EEG Risks

Single-pulse TMS is now in routine clinical diagnostic use in hundreds of neurophysiological laboratories worldwide. The ability of TMS to noninvasively stimulate brain areas presents a significant advance beyond techniques that require the invasive method of direct cortical or transcranial electrical stimulation. Magnetic fields pass through the scalp and skull without the impedance encountered by direct electrical stimulation, permitting enhanced control over the site and intensity of stimulation. The induced electrical current is well below that which is expected to cause harm to nervous tissue; thus, stimulation at <1 Hz carries virtually no risk of seizure and is therefore classified as a nonsignificant risk device. In numerous studies, single-pulse TMS has been found to pose no significant health risk to properly screened healthy volunteers.



Outcomes

The primary outcome of this pilot trial is to examine the safety and feasibility of repeated subanesthetic doses (0.5-0.8 mg/kg) of ketamine administered over 40-minute IV infusions in patients with BD to treat acute suicidality based on recruitment numbers, attrition rate, and a number of adverse events in the trial. The secondary outcome is to analyze the potential impact of ketamine on neurophysiological markers associated with cortical excitation and inhibition as a proxy of NMDA receptor activity in the cortex. The tertiary outcomes are to assess the intervention's potential effect on clinical outcomes, such as acute suicidality, depressive symptoms, and quality of life.

Participant Timeline

We intend to recruit 30 participants, adults 24-65 years old, diagnosed with BD and experiencing suicidal thoughts in their current episode, over the duration of 2 years from 1 site (CAMH). The trial period is shown in the CONSORT (Consolidated Standards of Reporting Trials) diagram (Figure 1).

Figure 1. Flowchart of the study design.

Sample Size

We calculated our sample size based on this study design, which is to test the safety and feasibility of ketamine infusions. We calculated that a minimum sample size of 30 participants is needed for the proposed investigation.

Recruitment

This is a single-site open-label pilot safety and feasibility study that will be conducted at the CAMH. The CAMH is a large urban academic institution offering psychiatric care to a diverse population across the province. We intend to recruit participants through CAMH General Division Ambulatory services, which annually provides over 500 consultations for mood-related concerns. The study's PI is a staff psychiatrist and clinician-scientist in General Division who provides outpatient services to a large population with mood disorders at local and provincial levels. PI is also an interventional psychiatrist working as a part of the Therapeutic Brain Intervention Centre, seeing many patients with treatment-resistant and severe mood disorders. She is also US certified in ketamine interventions and a member of the American Society for Ketamine Physicians (ASKP). This study group has extensive experience with recruiting patients for clinical trials as the PI of this study and coinvestigators are clinician-scientists who provide care to a large number of patients with mood disorders within the context of clinical trials. Thus, we believe recruiting 30 participants over 2 years is feasible.

In addition to group expertise, we will utilize a CAMH-wide recruitment strategy, specifically the Clinical Engagement and Research Recruitment (CLEARR) model, where all new referrals to the CAMH clinics are prescreened, and all patients are informed about clinical research at the time of their initial clinical assessment. The study site will make efforts to recruit a representative and ethnically diverse sample. CAMH services a very diverse inner-city population through numerous satellite clinics in several minority neighborhoods throughout the city. Toronto has diverse cultural representation as almost 75% of its population, aged 15 and older, have direct ties to immigration. In this study, we anticipate our recruitment will follow the ethnic distribution of White/non-Hispanic 50%, Asian 20%, Southeast Asian 15%, Black/non-Hispanic 10%, and Hispanic 5%. We also expect that 60% of our population enrolled at the CAMH site will be female based on our prior experience with clinical trials at the CAMH.

XSL•FO
RenderX

Data Collection Methods

Data will be collected on a baseline assessment, weekly during the course of IV ketamine, within a week after the completion of the intervention, and following 4 weeks for a final follow-up. Assessments will include psychiatric assessment, physical examination, and clinical assessments through manualized validated clinical scales (Multimedia Appendices 1 and 2).

Psychiatric assessment will include a consultation with a study physician to confirm a diagnosis. Demographic information, medical and psychiatric history, and concomitant medications will also be included.

A *physical examination* will include a physical exam performed by a study physician or a delegate, and blood work and electrocardiography for medical clearance according to standard clinical procedures also be reviewed by the study physician. Blood tests will include complete blood count with differential tests (white blood cells, red blood cells, hemoglobin, hematocrit, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, red cell distribution width, mean platelet volume, platelet, nucleated red blood cell count, neutrophil count, lymphocyte count, monocyte count, eosinophil count, basophil count); blood chemistry test, including liver function (alanine transaminase and aspartate transaminase), kidney function (blood urea nitrogen and creatinine), and electrolytes (sodium, potassium, chloride, and phosphate); and thyroid function (thyroid-stimulating hormone). Study participants' blood pressure will also be monitored before, during, and after treatment.

Clinical assessments will include (1) the MINI to clarify psychiatric inclusion and exclusion criteria; (2) the Antidepressant Treatment History Form (ATHF) to clarify on inclusion and exclusion criteria [26]; (3) the SSI will be administered at screening, baseline, weekly, and after treatment to confirm eligibility and to assess changes as a secondary outcome measure; (4) the HRSD-24, which will assess changes in depressive symptoms and will be administered at the baseline and after treatment; (5) the Young Mania Rating Scale (YMRS), which will be used to evaluate mania/hypomania symptoms at screening and throughout the study for eligibility and safety monitoring purposes [27]; and (6) World Health Organization Disability Assessment Schedule (WHODAS 2.0), which will be used as a standard measure of disability promoted and used at baseline and after treatment to assess changes in individual level of functioning [28].

Neurophysiological assessments will include (1) the Transcranial Magnetic Stimulation Adult Safety Screen to assess potential TMS risk factors; and (2) TMS-EMG/EEG. Our neurophysiological measures have been established and have a high test-retest reliability (ie, intraclass correlation >0.9) [18,19]. Data analysis will be performed using semiautomated methods developed and validated by our group [29]. TMS pulses will be administered to the left dorsolateral prefrontal cortex using a 7-cm figure-of-eight coil and 2 Magstim 200 stimulators (Magstim Company Ltd) connected via a BiStim module, and motor-evoked potential data will be collected using commercially available software (Signal; Cambridge Electronics). Each TMS session will include the establishment of the individual threshold for stimulation of motor cortex, and dorsolateral prefrontal cortex localization will be performed according to previously published methods [29,30]. The resting motor threshold will be determined by applying single pulses of TMS to the motor cortex while the coil is placed at the optimal position to elicit motor-evoked potentials from the right abductor pollicis brevis muscle. The resting motor threshold is defined as the minimum stimulus intensity that elicited a motor-evoked potential of >50 μV in more than 5 of the 10 trials [30].

TMS-EMG will be recorded from the abductor pollicis brevis with Ag-AgCl electrodes placed over the belly of the muscle. The signal will be amplified (Model 2024F; Intronix Technologies Corporation), filtered (band-pass 2 Hz-5 kHz), digitized at 5 kHz (Micro 1401; Cambridge Electronics Design), and stored in a laboratory computer for offline analysis. The participants will be instructed to relax throughout the study. Trials contaminated with voluntary muscle activity will be discarded.

TMS-EEG

EEG will be used to evaluate TMS-induced cortical evoked activity. EEG recordings will be acquired through a 64-channel EEG system [30]. A 64-channel EEG cap will be used to record the cortical signal, and 4 electrodes will be placed on the outer side of each eye and above and below the left eye to closely monitor the eye movement artifact. All electrodes will be referenced to an electrode placed on the vertex positioned posterior to the Cz (midline central) electrode. Direct current EEG signals will be recorded with a 20-kHz sampling rate and with a low-pass filter of 300 Hz, which in pilot experiments was shown to avoid saturation of amplifiers and minimize the TMS-related artifact. The EEG data will be downsampled to a 1-kHz sampling frequency and segmented concerning the TMS stimulus such that each epoch includes a 1000-ms prestimulus baseline and a 1000-ms poststimulus activity. Epochs will be baseline corrected concerning the TMS-free prestimulus interval. The baseline-corrected poststimulus intervals (approximately 25-1000 ms) that are not contaminated by TMS artifact will be extracted and digitally filtered using a zero-phase shift 1-100-Hz band-pass filter (48 dB per octave). Records will be manually reviewed at this stage, and trials contaminated with muscle activity, movement, and TMS artifacts will be excluded from further analysis. Finally, the average signals at each recording site will be computed from the movement-free epochs (approximately 80 trials per participant) and fed into an automated eye-blink correction algorithm [30]. The eye-blink–corrected average EEG waveforms will be imported into MATLAB (The MathWorks Inc), and further analyses will be carried out using the EEGLAB toolbox [31]. Furthermore, methods in this approach will be conducted according to previously published combined TMS-EEG studies [29-31].

Data Management

The REDCap (Research Electronic Data Capture) software will be used for data collection and overall study data management throughout this project. REDCap is a secure, web-based clinical data management and electronic data capture system and database. It is built and distributed by Vanderbilt University,

XSL•FO
RenderX

with a local instance installed on a central CAMH server overseen by the CAMH REDCap Operations Committee. All data are stored on-site and backed up daily. The system is developed and managed in compliance with HIPAA (Health Insurance Portability and Accountability Act), PIPEDA (Personal Information Protection and Electronic Documents Act), and FDA21 CFR (US Food and Drug Administration Code of Federal Regulations Title 21) Part 11 regulations, providing functions such as defined user roles and privileges, user authentication and encryption, electronic signatures, deidentification of protected health information, comprehensive auditing features to record and monitor access and data changes, and a validated software development life cycle. This system will collect data, design electronic case report forms, data entry, monitor and clean, and query and export data sets for statistical analysis.

Statistical Methods

Baseline participant characteristics will be reported and described using summary statistics—mean and SD for continuous data and number and proportion for categorical data. As the primary outcome is to assess feasibility, we will report on (1) recruitment numbers and attrition rates; (2) the number of individuals who experience side effects, and (3) the overall number and type of side effects. For neurophysiology, we will use an independent *t* test (paired 1-tailed) to compare components of TMS-evoked responses in the left dorsolateral prefrontal cortex in TMS-EEG data. In addition, we will apply a nonparametric cluster-based permutation test to investigate any significant changes in overall EEG channels. We will conduct a paired 1-tailed *t* test of the SSI and HRSD-24 scores from baseline to week 4 and monthly follow-up to assess preliminary clinical outcomes. We will also report the standardized mean difference as a measure of effect size (small: 0.2; medium: 0.5; large: 0.8).

Monitoring

Trial Monitoring

We will perform internal quality management of study conduct, data collection, documentation, and completion through proactive study monitoring using our team-based monitoring approach. Monitoring will be conducted prior to, during, and after the study concludes to ensure that good clinical practice is maintained. All data monitoring, auditing, and harms reporting will be performed according to CAMH Research Ethics Board and regulatory standards. The study investigator and delegated research personnel will monitor study participants according to the study protocol and continually assess the patient for adverse outcomes; all adverse events will be assessed in real-time to determine if they meet the criteria for a “serious adverse event” and how the event was “related” to the study intervention.

Harms

Adverse events occurring as of the first administered dose of the investigational product and 30 days after the last administered dose will be collected. All reported adverse events will be followed up to the resolution, or an appropriate posttrial follow-up plan will be determined. Serious unexpected adverse drug reactions will be reported as required by Health Canada, the Food and Drug Regulations—Division 5. For this pilot trial, all relevant adverse events and all serious adverse events will be reported to the Research Ethics Board directly if they meet applicable reporting requirements.

Auditing

At the time of this publication submission, the study also passed the CAMH Quality Assurance internal auditing process. Quality control procedures will be implemented beginning with the data entry system, and data quality control checks that will be run on the database will be generated. Any missing data or data anomalies will be communicated for clarification/resolution.

Research Ethic Approval

This study has received CAMH Research Ethics Board (approval number 179-2020) and Health Canada (approval number NOL251577) approvals.

Consent

We will obtain informed consent from each participant who agrees to participate in the trial. Patients meeting the criteria will be referred to the research analyst/study coordinator to discuss the study purpose, procedures, potential risks, and rights as research participants. Consent forms describing the study intervention, study procedures, and risks will be given to each participant, and written documentation of informed consent will be required prior to completing the initial screening visit and starting the study intervention. Once consent is obtained, the research personnel will confirm that inclusion and exclusion criteria are met before proceeding with baseline testing. Patients will be informed that they can withdraw participation at any point during the study. The participants will be given a copy of the information and consent documents for their records. The informed consent process will be documented, and the form will be signed before the participant undergoes any study-specific procedures. The rights and welfare of the participants will be protected by emphasizing that the quality of their medical care will not be adversely affected if they decline to participate in this study (Multimedia Appendix 3).

Confidentiality

Data confidentiality and confidentiality of the identities of the individuals participating in this study will be strictly maintained. Data forms that include identifying information will be kept in locked cabinets. Only the unique ID number assigned by the research coordinator will be used to represent participants during data entry, data transfer, data analysis, or other file management procedures. All information linking their identity will be kept separate from the research records. All information entered into a computer will be stored in a password-protected and encrypted file format on a secure server. If any participant withdraws from the study, any research information recorded for or resulting from the participant prior to the date that the participant formally withdrew consent will continue to be stored and used (in the manner described above) for research purposes (and will be disclosed by the investigators); however, no new data will be collected. Withdrawing from the study will not have any consequences for the participant. Participants’ identities will not be revealed in the publication or presentation of any results from this study.

XSL•FO

Access to Data

The data sets generated during and/or analyzed during this study are not currently publicly available due to the ongoing trial but will be available from the corresponding author upon reasonable request.

Dissemination Policy

The results of this study will be disseminated through publications and presentations at the scientific conferences.

Results

This study is currently ongoing and actively recruiting participants. So far, 5 participants have completed the trial, 1 is currently in active treatment, and 8 participants are on the waitlist to be screened. We anticipate initial results being available in the fall of 2023. This proposal was presented as a poster presentation at the Research to Reality Global Summit on Psychedelic-Assisted Therapies and Medicine, held in May 2022 in Toronto, Canada.

Discussion

Expected Findings

Developing effective interventions for acute suicidality in high-risk populations such as BD remains a major therapeutic challenge. Ketamine, an NMDA receptor antagonist, represents a promising intervention due to its rapid antidepressant and antisuicidal effects [11]. However, our understanding of its underlying neurophysiological mechanisms for suicidality in BD is limited. TMS-EMG and TMS-EEG can be used to produce a reliable neurophysiological measure of NMDA receptor–mediated neurotransmission [15]. To our knowledge, this is the first study to investigate the safety/feasibility and neurophysiological changes of repeated 40-minute ketamine infusions to treat suicidality in patients with BD. Results from this study will (1) inform the development of a larger, adequately powered randomized controlled trial to test the feasibility of a series of IV ketamine infusions to treat suicidality in patients with BD and (2) determine potential neurophysiological markers of clinical response.

Limitations

In general, a lack of a control group and a small sample size are limitations in ketamine clinical trials. However, given that this is a pilot open-label clinical trial, the sample size is sufficient (ie, the goal is not to assess generalizability or statistical significance). The lack of blinding in the control group is a common concern in ketamine trials because a placebo with comparable effects does not exist, and it is impossible to ensure blinding to the full extent. Because the study is conducted at a single site of a large psychiatric academic facility, the results may not be fully transferable to a broader population; however, the study will provide preliminary data on feasibility and safety to be used in a larger, adequately powered and controlled trial. Moreover, a small sample size may not allow drawing any meaningful conclusions around neurophysiological markers of response; however, results will inform a further larger clinical trial where we can test neurophysiological markers more accurately.

Clinical Significance

BD is an incapacitating psychiatric condition with high mortality rates due to suicide, where 25%-60% of patients will attempt suicide at least once in their lifetime, and about 10%-15% die by suicide. Current treatment options for suicidality are very limited. Subanesthetic doses of ketamine have been shown to have rapid antisuicidal effects [5]; however, research exploring ketamine's biological targets of treatment response remains limited. This study will provide preliminary data on the feasibility of repeated IV ketamine infusions to treat suicidality in patients with BD and investigate potential neurophysiological mechanisms to identify the biomarkers of clinical response.

Acknowledgments

This study has been funded partly by the 2020 Discovery Fund Seed Funding, an award supported by a generous philanthropic donation dedicated to the innovation required to solve major challenges in the effective diagnosis and treatment of mental illness.

Authors' Contributions

YK is the lead of this project as a principal investigator. DV, TK, and AT will monitor recruitment and treatment sessions. DB is a mentor and senior author who will assist with trial monitoring and access to facilities and trained personnel. RZ will assist with data analysis. All authors will work on the final manuscript.

Protocol

The Effect of Prophylactic Intravenous Amiodarone Administration on Reperfusion Ventricular Fibrillation in Patients With Left Ventricular Hypertrophy Undergoing Cardiopulmonary Bypass Surgery: Protocol for a Randomized Double-Blind Clinical Trial

Abstract

Background: Ventricular fibrillation (VF) is a common arrhythmia that occurs after the release of aortic cross-clamp (ACC) in patients undergoing cardiopulmonary bypass (CPB) surgery. Repeated defibrillation and long duration of VF could increase myocardial injuries. In patients with left ventricular hypertrophy (LVH), VF is easier to occur and more difficult to be terminated. Amiodarone, known as class III antiarrhythmic agent, has the prominent properties of converting VF and restoring the sinus rhythm. Before ACC release, administration of amiodarone has been confirmed useful to reduce occurrence of VF. However, few studies are focused on the effect of amiodarone before ACC release on reducing VF in patients with LVH.

Objective: This study aimed at determining the efficacy of prophylactic intravenous amiodarone administration on reperfusion VF after release of ACC in patients with LVH undergoing CPB surgery.

Methods: This will be a prospective, randomized, double-blind, placebo-controlled trial. The trial will enroll 54 patients with LVH aged 18-75 years who will undergo CPB surgery. All eligible participants will be randomly allocated to either the amiodarone or placebo group by using the block randomization in a 1:1 ratio. The primary end point will be the incidence rate of VF 30 minutes after ACC release and be assessed using the Fisher exact test. All data will be analyzed in accordance with the intention-to-treat principle.

Results: The study began in August 2022, and the data collection will take place for the next 2 academic years. As of this writing, 21 participants have already been recruited for the study.

Conclusions: With this trial, we are hoping to demonstrate that prophylactic infusion of amiodarone before ACC release could reduce the occurrence of reperfusion VF in patients with LVH.

Introduction

Background

Ventricular fibrillation (VF) is commonly seen after aortic cross-clamp (ACC) release during cardiopulmonary bypass (CPB) surgery [1]. It has been reported that the incidence rate of VF after ACC release ranges from 45% to 100% [1-6]. Left ventricular hypertrophy (LVH) has been found to increase the incidence rate of VF after ACC release, which is more difficult to be terminated [7]. Internal electrical defibrillation is an effective method to eliminate VF but repeated shock and long duration of VF could aggravate myocardial injury and reduce the patient's prognosis [8].

There are different factors leading to VF after ACC release including surgical trauma, insufficient myocardial protection, inadequate intracardiac deairing or left ventricular vent, abnormal electrolyte and acid-base metabolism, delayed rewarming before ACC release and myocardial reperfusion injury after ACC release, etc. Among these, myocardial reperfusion injury is the main reason resulting in VF after ACC release [9]. The ischemia of cardiomyocytes could cause the increase in extracellular potassium ions. When the blood supply is restored, the uneven recovery of extracellular potassium ions makes the cell membrane potentially unstable, which would easily lead to increased self-discipline or triggered arrhythmias [10]. At the same time, myocardial ischemia-reperfusion can increase intracellular calcium levels, resulting in delayed depolarization of cardiomyocytes and triggered electrical activity, which also induces ventricular arrhythmias. Furthermore, α-adrenergic receptors are activated in reperfusion cardiomyocytes over a short period of time, contributing to increased myocardial autonomic activity and intracellular calcium levels [11]. The ischemic cardiomyocytes gradually and slowly recover their activities after the blood resupply, during which they are prone to reentrant arrhythmias, and the effective refractory period of cardiomyocytes in ischemic regions decreases, which also provides conditions for the occurrence of reentrant arrhythmias [12]. Therefore, both reentrant and nonreentrant arrhythmias play a role in the occurrence of ischemia-reperfusion VF.

Long duration of VF has many side effects on cardiomyocytes after ACC release. A study showed that coronary artery blood supply was redistributed during VF, which resulted in subendocardial myocardial ischemia and cardiac dysfunction [13]. With the prolongation of VF duration, the resistance of subendocardial vessels increased gradually, which worsened the subendocardial ischemia of cardiomyocytes. Besides, myocardial edema also developed with the long duration of VF [14]. The ventricular wall tension and venous pressure would increase during VF and higher perfusion pressure would be required to achieve normal blood supply in CPB. Frequent and irregular myocardial contractions and increased pressure in the cardiac cavity could result in a higher oxygen consumption of myocardium. The abovementioned factors lead to the imbalance of oxygen supply and demand in myocardium, which seriously destroy the function of cardiomyocytes. Moreover, Khuri et al [15] discovered that metabolic acidosis was more severe in cardiomyocytes during VF and the postoperative mortality rate was higher in a group of patients. Creatine kinase–myocardial band (CK-MB) is a specific marker of myocardial injury. After ACC release, the postoperative CK-MB of patients with VF was significantly higher than that of patients without VF, and the degree of elevation was 75% related to the duration of VF [16].

Defibrillation could also damage the myocardium. Doherty et al [17] found that when the energy of defibrillation was more than 30 J, the damage of cardiomyocytes increased and the blood flow in cardiomyocytes decreased. Multiple defibrillations significantly increased myocardial damage compared with single defibrillation. The shorter time interval of each defibrillation also resulted in greater myocardial injuries. It was observed under electron microscope that the gaps between myocardial intercalated discs increased after defibrillation, thus affecting the myocardial contractile function. A clinical study showed that myocardial injury markers, cardiac troponin T, cardiac troponin I, and CK-MB were significantly elevated after cardiac shock, which further confirmed the myocardial injury owing to internal electrical defibrillation [18].

In patients with LVH, the volume of cardiomyocytes expands, but the corresponding coronary arteries do not increase, resulting in absence of subendocardial capillaries. The end-diastolic pressure and systolic cardiac function also increase, leading to increased myocardial oxygen consumption. These histological changes give rise to the imbalance of myocardial oxygen supply and demand, and ischemia of subendocardial myocardium, which reduces the tolerance of myocardium to ischemia-reperfusion [19]. Owing to the special structure of LVH, the perfusion fluid of CPB could not completely reach the subendocardial cardiomyocytes. Compared with the normal heart, the effect of myocardial protection during CPB is usually inadequate. The incidence of VF after ACC release increased significantly, and the energy and frequency of cardiac shocks in hypertrophic myocardium increased as well [20]. Thus, reducing the occurrence of VF has an important clinical significance.

Amiodarone is a class III antiarrhythmic agent with multiple electrophysiological effects, which has been used clinically in the management of both atrial and ventricular arrhythmias. Through hepatic metabolism, amiodarone is transformed to desethylamiodarone, which has the property of antiarrhythmic effects. Amiodarone is highly lipid soluble and is widely stored in fat, muscle, skin, liver, and lungs with a very long elimination half-life, averaging about 58 days [21]. The predominant antiarrhythmic effect of amiodarone is the inhibition of IKr and IKs channels leading to a prolongation of myocardial repolarization homogeneously. Amiodarone also slows heart rate and atrioventricular nodal conduction through inhibiting calcium channels and β-receptors. In addition, it also prolongs refractoriness and reduces intracardiac conduction velocity by blocking sodium channel [22,23]. It has been confirmed that intravenous amiodarone could protect myocardium from ischemia-reperfusion and prevent VF caused by reperfusion [24-26]. During ischemia-reperfusion, amiodarone can improve the metabolic efficiency of cardiomyocytes and reduce the

XSL•FO
RenderX

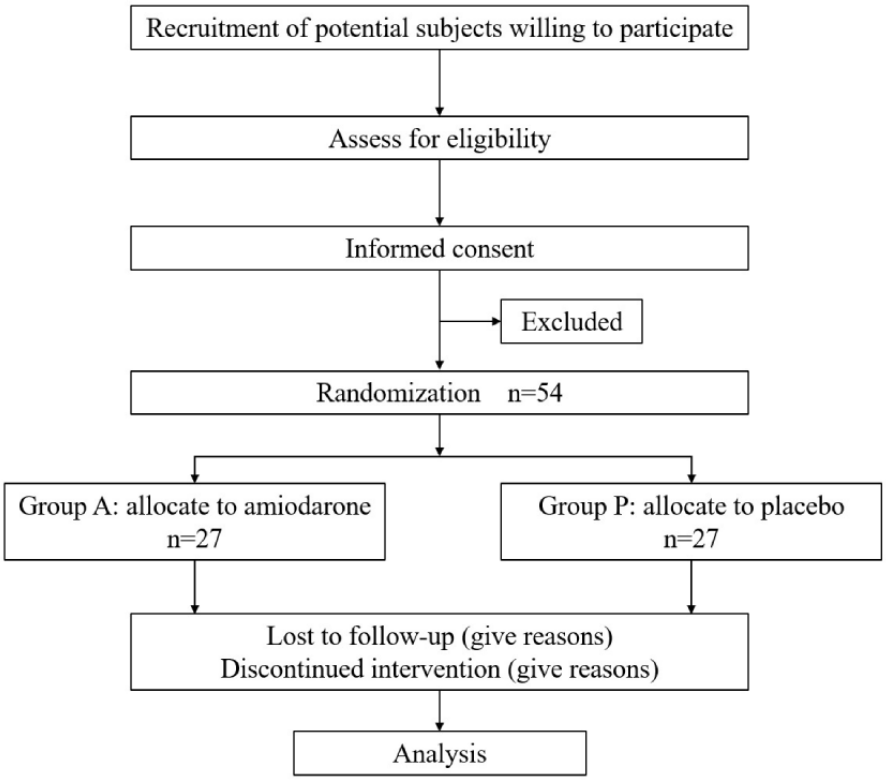
repolarization dispersion of cell membrane, which is one of the main factors causing ventricular arrhythmias.

Previous studies have shown the effectiveness of amiodarone on reducing the incidence rate of VF after ACC release [2,3,27,28]. Samantaray et al [3] reported that during coronary artery bypass grafting surgery, 150 mg of amiodarone was given 3 minutes before aortic opening, which decreased the incidence of VF after ACC release compared with the placebo-controlled group. However, in the study of Ayoub and colleagues [2], the administration of amiodarone 2 minutes before aortic opening failed to reduce the incidence of VF after ACC release during coronary artery bypass grafting surgery, but lidocaine instead reduced the occurrence of VF. Mauerman et al [27] also found that neither 300 mg of amiodarone nor 1.5 mg/kg of lidocaine reduced the occurrence of VF. Furthermore, the study of Yilmaz et al [28] showed that both 300 mg of amiodarone and 1.5 mg/kg of lidocaine decreased VF after ACC release compared with the placebo-controlled group, but there was no significant difference in reducing VF between amiodarone and lidocaine groups. Although the results from the abovementioned clinical studies are controversial, they generally hint that amiodarone has a therapeutic effect on reperfusion VF after ACC release.

In a case report of Morita et al [7], a 66-year-old female patient underwent aortic valve replacement due to severe aortic stenosis, and preoperative transthoracic echocardiogram showed the thickness of ventricular septal and left ventricular posterior wall up to 18 mm. Refractory VF after ACC release occurred and lidocaine infusion and multiple cardiac shocks were both ineffective. Thereafter, 150 mg of amiodarone was given through the root of aorta, and finally VF was terminated by one defibrillation. Suzuki et al [20] also reported a similar case of using amiodarone in terminating reperfusion VF during cardiac surgery. There is only a clinical trial about amiodarone in reducing reperfusion VF in patients with LVH [29]. In this trial, patients with LVH undergoing aortic valve replacement were randomly assigned to receive a bolus of 150 mg of amiodarone plus maintenance dose of 30 mg/hour or a bolus of 1 mg/kg of lidocaine plus maintenance dose of 1 mg/kg/hour after anesthetic induction. The incidence rate of VF was significantly lower in the amiodarone group than in the lidocaine group (20.6%, 7/34 vs 50%, 17/34, P=.02). Meanwhile, amiodarone could reduce the level of interleukin-6 and tumor necrosis factor after operation. In addition to the abovementioned studies, no more studies were focused on this area.

Objective

The objective of this study is to explore the outcomes of prophylactic intravenous amiodarone administration on reperfusion VF after ACC release in patients with LVH undergoing CPB surgery.



This study also concentrates on the effect of amiodarone on hemodynamic state after weaning from CPB in patients with LVH, which few previous studies have examined.

Methods

Study Design and Setting

This study is a prospective, single-center, randomized, double-blinded, placebo-controlled clinical trial to investigate effect of perioperative intravenous amiodarone on reperfusion VF after release of ACC in patients with LVH undergoing CPB. The study will be conducted in the First Affiliated Hospital of Nanjing Medical University, Nanjing, China. A schematic of the trial protocol is presented in Figure 1.

Figure 1. Trial flow chart.

XSL•FO
RenderX

Study Population

Fifty-four patients who meet the eligibility criteria will be recruited and randomly divided into 2 groups, including amiodarone group (group A) and placebo-controlled group (group P), 27 cases in each group. Informed consent will be obtained from all participants (Textbox 1).

Textbox 1. Inclusion and exclusion criteria of participants.

Inclusion criteria

Patients included in the trial are as follows:

- Subjects undergoing cardiopulmonary bypass surgery
- Aged between 18 and 75 years
- With left ventricular hypertrophy diagnosed by transthoracic echocardiogram preoperatively
- American Society of Anesthesiologists class I-III

Exclusion criteria

Patients fulfilling one or more of the following criteria will not be included:

- Preoperative use of class I or III antiarrhythmic drugs
- Corrected QT interval of ≥480 milliseconds or QT of ≥500 milliseconds
- Left ventricular ejection fraction <30%
- With thyroid dysfunction
- With electrolyte imbalances
- With hepatic or renal dysfunction
- With pulmonary interstitial fibrosis
- Allergic to amiodarone
- Undergoing emergency surgery
- Undergoing redo surgery

Randomization and Blinding

Thirty minutes before ACC release, the enrolled participants who meet the eligibility criteria will be randomly allocated in a 1:1 ratio to 2 groups, namely, group A (treated with amiodarone) and group P (placebo control). Block randomization will be used with a block size of 4, which will be implemented with SPSS (version 22.0; IBM Corp) by an independent statistician, and the randomization numbers will be given to an external data manager with no involvement in the study procedures and concealed on password-protected computer.

When a patient meets the eligibility criteria, the external data manager will return the corresponding allocation to the nurse anesthetist. The drugs will be prepared by the nurse anesthetists according to the allocation information, packaged with the same looking and labeled with numbers, and injected by the anesthesiologists. Both anesthesiologists and patients will be blinded to the regimen. The anesthesiologist will be notified of the study group by the nurse anesthetists in case of emergency. However, the nurse anesthetists have no role in assessing the treatment actions, analyzing, or interpreting the data.

Interventions

Treatment Regimen of Amiodarone

Thirty minutes before ACC release, the trial drugs will be administered through the central venous line. In group A, 150 mg of amiodarone will be diluted to 20 mL normal saline and pumped in 5 minutes. In group P, 20 mL normal saline will be pumped in 5 minutes (Table 1).

[a]Time point: t_1: baseline; t_1: intervention period, 30 minutes before aortic cross-clamp (ACC) release; t_2: 10 minutes after ACC release; t_3: 15 minutes after weaning from cardiopulmonary bypass; t_4: the end of surgery.

[b]✓: refers to crucial events at corresponding points in time.

[c]Group A: amiodarone group.

[d]Group P: placebo-controlled group.

[e]Primary end point: occurrence of ventricular fibrillation (VF).

[f]Secondary end point: t_2: the number and maximum energy of defibrillations to terminate VF; t_3: heart rate, mean arterial pressure, mean pulmonary arterial pressure, central venous pressure; t_4: the total dosages of vasoactive agents.

Anesthesia Protocols

All the patients will fast for 8 hours and abstain from water for 4 hours preoperatively and receive standardized general anesthesia. In the operating room, the patients will be routinely monitored including 5-lead electrocardiograph, peripheral blood oxygen saturation, invasive arterial blood pressure, bispectral index (BIS), and end tidal CO_2, which will be recorded every 3 minutes in each patient's electronic medical record. The induction of anesthesia will be performed as follows: 0.05 mg/kg midazolam, 0.3 mg/kg etomidate, 0.15 mg/kg cis-atracurium, and 4-6 μg/kg fentanyl. Approximately 5 minutes after induction, patients will be intubated and ventilated to maintain the end tidal CO_2 at 35-45 mm Hg. Then, the ultrasound-guided central vein catheterization will be conducted via the right internal jugular or subclavian vein. Swan-Gans catheter will be floated to pulmonary artery through the right internal jugular. Thereafter, transesophageal echocardiogram will be inserted for the intraoperative cardiac estimations. The patients continued receiving anesthesia by inhalation of sevoflurane 1%-2% and continuous pump of propofol 1-2 mg/kg/hour, dexmedetomidine 0.5 μg/kg/minute, and cis-atracurium 0.05-0.1 mg/kg/hour. The total dosage of fentanyl will be 30-50 μg/kg. During continuation of anesthesia, the BIS will be maintained between 40 and 60. Inotropic agents, vasopressors, vasodilators, or fluid administration will be applied to achieve the following hemodynamic status: a mean blood pressure of 50-80 mm Hg, cardiac index (CI) ≥2.2 L/min/m^2, and urine output ≥1.0 mL/kg/hour.

Surgical and CPB Procedures

The surgical procedures will be performed via median sternotomy with heparinization and standard CPB. The cannulation sites for CPB are at the discretion of the cardiac surgeon and dependent on the operation. The aortic cannulation is obtained with a patient size–appropriate cannula. Venous cannulation is obtained with a single 2-stage cannula in the right atrium or separate cannula in the superior and inferior vena cava. Anticoagulation is started with 400 μg/kg of heparin and maintained according to an activated clotting time of >480 seconds. CPB is initiated using a membrane oxygenator and the circuit is primed with 1500 mL of acetate Ringer solution and 200 mL of 50% human serum albumin. Patients are perfused by a nonpulsatile roller pump at a flow rate of 2.0-2.4 L/minute/m^2 and with mean arterial pressure (MAP) of 50-80 mm Hg. Moderate systemic hypothermia around 30-32 °C is maintained during CPB. Myocardial protection is achieved using intermittent antegrade or retrograde infusions of histidine-tryptophane-ketogluterate cardioplegia. Cardioplegic infusion is repeated every 120 minutes or when electrical activity of the heart is detected. After weaning from CPB, reversal of heparin is achieved with protamine.

Management of VF

Thirty seconds before ACC release, 1 mg/kg of esmolol will be given to all patients. When VF occurs after ACC release, internal electrical defibrillation with 20 J will be performed in the first attempt. If not successful, the second defibrillation with 20 J will be attempted after reusing 0.5-1 mg/kg of esmolol. If VF

XSL•FO
RenderX

persists, the third defibrillation with 30 J will be performed after giving 1 mg/kg of lidocaine. If VF termination is not achieved, the fourth defibrillation with 40 J will be attempted after administration of 50 mg of amiodarone. If VF still exists, administration of 100 mg of amiodarone and defibrillation with 50 J will be repeated until VF terminates.

End Points

The primary end point is the incidence rate of VF 10 minutes after ACC release. The secondary end points include the duration of VF, the number and maximum energy of defibrillations needed to terminate VF, the use of other antiarrhythmic agents, and epicardial temporary pacemakers after ACC release. Besides, the secondary end points also include heart rate, MAP, mean pulmonary arterial pressure, central venous pressure and CI 15 minutes after anesthetic induction and weaning from CPB, and the speed of vasoactive agents at the end of CPB and surgery and their total dosages.

Sample Size Estimation

The sample size is calculated based on the primary end point: the incidence rate of VF 10 minutes after ACC release using PASS (version 15.0; NCSS). According to the published studies, the incidence rate of VF after ACC release ranges from 45% to 100% [1-6]. We assumed that the incidence rate of VF 10 minutes after ACC release would be 70% in the placebo-controlled group and amiodarone could decrease the rate to 30%. To reach statistical significance with a power of 80% and an α value of .05 (2-sided), 21 patients are assessed to be needed in each group. Assuming a 20% dropout or missing data rate, we will recruit 27 patients in each group for a total of 54 patients.

Statistical Analysis

All data will be analyzed using SPSS (version 22.0; IBM Corp) and in accordance with the intention-to-treat principle, beginning immediately after randomization. All statistical tests will be considered significant if $P<.05$. Only 2-sided tests will be used. Baseline characteristics will be described and compared by using the Fisher exact test for the categorical variables and 2-sample *t* test or Wilcoxon rank sum test depending on the normality of the data distribution for the continuous variables. The continuous variables will be described by mean and SD values if normally distributed or median and interquartile range if not. The normality of distributions will be checked graphically and using the Kolmogorov-Smirnov test. If there is a violation of distribution assumption, appropriate transformation will be used. The categorical variables will be expressed as frequencies and percentages.

For the primary end point, the incidence rate of VF 10 minutes after ACC release will be compared by using the chi-square test. For the secondary end points, heart rate, MAP, mean pulmonary arterial pressure, central venous pressure, and CI will be compared between 2 groups by using a repeated measures ANOVA model during the 2 observation times. Other continuous secondary end point variables will be compared between 2 groups by using a 2-sample *t* test or a Wilcoxon rank sum test depending on the normality of the data distribution. The chi-square test or Fisher exact test will be used to compare categorical secondary end point variables.

If data are missing at random, the analyses will be carried out using multiple imputations. The multiple imputation procedure will be based on all available data for that patient and be conducted using the chained equation approach. If data are not missing at random, the analyses will be conducted using available data with appropriate interpretational reservations. We will also evaluate the data using the intention-to-treat principle and per-protocol data set and compare the analysis results to estimate reliability of our analytical results.

Adverse Events Observation

During trial agent infusion, if the mean arterial pressure is less than 50 mm Hg, 20-40 μg of norepinephrine will be administered through the CPB venous reservoir. After recovery of the autonomous cardiac rhythm, if the heart rate is <60 bpm or a type II second-degree or third-degree atrioventricular block develops, 0.5-1 mg of atropine will be used intravenously, and if it does not work, epicardial temporary pacing will be performed. If the QT interval is >440 milliseconds or the corrected QT interval is >400 milliseconds, 0.5-1 mg of atropine will be given to increase heart rate to >70 bpm and blood potassium will be ensured at >4.0 mmol/L.

Data Collection and Management

The data will be collected from paper case report forms (manually counter checked with source files by the data entry personnel) by the investigator and given to the statistician to analyze the data. The data will be recorded by their specific ID number instead of participant's name throughout the study unless otherwise specified. Access to data will be restricted to the investigators who signed the confidential disclosure agreement or to the institutional or governmental auditors during the study. All original documents and files will be archived for at least 5 years to allow inspection after the trial has ended. The process will be monitored by the Institutional Ethics Committee of the First Affiliated Hospital of Nanjing Medical University.

Ethical Considerations

This study has been approved by the Institutional Ethics Committee of the First Affiliated Hospital of Nanjing Medical University (2020-SR-175) and registered with the Chinese Clinical Trial Registry (ChiCTR2000035057). Informed consent will be obtained from all participants before recruiting to the study.

Results

The study began in August 2022, and the data collection will take place for the next 2 academic years. To obtain the total study sample, a total of 54 participants will be recruited. At present, 21 participants have already been recruited for the study.

Discussion

The clinical trial is designed in order to investigate the efficacy of prophylactic intravenous amiodarone administration on

XSL•FO
RenderX

reperfusion VF after release of ACC in patients with LVH undergoing CPB surgery.

Reperfusion VF is a common arrhythmia encountered after ACC release in patients undergoing CPB surgery. Repeated defibrillation and long duration of VF could increase myocardial oxygen consumption, damage cardiomyocytes, and decrease the patients' prognosis postoperatively. In patients with LVH, cardiac protection is often not as effective as the normal heart during CPB, and thus reperfusion VF is easier to occur and more difficult to be terminated.

Amiodarone, known as class III antiarrhythmic agent, has the properties of converting VF and restoring the sinus rhythm and can also be administered in patients with structural heart diseases. Before ACC release, administration of amiodarone has been confirmed useful to reduce occurrence of reperfusion VF. However, few proofs supported the effect of amiodarone before ACC release on reducing VF in patients with LVH. With this trial, we are hoping to further demonstrate that prophylactic infusion of amiodarone could reduce the occurrence of reperfusion VF in patients with LVH.

The limitation of this study may include the following aspects. First, this is a single-center trial with Asian patients in which there might be a selection bias. Second, the sample size is relatively small. However, according to the clinical experience in our center, the incidence of reperfusion VF is similar to those documented in the literature. So, the sample size could prove our hypothesis. We hope that in the future, a multicenter clinical trial with larger sample size could be performed to further elucidate this problem.

This study is believed to provide more proof regarding how to avoid reperfusion VF in patients with LVH undergoing CPB surgery, reducing myocardial damages occurred in those patients.

Data Availability

Access to data will be restricted to the investigators who signed the confidential disclosure agreement or to the institutional or governmental auditors during the study. All original documents and files will be archived for at least 5 years to allow inspection after the trial has ended.

Conflicts of Interest

Abstract

Background: Cisgender women in Kenya are at elevated risk of HIV acquisition during pregnancy and post partum. Acute HIV infection during pregnancy and breastfeeding accounts for approximately one-third of all vertical HIV transmissions. The World Health Organization recommends offering oral tenofovir-based pre-exposure prophylaxis (PrEP) to pregnant and postpartum women who are HIV negative but at substantial and ongoing risk for HIV acquisition. PrEP delivery for pregnant and postpartum women is expanding within routine maternal child health clinics in Kenya. However, approximately half of pregnant women discontinue PrEP within 30 days of initiation. Therefore, it is crucial to develop PrEP adherence strategies that enhance support for adherence when peripartum events and health issues pose challenges to sustaining PrEP adherence.

Objective: We are conducting a randomized controlled trial to determine the effect of a bidirectional communication platform named Mobile Solutions for Women's and Children's Health (mWACh), which utilizes two-way SMS text messaging between patients and remote nurses to support PrEP adherence and address maternal health concerns in real time during the peripartum period.

XSL•FO
RenderX

Methods: The mWACh-PrEP study is a randomized trial designed to support PrEP adherence during the peripartum period by comparing mWACh-PrEP to the standard of care (ie, in-clinic adherence counseling) among women who are HIV negative and initiating PrEP. Purposive sampling was used to select 5 facilities offering PrEP in antenatal clinics in Kisumu and Siaya Counties, and block randomization will be used to divide participants into groups. Participants in the intervention arm will receive a customized messaging curriculum via SMS text messages targeted toward their particular perinatal stage. The primary outcome, PrEP adherence at 6 months post partum, will be evaluated using a log-binomial regression model, adjusting for imbalanced baseline characteristics. Based on a previous study of directly observed dosing conditions, we will use a hair tenofovir concentration cutoff of 0.038 ng/mg (corresponding to 7 doses/week) as the primary adherence outcome measured at 6 months post partum (binary outcome). Qualitative interviews and cost-effective analyses will be conducted to understand the feasibility, acceptability, and economic impact of the intervention.

Results: Enrollment began in March 2022 and is projected to continue until July 2023, with follow-up through March 2024. The study results are expected to be reported in 2025.

Conclusions: This trial will provide insights into using mobile health to enhance PrEP adherence among pregnant and postpartum mothers. Additionally, the findings will have implications for the use of mobile health technology to improve adherence to other daily medications during the peripartum period.

Introduction

Background

Young cisgender women in East and Southern Africa have a high incidence of HIV, which persists during pregnancy and the postpartum period, with evidence of an over 2-fold increased acquisition risk during these periods [1,2]. HIV infection among pregnant women also negatively impacts infants. Moreover, acute HIV infections during pregnancy and breastfeeding account for approximately 26% of all vertical HIV transmissions [3,4]. Globally, 150,000 infants were newly infected with HIV in 2019 [5], substantially above the global goal of 20,000 new infections among children by 2020. To protect women and children and eliminate vertical transmission, the World Health Organization (WHO) recommends offering daily oral tenofovir (TFV)-based pre-exposure prophylaxis (PrEP) to pregnant and postpartum women who are HIV negative and at substantial ongoing risk for HIV as part of a comprehensive HIV prevention package [6].

PrEP provision to pregnant and breastfeeding women may prevent primary maternal HIV infections and help eliminate vertical HIV transmission globally. Kenya is a world leader in PrEP implementation for pregnant and postpartum women within maternal and child health (MCH) settings [7,8]. In a study integrating PrEP delivery within antenatal care (ANC) [9], most pregnant Kenyan women at risk of HIV acquisition accepted PrEP when offered during ANC [8]. However, >50% of pregnant women discontinued PrEP within 30 days of initiation [8]. Compared to nonpregnant women, pregnant women more frequently reported side effects, which often overlap with common pregnancy symptoms, as a reason for discontinuing PrEP [8,10,11] and less frequently had detectable tenofovir diphosphate (TFV-DP) levels in dried blood spots (DBS) collected at follow-up visits (52% vs 70%) [12], suggesting suboptimal adherence. Studies among women living with HIV found that motivation for antiretroviral therapy (ART) adherence wanes after breastfeeding cessation when the risk of vertical transmission diminishes [13-15]. In qualitative studies, women's reported motivation for PrEP in pregnancy was driven by the desire to have an infant who is HIV negative [10,11]. Postpartum PrEP adherence may be reduced if a mother perceives the medication is only beneficial to her infant, similar to ART adherence patterns among postpartum women living with HIV [13-15]. Moreover, remembering to take PrEP pills may be difficult with the additional demands of newborn care [16]. PrEP effectiveness depends on adherence [17-19]; therefore, PrEP programs must now focus on improving prevention-effective adherence to maximize reductions in HIV incidence [12].

Mobile health (mHealth) technologies for public health have enormous potential to support HIV prevention and adherence among at-risk populations [20-22], including in Kenya, where cell phone ownership among women is very high at ~90% [23]. SMS text messaging–based interventions have demonstrated effectiveness in increasing adherence to ART among people living with HIV [24-27] and better treatment outcomes among women living with HIV during the peripartum period [28]. More recently, the role of SMS text message–based strategies in supporting PrEP adherence has been investigated among men who have sex with men and transgender women in the United States [29,30]. SMS text message interventions have the potential to improve PrEP adherence and could be used to address issues faced by women using PrEP via real-time texting with a health worker [31-35].

XSL•FO
RenderX

Our team developed a bidirectional communication platform, Mobile Solutions for Women's and Children's Health (mWACh), utilizing two-way SMS text messaging between patients and remote nurses to support ART adherence and MCH among peripartum women [36]. The mWACh intervention was feasible, acceptable, and effective at improving selected ANC outcomes, including improving ART adherence among pregnant women initiated on ART and maternal and infant birth outcomes and adherence to contraceptives [37-39]. We adapted mWACh to send PrEP-tailored, Information-Motivation-Behavioral Skills (IMB) Model–based SMS text messages to facilitate adherence among pregnant women who initiated PrEP. In a nonrandomized pre- and posttest pilot, mWACh-PrEP recipients were more likely to persist with PrEP use (42% vs 22%) and to self-report high adherence (73% missed <1 pill/week vs 55%) [31]. Nurses adequately addressed issues raised by participants on PrEP use and side effects via text message.

It is essential to develop PrEP adherence strategies for pregnant women that address PrEP side effects that may overlap with pregnancy symptoms and enhance support for adherence when peripartum life events and health issues pose challenges to sustained PrEP adherence. Therefore, we are conducting a randomized controlled trial (RCT) to determine the effect of mWACh-PrEP on PrEP adherence during pregnancy and the postpartum period.

Study Objectives

The mWACh-PrEP trial (NCT04472884) aims to improve PrEP adherence among peripartum women using an IMB-informed approach. Our overall goal is to determine the effect of the mWACh-PrEP tool on PrEP adherence during pregnancy and the postpartum period among women at high risk for HIV acquisition who initiate PrEP within ANC and to estimate the cost-effectiveness for potential scale-up. We hypothesize that the mWACh-PrEP tool will improve PrEP adherence among women at risk for HIV, be acceptable to patients and providers, and be cost effective.

Methods

Study Design

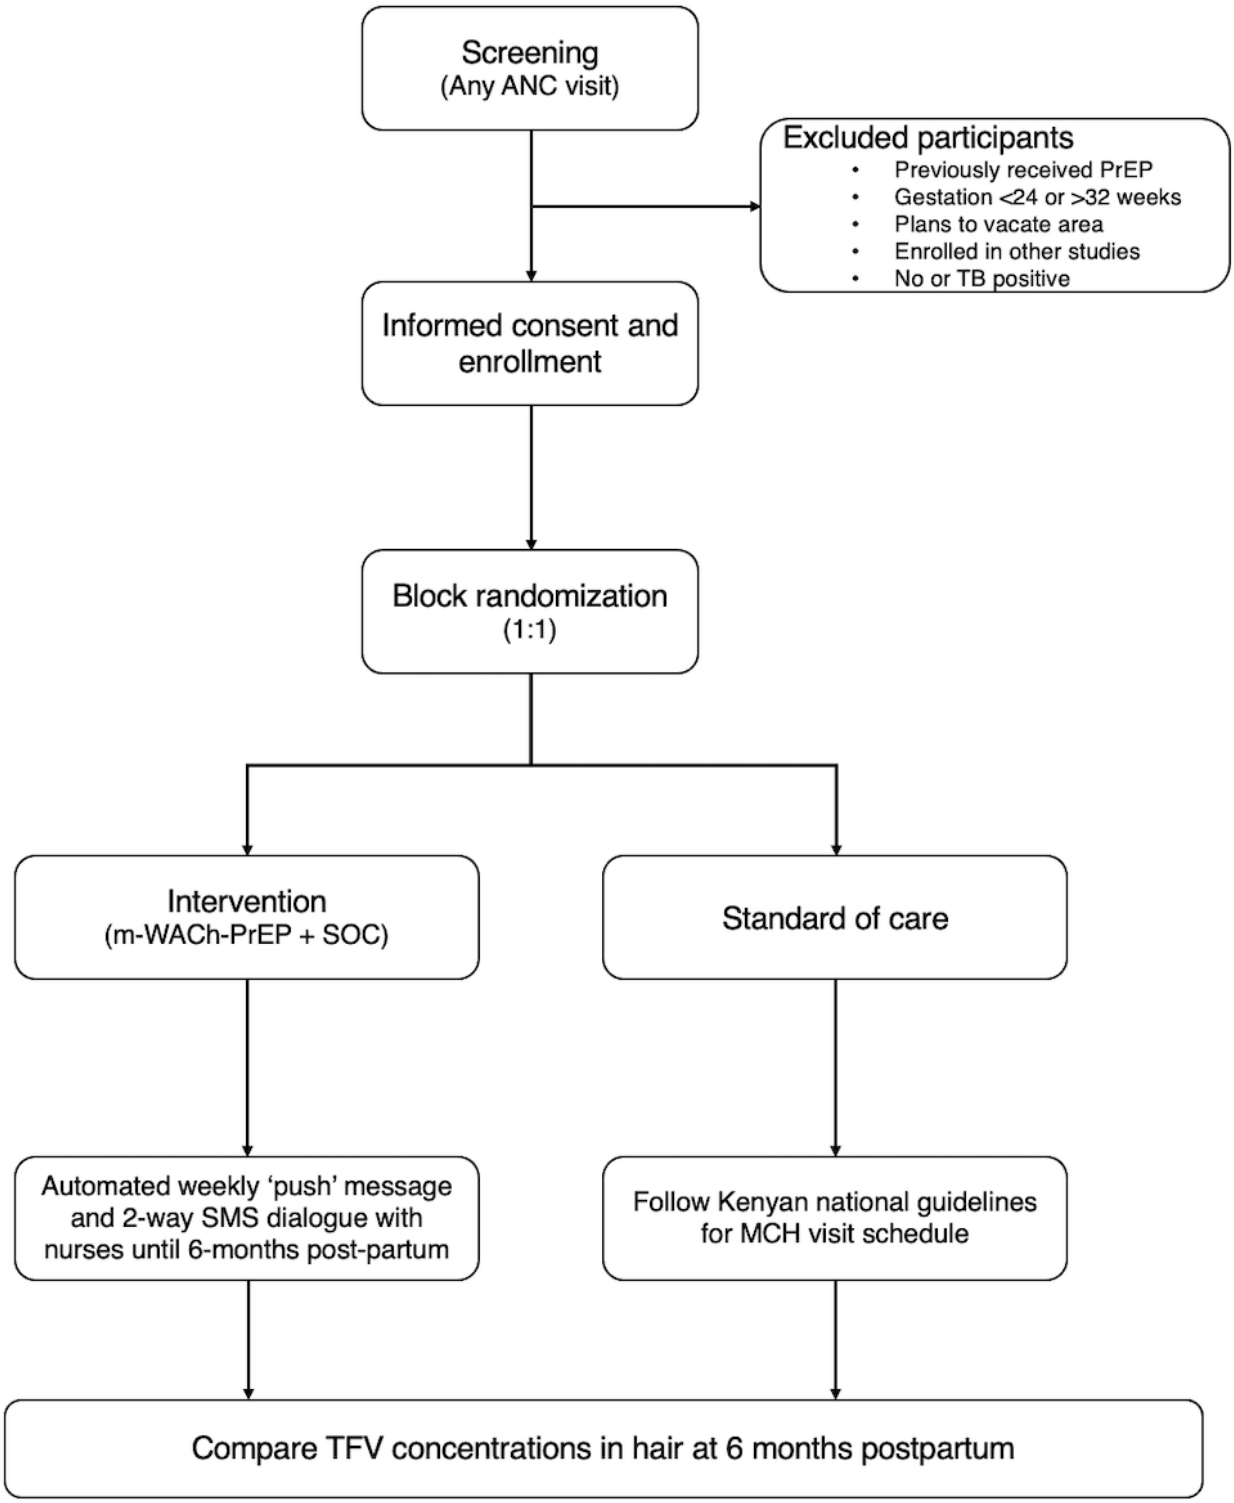
We are conducting a nonblinded individual-level RCT comparing 2 arms of PrEP adherence to determine the effect of the mWACh-PrEP tool on PrEP adherence among pregnant women at risk for HIV acquisition initiating PrEP within ANC clinics.

Study Setting and Population

Facility Selection Process

The study is being conducted in 5 public health facilities offering routine MCH services within Kisumu and Siaya Counties in Kenya. The facilities were selected based on high HIV prevalence areas, existing infrastructure, established rapport, and discussions with the Kenyan Ministry of Health and the local government of Kisumu County.

Participant Eligibility Criteria



Participating facilities are enrolling 600 pregnant women who are HIV negative (300 in each arm), between 24 and 32 weeks of gestational age (to allow for adequate follow-up during pregnancy), and receiving ANC at MCH clinics. Gestational age is ascertained using the last menstrual period and fundal height measurement, which is part of the routine care for women in this region. Eligibility criteria include HIV and tuberculosis negative, HIV acquisition risk score ≥6 (translating to HIV incidence 7.3 per 100 person-years) [40], initiated PrEP during routine ANC clinic in the participating clinics, ≥18 years, has access to a cell phone, plans to reside in the area for at least 1 year post partum, and plans to receive postpartum and infant care at the study clinic.

Randomization Arms

Two PrEP adherence models are compared: standard of care (SOC) comprising in-clinic adherence counseling only versus SOC plus the mWACh-PrEP tool. All women receive routine MCH care and PrEP services that include health education, clinical assessments, safety monitoring, screening for sexually transmitted infections (STIs), and treatment per national guidelines (including expedited partner treatment for those with STI diagnoses), HIV risk reduction counseling, assessment of psychosocial barriers, and standard in-clinic adherence counseling per national guidelines. Participants randomized to SOC receive in-clinic counseling on PrEP. Participants randomized to the intervention arm are registered in the mWACh-PrEP system, a bidirectional SMS text message communication platform that sends PrEP-tailored, theory-based, preprogrammed texts on PrEP adherence weekly during pregnancy and the postpartum period, in addition to receiving SOC services (Figure 1).

XSL•FO

Figure 1. Screening, enrollment, and follow-up procedure for this study. ANC: antenatal care; MCH: maternal and child health; mWACh: Mobile Solutions for Women's and Children's Health; PrEP: pre-exposure prophylaxis; SOC: standard of care; TB: tuberculosis; TFV: tenofovir.

Randomization

Block randomization using a 1:1 allocation in random-sized blocks stratified by recruitment site is being used to ensure a balanced allocation of each arm within sites. Before randomization, study nurses ensure all routine PrEP initiation services and study enrollment procedures are complete. Treatment allocation (mWACh-PrEP or SOC) for each consented participant is done by the study nurses within the individual's health facility using Research Electronic Data Capture (REDCap; Vanderbilt University). The randomization code is stored in an electronic format, and once assigned, it is unblinded. The randomization key for the database is restricted to the data manager and statistician.

XSL•FO
RenderX

Study Procedures

Main Study

Participant Screening and Recruitment

Pregnant women initiating PrEP as part of routine care are approached by the study staff while waiting for ANC and invited to participate in the study. Participants undergo screening, and all eligible participants who express interest undergo an informed consent process at the ANC clinic before the initiation of study procedures. Information on facility volume, clients approached, clients screened, and participants enrolled are reported daily by the study staff. Reasons for nonparticipation are captured from those who decline.

Enrollment Visit Data Collection

At enrollment, electronic questionnaires are administered to capture demographic, pregnancy, and medical history; mental health status; HIV results; risk perception; risk assessment; partner characteristics; PrEP attitudes; expected maternity care; health literacy; and COVID-19 experiences. Socioeconomic status is measured using the validated standard Demographic and Health Survey (DHS) Wealth Index [41]. Health literacy is assessed using the standard DHS panel of 8 items across 4 domains (capacity to interpret, obtain, understand, and make appropriate health decisions) [41]. Intimate partner violence (IPV) is assessed using the Hit, Insult, Threaten, Scream scale [42]. Symptoms of depression are assessed using the Edinburgh Postpartum Depression Scale and the Patient Health Questionnaire 9, which has been validated in Kenya [43]. An HIV acquisition risk score validated among pregnant and postpartum Kenyan women is used to assess the risk for HIV [40]. Additional data abstracted from the MCH clinics and PrEP records include details on PrEP initiation, confirmation of syphilis, and HIV test results.

SOC Arm Enrollment Visit and Study Procedures

Per national guidelines, all women initiated on PrEP in both arms receive in-clinic counseling on the benefits of sustained PrEP adherence at enrollment and subsequent refill clinic visits, HIV risk reduction, and assessment of psychosocial barriers.

Intervention Arm Enrollment Visit and Study Procedures

Participants randomized to the intervention arm are registered in the mWACh-PrEP SMS text messaging system with their preferred name for messaging, messaging language (ie, English, Kiswahili, or Dholuo), and day of the week and time for SMS text message delivery. Once registered, the participants receive weekly automated "push" messages on the day/time of their choice from enrollment until they are 6 months post partum. All automated "push" messages include the participant's nickname, clinic, and nurse name; an educational message or actionable advice targeting PrEP adherence and continuation and/or MCH topics; and a question related to the content. Through multiple messaging tracks, participants receive messages targeted to their perinatal status as well as supportive messages if they decide to discontinue or restart PrEP. SMS text message topics include adherence encouragement (IMB domain: motivation), PrEP efficacy and safety (IMB domain: information), self-efficacy for prevention of HIV, support for potential PrEP side effects, behavioral skills (eg, tips for remembering PrEP medications; IMB domain: behavioral skills [44,45]), and visit reminders (Figure 2)**.** Participants have the option to respond to automated messages or extemporaneously contact the study nurses at any time. Study nurses encourage participants to respond with concerns and questions (Figure 3). Participants have access to a two-way dialogue with remote nurses until their 6-month postpartum visit. Participants are free to voluntarily exit autonomously by texting "STOP," thereby ending all communication. All messaging is free to the participant using a reverse-billed short code. The mWACh system also includes multiple features to support study management and personalized counseling based on the participant's psychosocial status (Table 1).

Construct	Week	Example messages
Information		
Dosage	2 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. There are some misconceptions about PrEP in the community. People should not only take the PrEP pill just before potential exposure to HIV. Rather, it should be taken every single day for it to build up in your system and offer protection against HIV. Is there anything else that you have heard about PrEP in the community?
Side effects	2 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. A few PrEP users may experience side effects related to PrEP. Most side effects lessen after the first few weeks of use once the body is used to the medication. Please let us know if you are having any side effects. We can help you manage them or know if it is okay to continue.
Safety	19 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. PrEP is very safe and one of the ways you can protect yourself from HIV. With this pill, you can keep yourself safer from HIV. Are you still taking the medication? Do you have any questions or concerns?
Use logistics	4 weeks postpartum	{name}, this is {nurse} from {clinic}. At this time, you may have a lot to deal with as you adjust to having a newborn. Remember to continue taking care of yourself to prevent HIV by consistently taking PrEP. Do you have any questions?
Efficacy	1 week after PrEP initiation	{name}, this is {nurse} from {clinic}. PrEP is very effective at preventing you from getting HIV. For this effectiveness to be achieved, it is important to take the medication for the first 7 days after initiation without being exposed and thereafter daily. You can use condoms or abstain during this period. Do you have any concerns about PrEP?
Motivation		
Perceived benefits of adherence	4 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. PrEP is very effective at preventing you from getting HIV if you take it every day. It also helps prevent HIV in your baby if you are pregnant. If you miss too many doses it may not work. Are you having any challenges taking the medication?
Risk perception	17 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. PrEP is used when you think you might be at risk of HIV. If you think you are no longer at risk, like if your partner tests and is negative or you are no longer with a partner, you can stop PrEP. Do you have any questions?
Value of HIV Prevention	15 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. You are doing a great job taking care of yourself. Deciding to take PrEP is an important way to protect yourself from HIV. It is also important to be tested regularly. Do you have any questions about PrEP?
Behavioral Skills		
Discern seasons of high HIV risk	6 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. Some women choose to discontinue PrEP for many reasons. It is okay to stop the medication if you decide. We would want to know why people stop PrEP. Have you stopped taking PrEP? If you have why did you stop?
Remember to take PrEP daily	8 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. It can be difficult to take medications every day especially if you are trying to be discrete. Many people ask a friend to help remind them, set a timer on their phone, or take it with a meal. You can also put it in a different container you can carry with you in private. How do you remember to take your medication? Do you have any challenges taking it every day?
Manage PrEP use in relation to partner	9 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. PrEP enhances the power you have to make an independent decision regarding preventing yourself from HIV as you do not have to rely on your partner for this decision. Do you have any questions about PrEP?
Moderating Factors		
Psychological health	3 weeks after PrEP initiation	{name}, this is {nurse} from {clinic}. Sometimes new mothers can feel sad, anxious, or worried all the time. This happens to many women and can cause crying and difficulty sleeping. Are you having any of these problems?

[a]mWACh: Mobile Solutions for Women's and Children's Health.

[b]PrEP: pre-exposure prophylaxis.

[c]IMB: Information-Motivation-Behavioral Skills.

XSL•FO
RenderX

Data Collection at Follow-up Visits

Study participants are followed up until 9 months post partum to ascertain sustained PrEP adherence at 3 months after cessation of SMS text messages. All study visits for both arms will be aligned with Kenyan national guidelines for standard ANC and infant immunization visit schedules: monthly visits during pregnancy until delivery and then after delivery at 6 weeks, 14 weeks, 6 months, and 9 months post partum. At each visit, nurses administer questionnaires to assess sexual behavior; infant outcomes; IPV; symptoms of depression; and PrEP attitudes, use, and adherence. PrEP use disclosure is assessed at each follow-up visit by asking participants whether they have disclosed to anyone that they use PrEP and, if so, to whom they disclosed this (Table S1 in Multimedia Appendix 1).

Additional data on infant growth, birth weight, estimated gestation at birth, diagnosed preterm birth, and serial growth are abstracted from medical records. Additionally, *z* scores are calculated using WHO AnthroPlus software. Data on birth outcomes (stillbirth, pregnancy loss, mortality, or congenital anomalies) and birth length are abstracted from the MCH medical record or interview.

Laboratory Procedures

A combination of red blood cells from DBS and hair samples is used to assess PrEP adherence. A strong correlation between dosing frequency and TFV levels in hair has been demonstrated [46], and significant correlations were also seen between hair, plasma, peripheral blood mononuclear cells, and red blood cell levels (in DBS) of PrEP drugs or metabolites [47,48]. Plasma levels reflect exposure over the past 1 to 3 days [49] and are highly susceptible to intraindividual variation; therefore, measuring hair drug levels is a unique approach to determining drug exposure over a longer period [50,51]. DBS are collected from a finger or heel prick from all mothers and infants at all study visits for future assessment of TFV-DP and emtricitabine triphosphate in red blood cells.

Hair samples will be collected from participants at pregnancy follow-up visits and from both the participants and their babies at postpartum follow-up visits. These hair samples will be analyzed for TFV using validated liquid chromatography-tandem mass spectrometry methods at the University of California San Francisco (UCSF) Hair Analytical Lab (HAL). The UCSF HAL found that TFV concentrations in the hair under directly observed dosing conditions are similar by sex, and the same adherence benchmarks can be used for both women and men [50]. Additionally, hair TFV levels have not been shown to alter in pregnancy [51].

Data Management

The study staff is trained on data collection using REDCap and communication with participants in the intervention arm using the two-way mWACh-PrEP platform to send, receive, and respond to SMS text messages. Baseline and follow-up data are collected and stored electronically via REDCap, transported via a secure socket layer, and only accessible by authenticated users. Designated study staff generate weekly reports on study progress, performance indicators, adverse events, and troubleshooting problems. All study laptops used to collect data and study databases are encrypted and password protected. All data collected in this study will be available free of charge after registration to access or download files on a study-related website (URL to be determined) after the completion of primary analyses.

Data Analyses

Sample Size

The sample size was calculated to detect a difference between trial arms dependent on the frequency of PrEP adherence in the SOC arm of the cohort. Prior data from our PrEP in pregnancy studies indicate that the frequency of detectable PrEP drug levels is approximately 50% among pregnant women who initiate PrEP in MCH clinics within fully programmatic settings [12]. Since this study will exclusively enroll women who initiate PrEP in MCH, we anticipate that adherence will be similar or slightly higher. Assuming a PrEP adherence estimate of 50% in the SOC arm at 6 months post partum and a sample size of 600 (randomized 1:1), we will have 80% power to detect a minimum detectable difference of 12% between arms in PrEP adherence in the mWACh arm, assuming 15% attrition and a 2-sided test with a Cronbach α of .05 (Table S2 in Multimedia Appendix 1).

Statistical Methods and Analyses

The primary outcome, PrEP adherence at 6 months post partum, will be assessed in an intention-to-treat analysis comparing randomization arms mWACh-PrEP versus SOC. Enrollment characteristics will be compared between randomization arms to assess the balance between arms and control for any imbalanced factors. Based on a previous study of directly observed dosing conditions, we will use a hair TFV concentration cutoff of 0.038 ng/mg (corresponding to 7 doses/week) as the threshold of detection for the primary adherence outcome measured at 6 months post partum (detectable/nondetectable binary outcome) [52]. Protective PrEP drug level thresholds for cisgender women have not been established; however, current WHO and Kenyan national guidelines recommend daily (7 doses/week) oral PrEP for cisgender women. A log-binomial regression model will be used to estimate the relative risk, adjusting for any imbalances in baseline demographic, clinical, or behavioral characteristics between arms. Missing primary outcomes or loss to follow-up will be assumed nonadherent. To evaluate the sustained effect of mWACh-PrEP on PrEP-taking habits after the SMS text messaging intervention ends, the same model will be used to analyze our secondary outcome of PrEP adherence at 9 months post partum (3 months after cessation of mWACh-PrEP messaging).

Qualitative Analyses

Focus group discussions and semistructured in-depth interviews will be conducted to evaluate potential barriers and facilitators to the acceptability and feasibility of mWACh-PrEP implementation within routine ANC delivery settings (Figure 4). To evaluate personal experiences with the mWACh-PrEP intervention, a purposively selected sample of study participants will be recruited to participate in in-depth interviews. In-depth interviews will explore community, dyadic, and individual

XSL•FO
RenderX

factors influencing decision-making and how these influence individual perceptions of and experiences with mWACh-PrEP use. To gather perspectives on the mWACh-PrEP scale-up, we will invite the study's community advisory board (CAB) and county-level health officials overseeing ANC-PrEP programs to participate in focus group discussions. These focus group discussions will elicit perspectives on foreseeable barriers and facilitators of larger-scale implementation of mWACh-PrEP based on individual, community, and health system factors.

Discussions will be conducted in English, Kiswahili, or Luo depending on participants' preferences and be guided by prepiloted topic guides with the flexibility to explore additional probes and newly emerging content as necessary. All in-depth interviews and focus group discussions will be audio recorded, transcribed, and translated to English for analysis as necessary. Thematic analysis will be used to identify key elements of the patient/provider experience, including convenience, comfort level, and satisfaction of the mWACh-PrEP model, that influence intervention acceptability, feasibility, and potential scale-up.

Figure 4. Schematic of qualitative purposive stratified sampling approach (N=70). PrEP: pre-exposure prophylaxis.

		PrEP adherence		
		Non adherent at 6 months	Adherent at 6 months	
			Non adherent at 9 months	Adherent at 9 months
mWACh status	Responded to <10% of SMS	Non responder; non adherent *(n=10)*	Non responder; waned adherence *(n=10)*	Non responder; persistent adherence *(n=10)*
	Responded to >25% of SMS	Responder; Non adherent *(n=10)*	Responder; waned adherence *(n=10)*	Responder; persistent adherence *(n=10)*
	Declined registration	*(n=10) Sampled regardless of adherence status*		

Cost-effectiveness Analysis

Overview

We will project the cost-effectiveness of implementing mWACh-PrEP intervention within ANC compared to the SOC per averted disability-adjusted life year (DALY) using a payer perspective and collect intervention costs from expense reports, staff, and expert interviews. Costs will be divided into mutually exclusive categories, including personnel, equipment, supplies, buildings and overhead, and start-up. We will convert the local currency, Kenyan shillings, to US dollars. Sensitivity analyses will be conducted to identify influential assumptions.

Costing

Time and motion observation of intervention activities will be conducted to calculate staff time and resources necessary for the mWACh-PrEP intervention. A research assistant (RA) will collect data on the time and motion of patient/provider interactions to inform costs and productivity assumptions. The RA will also conduct a survey with health care workers to assess daily responsibilities associated with the mWACh-PrEP intervention, including time to send and respond to client SMS text messages and routine service provision. Research time (eg, administering study questionnaires) and other research costs will be separated from programmatic costs.

Modeling

We will parameterize a previously developed mathematical model with cost and outcome data from the mWACh-PrEP trial and project the averted HIV infections, HIV-related deaths, and DALYs associated with scaling up the mWACh-PrEP intervention in Kenya. We will calculate the incremental cost-effectiveness ratio as the difference in costs divided by the difference in effects (DALYs) for the intervention compared to SOC over a 20-year period. Costs and benefits will be discounted annually at 3%.

Secondary and Exploratory Analyses

Secondary outcome analyses will include sustained PrEP adherence by determining levels of detectable TFV in the hair at 9 months post partum, adherence cofactors, STI incidence, and prevention-effective adherence (time-varying alignment of adherence with risk behaviors). Exploratory analyses will include HIV incidence, perinatal outcomes, and expedited partner treatment outcomes by randomization arms (Table S3 in Multimedia Appendix 1).

Ethics Approval

Ethical approval was obtained from the institutional review board of the University of Washington (STUDY00010797) and the Kenyatta National Hospital Ethics and Research Committee (P319.05/2021). This study was registered at ClinicalTrials.gov. (NCT04472884). Any critical protocol deviations, adverse events, and future modifications will be communicated promptly

XSL•FO
RenderX

to these organizations. Additional permissions will be sought from all participating clinical sites.

Informed Consent

A written informed consent before recruitment is administered to all study participants, with each receiving a copy of the signed form. Additional permission will be obtained for audio recording and note-taking during the qualitative interviews.

All participants are informed that their participation is voluntary, and they can stop receiving the SMS text messages at any time by contacting the study staff or texting "STOP," which will cease communication between the study staff and the participant. All study staff is trained in protecting human participants and the clinical and emotional needs of pregnant and postpartum women on PrEP. The MWACh system is point-to-point encrypted; therefore, only study team members can access it through a password-protected laptop stored in a locked office. All data are deidentified and kept in password-protected databases in a locked study office that is accessible only to study personnel.

Patient and Public Involvement

A CAB has been established in Kisumu County to review the study objectives, methodology, and other study activities. The team comprises local community leaders, women from the community, the Kenyan Ministry of Health, and county health representatives from MCH departments. The CAB is anticipated to meet 2 times per year to review this study's progress. An external advisory panel (EAP) has been established to oversee the data and safety of study participants by reviewing study aims, statistical analysis plan, and progress. EAP meetings will be routinely convened to review study enrollment, retention, data missingness, and pooled study outcomes. Study results will be disseminated through peer-reviewed journals, technical reports, policy briefings, and oral presentations at relevant local and international conferences. Additionally, we will present results to clinical experts and policy advisors at the local county level, the Kenyan Ministry of Health, and the WHO. Routine hybrid meetings in the form of progress updates with CABs engaged in the study activities, facility staff, and study collaborators will be conducted to share study progress and findings.

Results

Study enrollment began in March 2022 and is projected to continue until July 2023, with patient participant follow-up through March 2024. The study results are expected to be reported in 2025.

Discussion

Anticipated Findings and Implications

This intervention study aims to determine the effect of the mWACh-PrEP tool on PrEP adherence among pregnant and breastfeeding women at high risk for HIV acquisition who initiate PrEP during ANC. The primary outcome is adherence at 6 months, while the secondary outcomes include sustained adherence at 3 months after cessation of the SMS text messaging intervention and other HIV and MCH indicators. This is the first intervention that aims to enhance PrEP adherence among women in the peripartum period research, and we anticipate that our findings will inform clinical practice for PrEP delivery during the peripartum period by providing effectiveness data on an mHealth PrEP adherence tool tailored for the peripartum period.

Study Strengths and Limitations

This is the first intervention study aiming to improve PrEP adherence among peripartum women using an IMB-guided approach tailored to pregnant and postpartum women on PrEP for HIV prevention. The development of adherence strategies for periods during and after pregnancy can have implications for other daily medications taken during pregnancy and the postpartum period when medication side effects overlap with typical symptoms, and life events pose challenges to sustained adherence. Furthermore, collected microcosting data will guide researchers and policy makers on the cost of scale-up and use of mHealth and the IMB-informed approach.

Daily oral tenofovir disoproxil fumarate (TDF)/emtricitabine is currently the only medication with a label indication as PrEP in Kenya and the only regimen recommended by the WHO for cisgender women. While several novel PrEP agents are being tested, including long-acting injectable cabotegravir (CAB-LA) [53], forthcoming results are still years away, and it will take longer for CAB-LA to reach pregnant or lactating women as there is no safety evaluation underway in these populations. Similarly, event-driven PrEP (ED-PrEP) is not approved by the US Food and Drug Administration. Moreover, WHO guidelines explicitly state that ED-PrEP is not appropriate for cisgender women, citing effectiveness concerns in this group [54]. Therefore, daily oral TDF/emtricitabine will likely remain the PrEP SOC for pregnant and breastfeeding women for several years. Because this is a programmatic RCT, the characterization of some secondary and exploratory outcomes will be limited. This design was intentional to optimize program/policy relevance. Costing data will be collected to understand how additional time spent by nurses on the intervention in already busy health facilities may potentially affect scale-up.

Dissemination Plan

To provide insights on the effects of mWACh-PrEP, we will communicate the study protocol, progress report, and results to the scientific community and policy makers. This will guide the clinical management of pregnant women who choose to initiate PrEP, informing future scale-up of the intervention as a population-level program. Dissemination of the results will potentially improve communication between researchers, ethical bodies, and policy makers and strengthen collaborations between participating partners through technical reports and policy briefings. For the scientific community, we will publish our findings in peer-reviewed journals and present them at international scientific conferences. Presentations and progress reports regarding the study will be shared with study participants and presented to the public at the facility level and to the Kenyan Ministry of Health.

XSL•FO
RenderX

Conclusion

This study will inform clinical practice and contribute to advancing strategies to enhance PrEP and other daily medication adherence during pregnancy and the postpartum period, which are both critical periods for MCH. If our mWACh approach positively affects MCH outcomes (eg, birth and infant outcomes), it could be readily integrated into other mHealth platforms aiming to improve MCH in the future. The study will also contribute to an mHealth adherence tool for pregnant women on PrEP with the goal of enhancing PrEP use and ultimately reducing HIV incidence in this important population that is disproportionately affected by HIV.

Acknowledgments

This study was funded by the National Institute of Nursing Research (R01NR019220) with support from the University of Washington Center for AIDS Research (P30 AI027757). JP was additionally supported by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (R01HD108041 and R01HD100201). MS received additional support from the National Institute of Mental Health (K01MH115789).

We would like to thank the study staff and participants for their time and contributions. We thank the Kenyan Ministry of Health, the Kisumu and Siaya County Department of Health, the Siaya County Department of Health, and the facility heads for their collaboration with this study.

Data Availability

The data sets generated and analyzed during this ongoing study are available from the corresponding author upon reasonable request.

Abstract

Background: Simultaneous motor-cognitive training is considered promising for preventing the decline in cognitive functioning in older adults with mild neurocognitive disorder (mNCD) and can be highly motivating when applied in the form of exergaming. The literature points to opportunities for improvement in the application of exergames in individuals with mNCD by developing novel exergames and exergame-based training concepts that are specifically tailored to patients with mNCD and ensuring the implementation of effective training components.

Objective: This study systematically explores the effectiveness of a newly developed exergame-based motor-cognitive training concept (called “Brain-IT”) targeted to improve cognitive functioning in older adults with mNCD.

Methods: A 2-arm, parallel-group, single-blinded randomized controlled trial with a 1:1 allocation ratio (ie, intervention: control), including 34 to 40 older adults with mNCD will be conducted between May 2022 and December 2023. The control group will proceed with the usual care provided by the (memory) clinics where the patients are recruited. The intervention group will perform a 12-week training intervention according to the “Brain-IT” training concept, in addition to usual care. Global cognitive functioning will be assessed as the primary outcome. As secondary outcomes, domain-specific cognitive functioning, brain structure and function, spatiotemporal parameters of gait, instrumental activities of daily living, psychosocial factors, and resting cardiac vagal modulation will be assessed. Pre- and postintervention measurements will take place within 2 weeks before starting and after completing the intervention. A 2-way analysis of covariance or the Quade nonparametric analysis of covariance will be computed for all primary and secondary outcomes, with the premeasurement value as a covariate for the predicting group factor and the postmeasurement value as the outcome variable. To determine whether the effects are substantive, partial eta-squared (η^2_p) effect sizes will be calculated for all primary and secondary outcomes.

Results: Upon the initial submission of this study protocol, 13 patients were contacted by the study team. Four patients were included in the study, 2 were excluded because they were not eligible, and 7 were being informed about the study in detail. Of the 4 included patients, 2 already completed all premeasurements and were in week 2 of the intervention period. Data collection

XSL•FO
RenderX

is expected to be completed by December 2023. A manuscript of the results will be submitted for publication in a peer-reviewed open-access journal in 2024.

Conclusions: This study contributes to the evidence base in the highly relevant area of preventing disability because of cognitive impairment, which has been declared a public health priority by the World Health Organization.

Introduction

Background

Aging is typically accompanied by structural [1,2] and functional [2-4] brain changes associated with a gradual decline in physical [5] and cognitive [1,3,6] abilities. Decline in cognitive functioning exists on a continuum from healthy aging to pathological conditions, such as “mild cognitive impairment” (MCI) or “dementia” [7-9]. MCI has evolved over the last decades [8] and was incorporated in the latest Diagnostic and Statistical Manual of Mental Disorders 5th Edition (DSM-V) and the International Classification of Diseases 11th Revision, as mild neurocognitive disorder (mNCD) [10-13]. Although slightly different definitions have been used in the literature, the core criteria remain [7,8]. According to DSM-V, mNCD is characterized by: “(A) Evidence of modest cognitive decline from a previous level of performance in one or more cognitive domains [...]; (B) cognitive deficits do not interfere with the capacity for independence in everyday activities [...]; (C) Cognitive deficits do not occur exclusively in the context of delirium. (D) Cognitive deficits are not better explained by another mental disorder (eg, major depressive disorder, schizophrenia)” [12]. In individuals with mNCD, deterioration in episodic memory and executive function represent the most prevalent cognitive impairment [14] and are associated with structural [7,15] and functional [7,15,16] brain changes. In addition to cognitive decline, individuals with mNCD may also experience problems in motor function [17,18], impaired balance [18], a higher fall risk [17,19], or difficulties in everyday functioning [20-22]. However, individuals with mNCD retain their capacity for independence in everyday activities [12].

In 2021, over 55 million people were living with major neurocognitive disorder (MNCD; also referred to as “dementia” [12]) [23]. The pooled prevalence of mNCD increases with age and is estimated to be approximately 16% [24], more than twice as high as the prevalence of MNCD [23,25]. The global increase in life expectancy [26] and insufficient levels of physical activity [27] serve as important risk factors for cognitive decline [9,24,28-30] and are expected to boost the incidence and prevalence of mild to major neurocognitive disorders (MNCD). Moreover, individuals with mNCD are at an increased risk of developing dementia. The annual conversion rate of mNCD to MNCD is approximately 4.9 in community settings and 9.6 in specialist clinical settings [31]. Between 14% (clinical population) and 31% (community-based cohort) revert to normal cognitive function [32]. Nonetheless, the pooled progression rate is estimated to be 34%, which is more than twice as high as the pooled reversion rate of 15% [24]. Consequently, the worldwide prevalence of dementia is expected to nearly double over the next 20 years [25]. To counteract this development, the World Health Organization has declared the prevention of disabilities caused by cognitive impairment a public health priority [33].

Individuals with mNCD may represent an optimal target population for pharmacological and nonpharmacological interventions [7]. However, no pharmacological treatment that effectively decelerates or prevents the progression from mNCD to MNCD or decreases the impact of cognitive decline on functioning exists [34-37]. The American Food and Drug Administration recently approved a new but controversial pharmacological agent (aducanumab) to treat individuals with mNCD due to Alzheimer disease (AD) [38,39]. In Europe, Biogen Netherlands BV withdrew its application for marketing authorization of Aduhelm for the treatment of early stages of AD due to insufficient data [40]. Evidence for other pharmacological treatment options (eg, cholinesterase inhibitors, antihypertensive, anti-inflammatory, or lipid-lowering medication, or hormone therapies) and nutritional supplements is largely insufficient and does not support their use for improving cognitive performance, slowing down cognitive decline, or reducing the risk of developing dementia [41-46]. Several nonpharmacological interventions, such as lifestyle changes that target modifiable risk factors such as diabetes mellitus [47-49], hypertension [47-49], obesity [49], depression [49,50], physical [29,49] or cognitive inactivity [30,49], or smoking [49,51], may hold promise for slowing down cognitive decline or reducing the risk of developing dementia [52]. It has been estimated that up to half of the world’s cases of AD, the leading cause of m-MNCDs [12]—may be attributable to these 7 potentially modifiable risk factors [49]. A 10%-25% reduction in these risk factors is estimated to reduce AD prevalence by up to 3 million individual cases worldwide [49]. As physical inactivity is associated with most other modifiable risk factors, an increase in physical activity is believed to have an impact on m-MNCD prevalence [49]. In addition, the theory of cognitive reserve suggests that, “education and mental stimulation throughout life may lower risk of AD and dementia by helping to build a ‘cognitive reserve’ that enables individuals to continue functioning at a ‘normal’ level despite experiencing neurodegenerative changes” [49,53,54]. According to recent network meta-analyses, nonpharmacological interventions

XSL•FO
RenderX

targeting modifiable risk factors, such as physical and cognitive exercises, outperform pharmacological therapies [55,56]. It can be hypothesized that a shift from pharmacological to nonpharmacological interventions with multi-domain treatment strategies, including physical exercises and cognitive stimulation, may lead to better results [9,36].

Aerobic training [57-59] and multicomponent physical exercises [57,59,60] are beneficial exercise modes for cognition in patients with NCDs, whereas cognitively engaging exercises appear to have the strongest effect on cognition [61,62]. Combined motor-cognitive training seems to be the most effective type of training for improving cognitive functioning in older adults with mNCD [61,63-65]. These findings are consistent with the "guided-plasticity facilitation" framework [66-68]: physical exercise enhances brain metabolism and promotes neuroplastic processes, whereas these changes in brain plasticity are guided by cognitive stimulation [66,67,69]. Combined motor-cognitive training can be categorized into "sequential," "simultaneous-additional," and "simultaneous-incorporated" motor-cognitive training [68]. Incorporating cognitive tasks into motor tasks is more beneficial than "classical" dual-task approaches or sequential motor-cognitive training in terms of stabilizing neuroplasticity effects [68].

Technological innovations (eg, exergames) provide new options to engage older adults with mNCD in (simultaneous-incorporated) motor-cognitive training [70]. "Exergaming is defined as technology-driven physical activities, such as video game play, that requires participants to be physically active or exercise in order to play the game" [71]. When exergames are specifically designed and implemented with a purpose beyond play, it is a "serious game" [72,73]. Exergame-based interventions are highly accepted in individuals with mNCD and increase training adherence and engagement by facilitating training motivation and satisfaction [74]. Furthermore, exergaming offers "the unique opportunity for patients to interact in an enriched environment, providing structured, scalable training opportunities augmented by multi-sensory feedback to enhance skill learning and neuroplasticity through repeated practice" [75], an additional advantage compared with conventional motor-cognitive training. There are consistent positive effects on cognitive functioning, favoring exergaming in people with m-MNCD [74]. Nonetheless, it is currently difficult to draw reliable conclusions about the effectiveness of exergaming in preventing and treating neurocognitive disorders because of the substantial variations in exergame-based training [74]. Gavelin et al [63] synthesized smaller effects on cognitive outcomes for exergaming (standardized mean difference [SMD] 0.13, 95% CI −0.22 to 0.44) compared with sequential (SMD 0.25, 95% CI −0.05 to 0.55) or simultaneous (SMD 0.45, 95% CI 0.11-0.78) motor-cognitive training in individuals with mNCD compared with passive control groups [63]. To the best of our knowledge, 11 studies have investigated exergame-based motor-cognitive training in older adults with mNCD [76-86]. Most of these studies used commercially available exergame systems [76-82], where the training content was not specifically developed for individuals with mNCD. In addition, only one of these studies applied training that individually prescribed content based on a patient's cognitive abilities [82]. This may explain the small effect findings of Gavelin et al [63], and points to opportunities for improvement in the application of exergames in individuals with mNCD by developing novel exergames and exergame-based training concepts that ensure the implementation of effective training components specifically tailored to the requirements and needs of individuals with mNCD [87]. It seems fair to state that purpose-developed exergames and exergame-based training concepts specifically targeting individuals with mNCD and implementing effective training components will have larger effects on individuals with mNCD.

Prior Work

We developed an exergame-based motor-cognitive training concept ("Brain-IT") specifically for older adults with mNCD. It was developed using the "Multidisciplinary Iterative Design of Exergames: A Framework for Supporting the *Design* section, Development, and Evaluation of Exergames for Health" [88]. The target group, therapists, and experts from different fields were involved in the development process to ensure that the training met the requirements and needs of older adults with mNCD and to foster the usability and acceptance of the approach in "real life." This interactive and participatory design and development process allowed the identification of the key requirements for exergame design as well as the training characteristics. These formed the basis for determining the components of the resulting "Brain-IT" training concept. It ensures the implementation of effective training components and is specifically tailored to the requirements and needs of older adults with mNCD. A detailed description of this design and development process is outlined in a previously published methodological paper that contains our complete training concept with sufficient details to allow full replication [89].

The original "Brain-IT" training concept was already shown to be feasible, usable, and highly accepted in our pilot feasibility randomized controlled trial (RCT), including a small sample of older adults with mNCD (n=18; under peer review; registered at ClinicalTrials.gov NCT04996654). Minor modifications were incorporated to further optimize the "Brain-IT" training concept, making it applicable for the systematic evaluation of effectiveness in samples of older adults with mNCD.

Explanation and Choice of Comparators

According to a recent systematic review summarizing worldwide available clinical practice guidelines and consensus statements, recommendations for the treatment and management of individuals with mNCD can be classified into 4 categories: interventions for risk reduction, pharmacological interventions, nonpharmacologic interventions, and counseling. Recommendations for nonpharmacological interventions mainly include physical and cognitive activity interventions; however, the specific training characteristics (eg, frequency, intensity, type, volume, and progression) are not specified [90].

In line with these recommendations, in Switzerland, usual care for mNCD typically includes treating medical conditions other than mNCD (eg, diabetes mellitus and depressive symptoms), controlling comorbidities (eg, hypertension and obesity), and

XSL•FO
RenderX

managing risk factors (eg, smoking habits and physical and cognitive inactivity). In this regard, usual care may include medication, recommendations for changing lifestyle habits (eg, living a cognitively, physically, and socially active life), physiotherapy to treat specific health problems, such as back pain or mobility problems, occupational therapy, or day clinic visits. This justifies the selection of usual care as the control intervention.

Objectives and Hypotheses

This study explores the effectiveness of the "Brain-IT" training in improving global cognitive functioning in older adults with mNCD. With this, we aim to obtain a sufficiently precise estimate of the treatment effect to minimize the sample size needed for a future full-scale RCT.

- Null Hypothesis ($H_0$0): In older adults with mNCD, the addition of the "Brain-IT" training to usual care has no significant effect on global cognitive functioning compared with usual care.
- Alternative Hypothesis (H_A): In older adults with mNCD, the addition of the "Brain-IT" training to usual care results in differing effects on global cognitive functioning compared with usual care.

As secondary objectives, the effects of the "Brain-IT" training on (a) domain-specific cognitive functioning (ie, learning and memory, complex attention, executive function, and visuospatial skills), (b) brain structure and function, (c) spatiotemporal parameters of gait, (d) instrumental activities of daily living (IADL), and (e) psychosocial factors (ie, QoL [quality of life], and levels of depression, anxiety, and stress), and (f) cardiac vagal modulation (ie, resting vagally-mediated heart rate variability [vm-HRV]) in older adults with mNCD as compared with usual care will be explored. (B) Brain structure and function will be evaluated to explore the possible underlying neural changes in training in relation to adaptations in cognitive performance. The following hypotheses are formulated for the remaining outcomes:

- Null Hypothesis (H_0): In older adults with mNCD, the addition of the 'Brain-IT' training to usual care has no significant effect on (a) domain-specific cognitive functioning, (c) spatiotemporal parameters of gait, (d) IADL and (e) psychosocial factors (ie, QoL, and levels of depression, anxiety, stress), and (f) cardiac vagal modulation (resting vm-HRV) compared with usual care.
- Alternative Hypothesis (H_A): In older adults with mNCD, the addition the "Brain-IT" training to usual care results in differing effects on (a) domain-specific cognitive functioning, (c) spatiotemporal parameters of gait, (d) IADL, (e) psychosocial factors (ie, QoL, and levels of depression, anxiety, and stress), and (f) cardiac vagal modulation (resting vm-HRV) compared with usual care.

The rationale and description of the specific hypotheses for (c) spatiotemporal parameters of gait are explained in more detail in the section "Methods—Outcomes—Secondary Outcomes—Spatiotemporal Parameters of Gait."

Methods

This study protocol (version 1.0; July 20, 2022) was developed in accordance with established guidelines from the "SPIRIT 2013 Statement: Defining Standard Protocol Items for Clinical Trials" [91,92] (see the checklist in Multimedia Appendix 1).

Ethics Approval

All the study procedures will be performed in accordance with the Declaration of Helsinki. The study protocol was approved by the Ethics Committees of Zurich and Eastern Switzerland (EK-2022-00386).

Trial Design and Study Setting

A 2-arm, prospective, parallel-group, single-blinded (ie, outcome evaluator of pre- and postintervention measurements blinded to group allocation) RCT with a 1:1 allocation ratio (ie, intervention: control), including 34 to 40 older adults with mNCD, will be conducted between May 2022 and December 2023. The control group will proceed with usual care as provided by the (memory) clinics where the patients are recruited, while the intervention group will perform a 12-week training intervention according to the "Brain-IT" training concept in addition to usual care (see section "Methods—Interventions"). The study was registered at clinicaltrials.gov before the start of patient recruitment (NCT05387057; date of registration: May 18, 2022; see Table 1 for details) and will be reported according to "The Consolidated Standards of Reporting Trials (CONSORT) 2010 statement" [93] and elaboration paper [94]. The study setup is multicentric (Zurich and St. Gallen) and national (Switzerland).

After recruitment and providing written informed consent (see section "Methods—Recruitment"), participants will be screened on eligibility (see section "Methods—Eligibility Criteria"), and premeasurements will be scheduled for all eligible participants. Pre- and postintervention measurements will take place within 2 weeks before starting and after completing the intervention. For participants recruited in Zurich, preintervention measurements will take place at ETH Hönggerberg (Robert-Gnehm-Platz 1, CH-8093 Zurich). For participants recruited in St. Gallen, premeasurements will take place at the Eastern Switzerland University of Applied Sciences (Vadianstrasse 29, CH-9000 St Gallen). The measurements will take approximately 90 minutes. For all participants with no contraindications to magnetic resonance imaging (MRI), an additional appointment to conduct an MRI scan (duration: approximately 1 hour [including preparation]) at University Hospital Zurich (Rämistrasse 100, CH-8006 Zurich) will be scheduled. All measurements will be led by 2 investigators from our research team trained in the application of the measurement techniques and protocols. Pre- and postintervention measurements will be scheduled to occur at approximately the same time of the day (±2 h) for each participant. To minimize the influence of transient confounding effects on HRV, all participants will additionally be instructed verbally and in writing to follow a normal sleep routine the day before the experiment, to avoid intense physical activity and alcohol consumption within 24 hours before measurements, and to refrain from coffee–or caffeinated drinks as well as food

XSL•FO
RenderX

consumption at least 2 hours before measurements [95]. After completing premeasurements, participants will be randomly allocated to the intervention or control group and will be instructed about their respective intervention procedures (see section "Methods—Interventions"). For participants in the intervention group, the exergame device will be installed in their homes; they will receive safety instructions and will be familiarized with the exergame training system. Subsequently, the study intervention will be started (see section "Methods—Interventions—Intervention Group"). After completing the 12-week intervention period, postintervention measurements will be performed for both groups. No compensation will be granted to the participants, but detailed feedback on individual performance as well as the study outcomes in general will be provided at the end of the trial. Figure 1 summarizes the study procedures.

Data category	Information
Key secondary outcomes	• Changes in Learning and Memory • Changes in Complex Attention • Changes in Executive Function • Changes in Visuospatial Skills • Changes in Brain Structure and Function • Changes in Spatiotemporal Gait Parameters • Changes in instrumental activities of daily living • Changes in Psychosocial Factors • Changes in vagally-mediated Heart Rate Variability • For all secondary outcomes: (Time Frame: both, the pre- and postintervention measurements of the primary outcome measurement will take place within 2 weeks before starting or after completing the intervention)

[a]N/A: not applicable.

Figure 1. Graphical overview of the study procedures. The cubes are used to illustrate the randomization process (variable block randomization (ie, block sizes=4, 6, 8) with a 1:1 allocation ratio stratified by sex and per institute (study center), as described in section "Methods–Randomization").

Recruitment

Older adults with mNCD will be recruited between May 2022 and September 2023 in collaboration with (memory) clinics in a larger area of Zurich and St. Gallen. Suitable patients will either be identified from medical records and patient registries of (memory) clinics, or from recent diagnostics performed by medical doctors or therapists authorized to search for medical records. Alternatively, suitable patients will be identified by an informant (ie, health care professionals) based on suspicion of MCI in one of their patients (see *Methods—Eligibility Criteria* section). Identified patients will be verbally informed about the study and will receive leaflets by their physicians or therapists containing key information about study participation and researchers' contact details. If patients are interested in being informed about the study in detail, they will be asked to provide consent to share their contact details with the research team and will be contacted by phone or email by a trained investigator of the study team. In case of initial interest in participating in the study, all interested subjects will be fully informed about the study procedures in-person (at the interested persons' home or at one of the study centers, depending on their preferences) by providing verbal explanations and an information sheet. After sufficient time for consideration (ie, at least 24 hours after handing out the study information sheet, but on average around 1 week), suitable patients willing to participate in the study will provide written informed consent in a second in-person meeting with one of the trained investigators of the study team at the home of the interested persons or at one of the study centers. After providing written informed consent, participants will be fully screened for eligibility (see section "Methods—Eligibility Criteria"), and premeasurements will be scheduled.

Eligibility Criteria

All eligibility criteria are detailed in Textbox 1.

XSL•FO
RenderX

Textbox 1. Description of all eligibility criteria.

Inclusion criteria

- Participants fulfilling all the following inclusion criteria were eligible:
  - (1=mild neurocognitive disorder) clinical diagnosis of "mild neurocognitive disorder" according to International Classification of Diseases 11th Revision [13] or Diagnostic and Statistical Manual of Mental Disorders 5th Edition [12] OR (2=screened for mild cognitive impairment [sMCI]) patients sMCI according to the following criteria: (1) informant (ie, health care professional)-based suspicion of MCI confirmed by (2) an objective screening of MCI based on the German version of the using the quick mild cognitive impairment screen [96] with (2A) a recommended cut-off score for cognitive impairment (MCI or dementia) of <62/100 [97], while (2B) not falling below the cut-off score for dementia (ie<45/100 [97]).
  - Speaking German
  - Able to stand at least for 10 minutes without assistance

Exclusion criteria

- The presence of any of the following criteria led to exclusion:
  - Mobility impairments (ie, gait and balance) that prevent experiment participation
  - Presence of additional, clinically relevant (ie, acute or symptomatic or both) neurological disorders (ie, epilepsy, stroke, multiple sclerosis, Parkinson's disease, brain tumors, or traumatic disorders of the nervous system)
  - Presence of any other unstable or uncontrolled diseases (eg, uncontrolled high blood pressure and progressing or terminal cancer)
- COVID-19–specific risk factors (according to the Swiss Federal Office of Public Health) are additional exclusion criteria. In case of COVID-19–specific exclusion criteria, participation in the study will only be allowed when the patients' treating physician provides written informed consent allowing participation in the study despite the presence of COVID-19–specific exclusion criteria. COVID-19–specific exclusion criteria include:
  - High blood pressure (self-reported; systolic ≥140 mm Hg or diastolic ≥90 mm Hg)
  - Chronic respiratory condition
  - Uncontrolled type 2 diabetes
  - Condition or therapy that weakens the immune system
  - Unstable cardiovascular disease
  - Cancer (present or under treatment)
  - Serious obesity (BMI≥40 kg/m^2)

Interventions

Control Group

The control group will proceed with the usual care provided by the (memory) clinics where the patients are recruited. As described in section "Introduction—Choice of comparators" and based on clinical practice guidelines [90], in Switzerland, usual care is highly individual, varies between (memory) clinics where patients are recruited, and it is unclear whether patients comply with the recommendations of their clinicians. Therefore, details about all structured or guided usual care activities or both, as well as medication intake, will be assessed in both the intervention and control groups. If there are relevant between-group differences in usual care, these differences will be accounted for in the analysis and discussion of results.

Intervention Group

Participants in the intervention group will perform a 12-week training intervention in addition to their usual care (as provided by the [memory] clinics where patients were recruited). The training will be prescribed according our "Brain-IT" training concept. This motor-cognitive training concept represents a guideline for applying exergame-based motor-cognitive training by standardizing the training characteristics (eg, training frequency, intensity, and duration) as well as the structure and content of the training, whereas the exergame device and the specific games used within each of the defined neurocognitive domains can be replaced by alternative exergames. In this project, our training concept was implemented using the "Senso (Flex)" (Dividat AG). This platform was found to be suitable for the "Brain-IT" training [87] and is a widely used means for motor-cognitive training within geriatric populations, physiotherapy, and rehabilitation in Switzerland. The original "Brain-IT" training concept has recently been published with sufficient detail about the exergame components as well as the exercise and training characteristics (ie, including all predefined levels of task demands as well as the detailed progression rules) to allow full replication (ie, consider supplementary file 3 of [89]). Some minor modifications were implemented in the "Brain-IT" training concept for use in this study, based on the findings of our pilot feasibility RCT (under peer review; registered at ClinicalTrials.gov NCT04996654). This will be complemented in cases in which suitable new games become available throughout the study. The final (modified) "Brain-IT"

XSL•FO
RenderX

training concept will be published with the manuscript reporting the results of this study, and will additionally provide specific information that would theoretically allow adaptation of the training to other hardware and software solutions. To ensure replicability, the "Brain-IT" training concept was planned and will be reported using the Consensus on Exercise Reporting Template [98].

For an overview, the "Brain-IT" training concept consists of individually adapted multidomain exergame–based simultaneous motor-cognitive training with incorporated cognitive tasks that is adopted with a deficit-oriented focus on the neurocognitive domains of (1) learning and memory, (2) executive function, (3) complex attention, and (4) visuospatial skills. Each participant is instructed to train 5 times per week for 24 minutes per session, resulting in a weekly training volume of 120 minutes. All training sessions are planned to take place at participant's homes using the "Senso Flex" hardware (Dividat AG; CE certification pending; see left side of Figure 2). The "Senso Flex" is a home-based version of the "Senso" (Dividat AG; CE certification; see right side of Figure 2). It consists of a 1.11×0.99 m rollable mat that is plugged into a portable computer and a frontal television (or other screen) at home. Both systems divide the pressure-sensitive stepping area into five fields: (1) center (home position), (2) front, (3) right, (4) back, and (5) left. The device detects the participants' position and timing of movements to interact with different game scenarios programmed in the training software. Weight shifting, walking on the spot, and steps in 4 directions (ie, front, right, back, and left) enable interaction with and control of the exergame scenarios displayed on a frontal screen. Visual, auditory, and somatosensory (vibrating platform; only available on the "Senso") feedback is provided in real time to enrich the game experience. Various games are available for training different neurocognitive domains (more details on how the device is implemented in our training concept have been provided [89]).

Adherence to the training will be monitored (see section "Outcomes—Other Outcomes—For the intervention group," ie, exergame training), and participants will be actively motivated and reminded to adhere to the training by the person responsible for supervision and correspondence with the respective study participant. Upon the request of participants, training can be paused for a maximum of 2 weeks (eg, because of holidays).

Figure 2. Exergame Device used as means to implement the "Brain-IT" training concept in this study: "Senso Flex" for home-based use (left side) and its stationary version ("Senso" for stationary use in physiotherapies, nursing homes, or rehabilitation clinics (right side). Photos provided by Dividat AG.

Outcomes

Overview

To ensure comparability of the study outcomes, global cognitive functioning will be assessed as the primary outcome. As secondary outcomes, domain-specific assessments evaluating the key neurocognitive domains (as defined in [10] in line with DSM-V [12] and according to recommendations [7]) of (1) learning and memory; (2) complex attention; (3) executive function; and (4) visuospatial skills, as well as brain structure and function, spatiotemporal parameters of gait, IADL, psychosocial factors (ie, QoL, and levels of depression, anxiety, and stress), and cardiac vagal modulation (resting vm-HRV) will be assessed. Table 2 provides an overview of all endpoints.

[h]vm-HRV: vagally-mediated heart rate variability.

[i]5 min resting vm-HRV measurement with heart rate monitor (Polar M430) and sensor (Polar H10) analyzed using Kubios HRV Premium (Kubios Oy, Kuopio, Finland, version 3.4) [118].

Primary Outcome

The German version of the quick mild cognitive impairment (Qmci) screen will be used to assess global cognitive functioning [96,99]. The Qmci has been validated against the standardized Alzheimer's Disease Assessment Scale-Cognitive Subscale (ADAS-cog) [96,119], which is considered the gold standard for assessing the efficacy of antidementia treatments [120-122]. The Qmci was shown to "correlate strongly, significantly and correspondingly over time to the standardized ADAS-cog and that both are equally sensitive with similar responsiveness to deterioration over time" [119], "suggesting that the Qmci could be substituted for a more detailed neuropsychological instrument in clinical trials" [96,119]. Furthermore, it is accurate in differentiating mNCD from normal cognition and MNCD [119]. In this regard, it has also been externally validated and has shown a higher level of accuracy, sensitivity, and specificity than commonly used tests such as the (Standardised) Mini Mental State Exam ([S]MMSE) and the Montreal Cognitive Assessment for detecting cognitive impairment (MCI and dementia) [123]. In comparison to the (S)MMSE and Montreal Cognitive Assessment, the Qmci includes a more detailed scoring system and a logical memory task that allows the Qmci to detect more subtle cognitive abnormalities and avoid ceiling effects [123]. Qmci was scored as the point rate out of a maximum score of 100. It consists of 6 subtests: orientation (10 points), registration (5 points), clock drawing (15 points), delayed recall (20 points), verbal fluency (20 points), and logical memory (30 points) [99,124]. Qmci will be administered and evaluated according to published guidelines [99].

To the best of our knowledge, the smallest unit of clinically meaningful change has not yet been determined for the Qmci. However, changes in Qmci scores were very similar to changes in standardized ADAS-cog scores. Longitudinal data of more than 360 patients with m-MNCD were analyzed for responsiveness of the Qmci and the standardized ADAS-cog [125] by calculating standardized response mean from baseline to scores obtained at 1, 3, 6, 9, and 12 months. The mean change between months 1 and 12 was 5 points (SD 7.56) for the standardized ADAS-cog scores, and 5.41 points (SD 10.02) for the Qmci. The paired-samples *t* test showed no statistically significant difference in standardized response means for standardized ADAS-cog and Qmci (t_{357}=0.32; *P*=.75) [119]. Therefore, it is anticipated that the smallest units of clinically meaningful changes between these 2 measures are similar. For the standardized ADAS-cog, the minimal clinically relevant change is estimated to be 3 points for individuals with mNCD compared with ≥4 points based on previous recommendations made by a consensus committee of the Food and Drug Administration for patients in more advanced stages [126,127]. Therefore, it is assumed that a change of ≥3 points in the Qmci score can be regarded as a clinically meaningful change.

Secondary Outcomes

Learning and Memory

Learning and memory will be assessed using the German version of the subtests "logical memory" of the Wechsler Memory Scale—fourth edition (WMS-IV-LM) [100,101] and a computerized version of the digit span forward (DSF) test (psychology experiment building language [PEBL; PEBL-DSF]) [102-104].

The WMS-IV-LM measures auditory verbal contextual learning and memory with excellent reliability and validity [101]. The validated older adults battery (aged 65 years or older) of the German version of the WMS-IV-LM [100,101,128] will be used for all participants. The test will be instructed, conducted, and evaluated according to the standardized administration and scoring manual [100]. During the 20 to 30 minutes retention phase, unrelated assessments (eg, gait analysis, questionnaires) will be performed that do not interfere with memory.

The PEBL-DSF test assesses immediate recall and will be executed using the PEBL Test battery software [version 2.1 (2), with default settings] [102-104]. Participants were required to remember and repeat the digit sequences presented on the screen. Span length covers 2 to a maximum of 8 digits. For each digit span, 2 trials will be presented before increasing the sequence length (in case at least one of the 2 trials is completed correctly). For every correct replication of a digit sequence, 1 point will be scored, summing up to a total point score. In addition, the length of the longest correctly repeated digit sequence will be recorded as the maximum span. Instructions will be presented on the screen and will be explained verbally to each participant before starting the test.

XSL•FO
RenderX

Complex Attention

Complex attention will be assessed using a computerized version of the Trail Making Test—Part A (PEBL-TMT-A) [102,104] and the subtest "Go-NoGo" of the Test of Attentional Performance (test of attentional performance [TAP] Go-NoGo) [105].

The TMT-A is a valid and reliable neuropsychological test for assessing psychomotor processing speed and visuo-perceptual abilities [129-134]. A computerized version of the TMT-A PEBL Test battery software [version 2.1 (2), with default settings] will be used [102,104,135]. Participants will be verbally instructed, and a short practice session will be conducted before starting the test. The completion time will be limited to 300 seconds. Completion times (seconds; including time for error correction) and the number of errors will be measured.

The TAP (version 2.3.1, PSYTEST, Psychologische Testsysteme, Herzogenrath, Germany) is a valid and reliable computerized test battery to assess various attentional and executive functions [105,136], with norm values for healthy older adults provided by the supplier [105,137]. The TAP Go-NoGo will be used to assess selective attention and inhibition. The test form "1 of 2" will be instructed, conducted and evaluated according to the standardized protocol of the manufacturer. The median reaction time and number of errors will be measured [105].

Executive Function

Executive function will be assessed considering planning (ie, using the HOTAP picture-sorting test part A [106]), working memory (ie, using a computerized version of the Digit Span Backward test; PEBL Digit Span Backward [PEBL-DSB]) [102-104], and cognitive flexibility (ie, using a computerized version of the Trail Making Test-Part B [PEBL-TMT-B] [102,104]).

HOTAP picture-sorting test part A [106] will be used to measure planning ability. A set of photo cards containing actions typical of everyday life (eg, making coffee, washing clothes, and grocery shopping) will be presented. Participants will be verbally instructed to sort photo cards on which the individual substeps of these typical everyday actions are depicted. The test will be conducted according to the manufacturer's standardized protocol. The outcome variable is a combination score calculated as the sum of points divided by the time needed to arrange the cards [106].

The PEBL Digit Span Backward (PEBL-DSB) [102-104] test will be used to assess the short-term working memory capacity. It will be instructed, administered, and scored identical to the PEBL-DSF, but participants will have to remember and repeat the digit sequences in reverse order.

The TMT-B is a valid and reliable neuropsychological test for assessing cognitive flexibility [129-134]. It consists of 25 randomly allocated circles distributed over a sheet of paper. A computerized version of the TMT-A (PEBL Test battery software [version 2.1 (2), with default settings]) will be used [102,104,135]. It will be instructed, administered, and scored identical to the PEBL-TMT-A.

Visuospatial Skills

Visuospatial skills will be tested using a computerized version of the classic Shepard and Metzler mental rotation task [138]. The PEBL-Mental Rotation Task (PEBL-MRT) will be executed using PEBL Test battery software [version 2.1 (2), with default settings] [102,104,107]. Instructions will be presented on the screen and will be explained verbally to each participant before starting the task. Pairs of differently rotated 2D polygons will be presented simultaneously on the screen. Participants need to decide as quickly as possible whether the 2 presented objects are identical (ie, pressing <Lshift> on the keyboard) or different (ie, pressing <Rshift> on the keyboard). Median reaction time of correct answered trials as well as performance (number of correct answered trials) are an indicator for mental rotation ability [107,138]. Trials with reaction times less than 0.2 seconds or greater than 13 seconds will be excluded from the data analysis [107].

Brain Structure and Function: Data Acquisition

Brain structure and function will be evaluated by MRI using a 3.0 Tesla Philips whole-body scanner (Philips Medical Systems, Best, and Netherlands) to explore possible underlying neural changes of training in relation to adaptations in cognitive performance. Only participants having no contraindications to MRI (ie, any MRI-incompatible metallic parts within the body, metallic or electronic implants [eg, heart pacemaker, brain pacemaker, and cochlear implants], and strong claustrophobia) will be measured. During measurements (duration=approximately 35 min), participants will lay comfortably in the MRI scanner and will be asked to avoid head movements. Data will be collected according to the Canadian Dementia Imaging Protocol (CDIP) [139] for comparison with other studies. The CDIP was developed to harmonize MRI acquisitions in the context of studying primary and secondary causes of morbidity of neurodegeneration in a wide range of neurological pathologies related to aging [139]. First, the following parts of the core CDIP will be applied: anatomical imaging (1.) and connectivity and functional imaging (2. – 3.) [139]:

- a 3D isotropic t1-weighted (t_1w) scan (duration=6.5 minutes) for assessing fine anatomical detail and brain atrophy (voxel size=1.0×1.0×1.0 mm^3) with an acceleration factor of 2 (TFE-Sense: 2);
- diffusion tensor imaging (DTI; duration=6 minutes) for assessment of white matter microstructural integrity and connectivity, with resolution 2.0×2.0×2.0 mm^3, a minimum of 30 uniformly distributed directions with b=1000 second/mm^2, (EPI-Sense 2-32 directions; we use the vendor-provided directions set), and an acceleration factor of 2; and
- a resting state fMRI (duration=9 minutes) for assessment of functional networks and pathways using a T^*_2-weighted blood oxygen level-dependent-sensitive sequence, with resolution of 3.5×3.5×3.5 mm^3, repetition time=2110 milliseconds, 300 volumes over time, and slice order=ascending.

XSL•FO
RenderX

During resting-state fMRI data acquisition, participants will be asked to fixate on a cross displayed on the screen. At the end of this scan, participants must respond to written instructions by button press to check whether they were awake during the measurement.

In addition, task-based (event-related) fMRI measured with an episodic memory task (face-occupation matching task; duration: approximately 10 min) will be conducted. The face-occupation matching task was described in [140] and has been used in fMRI [141]. It was shown to robustly activate the hippocampus bilaterally and provide a differential signal for correct and incorrect trials [141]. The task was adapted specifically for older adults with mNCD [142] and will be run in PsychoPy (version 3.2.4) [143]. It includes 6 rounds, each containing (1) an encoding phase, (2) a retention phase, and (3) a retrieval phase including a cued recall task and a recognition task (see Figure 3 for an overview).

During the *encoding* phase, 5 face-occupation pairs will be presented in each round in a randomized order. A total of 30 face-occupation pairs (15 different face-occupation combinations) will be presented (Figure 3). Photographs of unfamiliar faces of older adults with neutral expressions were derived from the FACES database [144] and will be equally balanced over sex. Each face-occupation pair will be shown for 3.5 seconds. To ensure that participants view both faces and occupations, they will be asked to indicate whether each respective occupation "suits" (ie, pressing a button with their right index finger) or does not suit the presented face (ie, pressing a button with their right middle finger).

During the *retention* phase, 5 silhouettes will be presented in randomized order in each round. A total of 30 silhouettes will be presented. Each silhouette will be shown for 3.5 seconds. Participants will be asked to indicate by button press whether each silhouette corresponds to a woman (pressing a button with their right index finger) or a man (pressing a button with their right middle finger).

In the *retrieval* phase, a cued-recall task will be performed followed by a recognition task. In the cued recall task, participants will be asked to decide which of 2 educational degrees (ie, study [pressing a button with their right index finger] or apprenticeship [pressing a button with their right middle finger]) the previously encoded occupation of the person matched. In the recognition task, participants will have to decide between correct and distractor occupation via a button press (right index finger or right middle finger). For both the tasks, the response window will be 3.5 seconds. The photographs will be presented in the same order as those in the encoding phase.

The same recording parameters as in resting-state fMRI will be used. There are 4 alternative task conditions (ie, other face-occupation pairs). The task condition will be randomly allocated using random.org [145], while ensuring that 2 different conditions are used in the pre- and postintervention measurements for each participant.

Figure 3. Graphical overview of the episodic memory task (face-occupation matching task).

Brain Structure and Function: Data Analysis

Processing and volumetric segmentation of t_1w morphological data is performed using the longitudinal pipeline of the FreeSurfer software package (version 7.2.0 or newer with default parameters) [146,147], as described in [148]. Gray matter volumes and WMVs are determined for the following key regions of interest (ROIs): total brain (ie, total brain volume without ventricles [brainsegvolnotvent] from the aseg file), hippocampus, dorsolateral prefrontal cortex, PFC, and anterior cingulate cortex (ACC). Similar to Anderson-Hanley et al [77,78], we will combine the following regions to obtain the defined key ROIs of the dorsolateral prefrontal cortex, PFC, and ACC, because these are not directly extracted using the FreeSurfer software package: dlPFC=frontal middle gyrus and sulcus from the Destrieux et al [149] atlas; ACC=rostral and caudal anterior cingulate cortices from the Desikan et al [150] atlas; PFC=ACC+medial orbitofrontal and transverse frontopolar regions [151].

DTI data will be processed using the TractoFlow pipeline [152,153], a diffusion MRI tractography processing pipeline based on Nextflow [154] and Singularity [155], for human brain tractography reconstruction. In patients with m-MNCD, DTI abnormalities are concentrated in the posterior regions, whereas the most reported regions of DTI alterations are the temporal lobes, with a particular emphasis on the parahippocampal white matter and posterior cingulum [156,157]. Therefore, MD and FA will be calculated for the parahippocampal white matter and posterior cingulum, defined as key ROIs for this study. In addition, tract-based spatial statistical analysis will be performed to study white matter changes at voxel-to-voxel (whole-brain)

XSL•FO
RenderX

levels. Tract-based spatial statistical analysis is based on a general linear model and will be performed using FSL's randomization tool [158] with 5000 permutations to correct for multiple comparisons (P<.05, corrected). All results will include threshold-free cluster enhancement [159]. The threshold-free cluster enhancement correction method is somewhat similar to cluster-based thresholding but is generally more robust and avoids the need for an arbitrary initial cluster-forming threshold. Two contrasts will be computed at the individual and group levels, testing for positive and negative differences in FA and MD parameters pre- and postintervention. We will include age and sex as key covariates in the general linear model.

Data of *resting state and task-based fMRI* will be preprocessed to minimize data artifacts from thermal noise of MRI, system noise of the MR hardware, and subject-related noise resulting mostly from head motion [160]. The preprocessing steps will include slice time correction, motion correction, coregistration, and spatial smoothing (Gaussian kernel with 7 mm full width at half maximum) of the signal [161]. For functional connectivity (FC) analysis, preprocessed resting-state functional data will be analyzed using the latest release of the Functional Connectivity Toolbox (currently CONN 21a; [162,163]) in SPM12. The CONN utilizes a component-based noise correction method (CompCor) that increases selectivity and sensitivity and allows a higher degree of interscan reliability [164]. In addition to the described preprocessing steps, a band-pass filter (0.01-0.1 Hz) will be applied to remove linear drift artifacts and high-frequency noise. The CONN also accounts for outlier data points and movement time courses as nuisance regressors. The 6 motion parameters, WM and CSF, will be included as regressors of no interest, thereby reducing noise and signals that are unlikely to reflect neuronal activity related to FC. Age and sex will be included as key covariates of no interest. Significance was set at P<.05 with Family Wise Error-level correction for multiple comparisons (with P<.05 2-sided false-discovery rate correction) [163].

Bilateral hippocampal masks were selected as seeds from an Anatomical Automatic Labeling template [165]. Individual FC maps for the hippocampal seed will then be generated based on correlations between the mean signal time course within each seed region and the rest of the brain, similar to Suo et al 2016 [166], with the following selected key ROIs (ie, brain regions related to cognitive functioning, similar to Zhong et al [167]): precuneus or posterior cingulate cortex, medial prefrontal cortex, medial temporal lobe, angular gyrus, lateral temporal cortex, and medial, lateral, and inferior parietal cortex.

Spatiotemporal Parameters of Gait

Spatiotemporal parameters of gait will be evaluated to explore whether the addition of the "Brain-IT" training to usual care effectively improves gait. The gait of individuals with mNCD differs from that of healthy controls in terms of (among others; 1) slower single-task gait speed at the preferred walking speed (m/s) [18,168], (2) longer stride duration (ms) [18,168], (3) shorter stride length (cm) [18,168], (4) longer stance time (ms) [168], (5) longer swing time (ms) [168], (6) longer single support time (ms) [168], and (7) longer double support time (ms) [168]. Furthermore, individuals with mNCD typically show greater variability and coefficient of variation of gait parameters compared with cognitively healthy individuals [168].

According to the literature summarized above, we assume that an effective intervention leads to an (1) increase in single-task gait speed at the preferred walking speed, (2) decrease in stride duration, (3) increase in stride length, (4) decrease in stance time, (5) decrease in swing time, (6) decrease in single support time, and (7) decrease in double support time.

On the basis of this, we have elaborated our alternative hypotheses in more detail. It is hypothesized that in older adults with mNCD, the addition of the "Brain-IT" training to usual care results in differing effects on (c_1) single-task gait speed at the preferred walking speed, (c_2) stride duration, (c_3) stride length, (c_4) stance time, (c_5) swing time, (c_6) single support time, and (c_7) double support time compared with usual care.

Spatiotemporal gait parameters will be assessed using a BTS G-WALK (BTS Bioengineering SpA, Garbagnate Milanese, Italy) inertial sensor attached with semielastic belt to participants' lower back. The BTS G-WALK sensor delivers valid [169-171] and reliable [169,172] spatiotemporal gait parameters. All the acceleration data will be sampled at a frequency of 100 Hz. Data will be transmitted for analysis through Bluetooth 3.0, connection to the software program BTS G-Studio (BTS Bioengineering SpA, Italy). A gait-analysis protocol consisting of a figure of 8 walking path (ie, distance between cones of approximately 8 m) will be applied [108]. At least 50 consecutive gait cycles are required to ensure the reliability of the spatial and temporal parameters of gait variability [173]. Therefore, participants will perform 5 to 10 repetitions of the figure of 8 walking path at the preferred walking speed, depending on their walking speed and stride length. Comparative quantitative reference values for healthy older adults are available [174].

IADL Functioning

IADL functioning will be assessed using the Amsterdam IADL questionnaire short version, German for Switzerland, which has demonstrated good psychometric properties [109]. In addition, the original version of the Amsterdam IADL questionnaire was sensitive to longitudinal changes [175] and has been recommended for use in research settings [176]. The closest informant (eg, spouse, child, or friend) will fill out the questionnaire twice (within 2 weeks before the study participant starts or completes the intervention). Each item is scored on a 5-point Likert scale ("no difficulty" to "unable to perform"). Scoring is based on the item response theory. Item response theory latent trait levels are transformed to a T-score, with a range from 20 to 80, a mean of 50, and an SD of 10. A higher t score indicates better functioning [109].

Psychosocial Factors

QoL will be evaluated in interview format using the Quality of Life-Alzheimer Disease (QOL-AD) scale [110]. The QOL-AD is a valid and reliable self-report 13-item scale assessing various domains of QOL in cognitively impaired patients [110,177]. The German version of the QOL-AD scale, which has high test-retest reliability and good construct validity [111,112] will

XSL•FO
RenderX

be used. Administration and evaluation will follow standardized instructions [112,178]. Comparable values are available for individuals with mNCD [179].

Levels of depression, anxiety and stress will be assessed using the short version of the Depression, Anxiety and Stress scale-21 (DASS-21) [113-115]. The DASS-21 has high reliability and good convergent and discriminant validity [113,180]. The validated German version of the DASS-21 will be administered and scored according to guidelines and scoring template [116,117]. Normative data of the 3 subscales are available and suggest cut-off scores of 10, 8, and 15, indicating significant depression, anxiety, or stress, respectively [116]. Comparative values for individuals with mNCD are available [181].

Cardiac Vagal Modulation (Resting Vagally-Mediated Heart Rate Variability)

To determine resting vm-HRV, all participants will be instructed to sit in a comfortable position on a chair without speaking, both feet flat on the floor with knees at a 90º angle, hands on the thighs (ie, palms facing upward), and eyes closed [95]. Measurements will be performed in a quiet room with dimmed light at room temperature. Data will be collected using a heart rate monitor (Polar M430) and sensor (Polar H10). The initial acclimatization phase will last for 5 minutes followed by a 5-minute resting measurement, the recommended standard duration for short-term recordings [95,182]. The start of the resting measurement will not be announced to the participants [95].

For resting HRV measurements, a sampling rate of 1000 Hz will be used to provide a temporal resolution of 1 milliseconds for each RR interval [183]. R-R data recordings will directly be transmitted to the Kubios HRV Premium (Kubios Oy, Kuopio, Finland, version 3.4) for analysis. Kubios HRV is a scientifically validated software for HRV analysis and has achieved the gold standard status in research [118,184-186]. The automatic beat correction algorithm and noise handling provided by the software will be used to correct for artifacts or ectopic beats. This algorithm has been validated for measurements at rest [184]. After removing interbeat-interval time series nonstationarities by detrending analysis using the smoothness priors method approach (settings: detrending method=smoothing priors, Lambda=500, f_c=0.035 Hz), the mean values of mainly vagal-mediated HRV indices will be calculated for each segment. For this purpose, the mean R-R time intervals (mRR; ms), root mean square of successive RR interval differences (ms), percentage of successive RR intervals that differ by more than 50 milliseconds (%), absolute power of the high-frequency (0.15-0.4 Hz; high frequency [HF]) band (ms^2), relative power of HF (in normal units; HF [n.u.] = HF [ms^2] / (total power [ms^2]—very low frequency; 0.00-0.04 Hz [ms^2]), and Poincaré plot SD perpendicular to the line of identity (SD1; ms) will be considered [95,182,187-189]. In addition, the parasympathetic nervous system tone index (parasympathetic nervous system index) will be calculated to compare parasympathetic nervous system activity with normal resting values [189].

Other Endpoints

Safety Endpoint Variables

A protocol will be kept of all (serious) adverse events.

Baseline Factors

Baseline factors are collected through demographic data, including age, sex, height, weight, BMI, years of education, physical activity behavior (ie, measured with the German version of the International Physical Activity Questionnaire Short Form—short form [190,191] and analyzed according to published guidelines for data processing and analysis of International Physical Activity Questionnaire Short Form—short form [192]), clinical subtype (ie, mNCD due to AD, mild Frontotemporal NCD, mNCD with Lewy Bodies, or mild vascular NCD), medication intake, and changes in medication intake between pre- and postintervention measurements.

Adherence and Compliance Protocol

For the intervention group (ie, exergame training):

- Adherence Protocol (number of sessions completed per week per participant; automatically assessed in the Exergame Training Software) to calculate the mean adherence rate (%) = number of training sessions attended / total number of training sessions offered; calculated as the average of each participant's weekly adherence with a maximum of 100%.
- Compliance Protocol (training time completed per week per participant; automatically assessed in the Exergame Training Software) to calculate the mean compliance rate (%) = training duration attended (min) / total training duration offered (min), calculated as the average of each participant's weekly compliance, with a maximum of 100%.

Participant Timeline

[m]DASS-21: Depression, Anxiety and Stress scale-21.

[n]vm-HRV: vagally-mediated heart rate variability.

Sample Size

The optimal sample size was justified based on Whitehead et al [193], and the following assumptions: the future main (full-scale) RCT will be planned with identical design and primary outcome as this study, with a two-sided type 1 error rate of 5% and a statistical power of 80%.

Our pilot feasibility RCT revealed a medium effect size (η^2_p=0.080; under peer review; registered at ClinicalTrials.gov NCT04996654). The observed medium effect size is slightly higher than the pooled evidence of exergame-based or combined motor-cognitive training interventions in older adults with NCD on global cognitive functioning. For exergame-based interventions in individuals with mNCD, Wang et al [194] reported a medium SMD of 0.57 (*P*=.21, 95% CI −0.32 to 1.47; *k*=1; n=20, compared with cognitively active control), while Gavelin et al (2021) reported an SMD of 0.13 (*P*>.05, 95% CI −0.22 to 0.48; *k*=2; n=109, compared with passive control) [63]. Stanmore et al [195] reported a small pooled effect of Hedges *g*=0.340 (*P*=.02, 95% CI 0.06-0.62; *k*=6; n=193) for patients with cognitive impairment. Further meta-analytic results for individuals with mNCD are limited to simultaneous motor-cognitive training with reported small-to-medium effect sizes, including SMDs of 0.45 [61], 0.48 [196], 0.531 [61], and 0.69 [197]. On the basis of this, a medium effect size of a SMD of 0.5 seems reasonable and is anticipated. This leads to a justified optimal sample size of n=14 per arm.

In our pilot feasibility RCT, we observed an attrition rate of 20% (under peer review, registered at ClinicalTrials.gov NCT04996654). This is consistent with recent systematic reviews synthesizing mean attrition rates of 17% (range, 0 to 59%) [198] in physical training interventions, 10% for combined motor-cognitive training interventions [199], and 15% (range 0%-31%) [200] for exergame-based interventions for patients with m-MNCD. Therefore, an attrition rate of 20% is anticipated. To ensure an adequate number of participants, a wide upper safety margin for an attrition rate of up to 40% is selected.

On the basis of these considerations, we will aim to recruit 17 to 20 older adults with mNCD per group, leading to a total sample size of 34 to 40. This will provide a sufficiently precise estimate of the treatment effect to minimize the sample size needed for a future full-scale RCT [193].

Randomization

Sequence Generation

Participants will be randomly allocated to the intervention or control group. Variable block randomization (ie, block sizes=4, 6, and 8) with a 1:1 allocation ratio stratified by sex and institute (study center) will be used.

Allocation Concealment Mechanism

To ensure allocation concealment, random allocation will be computer generated using a validated variable block randomization model implemented in the data management system Castor EDC (Ciwit BV) [201].

Implementation

Randomization process will be set up by PM before starting patient recruitment. PM will also oversee the enrollment of participants. Participants will individually be assigned to the intervention or control group by the investigator responsible for supervision and correspondence with the respective study participant after completing premeasurements. Randomization allocation can be viewed in eCRFs by investigators who have been assigned right to do so. The eCRF is implemented in the Castor EDC data management system [201]. None of the investigators performing postintervention measurements will have access rights to view the randomization allocation in eRCFs.

Blinding

Outcome evaluators of pre- and postintervention measurements will be blinded to the group allocation (single blinding). To ensure blinding and blind-keeping of outcome assessors, detailed study-specific guidelines for all relevant procedures related to blinding and blind-keeping of outcome assessors have been established, which will be followed by all involved study investigators. For data assessed throughout the intervention period (ie, only applicable to the intervention group), blinding of investigators is not possible. The blinding of participants will also not be possible because usual care will be used as a control intervention.

Participant Retention

Once a patient is included, a trained investigator will be assigned as the person responsible for supervision and correspondence with the respective study participant and will make all reasonable efforts to achieve participant's retention in the study. Examples include providing written information sheets and reminders about study appointments, involving carers or relatives as personal support for study participants, and providing assistance with travel to the study center. Specifically, in the intervention group, each participant is provided with a training manual that is individually adapted to ensure that they use the training system correctly.

Data Management

All study investigators will be thoroughly trained for all study procedures according to the Guidelines of Good Clinical Practice and in line with detailed working instructions and a data management plan (Multimedia Appendix 1). In short, local principal investigators are in charge for methodological standards and quality of data collection using data management system Castor EDC (Ciwit BV) [201]. The data management

XSL•FO
RenderX

plan specifies standard procedures for data management, evaluation, and storage. All data entries will be cross-checked by a second investigator before exporting for analysis. Range checks for data values were preprogrammed for data entry into the eCRFs. To minimize bias during the assessment of all clinical outcome measures, detailed working instructions were prepared, including standardized measurement procedures and standardized instructions of participants for all measurements.

Statistical Methods

Statistical analysis will be executed using R (The R Foundation), in line with RStudio (RStudio Inc). For demographics as well as training adherence and compliance, all collected data will be included (ie, including data of dropouts up to the time point of their withdrawal). For primary and all secondary outcomes, the data of all participants who completed pre- and postintervention measurements, regardless of protocol adherence, will be included in the statistical analyses. Questionnaire scores will be regarded as ordinal data. Data will be reported as mean (SD) values for continuous parametric data and median (IQR) values for continuous nonparametric data.

For all outcomes, descriptive statistics will be computed first. Normality distribution of data will be checked using the Shapiro-Wilk test. The level of significance will be set to $P \leq .05$ (2-sided, uncorrected).

For all demographic variables, between-group differences (ie, intervention vs control) will be tested using an independent *t* test or Mann-Whitney *U* test in case the data are not normally distributed. For primary and secondary outcomes, the assumption of homogeneity of variance will be checked using Levene test. In case all assumptions for a 2-way analysis of covariance (ANCOVA) are met, effectiveness of the "Brain-IT" training will be analyzed using a two-way ANCOVA with the premeasurement value as covariate for the predicting group factor and the postmeasurement value as outcome variable [202]. If not all assumptions are met, the Quade nonparametric ANCOVA will be used. Because of the stratification by sex in the randomization process, no sex-specific statistical analysis will be computed. However, if there are relevant between-group differences in sex distribution or other demographic variables, these will be included in the statistical analyses as additional covariates. To determine whether the effects are substantive, partial eta-squared (η^2_p) effect sizes will be calculated for all primary and secondary outcomes. Effect sizes will be interpreted as small ($0.01 \leq \eta^2_p < 0.06$), medium ($0.06 \leq \eta^2_p < 0.14$), or large ($\eta^2_p > 0.14$) [203].

Statistical analysis will be performed by PM after data collection is completed. As this is a small-scale RCT, no interim analysis will be performed.

Monitoring

External monitoring will be performed at three time points: (1) before starting recruitment (site initiation visit); (2) after inclusion of 10 participants (routine monitoring visit); and (3) after completing all postintervention measurements and database lock (close-out visit) by Dr Ruud Knols (Physiotherapy and Occupational Therapy Research Centre, Directorate of Research and Education, University Hospital Zurich). Monitoring activities will be performed according to the ICH-GCP and according to a detailed monitoring plan that is based on adaptations of the "Monitoring Plan Template" of the Swiss Clinical Trial Organization to meet study-specific requirements.

Ethics and Dissemination

Research Ethics Approval and Protocol Amendments

The study protocol was approved by the Ethics Committees of Zurich and Eastern Switzerland (EK-2022-00386). Any substantial amendment to the study protocol will have to be approved by the Ethics Committees of Zurich and Eastern Switzerland, and the trial registration at clinicaltrials.gov (NCT05387057) will be updated accordingly. Any substantial amendments to the study protocol that may occur after publication of this study protocol will be reported in the final publication of the study results.

Consent or Assent

As described in detail in section "Methods - Recruitment", suitable patients willing to take part in the study will provide written informed consent in a second in-person meeting with one of the trained investigators of the study team at the interested persons home or at one of the study centers, depending on their preferences.

Confidentiality

Measures to ensure data confidentiality are detailed in the data management plan (Multimedia Appendix 1).

Access to Data

As detailed in the data management plan (Multimedia Appendix 1), anonymized data sets from this project that underpin a publication will be deposited in the Zenodo repository and made public after completing data collection.

Ancillary and Posttrial Care

In the event of study-related damage or injuries, the liability of the institution ETH Zurich provides compensation, except for claims arising from misconduct or gross negligence. Insurance is covered by ETH Zurich public liability insurance (Police Nr 30/4.078.362 of "Basler Versicherung AG"). After completion of study participation, all participants will be offered to use the training device at their own responsibility, either by purchasing a "Senso Flex" (if market launch of the "Senso Flex" has already taken place at that time) or by using a "Senso" in one of a nearby physiotherapies, nursing homes or rehabilitation clinics offering the system.

Dissemination Policy

Each participant will be informed of their personal results by providing a written report summarizing the patients' relevant results. The report will be handed out in person and explained by a trained investigator to ensure that the patients understand their results. In addition, upon request, an information letter will be sent to participants at the end of the study to inform them about the findings obtained in this study.

A manuscript of the results will be published in a peer-review open-access journal as well as on ResearchGate and original

XSL•FO
RenderX

data sets will be made available in a publicly accessible repository. Standard journal authorship criteria will be applied; there will be no use of professional writers. In addition, the results of this study will be disseminated via open-access journal articles and conference presentations to inform health care professionals, the public, and other relevant groups about the study results and the knowledge gained.

Results

Upon the initial submission of this study protocol, 13 patients were contacted by the study team. Four patients were included in the study, 2 were excluded because they were not eligible, and 7 were being informed about the study in detail. Of the 4 included patients, 2 already completed all premeasurements and were in week 2 of the intervention period. Data collection is expected to be completed by December 2023. A manuscript of the results will be submitted for publication in a peer-reviewed open-access journal in 2024.

Discussion

Principal Findings

This RCT will systematically evaluate the effectiveness of a newly developed nonpharmacological exergame-based training targeted at improving cognitive functioning in older adults with mNCD. The results of this study should provide information on whether the addition of our modified and improved exergame-based training (according to the "Brain-IT" training concept) to usual care is effective in improving global cognitive functioning, and a future full-scale RCT is warranted. The study will thus contribute to the evidence base in prevention of disability because of cognitive impairment, which has been declared a public health priority by the World Health Organization [33].

Comparison With Prior Work

Technological innovations (eg, exergames) provide new options to engage older adults with mNCD in (simultaneously-incorporated) motor-cognitive training [70]. So far, only 1 study has applied exergame-based training that was individualized content-wise based on the cognitive abilities of older adults with mNCD [82]. Furthermore, most previous studies used commercially available exergame systems [76-82], where the training content was not specifically developed for individuals with mNCD. These studies have shown rather limited effects on global cognitive functioning [63], although combined motor-cognitive training seems to be the most effective type of training for improving cognition in older adults with mNCD [61,63-65].

Limitations

There are some limitations to this RCT that must be mentioned. First, we will only explore the effectiveness of the addition of the "Brain-IT" training concept to usual care. In line with this, the sample size for this RCT was justified to provide a sufficiently precise estimate of the treatment effect to minimize the sample size needed for a future full-scale RCT [193]. As a result, the statistical analyses will most probably be insufficiently powered, and confirmatory studies are needed following this study. Second, usual care interventions are assessed by self-report of patients. To counteract possible biased information, the study team will ask specific questions about whether participants are engaged in typical usual care interventions (as described in section "the Methods and Materials section—Interventions—Control Group") and actively involve participants' proxies when collecting this information. Third, patients screened for MCI according to predefined criteria are recruited in addition to patients with a clinical diagnosis of mNCD, which will increase the heterogeneity of the study population. In line with this, in our project, we aim to investigate an individualized exergame-based training concept not only to treat clinically diagnosed patients with mNCD but also to prevent progression to dementia in individuals at risk who might not have been diagnosed (yet).

Conclusions

This study will contribute to the evidence base in the highly relevant area of prevention of disability because of cognitive impairment, which has been declared a public health priority by the World Health Organization.

Acknowledgments

This sponsor-investigator initiated study is funded by Synapsis Foundation—Dementia Research Switzerland (grant 2019-PI06) and "Gebauer Stiftung," and financially supported by "Fondation Dalle Molle." "Senso Flex" training systems are provided free of charge by Dividat AG for the duration of the study. Neither the funder nor Dividat AG played any role in the design of this study, nor did they play any role in the collection, management, analysis, and interpretation of data, writing of the report, or decision to submit the report for publication.

Authors' Contributions

PM was responsible for the conception and writing of the study protocol under the supervision of EdB. LM and AS contributed to magnetic resonance imaging methodology, and FB contributed to the recruitment strategy and eligibility criteria for participants. All authors have contributed to the revision of the manuscript. All authors have read and approved the submitted version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Although many autistic children receive massage as a complementary therapy, it is not included in evidence-based practice for autism because evidence of its efficacy is lacking. Further, prior studies have failed to identify objective indicators of core symptoms or elucidate their mechanisms.

Objective: We developed a parent-delivered traditional Thai massage (TTM) intervention for children with autism, aiming to experimentally determine whether children with autism truly experience positive effects from parent-delivered TTM and determine possible mechanisms of the observed effects.

Methods: A 2-armed, parallel randomized controlled trial was conducted between February 2022 and June 2022. Forty-eight children with autism (aged 7-12 years) were recruited from the Hainan Special Education School and randomly assigned to either a parental TTM or control group at a ratio of 1:1 based on random numbers generated with Online Research Randomizer. The generated sequences were concealed in an opaque envelope. Individuals in the parental TTM group received 16 parent-delivered TTM sessions over 8 weeks at the school's health room after school, and the control group maintained a normal daily routine. Outcomes were assessed on admission, after 8 weeks, and at a 2-month follow-up and included the effect of massage treatment on autism symptoms, measured with the Autism Treatment Evaluation Checklist score (evaluated by parents and a blinded teacher), physiological parameters (ie, heart rate variability and gait), and the Parenting Stress Index, Fourth Edition–Short Form.

Results: We finished all data collection on June 20, 2022. Data analysis will be started, and we expect to publish results in 2023.

Conclusions: This study will provide further evidence for massage treatment of autism and provide support for family-based care.

Introduction

Background

Autism is a neurodevelopmental disorder that affects central nervous system development. The core symptoms are characterized by social interaction and social communication deficits and restrictive-repetitive behavior patterns [1]. The disorder is not associated with any particular culture, ethnicity, race, or socioeconomic group [2]. The majority of individuals with autism also have motor disorders, sensory disorders, anxiety, hyperactivity, sleep disorders, or autonomic nervous system (ANS)-associated disorders [3-5]. The prevalence of autism has risen rapidly in the last decade. An assessment commissioned by the World Health Organization in 2012 estimated the global prevalence of autism to be approximately 1% [6]. An updated report from the US Centers for Disease Control and Prevention showed that 1 in 44 children aged 8 years was estimated to have autism spectrum disorder (ASD) [7]. A survey found that the incidence of autism among children in China was comparable to that in Western countries [8].

A variety of motor disorders are common in autism [9]. Postural [10] and gait abnormalities [11,12] can appear as early as infancy [13] and persist into childhood [14,15] and adulthood [16]. Previous studies showed that motor impairment may result in atypical movement [17] and limit social interaction [18] due to sensory integration impairment [16]. This could, in turn, lead to the development of core autistic symptoms [18,19] and reduced quality of life [20].

The core symptoms of autism can be explained in part by ANS dysregulation [3,21,22]. Messina et al [23] found sympathetic activity, such as heart rate variability (HRV; the variation in time between each heartbeat), which is controlled by the ANS, may be considered an important tool for autism assessment. Measurements of HRV are considered to be the standard noninvasive method for assessing ANS function [23] and have also been suggested to be a valuable situation-specific marker of the effective regulation of children's binary social interactions [24]. Previous reports showed that tonic HRV was significantly reduced in children with ASD compared with typically developing children [22,25]. Lory et al [25] suggested that ANS disorders in autism may lead to atypical attentional responses to sensory stimuli.

Atypical sensory responses (hyper- or hyporeactivity to sensory stimuli) are present in 90% of children with autism [26] and have been listed in the core diagnostic criteria for autism in the Diagnostic and Statistical Manual of Mental Disorders, 5th Edition, with abnormal tactile responses commonly reported [27]. Thye et al [19] reviewed the evidence of a relationship between sensory and social behavior in autism, especially in terms of touch and tactile processing irregularities, and concluded that it may be associated with social dysfunction.

Prior Work

Massage is a touch-based therapy [28] defined as the use of the hands, feet, arms, or elbows to touch or manipulate the body surface of the person being massaged for healing and maintenance purposes [29]. Massage originates from human instinct and was developed as a kind of technology by the ancients. Historical records of massage therapy date back 3000 years, and massage therapy is mentioned in the earliest medical book in China, the *Huangdi Neijing* (*The Yellow Emperor's Classic of Internal Medicine*), which recorded the theory of Chinese medicine and massage theory. The value of massage as a form of therapy has been recognized throughout history by ancient civilizations in China, India, Japan, Thailand, and, later, the ancient Egyptians, as well as the Greeks and Romans [30]. Since then, massage therapy has been continuously developed and applied, and is widely used in clinical practice to relieve pain, eliminate fatigue, and promote rehabilitation. A review by Field [31] outlined the clinical implementation of massage theory in recent years. Massage has recently been employed as a complementary therapy in the treatment of autism. It has been reported that 11% to 16% of people with autism receive massage therapy [32]. Initial studies in this area of research suggest that massage might have positive impacts on social communication [33,34], stereotypic behavior [35,36], sensory profiles [37,38], and language ability [39,40] in autism. According to research findings, positive touch stimuli can increase oxytocin release [41,42]. Oxytocin is known to be involved in ANS circuit regulation [41], which affects both emotional and social processes [43]. Suitable pressure stimulation is the critical feature of massage, and stimulation of pressure receptors has been shown to result in increased vagal activity. Increased vagal activity is associated with slower heart rate and enhanced attentiveness [31].

Traditional Thai massage (TTM) is believed to have ancient origins and has 3 distinctive features: deep pressure massage, work on meridian (energy) lines, and stretching of the affected muscles and joints. TTM is widely used in health care [44,45] and rehabilitation [46,47]. The results of studies conducted to date suggest that TTM may facilitate immediate and short-term improvement in HRV [48,49] and some gait parameters in nonautistic patients [50,51]. Since an increase in HRV reflects a state of relaxation due to parasympathetic activity induced by TTM, patients either with or without autism can relax and reduce their restrictive-repetitive behavior patterns. Consequently, they should improve their gait pattern and speed. TTM has also been effectively used in the rehabilitation of children with disabilities by the Bangkok Foundation for Children with Disabilities [52]. However, we only found one study [53] that reported the effects of TTM administered by masseurs on autistic behavior, and its methodology and conclusions were questionable [54]. It appears that more research is needed to explore the effects of TTM on autism by using both subjective and objective evaluation.

Furthermore, the refractory and lifelong nature of autism has profound implications for parents of autistic children and evidence shows that parents of children with autism experience more parenting stress than parents of nonautistic children or children diagnosed with other disabilities [55,56]. One recent review suggested that family-based interventions for mental disorders in children are becoming increasingly important, with more positive outcomes when parents are involved in the treatment [57]. Previous research revealed that parents who engaged in a massage-based intervention not only satisfied family-based care needs [58] but also showed relieved anxiety

XSL•FO
RenderX

[42] and strengthened parent-child bonding [37,38,59]. The effects of TTM delivered by the parents of autistic children on these outcome measures have not been verified. This study aims to assess the effects of parental-delivered TTM in children with autism by evaluating changes in symptoms and physiological parameters (ie, gait and HRV). The primary objective of the study is to assess the effectiveness of parental TTM in improving symptoms of autism according to the Autism Treatment Evaluation Checklist (ATEC). Secondary objectives are to evaluate instant and cumulative effects of the parental TTM intervention via an assessment of gait and HRV and explore the relationship between symptom improvement and observed changes in physiological parameters. The tertiary objective is to examine changes in levels of parental stress after parents have administered the TTM intervention. The following four research questions will be addressed: (1) Do core symptoms significantly improve (ie, does ATEC score improve) in autistic children after parental TTM in comparison with the control group? (2) Do HRV and gait indicators significantly improve in children with autism after parental TTM? (3) Is ATEC score improvement related to observed changes in physiological parameters? (4) How does parental stress change throughout the intervention period, as measured by the Parenting Stress Index, Fourth Edition–Short Form (PSI-4-SF)?

Methods

Participants

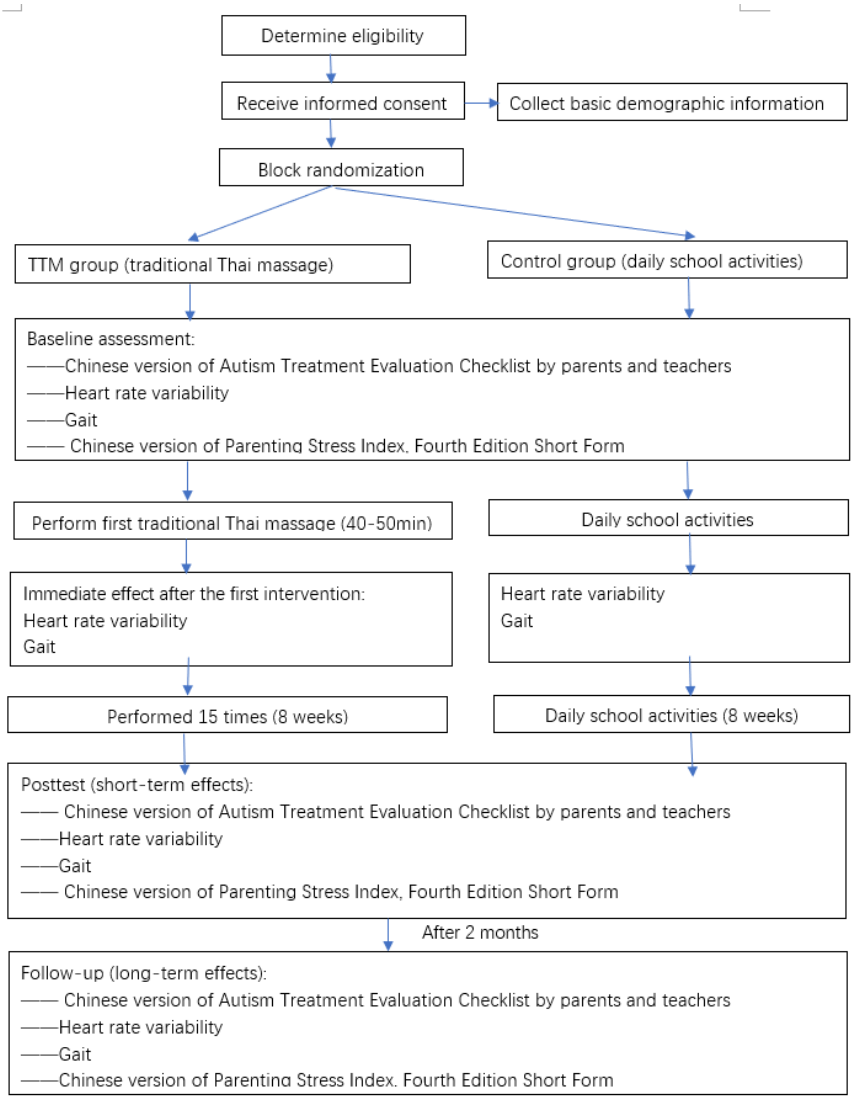
Inclusion Criteria

The following inclusion criteria were applied to select autistic children: they had autism diagnosed by a child psychologist, were aged 7 to 12 years, were not already receiving systemic massage therapy, and were able to follow instructions. The children's primary caregivers met the following criteria: they had been providing ≥1 year of childcare, were able to communicate with the massage trainer, and were able to read the questionnaire. Teachers met the following inclusion criteria: they served as primary caregivers for autistic children at school, had provided care for at least one semester, and were willing to participate in research.

Exclusion Criteria

This study applied exclusion criteria to 3 groups of people: the autistic children, their parents, and their teachers. For autistic children, the following exclusion criteria were applied: contraindications to TTM, such as fractures, fever, or psychoactive medication, and administration of other specialized interventions during the experimental period. Parents were excluded if they were not available at the allotted time. Further, teachers with insufficient time to complete the questionnaire were excluded.

Sample Size



The sample size calculation was based on research by Najafabadi et al [60]; no previous study has used both an autism massage intervention and the ATEC scale. The standard deviation of the social ATEC scores of the 2 groups was used to calculate the sample size needed to achieve a power of 80% and a 2-sided significance level of 5%. A dropout rate of 10% was assumed to determine the principal of intention for estimating the final sample size needed. According to a previously reported formula [61], a total of 48 participants were recruited for the study.

Design and Setting

A randomized controlled trial (RCT) was conducted between February 2022 and June 2022. Participants were recruited from the Hainan Special Education School in Hainan Province, China. A recruiting poster and presentation were posted on the bulletin board at the school. Figure 1 depicts a flowchart of the study protocol prepared according to the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [62] (Multimedia Appendix 1). Before recruiting the participants, informed consent forms (Multimedia Appendix 2) were sent to the parents via the teachers, and if the parents agreed to participate, they signed the form and submitted it to a designated box within 2 days. The children with autism who could communicate with their parents also gave either verbal or written informed consent.

XSL•FO
RenderX

Figure 1. Flowchart depicting the study design.

Randomization

Forty-eight participants (aged 7-12 years) from grades 1 to 6 were randomly assigned to parental TTM and control groups by random numbers generated with Online Research Randomizer (Geoffrey C Urbaniak and Scott Plous). The random numbers were then concealed in an opaque envelope.

Blinding

Since the massage intervention took place after school hours, parents brought their children to the health room, which is located far from the teaching building. Teachers were blinded to the group assignments of the children included in the study. Parents were asked to refrain from discussing the intervention to prevent contamination of the control group. Data collectors were also unaware of group placement.

Ethical Considerations

This study complies with the ethical standards of the relevant national and institutional guidelines on human experimentation and was approved by the Khon Kaen University Ethics Committee for Human Research (HE642167). The study followed the Helsinki Declaration. Results will be published in a peer-reviewed journal and presented at domestic and international academic conferences to further promote communication. This protocol was registered with the Chinese Clinical Trial Registry (ChiCTR2100051355).

Researchers provided parents with information about the study and obtained informed consent from them while their children were in school. The parent or guardian signed the document and returned it to the school researcher or the teacher. Before the study, the parents were responsible for asking their children about their willingness to participate in the study. Children whose parents provided informed consent took part in the study. The researchers explained the study methods verbally to the children and parents and demonstrated the tests that would be performed on the children; the teachers and parents observed each child's reaction to determine if the child consented or not before the test.

In the massage group, the participants were paid US $7 for each TTM session. In the control group, each volunteer participated in the evaluation 4 times and was paid US $7 each time. The decision was made that after data collection was finished, if good results were obtained in the parental TTM group, the control group would also be given training in TTM. Each teacher

XSL•FO
RenderX

volunteer who participated in the 3 stages of assessment received US $30 for each stage.

Intervention

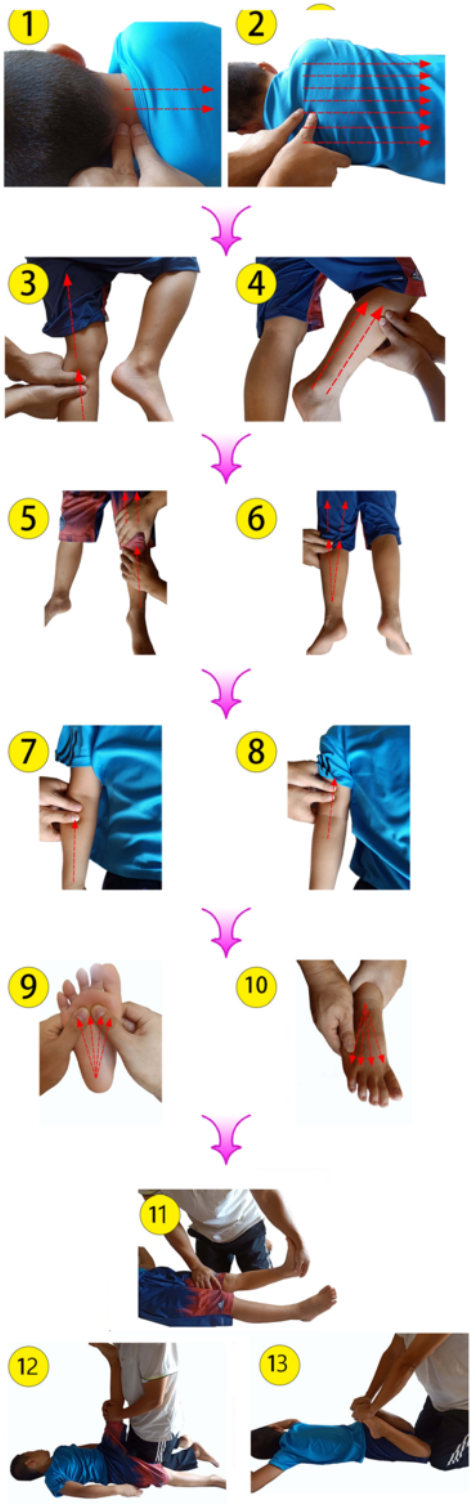
Children assigned to the TTM group received sixteen 40-to-50-minute parent-delivered TTM sessions over an 8-week period (2 sessions per week) in the health room of the school after school had finished. Gifts and rewards were given to parents and children to increase intervention adherence rates. The control group maintained a normal daily routine when in school.

TTM Training

The parents of autistic children who were enrolled in the study took part in 3 TTM training sessions. Each 3-hour session was hosted by experts at the health room of Hainan Special Education School. Parents of participants in the intervention group were trained in TTM by an experienced traditional Thai masseur with a massage qualification until they became able to perform the experimental intervention. Thereafter, the massage trainer monitored the parents to ensure that they continued to perform TTM properly at each session.

TTM Procedure

The TTM method involves pressure massage and muscle stretching. Pressure massage involves massaging with the thumbs and pressing with the palms until slight muscle resistance is felt. The children may feel slight muscle tightness, but the massage should not be painful. The masseur will maintain pressure for 5 to 10 seconds and then release it to allow energy or blood to flow freely around the massage area; this is repeated 2 to 3 times for each body part. Muscle stretching includes the masseur observing the children and asking them whether they feel that the stretch is too deep; if the stretch is acceptable, they hold the appropriate position for 15 to 30 seconds [63]. The 9 steps of TTM are based on standard practice. However, they have been modified for this patient population: gentle touch is used to facilitate relaxation and promote social communication, motor control, and a sense of confidence in and love for the children. Starting from the head and continuing to the limbs easily promotes relaxation. Stretching at the end of the session is one of the principles of TTM.



In the starting position, the children lie on their side with the upper leg bent at the knee forming a 90° angle with a pillow placed under the head and a straight lower leg. The parent performing the massage kneels or sits behind the child. Massage strategies for distinct massage types should be performed as described in Table 1 and Figure 2.

Table 1. Traditional Thai massage procedures for children with autism and the order in which they are performed.

Target area	Description of procedure
1. Neck (lateral position)	Massage is started in the neck region and extends along the back muscles toward the lumbar area. Massage is performed along the side of the neck toward the shoulders.
2. Back and waist	The paravertebral muscles, which are close to the thoracolumbar spine, are massaged toward the waist level. There are 3 lines of massage. One is started on the upper back near the spinous processes of T1 to L5 on each side of the back. The second line is about 1 cm along the side of the first one. The third line is about 1 cm along the side of the second one. A pressing massage style should be applied on the 3 lines, which should be initiated in the thoracolumbar region and continue toward the top of the sacrum.
3. Inner thigh (straightened legs)	Thumb pressure should be applied to the medial side of a straightened leg from the Achilles tendon toward the groin (along the line in panel 3 of Figure 1). This type of massage should be performed along 2 massage lines. The first massage line extends along the medial side of the leg, and the second massage line extends along the backside of the leg.
4. Outer leg massage (on the bent leg side):	Both hands are placed on the lower leg of the child. The lateral part of the lower leg should be pushed down using the thumb. This massage style should be applied from the area above the lateral malleolus and continued to the side of the knee joint. The top of both knees are pressed toward the middle of the hip. Outer leg massage should be performed along the 2 massage lines. The first line extends along the front of the leg, and the second line is positioned slightly behind the first line.
Repeat on opposite side	The child lies on the other side and procedures 1 to 4 are repeated.
5. Leg (supine position)	Massage is performed in front of the ankle to near the groin.
6. Leg massage (prone position)	Massage is initiated behind the heel around the Achilles tendon and continues toward the gluteal and hamstring muscles.
7. Arm	With the child in a prone position, thumb pressure is applied along the back of the lower and upper arm toward the shoulder. The procedure is then repeated on the other arm. In the supine position, push massage is applied upward from the center of the forearm and along the center of the arm toward the axilla.
8. Foot (supine position)	A foot massage is performed by applying pressure from the heel to all 5 toes. Then, the tip of each toe should be pulled gently.
9. Muscle stretch (the appropriate position is held for 15 to 30 seconds)	With the child in a supine position, the heel is stretched and the child's foot is lifted until tension is felt. In the prone position, the child's knees are flexed as much as possible by applying gentle pressure to the soles of the feet.

XSL•FO
RenderX

Figure 2. Traditional Thai massage procedure: (1) neck massage, (2) back and waist massage, (3) inner thigh massage, (4) outer leg massage, (5) leg massage in the supine position, (6) leg massage in the prone position, (7, 8) arm massage, (9, 10) foot massage, and (11-13) muscle stretching. The procedure is performed in the numbered order.

Fidelity

The fidelity measurement represents the number of times parents use massage with their children, incorporating any adjustments to the massage technique made by the expert. More than 90% attendance is expected, and the expert will correct improper technique in real time.

Primary Outcome Measurement: ATEC

The ATEC questionnaire was developed by Dr Bernard Rimland and Dr Stephen M Edelson at the Autism Research Institute in the United States in the mid-1990s to help researchers and parents evaluate the effectiveness of various treatments for autistic children and adults [64]. It is not used to diagnose autism. It comprises 4 subscales: speech, language, and

XSL•FO
RenderX

communication; sociability; sensory and cognitive awareness; and health and physical behavior. The maximum score is 179, with higher scores indicating autism of increased severity. The sensitivity and specificity of the Chinese version of the ATEC total scale and its subscales have been determined to range from 0.922 to 0.987 and 0.803 to 0.887, respectively; the scale has also been determined to have high reliability [65].

Secondary Outcome Assessments

Gait

Gait was measured using a wearable BTS G-Walk device (BTS Bioengineering Company). Experimental gait data were collected at a frequency of 100 Hz and transmitted to a computer via a Bluetooth connection. All gait parameter measurements have been determined to have high test-retest and intertrial reliability (intraclass correlation coefficient: 0.728-0.969 and 0.84-0.99, respectively) [66,67]. Wireless internet was required for the gait tests, which were carried out on a flat surface that measured at least 10 × 10 m. Prior to performing the test, the height of the participant was entered, and an adjustable elastic band was placed around the participant's waist. When taking the test, participants stood in place for a few seconds. After confirming that the sensor was connected to the computer via Bluetooth and the connection was stable, each child volunteer followed a marked 7-m path back and forth while walking normally. Teachers or parents were allowed to provide verbal cues but not physical assistance.

HRV Measurement

UBiomacpa (version 1; Biosense Creative) was used to detect the activity of the autonomic nervous system. The HRV test was carried out in an independent, quiet room at an ambient temperature of 26 °C. Before starting the test, the tester ensured that the equipment was properly connected. After receiving TTM, the autistic children were placed in a sitting position with a pulse sensor attached to their left index finger, and they underwent an HRV test for 2 minutes that was administered by a physiotherapist. When the test was complete, the device automatically generated a data report via a connected computer.

PSI-4-SF Assessment

The PSI-4-SF consists of 36 items in the following 3 dimensions: parent distress, parent-child dysfunction interaction, and difficult child [68]. The Chinese version of the PSI-4-SF has an internal consistency and reliability that ranges between 0.92 and 0.95 for each subscale. For the whole scale, the value is 0.97, indicating that this scale has good consistency and stability [69].

Data Collection, Management, and Analysis

IBM SPSS (version 25; IBM Corp) will be used for data analysis. Missing outcome data will not be imputed in the analysis, but the multiple imputation method will be used to explore the potential impact of missing data on outcomes. Demographic data will be expressed as means with standard deviation and percentages. $P<.05$ will be considered statistically significant. Holm correction of P values will be applied for multiple comparisons to compare the immediate effects of TTM for autistic children and effects in the short and long term. The primary outcome is the ATEC score, which will use generalized estimating equations. Time will be the covariate and the model will include group, time, and the group × time interaction. A 2-tailed paired t test or Wilcoxon signed-rank test will be used to test ATEC score, HRV, and gait parameters, as well as PSI-4-SF score changes within each group after testing for normal distribution. The relationship between physiological effects and ATEC results will be evaluated using a correlation test. A coefficient value <0.4 indicates a low degree of correlation, a value between 0.4 and 0.7 indicates a medium degree of correlation, and a value >0.7 indicates a high degree of correlation between variables.

Two trained assessors will be responsible for data collection, electronic double entry of the data, and management of the database. A team from the Key Laboratory of Data Science and Smart Education at Hainan Normal University, which is independent of the study team, will be responsible for data monitoring.

Harms

No adverse events from TTM interventions have been reported in previous studies. Furthermore, in both intervention and control groups, data collection did not cause physical harm to the children and did not create psychological, social, or financial risks. If there is a risk of affecting the body (ie, pain or injury) or mind (ie, dissatisfaction, discomfort, hate, or boredom) of any participant, we decided to temporarily suspend or stop that individual's participation and data gathering. Moreover, if any severe adverse events, such as death or other medical occurrences resulting in hospitalization, were to occur during the massage intervention sessions, the researcher planned to terminate the intervention and immediately report the event to the nearest local hospital in China. The researchers will report whether any such adverse events occurred to the ethics committee as required and describe them in the final paper.

Confidentiality

The research group will keep the data confidential, and the research group will use passwords to record and access data. In this study, only the research group will have access to the data, and the research group will not state the names of the participants under any circumstances if the study results are published in a journal. The participants' personal information will be stored in a specific file with a preset code.

Ancillary and Posttrial Care

Participants could contact the researchers during the trial or 1 month after participation ended. Plans were made for participants with serious adverse events to receive a timely and appropriate response.

Patient and Public Involvement

The patients and public will not be involved in the design, conduct, reporting, or dissemination of this research.

Results

We finished all data collection on June 20, 2022. Data analysis will be started, and we expect results to be published in 2023.

XSL•FO
RenderX

The normal distribution of the data will be determined before descriptive statistics for all variables are calculated. The participants' demographic information will be reported as descriptive data. The primary outcomes will be expressed as continuous variables, and generalized estimating equations will be used to evaluate the effect of TTM on the children (via the ATEC score) at 3 time points: immediate, short term, and long term. Changes in physiological parameters (ie, HRV and gait parameters) after the intervention will be analyzed. Further, the relationship between ATEC score and physiological parameters will be identified with a correlation analysis. Finally, changes in parental stress throughout the intervention period will be investigated with the PSI-4-SF.

Discussion

This study aims to assess the effects of parent-delivered TTM in children with autism by evaluating changes in symptoms and physiological parameters (ie, gait and HRV). In practice, massage has previously been used to treat autism. However, this treatment has not been included in evidence-based practice for autism due to the lack of long-term, extensive scientific research to supports its use. At present, studies of interventions have mainly focused on qigong massage and tui na massage. Furthermore, we found that outcome measures in most prior studies were based on questionnaires and scales evaluated before and after the intervention, and that there was a lack of studies that explored the mechanisms that underlie core symptom improvement. Presumably, massage adjusts the body and mind via sensory processes [70,71] and neural and hormonal regulation (eg, changing oxytocin levels).

In comparison with prior work, this will be the first RCT to explore parental TTM in terms of its physiological and psychological effects on children with autism. We will use objective indices to investigate possible mechanisms underlying the observed effects. Our study may highlight the value of complementary and alternative therapies for adjunctive treatment of autism to enhance family-based interventions. Both parents and blinded teachers will be evaluated for effects that might cause bias. Finally, the variability of massage manipulation by parents was minimized by expert training, examinations, and supervision.

Acknowledgments

We would like to thank the teachers and staff at the school and the students who participated in this study. The authors thank Dr Glenn Borlace for English language assistance through the publication clinic at Khon Kaen University. This work was supported by the Humanity and Social Science Youth Foundation of the Ministry of Education (18XJC890004) and the Research and Service Institute of Autism Project (RSIA015). The funders of the study had no role in the study design, data collection, data analysis, data interpretation, or writing the report.

Data Availability

Data sharing is not applicable to this study as no new data were generated or analyzed. The data sets generated or analyzed after the experiments will be made available from the corresponding author on reasonable request.

Authors' Contributions

HR and WE contributed to conceptualization. HR, WE, and CA contributed to design and methodology. HR contributed to investigation. HR and HW contributed to writing the original draft and revision.

Conflicts of Interest

None declared.

Abstract

Background: Extracorporeal membrane oxygenation (ECMO) provides support for the pulmonary or cardiovascular function of children in whom the predicted mortality risk remains very high. The inevitable host inflammatory response and activation of the coagulation cascade due to the extracorporeal circuit contribute to additional morbidity and mortality in these patients. Mixing nitric oxide (NO) into the sweep gas of ECMO circuits may reduce the inflammatory and coagulation cascade activation during ECMO support.

Objective: The purpose of this study is to test the feasibility and safety of mixing NO into the sweep gas of ECMO systems and assess its effect on inflammation and coagulation system activation through a pilot randomized controlled trial.

Methods: The Nitric Oxide on Extracorporeal Membrane Oxygenation in Neonates and Children (NECTAR) trial is an open-label, parallel-group, pilot randomized controlled trial to be conducted at a single center. Fifty patients who require ECMO support will be randomly assigned to receive either NO mixed into the sweep gas of the ECMO system at 20 ppm for the duration of ECMO or standard care (no NO) in a 1:1 ratio, with stratification by support type (veno-venous vs veno-arterial ECMO).

Results: Outcome measures will focus on feasibility (recruitment rate and consent rate, and successful inflammatory marker measurements), the safety of the intervention (oxygenation and carbon dioxide control within defined parameters and methemoglobin levels), and proxy markers of efficacy (assessment of cytokines, chemokines, and coagulation factors to assess the impact of NO on host inflammation and coagulation cascade activation, clotting of ECMO components, including computer tomography scanning of oxygenators for clot assessments), bleeding complications, as well as total blood product use. Survival without ECMO and the length of stay in the pediatric intensive care unit (PICU) are clinically relevant efficacy outcomes. Long-term outcomes include neurodevelopmental assessments (Ages and Stages Questionnaire, Strength and Difficulties Questionnaire, and others) and quality of life (Pediatric Quality of Life Inventory and others) measured at 6 and 12 months post ECMO cannulation. Analyses will be conducted on an intention-to-treat basis.

XSL•FO
RenderX

Conclusions: The NECTAR study investigates the safety and feasibility of NO as a drug intervention during extracorporeal life support and explores its efficacy. The study will investigate whether morbidity and mortality in patients treated with ECMO can be improved with NO. The intervention targets adverse outcomes in patients who are supported by ECMO and who have high expected mortality and morbidity. The study will be one of the largest randomized controlled trials performed among pediatric patients supported by ECMO.

Introduction

Extracorporeal membrane oxygenation (ECMO) has gained widespread acceptance as a rescue treatment for refractory cardiovascular and respiratory failure among neonates, children, and adults [1-3]. While morbidity and mortality in ECMO are predominantly affected by the severity of preexisting disease, the contribution of iatrogenic factors to patient-centered outcomes is becoming increasingly recognized [4]. Despite major improvements in ECMO devices, the exposure of host blood to large artificial organ surfaces, mechanical cell stress, and reperfusion injury result in the activation of the coagulation system and generate a severe inflammatory response [5]. Studies on extracorporeal circuits (including bypass circuits) have shown that hypoxic-ischemic injury and the release of damage-associated molecular patterns trigger an inflammatory cascade closely related to sepsis-induced systemic inflammatory response syndrome. It is characterized by endotoxin release, leukocyte and complement activation, and widespread activation of inflammatory mediators, resulting in endothelial leak, increased oxygen consumption, and organ dysfunction [6]. Both intrinsic factors and extrinsic factors, such as exposure to injured tissue, contribute to excessive inflammation and coagulation system activation and may be further aggravated by cross talk across the complement and coagulation systems [7]. Therefore, it is not surprising that thrombosis and hemorrhage remain among the most common complications seen with ECMO [8].

These ECMO-related side effects expose patients to substantial morbidity and can lead to death or devastating long-term outcomes, even if the primary reason for requiring ECMO has been resolved. Importantly, some pediatric data show that more than 85% of patients who die during or after their ECMO run have developed either bleeding or clotting complications [9].

Nitric oxide (NO) mediates anti-inflammatory host responses and regulates both endothelial functions as well as microvascular inflammation. The mixing of NO into the sweep gas that runs into the oxygenator in neonates and children undergoing cardiopulmonary bypass has been investigated in several pilot studies with promising results, and a large randomized controlled trial (RCT) has recently been published [10-13]. In this trial, the effects of NO used in a bypass circuit for pediatric cardiac surgery were tested [13]. No effect on mortality or on the duration of ventilation was observed, though the safety of NO was high. The treatment duration on cardiopulmonary bypass is a few hours, whereas ECMO support lasts days to weeks, making the 2 clinical scenarios not directly comparable. In addition, mixing NO into the sweep gas (at 30, 50, and 80 ppm) in an animal model of ECMO significantly reduced the host response, with suppression of tumor necrosis factor α (TNF-α) and interleukin (IL)-6 expression (Fraser J, unpublished data, April 2023). A single-center observational study using historical controls reported the safety and outcomes of NO at 20 ppm mixed into the sweep gas of the ECMO oxygenator. The authors observed a lower blood product administration and a marginal improvement in the survival of patients on NO compared to the historical controls without any NO. There are no randomized studies on the effect of NO mixed into the oxygenator on patients treated with ECMO.

The Nitric Oxide on Extracorporeal Membrane Oxygenation in Neonates and Children (NECTAR) study was designed to investigate in a randomized clinical trial whether mixing NO into the sweep gas in neonates and children treated with ECMO is feasible (recruitment, randomization, and protocol compliance) and safe (accurate NO delivery and methemoglobin levels). Efficacy will be tested by measuring ECMO-free days (the number of days that patients spend alive and free from ECMO is censored at 30 and 90 days) and by assessing the inflammatory host response and coagulation activation. We hereby describe the NECTAR trial protocol.

Methods

The NECTAR trial is an investigator-initiated, 50-patient, open-label, single-center, pilot RCT with neonates and children who require ECMO support.

Study Setting

A tertiary pediatric intensive care unit (PICU) in Australia with approximately 30 ECMO runs annually.

Participants

Eligible children will be identified during the clinical deterioration typically seen prior to ECMO support commencement, such as progressive respiratory, cardiovascular, and cardiorespiratory failure, including cardiopulmonary arrest. If the situation permits, prospective consent will be sought;

XSL•FO
RenderX

otherwise, delayed consent or consent to continue the approach will be applied.

Inclusion Criteria

All infants and children (birth to ≤16 years) that are commenced on ECMO will be eligible for inclusion in the study if there is the ability to obtain prospective consent or consent to continue from parents or guardians. In addition, infants or children that are commenced on ECMO at the colocated Neonatal Intensive Care Unit will be eligible for inclusion in the study. Patients who are commenced on ECMO outside of these units will not be eligible for the study.

Exclusion Criteria

Neonates and children treated with ECMO who were retrieved to the PICU on ECMO, those with preexisting methemoglobinemia (methemoglobin [MetHb]>3%), and patients managed on a ventricular assist device only without an oxygenator were present in the ECMO circuit.

Randomization and Blinding

Treatment group allocation will be performed using a web-based REDCap electronic data capture tool hosted by The University of Queensland [14,15]. A randomization sequence using variable block randomization with a 1:1 ratio was uploaded into REDCap prior to the screening of the first patient. Randomization is stratified by veno-arterial (VA) versus veno-venous (VV) support. Where conversion of VV to VA or VA to VV occurs, patients will remain in the initial randomization allocation and strata. When a second ECMO run is commenced, the patient will be randomized again.

Consent

Prospective consent will be sought from the parents or guardians of any child for whom a decision to be commenced on ECMO has been made. Where possible, this consent will be obtained before the commencement of ECMO. However, due to parental stress and cognitive overload at the time of cannulation, consent can also be obtained following randomization under the consent to continue model (termed “delayed consent” previously) [16]. Prior to or after ECMO commencement, parents will be provided with study information, including printed study flyers and links to web-based study documentation.

Blinding of the Intervention

Blinding is not possible, as the NO delivery device makes a distinctive noise during standard operation. Further, the NO levels need to be adjusted depending on sweep flow, which requires nurses by the side to identify whether NO is being delivered or not.

Interventions

Infants and children will be randomly assigned to receive either NO or standard care. Those allocated to the intervention (NO) will receive 20 ppm of NO mixed into the sweep gas running into the oxygenator during their ECMO run. The NO concentration will be maintained at 20 ppm using a NO delivery system (Sokinox, Maquet), or a similar device. Continuous sampling of NO and NO_2 concentrations is performed by the Sokinox machine by gas aspiration after the NO injection site. Patients allocated to the standard study arm will receive the standard oxygen-air mix in the ECMO oxygenator as per institutional practice and protocol.

Relevant Concomitant Coagulation Management and Intensive Care Treatment

Apart from mixing NO into the sweep gas flow of the ECMO system, no other patient management parameters will be changed, and institutional practices and protocols will be followed. Methods and goals of anticoagulation will remain unchanged for any other ECMO management and treatments, such as decisions to decannulate, ventilation support, inotrope management, fluid intake, fluid removal practices, or antimicrobial or immunological treatments.

Safety Data Monitoring

A data and safety monitoring board (DSMB) will monitor the conduct of the study and the accrual of data. The DSMB will consist of a chairperson (experienced in clinical trials), a pediatric intensivist, a cardiac surgeon, and a statistician. The DSMB will be independent of the study investigators and will monitor adverse events in the study as well as ensure the validity and timeliness of the data collection. The DSMB may advise the Chief Investigator to terminate the trial, which would necessitate safety concerns in this step. The DSMB is expected to meet at least 4 times during the study period.

Monitoring

The study team will be responsible for all documentation of the study nurse’s and the investigator’s training records and credentials. All consent forms will be reviewed by the study team. The perfusion data collection forms will be compared to the source documentation to ensure both the completeness and accuracy of the data. All severe adverse events will be recorded and reported to the local Human Research and Ethics Committee (HREC) as per the institutional guidelines.

Ethics Approval

This protocol and the informed consent document, and any subsequent modifications, have been reviewed and approved by the human research ethics committee (reference number HREC/18/QCHQ/49018). This study will be conducted in compliance with this version of the protocol. Any change to the protocol document or informed consent document that affects the scientific intent, study design, patient safety, or anything that may affect a participant’s willingness to continue in the study is considered an amendment, and therefore will be written and filed as an amendment to this protocol or the informed consent document. All protocol deviations will be reported to the principal investigator, recorded in REDCap, and reported to HREC. Protocol deviations and violations will be assessed for clarification by the principal investigator. The study was approved by the local HREC (HREC/18/QCHQ/49018) and has been registered with the Australian New Zealand Clinical Trials Registry (ACTRN12619001518156). The NECTAR trial commenced recruitment in August 2020

Sample Size

The NECTAR trial is a pilot RCT with the main focus on feasibility, safety, and exploration of efficacy. A sample size

XSL•FO
RenderX

of 50 patients has been chosen in line with the recommendations for pilot studies that anticipate a medium effect size for a continuous primary outcome for the main trial [17].

Data Collection, Management, and Analysis

Data Collection

Baseline variables (demographics, primary diagnosis, comorbidities including syndromes), precannulation disease severity, precannulation surgery (such as cardiac surgery), cannulation technique, primary and secondary end points, as well as predetermined physiological variables of interest, will be recorded and entered prospectively into a purpose-built REDCap database [14,15]. Treatment that is administered continuously (such as heparin or inotropes) will be recorded as maximal values that were maintained for at least 4 hours. Physiological and blood parameters will be recorded precannulation, at 1, 12, and 24 hours post cannulation, and daily thereafter. The duration of circulatory, renal, and ventilatory support on and off ECMO will be recorded. Gross functional performance assessment will be recorded upon admission to the PICU and upon discharge from the hospital [18].

Participant data confidentiality will be ensured by the study coordinator, the research staff, and the institution sponsoring the trial. All data, as well as the study protocol and any other information that this trial may generate, will be held in strict confidence.

Biobanking

Blood samples for inflammatory and coagulation pathway activation will be collected prior to cannulation, as well as at 1, 12, and 24 hours post commencement of ECMO. These samples will be frozen using standard operating procedures and batch tested.

Results

Study Outcomes

The NECTAR trial is a pilot RCT; hence, it will focus on safety and feasibility outcomes in addition to exploring efficacy outcomes as described in Textbox 1. This work was supported by grants from the Children's Hospital Foundation, Brisbane, Australia, and by a grant from the Thrombosis and Hemostasis Society of Australia. The results are expected to be published at the end of 2023 or early 2024.

XSL•FO
RenderX

Textbox 1. Main study outcomes and secondary analyses for the Nitric Oxide on Extracorporeal Membrane Oxygenation in Neonates and Children (NECTAR) trial.

Main study outcomes

- Feasibility outcomes
  - Monthly recruitment rate
  - Randomized to screened patient ratio
  - Compliance with the study protocol (with particular focus on the timing of the initiation of nitric oxide (NO) and the maintenance of NO for the duration of the study)
- Safety outcomes
  - Failure rate of gas delivery
  - Carbon dioxide control of patients
  - Methemoglobin levels
- Efficacy outcomes
  - Host systemic inflammation levels at 1, 12, and 24 hours
  - Coagulation system activation and consumption
  - Clotting and bleeding complications
  - Rate of clotting and bleeding events

Secondary outcomes

- Survival without extracorporeal membrane oxygenation (ECMO), censored at 30 and 90 days post randomization. Patients dying within 30 and 90 days of presentation will be considered as 0 days, to account for the competing effect of mortality on ECMO-free survival.
- Survival free of pediatric intensive care unit (PICU; censored at 30 and 90 days)
- Hospital length of stay post randomization
- Median daily blood product usage
- Complement system activation
- Child neurodevelopment, function, and quality of life at 6 and 12 months, as measured by:
  - Ages and Stages Questionnaire (<5 years of age) OR Strength and Difficulties Questionnaire (>5 years of age)
  - Pediatric Quality of Life Inventory
  - Pediatric Emotional Distress Scale (2-5 years) OR Children's Revised Impact of Events Scale (>5 years)
  - Behavior Rating Index of Executive Functioning – Preschool (2-5 years) OR Behavior Rating Index of Executive Functioning – 2 (>5 years)
  - Vineland Adaptive Behavior Scale
- Parent functioning at 6 and 12 months, as measured by:
  - Parenting Stress Index – Short Form
  - Kessler-6
  - Primary Caregiver – Post Traumatic Stress Disorder Scale

Feasibility Outcomes

The focus will be on the monthly recruitment rate, the randomized to screened patient ratio, and protocol adherence, that is, how many blood collection points, computer tomography scans of oxygenators, and daily indirect oxygenator clot measurements (by extracorporeal life support assessment monitor) were completed.

Safety Outcomes

There will be a focus on sweep gas delivery failure related to NO administration. Specifically, an arterial oxygen saturation of less than 80 due to a sweep gas interruption related to NO administration or carbon dioxide control outside of 30 to 50 mm Hg due to NO administration will be recorded as a safety event. The methemoglobin (MetHb) levels during the time of ECMO will be measured, and events above 3% related to NO administration will be noted.

XSL•FO
RenderX

Efficacy Outcomes

Host inflammation and complement components will be assessed before cannulation and at 1, 12, and 24 hours post cannulation by determining serum concentrations of C-reactive protein, procalcitonin, IL-1b, IL-6, IL-8, IL-10, and TNF-α. At the same time points, coagulation system activation will be assessed by measuring the international normalized ratio (INR), prothrombin time (PT), activated partial thromboplastin time (APTT), thromboelastography (TEG), antithrombin, soluble CD40L, P-selectin, platelet factor 4 levels, and ADAMTS13 release (see Textbox 2). A single measurement of Von Willebrand factor at initiation followed by daily measurements will be performed. After the initial 24 hours, further daily laboratory testing will include D-Dimers, TEG, INR, PT, APTT, anti Xa and activated clotting time (by TEG), and plasma-free hemoglobin. Clotting and bleeding complications and the rate of clotting and bleeding events will be measured. Clotting events are defined as the need to change ECMO circuit componentry due to high transmembrane pressures, high D-Dimers, or high free plasma hemoglobin. Bleeding rates will be measured by both the amount of bleeding per day as well as the daily requirement for blood product administration.

Textbox 2. Coagulation, inflammation, and complement system measurements.

Coagulation system measurements

- Change in granule (soluble CD40 ligand and P-selectin) and chemokine (platelet factor 4) levels released by activated platelets
- ADAMTS13 release
- Change in van Willebrand factor concentrations during and after the extracorporeal membrane oxygenation (ECMO) run

Changes in inflammatory and complement system activation

- Change in C-reactive protein, procalcitonin, interleukin (IL)-1b, IL-6, IL-8, IL-10, and tumor necrosis factor α (inflammatory mediators) levels; Complement (C)1q, Complement Factor B, Complement Factor H, C5a, C9, and Mannose-Binding Lectin (classic and alternate complement pathways); and C3, C3 and CH50.

Secondary Clinical Outcomes

The secondary clinical outcomes include mortality at 30 and 90 days. ECMO-free and PICU-free survival censored at 30 and 90 days post randomization, length of stay at the hospital post randomization, average daily blood product usage, complement system activation with measurements of complement (C)1q, C5a, C9, C3, C4, complement factor B, complement factor H, and Mannose-binding Lectin, as well as neurodevelopmental function and quality of life at 6 and 12 months, will be considered (Textbox 3).

Textbox 3. Subanalyses for the Nitric Oxide on Extracorporeal Membrane Oxygenation in Neonates and Children (NECTAR) trial.

- Cardiac, respiratory, and extracorporeal membrane oxygenation–assisted cardiopulmonary resuscitation outcomes (proportions alive at 30 and 90 days for each group)
- Circuit duration (time to decannulation or time to circuit change) per treatment group
- Renal function measured as creatinine and urine output changes during extracorporeal membrane oxygenation (ECMO) per treatment group
- Renal replacement treatment on ECMO (type of renal replacement therapy, duration of slow continuous ultrafiltration, type of filter, and duration of filter viability)
- Incidence of seizures diagnosed during ECMO or up to 48 hours after decannulation
- Transmembrane oxygenator pressure assessment every 24 hours
- Oxygenator clot volume as assessed by the extracorporeal life support assessment monitor
- Oxygenator clot volume (by computer tomography imaging)
- Hemolysis (plasma-free hemoglobin) per treatment group
- Mean daily heparin dose per kg required to meet target anticoagulation per treatment group

Subanalyses

We will further investigate the oxygenator's function and structure. The former will be done by postoxygenator blood gas sampling, and the latter by oxygenator clot volume assessment by computer tomography scanning. Outcomes by age group (<28 days, 28 to 365 days, and greater than 365 days) will be analyzed.

Statistical Analysis Plan

Analysis Plan

Descriptive statistics will be used to report the baseline characteristics of the total study cohort and each subgroup. The primary efficacy outcome measure investigating days free of ECMO will be analyzed using quantile regression incorporating treatment group and VA or VV support (stratification variable) as fixed effects, with the treatment group effect estimate and 95% CI reported (assuming the data is abnormally distributed).

XSL•FO
RenderX

Exploratory subgroup analysis by cardiac, respiratory, and ECMO-assisted cardiopulmonary resuscitation support will be performed. Analysis of secondary outcomes includes comparisons of measurements and proportions, with confidence intervals of differences as the major method of presentation. The primary analysis will be by intention-to-treat. If appropriate, per-protocol analyses will be performed as well and compared to the intention-to-treat. Statistical significance will be set at the .05 level and no adjustment for multiple comparisons will be made, noting the exploratory nature of the analysis. CIs will be generated using quantile regression for abnormally distributed continuous data, a 2-sided *t* test for normally distributed data, and a test of 2 proportions for binary data.

Long-term Outcomes

Neurodevelopmental and functional outcomes (using phone interviews and web-based questionnaires) will be documented at baseline (assessment of premorbid function during PICU admission) using the test battery described in Table 1. Assessments will focus on neurodevelopment, quality of life, executive functioning, adaptive behaviors, functioning, and parental outcomes. Assessments will occur at 6 and 12 months post cannulation. The following will be used for children younger than 5 years (for respective neurodevelopmental assessment areas): (1) ages and stages questionnaire, (2) pediatric emotional distress scale, and (3) behavior rating index of executive functioning for preschoolers. For all other children (and other neurodevelopmental function assessments), the following will be used: (1) strengths and difficulties questionnaire, (2) children's revised impact of events scale, (3) vineland adaptive behavior scale, (4) pediatric cerebral performance category, (5) pediatric outcome performance category, and (6) pediatric quality of life inventory. For parental outcomes, the Kessler scale, as well as the Primary Carer – Post Traumatic Stress Disorder and Parenting Stress Index – Short Form will be used.

The neurodevelopmental outcomes will be reported separately from the main study.

Table 1. Long-term outcome measures at 6 and 12 months after pediatric intensive care unit discharge.

Measure	<5 years of age	≥5 years of age
Neurodevelopment	Ages and Stages Questionnaire (ASQ)	Strengths and Difficulties Questionnaire (SDQ)
Quality of life	Pediatric Quality of Life Inventory	Pediatric Quality of Life Inventory
Distress	Pediatric Emotional Distress Scale (2-4 years) (PEDS)	Children's Revised Impact of Events Scale (≥5 years) (CRIES)

Adverse Events

Given the severity of the underlying disease leading to the requirement for ECMO, patients are expected to have a high rate of adverse events unrelated to the study intervention. Events that are in the expected range of adverse events during standard treatment will therefore not be reported as related to the study intervention, as previously described [19]. Adverse events that are likely related to the study intervention will be reported. Adverse events likely related to NO delivery during ECMO support, such as failure to deliver sweep gas to the oxygenator, poor patient carbon dioxide control due to sweep gas failure, and increased MetHb (MetHb >3%) at any of the blood gas sampling points, will be reported [11,12]. Death will be reported as an adverse event and will be assessed as to whether it may be related to the study intervention. The study team, together with the treating physician, will assess each patient's case and make an initial assessment of whether death occurred due to the intervention. The final assessment is to be confirmed with the DSMB.

Discussion

Principal Findings

The NECTAR trial will be the first RCT to assess the effect of NO on bleeding, clotting, and inflammatory complications in neonates and children supported on ECMO. It will establish the feasibility and safety of the procedure to allow the design of a trial powered for patient-centered outcomes.

Children requiring ECMO support continue to have a very high mortality risk. Both bleeding and clotting events are significantly associated with mortality and morbidity in this group of patients, and—in combination with inflammatory activation—they continue to pose a challenge to which no therapeutic answer has been found to date. The addition of NO to the sweep gas to reduce bleeding, clotting, and inflammatory complications is a promising therapeutic approach that has so far only been tested in vitro, in historical comparisons, or in RCTs on cardiopulmonary bypass settings rather than ECMO. Given the anticipated high safety of the intervention, the approach has the potential to improve patient-centered short- and long-term outcomes.

XSL•FO
RenderX

Limitations

The patient group requiring ECMO is very heterogeneous, and due to the pilot study size, achieving a normal distribution of risk factors in the 2 study groups may be unlikely. In addition, this pilot trial is not powered to assess associations between the intervention and clinical outcomes such as ECMO-free survival. It is designed to test the feasibility, safety, and efficacy of such an intervention and the conduct of such a study while exploring clinical and laboratory data in relation to the study groups.

Conclusions

Inflammatory and coagulation system activation of patients during ECMO support remains a major contributor to ECMO-related morbidity and mortality. NO may be an effective treatment for children supported on ECMO to mitigate inflammation and coagulation system activation. Data from the NECTAR pilot study will inform the design of a larger, definitive trial.

Acknowledgments

The authors acknowledge the input from Warwick Butt, Senior Intensivist Royal Children's Hospital Melbourne, John Fraser, Director Intensive Care Unit St Andrew's Hospital, Emma Haisz, and the Extracorporeal membrane oxygenation Clinical Nurse Consultant (ECMO CNC) as well as nurse educators for setup and training of staff. Further, the ECMO specialists are acknowledged, without whom the trial would not have been possible. Lastly, the study team would like to acknowledge the patients and parents who are willing to participate in the trial. This work was supported by grants from the Children's Hospital Foundation, Brisbane, Australia, and by a grant from the Thrombosis and Hemostasis Society of Australia. LS has been supported by a National Health and Medical Research Council (NHMRC) Practitioner Fellowship and by the Children's Hospital Foundation, Brisbane, Australia. AS has been supported by a NHMRC Practitioner Fellowship and by the Children`s Hospital Foundation, Brisbane, Australia. AB acknowledges support through an Australian Research Council Future Fellowship (FT220100487) and by the Frazer Institute, The University of Queensland. The funding sources had no involvement in study design, analyses, or interpretation of the results. Air Liquide will provide nitric oxide (NO) delivery devices as well as NO to study centers but has no involvement in study design, conduct, analyses, or interpretation of the findings.

Data Availability

Deidentified participant data will be shared upon reasonable request after the publication of the original paper. Data will be available for use if the request is approved by the appropriate institutional review board and the Trial Steering Committee and a signed data access agreement is in place.

Authors' Contributions

The first draft of the protocol was written by ACM and LS. KG wrote the section on statistical analyses. The final study protocol was established with input from LS, ACM, KJ, KG, JR, AB, PSV, DL, and AS. ACM prepared the final protocol manuscript, which was reviewed and approved by all authors.

Conflicts of Interest

ACM, LS, DL, KJ, KG, JR, and AB have no conflicts of interest to declare. AS has received grants from Fisher and Paykel.

Abstract

Background: The gains made against malaria have stagnated since 2015, threatened further by increasing resistance to insecticides and antimalarials. Improvement in malaria control necessitates a multipronged strategy, which includes the development of novel tools. One such tool is mass drug administration (MDA) with endectocides, primarily ivermectin, which has shown promise in reducing malaria transmission through lethal and sublethal impacts on the mosquito vector.

Objective: The primary objective of the study is to assess the impact of repeated ivermectin MDA on malaria incidence in children aged ≤10 years.

Methods: Repeat Ivermectin MDA for Malaria Control II is a double-blind, placebo-controlled, cluster-randomized, and parallel-group trial conducted in a setting with intense seasonal malaria transmission in Southwest Burkina Faso. The study included 14 discrete villages: 7 (50%) randomized to receive standard measures (seasonal malaria chemoprevention [SMC] and bed net use for children aged 3 to 59 months) and placebo, and 7 (50%) randomized to receive standard measures and monthly ivermectin MDA at 300 µg/kg for 3 consecutive days, provided under supervision to all eligible village inhabitants, over 2 successive rainy seasons. Nonpregnant individuals >90 cm in height were eligible for ivermectin MDA, and cotreatment with ivermectin and SMC was not permitted. The primary outcome is malaria incidence in children aged ≤10 years, as assessed by active case surveillance. The secondary safety outcome of repeated ivermectin MDA was assessed through active and passive adverse event monitoring.

Results: The trial intervention was conducted from July to November in 2019 and 2020, with additional sampling of humans and mosquitoes occurring through February 2022 to assess postintervention changes in transmission patterns. Additional human

XSL•FO
RenderX

and entomological assessments were performed over the 2 years in a subset of households from 6 cross-sectional villages. A subset of individuals underwent additional sampling in 2020 to characterize ivermectin pharmacokinetics and pharmacodynamics. Analysis and unblinding will commence once the database has been completed, cleaned, and locked.

Conclusions: Our trial represents the first study to directly assess the impact of a novel approach for malaria control, ivermectin MDA as a mosquitocidal agent, layered into existing standard-of-care interventions. The study was designed to leverage the current SMC deployment infrastructure and will provide evidence regarding the additional benefit of ivermectin MDA in reducing malaria incidence in children.

Introduction

Background and Previous Studies

Widespread implementation of new malaria control tools since the turn of the century has dramatically reduced malaria parasite transmission and malaria-related morbidity and mortality across the globe, especially in African countries. Improved access to vector control interventions (indoor residual spraying [IRS] and insecticide-treated bed nets [ITNs]), point-of-care diagnostics (rapid diagnostic tests [RDTs]), and efficacious treatment (artemisinin-based combination therapies) have all contributed to this success. ITNs appear to have made the most dramatic impact, with models estimating that 68% of the decline in *Plasmodium falciparum* prevalence in Africa between 2000 and 2015 could be attributed to this vector-focused intervention [1]. In addition to these tools, the use of intermittent preventive treatment in pregnancy (IPTp) and seasonal malaria chemoprevention (SMC) have contributed to morbidity reductions. IPTp entails the administration of at least 3 antenatal doses of sulfadoxine-pyrimethamine (SP) to pregnant women living in malaria endemic regions. SMC, implemented primarily in the seasonal Sahel region of West Africa, entails the use of amodiaquine (AQ) and SP in children aged 3 to 59 months, administered over 3 days during each month of the rainy season [2]. Studies suggest that SMC is very effective in reducing malaria morbidity, with reductions in incidence of up to 70% [2]; the target age group was recently widened to include all age groups at risk of severe disease, and several countries are already piloting or implementing SMC in all children aged <10 years [2]. In most settings, Ministries of Health (MoHs) work with local communities to deliver SMC door to door over 4 months, even though other delivery approaches and tailoring of the number of months of administration are being discussed and implemented in different regions [2].

Unfortunately, despite these impactful interventions, gains against malaria have been uneven across Africa and have largely stagnated or reversed since 2015 [3]. Given the major contribution of vector control interventions to malaria control, it is not surprising that widespread mosquito resistance to the insecticide classes being used in ITNs and IRS (including pyrethroids, carbamates, and organophosphates) and behavioral avoidance (biting outdoors, resting outdoors, or biting at times when individuals are not sleeping under ITNs) are principal reasons for this stagnation in gains. For example, despite high SMC and ITN coverage, Burkina Faso remains as one of the countries with the highest malaria burden, as all major malaria vectors are resistant to pyrethroids [4].

In light of these challenges, it is clear that additional control methods are needed against the *Anopheles* vector. A promising option is the use of endectocides, drugs that kill both endoparasites (such as parasitic worms) and ectoparasites (such as fleas, lice, and mosquitoes) that feed on treated hosts [5-8]. The most well studied of these is ivermectin, a semisynthetic avermectin derivative that was first licensed in 1981 and has been administered for decades at a dose of 150 to 400 µg/kg once or twice a year as mass drug administrations (MDAs) to treat and eliminate onchocerciasis, lymphatic filariasis, and scabies [9]. Importantly, it has a broad spectrum of activity that also targets invertebrate-specific ligand-gated ion channels, hyperpolarizing their neurons and causing flaccid paralysis, death, and other sublethal effects [10]. Our team and others have pioneered the development of ivermectin as a novel malaria transmission control tool through laboratory and natural field experiments [11-14] and recent clinical trials [15-17], including a recent cluster-randomized trial (Repeat Ivermectin MDA for Malaria Control [RIMDAMAL]; conducted by our group) of repeated low-dose (150 µg/kg) ivermectin MDA during the rainy season in Burkina Faso that reduced malaria incidence by 20% in children aged <5 years [18].

Goal of This Study

Although RIMDAMAL supported the potential impact of repeated MDA with ivermectin on malaria incidence, the doses and frequency were not optimized for either maximizing efficacy or ease of implementation. In particular, low-dose ivermectin is unlikely to achieve sufficient and sustained drug levels to reduce malaria transmission if given monthly. On the basis of pharmacokinetic and pharmacodynamic modeling, we determined that a repeated monthly dose of 300 µg/kg daily for 3 days would be expected to achieve sufficient blood levels to have a clinically relevant impact on malaria rates in children

XSL•FO
RenderX

[1,7,19]. In addition, to facilitate the implementation of repeated ivermectin MDA on a wide scale, we hypothesized that combining the delivery of SMC (already standard practice in most of Sahel) with ivermectin would facilitate the deployment of our intervention and provide a multifaceted and layered approach for malaria control, targeting both the parasite and the mosquito simultaneously, which is critical to making further gains toward reducing the burden of malaria [1,7,20]. Therefore, we designed the RIMDAMAL II trial, a double-blind, cluster-randomized, and placebo-controlled trial for integrated control of malaria. The trial aims to assess the impact of a combined approach of repeated ivermectin MDA and SMC on malaria incidence in children compared with that of repeated placebo MDA and SMC. The trial was implemented in the high-transmission, highly seasonal Diébougou region of Southwest Burkina Faso, the same general location as RIMDAMAL.

Methods

Study Design Overview

RIMDAMAL II is a double-blind, placebo-controlled, cluster-randomized, and parallel-group trial (ClinicalTrials.gov: NCT03967054; pactr.org: PACT201907479787308) designed to determine the efficacy of adding seasonal ivermectin MDA to the standard-policy malaria control measures in Sahel (SMC in children aged 3 to 59 months, long-lasting ITN coverage, and IPTp), for reducing the incidence of uncomplicated malaria episodes among children in enrolled villages (Figure 1). The study includes 14 randomized villages (n=7, 50% control and n=7, 50% intervention clusters). The primary end point is the incidence of malaria over 2 consecutive ivermectin MDA intervention seasons in children aged ≤10 years (Figure 2).

Study Objectives

Primary Objective

Primary objective is to assess the impact of a combined approach of repeated ivermectin MDA and SMC on malaria incidence in children aged ≤10 years (active case detection [ACD] cohort; assessed weekly), with the purpose of testing the superiority of ivermectin compared with placebo for reducing malaria incidence. Our hypothesis is that ivermectin MDAs (the intervention), coinciding with standard-of-care control procedures in Burkina Faso (4 SMC rounds during the rainy season, maximum ITN coverage, and IPTp), will significantly reduce the incidence of childhood malaria (defined in the following sections) in the intervention arm compared with the control arm (standard-of-care control measures without ivermectin MDA).

Secondary Objectives

Secondary objectives include the following:

1. Safety—To measure whether ivermectin MDAs will increase harms for the participants (ie, safety of repeated administrations of high-dose ivermectin)
2. Entomology—To measure entomological indices between the intervention and control arms and over the time of the intervention phase (mosquito survival rate after blood feeding, mosquito population age structure, *Plasmodium* species sporozoite rate, and human exposure to *Anopheles* mosquito bites) between the intervention and control arms
3. Parasitology—To measure the parasitological indices obtained from blood samples collected during the active case surveillance of cohort children between the intervention and control arms and over the time of the intervention phase, including asexual parasite prevalence, species, density, multiplicity of infection, and molecular force of infection (mFOI)
4. Pharmacokinetics and pharmacodynamics—To characterize the pharmacokinetics and pharmacodynamics of ivermectin across the age spectrum and the relationship between ivermectin pharmacokinetics and its entomological effects via membrane feeds

Study Setting

The study was conducted in villages surrounding the town of Diébougou, situated in the Southwest region of Burkina Faso. The region has highly seasonal intense malaria transmission, typically lasting from June to October or November. SMC was also routinely administered in this region for the 4 months of the rainy season (July to October) to all eligible children aged 3 to 59 months. Village residents represent multiple diverse ethnic Burkinabé groups including Dagara, Mossi, Dioula, and others. Previous entomology studies in the area demonstrated that the primary vector responsible for malaria transmission is *A gambiae sensu strictu* with secondary contributions largely from *A funestus* and *A coluzzii* [18,21,22]. The primary means of subsistence are farming, livestock rearing, and trading.

Village and Household Selection

In this region, families typically reside in clustered, grouped homes that consist of extended family households. As a first step, a catchment area for potential clusters within the Diébougou health district was determined using Google Earth Pro (version 7.3.6.9345; Google LLC) that was roughly square in shape (approximately 35 km^2), bounded to the north by the Bougouriba river, to the east by road N12, to the south by the road from Tiankora to Tomena, and to the west by an artificial line that went north from Tomena to the Bougouriba river. Using these satellite images, population centers in this catchment area were outlined based on an analysis of housing structures and an approximation of the number of concessions (extended family households) within each population center. In total, 147 villages or sectors were identified from this analysis, each consisting of between 5 to >100 households. Artisanal gold mining operations were also identified using the maps. From this final map, 18.4% (27/147) of the villages (clusters) were selected based on the following criteria: (1) clusters were accessible to the clinical team during the rainy seasons via motorcycles, which would be their primary mode of transport, providing them with safe road access and allowing them to conduct field visits and return to the field station in Diébougou in 1 day; (2) clusters were at least 2 km away from an artisanal gold mine for the safety of the study team and to minimize contamination from mosquito and human movement to and from these areas; (3) clusters had clearly defined boundaries, allowing field technicians to sample from a single cluster easily without inadvertently including households from neighboring villages; (4) clusters were accessible by study car and no more than 2 km away from an accessible road to facilitate emergency transport of participants to the hospital if necessary; (5) based on an estimated 8 individuals per household, selected clusters had between 20 and 50 households—this was estimated to provide an average of approximately 100 cohort children per cluster, which would enable a single nurse to care for each cluster; and (6) clusters were at least 2 km away from any other enrolled cluster to avoid contamination from mosquito migration. As a final step, in April 2019, the study team selected the final 52% (14/27) of the villages (clusters) based on visits to each village to verify satellite data, household numbers, and village boundaries. All finalized villages and households were enumerated and mapped using handheld GPS devices.

Before the rainy season of year 2, following the review of GPS satellite mapping data, it was determined that a small number of households in a subset of villages were not enrolled in 2019 despite being located at the outer boundaries of participating villages. Owing to their proximity to enrolled households and location within the initial intended catchment area, these households were added to the potential list for enrollment and approached in year 2.

Study Enrollment and Informed Consent

Before village engagement, approvals were attained from the *Comité d'Ethique Institutionnel pour la Recherche en Santé*, *Comité d'Ethique pour la Recherche en Santé*, and MoH through the *Comité Technique d'Evaluation des Essais Cliniques*, followed by permission from regional health authorities (*Directeur Régional de la Santé* and *Médecin Chef de District*). Following these approvals, community engagement began first with village chiefs and elders and the *Agent de santé*

XSL•FO
RenderX

Communitaire (ASC) and subsequently with village residents. All eligible village residents were asked to enroll, which encompassed people of all ages, genders, and reproductive capabilities. Inclusion criteria for enrollment were residence in the study village and ability to understand the information and provide consent or assent. Exclusion criteria for receiving the intervention included (1) sleeping outside of the study village for ≥3 nights per week; (2) height <90 cm; (3) current receipt of SMC; (4) permanent disability or serious medical illness that prevents or impedes study participation and comprehension; (5) pregnancy (screened for in women of childbearing age—12 to 45 years—using a pregnancy urine rapid test the week before each MDA) and older women who have not yet reached menopause; (6) breastfeeding, if the infant is within 1 week of birth; (7) known allergy to ivermectin; (8) possibility of *Loa loa* infection, as assessed by travel history to Angola, Cameroon, Chad, Central African Republic, Congo, Democratic Republic of the Congo, Equatorial Guinea, Ethiopia, Gabon, Nigeria, and Sudan; or (9) enrollment in any other active clinical trials. For the ACD cohort, inclusion criteria were residence in the study village, aged ≤10 years, and parent or guardian consent. Exclusion criteria for the ACD cohort included (1) sleeping outside the study village for ≥3 nights per week or (2) permanent disability or serious medical illness that prevents or impedes study participation.

Eligibility for ACD was determined at the beginning of each intervention season and retained for the remainder of that season:

1. Newborns were eligible for inclusion.
2. Children who turned 11 years during an intervention season remained eligible for the ACD cohort for the remainder of that season.
3. If a participant aged out of the ACD cohort in the first season, they were not eligible for the ACD cohort in the second season.

Eligibility for SMC was determined by the MoH community workers and not by the RIMDAMAL II study team. Participants may age out of SMC (>59 months) in the first season and become eligible for MDA (height ≥90 cm and aged >59 months) in the second season. They did not become eligible for MDA during the season in which this occurred, that is, individuals had to be ≥90 cm at the beginning of the season to receive ivermectin during that season. Cotreatment with ivermectin or placebo and SMC was not allowed during the study because no data were available about the safety of coadministration.

Informed consent was obtained through a multitiered process. After obtaining the permissions stated previously, the head of each household was approached by the study team. Informed consent was obtained from all willing heads of households. Following consent of the head of household, individual consent was obtained from each willing villager. For those aged <18 years, the consent of a parent or guardian was obtained, and for those aged between 12 and 17 years, an additional assent was obtained. Informed consent procedures were repeated before the year-2 intervention season for any potential new villagers who were not present for the informed consent process before the beginning of the study in year 1. Obtaining consent was also an ongoing process throughout the trial, and any participant who refused treatment or wished to withdraw from the study was able to do so without prejudice.

Cross-sectional Transect Household Selection

A subset of villages and households was selected for more intensive sampling of both humans and mosquitoes to enhance parasitological and entomological secondary studies. Before the beginning of the trial, 6 villages were chosen at random by the study pharmacist, who was unblinded, such that 3 (50%) villages were intervention clusters and 3 (50%) villages were control clusters. Within each of these villages, 8 households were chosen based on GPS mapping and location on spatial transects (east-west and north-south). Households closest to the transects were selected based on location: 2 innermost and 2 outermost households on each transect (8 households per village; 48 households in total). Selected households were subject to more frequent cross-sectional sampling of all individuals living in the household (regardless of age) and to intensive entomological sampling.

Trial Medication and Interventions

The intervention, ivermectin or ivermectin placebo (Iver P; Laboratorio Elea; 6-mg tablet) at 300 µg/kg dose estimated by height bands, was administered orally for 3 days to eligible individuals who are not receiving SMC. Per the package insert, dosing of ivermectin or placebo was according to height:

1. 90 to 119 cm (15-25 kg)=1 tablet per day for 3 days
2. 120 to 140 cm (26-44 kg)=2 tablets per day for 3 days
3. 141 to 158 cm (45-64 kg)=3 tablets per day for 3 days
4. >158 cm (65-84 kg)=4 tablets per day for 3 days

Ivermectin tablets were stored in a temperature-controlled room at *Institut de Recherche en Sciences de la Santé* in Bobo-Dioulasso until the beginning of each intervention season and then brought to the temperature-controlled field-based pharmacy in Diébougou. Ivermectin or placebo were administered on a monthly schedule from approximately July to October (4 rounds) as a 3-day course to all eligible individuals according to exclusion and inclusion criteria. The intervention period lasted 2 rainy seasons (one in 2019 and another in 2020). The interventional drugs were administered by the study team via the door-to-door delivery method. Whenever possible, dispensing of ivermectin MDA was conducted alongside community health workers distributing SMC to the same households. In the week before each MDA, the study team members requested a urine pregnancy test for any women of childbearing age (12-45 years) or who had not yet reached menopause. For those who were pregnant or did not agree to pregnancy testing, ivermectin was not administered for that round of MDA. Directly observed therapy was conducted for initial doses, whereby the first day of treatment of each month were handled by the study team. If a participant was not available, the dose was left with the village ASC to be provided to the participant later in the day. MDA on the second and third days were also observed, if possible, with doses provided to the ASC for any missing participants. Any doses that were observed and vomited within 30 minutes were readministered. The status of whether doses were observed was recorded for each participant. For all participants who received MDA, active

XSL•FO
RenderX

surveillance was conducted on the following day to assess for any adverse events (AEs). Participants were encouraged to consume ivermectin with water and to avoid food for 2 hours after dosing, even though this was not enforced in practice.

IRS was not administered in these villages in the 7 years before the study, aside from a single village that received Actellic 300CS (Syngenta AG) in 2017, and no IRS was deployed during the study. All study villages (14/14, 100%) were part of the periodic MoH ITN distribution cycle, having received pyrethroid ITNs within 2 years before the beginning of the study via mass distribution campaigns. Following the initiation of the study, the MoH relayed that villages in the Diébougou health district were expected to receive new Interceptor G2 ITNs, which were ultimately deployed in October 2019. These new long-lasting insecticidal nets (LLINs) are made with 2 different insecticides (chlorphenapyr and α-cypermethrin) to circumvent the prevalent pyrethroid resistance seen among anophelines in Burkina Faso and much of sub-Saharan Africa.

SMC was provided and distributed by the MoH. It was administered monthly from July to October (for 3 consecutive days) with SP and AQ (eg, SPAQ-CO; Guilin Pharmaceutical). SMC was dosed as 500/25 mg SP and 153 mg AQ for children aged 12 to 59 months and 250/12.5 mg SP and 76.5 mg AQ for children aged 3 to 11 months. As per standard practice in Burkina Faso, the first dose (AQ and SP) is directly observed by MoH staff, and doses on days 2 and 3 (AQ only) are provided to the parents or guardians to administer at home. For pregnant women, IPTp is provided by the MoH and followed World Health Organization policy, which recommended at least 3 treatments, 1 month apart, starting in the second trimester (eg, Fansidar; Roche; 500/25 mg SP per tablet; 3-tablet dosage=1500/75 mg SP).

Ivermectin was also administered to all villages as part of the yearly MDA elimination campaigns, at a single dose of 150 µg/kg orally. According to MoH district leaders, study villages received ivermectin MDA as a single dose for eligible individuals from September 2, 2019, to September 7, 2019, and from November 10, 2020, to November 19, 2020, meaning that study participants received an extra dose of ivermectin 150 µg/kg during the intervention rounds in 2019 and 1 month after the intervention rounds in 2020. Ivermectin MDA was administered by the MoH and not by the study team.

Outcome Measures

Primary Clinical Efficacy Outcome

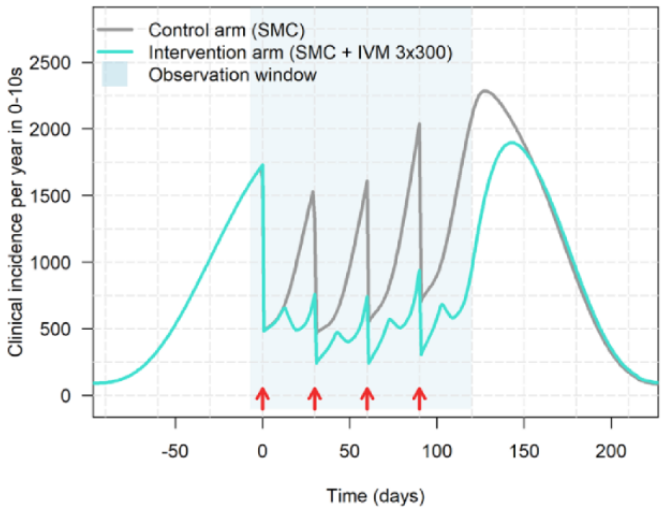
The primary outcome is the incidence of malaria episodes in the ACD cohort, which comprised children aged ≤10 years, as assessed by active case surveillance by study team nurses assigned to each village and required to visit each child a minimum of once per week during the intervention phases. In this field setting, malaria incidence in children is the most clinically relevant outcome measure for an antivector intervention that targets blood-feeding mosquitoes, and its reduction following repeated ivermectin administration has been validated in our previous RIMDAMAL study [18]. Study nurses were instructed to visit each child weekly to monitor for malaria episodes. At each visit, malaria was defined as a temperature ≥37.5 °C (axillary or equivalent at another site) or history of fever in the last 24 hours with a positive RDT for *Plasmodium* of any species. Study nurses and physicians routinely visited local clinics serving the study villages to capture malaria cases in study participants that were not detected during weekly monitoring in the villages.

Secondary Outcomes

Secondary outcomes include the following:

1. Safety and tolerability—AE monitoring occurred throughout the intervention periods in both years through active and passive case surveillance. AE monitoring occurred for all enrolled participants, regardless of age, and will be further characterized by their relationship to the intervention and as serious AEs based on their severity. Active AE monitoring entailed assessments 24 hours following each dose of MDA in all participants available at the time of a nurse's visit and weekly visits for children in the ACD cohort. Nurses conducted passive AE monitoring over the course of the week during routine study activities.
2. Entomology—Entomological outcomes include the following. (1) *Human biting rate (HBR)*—this is defined as the number of mosquitoes captured per person per period. For aspirated, indoor-resting, blood-fed mosquitoes, HBR is calculated by dividing the house or household catch by the number of humans living in that house or household. For host-seeking mosquitoes caught in light traps placed next to individuals sleeping in tents (outdoors) or under bed nets (indoors), HBR is simply the catch number per person. (2) *Sporozoite rate*—a representative proportion of mosquitoes captured per period and per mosquito species will be tested for the prevalence of infection with *Plasmodium* sporozoites through genetic testing of their heads and thoraces. (3) Changes in participants' antibody responses to *Anopheles* saliva proteins—paired sets of antibodies from individual participants will be tested for binding to *Anopheles* saliva proteins, and the binding change per person over the study period will be calculated. (4) *The survival of blood-fed mosquitoes*—blood-fed mosquitoes were collected per period, brought back to the field insectary, and held for 3 days to measure their survivorship over that time. A subset of blood-fed mosquitoes from cross-sectional households was stored for the assessment of mosquito biting preference [23].
3. Parasitology—Parasitological outcomes include the following. (1) *Parasite prevalence*—parasite prevalence will be assessed for both *P falciparum*and non-*falciparum* species. (2) multiplicity of infection (also sometimes referred to as complexity of infection) is defined as the number of unique clones per individual at the time of diagnosis of malaria infection. (3) *mFOI* (also sometimes further subclassified as molecular force of blood-stage infection) is defined as the number of new *Plasmodium* clones acquired over time that were not present in the preceding intervals.
4. Pharmacokinetics and pharmacodynamics—Outcomes include (1) the pharmacokinetic profile of ivermectin in 3 different age groups (5-10 years, 11-18 years, and >18 years) sampled over 28 days and (2) the relationship

XSL•FO
RenderX



between ivermectin plasma concentration and mosquitocidal effects over time via membrane feeds.

Power and Sample Size Considerations

The primary end point for the trial is the incidence rate of malaria episodes in children aged ≤10 years, as assessed by active case surveillance by study nurses with weekly visits to each child, starting at the first round of MDA in year 1, continuing for 4 months and beginning again with the fifth round of MDA in year 2, and ceasing 4 weeks after the last round of MDA. The dosing regimen, sample size, and power for RIMDAMAL II were guided by the Malaria Transmission model developed at Imperial College, London [24], and are based on data from the RIMDAMAL and Efficacy and Safety of High-Dose Ivermectin for Reducing Malaria Transmission (IVERMAL) trials [1,17-19,25]. The model predicts an effect size in the intervention arm over the control arm of 43% (Figure 3). Calculations assume seasonal incidence rates (per year) of approximately 1.06 and 0.60 in the control and intervention arms, respectively, thus corresponding to an incidence rate ratio of 0.60/1.06=0.57 (ie, incidence rate reduction of 0.43). The initial sample size evaluation shows that RIMDAMAL II has 80% power with 6 villages per arm and 48 children per cluster, assuming a coefficient of variation between clusters of 0.22, which was informed by variation in RIMDAMAL. However, shortly before trial initiation, the sample size was increased from 12 to 14 villages (7 per arm) with approximately 100 children per village or cluster. In a recently published simulation study, the large sample size provides >90% power in the statistical models that were considered for the primary analysis of trial results [26].

This effect size and resulting sample size calculations assumed a moderate level of LLIN coverage with a low-efficacy net owing to high levels of pyrethroid resistance in the region. However, during study planning, it emerged that Interceptor G2 ITNs were to be distributed toward the end of the first year of the intervention. Updating the modeled incidence rates by assuming that the new ITNs would result in an additional 30% reduction, while also increasing the number of children per cluster, meant that even with new LLIN distribution, the number of clusters was still adequate to achieve 80% power.

Figure 3. Initial modeled impact of 4 monthly rounds of seasonal malaria chemoprevention (SMC) compared with 4 monthly rounds of SMC and ivermectin (IVM) 3×300. The resulting annualized incidence rates over the observation window were 1.06 in the control arm and 0.60 in the intervention arm.

Randomization and Blinding Procedures

The randomization unit was the study village (cluster). Before a public randomization event, the study pharmacist, who is the only nonblinded member of the study team, initiated the masking procedure in private, whereby 14 identical cards were made with the numbers 1 to 14 written on them, and these were placed in a container, mixed, and then randomly pulled from the container. In total, 7 numbered cards were randomly placed in each of 2 other containers labeled *ivermectin* or *placebo*. The results of this masking were identically recorded on 3 separate documents, signed by the study pharmacist, and sealed in 3 opaque envelopes kept by the study pharmacist and the 2 principal investigators until the unblinding to be performed after the intervention phase and database cleaning is complete. Following the masking procedure, a public randomization event was conducted before the initiation of the study at the facilities of the district health authority, which was attended by the district medical director, representatives of each village, and members of the study team. At this event, each village's representative randomly drew 1 card from an opaque container that contained 14 identical cards, except for the numbers 1 to 14 marked on them, and each representative signed and dated a document with the record of the number they drew next to the name of their village. This randomization key was copied for the principal investigators, and the original document was given to the study pharmacist, who used it to match the village to the intervention (ivermectin or placebo) previously assigned to each number during the masking procedure.

The study pharmacist was in charge of the drug stock rooms, and he allocated the tablets for each MDA round according to the original randomization throughout the trial. Drug was distributed in sealed containers labeled with the number code. All study personnel, apart from the pharmacist, remained blinded throughout the study.

XSL•FO

Study Procedures

Enrollment

Enrollment forms were completed after obtaining consent from all participants in years 1 and 2 and recorded on study tablets. Year-2 enrollment forms included a reassessment of eligibility criteria and captured additional information about the village participants who were not eligible for MDA owing to them sleeping in the village ≥3 nights per week. Baseline pre-MDA filter paper samples were obtained from a subset of ACD participants in year 1 from each village and from all study participants in year 2.

ACD Cohort Follow-up

Active case surveillance was conducted by study nurses visiting each enrolled ACD cohort child weekly following the beginning of the first MDA and ending 30 days following the last MDA of the season. At each visit, the nurse recorded patient information in the electronic case record form, measured the child's temperature, recorded whether either a history of fever in the past 24 hours or current fever was present, and obtained a blood sample by capillary finger prick method (for RDT, blood smear slide and filter paper [Whatman 3MM] samples were collected). The RDT detected both parasite-derived histidine-rich protein 2 and lactate dehydrogenase (SD Bioline Malaria Ag Pf/Pan; Abbott). All clinical decisions were made based on the RDT result, and if positive for either antigen, results were recorded, and participants were treated with artemether-lumefantrine, according to the Burkina Faso MoH guidelines. Episodes of malaria were classified as complicated based on standard World Health Organization criteria [2]. Patients with complicated malaria were referred to the district hospital immediately. Routine visits were made to local clinics and hospitals to determine whether any participant required management for any AEs that were not captured during routine village-based surveillance.

During each weekly visit, the nurse inquired about any AEs following the receipt of MDA doses or during any intervening time since the last visit. Passive AE monitoring was performed if AEs were communicated to the nurse during other nonstudy visit encounters. Household surveys were performed over the course of the study to ascertain the use of malaria control measures and gather other demographic and social information. In year 2, infection prevention and control measures were implemented to limit the risk of COVID-19 among study staff and participants. Measures included the use of personal protective equipment and the purchase and use of washing stations within each village.

AE Monitoring

As noted previously, active and passive AE monitoring occurred in all enrolled villagers, regardless of age. Study nurses and physicians were trained on how to monitor, record, and report AEs. In addition, AEs were followed to resolution when feasible. Severity assessments by the study physicians were performed in consultation with the study nurses and on-site physicians. AEs were graded on a 5-point scale and grouped according to body system and preferred terms using Medical Dictionary for Regulatory Activities. Relationship to the study intervention was determined by the study physician and reviewed by the study's principal investigators before unblinding.

Cross-sectional Transect Household Assessments

Before the beginning of MDA 1 in year 1, cross-sectional households were visited to complete a baseline questionnaire and collect a capillary finger prick sample on filter paper. In year 1, additional blood samples were obtained on filter paper in the middle of the season and approximately 4 weeks following the last MDA. In year 2, filter paper samples were obtained from all cross-sectional household participants before each MDA and 4 weeks following the last MDA. In addition, before and after each season, a hemoglobin measurement was performed using point-of-care HemoCue. Entomology collections in cross-sectional households are described in the following sections. Cross-sectional questionnaires were administered to ascertain the use of malaria control measures and to assess housing and environmental aspects related to malaria risks.

Parasitological Assessments

Parasite prevalence and speciation will be determined using molecular assays on DNA extracted from filter paper samples using established methods. *P falciparum* clonality (complexity of infection and mFOI) will be assessed using either length-polymorphic markers or single nucleotide polymorphism–based genotyping using deep amplicon sequencing [27,28].

Entomological Assessments

Mosquito sampling was conducted in a subset of cross-sectional villages, within the cross-sectional transect households only. Overall, 2 sampling methods were used; the first method was indoor aspirations of resting mosquitoes collected in the morning in all cross-sectional household sleeping rooms, and the second was light traps placed in 1 cross-sectional household located in the center of the village to collect host-seeking anophelines overnight. For the light traps, one was placed outdoors hanging under the rain tarp of a camping tent that was occupied by a sleeping person, and another was placed indoors hanging next to a person sleeping under a bed net. Mosquito sampling intervals occurred in these 6 cross-sectional villages over the course of a week and were conducted 1 week after each MDA and 3 weeks after each MDA for a total of 16 sampling intervals across the entire intervention period.

Pharmacokinetics and Pharmacodynamics Assessments

In October 2020, following the third round of ivermectin MDA, a pharmacokinetics and pharmacodynamics substudy was performed for individuals residing in 6 villages (n=3, 50% intervention and n=3, 50% control villages). In total, 178 participants were enrolled in the substudy, approximately 90 each from the intervention and control villages, with all team members except the pharmacist blinded to the village study arm. Participants were enrolled to achieve roughly equal numbers from three age groups: (1) 5 to 10 years, (2) 11 to 18 years, and (3) >18 years. Sparse pharmacokinetics sampling was conducted for each individual at up to 7 time points over 28 days, with additional blood collected for entomological and safety assessments (chemistries and blood counts).

XSL•FO
RenderX

Pharmacokinetics data will be analyzed using nonlinear mixed effects modeling, and entomological assessments will be performed using membrane feeds on participant plasma.

Data Management

Data were gathered in an electronic data capture system (REDCap [Research Electronic Data Capture; Vanderbilt University] database system). All electronic case report forms containing participant demographic and clinical data (active case surveillance data on the children cohort and AE data for all participants) were entered on password-protected tablets that were maintained and updated daily by the clinical team working at the field site. Only the study team will have access to the source data. Long-term maintenance of the participant codes is held only by the study's principal investigators on password-protected computers and files. Database records were individually checked for inconsistencies and cross-checked with the study team and other data sources, as applicable. Study data devoid of identifiers will be provided to the research community following the publication of the primary outcomes.

Ethics Approval and Regulatory Oversight

Institutional review board approvals were obtained and maintained from the Colorado State University (19-9144H/1691), Yale Human Investigations Committee (under a Streamlined, Multisite, Accelerated Resources for Trials Institutional Review Board Reliance platform agreement with the Colorado State University; 2000024138), *Comité D'Ethique Institutionnel Pour La Recherche en Sciences de La Santé* (A031-2018), *Comité D'Ethique Pour La Recherche en Santé* (2019-01-009), and *Comité Technique D'Examen Des Demandes D'Autorisation D'Essais Cliniques* (2019-0580). The protocol was approved by the National Institutes of Health Division of Microbiology and Infectious Diseases (protocol number 18-0007). An independent data and safety monitoring board was convened by the Division of Microbiology and Infectious Diseases. Protocol violations and serious AEs were reported to the abovementioned regulatory bodies according to institutional requirements. An independent study monitor (an in-country contract research organization, CliMAfrica-CRO, Burkina Faso) provided external monitoring for the study, beginning before study initiation and until completion of the study. The CONSORT (Consolidated Standards of Reporting Trials) extension for cluster trials will be completed and made available at the time of reporting primary study results for publication.

Statistical Analysis

Primary Clinical Outcome

We will use an intention-to-treat analysis method for our primary clinical outcome, which is the incidence rate in children in the ACD cohort [26]. Person time will be defined in 7-day consecutive intervals, with ≥1 visits occurring during each interval considered as a single eligible person week. A Poisson mixed effects regression model with a village-level random effect will use the counts of malaria episodes with exposure time (modeled as an offset) in each participant to estimate the malaria incidence rate for all participants in the intervention and control villages. The primary analysis will be adjusted for other covariates such as ITN use and participant age. The estimate for the primary analysis is the exponentiated coefficient for the treatment covariate across both seasons. This rate ratio is the ratio of malaria incidence rate in the treatment villages to the rate in the control villages. The model will be fit with a Kenward Roger *df* correction to account for the limited number of clusters. The primary conclusion about the relative efficacy of ivermectin MDA will be based on the treatment effect coefficient, its 95% CI, and *P* value testing difference from 0 (rate ratio of 1). The primary analysis method and model were selected based on the results of a simulation study of the statistical properties of many models that have been proposed for the analysis of cluster-randomized trials using count-based outcomes [26].

The primary analysis will evaluate the efficacy of ivermectin treatment as described previously. The robustness of this conclusion will be evaluated through analyses that will adjust for other covariates and assess the strength of the rate ratio in key subgroups. Sensitivity analysis will be performed to assess the impact of censoring a participant's time at risk for 14 days following the diagnosis and treatment of malaria owing to the impacts of treatment on risk of recurrent malaria.

Subgroup analyses will be performed to help inform the mechanism of action of ivermectin and determine whether the effects are similar across important subgroups. Subgroups include (1) children aged 0 to 3 months, who receive neither SMC nor intervention; (2) children aged 3 to 59 months, who receive SMC only; (3) children aged >59 months but are <90 cm in height, and therefore do not receive SMC or the intervention; and (4) those who receive MDA only (height ≥90 cm and aged ≤10 years).

Safety Analysis

Safety analysis will be assessed by relative risk (RR) in the following groups: (1) all participants were followed actively and passively for AEs, and the risk ratios of AEs of those in the intervention versus control clusters will be compared; (2) ACD-cohort SMC-treated children only—RR of AEs in children who receive SMC and live in ivermectin-treated clusters versus those who receive SMC and live in placebo-treated clusters; (3) ACD-cohort ivermectin-treated or placebo-treated children only—RR of AEs in those children receiving ivermectin MDA versus those receiving placebo; and (4) non-ACD participants who were enrolled in the study were followed actively for 24 hours after each study intervention and then passively for the rest of the MDA round.

Results

Consent process and recruitment for the study began on July 13, 2019. The first round of MDA began on July 26, 2019, and the last round of MDA in year 1 began on October 16, 2019. MDA in year 2 began on July 20, 2020, and the last round of MDA began on October 12, 2020. SMC and ivermectin MDA distribution occurred on the same days for all MDA except MDA 1 in 2019, in which ivermectin MDA was delayed relative to SMC by 2 days. Statistical analysis will be conducted once the database is completed, cleaned, and locked, and the clinical trial protocol is publicly available. The study team will be

XSL•FO
RenderX

unblinded after the clinical trial protocol and statistical plan is finalized and publicly available.

Discussion

Principal Findings

With gains in malaria stagnating since 2015 and reversals being seen in several countries, particularly in sub-Saharan Africa, novel control methods are urgently needed [3]. Novel interventions in conjunction with other measures will likely be needed, as no single intervention is expected to have a sufficient, durable, and sustainable impact to reduce malaria morbidity and mortality in the long term. Previous studies by our group and others demonstrated that ivermectin, when used at 150 µg/kg, similar to doses used for MDA campaigns to eliminate lymphatic filariasis, onchocerciasis, and scabies (150-400 µg/kg), showed lethal and sublethal effects on mosquitoes following blood meal ingestion [15,29-32]. The same dosage was then shown to affect malaria incidence when administered more frequently (every 3 weeks) in the RIMDAMAL trial [18]. Modeling studies have demonstrated that a monthly regimen of 300 µg/kg administered on 3 consecutive days is likely to have a significant impact on malaria incidence [1]. The safety and mosquitocidal impact of this regimen were recently demonstrated in a randomized trial of adults with malaria living in Kenya [17].

RIMDAMAL II builds on these insights and will assess whether the high dose of ivermectin MDA, when administered in operational conjunction with SMC delivery, is associated with significant reduction in malaria incidence in children aged <10 years, as compared with standard interventions alone (SMC and ITN use). Malaria incidence was chosen as the primary outcome, as this was felt to reflect a meaningful outcome measure that could have an impact on policy decisions. The study is cluster randomized and placebo controlled, with all study investigators being blinded to intervention allocation, which is a rigorous design to test the community-level impact of this novel intervention. The study intervention was also conducted over 2 seasons and involved both active and passive follow-up of AEs for all enrolled participants, thus providing a strong evidence base to assess the safety of repeated high-dose ivermectin for malaria transmission reduction. Secondary outcomes will provide parasitological, entomological, and pharmacokinetic outcome measures to further enhance our understanding of the mechanisms by which ivermectin may exert its effects. Additional sampling in the year following the intervention will provide information on any postintervention effects of ivermectin MDA.

Community-level trials are subject to several challenges during planning and execution. The identification of appropriate clusters that are sufficiently distanced from one another to avoid contamination and of appropriate size to enable rigorous surveillance of all participants can be challenging, but it also reflects the reality of spatial demographics in rural African settings. During the planning stages, attempts were made to identify ideal villages for inclusion, while balancing with practical limitations in the field (refer to previous sections).

Cluster-randomized, community-based trials are also open to external factors that can challenge the execution phases of the study. During RIMDAMAL II, the COVID-19 pandemic spread around the globe just before the beginning of the second intervention season. In recognition of the potential impact that the COVID-19 pandemic could have on multiple aspects of the study (safety of the staff and participants, availability of supplies, ability to differentiate malaria and COVID-19, etc), extensive discussions and preparations occurred before year 2 of the study. Efforts included the training of the staff on appropriate infection prevention and control measures, purchase and shipment of personal protective equipment from the United States to Burkina Faso, and purchase of handwashing stations for each village. At the conclusion of year 2 of the intervention, there was no overt evidence of COVID-19–related clinical impacts in our enrolled villages; however, precise data on COVID-19 case counts in the region were not available.

A second challenge was the decision by the Burkina Faso MoH and certain research partners to deploy ITNs with different insecticide chemistries in Southwest Burkina Faso. In the region of Diébougou, new Interceptor G2 ITNs were deployed in October 2019, at the end of year-1 intervention season. The timing of distribution created challenges and opportunities, which will be assessed in the analysis, as both year-1 and year-2 outcomes largely occurred under the use of deltamethrin and chlorphenapyr or α-cypermethrin nets.

RIMDAMAL II will be the first cluster-randomized trial to directly assess the impact of repeated high-dose ivermectin MDA on malaria incidence. The trial uses high-dose, monthly ivermectin coupled operationally with SMC, and the assessment of primary outcome includes children who received only SMC (those aged 3-59 months) and those who received only ivermectin (and no SMC; those aged 60 months to 10 years). Statistical analysis planning supports the adequacy of the cluster size and the approach to assess the primary outcome [26]. The study encountered challenges with the emergence of COVID-19 globally and the deployment of ITNs with new chemistries locally in year 2. Following the final analysis and dissemination of results, if the intervention is found to be efficacious and safe, the design will facilitate the potential consideration of this multilayered novel approach for malaria control in seasonal high-transmission settings.

Conclusions

RIMDAMAL II will be the first cluster-randomized trial to directly assess the impact of repeated high-dose ivermectin MDA on malaria incidence in children. The results will inform policies and future studies on the use of mosquitocidal agents as novel components for malaria control.

Acknowledgments

The authors would like to thank the study nurses, laboratory technicians, and entomology team for their contribution. The authors would like to thank the Burkina Faso Ministry of Health, local health care providers, and villagers who participated in the study. The authors thank Laboratorio Elea, Argentina, for providing ivermectin and the placebo. The trial was funded by the National Institute of Allergy and Infectious Diseases (grant 5U01AI138910).

Data Availability

Data for the trial will be made available on the Clinical Epidemiology Database Resources [33].

Authors' Contributions

BDF, SP, and RKD conceived of the study. SP and BDF drafted the manuscript. AFS and GC served as the study coordinators. AS was the primary medical officer and oversaw the field activities. BDF and RKD oversaw the design and entomology activities. TM, BDF, AS, LG, MC, and SP oversaw the creation and management of the database. MW oversaw laboratory management at Yale. TB assisted with the study design. SR, CLJ, HCS, and JK provided the modeling and statistical analysis plan. KR performed regulatory oversight.

Conflicts of Interest

In October 2020, BDF and SP joined the Scientific Advisory Board as consultants for the IMPACT project being run by MedinCell. RKD and AFS are investigators for the IMPACT project. BDF also performed a 1-time consultation for Lyndra Therapeutics Inc in July 2020.

Abstract

Background: With the advent of antiretrovirals, people living with HIV are living near-normal lifespans. However, people living with HIV are at greater risk of experiencing cognitive impairment and reduced brain integrity despite well-controlled viremia. A robust literature supports exercise interventions as a method of improving cognition and structural brain integrity in older individuals without HIV. The effects of exercise on cardiometabolic, neurocognitive, and neural structures in middle-aged to older people living with HIV are less well known, with few prospective studies examining these measures.

Objective: This prospective randomized clinical trial will examine the effects of a 6-month exercise training intervention compared to a 6-month stretching intervention (control) on cardiorespiratory fitness, physical function and strength, cognition, and neuroimaging measures of brain volumes and cerebral blood flow in people living with HIV.

Methods: Sedentary middle-aged to older people living with HIV (ages≥40; n=150) with undetectable HIV viral load (<20 copies/mL) will be enrolled in the study. At the baseline and final visit, fasting plasma lipid, insulin, glucose, and brain neurotrophic factor concentrations; cardiorespiratory fitness; cognitive performance; brain volumes; and cerebral blood flow via a magnetic resonance imaging scan will be measured. Participants will be randomized in a 2:1 ratio to either the exercise or control stretching intervention. All participants will complete their assigned programs at a community fitness center 3 times a week for 6 months. A professional fitness trainer will provide personal training guidance at all sessions for individuals enrolled in both arms. Individuals randomized to the exercise intervention will perform endurance and strength training exercises, while those randomized to the control intervention will perform stretches to increase flexibility. A midpoint visit (at 3 months) will assess cognitive performance, and at the end point visit, subjects will undergo cardiorespiratory fitness and cognition testing, and a magnetic resonance imaging scan. Physical activity throughout the duration of the trial will be recorded using an actigraph.

Results: Recruitment and data collection are complete as of December 2020. Data processing, cleaning, and organization are complete as of December 2021. Data analysis began in January 2022, with the publication of study results for primary aims 1 and 2 expected by early 2023.

XSL•FO
RenderX

Conclusions: This study will investigate the effects of a 6-month aerobic and resistance exercise training intervention to improve cardiometabolic risk factors, cognitive performance, cerebral structure, and blood flow in sedentary people living with HIV. Results will inform clinicians and patients of the potential benefits of a structured aerobic exercise training program on the cognitive, functional, and cardiometabolic health status of older people living with HIV. Assessment of compliance will inform the development and implementation of future exercise programs for people living with HIV.

KEYWORDS

cardiorespiratory fitness; cognition; exercise; HIV; magnetic resonance imaging; resistance training

Introduction

Overview

In the era of combination antiretroviral therapy (cART), people living with HIV are living near-normal lifespans [1]. Despite this, cognitive impairment is still prevalent in people living with HIV, even in those with well-controlled viremia [2]. Current adjunctive therapies to cART, such as cognitive training or other medications designed to treat comorbid conditions (ie, anticholinergics and lithium), have not demonstrated significant benefit in improving cognition and quality of life in people living with HIV. Consequently, there is a critical need for the development of adjunctive therapies that improve cognition in people living with HIV.

The effects of aerobic and resistance exercise (EXS) training interventions on physical and brain health have been well documented in people without HIV. These interventions are especially important in older adults, as older individuals tend to exhibit more sedentary lives than younger individuals [3]. Improved physical functioning and physical fitness have been reported in older people without HIV who completed exercise intervention programs [4-7]. Older adults have also demonstrated improvements in cardiorespiratory health (ie, VO_2 maximum [VO_{2max}], the maximum rate of oxygen consumption during exercise) after completing an exercise program [8]. Reviews of the extant literature reveal that exercise intervention programs improve cognitive performance or slow cognitive decline, specifically in domains such as attention, processing speed, executive function, and memory [9-12] in both clinical populations (mild cognitive impairment and Alzheimer's disease) and otherwise healthy older adults. Neuroimaging indices of brain integrity also improve in response to engagement in structured exercise interventions in older adults. Specifically, increased brain volumes [13,14], changes in cerebral blood flow (CBF) [15-17], and improved brain network connectivity [16,18,19] have been observed in individuals completing exercise interventions. These results are particularly evident in the frontal and temporal regions (including the hippocampus), each of which is critical for executive function, learning, and memory.

Research into the efficacy of an exercise intervention in improving physical and brain health in people living with HIV is less established. Longitudinal intervention studies have primarily focused on physical health outcomes, with evidence of improved blood pressures (BPs), cardiorespiratory fitness ($VO_{2\ max}$), inflammatory markers, physical strength, and body composition in people living with HIV following completion of an EXS training program or other activity programs, such as yoga [20-25]. The relationship between exercise and cognitive outcomes in people living with HIV has primarily been assessed using association studies and self-reported levels of physical activity. The effects of self-reported exercise or physical activity on cognitive function in the setting of HIV have produced conflicting results, with both positive [26-30] and null findings [31] reported. Because these studies did not include an intervention component, a causal effect of exercise on cognition was not able to be established.

Few studies have used neuroimaging to examine the effects of exercise on structural brain integrity in people living with HIV. While one cross-sectional study reported larger putamen volumes in a group of physically active people living with HIV compared to sedentary people living with HIV [30], to our knowledge, there have been no prospective studies examining neuroimaging markers of brain integrity before and after completion of an EXS training intervention in older people living with HIV. Therefore, the purpose of this clinical trial is to examine the effects of a 6-month EXS training intervention (vs a stretching control group) on cardiorespiratory and physical function, plasma markers of cardiometabolic risk and neurotrophic peptides, cognitive performance, and neuroimaging metrics in a sample of sedentary older people living with HIV who are on a stable cART regimen and virologically well controlled.

Aims

The primary objective of this study is to compare the effects of supervised EXS training versus a social-interaction stretching (SIS) group on brain health in people living with HIV aged ≥40 years.

Aim 1

The aim is to examine the effects of exercise training on cognitive function in people living with HIV aged ≥40 years.

Hypothesis 1a

A 26-week EXS program will enhance cognitive function (domain-specific executive function, attention, and memory) more than an SIS program in physically inactive people living with HIV.

XSL•FO
RenderX

Hypothesis 1b

Greater improvements in cardiorespiratory fitness and physical function (daily physical activity, muscle strength, and muscle mass) in the EXS group will be associated with better cognitive performance.

Aim 2

The aim is to examine the effects of exercise training on brain structural and functional measures in people living with HIV aged ≥40 years.

Hypothesis 2a

A 26-week EXS program will associate with improved brain structural and functional measures (CBF and brain volumetrics) more than an SIS program in physically inactive people living with HIV.

Hypothesis 2b

Greater changes in physical function (daily physical activity, cardiorespiratory capacity, muscle strength, and muscle mass) in the EXS group will be associated with increases in CBF and larger brain volumetrics.

Hypothesis 2c

Improved neuroimaging changes will be associated with enhanced cognition in people living with HIV.

Exploratory Hypothesis

Improvements in brain integrity due to EXS will be accompanied by reduced systemic inflammation and improved glucose regulation.

Methods

Participants

All study visits are conducted at Washington University in St. Louis. Participants are recruited from local clinic referrals, flyers posted in pharmacies, food pantries, and advocacy groups in addition to word of mouth. Our team has also met with caseworkers and physicians to introduce them to this study.

Inclusion criteria are as follows: age 40-80 years, sedentary lifestyle (defined as structured exercise for less than 2 hours per week for the last 6 months), known HIV infection, on a stable cART regimen with an undetectable plasma HIV RNA (<50 copies/mL) for at least 12 months prior to enrollment, able to receive a magnetic resonance imaging (MRI) scan, and able to attend 3 EXS or SIS sessions a week over 6 months. It should be noted that the study inclusion criteria originally only enrolled older people living with HIV older than 50 years. However, due to difficulty in enrolling this population, the study opened enrollment to people living with HIV older than 40 years during the final year of enrollment.

Exclusion criteria are as follows: history of serious cardiovascular or cerebrovascular disorder (ie, stroke and uncontrolled hypertension), pulmonary disease, or significant neurological disorders; substance use disorder within the last 6 months; pregnant or breastfeeding; currently prescribed anticoagulants or medications known to affect glucose and lipid metabolism (other than statin medications); or any other medical condition that, in the opinion of the principal investigator, makes the patient unsuitable for inclusion in the study (eg, severe psychiatric illness).

Study Visits

Baseline Visit 1

Cardiovascular Visit

After obtaining informed consent from each volunteer and after 10 minutes of rest, BP, heart rate (HR), temperature, waist circumference (mid-way between right costal margin and anterior superior iliac crest), height (by using a stadiometer), weight, and fasting blood glucose level (Accucheck) are collected. Female participants are administered a urine pregnancy test (McKesson Consult Diagnostics, manufacturer #5000) before testing begins.

Whole-body dual-energy x-ray absorptiometry (DXA) scan is performed on a GE-Healthcare Lunar I scanner. DXA outcome variables, quantified through the use of Encore Software (version 16), include BMI, total mass, lean mass, fat mass, android and gynoid mass, visceral adipose tissue mass, and fat tissue mass for each arm, leg, and the trunk.

Once the DXA is completed, an intravenous tube is placed in the participant's arm for the blood draw (see Bloodwork section below). Once blood is collected, an electrocardiogram machine (Case V6.73) is obtained. The study physician then conducts a medical history and physical examination.

After the electrocardiogram, the participant completes a graded maximal exercise test on a recumbent cycle ergometer with concurrent indirect calorimetry (ParvoMedics True One System) with a 2-way valve and mouthpiece (Hans Rudolph Inc) in order to measure VO_2. Test workload is initiated at 20 W. Once exercise starts, the participant is asked at 1-minute intervals to rate their perceived exertion on a scale of 6-20, and the resistance is increased by 10-20 W every minute until volitional exhaustion. HR is recorded once every minute, while BPs are collected every 2 minutes. After the session, the participant is monitored for 5 minutes until BP reaches baseline value. Maximal $VO_{2\ max}$ (mL O_2/kg/min) is recorded as the highest VO_2 reached during the test. Exercise tests are considered maximal if the participant reaches ≥85% projected peak HR (220 – age) or respiratory exchange ratio ≥1.1 [32].

After testing, an actigraph (ActiGraph GT3X+) is attached to the nondominant wrist of each subject to record daily physical activity. This actigraph is initialized using the ActiLife v6.13.4 program and set to start recording 1 hour after the end of the study visit with a sampling rate of 100 Hz. The actigraph is worn continuously for 1 week and is collected at baseline visit 2. Once returned, actigraph data are downloaded and integrated into a 60-second epoch-length format to be analyzed using ActiLife. Average time spent sedentary, lightly active, moderately active, vigorously active, and in moderate-to-vigorous physical activity are the primary outcome variables generated by the ActiLife scoring program.

XSL•FO
RenderX

Bloodwork

Fasting (12 hours) samples are collected during the cardiovascular visit and sent to the Core Laboratory for Clinical Sciences, Barnes Jewish Hospital, Washington University in St. Louis; Quest Diagnostics; or Temple University for processing. The following measures are reported from these samples: comprehensive metabolic panel and lipid panel, C-reactive protein, complete blood count, hemoglobin A1C, insulin and c-peptide, insulin-like growth factor 1, CD4 T-cell count, CD8 T-cell count, HIV RNA viral load, interleukin-6, C-X-C motif chemokine ligand 10, vascular endothelial growth factor, apolipoprotein E, leptin, neopterin, adiponectin, as well as archived plasma and serum. For serum, blood is allowed to clot for 30 minutes and then centrifuged at 2000×*g* at 4 °C for 10-15 minutes before aliquoting and storing in 80 °C freezer. For plasma, samples are centrifuged at 1500×*g* at 4 °C for 10 minutes before aliquoting and storing in 80 °C freezer.

Baseline Visit 2

MRI Scan Visit

One to 2 weeks after the initial visit, MRI scanning and neuropsychological (NP) evaluation are performed. An MRI safety form is completed before the scan to ensure there are no contraindications. Participants complete a urine drug screen (Alere Multi-drug Screen Test Panel; DOA-3104) before the scan. Scans are conducted on a 3T Siemens Prisma scanner using a 20-channel head coil. Collected scans include a T1, 3D-pseudo continuous arterial spin labeling, blood oxygenation level–dependent scan for resting state functional connectivity, diffusion basis spectrum imaging, and fluid-attenuated inversion recovery. For anatomical and pathological analysis, high-resolution magnetization-prepared rapid acquisition and T2 scans are acquired. Arterial spin labeling is acquired using a standard sequence (repetition time =3500 seconds, echo time =9 milliseconds, 90° flip angle, voxel size=3.4×3.4×5 voxels, 64×64 acquisition matrix, 22 axial slices with a 1-mm gap). We use pipelines developed by the Washington University in St. Louis Central Neuroimaging Data Archive and FreeSurfer software (version 5.3) to process the imaging data. Brain volumes and CBF are the primary outcome variables generated from MRI scan data. Additional data acquired from the performed sequences, including blood oxygenation level–dependent scan and diffusion basis spectrum imaging data, are considered in secondary analyses.

NP Testing

Participants complete the questionnaires and NP testing after the MRI. Web-based questionnaires assessing mental health, substance use, sleep quality, and subjective memory performance are first administered using an iPad (iPad Air 2, model MH182LL/A; Table 1). Following the questionnaires, the NP testing begins with allowances for breaks when needed. Most tests are administered in paper and pencil format, with some tests administered on the iPad. Questionnaires and NP testing take 2-3 hours to complete (Textbox 1).

Table 1. Questionnaires administered at baseline and end point visits.

Domain and questionnaire	Function
Substance use	
KMSK[a]-Lifetime [33]	Quantify lifetime heaviest use of alcohol, tobacco, marijuana, cocaine, heroin, and opiates
KMSK-30 Day [33]	Quantify use of alcohol, tobacco, marijuana, cocaine, heroin, Rx benzodiazepines, illicit benzodiazepines, Rx opiates, illicit opiates, illicit barbiturates, amphetamines, and methamphetamines in past 30 days
Fagerstrom Test for Nicotine Dependence [34]	Nicotine dependence
Sleep	
Pittsburgh Sleep Quality Index [35]	Measures quality and patterns of sleep
Activities of daily living	
Patient Assessment of Own Functioning [36]	Measures perceived daily functioning impairments
Activity	
International Physical Assessment Questionnaire [37]	Measure of physical activity
Patient-Centered Assessment and Counseling for Exercise [38]	Assess physical awareness
Mood	
Beck Depression Inventory-II [39]	Measures characteristic attitudes and symptoms of depression
Centers for Epidemiologic Studies-Depression Scale [40]	Measures self-reported symptoms associated with depression
Memory	
Prospective Retrospective Memory Questionnaire [41]	Self-report measures of prospective and retrospective memory slips in everyday life.

Premorbid IQ

- Wide range achievement test 3–reading and recognition [56]

Study Arm Randomization

Group randomization is performed after all baseline appointments are completed and the participant is determined to be safe to exercise. A randomization program is employed by the study senior statistician to assign group membership with a 2:1 ratio in EXS and SIS arms, respectively. All study staff directly involved with participant testing are blinded to the randomization; only the personal trainer is aware of the study arm designation. All participants are instructed not to disclose their randomization to study staff.

Interventions

Overview

Each participant is familiarized with the gym facility where the intervention takes place. At the first session, participants are given a Polar chest HR monitor and then instructed to complete a 5-minute warm-up (options include walking on the indoor track, stationary cycling, elliptical, or treadmill). After warm-up, participants complete a 6-minute walk test [57] as an assessment of cardiovascular fitness. Distance walked in meters during the 6-minute period is recorded. The 6-minute walk test is repeated several times throughout the course of the study intervention

XSL•FO
RenderX

for all participants, at intervention visits 20, 40, 60, and at the final visit.

For all subsequent intervention visits, HR is recorded through use of the Polar chest HR monitor, and the 5-minute warm-up is completed before beginning the EXS or SIS session.

Participants are scheduled for 3 intervention visits per week, with all visits supervised by the personal trainer. A participant's intervention is complete after 26 weeks have elapsed. Adherence is defined as the participant completing ≥80% of the expected 78 intervention visits.

EXS Intervention

After the 5-minute warm-up, the participant has the option to start either the cardiorespiratory training portion or resistance training portion first, followed by the other for the second half of the daily session. Resistance training covers a full-body workout including 3 lower body and 4 upper body areas, with exercises including leg press, knee extension, knee flexion, seated row, chest press, latissimus dorsi pulldown (lat pulldown), and triceps extension. A combination of guided motion machines and free weights is used.

At the second gym session, a 1-repetition maximum (1RM; measured in pounds) is assessed for each of the major muscle group stations (leg press, lat pulldown, seated row, and chest press) to establish peak muscular strength. The rate of perceived exertion scale (1-10) is used to measure intensity. The 1RM is reevaluated after each month.

During the course of the EXS intervention, the trainer begins the resistance training program with weight for each exercise set to 60% of each 1RM. Three sets of 8-10 repetitions are completed for each exercise for the first 3 months. The trainer increases the weights to 70% of the reevaluated 1RMs for the final 3 months. A rest period of 2 seconds is allowed between each repetition, 1-2 minutes of rest is allowed between each set, and 2-4 minutes of rest between each exercise station or machine.

Cardiorespiratory training includes brisk walking on the indoor track, stationary cycling, treadmill, and elliptical machines. Participants may use a combination of different cardiorespiratory machines to reach their target duration and HR. Target HR begins at 50% of the heart rate reserve (HRR) as assessed during the initial cardiorespiratory testing. Throughout the study, the target HR increases to 85% of the participants' HRR. Duration is progressively increased from 10 to 40 minutes of continuous exercise as the participant acclimates to the exercise program. Intensity is increased as exercise yields a lower HR than previously observed or by 5%-10% per month. After each session, the participant cools down to bring their HR to a comfortable level that would allow conversation. The trainer then demonstrates a stretching routine that covers the major muscle groups of the body (quadriceps, hamstrings, hips or glutes, chest, back, shoulders, and triceps).

SIS Intervention

The SIS group serves as a control group against which to gauge the effects of aerobic and resistance training on brain integrity. Participants in this group follow the same intervention schedule and timeline as the EXS group. SIS participants are supervised by the same personal trainer and receive the same amount of attention and class interaction as participants in the EXS program. This group receives instructions on stretching, range of motion (RoM), limbering, and toning, but intensity is less than that achieved in the EXS group. Activities will focus on flexibility enhancement. As the participant's level of flexibility increases, stretches with increasing levels of difficulty are incorporated into the program.

For the stretching intervention, the participant begins with the 5-minute warm-up. During the second session, the trainer conducts RoM testing for hip flexion, shoulder flexion, ankle dorsi, and plantar flexion on both sides of the body using a goniometer. The RoM is reevaluated after each month.

During each SIS visit, the trainer demonstrates and provides a list of stretches that may include but are not limited to the following muscle groups: hamstrings, gluteals, lower back, upper back, chest, calves, shoulders, triceps, and arm and wrists. Participants complete 10-12 stretches with 30-60 second intervals for each stretch. These stretches are repeated 2-3 times on each side of the body during each session. HR is maintained between the established resting HR and 50% of the HRR.

Midpoint (3-Month) Visit

Once the participant has completed 3 months (36-40 gym visits), a midpoint visit is scheduled. At the midpoint visit, an abbreviated NP battery is administered (see Textbox 1). This battery includes tests that were administered during the baseline NP testing, with alternative versions of NP tests used when available. Additionally, the participant is again provided an Actigraph to be worn for 1 week in order to assess daily activity during participation in the study.

End Point (6-Month) Visit

Once the intervention portion (78 sessions) is completed, the end point (6-month) visits are scheduled. End point visits are repeats of the baseline visits 1 and 2, with the cardiovascular testing visit occurring first. The DXA scan and $VO_{2\,max}$ test are completed, fasting blood samples are collected, and the participant is given an Actigraph to wear on the nondominant wrist for 1 week. After 1 week, the participant returns for the follow-up MRI and NP testing visit. Upon completion of the study, participants are given a 6-month membership to a local fitness facility.

Midpoint and end point visits are completed for all participants, regardless of assigned intervention.

Secondary End points

This study aims to also identify key implementation factors needed for scale-up of an EXS program in older people living with HIV from a single site to HIV clinics at multiple institutions. In order to gain a sound understanding of contextual factors that affect implementation of an EXS program for older, sedentary people living with HIV, we are conducting interviews and focus groups with staff and participants at several time periods during the intervention. This allows us to (1) tailor aspects of the program to coincide with reported barriers to implementation, (2) develop strategies to enhance adherence,

XSL•FO
RenderX

and (3) make recommendations for future intervention strategies based on modifiable psychosocial characteristics of people living with HIV as they progress through the intervention.

Planned Recruitment and Power Analyses

The recruitment goal for this study is 150 older participants living with HIV, with 100 randomized to the EXS intervention and 50 participants randomized to the SIS control intervention. With this sample size, we calculated 80% power to detect an effect size (Cohen *d*=0.49) in the primary analyses (aim 1 hypotheses *a* and *b*; aim 2 hypothesis *a*). Anticipating a 20% dropout rate at 26 weeks (final EXS n=80; SIS n=40), we would have 80% power to detect an effect size (Cohen *d*=0.55). For aim 2 hypothesis *b*, and anticipating a 20% dropout rate, we would have 80% power to detect a predictor explaining R^2=0.10 or 10% of the variation in the outcome.

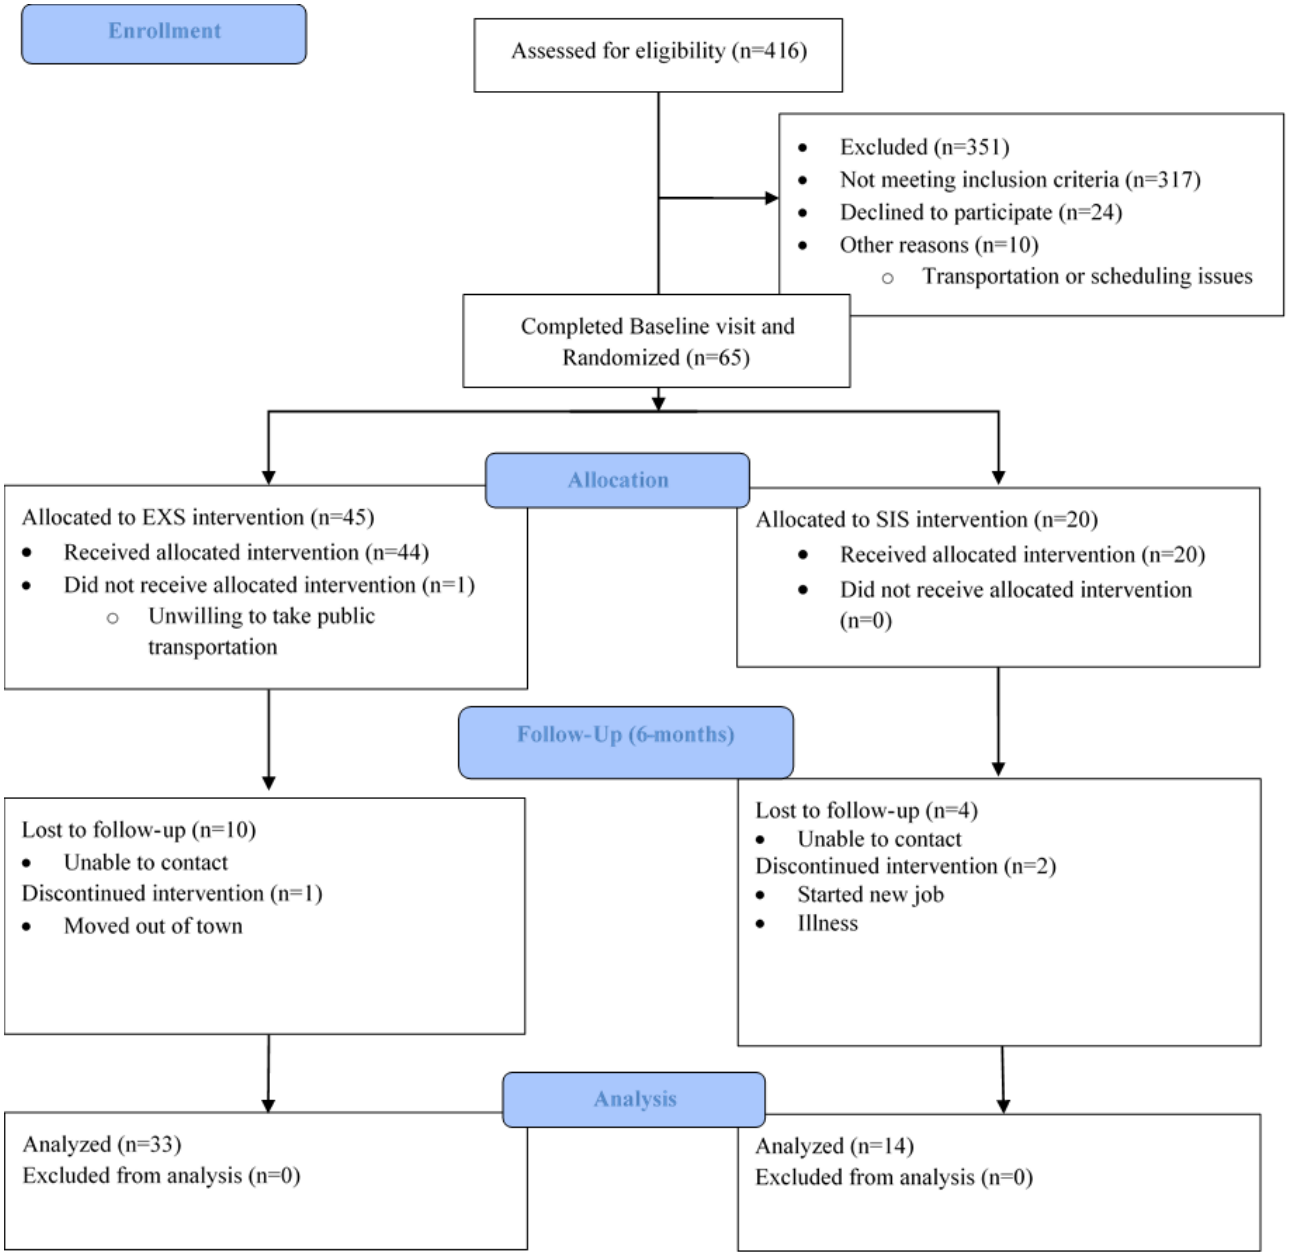
Statistical Analyses

For aim 1, planned statistical analyses include *t* tests examining change in cognition (domain and global cognition *z* scores), cardiorespiratory fitness, physical function, and questionnaire data from the baseline to end point visits between the EXS and SIS groups. This analysis uses all randomized participants under the intent-to-treat paradigm. Additionally, linear models are used to determine the mediating effect of the cardiorespiratory fitness and physical function markers on the change from baseline in domain and global cognition *z* scores by including these markers, together with group assignment, as predictors in the model.

For aim 2, similar analyses are conducted to those as described for aim 1, with brain volumetrics and CBF values used in place of cognitive performance. Brain volumes are adjusted for intracranial volume. Linear regression analyses are conducted to examine relationships between changes in brain volumetrics or CBF and changes in cognitive performance from baseline to end point visits.

For the exploratory hypothesis, linear regression models are used to examine relationships between changes in inflammatory or metabolic markers and changes in brain volumetrics, CBF, or cognitive performance. Group assignment is included as a predictor in the model.

Ethics Approval



Before completing any study procedures, all participants provided written informed consent that was approved by the Institutional Review Board at Washington University in St. Louis (IRB #201508002). All study procedures were in accordance with the ethical standards described by the Helsinki Declaration. Study participants are assigned an identification number, allowing all stored records to be deidentified. Deidentified data are kept in a locked file room or stored in a password-protected database on a password-protected computer. All participants are monetarily compensated for their participation, prorated to each study visit or gym visit completed, up to US $815. Participants can withdraw from the study at any point.

Results

Recruitment and data collection are complete as of December 2020 (Figure 1). Recruitment and data collection were paused between March 2020 and September 2020 due to the COVID-19 pandemic and again paused in November 2020 due to increasing COVID-19 cases. Consequently, the decision was made to terminate the recruitment phase due to limited time for any newly enrolled participants to complete the 6-month intervention. Baseline study participant demographic and clinical characteristics are provided in Table 2. A total of 65 individuals were enrolled and randomized at a baseline visit, with 47 completing the study. As of July 2022, the study remains open for data processing and analyses. Data processing, cleaning, and organization are complete as of December 2021. Data analysis began in January 2022, with publication of study results for primary aims 1 and 2 expected by early 2023.

[b]SIS: social-interaction stretching.

Discussion

Exercise interventions have demonstrated beneficial effects on physical fitness and brain integrity in middle-aged to older adults without HIV infection [4-7]. However, few studies have examined these relationships in people living with HIV. Adjunctive therapies designed to improve brain integrity are needed as the population of people living with HIV over the age of 50 years continues to grow and experience cognitive impairment and decline despite cART and well-controlled viremia. This study was designed to examine the effects of a 6-month exercise intervention on cardiometabolic risk, cardiorespiratory and physical fitness, cognitive performance, and neuroimaging metrics of brain integrity in a sample of sedentary people living with HIV aged ≥40 years on stable cART and who are virologically well controlled.

This study has several important strengths that underlie its potential contributions to the field of therapeutic interventions for older people living with HIV. First, this study recruits a sizeable sample of sedentary people living with HIV, primarily over the age of 50 years, to complete an exercise intervention or an attention control program involving stretching. To date, the few interventional studies examining effects of an exercise program in people living with HIV have included a relatively small number of individuals, limiting the generalizability of the results, and have primarily been conducted in younger (age ≤40 years) individuals. However, people living with HIV aged >50 years are estimated to make up over half of all individuals currently living with HIV in the United States [58] and are at a higher risk for cognitive impairment compared to younger individuals [59,60]. Additionally, this group of people living with HIV is well characterized in terms of physical health, blood inflammatory markers, cognitive ability, and brain imaging, allowing for in-depth analyses examining the effects of the EXS intervention on these outcomes. The 6-month duration of the intervention with midpoint data collection also allows for the potential capture of both acute and long-term effects of exercise on the brain in people living with HIV. Finally, the inclusion of a focus group will help inform future exercise programs for people living with HIV by assessing the feasibility of such programs barriers and facilitators for enrollment and retention, as well as predictors of successful adherence to the program.

This study design does have inherent challenges. Recruitment and retention are challenges for any prospective study requiring lifestyle changes for a long duration. Our inclusion and exclusion criteria require a participant to be healthy enough to safely participate in a 6-month supervised exercise program, limiting its generalizability; however, this requirement selects a population who are potentially the most likely to tolerate and complete the study intervention and therefore benefit from participation. Finally, the nature of the study may also introduce a recruitment bias into the sample, as people living with HIV who are willing and able to travel to the study site 3 times a week for 6 months during normal working hours may have baseline differences in socioeconomic status, physical health, and cognitive ability than people living with HIV who are not able to meet these requirements. However, by focusing recruitment on a diverse sample (eg, sex, race or ethnicity, education level, and cognitive ability) and by using group interviews to systematically assess these obstacles, we hope to broaden the generalizability of this intervention to a larger proportion of the population living with HIV. Results gained from this study will help inform clinicians as to possible benefits gained from prescribing an exercise program to middle-aged to older people living with HIV who may be experiencing cognitive issues, as well as help advise the development and implementation of future exercise programs for people living with HIV.

Abstract

Background: Heart failure (HF) is characterized by an increasing prevalence, representing a public health problem and a significant cause of morbidity and mortality. Self-care is a cornerstone approach for optimizing therapy for patients with HF. Patients play a crucial role in managing their condition, given that several adverse health outcomes might be avoided with adequate self-care. In this regard, the literature describes motivational interviewing (MI) as highly favorable for treating chronic diseases, with promising results supporting its efficacy in enhancing self-care. Moreover, caregivers' availability constitutes a fundamental supporting factor among the strategies to improve self-care behaviors in people with HF.

Objective: The primary study aim is to test the efficacy of a structured program, including scheduled MI interventions, in improving self-care maintenance in the 3-month follow-up from the enrollment. Secondary aims comprehend the assessment of the effectiveness of the above intervention on secondary outcomes (eg, self-care monitoring, quality of life, sleep disturbance) and the corroboration of the superiority of caregivers' participation to the intervention over the program administrated only to individual patients in enhancing self-care behaviors and other outcomes at 3, 6, 9, and 12 months from the enrollment.

Methods: This study protocol designed a prospective, parallel-arm, open-label, 3-arm, controlled trial. The MI intervention will be administered by nurses trained in HF self-care and MI; the education program will be provided to nurses by an expert psychologist. Analyses will be performed within the framework of intention-to-treat analysis. Comparisons between groups will be based on an alpha of 5% and 2-tailed null hypotheses. In the case of missingness, analyzing the extent of the missingness and identifying underlying mechanisms and patterns will guide imputation methods.

Results: The data collection was started in May 2017. We completed the data collection with the last follow-up in May 2021. We plan to perform data analysis by December 2022. We plan to publish the study results within March 2023.

Conclusions: MI enhances potential self-care practices in patients with HF and their caregivers. Although MI is effectively largely employed either alone or combined with other treatments and is administered in different settings and ways, face-to-face interventions seem to be more effective. Dyads with higher shared HF knowledge are more efficient in promoting self-care adherence behaviors. Moreover, patients and caregivers may perceive proximity with health care professionals, resulting in a

XSL•FO
RenderX

better ability to follow the received health professionals' directions. The scheduled in-person meetings with patients and caregivers will be exploited to administer MI, respecting all the safety regulations for infection containment. The conduction of this study may support changes in clinical practice to include MI to improve self-care for patients with HF.

Introduction

Heart failure (HF) is defined as "a clinical syndrome with symptoms and or signs caused by a structural and/or functional cardiac abnormality and corroborated by elevated natriuretic peptide levels and or objective evidence of pulmonary or systemic congestion" [1]. HF is characterized by an increasing prevalence and burden, representing a public health problem and a major cause of morbidity and mortality [1,2]. Globally, the overall estimated incidence of HF disease is 1-4 cases per 1000 person-years, with a prevalence of 10-30 cases per 1000 persons [3]. The incidence of the disease in Europe is about 5 per 1000 person-years, with a prevalence of 1%-2% in adults [4]. The prevalence of HF increases significantly with age: 6.6% of men with HF are aged 60 to 79 years, and 10.6% are aged 80 years and older [5].

Due to the impact of the disease, some authors have defined HF to be the "global outbreak" of the 21st century about 25 years ago [6,7]. An estimated 64.3 million people worldwide are affected by HF [7]; the growing and aging of the population, the high survival rate after an acute coronary event, and the effectiveness of secondary prevention and drug treatment result in a constant increase in the number of patients living with HF [4,7-9]. HF is most frequently diagnosed in patients who are hospitalized and 65 years and older [10]. People surviving at 1 and 5 years of follow-up have increased by about 20% compared to 1950-1970s [11]; however, 5-year mortality is still high, resulting in 24.4% for people aged 60 years and 54.4% for people aged 80 years [5].

Outcomes related to HF have improved in recent years [4]. Thus far, hospitalization and rehospitalization still impact the health care system; treating patients with HF costs US $30 billion every year, and this figure is destined to grow further, reaching US $70 billion by 2030 in the United States [5]. Once HF is first diagnosed, patients are readmitted to the hospital about once a year; this trend contributes to increasing health care resource consumption and worsens patients' quality of life (QoL) [7,12]. Moreover, HF is associated with considerable morbidity and mortality [13]. A 60- to 90-day mortality from diagnosis is about 10% in patients with HF; 1-year mortality is about 36% [14].

Self-care is a cornerstone approach for optimizing therapy for patients with HF [15]. Self-care is defined as an active, cognitive process through which people engage to maintain their health (self-care maintenance) and recognize and manage signs and symptoms (self-care monitoring and management, respectively) [16]. Precisely, self-care maintenance is defined by behaviors to preserve physical and psychological status, self-care monitoring encompasses behaviors about the ability to recognize signs and symptoms, and self-care management consists of the ability to manage signs and symptoms when they occur [17,18]. The consequences of inappropriate self-care behaviors can be dramatic, resulting in emergency hospital admissions, recurrent hospitalizations, and preventable complications. Poor adherence to treatments and improper disease management are the main causes of the exacerbation of HF [19-21]. In this regard, patients play a key role in the management of their condition, given that several negative health outcomes might be avoided with effective self-care [20,22].

Caregivers' availability constitutes a key supporting factor among the strategies to improve self-care behaviors in people with HF [23]. Studies involving patients with HF and their caregivers [24-26] report that self-care in HF is a "dyadic phenomenon" [27]: informal caregivers, such as a family member or a close friend, are fundamental in contributing to HF patients' self-care, as they provide tangible and emotional support and cooperation [23]. Caregivers tend to adapt their conduct based on patients' ability to care for themselves: they may act by reminding self-care behaviors or replacing the patient in the self-care process.

Many international studies have tested interventions to improve self-care in patients with HF involving caregivers to enhance the effectiveness of educational interventions [25,28,29]. Among the interventions reported in the literature, motivational interviewing (MI) has been described as highly favorable for treating chronic diseases, with promising results supporting its efficacy in enhancing self-care [30]. This intervention is a directive client-centered counseling approach for eliciting behavioral change by helping people to explore and resolve ambivalence. MI considers several critical factors in improving self-care in patients with HF and is based on brief interventions, which are feasible in several health care settings [30,31].

A recent study involving patients with HF and their caregivers tested the efficacy of MI in improving self-care maintenance, self-care management, and self-care confidence in adults with HF at the 3-month assessment after enrollment [32]. In this study, a 1-year follow-up was also performed, and the MI was performed only once. The influence exerted by caregivers on self-care behaviors employed by patients was also assessed using a 3-arm design [32]. More precisely, in the first arm, MI

XSL•FO
RenderX

was administered to patients only; in arm 2, MI was administered to patients and caregivers; and in arm 3, participants received usual care (standard education). The study demonstrated that MI performed by trained nurses effectively improved self-care in patients with HF, especially in the arm where it was administered to both patients and caregivers [32]. However, the 1-year follow-up showed that the effects of MI on self-care confidence and on proxy measurement of specific self-care behaviors, such as physical activity and functioning, did not last over 3 months if administered only one time [32]. Similar results emerged from a recent meta-analysis [33].

Thus far, it is still unclear if administrating face-to-face MI more than once over 1 year might stabilize the positive effects of MI on self-care behaviors in patients with HF, and additional evidence is required to determine whether performing a MI on the dyad (patients and caregivers) is better than applying MI only to the individual patient [33]. For these reasons, this study protocol designed a prospective, parallel-arm, open-label, 3-arm, controlled trial for purposing the following aims: (1) to test the efficacy of a structured program including scheduled MI interventions in improving self-care behaviors (specifically, self-care maintenance) among patients with HF at 3 months from the enrollment; (2) to test the effect of a structured program including scheduled MI interventions on secondary outcomes (eg, self-care monitoring, QoL, sleep disturbance) at 3, 6, 9, and 12 months from the enrollment; and (3) to corroborate the superiority of the caregivers' participation to the structured program including scheduled MI interventions over the program administrated only to individual patients in enhancing self-care behaviors.

Methods

Trial Design

This is a prospective, parallel-arm, open-label, 3-arm, controlled, and superiority randomized controlled trial (RCT). This protocol was designed and reported following the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 statement: defining standard protocol items for clinical trials (see Multimedia Appendix 1).

Sample and Setting

Outpatients referred to the heart failure clinic and inpatients at discharge after hospitalization for HF will be enrolled in the study. The single center where the study will be implemented is the IRCCS Policlinico San Donato, northern Italy. The recruitment strategy will be based on enrolling patients continuously until the predetermined sample size is achieved.

Randomization, Allocation Concealment, and Blinding

Patients and caregivers will be randomized into 3 study arms by a computer software program that generates the random sequence. A simple randomization algorithm will be used to generate the sequences, and the randomization list will be concealed by using cloud-based software with restricted access only to the statistician who developed the randomization list and who will not be involved in the data analysis.

In the control group, patients receive MI, and caregivers receive traditional educational treatment. In the first interventional arm, MI will be used to reinforce the education of patients and caregivers will receive standard education. In the second interventional arm, MI will be used to reinforce self-care education in patients and caregivers. The standard educational approach will be adopted for all patients and caregivers and will be based on the preidentified informational materials about self-care in patients with HF.

The nature of the intervention does not allow researchers to employ the blindness of participants and investigators because the interventionist and the enrolled subjects will be aware of the allocated arm; in this regard, the study is considered open-label. However, blinding will be employed in the outcome assessment as the outcome assessors will have to follow predefined standard operative procedures that encompass their blinding in assessing self-care. Furthermore, blinding will be ensured during the data entry process and analytics. Data will be managed with the Research Electronic Data Capture (REDCap) platform, a secure, web-based software application and workflow methodology designed to collect and manage data for research studies.

Inclusion and Exclusion Criteria

The following inclusion criteria will be used for patients: being 18 years and older, diagnosis of HF with New York Heart Association (NYHA) Class II-IV, no acute coronary events within 3 months, consent to participate in the study, score ≤ 2 to at least 2 items of the Self-Care of Heart Failure Index 6.2 (SCHFI 6.2) at baseline [34], scores on Six Item Screener >4 [35], living at home, understanding of spoken and written Italian. The exclusion criteria for patients will be severe cognitive impairment (score 0-4 on the Six-item Screener) [35], acute coronary events that occurred within 3 months, living in nursing homes or residential settings, and caregivers unwilling to participate in the study.

The following inclusion criteria will be used for caregivers: being 18 years or older, being the primary informal caregiver identified by the patient, consent to participate in the study, and understanding of spoken and written Italian. Their unavailability will give the exclusion criterion for caregivers to participate in the study.

Instruments and Outcomes

The measurements for patients will be based on collecting sociodemographic and clinical characteristics data (eg, age, gender, NYHA class), SCHFI 6.2 [34], Heart Failure Somatic Perception Scale to assess patient's ability to feel the symptoms of HF [36], Six Item Screener to identify subjects with cognitive impairment [35], Kansas City Cardiomyopathy Questionnaire (KCCQ) to assess HF-specific QoL [37], Mutuality Scale (MS) to assess the feeling of intimacy and positive relationship between patient and caregiver [38], 12-Item Short Form Survey (SF-12) to measure generic health-related QoL [39], Pittsburgh Sleep Quality Index (PSQI) to assess sleep quality [40], Hospital Anxiety and Depression Scale (HADS) to detect depression and anxiety [41], Montreal Cognitive Assessment (MoCA) to detect

XSL•FO
RenderX

mild cognitive impairment [42], and Charlson Comorbidity Index (CCI) to assess comorbidities [43].

The measurements for caregivers will be based on collecting sociodemographic data (eg, age, gender, marital status, and relationship with the patient), the Caregiver Contribution to Self-care of Heart Failure Index (CC-SCHFI) to measure the caregiver contribution to self-care in patients with HF [44], SF-12 [39], MS [38], Caregiver Preparedness Scale to assess how the caregiver feels prepared to care [45], HADS [41], Multidimensional Scale of Perceived Social Support to assess the level of social support perceived by patients with HF in managing the disease [46], and PSQI [40].

All the tools used to assess both patients' and caregivers' outcomes are constituted by validated and widely used instruments. The SCHFI 6.2 [34] is an instrument adopted to assess patients' self-care, which is the primary outcome. It is a widely used scale that comprises 3 subdimensions: self-care maintenance, self-care management, and self-care confidence. A 0 to 100 score can be attributed to each dimension; scores higher than 70 indicate an adequate self-care level. The SCHFI 6.2 [34] will also be used to assess the self-care maintenance at 6, 9, and 12 months from enrollment. Several additional secondary outcomes will be evaluated at a patient level using the measurements described below.

The Heart Failure Somatic Perception Scale is the instrument used to measure physical HF symptoms. It is an 18-item Likert scale that assesses the extension of the discomfort due to symptoms perceived by patients in the week before assessment. The score for each item can range from 0 (*I did not have the symptom*) to 5 (*extreme discomfort*). Once scores are summed, higher values indicate higher symptoms bothersomely.

The Six Item Screener [35] is adopted to identify cognitive impairment or dementia; patients' assessment using this tool requires a 3-item recall test, and it only takes 1 to 2 minutes to be administered: the subject should be able to repeat the 3 items initially and recall them after 5 minutes. The number of errors recorded in patients' answers is used as a cutoff point. The KCCQ [37] assesses physical function, symptoms, social function, self-efficacy, and QoL in patients with HF. The KCCQ is a 23-item Likert scale used to measure the health status responsive to changes in clinical condition. The KCCQ scoring regarding health status can range from 0 to 100: 0-24 indicates very poor to poor; 25-49 poor to fair; 50-74: fair to good; and 75-100 good to excellent.

The MS is a 15-item Likert instrument used to measure mutuality from the patient's or the caregiver's perspective. Each item can range from 0 to 4. The mean of all item scores constitutes the overall scale score; higher scores indicate better mutuality. The SF-12 [39] is a practical, reliable, and valid tool adopted to measure physical and mental health status. It is a 12-item short-form health survey with eight domains and 1 or 2 items per domain: physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional, and mental health. The Physical Component Summary (PCS) and Mental Component Summary (MCS) scores are composed of each health domain score. Scores range from 0 to 100; higher scores indicate better physical and mental health functioning. A score of 50 or less on the PCS-12 determines the physical condition; a score of 42 or less on the MCS-12 indicates "clinical depression."

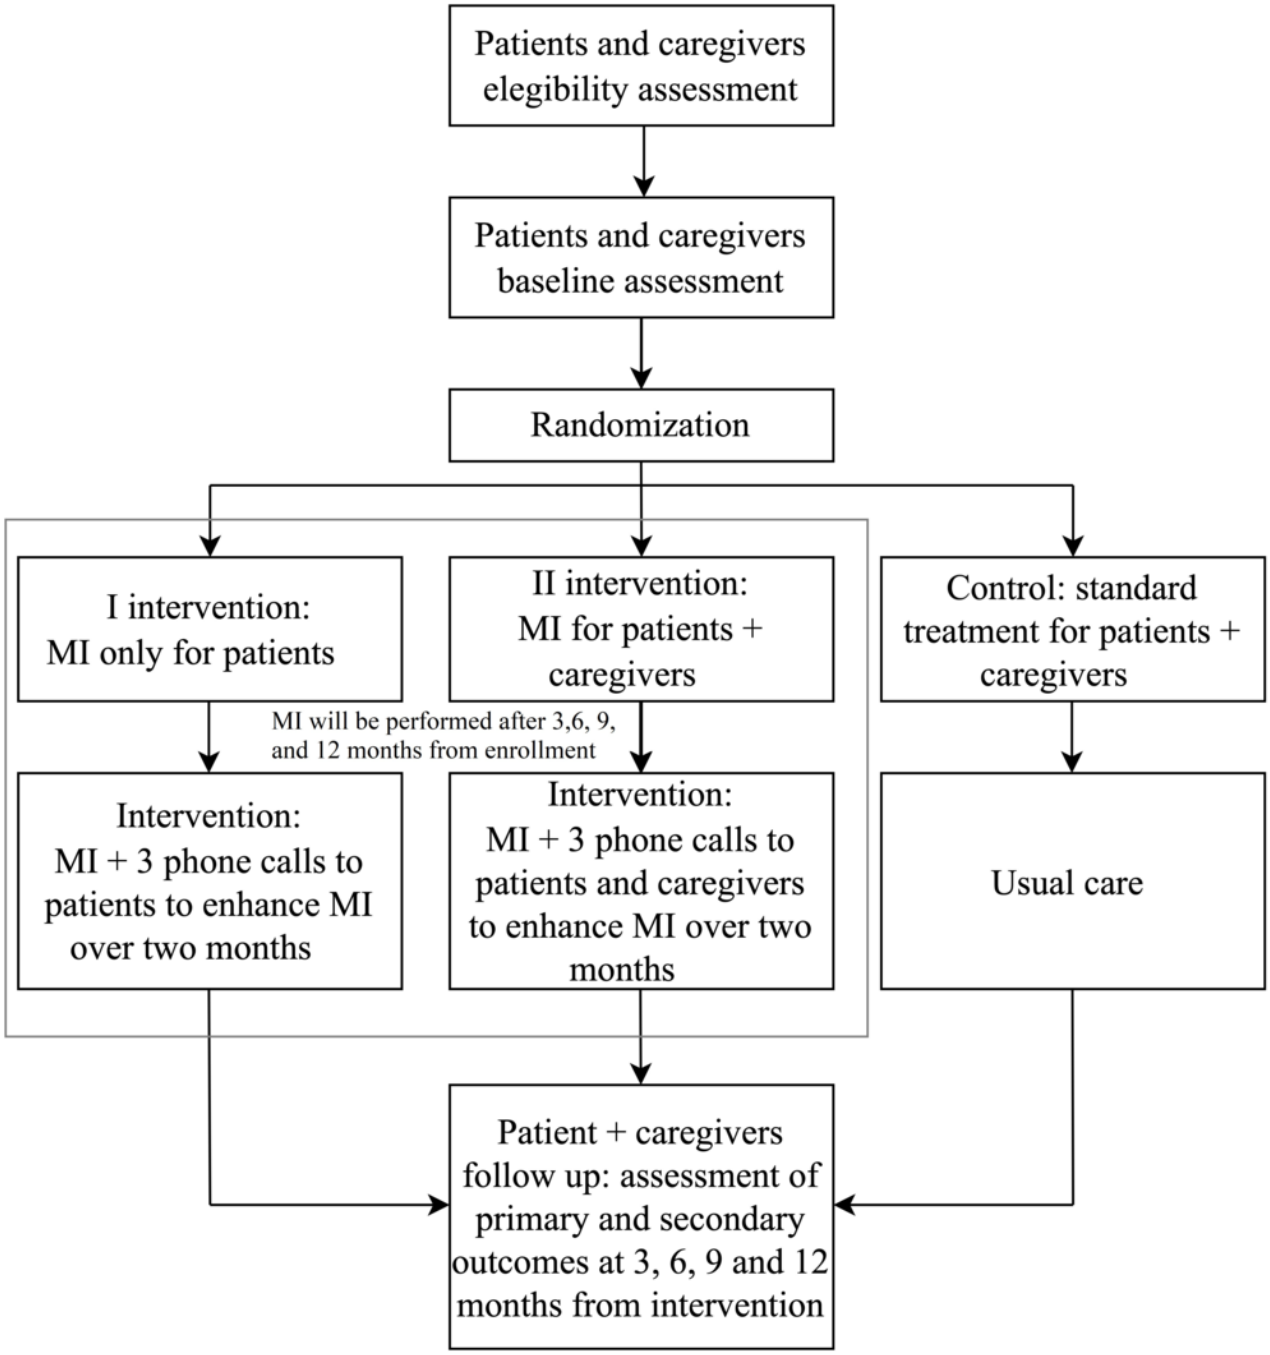
The PSQI [40] is a self-report questionnaire used to screen patients for the presence of significant sleep disturbance experienced in the month before the assessment. The measure consists of 19 individual items, creating 7 components that are summed to obtain a global PSQI score ranging from 0 to 21; higher scores indicate worse sleep quality. The HADS [41] is a 14-item measure used to detect anxiety and depression in patients. Items are rated on a 4-point scale. The HADS produces 2 scales, 1 for anxiety (HADS–A) and 1 for depression (HADS–D); anxiety and depression are confirmed by scores equal to or greater than 11.

The MoCA is used to detect mild cognitive dysfunction. It assesses different cognitive domains: attention and concentration, executive functions, memory, language, visuoconstructional skills, conceptual thinking, calculations, and orientation. Scores on the MoCA range from 0 to 30; a score of 26 and higher is considered normal. The CCI [43] predicts 10-year survival in patients with multiple comorbidities. The updated index of 12 comorbidities predicts in-hospital mortality; the severity of comorbidity is categorized into 3 grades: mild, moderate, and severe, with CCI scores of 1-2, 3-4, and ≥5, respectively.

The following tools have been used to evaluate the caregivers' specific secondary outcomes. The CC-SCHFI [44] comprehends 10 items that assess the caregiver's contribution to maintaining a stable condition and 10 items that assess the caregiver's ability to monitor and recognize symptoms of HF decompensation, implement adequate treatments, evaluate those treatments, and help patients to take part in each phase of the self-care process. Each measure uses a 4-point Likert response scale with a score from 0 to 100; higher scores indicate a higher contribution to self-care.

The Caregiver Preparedness Scale is an instrument that consists of 8 items that ask caregivers how prepared they feel to handle multiple domains of caregiving. Responses are rated on a 5-point Likert scale with scores ranging from 0 to 4. The scale is scored by calculating the mean of all items. Higher scores indicate higher caregiver preparedness. The Multidimensional Scale of Perceived Social Support is a 12-item scale of perceived appropriateness of the support offered by family, friends, and significant other. The measure uses a 5-point Likert scale. The score can range from 12 to 84, and a higher score indicates greater social support perceived by the caregiver.

Intervention and Participant Timeline



All patients meeting the inclusion criteria and not any exclusion criteria will be randomized by the researchers responsible for the study after having signed a consent form. Patients will be informed about the single allocation and will not be aware of the randomization list and allocation sequence. The intervention will be administered by nurses trained in HF self-care and MI.

The study flowchart is shown in Figure 1. In the first interventional arm, the MI intervention will be administered to patients only, and caregivers will receive standard education.

XSL•FO
RenderX

MI is used to reinforce areas of inadequate self-care (eg, low physical activity or not having a low-salt diet) and to agree with the patients on the steps to be adopted to modify their behavior. MI focuses on a tailored patient approach to improve patients' adherence to self-care behaviors. The intervention will last approximately 30 minutes. Thereafter, the nurse who performed the MI will contact the patients over the phone 3 times every 2 weeks from the first MI during the first 2 months after MI to strengthen the intervention. Then, the intervention will be used again after 3, 6, 9, and 12 months from enrollment. After each MI session, both patients and caregivers will be asked to complete the follow-up questionnaires post enrollment as described in the "Instrument" section. In the second interventional arm, MI intervention will be administered both to patients and caregivers. The intervention will be administered to the dyad in 1 session, and patients and their caregivers will receive the reinforcing educational treatment calibrated on the specific lacking areas of patients' self-care behaviors. After each MI session, both patients and caregivers will be asked to complete the follow-up questionnaires post intervention. In the control group, the dyads will receive only traditional educational treatment and complete the questionnaires after 3, 6, 9, and 12 months of follow-up post intervention. Enrolled dyads will be monitored by the research team responsible for recruitment and follow-up.

Training for Nurses

Nurses will participate in a training program to acquire the competence to conduct a MI. The education program will be provided to nurses by an expert psychologist.

Sample Size Calculation

For determining sample size, based on a recent literature review [33], it was hypothesized that both experimental arms would show an improvement in self-care maintenance, and the adequacy of self-care maintenance scores in the experimental arm was shown in approximately 50% (n=250) of patients. Current Italian data indicated that roughly 20% (n=238) of Italian adults with HF reported adequate scores of self-care maintenance (scores higher than 70 are considered adequate) [47,48]. For this reason, the sample size estimation was based on a 2-sample proportions test: the expected proportion in experimental arms was equal to 50% of adequate scores (proportion 1) versus 20% of the adequate score in the control group based on the current descriptive literature (proportion 2, delta=30%). Setting alpha at .05 and power at 0.90, the number per group to identify significant differences was equal to 52. Therefore, as the study has 3 arms, 156 participants are required to test the differences in proportions between groups. Given the likelihood of a 15% rate of dropouts as per previous studies [32], the total sample size was equal to 180 diads (n=60 per arm). A consecutive screening and enrollment will be performed.

End Points

The end points of this study are designed for the specific aim focused on testing the efficacy of a structured program, including scheduled MI interventions, in improving self-care maintenance. Precisely, the primary end point is the difference between self-care maintenance levels between the 2 groups in the 3-month follow-up. The secondary end points are the differences between self-care maintenance, self-care monitoring, and self-care management at 6, 9, and 12 months of follow-up after enrollment.

Statistical Analysis

Analyses will be performed within the framework of intention-to-treat analysis. Sociodemographic and clinical characteristics will be summarized and compared between groups in the baseline. For the primary end point, the differences between proportions of adequate self-care maintenance in the 3-month follow-up will be assessed using the chi-square test (or the Fisher exact test if adequate) and performed to compare the first experimental arm (MI delivered only to patients) and control group and between the second experimental arm (MI delivered to the dyad) and control group.

In addition, beyond the comparison between proportions aimed to detect clinically meaningful differences between groups, the standardized 0-100 scores of self-care maintenance will be compared using a 1-way ANOVA with post hoc comparisons adjusting the significance according to Bonferroni. A stepwise logistic regression model based on a dichotomic outcome (adequate self-care vs inadequate self-care scores) will be used to encompass the effects of clinical and sociodemographic covariates in determining the association between the group and the proportion of adequate self-care. The first step of the stepwise approach will include the trial group as an independent variable to determine the odds ratios, highlighting the associations between each group and the dichotomic outcome. The second step will allow authors to include the covariates that show significant linear relationships with the outcome to adjust the associations described in the first step. This model will be evaluated using goodness-of-fit tests, such as the Hosmer-Lemeshow test. The same approach will be used by considering the standardized 0-100 scores of self-care maintenance as the dependent variable and, therefore, in the framework of multiple linear regression. While the logistic regression will provide an association between the adequacy of self-care maintenance and the arm by accounting covariates for adjusting the estimate, the multiple linear regression will highlight the amount of variance explained by belonging to each arm, accounting for the same covariates used in the logistic regression.

The analytical strategy for testing the secondary end points will be the same adopted for the primary end point. In addition, in the framework of time-to-event analysis, the cumulative probability of shifting from inadequate to adequate self-care (ie, the event will be defined as each shift from self-care maintenance scores under 70 to scores equal to or greater than 70) at 6, 9, and 12 months of follow-up after enrollment will be described using Kaplan-Meier curves and inferentially tested using log-rank tests.

The aims focused on testing the effect of the structured program based on MI interventions on secondary outcomes (eg, self-care monitoring, QoL, sleep disturbance) at 3, 6, 9, and 12 months from the enrollment and corroborating the superiority of the caregivers' participation to the MI interventions over the MI interventions administrated only to individual patients in enhancing self-care behaviors are not used for determining specific end points. Therefore, the analytical plan for assessing those aims will be based on exploratory analyses based on comparing the secondary outcomes scores between the study arms.

In the case of missingness, analyzing the extent of the missingness and identifying underlying mechanisms and patterns will guide imputation methods. If missing at random criteria will be plausible, multiple imputations based on random effect models will be considered for missingness >5% of the outcome assessments at each time point of the trial. Inferential analyses will be based on an alpha of 5% and 2-tailed null hypotheses using Stata 17 (StataCorp).

Ethical Considerations

The study protocol and template consent forms have been reviewed and approved by the Ethical Committee of San Raffaele Hospital (approval #74/INT). Also, the study protocol has been registered at ClinicalTrials.gov (NCT05595655). Any amendments to the protocol will be submitted to the committee. Patients and caregivers will have to sign the informed consent forms before the randomization. Patients and caregivers may leave the study at any time. The withdrawal from the study will not imply any prejudice, as fully documented and explained in the informed consent. The full protocol will be available freely.

Results

The data collection was started in May 2017. We completed the data collection with the last follow-up in May 2021. We plan to perform data analysis by December 2022. We plan to publish the study results within March 2023.

Dissemination

Data collected during the study will be considered the property of the principal investigator and the promoter. Participants' sensitive data will be processed according to the current privacy legislation. Study results may be published in peer-reviewed journals or submitted to relevant national and international conferences. The data monitoring committee will be constituted of professional monitors identified by the institution and the principal investigator. The monitoring process will encompass all the procedures to guarantee proper transparency and study conduction. No competing interests will be presented by the data monitoring committee.

Discussion

The general aims of this RCT will be to test the effectiveness of a program of MI interventions in improving self-care behaviors among patients with HF and the caregiver's contribution to self-care and to assess the extent to which caregivers' participation in a program of MI interventions impacts on enhancing self-care behaviors employed by patients. Moreover, this study aims to describe the patient's clinical course and to evaluate the persistence of the results achieved over 1-year time. Several secondary outcomes resulting from questionnaires administered to patients and caregivers will be considered as well, such as sleep quality [40] or HF-specific QoL [7]. Although this study may seem like the Motivational Interviewing to Improve Self-care in Heart Failure Patients (MOTIVATE-HF) study [32], we would like to highlight a difference detectable in the intervention setting administered to patients and caregivers. In fact, in this RCT the interventionist will meet up with the dyad 5 times over 1 year, while in the MOTIVATE-HF study [32] the dyad met up face-to-face with the interventionist only once, and the intervention was bolstered via phone calls. We believe that an intervention including more face-to-face administration would be more powerful in acting on the outcomes of interest.

Although MI is effectively largely used either alone or combined with other treatments and is administered in different settings and ways (ie, patients' homes; over the telephone; and in hospitals, clinics, or nursing homes), face-to-face interventions seem to be more effective [49]. There is rationale to believe that a more intensive intervention program would even ameliorate and better support patients' self-care behaviors. Moreover, involving caregivers in this intensive intervention program would make them feel more participatory and aware of the patient's care process, recognizing their pivotal role in disease management and enhancing their knowledge about HF disease. Besides, dyads with higher shared HF knowledge are more efficient in promoting self-care adherence behaviors [29]. Moreover, both patients and caregivers may perceive proximity with health care professionals, resulting in a better ability to follow the received health professionals' directions [50]. Self-care is built up on attitudes, behaviors, knowledge, and self-efficacy, and the literature suggests that HF self-care management is more challenging than self-care maintenance and is enhanced by the presence of a caregiver who needs to be properly trained and involved [50,51].

This study protocol presents some limitations that need to be pointed out. First, the monocentric design could affect the generalizability of the results, and the nature of the intervention does not permit a double-blind study design. Moreover, the rather short follow-up (1 year) does not give correct estimates of the lifetime effects of the intervention. Lastly, study participants might be healthier than the average person with HF, as they are usually health conscious with a better lifestyle.

The COVID-19 pandemic still causes mobility restrictions for the population to control infection spread; in particular, people living with a disease, such as patients with HF, are forced to be followed up with remotely by health care professionals to reduce the risk of infection [52,53]. This paradigm shift based on telemedicine and remote monitoring may be fundamental to preventing HF from worsening during circumstances discouraging outpatient visits [52]. However, when circumstances permit, patients' encounters with health care professionals are recommended to guarantee a periodic proper assessment for early signs of worsening disease [54]. The in-person meetings with patients and caregivers will be exploited to administer MI, respecting all the safety regulations for infection containment.

Conclusion

MI potentially enhances self-care practices in patients with HF and their caregivers. The conduction of this study may support changes in clinical practice to include MI to enhance the self-care of patients with HF.

Abstract

Background: Farmers in Indonesia have a high risk for hypertension owing to their lifestyle and working environment. Diet management is a solution to reduce hypertension, and Indonesia has natural resources in the agricultural sector that could help manage hypertension. Optimizing vegetable and fruit intake in a plant-based diet (PBD) could help maintain blood pressure among farmers in Indonesia.

Objective: This study aims to explore the health problem of hypertension and the characteristics of local food sources to formulate a PBD menu for treating hypertension, as well as assess the prevalence of hypertension, level of acceptability of a PBD, and associated sociodemographic factors. Further, we want to examine the effectiveness of a community-based nursing program for managing hypertension using a PBD.

Methods: We will use the exploratory sequential mixed methods approach. There will be a qualitative study (phase I) in 2022 and a quantitative study (phase II) in 2023. We will analyze data using a thematic framework in phase I. In phase II, the study will involve (1) questionnaire development and validation; (2) examination of the prevalence of hypertension, the level of acceptability of a PBD, and the associated factors; and (3) a randomized controlled trial. We will recruit farmers with hypertension who meet the study criteria. Moreover, in phase II, we will invite expert nurses and nutritionists to assess the face and content validity of the questionnaire. We will use multiple logistic regression models to estimate the associated sociodemographic factors and the level of acceptability of a PBD. Furthermore, a linear generalized estimating equation will be used to estimate the parameters of a generalized linear model with a possible unmeasured correlation between observations from different time points for systolic and diastolic blood pressure.

Results: A model PBD for hypertension management is expected to be developed. In 2022, we will collect information on hypertension and the characteristics of local food sources for managing hypertension, and will formulate a PBD menu to treat hypertension among farmers. In 2023, we will develop a questionnaire to assess the acceptability of a PBD to manage hypertension among farmers, the prevalence of hypertension, and the sociodemographic factors associated with hypertension among farmers. We will implement a community-based nursing program for managing hypertension using a PBD among farmers.

Conclusions: The PBD model will not be readily available for other agricultural areas since validation of local food variation is required to design the menu. We expect contributions from the local government to implement the intervention as one of the policies in the management of hypertension for farmers in the agricultural plantation areas of Jember. This program may also be implemented in other agricultural countries with similar problems, so that hypertension can be optimally treated among farmers.

KEYWORDS

hypertension; farming; plant-based diet; nursing

Introduction

Hypertension contributes to 12.8% of the total 7.5 million deaths worldwide [1]. The prevalence of hypertension in Indonesia is 33.4% [2], while in East Java province, it is 20.43% [3]. Farming communities have a high risk of health problems [4], including hypertension [5-7]. Hypertension among farmers in Indonesia has reached 36.1% [8]. Our previous study found that the incidence of hypertension among farmers in agricultural areas was 35.8% [9]. This shows the magnitude of the problem of hypertension among farmers, and there is a need for the management of care using an agricultural health nursing (agronursing) approach to realize the health status of farmers.

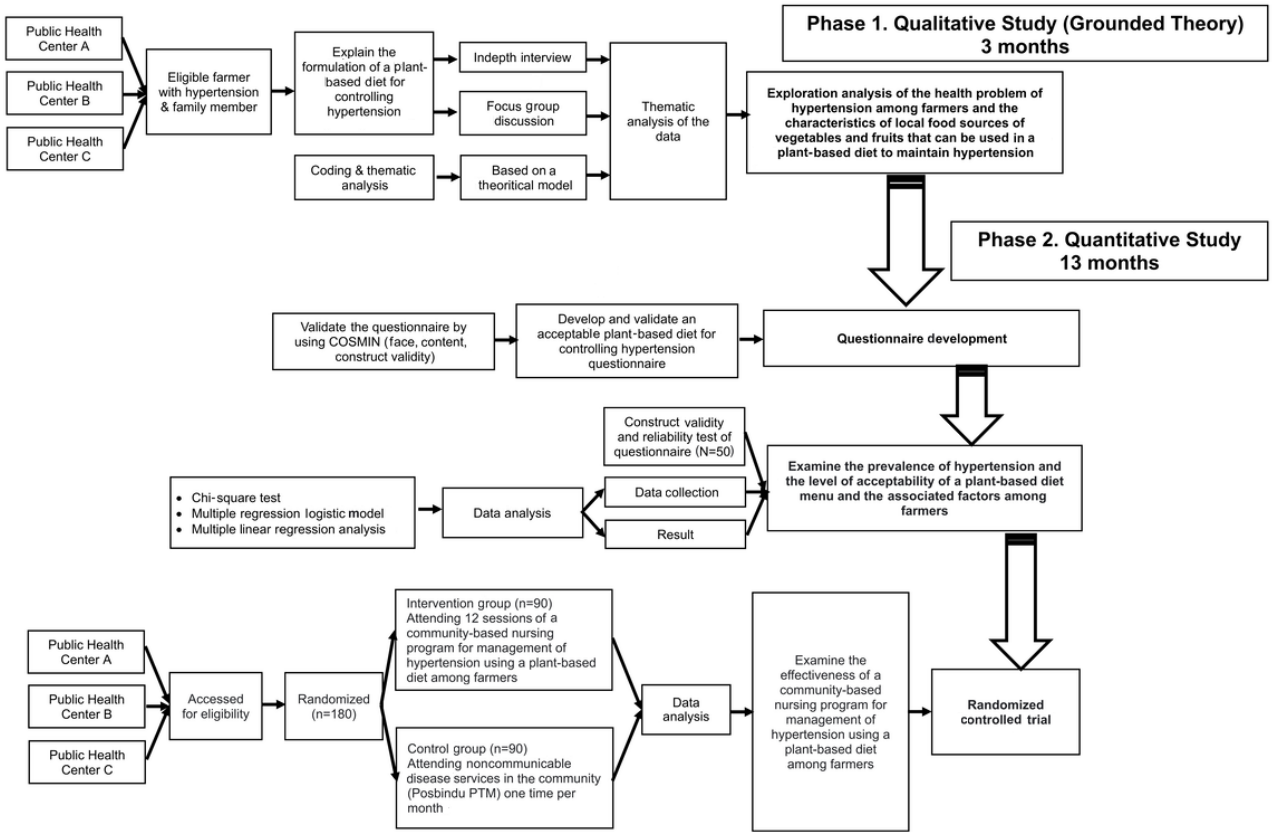
Agronursing can facilitate occupational health and safety among farmers [9]. Farmers' health problems are generally caused by a lack of knowledge and skills in health management, which can lead to hypertension [10]. Most farmers with hypertension have a low level of education, so skills in self-care management are lacking [11]. Hypertension among farmers is also caused by an unhealthy lifestyle [9] and inadequate nutrition [12]. High consumption of unhealthy foods among farmers, such as high-sodium foods [6], and low knowledge about diet [13] can increase the risk of hypertension in farmers. Therefore, dietary management with a plant-based diet (PBD) needs to be introduced, and the basic principles of hypertension nursing care for farmers need to be developed.

Natural agricultural resources should be considered in the management of hypertension among farmers. The basic principles of hypertension care among farmers should be developed through optimizing the agricultural sector's potential by consuming a PBD that prioritizes vegetables and fruits [14]. Therefore, it is necessary to formulate the basic concepts and principles of a PBD in nursing care management for farmers with hypertension based on the agronursing approach.

The agronursing approach to treat hypertension among farmers focuses on promotive and preventive measures to reduce the risk of disease occurrence or disease worsening from previous conditions [15]. Moreover, it focuses on the health status of individuals in carrying out their work (in this case, farmers who work in fields) in order to improve overall health (physically, mentally, and socially) [16]. The PBD concept is expected to be able to overcome the problem of hypertension among farmers in agricultural areas, which is synergistic with the culture and local wisdom of the agricultural population. Therefore, the objectives of this study are as follows: (1) to explore the health problem of hypertension among farmers and the characteristics of local food sources of vegetables and fruits that can be used in a PBD to manage hypertension; (2) to examine the prevalence of hypertension, the level of acceptability of a PBD, and the associated factors among farmers; and (3) to examine the effectiveness of a community-based nursing program for the management of hypertension using a PBD among farmers.

Methods

Study Overview



The exploratory sequential mixed methods approach will be used to achieve the research objectives in the following 2 phases: qualitative study (phase I) and quantitative study (phase II) (Figure 1). In phase I, we will explore the health problem of hypertension among farmers and the characteristics of local food sources of vegetables and fruits that can be used in a PBD to manage hypertension through semistructured interviews. Then, we will formulate a PBD menu to treat hypertension among farmers.

In phase II, we will conduct a quantitative study. In this phase, the following 3 activities will be performed: (1) we will develop and validate a questionnaire as the assessment instrument; (2) we will examine the prevalence of hypertension, the level of acceptability of a PBD, and the associated sociodemographic factors among farmers; and (3) we will examine the effectiveness of a community-based nursing program for managing hypertension using a PBD among farmers.

This study will use farmers with hypertension and their families in the planning of phases I and II.

Figure 1. Study overview. COSMIN: consensus-based standards for the selection of health measurement instruments; Posbindu PTM; Pos Pembinaan Terpadu Penyakit Tidak Menular.

Phase I: Qualitative Phase

Overview

We will perform a semistructured interview involving farmers with hypertension and the family members of eligible participants to address the research objectives. The qualitative study will provide insights on health problems related to hypertension and the characteristics of local food, and will help formulate a PBD to control blood pressure from the perspective of agricultural health nursing care services. After undergoing training in conducting qualitative studies, 5 investigators (TS, HR, FK, IR, and RAY) will conduct interviews in the field.

Setting

This study will recruit eligible participants selected from 3 public health centers (PHCs) in Jember, East Java Province of Indonesia. Jember, East Java Province is a province representing Indonesia's agricultural sector. It is known that Jember Regency is an agricultural area, and most of its people make a living as farmers or work in agriculture. The agricultural land in Jember Regency is very fertile. Therefore, most land in Jember Regency is used for agriculture and plantations. This is very suitable as the main livelihood of the people of Jember Regency is related to the agricultural sector.

Jember Regency is considered one of the rice barns of East Java Province, reflecting that the agricultural sector plays an important role (leading sector) in the economy of Jember Regency, and it can be said that Jember has an agrarian economic structure. Since Jember's economy is generally based on agriculture, the maintenance and management of natural resources are very important, and it is hoped that the economic development carried out is oriented toward environmentally sound development. Regarding cultivations, all areas except the city center have food crops; the slopes of Mount Argopuro have plantations of tea, coffee, cocoa, and rubber; the slopes of Mount Raung have plantations of coffee and tobacco; and central to southern areas have plantations of tobacco, sugarcane, and coconut. In Jember, 42.9% of the population has jobs in agriculture [17]. Based on data [18] released by BPS Kabupaten Jember, the population of Jember Regency in 2020 was projected to reach 2,536,729 people, consisting of 1,264,968 male residents and 1,271,761 female residents, and the population density in Jember Regency in 2020 reached 770.26 people/km^2.

Participants

The inclusion criteria for recruiting the purposive sample are as follows: (1) farmers aged 20-65 years from other parts of East Java Province, Indonesia (citizens) living in 3 PHCs of Jember; (2) residents living in 3 PHCs of Jember; (3) those with hypertension; (4) those who consume fruits and vegetables to control their blood pressure; (5) those who attend the Integrated Health Center (IHC) for noncommunicable diseases (NCDs) in the community; and (6) those having and living with family for care provision. We will exclude older people who are not citizens of Indonesia and those who are unwilling to be interviewed or unable to communicate clearly due to language problems. To obtain more insights on the acceptability of a PBD, the family members of eligible farmers with hypertension will be included in the interview. The inclusion criteria are as

XSL•FO
RenderX

follows: (1) employment as a farmer; (2) age 45-65 years; (3) presence of grade I/II hypertension according to the Eighth Joint National Committee on Prevention, Detection, and Treatment of High Blood Pressure (JNC VIII) criteria; and (4) presence of relatives who stay in the same house with their parents or take care of their parents by helping them with preparing food or assisting them in daily routines. We will exclude farmers with hypertension having other chronic diseases (diabetes mellites, chronic kidney disease, heart disease, and stroke).

Sampling Process

Phase I is estimated to last 3 months. The snowball sampling method will be used to recruit participants. The investigators (TS, HR, FK, IR, and RAY) will recruit participants in Jember based on the inclusion and exclusion criteria. The interviewees will be asked to recommend other eligible participants among farmers and their family members who wish to participate in this research. Investigators will contact eligible participants to explain the study details, confirm their interest in participating, and determine their preferred interview method (eg, individual interview or focus group discussion). Payment of US $10 will be made to participants for participating in this study (online transfer to their bank accounts).

Data Collection

Phase I will involve the following 2 data collection methods: in-depth interviews and focus groups using semistructured interview guides. Further, in-depth interviews may be conducted with certain respondents who have attended the previous focus group interviews to gain more perspectives and clarify the focus groups' findings. Each focus group will consist of 4 to 6 participants. An earlier scoping review conducted by the same research team will help identify health problems related to hypertension among farmers. Then, we will explore the characteristics of local food sources to manage hypertension and formulate a PBD. The findings will provide additional information for developing the interview guides and questions (eg, "Can you describe your health problem related to your hypertension?" "How would you control your blood pressure with a plant-based diet?" "What kinds and contents of local foods would you use for controlling hypertension?" "How would you formulate a plant-based diet menu to control hypertension?" "What do you expect from a plant-based diet?" and "Would you adopt a plant-based diet? If yes, why? If no, why not?"). The preliminary semistructured interview guides, which contain open-ended questions and probes to explore the acceptability of a PBD, will be pilot tested.

We plan to interview the farmers and the family members of eligible farmers with hypertension. We will recruit 30 participants initially, but the final sample size for this qualitative study will be determined when data saturation is reached, for example, when additional data collection reveals no substantial new information. Each in-depth interview will take between 30 and 45 minutes, and the focus group interview will take around 45 to 60 minutes. Before the interviews, participants will provide their sociodemographic and related information, such as age, education, occupation, income, insurance, and health condition. Information about this research, including the hypertension problem and the characteristics of local foods used in a PBD, will be explained to all participants in Bahasa Indonesia before they are asked to provide informed consent. All interviews will be conducted in the Bahasa Indonesia language and will be audio recorded. Investigators will take down field notes, and transcripts will be translated line by line into English. All data will be translated into English to allow discussions with non-Indonesian researchers.

Qualitative Data Analysis Plan

Interviews will be video recorded, and all data will be transcribed verbatim. Data in Bahasa Indonesia will be translated into English for co-investigators who are only proficient in English. Qualitative data will be analyzed to identify a thematic framework [19], guided by a theoretical model of a PBD for controlling hypertension in farmers [20]. The emerging codes will be analyzed thematically according to the framework if they are coherent. The team members will repeatedly read each document and transcript to familiarize themselves with the whole data set and ensure the accuracy of the transcription reviews. Codes will be applied to raw data and then grouped into clusters to generate themes. Consensus on the codes and themes must be reached among at least three of the investigators (TS, HR, FK, IR, and RAY). The data will be compared in an ongoing manner to identify the true meaning of the data. Member checking and investigator reflexivity will be used to increase the credibility and reliability of the data. Data credibility will be enhanced through further analysis of interview and field notes, and views from the different categories of farmers having different sociodemographic backgrounds (eg, those with different grades of hypertension), as well as through triangulation involving multiple investigators. The content of the interviews will be shared with some participants, and their feedback on the findings will be sought for validation purposes (respondent validation). Investigators involved in the data analysis will collect and explain their biases or assumptions during data analysis and interpretation (reflexivity). Raw data, interpretations, and conclusions will be discussed with peers (peer debriefing). Confirmability will be enhanced by keeping an audit trail of the audio/video files, electronic documents, original field notes, and translations [21].

Phase II: Quantitative Phase

Activity 1: Questionnaire Development and Validation

Overview

In activity 1, we will develop a questionnaire of an acceptable PBD for controlling hypertension, according to the qualitative data in phase I. The quotations from raw data will become questionnaire items, themes will become scales, and codes will become variables. A Likert score will be used for measurement (range of 1 to 4 points), which will determine the levels of expectations and acceptability. Based on the scores of the items or the summed scores, expectations and acceptability can be categorized into the following 3 categories: affordable, accessible, and achievable. Categorization will be performed using a statistical formula. If the data are normally distributed, the grade level will be based on the mean value; otherwise, the median will be used ($X <$ mean/median – 1 SD; mean/median – 1 SD $< X <$ mean/median + 1 SD; mean/median + 1 SD $< X$).

XSL•FO
RenderX

The questionnaire will have the following 2 sections: (1) sociodemographic characteristics of hypertension and (2) acceptable PBD for controlling hypertension. The instructions and descriptions of the definition, concept, and criteria of a PBD will be provided at the beginning of the questionnaire. The Pender Health Promotion Model will guide the questionnaire's qualitative analysis and item design. After performing a member check and assessing face and content validity with an expert committee, we expect the final version of the questionnaire. The expert committee will include investigators with expertise in qualitative research (HR), statistical analysis (FK), public health (TS), and research methodology (RAY and IR).

Validation and Reliability

A cognitive debriefing involving 10 people to further assess the face and content validity of the questionnaire will be performed (5 expert nurses on hypertension and 5 nutritionists). Feedback will be discussed by the expert committee, and it will determine the appropriateness and completeness of the questionnaire and ethical considerations in the process. The next analysis step is the COSMIN (consensus-based standards for the selection of health measurement instruments) checklist developed in an international Delphi study to estimate the quality of selected measurement instruments. It measures internal consistency, reliability, measurement error, content validity (as well as face validity), structural validity, hypothesis testing, cross-cultural validity (the 3 aspects of construct validity), criterion validity, and responsiveness. Based on the checklist, items will be sorted by experts in the group to establish face, content, and construct validity in activity 1. The duration to finish the questionnaire is estimated to be less than 30 minutes. Further validation of the questionnaire will be conducted in activity 2. Cronbach alpha will be applied to prove the internal consistency (0.70 or higher is considered as good) of the expectations and acceptability questionnaire. Exploratory factor analysis using principal component analysis will be performed to examine the structural validity of the expectations and acceptability questionnaire separately.

In addition, the Kaiser-Mayer-Olkin test of sampling adequacy, the Bartlett test of sphericity, and the scree plot will be used to check the unidimensionality of the expectations and acceptability questionnaire. The convergence criteria will be set at an eigenvalue above 1. Construct validity (hypothesis testing) will be tested when comparing the responses to the expectations or acceptability of 1 item (yes or no). We hypothesize that the highest tertile expectation will be associated with willingness measured by a repeat measurement value of at least 2.0. The highest tertile acceptability will be related to willingness measured by a repeat measurement value of at least 3.0. It is also hypothesized that expectations and acceptability will correlate at a coefficient of at least 0.4. One-month intrarater test-retest reliability will be assessed in a random sample of at least 50 older people throughout the data collection period in activity 2.

Activity 2: Survey

Overview

In activity 2, we will conduct a survey to identify the prevalence of hypertension, the level of acceptability of a PBD, and the associated sociodemographic factors among farmers. We will use the questionnaire developed in activity 1. Written informed consent will be obtained, and each participant will be required to indicate agreement for participation before filling out the questionnaire and submitting it.

Setting

To obtain a representative sample according to the criteria that have been set, we will select 3 PHCs located in agricultural areas in Jember, East Java, Indonesia. The PHCs we have selected include Banjarsengon, Sukorambi, and Panti. There are quite a lot of farmers in the Panti area, with 14,322 active farmers having quite complex hypertension problems [22]. Farmers in Banjarsengon and Sukorambi also show a similar condition. These 3 PHCs are expected to have a sufficient number of farmers with hypertension who could respond and complete the questionnaire.

Participants

The criteria for recruiting our representative sample are as follows: (1) farmers aged 20-65 years from other parts of East Java Province, Indonesia (citizens) living in 3 PHCs in Jember; (2) residents living in 3 PHCs in Jember; (3) those with grade I/II hypertension according to the JNC VIII criteria; (4) those who attend the IHC for NCDs in the community; and (5) those having and living with family for care provision. We will exclude (1) farmers with psychiatric disorders that may impair their ability to answer or complete the questionnaires and (2) farmers with cognitive impairment.

Sample Size Estimation

The sample size will be determined based on a G*Power analysis. Since no previous similar study has been conducted, this study takes the best estimate of the minor difference in the proportion of expectations and acceptability of a smart nursing home among elderly people to be at 10%. Using G*Power 3.1.2 (Institute for Experimental Psychology in Dusseldorf Germany) with 0.90 power and significance at a 2-sided α of .05, the estimated sample size is 263.

Measures

To meet the study objectives, the questionnaire will consist of the following sections: (1) sociodemographic characteristics and (2) the level of acceptability of a PBD to treat hypertension among farmers. The sociodemographic characteristics will include age, gender, marital status, education (no formal education, elementary school, middle school, and high school or higher), household monthly income per capita (less than US $65.82, US $65.82-131.65, US $131.66-197.47, and over US $197.47), duration of hypertension (years), grade of hypertension based on the JNC VIII criteria, and living condition (with children or a spouse). In section 2 of the questionnaire, a 4-point Likert scale will be used to assess the level of acceptability of a PBD to treat hypertension among farmers. Expectations will be measured as follows: 1, strongly disagree;

XSL•FO
RenderX

2, disagree; 3, agree; and 4, strongly agree. A higher score will indicate a higher level of acceptability of a PBD to treat hypertension among farmers. The association of sociodemographic factors with the different categories of expectations and acceptability will be determined through statistical analysis.

Sampling Process

Representative research respondents will be selected by collecting available data on public health services. Farmers with hypertension are listed as regular patients in the Posbindu PTM (Pos Pembinaan Terpadu Penyakit Tidak Menular) program of the public health services. The data obtained will be assessed in a random process to select respondents using a simple random sampling technique. We will use a randomizer application that is available online to select respondents. Respondents selected from the randomizer application will then be included in the list of research respondents. We will follow the activities of the Posbindu PTM program as well as meet with research respondents who have been selected to be able to collect research data. We will print out the questionnaire and give it to the research respondents to fill out. Our team will assist farmers in filling out questionnaires to ensure that the questionnaires given are filled out completely and accurately.

Analysis Plan

The data from the questionnaire will be inputted into SPSS (IBM Corp) for analysis. We will perform data cleaning to check each data point from the questionnaire and ensure there are no missing data from the entire questionnaire. We will only use completed questionnaires for analysis. After the data cleaning process is complete, we will perform the data analysis process.

We will use descriptive statistics to describe the characteristics of the respondents and the level of acceptability of a PBD to treat hypertension among farmers according to data distribution. Numerical variables will be shown as means and standard deviations or medians and interquartile ranges, while categorical variables will be shown as absolute frequencies and percentages. We will use the chi-square test to examine the sociodemographic factors associated with farmers' different categories of acceptability. With the 95% CI, a *P* value of <.05 will be considered statistically significant.

We will use multiple logistic regression models to estimate the associated and independent factors from the sociodemographic factors and the level of acceptability of a PBD among farmers. In the case of a low event rate and low sample size for expectations and acceptability in the definite form, we may recode them into tertiles and use the lowest score category as the reference group. Alternatively, we may conduct multiple linear regression analyses with the 2 dependent variables as continuous variables. We will also include any independent factors with a *P* value <.20 from the univariable regression analysis in the multiple regression analysis. Multicollinearity between independent variables will be checked according to a tolerance value <0.4 (variance inflation factor ≥2.5). In the presence of multicollinearity, we will select the more critical or essential variables from clinical perspectives for use in the final regression analysis. We will check all models, check Q-Q plots for normality, check residual plots for linearity, and check homogeneity assumptions, as well as assess model fitting.

Activity 3: Randomized Controlled Trial

Overview

In activity 3, we will perform a randomized controlled trial (RCT) on the effectiveness of a community-based program for managing hypertension using a PBD among farmers. We will evaluate the effectiveness of a PBD menu for the outcomes (blood pressure and acceptability of a PBD) of farmers with hypertension.

Design

An RCT will be performed for the community-based program in 2 groups (with pretest and posttest) using the CONSORT (Consolidated Standards of Reporting Trials) guidelines. An RCT is preferred to reduce selection bias [23]. Participants in this study will be randomly allocated to either the control or intervention group. The control group will receive a standard health education intervention for managing hypertension, while the intervention group will receive the PBD formula. A single-blind technique will be used so that participants will be unaware if they are in the control or intervention group.

Participants

The target population of this study is farmers with hypertension from 3 PHCs in Jember, East Java, Indonesia. Three PHCs have been chosen to represent the characteristics of agricultural areas with a high hypertension problem. The 3 PHCs have implemented the Integrated Health Program (IHP) for NCDs.

Inclusion and Exclusion Criteria

The inclusion criteria are as follows: farmers aged 45-65 years with stage I hypertension (systolic blood pressure [SBP]: 140-159 mmHg and diastolic blood pressure [DBP]: 90-99 mmHg) according to the JNC VIII criteria, farmers performing appropriate work, and those providing a commitment to attend the study for 3 months. We will exclude those who have experienced stroke as they are not eligible for participation, those with hypertension of stage II or higher, those taking medications, and those who have been hospitalized.

Sample Size Determination

The sample size will be determined using a traditional sample size calculation based on the McNemar test. The sample size in the McNemar test in this study should fulfill the following criteria: (1) directional hypothesis for 1 tail; (2) magnitude of expected change using the odds ratio (OR; OR=2); (3) alpha value of .05; and (4) required power of 0.8 or higher. The OR and the proportion are expected to change as a result of the intervention. Considering a 2-tailed approach, an effect size of 2.0 at an α value of .05 and power of 80%, and a change in 75% of the population as a result of the intervention, 96 participants would be needed to detect the effect.

Randomization

Initially, public health nurses (PHNs) will visit the study areas and make announcements about the study for farmer participation. The recruitment will be open for 6 months. Farmers will visit the PHC and will be provided an explanation

XSL•FO
RenderX

of the study. Informed consent will be obtained, and farmers will be randomized using a computer-generated number. The allocation sequence will be concealed from the researchers and farmers. The computer-generated number system will randomize the initial name of the farmers from the PHC. The PHNs from the PHC will then obtain informed consent and manage the study groups.

Outcome Measures

The main outcome measures in this study are SBP and DBP, which will be measured using a standard protocol employing a stethoscope and sphygmomanometer after stabilizing subjects for more than 10 minutes. Measurements of SBP and DBP (mmHg) will be categorized according to the JNC VIII criteria to determine hypertension for participants aged >18 years [24]. The length of work per day, time of rest during working, and hours of sleep per day will be assessed among the farmers. These factors will be measured as they can influence blood pressure among farmers, according to a previous study [2]. Manual blood pressure measurement is usually performed using a mercury device or a calibrated needle (aneroid). SBP and DBP are determined through auscultation by listening for the appearance and disappearance of Korotkoff sounds in the brachial artery. Blood pressure measurements will be taken after a 14-minute rest period, during which the researcher and the participant will have a conversation to reduce tension associated with the "white coat" effect. Measurements will be taken at the same time (ie, 8 AM before activities) with the same tool. Participants will be told not to wear clothes that are too thick. Blood pressure test results will be more accurate if the cuff is placed directly over the skin. Participants will be told to empty their bladder before measurement. For the measurement, participants will be told to sit with their arms on a table so that the elbows are in line with the heart, the back is well supported by the back of the chair, and the feet are on the floor.

Data Collection Plan

At baseline, sociodemographic data, including age, gender, education level, smoking, hours of work, rest during working, and hours of sleep per day, will be obtained using a self-administered questionnaire. For measuring SBP and DBP at the PHC, participants will sit in a chair and relax for 10 minutes. Then, PHNs will measure blood pressure at least twice. If the blood pressure values obtained in the second measurement differ from the values in the first measurement by ≥10 mmHg, a third measurement will be carried out. The 2 measurement values with the smallest difference will be averaged to obtain the final value [24].

Intervention Group Arm

The intervention group will receive a community-based intervention program involving a PBD.

Control Group Arm

The control group will receive a standard education intervention through the IHC for NCDs and available health services that can be accessed every month in the community.

Intervention

The intervention group will receive a PBD formulated by the researchers. Farmers will consume the plant-based food 3 times per week. For the PBD, we will adopt a standard protocol from previous studies [1]. Therefore, we have decided to provide the PBD for 6 months.

In the control group, participants will receive education on health and safety on attending the IHP for NCDs, and they will adopt healthy behaviors according to the health education. As they will receive health education, they will be able to lead a healthy life in the agricultural environment, with occupational health and safety.

In both study groups, health education will be provided before the program, which will include information on how to manage a healthy lifestyle while working as farmers, including diet, exercise, rest, and sleep, and how to address blood pressure problems among farmers. Participants will receive this health education in a single session for 60 minutes at the first screening meeting. All participants will receive a manual book on a healthy lifestyle in an agricultural setting.

The blood pressure of participants in both study groups will be maintained. If the blood pressure increases to hypertension stage II or above, appropriate treatment will be provided by the medical doctor in the PHC and the participant will be excluded from the study. Data will be obtained at registration and at the pretest and posttest assessments. For blood pressure data, we will use rounded values, with values ending in 0-4 being rounded to "0" and values ending in 6-10 being rounded to "10" (eg, 120-124 mmHg will be rounded to 120 mmHg, 125 mmHg will be used directly, and 126-130 mmHg will be rounded to 130 mmHg).

Data Analysis Plan

SPSS version 22.0 (IBM Corp) will be used for the analysis. The significance level will be set as $P<.05$. Numerical data will be presented using means and standard deviations, while categorical data will be presented using frequencies and percentages. Furthermore, a linear generalized estimating equation (GEE) will be used to estimate the parameters of a generalized linear model with a possible unmeasured correlation between observations from different timepoints for SBP and DBP (comparing pretest and posttest).

Ethical Considerations

This study has received ethical approval from the Ethics Committee for Research Involving Human Subjects, Faculty of Dentistry of Universitas Jember (approval number: 1548/UN25.8/KEPK/DL/2022, with an amendment on June 29, 2021) and conforms to the requirements of the World Medical Association's Declaration of Helsinki. All the participants will provide written informed consent before their inclusion.

This study will use descriptive analytics in health and community service units with a quantitative approach through surveys and qualitative interviews at health and community service units. This research will not cause harm to the participants. Each participant will provide informed consent. We will give autonomy rights to prospective participants.

XSL•FO
RenderX

Participants will be provided an explanation of the study, including the objectives, benefits, implementation process, and participant rights. Participants will be informed that there is no risk of harm if they do not participate in the study or leave the study while the research process is in progress.

The study will pay attention to safety aspects for both the researchers and participants, and will be performed according to the applicable COVID-19 protocol. The interviews will be adjusted according to the participants' time. Participants will receive compensation (transportation fee) and food for each data collection. The design of this study involves an intervention group and a control group, and we will try to minimize the occurrence of unwanted incidents during the implementation of the intervention. We will provide leaflets containing educational materials for a PBD when the last measurement is taken. Participants in the control group will be offered a discussion session after reading the leaflet provided, but there is no compulsion to join the discussion session. All participants in the intervention group will receive the same intervention regardless of ethnicity, religion, and race.

The confidentiality of the participants' data will be maintained, and the identity of the participants will not be disclosed. The data obtained will only be used for research purposes. To keep participants' data confidential, the survey sheet will have a special code that does not display the personal data. Moreover, a statement will be provided that qualitative study data are anonymous or deidentified. Furthermore, a brief description of the protections in place will be provided.

Results

This research has been funded by DRPTM Kementerian Pendidikan, Kebudayaan, Riset dan Teknologi Skema Riset Penelitian Dasar Unggulan Perguruan Tinggi (PDUPT) in 2022 (0277/E5/AK.04/2022). The research started in May 2022, and phase I of the study is scheduled to begin in May 2023, with a total research duration of 2 years. A model PBD for the management of hypertension is expected to be developed from using local food–related agronursing services. In 2022, we will collect data on hypertension and the characteristics of local food sources to manage hypertension, and formulate a PBD menu to treat hypertension among farmers. A thematic analysis of the qualitative data of farmers in the agricultural sector will be performed. In 2023, we will develop a questionnaire to assess the acceptability of a PBD to manage hypertension among farmers, the prevalence of hypertension, and the sociodemographic factors associated with hypertension among farmers. Furthermore, we will introduce a community-based nursing program for the management of hypertension using a PBD among farmers.

Discussion

Contributions of the Study

This paper describes a protocol for the management of hypertension using a PBD among farmers. We hypothesize that the formulation of the PBD concept can overcome the problem of hypertension among farmers in agricultural areas, which is synergistic with the culture and local wisdom of the agricultural population. The findings of this study may contribute to the development of a better solution for hypertension among farmers in Indonesia and may be relevant to a special group of readers interested in this research. It is believed that innovations of the intervention can be used and integrated to promote nursing care within the fields of health assessment, activities of daily living, and care management, which could improve the quality of life and quality of care for farmers in agricultural areas.

The concept of a PBD as a solution for hypertension is based on meeting the nutritional needs of plant-based proteins and minimizing intake from animal and processed sources [24]. Maximized intake of nutrients in a PBD involves high intake of fiber, vegetable protein, vitamins, polyphenols, and unsaturated fatty acids, and low intake of sodium. Food processing in a PBD can be adapted to the culture and habits of the local community to facilitate the consumption process and maintain consistency in the implementation of the process. A PBD is expected to provide considerable benefits to overcome hypertension in farmers. Optimal nutrition and fiber in a PBD will provide strong protection for organ systems in the body and will help systems to work synergistically to reduce inflammation and oxidation in the body [19].

A PBD model will provide farmers with an alternative solution that has independent, safe, and comfortable features for their needs. It could also be used to adapt and transform existing hypertension programs for farmers and their family members. With a better understanding of farmers' expectations and acceptability of a PBD model in public health, researchers, stakeholders, and policymakers may be able to effectively develop a complete model that incorporates appropriate technologies and integrates relevant medical services, and yet remains affordable to benefit the majority of farmers. This would facilitate the transformation of traditional hypertension interventions to smart and local interventions, which include necessary skill sets or required training for PHNs and other health care professionals to meet expectations.

The findings of this study will be presented at conferences and published in peer-reviewed journals. We will publish the results of this research in academic journals. We will also present this research at national and international conferences. The data from this study will be presented in a research report to the Ministry of Cultural Education, Research and Technology, and Higher Education on the BIMA system dashboard (BIMA – Kemdikbudristek) as restricted data. In addition, research data will be reported to the Institute for Research and Community Service, University of Jember (organizer in research activities). Furthermore, the research results of the first year and second year will be presented in a manuscript. The manuscript will be submitted to a reputable international journal in the areas of hypertension and NCD management.

Disseminating our study findings will significantly contribute to the advancement of science and holistic nursing services for farmers with hypertension in the community.

XSL•FO
RenderX

Limitations of the Study

This study will examine the effectiveness of a community-based nursing program for the management of hypertension using a PBD among farmers in Indonesia. However, this protocol may have some limitations. First, the program requires participant compliance for carrying out regular training to maintain blood pleasure, and some participants may drop out of this study for various reasons, such as noncompliance with the consumption of a PBD. Therefore, a dairy is required to continuously monitor the diet. Second, the measurement of blood pressure may be biased because of different enumerators and sphygmomanometers. This can be minimized by interrater enumerator measurements and instrument calibration.

Conclusion

We believe the findings of this research will be beneficial for farmers in the agricultural and plantation areas of Jember, who experience hypertension. We will compile the results of our research by comparing and discussing the results in terms of the results of previous similar studies. Future research is expected to improve the results of this study in terms of determining the preparation of hypertension management using a PBD for farmers. We expect contributions from the local government to implement the intervention as one of the policies in the management of hypertension for farmers in the agricultural plantation areas of Jember. This program may also be implemented in other agricultural countries with similar problems, so that hypertension can be optimally treated among farmers.

Acknowledgments

We would like to thank the Direktorat Riset dan Teknologi dan Pengabdian Masyarakat (DRTPM) Ministry of Education and Culture and Higher Education, Research and Technology (Kemendikbud Ristek Dikti) for supporting the research of Basic Research HPenelitian Dasar Unggulan Perguruan Tinggi (PDUPT) 2022 (number: 0277/E5/AK.04/2022). We would also like to thank the Department of Research and Community Service (LP2M), Faculty of Nursing Universitas Jember, and Public Health Centers (Puskesmas) for supporting the research activities. All authors declared that they had insufficient or no funding to support open access publications of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Authors' Contributions

All authors have critically reviewed and approved the final draft and are responsible for the content of the manuscript. TS contributed to conceptualization, methodology, validation, formal analysis, investigation, resources, data curation, writing – original draft, writing – review and editing, supervision, project administration, and funding acquisition. RAY contributed to conceptualization, methodology, validation, formal analysis, investigation, resources, data curation, writing – original draft, and writing – review and editing. HR contributed to validation, formal analysis, investigation, data curation, and writing. IR contributed to validation, formal analysis, investigation, data curation, and writing – original draft. FK contributed to validation, formal analysis, and investigation.

Abstract

Background: More than 75% of patients with breast cancer treated with chemotherapy experience cognitive impairments (eg, memory and attention problems), commonly known as *chemo-brain*. Exercise, especially aerobic high-intensity interval training (HIIT), is associated with better cognitive function in healthy populations. However, clinical trials testing the impact of exercise interventions on chemotherapy-induced cognitive decline in patients with cancer are lacking, and the mechanisms through which exercise could improve cognitive function are unclear.

Objective: The objective of the Improving Cognitive Function Through High-Intensity Interval Training in Breast Cancer Patients Undergoing Chemotherapy trial is to examine the effects of HIIT on cognitive function in patients with breast cancer undergoing chemotherapy.

Methods: This 2-arm, single-center, pilot randomized controlled trial will randomize 50 patients with breast cancer undergoing chemotherapy to HIIT or attention control. The HIIT group will perform a supervised 16-week, thrice-weekly intervention, with each session including a 5-minute warm-up at 10% maximal power output (POmax), 10 sets of alternating 1-minute high-intensity (90% POmax) and 1-minute recovery (10% POmax) intervals, and a 5-minute cooldown (10% POmax). The attention control group will receive a stretching program with no exercise components and be asked to maintain their exercise levels for 16 weeks. The primary outcomes of the study are executive function and memory measured using the National Institutes of Health toolbox and resting-state connectivity and diffusion tensor imaging microstructure evaluated using magnetic resonance imaging. The secondary and tertiary outcomes include cardiorespiratory fitness, body composition, physical fitness, and psychosocial health. The study has been approved by the institutional review board of the Dana-Farber Cancer Institute (20-222).

Results: The trial was funded in January 2019, with recruitment started in June 2021. As of May 2022, a total of 4 patients have consented and been randomized (n=2, 50% to exercise; n=1, 25% to control; and n=1, 25% nonrandomized). Trial completion is expected in January 2024.

Conclusions: This first-of-its-kind study incorporates a novel exercise intervention (ie, HIIT) and comprehensive cognitive measures. If positive, our findings will establish the pilot efficacy of HIIT on chemotherapy-induced cognitive function in patients with breast cancer, providing the foundation for future larger phase-II and phase-III trials to confirm the findings and potentially establish HIIT as a standard of care for women undergoing chemotherapy for breast cancer.

Introduction

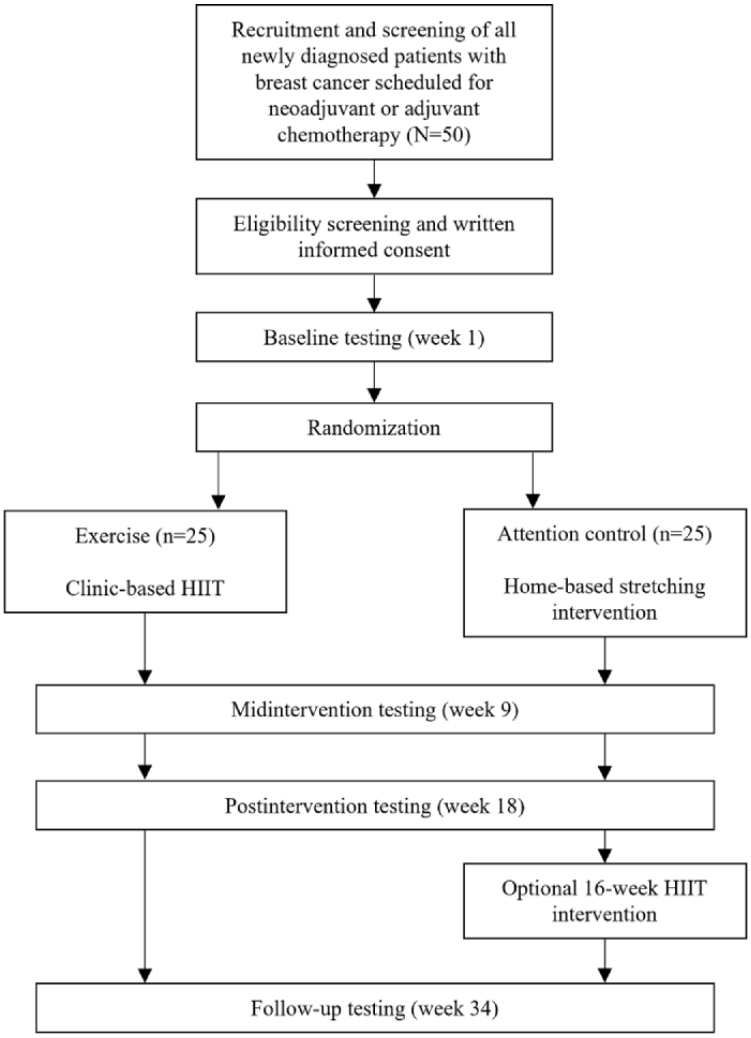
Background

Breast cancer is the most commonly diagnosed cancer among women in the United States, with approximately 280,000 new cases each year [1]. Advances in breast cancer treatment have increased breast cancer–specific and overall survival for women with early-stage breast cancer, but side effects of therapy affect quality of life and functional status during and after cancer treatment. In particular, up to 75% of patients with breast cancer treated with chemotherapy experience treatment-related cognitive impairments commonly referred to as *chemo-brain* [1,2]. Although *chemo-brain* is often associated with chemotherapy, similar cognitive changes may also present as a result of the cancer itself or conditions resulting from cancer treatment (eg, pain and infection). These alterations in memory, concentration, and other cognitive abilities may represent long-term effects that diminish the quality of life of patients with breast cancer and increase the risks of patient morbidity and mortality [3,4].

Although the neurological mechanisms underlying *chemo-brain* remain unresolved, previous studies have demonstrated an association between physical activity, such as walking or cycling, and enhanced cognitive function in patients who have undergone chemotherapy treatment [5-7]. High-intensity interval training (HIIT) in particular has been shown to improve cognitive flexibility, executive function, and psychological well-being in both older adults and youths [8-11]. This exercise modality consists of brief periods of intense exercise interspersed with recovery intervals and is a safe and feasible exercise approach for patients with breast cancer undergoing chemotherapy [12-14]. However, the impact of HIIT on cognitive function in women undergoing chemotherapy for breast cancer remains unknown.

Objectives

The primary aim of the Improving Cognitive Function Through High-Intensity Interval Training in Breast Cancer Patients Undergoing Chemotherapy (CLARITY) trial is to examine the impact of a 16-week HIIT exercise intervention on cognitive function assessed using the Montreal Cognitive Assessment, the National Institutes of Health (NIH) toolbox, and quantitative magnetic resonance imaging (MRI) of the brain. We hypothesize that executive function and memory scores will be higher after exercise compared with baseline and the attention control (AC) group and that participants in the HIIT intervention will have enhanced functional brain connectivity and structural white matter tracts compared with baseline and the AC group. The secondary aims are to examine the effects of HIIT on body composition; biomarkers related to metabolic dysregulation, inflammation, and cardiotoxicity; physical fitness and function; and quality of life and psychosocial outcomes in patients diagnosed with early-stage breast cancer undergoing chemotherapy. We hypothesize that participants in the HIIT intervention will have improved body composition and psychosocial health compared with baseline and the AC group.



Methods

Study Design

The CLARITY trial is a 2-arm randomized controlled trial underway at the Dana-Farber Cancer Institute (NCT04724499). Outcomes are measured at baseline (week 1), midintervention (week 9), after the intervention (week 18), and at follow-up (week 34; HIIT group only; Figure 1). A total of 50 women diagnosed with breast cancer who are chemotherapy-naïve are randomized either to a 16-week clinic-based HIIT intervention or an AC group who will be provided with a 16-week flexibility intervention. After the initial 16-week intervention period, the HIIT group completes a further 16-week follow-up period of self-directed exercise. The AC group does not complete the follow-up period and is instead offered the HIIT program. Only the AC participants who choose to partake in the HIIT program complete testing at the follow-up point (week 34).

XSL•FO
RenderX

Figure 1. Study schema of the Improving Cognitive Function Through High-Intensity Interval Training in Breast Cancer Patients Undergoing Chemotherapy trial. HIIT: high-intensity interval training.

Participant Eligibility

Women are eligible if they are (1) newly diagnosed with breast cancer, (2) planning to receive neoadjuvant or adjuvant chemotherapy (regardless of duration and regimen of drug), (3) aged >18 years, (4) nonsmokers (within the previous 12 months), (5) inactive (defined as <60 minutes of structured exercise per week), (6) cleared by their clinicians for exercise, and (7) English-speaking. Exclusion criteria include (1) having a second malignancy or metastases; (2) pregnancy; (3) weight loss of >10% within the past 6 months; (4) having any uncontrolled comorbidity, condition, or contraindication that may prevent participation in high-intensity exercise; (5) having a pacemaker or any implantable device not safe for MRI; (6) claustrophobia; and (7) having a history of coronary heart or artery disease, chronic or acute congestive heart failure, or history of systolic or diastolic insufficiencies.

Recruitment and Informed Consent

Participants are currently being recruited through clinician referral and screening of patient lists at the Dana-Farber Cancer Institute, Boston, Massachusetts, as well as by way of advertisements in patient waiting rooms, the Partners Rally Platform, and other relevant breast cancer community newsletters and servers. Pending accrual rate, potential additions to recruitment efforts to boost enrollment include offering travel compensation for testing visits for those who live outside the city and offering exercise sessions at additional satellite locations. All participants require clinician clearance before being formally screened via phone. Phone screening comprises 2 short questionnaires to determine eligibility: the Godin Leisure Time Questionnaire [15] to assist in determining the participant's current exercise levels and the Physical Activity Readiness Questionnaire [16] to confirm the participants' health status and how this relates to undertaking an exercise program. Upon confirmation of eligibility and interest, participants consent via wet or electronic signature.

Ethics Approval

Approval of the trial protocol was obtained from the institutional review board at the Dana-Farber Cancer Institute (20-222).

Randomization and Blinding

After baseline testing, participants are randomly allocated to either the HIIT or AC group using a 1:1 ratio and a permuted blocked design with varying block sizes where investigators are blinded to this process. The study biostatistician and coinvestigator (HU) prepared the randomization list before study start-up, after which the investigators access through a web-based application to conduct randomization and

XSL•FO
RenderX

subsequently verbally inform the participants of their group allocation. Testers and participants are blinded to group allocation during baseline testing. Owing to the nature of the intervention and logistical limitations, participants and study staff cannot be blinded to the intervention allocation.

Measurements

Overview

Testing is completed on 2 consecutive days at baseline, after the intervention, and at follow-up, with only 1 day required for testing at midintervention. At baseline, the first testing day may occur before the first dose of chemotherapy or within 10 days of the first infusion. The second day of testing is completed within 1 to 6 days of testing day 1 and may occur after the first cycle of chemotherapy. All measures are collected at all time points unless otherwise specified, and study staff members trained in exercise oncology will be supervising and leading all the tests unless otherwise specified (Table 1).

Primary Outcomes

Executive Function and Memory

To assess executive functioning and abilities, we use the NIH toolbox [17] and the Montreal Cognitive Assessment to assess global cognition; both tests are conducted at baseline, after the intervention, and at follow-up. From the NIH toolbox, the following tests are administered: Auditory Verbal Learning Test for immediate recall (memory), Picture Sequence Memory Test for episodic memory, Oral Reading Recognition for language, flanker task for executive function and attention, List Sorting Test for working memory, Oral Symbol Digit Test for processing speed, Dimensional Change Card Sort Test for executive function, and Pattern Comparison for processing speed. We also include an episodic memory composite that is derived from tests supported by the hippocampus and surrounding medial temporal lobe [18].

Resting-State Connectivity and Structural Diffusion Tension Imaging Connectivity

The MRI (Table 2) is conducted at baseline, after the intervention, and at follow-up by authorized MRI personnel. All imaging is performed on a single Siemens 3T Prisma MRI system with a 32-channel head coil. 3D T1 magnetization-prepared rapid acquisition with gradient echo imaging (1-mm isotropic voxels and 6-min, 38-s gradient time) is performed as the primary anatomic imaging sequence. Automated brain region segmentation is performed using the open-source FreeSurfer program (Martinos Center for Biomedical Imaging) [19] with manual correction [20]. Segmentation is used for primary volumetric analyses [21,22]. We examine the amygdala-hippocampus complex and thalamic and ventricular volumes and perform an exploratory comprehensive volumetric analysis. Multishell diffusion tensor imaging (DTI) is performed with 107 directions obtained in both the anteroposterior and posteroanterior directions (2-mm slice thickness and 6-min, 7-s gradient time each). DTI data are processed using the open-source 3D Slicer program (The Slicer Community) [23]. This technique enables traditional DTI analyses that are considered measures of cerebral microstructure and axonal and myelin pathology [24,25]. This technique also enables more novel analyses of free-water imaging [26], neurite orientation dispersion and density imaging [27], and diffusion kurtosis imaging [28], which can help evaluate for neuroinflammation and vasogenic and cytotoxic edema. Resting-state functional MRI (fMRI) is performed and analyzed using the Resting-State fMRI Data Analysis Toolkit (Hangzhou Normal University) [29]. We are examining the intrinsic network connectivity between the prefrontal cortex and hippocampus in addition to seed voxels in the posterior cingulate and precuneus of the default mode network [30].

[h]rsfMRI: resting-state functional magnetic resonance imaging.

Secondary Outcomes

Blood Biomarkers

A trained phlebotomist performs a fasting blood draw, obtaining both serum-separating tubes and EDTA samples. After being processed and aliquoted, the blood serum and plasma samples are stored in a −80 °C freezer for later batched analysis. Analysis of bloods through commercially available kits (Thermo Fisher Scientific) will be used for leptin, adiponectin, insulin, estradiol, matrix metalloproteinases, tissue inhibitors of metalloproteinases, interleukin-6, sex hormone–binding globulin, tumor necrosis factor-α, brain natriuretic peptide, N-terminal probrain natriuretic peptide, cardiac troponin I, and C-reactive protein. These biomarkers were selected based on their potential mechanistic role in how exercise may affect cognitive function [31-34].

Anthropometric Measures

Height (cm), weight (kg), and waist and hip circumference (cm) are assessed according to standard procedures [35], with height and weight used to calculate BMI (kg/m^2). Body composition is assessed using bioelectrical impedance (Tanita 780), providing both appendicular and whole-body measures of fat and lean mass (kg).

Cardiorespiratory Fitness and Exercise Capacity

To assess maximal oxygen consumption (VO_{2max}) and accurately prescribe the exercise intervention, a maximal cardiopulmonary exercise test is completed on a cycle ergometer (ErgoSelect

XSL•FO
RenderX

100; Ergoline) using an incremental ramp protocol [36]. Participants complete a 5-minute warm-up at a resistance of 40 W and then proceed into an incremental ramp protocol increasing 10 W every minute until volitional fatigue. Cadence is kept between 60 and 80 revolutions per minute. Heart rate (HR; FT4; Polar USA) and rate of perceived exertion (Borg scale 1-10) are recorded every minute and at the end of the test. Expired gas analysis (TrueOne 2400; ParvoMedics, Inc) is used to measure VO_{2max}. The results of this test are used to calculate the target maximal power output (POmax) in watts for the high-intensity and recovery intervals of the HIIT program. In addition, the 6-minute Walk Test is used to estimate exercise capacity [37,38]. Participants will be instructed to walk as far as they can in 6 minutes up and down a 10-m walking course within a hallway. The distance achieved in 6 minutes will be measured in meters.

Muscular Strength

Muscular strength is assessed using an estimated 1-repetition maximum (RM) from 10-RM of leg press, leg extension, and leg curl (SportsArt and Matrix Fitness). Participants perform 1 to 2 warm-up sets of 6 to 8 repetitions. The participant proceeds to complete sets of 10 repetitions with increasing weights in each set until volitional fatigue is reached on the 10th repetition; a maximum of 3 sets are used to reach 10-RM. The weight of the participant's 10-RM is recorded in kilograms and used to estimate 1-RM using validated equations [39,40]. Isometric handgrip strength is measured in the dominant upper limb (Camry Digital Hand Dynamometer). Participants perform 3 trials in a standing position with their arms down by their side, with the highest result used for analysis.

Physical Function

Physical function is assessed using the Short Physical Performance Battery (SPPB) [41], Timed Up and Go (TUG) [42], gait speed [43], Margaria stair climb [44], and sit-to-stand [45] tests. The SPPB comprises three sections: (1) balance with feet together, semitandem, and full tandem is held for up to 10 seconds with no support (only 1 attempt is given for each position, and the time in seconds to complete it is recorded); (2) usual gait speed over 4 m is timed, where the participant completes 2 attempts with the fastest time (seconds) recorded; and (3) chair stand, where the time (seconds) to complete 5 chair sit-to-stands is recorded, and only 1 attempt is given after a familiarization practice. Each section of the SPPB is given a score dictated by performance to then provide a summary score. The TUG test times how fast it takes a participant to stand up from a chair, walk around a cone placed 3 m away from the chair where they start, and end in a seated position. Participants attempt the TUG 3 times after a familiarization practice, where the average of the 3 trials is calculated. Gait speed is assessed over a 6-m flat surface where the time to walk the 6-m course at a usual and fast pace is recorded. In total, 2 attempts for each speed are completed. The Margaria stair climb is completed in a stairwell of 10 stairs. The participant walks or runs up the stairs as fast and safely as they can. The time (seconds) the participant takes from stair 3 to stair 9 is recorded; 3 attempts are given after a familiarization practice, where the average time of the 3 trials is calculated. Power (kg) is calculated from the stair climb using a validated equation [44]. The sit-to-stand test involves participants completing as many sit-to-stands as possible from a seated chair position to a standing position with full hip extension in 30 seconds; 1 attempt is given, with the number of full movements with correct technique recorded.

Psychosocial Measures

Health-related quality of life is assessed using the Functional Assessment of Cancer Therapy-Breast, which has an internal consistency coefficient of Cronbach α=.90 [46]. This is a 37-item questionnaire specifically designed for patients with breast cancer and measures the following 5 domains: physical, social, emotional, and functional well-being and a breast cancer subscale. Cancer-related fatigue is assessed using the Brief Fatigue Inventory, which has an internal consistency coefficient of Cronbach α=.96 [47]. This is a 6-item questionnaire that produces a global fatigue score by averaging all the items of the Brief Fatigue Inventory. Depressive symptoms are assessed using the Center for Epidemiologic Studies Depression Scale, which has an internal consistency coefficient of Cronbach α=.82 [48,49]. This is a 20-item questionnaire designed to measure a participant's current level of depressive state using the following 6 scales reflecting major facets of depression: depressed mood, feelings of guilt and worthlessness, feelings of helplessness, psychomotor retardation, loss of appetite, and sleep disturbance. The State-Trait Anxiety Inventory is a 40-item questionnaire, which will be used to examine anxiety. The State-Trait Anxiety Inventory has an internal consistency coefficient of Cronbach α=.86 to .95 [50]. Sleep quality will be assessed using the Pittsburgh Sleep Quality Index, which has an internal consistency coefficient of Cronbach α=.83 [51,52]. This is a 19-item questionnaire evaluating 7 domains—subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleep medication, and daytime dysfunction—and provides a global score. The impact that pain has on quality of life will be assessed using the Brief Pain Inventory-Short Form, which has an internal consistency coefficient of Cronbach α=.81 to .89 [53,54]. This is a 9-item questionnaire and has been validated for use in patients with breast cancer [53]. Finally, barriers to recruitment and exercise adherence are assessed using the Barriers to Recruitment Participation Questionnaire and Exercise Benefits/Barriers Scale, which have an internal consistency coefficient of Cronbach α=.93 [55,56]. The Barriers to Recruitment Participation Questionnaire is a 17-item questionnaire, and the Exercise Benefits/Barriers Scale is a 43-item questionnaire.

Peripheral Neuropathy

Peripheral neuropathy is measured using two tests: (1) the Semmes-Weinstein Monofilament Examination and (2) vibration testing using the on-off method [57-59]. For both tests, participants are seated in an upright position with their eyes closed and socks and shoes off. The Semmes-Weinstein Monofilament Examination is used to evaluate protective sensation at 2 sites—pad of the great toe (foot) and pad of the index finger (hand)—with the nylon monofilament applied 4 times to each site. The vibration sensation is evaluated by applying a tuning fork to the bony prominences of the great toe, thumb, and medial malleolus. Correct identification of the side

XSL•FO
RenderX

of the body and on-off vibration sensation for the respective tests is recorded.

Lymphedema Assessment

Lymphedema is assessed using geometric arm volume calculations on both upper limbs [60]. We calculate arm volume using circumferential measurements taken at the following anatomic landmarks: axillary fold, halfway between the axillary fold and antecubital fossa, antecubital fossa, halfway between the antecubital fossa and wrist, and wrist. Circumferential measurements are taken with a constant-tension tape measure. Calculations for limb geometric volume are done using the frustum (truncated cone) volume, as described by Taylor et al [60]. A percentage difference between the lymphedema limb and the uninvolved limb is calculated to determine the amount of lymphedema. Lymphedema has been defined in recent literature as a >10% difference in volume calculation for the arm compared with the uninvolved upper extremity [60].

Shoulder Function and Range of Motion

Upper-body function is assessed using the Y Balance Test Kit (Move2Perform) [61]. Participants begin in a 3-point plank position on the toes or knees depending on ability. The tested shoulder is the supporting limb placed on the connecting block, the nontesting limb is placed on the medial block, and the feet are placed shoulder-width apart. From this position, the participant uses their nontesting limb to move each reach block one at a time in the medial, inferolateral, and superolateral directions in a controlled manner as far as they can and then return to the starting position. The test is performed 3 times on each side with a 30-second rest between trials. The reach distance in each direction is recorded, where the highest value in each direction is used to calculate an average composite score.

Bilateral upper-body strength and power are assessed through the seated medicine ball throw [62]. Participants are instructed to sit on the floor with their head, shoulders, and back against the wall and legs extended; legs may be bent if ability does not allow for full extension. To calculate a relative throwing distance, arm-reach distance is measured from the wall in meters. Using a 2-kg medicine ball covered in chalk, the participant performs a chest pass holding the ball with both hands and throwing it forward in a straight line as far as they can with head, shoulders, and back maintaining full contact with the wall. A measuring tape is used to measure the distance from the wall to the most proximal point of the chalk mark, with the participant's reach distance subtracted to provide a final distance in meters. In total, 3 test trials will take place after a practice throw with a 1-minute rest between each trial. The average of the 3 trials will be calculated.

Shoulder function is assessed through the shoulder performance test using the following tasks: overhead reach, hand behind the head, and hand behind the back. All movements are completed in a standing position starting with the arms by the side. The time (seconds) taken to complete the respective tasks using the correct technique 20 times is recorded. Each task is repeated to the right and left.

Upper-body function is assessed using the closed kinetic chain upper-extremity stability test [63]. Participants begin in a 3-point plank position on the toes or knees, depending on ability, with hands 36 inches (91.4 cm) apart, shoulders perpendicular to hands, and feet hip-width apart. From this position, the dominant hand reaches across the body, touches the nondominant hand, and returns to the starting position. Subsequently, the same movement is performed by the nondominant hand. Participants are instructed to perform as many alternating touches as possible in 15 seconds while maintaining the correct push-up position. In total, 3 trials occur after familiarization, with 45 seconds of rest in between each trial.

Shoulder active range of motion (AROM) is measured on both upper limbs. Using a goniometer (EZ Read; Jamar), AROM is assessed in external rotation at 0°, external rotation at 90°, forward flexion, and abduction [64,65]. The participant stands for all tests except for external rotation at 90°, where the participant is lying on the ground with knees bent and feet hip-width apart. The starting position of the measured limb is dictated by the AROM being tested. The participant is asked to actively perform the required motion with the angle of movement recorded in degrees. In total, 3 active trials are performed after the tester passively moves the participant's limb in the tested motion.

Physical Activity and Sedentary Behavior

Physical activity and sedentary behavior are assessed using the ActiGraph wGT3X-BT (ActiGraph LLC) at baseline, after the intervention, and at follow-up only. Patients wear the accelerometer on their hip for 7 consecutive days, excluding water-based activities and sleep. ActiLife software (ActiLife 6; ActiGraph LLC) is used to analyze the ActiGraph data. Only wake wear time is used, with a minimal data collection period set for inclusion in the analysis of 4 days of at least 600 minutes per day. Nonwear time is excluded from the analysis, defined as ≥90 minutes of consecutive zeros with a 2-minute spike tolerance [66]. Commonly used cutoff points among patients with cancer will be used to classify sedentary time (<100 counts per minute), light physical activity (100-1951 counts per minute), and moderate to vigorous physical activity (≥1952 counts per minute) [67-69].

Covariates

Participant Characteristics

Participant demographic and medical history data are collected at baseline with the administration of a study-tailored questionnaire. In addition, patients complete the Socioeconomic Status Questionnaire to determine economic demographics, education level, and socioeconomic status [70]. Changes in demographic and medical history data (eg, medical conditions, medication, and cancer treatment) will be monitored throughout the study period and confirmed at each testing time point.

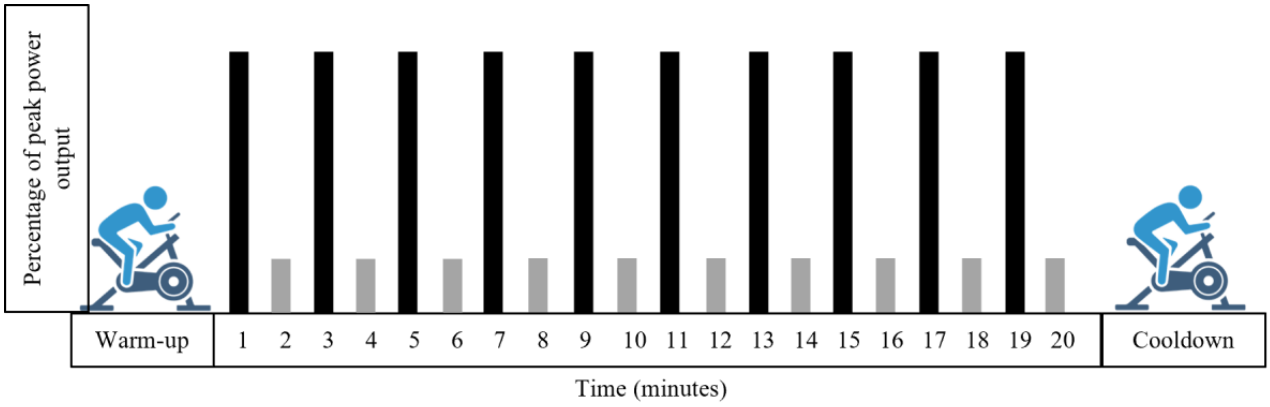
Dietary Intake

Recent dietary patterns are assessed using the automated self-administered 24-hour dietary assessment tool [71]. Participants complete 3 assessments at home on 2 weekdays and 1 weekend day, recording all food and drinks consumed during the previous 24-hour period.

XSL•FO
RenderX

Physical Activity Logs

The AC group completes a daily activity log throughout the 16-week intervention. During the supervised exercise sessions, the HIIT group is asked about their physical activity completed outside the supervised sessions over the previous week. In addition, they complete daily activity logs during the follow-up period. In the activity logs, the participants are asked to record the type of exercise performed, the time spent performing the exercise, the intensity of the exercise bout (rate of perceived exertion [Borg scale 1-10] or average HR for the HIIT group if they are wearing an HR monitor), and the day of the week in which it was completed.



Intervention

HIIT Group

Participants randomized to this group partake in a clinic-based HIIT program using a cycle ergometer 3 days per week for 16 weeks under the supervision of a trained exercise oncology specialist. Before beginning the exercise session, participants undergo a screening procedure to ensure that they are fit to participate. Participants are permitted to participate in the exercise session if they present with normal body temperature (≤100 °F or ≤37.8 °C), resting HR (absence of bradycardia, <60 beats per minute; or tachycardia, >100 beats per minute), and resting blood pressure (≤200/120 mm Hg). In addition, participants complete the Exercise-Induced Feeling Inventory [72] before and after the HIIT session to assess the participants' feeling state changes after exercise and self-motivation to adhere to an aerobic exercise regimen. Participants also complete the Therapy-Related Symptom Checklist [73], a 25-item questionnaire, to assess and identify patient-reported symptom occurrence and severity.

The cycle-based HIIT exercise session consists of a 5-minute warm-up period at 10% of POmax (watts; calculated from the cardiopulmonary exercise test) followed by a 20-minute stimulus period consisting of alternating high-intensity interval bouts at 90% POmax (based on individual fitness level) with a recovery bout at 10% at a 1 minute:1 minute (work:recovery) ratio (Figure 2). Following the stimulus period, participants complete a 5-minute cooldown at 10% POmax (watts). An HR monitor wristwatch and transmitter are used to measure HR before exercise and at every minute during warm-up, exercise, and cooldown. Exercise sessions are completed with at least one full day of rest in between each session and are not to be completed on days when the participant has a chemotherapy infusion. Weekly goals will be set by the study staff for each participant based on their symptoms and how they feel overall, allowing for tailored sessions to accommodate individual fitness ability and treatment burden.

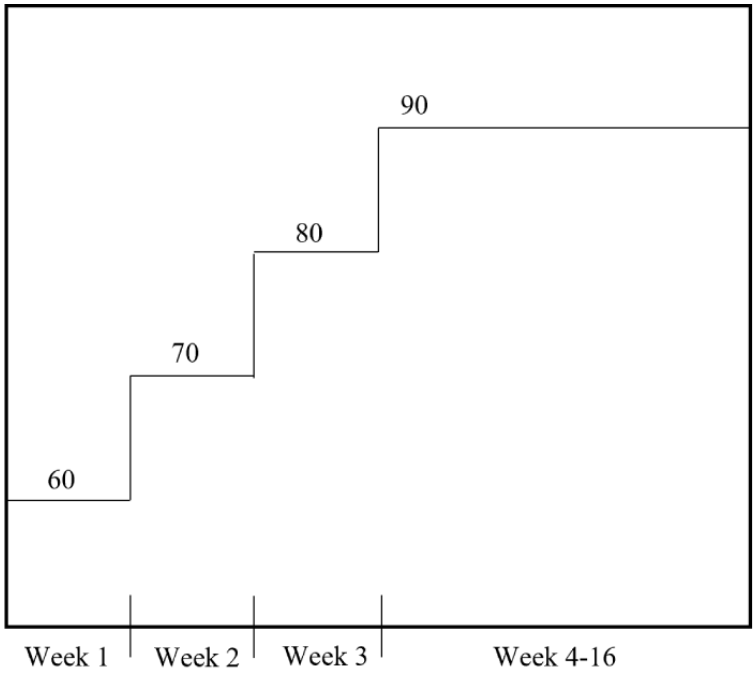


Figure 2. Example of a high-intensity interval training session and the high and low intensities performed.

Exercise intensity is gradually increased within the first 4 weeks of the intervention, whereby the participants begin the high-intensity interval bouts at 60% POmax, increase by 10% each week until 90% is reached, and then maintain at 90% for the remainder of the intervention (Figure 3). If a participant is unable to achieve compliance with the prescribed HIIT program, a moderate-intensity interval training (MIIT) program is substituted as an alternative exercise prescription. A single session is considered noncompliant if the number of high-intensity bouts achieving the target power output is <80% (eg, if ≥3 high-intensity bouts do not reach the prescribed power output). If 3 concurrent exercise sessions are reported as noncompliant, the participant is offered the MIIT program instead. Within the MIIT program, participants continue to complete intervals at a 1 minute:1 minute (work:recovery) ratio; however, the high-intensity bout is replaced with a moderate-intensity power output target. The intensity of the moderate interval is calculated as a percentage of the individual's estimated VO_{2max} and will be selected according to the highest intensity that the participant may tolerate or complete. After the aerobic exercise session, the participants will perform 1 set of 3 to 4 static stretching exercises held for 30 seconds.

XSL•FO
RenderX

Figure 3. High-intensity bout progression over the course of the 16-week high-intensity interval training intervention.

AC Group

Participants randomized to this group perform a home-based flexibility intervention 3 days per week for 16 weeks. The stretching protocol consists of the same stretching exercises as in the HIIT program. As flexibility exercises are low-intensity, low-impact, and low-volume, minimal caloric expenditure is expected. To increase compliance [74] and aid in the standardization of the home-based stretching [75], participants are provided with an instructional booklet of the flexibility exercises. Participants are asked to enter these stretching bouts into the daily activity log in addition to the other self-directed exercise sessions performed. Participants in the AC group are offered to participate in the same experimental exercise condition (HIIT) after the first 16-week study period; if they do not choose to participate in the HIIT program, they are not required to complete follow-up testing and are finished with the study after the first 16 weeks. The AC participants who choose to take part in the HIIT protocol after the initial 16 weeks return at the follow-up testing time point for final testing, which serves as post-HIIT testing.

Intervention Adherence

Participant adherence to the HIIT program is measured using (1) percentage and number of prescribed sessions attended (participants must attend ≥80% of the 48 sessions to be considered compliant with the HIIT program; eg, ≥38 sessions) and (2) average minutes of exercise per week (participants must complete ≥80% of the prescribed 90 minutes per week; eg, ≥72 minutes per week). To support adherence throughout the intervention, flexible hours are offered for exercise sessions, including before or after normal working hours and on weekends. In addition, all participants are given an additional 2 weeks beyond the 16-week intervention period to make up for any exercise sessions missed because of illness, work, or travel. Participants are provided with monetary compensation for each MRI completed and parking validation for every visit to the Dana-Farber Cancer Institute.

Adverse Events

Any expected and unexpected adverse events are or will be reported to the principal investigator, who then subsequently reports to the institutional review board of the Dana-Farber Cancer Institute. Serious events must be reported within 24 hours of occurrence or finding out about the event. All adverse events, both serious and nonserious, and deaths that are encountered from the initiation of the study intervention, throughout the study, and within 30 days of the last study intervention are followed to their resolution or until the principal investigator assesses them as stable or determines the event to be irreversible or the participant is lost to follow-up. The presence and resolution of adverse events are documented on the appropriate case report form and recorded in the participant's medical record.

Data Monitoring and Management

Data are monitored internally within the Dana-Farber Cancer Institute for timeliness of submission, completeness, and adherence to protocol requirements. Monitoring begins at the time of participant registration and will continue during protocol performance and completion. The study team collects, manages, and performs quality checks of the data. Potential audits or inspections may be conducted by the principal investigator or their designated representatives. All data are stored on a secure network drive using REDCap (Research Electronic Data Capture; Vanderbilt University), a Health Insurance Portability and Accountability Act–compliant web-based application hosted by Partners HealthCare Research Computing, Enterprise Research Infrastructure & Services, on password-protected computers. Any hard-copy data are stored in locked filing cabinets in card-access facilities. The results of this study will be presented in publication, conference, and invited speaker formats.

XSL•FO
RenderX

Sample Size Calculation

We will enroll 50 patients with breast cancer (n=25, 50% per group) in this study. We estimate that the dropout rate will at most be 20%. Assuming a 20% dropout, data from 40 (n=20, 50% per group) patients will be available for the analyses. With this sample size, we will be able to estimate within-group means for our outcome variables with a 95% CI of –0.47 to +0.47 SD units and mean differences between groups with a 95% CI of –0.64 to +0.64 SD units. Although the primary objective of the analysis for this pilot study is not to detect a between-group difference but to estimate the effect size for designing a subsequent confirmatory study, we also calculated a detectable effect size for the between-group comparison for reference. This sample size offers 80% power to detect a between-group difference at a .05 2-sided α level when the difference is 0.91 SD units.

Statistical Analysis

Analyses will reflect the trial hypotheses that involve comparisons of HIIT and AC. Initial descriptive analyses will evaluate baseline comparability between the 2 intervention groups using the 2-sample, 2-tailed *t* test or 2-sample Wilcoxon test for continuous variables and the chi-square test or Fisher exact test for categorical variables. The primary analysis variables will be changed from baseline to week 16 of neuroimaging and cognitive function measures. Summary statistics (mean, SD, median, IQR, minimum, and maximum) will be used to describe the distribution of the variables. The mean and median will be reported along with the corresponding 95% CIs. Paired tests will be performed for these continuous outcomes for each group to assess whether there is a significant difference between baseline and week 16 in each group. For between-group comparison, a 2-sample *t* test will be performed. Analysis of covariance will also be used to assess the intervention effect on those continuous outcomes (changes from baseline to week 16), adjusting for patient baseline characteristics and other clinical covariates, including any participant who is required to switch to MIIT. Furthermore, those who are transferred to the MIIT group will be included in the HIIT group in the primary analysis based on the intention-to-treat principle. As an exploratory analysis, we will identify baseline factors of the patients who are likely to be transferred to the MIIT group. We will then exclude those who are transferred to the MIIT group and compare the HIIT and AC groups adjusting for factors that affect the transfer from HIIT to MIIT. Chi-square tests will be used for group comparison of binary outcomes (eg, the occurrence of adverse events). The magnitude of the intervention effect on binary outcomes will be summarized using odds ratio and the corresponding 95% CI. For each analysis, a 2-sided *P* value of <.05 will be considered statistically significant. As this is a pilot study, we will not adjust for multiple testing. Linear mixed-effects models will be used to estimate the trajectories of those repeatedly measured continuous outcomes across the intervention to assess group differences and explore the impact of potential prognostic factors (eg, body weight, age, fat mass, race, and menopausal status) on outcomes. Linear mixed-effects models will also be used for exploratory analysis of potential neuroimaging biomarkers. The primary analysis will include all completed outcome assessments (regardless of whether the woman stayed on the intervention), inviting those who drop out of the intervention to return for outcome assessments. The only missing data would be of those who drop out of the intervention and do not return for outcome assessments. Preliminary analyses will compare women who do and do not contribute to this analysis of baseline characteristics. A sensitivity analysis will include multiple imputations of all missing outcome data, including those patients who have missing assessments.

Results

The CLARITY study was funded in January 2019 (American Institute of Cancer Research); however, recruitment was delayed until June 2021 as a result of the COVID-19 pandemic. As of May 2022, we have enrolled 4 patients in the study (n=2, 50% to exercise and n=1, 25% to control), with the fourth patient providing consent but withdrawing before baseline testing owing to chemotherapy not being pursued. In total, 50% (1/2) of the exercising patients also withdrew at week 6 of the intervention because of changes in time commitment. Recruitment is due to be completed in January 2024, with the primary results expected to be published in August 2024.

Discussion

Expected Findings

The CLARITY trial is the first randomized controlled trial to examine the impact of HIIT on cognitive function in patients with breast cancer undergoing chemotherapy. We hypothesize that undertaking HIIT will lead to improved executive function and memory scores and advance the current scientific knowledge regarding exercise and chemotherapy-induced brain function by incorporating (1) HIIT as an effective intervention that can enhance cognitive function; (2) multidimensional yet novel approaches to assess the effects of exercise on *chemo-brain*, such as fMRI, DTI, and the NIH toolbox; and (3) important secondary outcomes to provide a comprehensive understanding of the links between exercise and chemotherapy, including body composition, biomarkers related to metabolism, inflammation, cardiotoxicity, physical fitness and function, and quality of life and psychosocial outcomes.

Most patients with breast cancer experience cognitive decline during chemotherapy (up to 75%) [76,77], which may linger after treatment and even increase the risk of morbidity and mortality [78]. The onset of chemotherapy-induced cognitive decline has been an important clinical issue over the last few decades; however, the underlying mechanisms and potential interventions that can address cancer-related cognitive decline are still largely under investigation [3]. A promising nonpharmacological intervention is to engage in active physical movement, and a body of evidence supports the association between higher physical activity levels and improved cognitive function in patients with cancer [79]. A recent nationwide cohort study of 580 patients with breast cancer and 363 age-matched controls reported that patients who met the physical activity guidelines (ie, 150 minutes per week of moderate to vigorous physical activity) during chemotherapy showed significantly better self-reported cognitive function than those who did not

XSL•FO
RenderX

meet the guidelines [80]. Nevertheless, the impact of exercise interventions on cognitive function in women receiving chemotherapy for breast cancer is not known. Previous exercise oncology trials have reported the preliminary benefits of exercise for cognitive function, but the overall quality of studies has been poor [79], warranting rigorously designed exercise clinical trials to explore the efficacy and mechanisms of exercise and cognition outcomes in patients with cancer undergoing chemotherapy treatment.

There are potential biological mechanisms to explain the benefits of exercise for chemotherapy-induced cognitive function. Exercise induces the expression of neurotrophic and neuroprotective markers, including brain-derived neurotrophic factor [81] and vascular endothelial growth factor [82], which contribute to "neurogenesis" in certain brain areas (eg, the hippocampus), leading to an enhancement of memory space and consolidation [83]. This mechanism is particularly plausible given that the hippocampus can be degenerated by toxic chemotherapy agents [84,85], whereas exercise has shown to not only improve hippocampus-dependent cognitive capacities but also increase the volume of the hippocampus [86-89]. Furthermore, neurological degeneration is significantly influenced by inflammatory markers [90], and exercise training can create a systemic anti-inflammatory environment to fight against and restore chemotherapy-induced cognitive decline [91-93].

Prior work has suggested that HIIT has significant potential to address chemotherapy-induced cognitive decline. For example, HIIT significantly improved cognitive responsiveness when compared with continuous moderate aerobic exercise in healthy young adults [94]. HIIT resulted in shorter reaction times and better response accuracy than continuous moderate-intensity exercise, suggesting that HIIT-induced neural adaptations redistribute neural resources to efficiently accomplish goal-directed behavior during cognitively demanding tasks. The observed decrease in P3 amplitude from fMRI following HIIT along with enhanced behavioral outcomes may indicate the implementation of greater efficiency in neuroelectric function. In addition, HIIT has successfully improved cognitive performance in patients with multiple sclerosis with reduced cognitive performance [95] and cancer-related fatigue in patients with breast cancer [14]. Furthermore, HIIT has shown superior effects on cognitive function (ie, verbal memory and executive functions) when compared with continuous moderate-intensity exercise in older adults [8] and individuals with Parkinson disease [96]. Therefore, HIIT may have the unique capacity to improve cognitive function in patients undergoing breast cancer chemotherapy.

Of importance, HIIT is a clinically proven, safe, and cost-effective intervention [97,98]. A recent study investigating HIIT in patients with heart failure with reduced ejection fraction revealed that the number of adverse events was not statistically different between the HIIT and moderate-intensity exercise group [99]. Furthermore, lower volumes of HIIT compared with moderate continuous-intensity exercise elicit better cardiovascular and physical fitness outcomes such as VO_{2max}; therefore, it is a time-efficient exercise option that promotes greater gains in cardiovascular outcomes [98]. During chemotherapy, the optimal type, timing, and intensity of exercise interventions are unclear. As such, the exercise protocols examined during chemotherapy in previous breast cancer studies are varied, with many using aerobic interventions with common exercise prescriptions, including 3 to 5 times per week of 30-75 minutes of moderate-intensity (40%-70% predicted maximum HR) continuous exercise rather than the on-off interval strategy of HIIT [100]. Given the potential barrier of compliance to regular exercise participation during chemotherapy in patients with breast cancer, HIIT is an intriguing option for increasing cardiovascular benefits with shorter exercise duration, which serves as an efficient alternative to traditional endurance-based exercise training [12].

The strengths of our study include the randomized controlled design, comprehensive set of cognitive and biomarker measures, and the inclusion of delayed exercise for the AC group to enhance the retention rate. We also acknowledge that our study has several weaknesses. There is potential recruitment bias, such as participants in our study who are already interested in exercise and, therefore, relatively more fit than other patients with breast cancer undergoing chemotherapy who are not keen to participate in such exercise studies. In addition, the clinic-based setting of our intervention may not be reproducible in other intervention settings, such as home-, remote-, or community-based exercise programs. Upon publication of positive findings of this pilot study, future studies would be beneficial to understand effective dissemination strategies within the standard of care and the best timing of implementation of HIIT for patients with breast cancer undergoing chemotherapy to prevent chemotherapy-induced cognitive decline.

Conclusions

The CLARITY trial is a first-of-its-kind study that incorporates a novel approach using a high-intensity exercise intervention (ie, HIIT), comprehensive cognitive measures (ie, quantitative fMRI and the NIH toolbox), and important secondary outcomes (ie, biomarkers, physical fitness and function, and psychosocial health). This study is anticipated to contribute to the current evidence on the role of HIIT in managing cognitive function and various patient-reported outcomes in patients with breast cancer undergoing chemotherapy and will establish the pilot efficacy to inform future larger phase-II and phase-III trials to confirm the findings.

Abstract

Background: People living with psychosis face a substantially increased risk of poor psychological well-being and physical health and premature mortality. Encouraging positive health behaviors from an early stage is crucial to the health and well-being of this population but is often overshadowed by symptom management within early intervention services.

Objective: Experience-based co-design is a participant-centered approach that aims to combine service user narratives with service design methods to design systems of support for health and well-being. This study aims to use experience-based co-design principles to co-design a system that supports the health and well-being of young people experiencing first-episode psychosis (FEP), which considers the lived experience of these people within the context of early intervention services. We also aim to develop a set of principles to guide future systems to support the health and well-being of young people experiencing FEP.

Methods: Up to 15 young people living with FEP aged 16 to 24 years who are service users of early intervention services in psychosis, their immediate support networks (family or friends), and health professionals involved with early intervention services in psychosis will be invited to participate in a series of co-design workshops. Data will be collected in various forms, including expressive forms (eg, art and spoken word) and traditional methods (interview transcription and surveys), with phenomenographic and thematic analyses being used to understand these data. Furthermore, the co-design process will draw upon indigenous (Māori) knowledge and the lived experience of mental health services from the perspectives of the members of the research team. The co-design process will be evaluated in terms of acceptability from the perspective of service users via rating scales and interviews. The study will be conducted within the Lower North Island in Aotearoa New Zealand.

Results: Data collection will be performed between August 2022 and February 2023. Drawing from extended consultations with service users and service providers, we have developed a robust co-design process with which we intend to collect rich qualitative and quantitative data. The results of this process will be used to create a system of support that can be immediately applied and as preliminary evidence for funding and resource applications to deliver and evaluate a “full” version of the co-designed system of support.

Conclusions: The co-designed system of support and accompanying set of principles will offer a potentially impactful health and well-being intervention for young people experiencing FEP in Aotearoa New Zealand. Furthermore, making the co-design process transparent will further the field in terms of providing a blueprint for this form of participant-focused research.

Introduction

Background

The physical health of people living with serious mental illness is worse than that of the general population [1]. Cardiovascular disease is more prevalent in this population, and life expectancies are shortened on average by 25 years, a sobering statistic described as the "scandal of premature mortality" [2]. Ultimately, serious mental illness, particularly psychosis, has been identified as a significant independent risk factor for poor cardiovascular health and increased mortality [3]. Although antipsychotic medication has been implicated in the elevated risk of cardiovascular disease [4-6], modifiable risk factors such as smoking, substance use, poor diet, and insufficient physical activity also play an important role. The relationship between mental illness and poor physical health highlights the holistic nature of health such that physical and mental aspects (among other equally important parts such as social and spiritual well-being) are deeply interconnected [7]. Failure to support the health of people living with psychosis has led to international calls for interventions that prioritize both physical and mental health, with health behaviors as a key point of leverage [8].

The timing of these interventions is crucial. There is a critical window of opportunity to provide support for young people experiencing their first-episode psychosis (FEP) in maintaining positive health behaviors [9]. However, in a review of lifestyle interventions for people experiencing FEP, Gates et al [10] highlighted the lack of such programs, and even less are those programs that are based on robust evidence and theory in Aotearoa New Zealand (NZ). A lack of support for the physical health of people experiencing psychosis has been noted as a major source of inequity [1].

The long-term effectiveness of any health intervention depends on its feasibility within a given health service, which itself relies on the uptake and engagement by the target group and those who support them (eg, family and carers). A major factor in the acceptability of a lifestyle intervention is the extent to which it is suitably adapted to the specific population. People experiencing FEP may encounter barriers to health behaviors related to antipsychotic medication (eg, metabolic issues and effects on energy levels), psychological factors (eg, motivation and self-efficacy), stress, and a lack of support [11,12]. They are also likely to prioritize their own goals over those imposed on them by health services. Therefore, elucidating and addressing such barriers and understanding the goals of people experiencing FEP are crucial for intervention success.

Valuing lived experience positions service users as "experts by experience." As such, the personal experience of living with mental distress and using mental health services provides unique and essential insight into how to best serve the users of these services. Early and authentic involvement with people with lived experience can lead to enhanced credibility, quality, and relevance of services and to a greater sense of empowerment and agency for the service users involved in the development process [13-15]. Working alongside experts by experience is increasingly recognized as being crucial to service development, both within the mental health sector [13,14] and specifically with people experiencing psychosis [15].

Support from service providers is also necessary for the long-term sustainability of a new health intervention [16]. Frontline providers are responsible for implementing the intervention beyond the life of the project, as well as directly influencing the extent to which participants change their behaviors [17]. Therefore, when developing an intervention, we must understand how the intended intervention outcomes align with providers' service objectives, as well as the extent to which they can be adequately resourced and implemented in practical terms. By addressing these factors, we increase the likelihood of ongoing intervention success by encouraging service providers to "buy-in" [16].

Co-designing interventions alongside participants and service providers effectively optimizes intervention feasibility, uptake, and sustainability [18,19]. An additional benefit of co-design is that it supports participants' self-determination by providing them with an opportunity to exercise autonomy in terms of their physical health care [20]. To date, co-designed interventions that support the physical health of people experiencing FEP have been missing in Aotearoa NZ [1]. This research responds to global calls to develop such interventions [8] while aligning with localized health service contexts.

Research Objectives

Obtain Narratives Regarding the Lived Experience of Young People Being Healthy During FEP

How do young people experiencing FEP define health (ie, what "health" looks like and what components contribute to a healthy life)? What are the key barriers and facilitators to achieving positive health? What is missing in the current health care system or community that can support a healthy life?

Develop a System of Support for Leading a Healthy Life

Alongside service users, their family or support people and service providers cocreate a system of support, including specified components (eg, physical activity sessions or access to peer support groups) and format (eg, in-person or web-based connecting events).

Create a Set of Principles to Guide Early Intervention Health Care

Using data obtained across all stages of the co-design process, we aim to distill a set of principles that participants think should

XSL•FO
RenderX

guide the support of young people experiencing FEP. For example, such principles might include collaboration, social connections, action, listening, or autonomy.

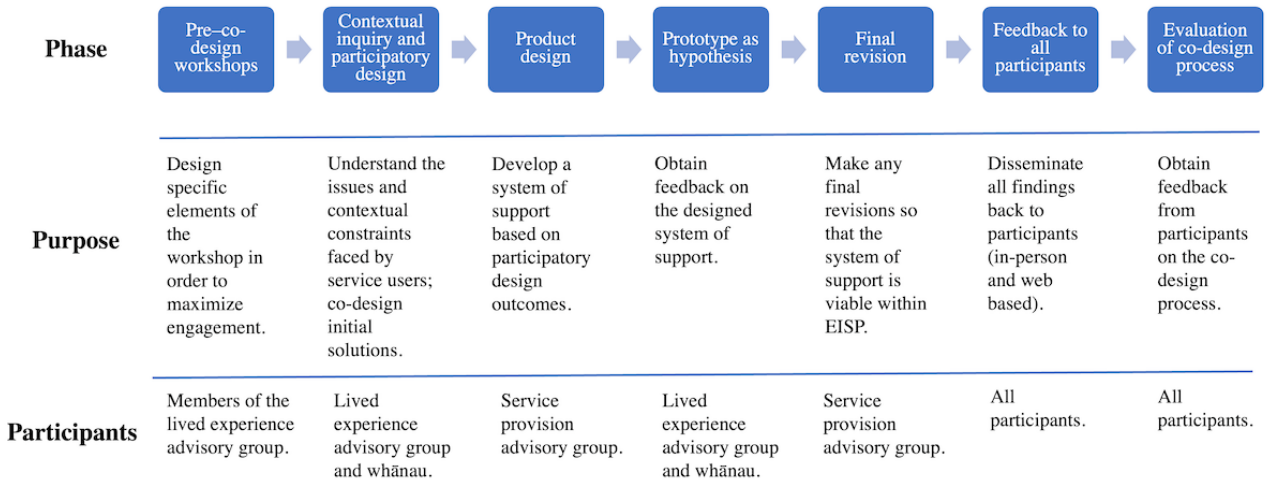
Devise a Strategy for the Future Delivery of a System of Support

Furthermore, we aim to obtain an understanding of the resources that are needed to deliver the components that have emerged from the co-design process and to create a plan to obtain these resources, whether internally from the existing health care system or externally from community, project, or research grants.

Methods

Design

An experience-based co-design (EBCD) approach [18] will be used to understand the lived experiences of service users experiencing FEP and to design an effective system of support for service users of early intervention services in psychosis (EISP). An iterative approach is an important aspect of EBCD because it allows for the reflection and hypothesis testing of prototype solutions [21].



The co-design process will include five key phases:

1. Contextual inquiry (understanding the context, including issues faced by participants and contextual constraints).
2. Participatory design (working with service users and service providers to identify initial solutions).
3. Product design (working with the service provision advisory group to develop a support system based on participatory design outcomes).
4. Prototype as hypothesis (asking service users to approve or provide comment on the developed system of support).
5. Final program revision.

For the purpose of this project, contextual inquiry and participatory design will be combined into one phase. In addition, a pre–co-design focus group with prospective service user participants is used to design the co-design workshops. Following these phases, the co-designed system of support will be presented to all stakeholders, and an audit will be conducted to identify the resources required to deliver and evaluate the system of support. Service users, their close supporters (eg, family members and other support people), and staff within the EISP will be consulted via a combination of interviews and focus groups across these phases. Involving service users and their support group in the design process will provide them with opportunities to exercise autonomy in their own health care, while service providers will offer critical insights regarding the intervention feasibility and will support future implementation success.

An overview of the co-design process and the involvement of the participants at different stages are summarized in Figure 1.

Figure 1. Overview of the co-design process.

Context

Critical to conducting research in Aotearoa NZ is the duty to uphold Te Tiriti o Waitangi (the Māori version of the Treaty of Waitangi), which recognizes shared governance between the Indigenous people of Aotearoa NZ and the British Crown as well as a responsibility for supporting Māori health. Failure to do so in the past is exemplified by the overrepresentation of Māori with FEP and psychosis [22]. This co-design project works in partnership with a Māori agency, Toi Tangata, to ensure that the project is informed by mātauranga Māori (Māori knowledge) so that the resulting system of support is culturally responsive and safe for Māori with FEP in Aotearoa NZ.

Furthermore, this project takes place against a background of change to Aotearoa NZ health service delivery. This change involves the dissolution of 20 district health boards into a larger unifying health board and the establishment of an independent Māori Health Authority. Relevant to this project, the reform has been identified as a catalyst for change toward strengthening primary health care contextualized to local communities and improving the way services are used and accessed [23].

Adopting a Māori Lens for Co-design

This project embeds Māori principles, which enable approaches that are engaging and creative. For example, a key principle is the process of whakawhanaungatanga (relationship building) to create a space in which participants feel safe to tell their

XSL•FO
RenderX

stories and narratives. Indeed, this narrative storytelling aspect is another key principle of Māori-based approaches, with pūrākau (stories) relating to one's own individual experiences being an important way to create meaning. The key features of this project that align with this approach are the use of water (wai) as a metaphor (Figure 2) and allowing participants to tell their story in different creative ways so that they are understood by their peers and researchers (Multimedia Appendix 1).

Furthermore, this research is guided by the Māori model of health, Te Whare Tapa Whā, that conceptualizes health as a whare (house) with its stability dependent on the 4 walls of well-being: tinana (physical), hinengaro (mental), wairua (spiritual), and whānau (social) health [7]. This model is inherently holistic compared with typical Western-influenced models, such that it acknowledges the importance of the dynamic relationship between the many dimensions of well-being. This holistic approach has the potential to benefit all clients of health services, including those who identify as Māori. Embedding Te Whare Tapa Whā and Māori principles into the project process and design is a strengths-based approach to incorporating mātauranga Māori into health care, rather than solely focusing on Māori health deficits.

Figure 2. "Navigating the Puna" framework used to guide contextual inquiry. Translations from Māori to English: "Moemoeā" is often used to mean "dreams and aspirations"; "mauri" often refers to one's "life force or essence". Copyright League of Live Illustrators, New Zealand.

Research Team and Partners

Researchers from the University of Otago and Te Herenga Waka Victoria University of Wellington are coleading this project. Other team members include a project manager and 3 early career researchers employed as research assistants or assistant research fellows. Throughout the research team, there are varying degrees of lived experiences of FEP and mental distress. Given the existing discrimination of people living with mental illness or distress in employment (both perceived and objective) [24,25], this was an opportunity to increase the research capacity within the workforce in terms of early career researchers with lived experience of FEP and mental distress, as well as to bring in crucial lived experience perspectives to the research process.

The Māori health agency Toi Tangata has codeveloped the co-design process alongside the research team and will

XSL•FO
RenderX

cofacilitate the workshops. In addition, the League of Live Illustrators will be embedded in some workshops to provide live interactive note-taking in the form of illustrations. Partners within the EISP will be project facilitators and assist with participant recruitment (service users, family members, and service providers).

A steering group will guide project decision-making from procedural and policy perspectives to maximize project impact. Steering group members include clinical and academic psychiatrists, representatives of nongovernment advocacy organizations, and both Māori and non-Māori public health researchers.

Participants

Lived Experience Advisory Group

This is the primary participant group. The community of young people experiencing FEP is heterogeneous in terms of cultural background, gender, and education. The research team will work closely with the EISP to identify participants within their services who are representative of these demographic characteristics.

Whānau

Recognizing the wider network of people who support young people experiencing FEP, we will seek the perspectives from service users' whānau. Whānau is a Māori word that is often translated to "family members"; however, whānau can also refer more widely to close family friends or people who support another person. Therefore, the word whānau is used throughout this manuscript to refer to both family members and people who support service users (in a nonprofessional capacity).

Service Provision Advisory Group

The service provision advisory group will consist of health professionals who support service users in some professional or voluntary capacity, which may include psychiatrists, clinical psychologists, occupational therapists, and pharmacists, who have experience in treating, managing, and supporting young people experiencing FEP. It is anticipated that they will mostly be working within the EISP (and therefore have an internal understanding of mental health services), but participation will also be open to people working in an adjacent supportive capacity (eg, nutritionists, physical activity providers, and community support workers).

The iterative procedure means that these groups will be consulted at least twice during the co-design process.

Recruitment

For the lived experience advisory group, study information will be relayed to EISP service users via posters, email, newsletters, and caseworkers working within EISP. In terms of sample size, approximately 125 clients are engaged with early intervention FEP services in the target catchment area. We aim to recruit up to 15 clients from this pool.

For the whānau workshop, members of the lived experience advisory group will be asked to identify their supporters and pass on the study information to them. We aim to recruit 1 whānau member per participant in the lived experience advisory group.

The project team will recruit service provision advisory group members through their existing networks and local early intervention symposia. Study information will also be circulated to relevant experienced health professionals via EISP staff team meetings, newsletters, and email.

Participant Remuneration

Our group recognizes that a co-design process that truly values the opinions and narratives of service users and their whānau should compensate them in a way that recognizes them as experts in their own health care. As such, members of the lived experience advisory group will receive NZ $100 (US $62) in vouchers as compensation for their time. In addition, these participants will be offered a choice of a framed print or tote bag depicting an illustration produced during the first workshop. Whānau participants will receive NZ $50 (US $31) for attending the single 2-hour workshop.

Members of the service provision advisory group who are employees of mental health services will not be remunerated, as participation is interpreted as part of their employment. Any members of the service provision advisory group who are engaged as volunteers and not in a professional capacity will be offered remuneration in line with service users and their whānau.

Co-design Workshop Format

Overview

The workshop format was developed in collaboration with members of the lived experience advisory group, the research team, and partners over a series of meetings. Together, this group contained expertise in the lived experience of psychosis and EISP, community engagement, mātauranga Māori, and co-design. A key objective in designing these workshops was to ensure that as many participants as possible have the opportunity to engage meaningfully with the project.

Two key decisions in the design were whether the workshops should include all participants (ie, service users, whānau, and service providers) or whether they should be separated into 3 distinct workshops and where the workshops should be held (ie, in-person or web-based workshops and specific location if in person).

Combined or Separated Groups

The group decided that the lived experience advisory group, their whānau members, and the service provision advisory group would each attend separate workshops, thus enabling frank and open discussions regarding service users' health and related barriers and not being inhibited by the presence of another group. However, the lived experience advisory group will be given the option of being accompanied by a whānau member or caseworker for support at each workshop they attend. One-to-one interviews (either web-based or in-person interviews) will be offered to members of the lived experience advisory group who are uncomfortable speaking within group situations or unable to attend workshop times.

XSL•FO
RenderX

Platform and Location

With regard to choosing web-based versus in-person workshops, members of the lived experience advisory group indicated a preference for in-person workshops to maximize engagement and relationship building. Feedback regarding whānau members was that they were often employed full time and had time and travel constraints. Therefore, whānau members will be invited to a web-based evening workshop during the contextual inquiry and participatory design phases.

Many members of the service provision advisory group are health professionals with time constraints in terms of their clinical duties. For workshops involving this group, in-person attendance will be offered for the first relevant session (product design) to create initial engagement and investment in the project. The second round of sessions involving the advisory group (product revision) will be offered as a web-based workshop and survey.

The venue chosen for the co-design and similar workshops involving service users is important in terms of setting participant expectations and creating a sense of security and willingness to share experiences. The research team considered the balance between being in a familiar space that was well known to service users (ie, EISP clinical services) and the need for a space that was not directly associated with a clinical setting, thus increasing the likelihood that participants would feel free to share their experiences (ie, in a neutral venue). It was decided that rooms at the University of Otago campus will be used for the first workshop involving the lived experience advisory group. For whānau, this did not apply because the workshop will be held on the web. For the advisory group, the venue will be EISP clinical service centers.

Workshop Facilitation

The workshops will be cofacilitated by diverse members of the project team across all the co-design phases. All facilitators have significant experience in facilitating workshops in community settings, including with young people experiencing FEP, whānau members, and service providers. Notably, several facilitators have lived experience of FEP and mental distress. This will create an opportunity for positive role modeling and increased the relatability of the workshop content. The workshop design draws from contact-based antistigma and discrimination intervention models, which have been used to guide efforts to counter stigma toward mental distress in Aotearoa NZ [26,27].

Although lived experience–directed antistigma interventions typically target groups who hold the power to discriminate, the model here also functions to alleviate internalized stigma for participants who experienced FEP. The power of the contact model [27] draws on the principles of all group members having equal status and providing the opportunity for relationship building, active cooperation, and the pursuit of a mutual goal. Other members of the facilitation team have extensive knowledge and experience in incorporating the Māori worldview into co-design processes.

Ethics Approval

The project has been approved by the University of Otago Health Ethics Committee (ref H22/048) and has undergone a Māori consultation in line with guidelines pertaining to research based in Aotearoa NZ. Considering that workshops may be used to address potentially sensitive health-based topics and thus present a small risk of psychological distress, an experienced clinical psychologist (not directly associated with EISP) will also attend sessions involving the lived experience advisory group to meet the ethical guidelines regarding psychological safety. The project has also been registered with the Australian NZ Clinical Trials Registry ACTRN12622001323718.

Results

Details of the co-design workshops are summarized in Multimedia Appendix 1.

Phase 1a: Contextual Inquiry and Participatory Design With the Lived Experience Advisory Group

The illustrated framework ("Navigating the Puna"; Figure 2) was developed by research team members with lived experience of mental distress, the Māori co-design partners (Toi Tangata), and artists from the League of Live Illustrators. The illustration encompasses the main objectives of contextual inquiry and participatory design (eg, experiences of health, barriers to and facilitators of health and well-being, and how health and well-being can be supported). "Navigating the Puna" is based on mātauranga Māori in that the puna (fountain or spring) represents the person with a lived experience of FEP. The illustration will be used as a framework to guide the first workshop with the lived experience advisory group (workshop 1a).

Contextual inquiry with the lived experience advisory group will seek to understand (1) how young people conceptualize health while living with FEP, (2) what constitutes a healthy life and the barriers and facilitators to leading a healthy life, and (3) the contextual constraints they encounter.

A phenomenographic approach will be used to provide participants in the lived experience advisory group the opportunity to express their experiences in a way that is meaningful to them and not constrained to typical focus group–style data collection. Phenomenography is "a qualitative research approach used to describe variations in people's experiences through their own discourse, not to derive general principles of how things appear but to make known the way(s) experiences can be commonly understood" [28], with the goal of discovering different ways of understanding the experience of phenomena [29-31].

In line with this approach, participants will be offered several platforms to describe their experiences. Opportunities will include writing or audio recording their experiences in the form of stories, simple descriptions, or voice notes. A data wall will be set up to which participants can contribute post-it notes at any point during the workshop as ideas occur. Alternative creative outputs include drawings, paintings, poetry, and clay sculptures. There has been an increasing trend in using creative

XSL•FO
RenderX

and art-based approaches in health care, for example, photovoice, visual artistic methods such as drawing and painting, and literary arts such as poetry and storytelling [32-39]. All these are accepted approaches for collecting phenomenographic data [29].

When possible, photos of creative outputs will be taken, and participants will be asked to provide a brief description of the output in their own words to aid later interpretation and analysis. Members of the research team will also collect data through a process of interactive note-taking using a whiteboard that will be visible to the participants throughout the day. These notes will be collated and photographed at the end of the workshop.

Data will be analyzed using an approach aligned with both thematic analysis [40] and phenomenographic analysis [41]. These approaches share a common process that is characterized by several stages: (1) familiarization (data are reviewed taking note of initial ideas); (2) identification (data that are related to the phenomenon being described are identified); (3) sorting (identified data are organized into "pools of meaning" according to similarities); (4) contrasting and categorizing (themes are contrasted, and categories are generated with descriptions); and (5) reliability checking (a portion of the data coded by independent researchers will be checked for intercoder reliability).

The result will be a collection of themes regarding service users' experiences of health and well-being while living with FEP and facilitators of and barriers to leading healthy lives.

For the participatory design aspect of the workshops (for both 1a and 1b), ideas with regard to possible program components, features, or structures that participants create will be noted, collated, and taken through to phase 2 with the service provision advisory group.

Phase 1b: Contextual Inquiry With Whānau

A web-based focus group will be held with whānau to explore their experiences of supporting a young person living with FEP and their perspectives on what additional supports are required from health care services. This focus group will be audio recorded and analyzed using thematic analysis as described in the previous section. The findings from phase 1b will supplement the themes identified from the lived experience advisory group.

Phase 2: Product Design With Service Provision Advisory Group

An in-person focus group will be held, and the sessions will be audio recorded. Key areas that will be addressed include participants' experiences in supporting young people living with FEP in terms of maximizing health and well-being, perceived barriers to and facilitators of positive health behaviors, and any other aspects that they see as being relevant.

A summary of findings from the previous workshops with the lived experience advisory group and their identified whānau will be presented. Participants will be asked to respond to the proposed solutions to ascertain which features and components they see as feasible in the context of the existing EISP and which of these may be feasible in the future. Participants will be asked to identify other potential approaches to supporting health and well-being that align with the initial design solutions proposed by the lived experience advisory group.

The research team will collate these responses and integrate them with the initial co-designed system of support from the previous workshops, resulting in a "prototype" support system or program.

Phase 3: Prototype as Hypothesis With the Lived Experience Advisory Group

A web-based focus group with the lived experience advisory group will be held, and sessions will be audio recorded. The prototype will be presented to participants, who will be asked to provide feedback in terms of the acceptability and likelihood that they would use it. Participants will also be asked to identify any issues that they foresee with the prototype and any revisions to overcome such issues. Any omissions in terms of requested features, components, or formats will be explained.

The research team will collate these responses and integrate them to create a new revised version of the system of support or program.

Phase 4: Final Revision With the Service Provision Advisory Group

Feedback will be sought on the revised version of the system of support or program in the form of a web-based survey. The system or program is presented in full as a web-based static document, and the feedback sought will pertain to the feasibility of the various features in the form of 1 to 10 rating scales. For features that are deemed unfeasible, participants will be asked to provide a rationale for this. Participants will be able to leave open-text feedback on each feature or program as a whole.

Post–Co-design Reflection and Presentation of Findings

The project team will produce a final version of the system or program that will account for the data and feedback offered by all participants. This will be presented to all participants and invited guests during a seminar.

Evaluation of the Co-design Process

Members of the lived experience advisory group will be asked to provide feedback on the co-design process. Feedback will be sought at the final program presentation, with an option to provide web-based feedback. Specifically, feedback will be sought regarding (1) the extent to which participants felt like their autonomy was supported during the co-design process, (2) the extent to which participants came away with a sense of hope for their own lives and for their health care, (3) whether participants felt listened to throughout the process, and (4) to what extent participants feel confident that change might happen as a result of the co-design workshop.

This feedback will be collected using rating scales (eg, "On a scale of one to ten, how much confidence do you have that change might occur as a result of this co-design process?").

Regarding autonomy and feelings listened to, the Healthcare Climate Questionnaire (HCCQ) will be used. The HCCQ also contains questions pertaining to perceptions of being listened

XSL•FO
RenderX

to by facilitators (eg, "The workshop facilitators listened to how I would like to do things regarding my health").

Postproject Audit

The research team will work with project facilitators at the EISP and health care managers to identify a minimal deliverable version of the system or program and if necessary, identify potential sources of funding to deliver and evaluate a "full" version of the system or program (eg, research grants, internal health care funding, and Ministry of Health grants). This audit will take the form of a discussion group and feedback via e-mails.

Discussion

Overview

This project has four objectives: (1) to understand the lived experiences of young people in being healthy during FEP, (2) to develop a system of support for leading a healthy life, (3) to create a set of principles that guide early intervention health care for young people experiencing psychosis, and (4) to devise a strategy for the future delivery of a system of support for health and well-being within this community. To achieve these objectives, an EBCD approach will be undertaken, within which we will work alongside and listen to key stakeholders (service users with lived experiences, their whānau, and service providers) through a series of workshops. The results of this project will provide us with (1) a richer understanding of the lived experiences of young people living with FEP, (2) a co-designed system of support for health and well-being, (3) a set of guiding principles for developing such systems of support, and (4) a clear strategy for delivering and evaluating the co-designed system.

This co-design project responds to the lack of interventions aimed at supporting the health of young people experiencing FEP [8]. Close collaboration with experts in the lived experience of FEP and mātauranga Māori works to ensure the relevance of, and engagement with, the co-design process and the resulting support system by end users in Aotearoa NZ. This approach answers the calls for health care research and services to genuinely engage with indigenous (Māori) knowledge systems in a collaborative rather than prescriptive and tokenistic manner [42]. This collaborative approach also works alongside EISP service providers to support the longevity of the end product beyond the life of the project.

Limitations

This project is specific to the context of Aotearoa NZ. Although it provides a useful example of how to engage with young people with lived experiences of FEP, Indigenous stakeholders, and EISP providers, careful consideration is needed when working outside of this specific context. In addition, the authors acknowledge that young people experiencing FEP engage in a wide variety of services. This project is co-designed specifically with young people at the stage of FEP and with EISP providers. Therefore, reproducing this study with other services and with persons at a different stage of diagnosis may likely produce a different result. Given that physical health inequities are experienced by people with serious mental illnesses in broader terms [8], further research is needed to investigate how this approach may be applied to people with other diagnoses and service providers.

A further limitation is that although the power of the contact model is named as a key guiding framework for the co-design process, a true representation of this model would have resulted in combined group discussions (ie, service providers, service users, and whānau). However, our priority was to create a safe space for service users to discuss, and owing to the explicit request of the service users within our consultation round, we decided to keep these stakeholder groups separate, resulting in a power of contact model adapted to suit our primary participants.

This protocol provides an example of how health professionals and researchers can engage in the co-design process toward a more collaborative way of working and participant-centered support. It is our hope that the results of this project will address the inequities that young people experiencing FEP face and improve their health and well-being. Furthermore, we hope that the guiding principles produced by this project can be applied to develop similar support systems in communities outside the area in which this research takes place.

Acknowledgments

Toi Tangata provided significant support by working with members of the lived experience team to design and facilitate co-design workshops, in addition to deepening the authors' understanding of Māori knowledge, worldview, and language throughout the project development. The League of Live Illustrators cocreated the materials used to frame the co-design workshops alongside the lived experience team and Toi Tangata. Early intervention in psychosis services provided significant support in recruiting all project participants. The authors acknowledge and thank the members of the lived experience team who were fundamental in developing the co-design process. The project is funded by a Lottery Health New Zealand project grant. The salary of the lead author is funded by the University of Otago Division of Health Sciences Postdoctoral Fellowship awarded for the purpose of this research.

Data Availability

The data collected in this study will be deidentified and made openly available in Figshare [43].

Abstract

Background: COVID-19 has highlighted already existing human resource gaps in health care systems. New Brunswick health care services are significantly weakened by a shortage of nurses and physicians, affecting regions where Official Language Minority Communities (OLMCs) reside. Since 2008, Vitalité Health Network (the "Network"), whose work language is French (with services delivered in both official languages, English and French), has provided health care to OLMCs in New Brunswick. The Network currently needs to fill hundreds of vacant physician and nurse positions. It is imperative to strengthen the network's retention strategies to ensure its viability and maintain adequate health care services for OLMCs. The study is a collaborative effort between the Network (our partner) and the research team to identify and implement organizational and structural strategies to upscale retention.

Objective: The aim of this study is to support one of New Brunswick health networks in identifying and implementing strategies to promote physician and registered nurse retention. More precisely, it wishes to make 4 important contributions to identify (and enhance our understanding of) the factors related to the retention of physicians and nurses within the Network; determine, based on the "Magnet Hospital" model and the "Making it Work" framework, on which aspects of the Network's environment (internal or external) it should focus for its retention strategy; define clear and actionable practices to help the Network replenish its strength and vitality; and improve the quality of health care services to OLMCs.

Methods: The sequential methodology combines quantitative and qualitative approaches based on a mixed methods design. For the quantitative part, data collected through the years by the Network will be used to take stock of vacant positions and examine turnover rates. These data will also help determine which areas have the most critical challenges and which ones have more successful approaches regarding retention. Recruitment will be made in those areas for the qualitative part of the study to conduct interviews and focus groups with different respondents, either currently employed or who have left it in the last 5 years.

Results: This study was funded in February 2022. Active enrollment and data collection started in the spring of 2022. A total of 56 semistructured interviews were conducted with physicians and nurses. As of manuscript submission, qualitative data analysis

XSL•FO
RenderX

is in progress and quantitative data collection is intended to end by February 2023. Summer and fall 2023 is the anticipated period to disseminate the results.

Conclusions: Applying the "Magnet Hospital" model and the "Making it Work" framework outside urban settings will offer a novel outlook to the knowledge of professional resource shortages within OLMCs. Furthermore, this study will generate recommendations that could contribute to a more robust retention plan for physicians and registered nurses.

Introduction

Background

In Canada and elsewhere, COVID-19 has highlighted the human resource gaps already present in health care systems. In New Brunswick, health care services are weakened by a shortage of registered nurses and physicians, mainly affecting rural areas, where Francophone and Acadian communities are concentrated and considered as Official Language Minority Communities (OLMCs) [1]. These OLMCs have greater social and health disparities (eg, smoking and obesity) [2] and are older than their Anglophone counterparts, which are the majority population in New Brunswick [3,4]. In other words, being part of a linguistic minority group is a potential barrier to health care and services access and makes people vulnerable to health inequities [3-5].

Since 2008, a total of 2 health networks have been providing health services and care to the population of New Brunswick: Vitalité Health Network (the "Network") and Horizon Health Network. They are required by the Regional Health Authorities Act to provide services to users in the official language of their choice (English or French). It is worth mentioning that the same law stipulates that the language of operation of Horizon Health Network is English, whereas it is French for the Vitalité Health Network. The Network, our partner, covers 4 geographic regions, 3 of which are in rural areas where many Acadian and Francophone communities reside. The fourth zone includes a more urban area, where both health networks provide health services. The New Brunswick population currently totals 775,610 citizens, 30% of whom report French as their first language [6]. The Network manages and delivers health care and services to Francophone citizens in the province, representing approximately 241,100 people living in the 4 geographic territories [6]. It has approximately 7700 part-time and full-time employees, including 560 physicians [7].

The latest data show that there are 100 vacant physician positions [8] and 200 vacant registered nurse positions [9]. For the past year, a shortage of staff has caused the closure of the obstetric services in the Restigouche region [10]. Also, the departure of oncologists has recently affected the Dr Georges-L.-Dumont University Hospital Centre in Moncton. Several media papers have addressed these issues [11]. Provincial projections predict a critical shortage of more than 1300 registered nurses in the next 5 to 7 years, and approximately 35% of family physicians will retire [12]. Given these staff shortages, combined with the global COVID-19 pandemic, it is imperative to strengthen the Network's retention strategies to ensure its viability and reduce the health disparities in OLMCs.

Theoretical Frameworks

The conceptual framework is based on the "Making it Work" framework [13,14] and the "Magnet Hospital" model [15], in addition to the delivery of health care services in OLMCs. The inclusion of the linguistic minority variable will lead us back to our objectives or research questions and will provide theory-based results, increase credibility, and foster transferability to practice settings [16].

The "Making it Work" Framework

The "Making it Work" framework, which focuses on rural and remote recruitment and retention, is based on 9 key strategic elements that primarily address determinants of the environment that are grouped under 3 main activities (ie, planning, recruiting, and retaining) and are briefly described [13,17] (see Figure 1). The Network's Board of Directors decided in 2020 to take a closer look at this framework, which has been the focus of a framework in Northern Ontario [14,18]. The framework was launched in 2011 by an international collaborative, addressing the challenges of recruiting and retaining health professionals in rural and remote northern settings and has been the focus of the Northern Ontario School of Medicine, which has sites throughout the north of Ontario, 1 being in the OLMC of Sudbury [19].

XSL•FO
RenderX

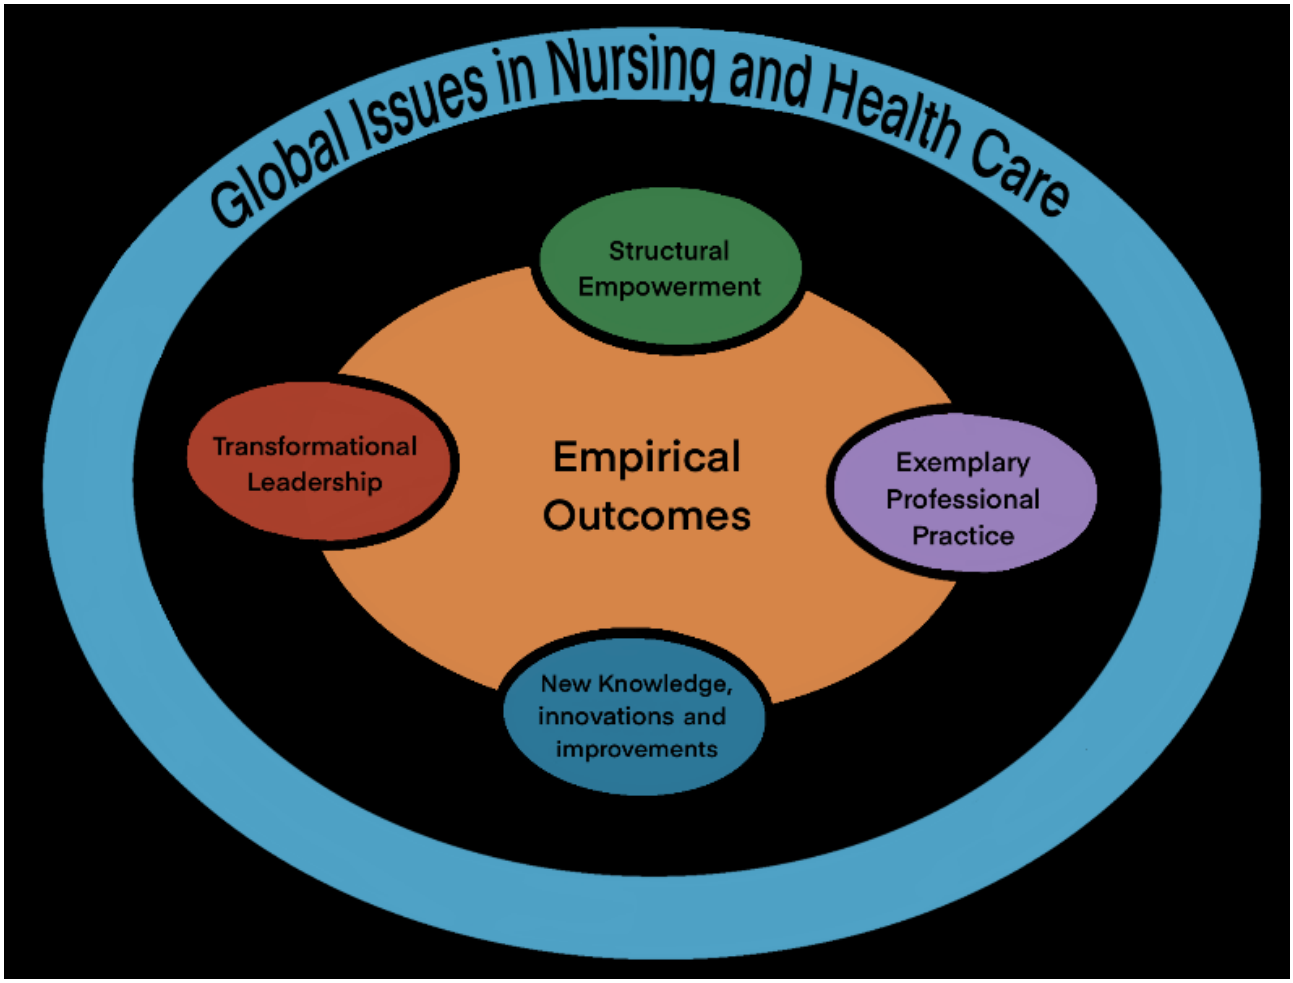
Figure 1. Making it Work framework (adapted from École de médecine du Nord de l'Ontario [20], which is published under Creative Commons Attribution 4.0 [CC BY 21]).

Planning thus involves assessing the population's health needs and aligning service delivery models with them [17]. This task also includes developing job profiles for the professionals the organization wishes to recruit, including skills specific to working in rural and remote settings [17]. *Recruitment* focuses on sharing information about the work environment, practice, population served, and available housing in the area [17]. Recruiting also involves consideration of community engagement and support for the professional's family, such as employment opportunities for the spouse. Finally, elements included in the *retention* component of the model are related to team cohesion, professional development, and training [17].

In total, 5 conditions are contingent on the success of the framework [17,22]: acknowledgment of the unique challenges of rural and remote areas (eg, the unique aspects of living and working in these areas compared to urban settings), engagement of communities and consideration of their perspectives (in workforce planning or policy-making), adequate investments (targeting professional development and training internships, in particular), an annual cycle of activities (as opposed to actions driven by urgency) that promote recruitment and retention (like attention-drawing job descriptions or performance standards), and finally, continuous monitoring and evaluation (to modify interventions based on experiences and improve quality to meet the needs of the population). Conjointly, these conditions promote the establishment of a stable and appropriately qualified professional workforce in rural and remote communities, in this case, the OLMCs.

The Magnet Hospital Model

The Magnet Hospital model emerged in the early 1980s when the American Academy of Nursing appointed a task force to



XSL•FO
RenderX

study the facilitating factors and barriers to professional nursing practice in hospitals [15]. McClure et al [23] revisited the work done by these forerunners, focusing on organizational culture and quality of care:

> *We found that all these settings had a commonality: their corporate cultures were totally supportive of nursing and of quality patient care. What we learned was that this culture permeated the entire institution. It was palpable, and it seemed to be almost a part of the bricks and mortar. Simply stated, these were good places for all employees to work (not just nurses), and these were good places for patients to receive care. The goal of quality was not only stated in the mission of these institutions, but it was lived on a daily basis.* [p. 199]

Thus, the Magnet Hospital model, or the "magnet" hospital, means "literally, the ability to retain and attract staff, and figuratively, the ability to foster well-being to their patients" [24]. The evolution of this model over the past few decades led to the model presented in Figure 2.

Figure 2. An evaluation of the nursing practice environment and successful change management using the new generation Magnet Hospital model [25].

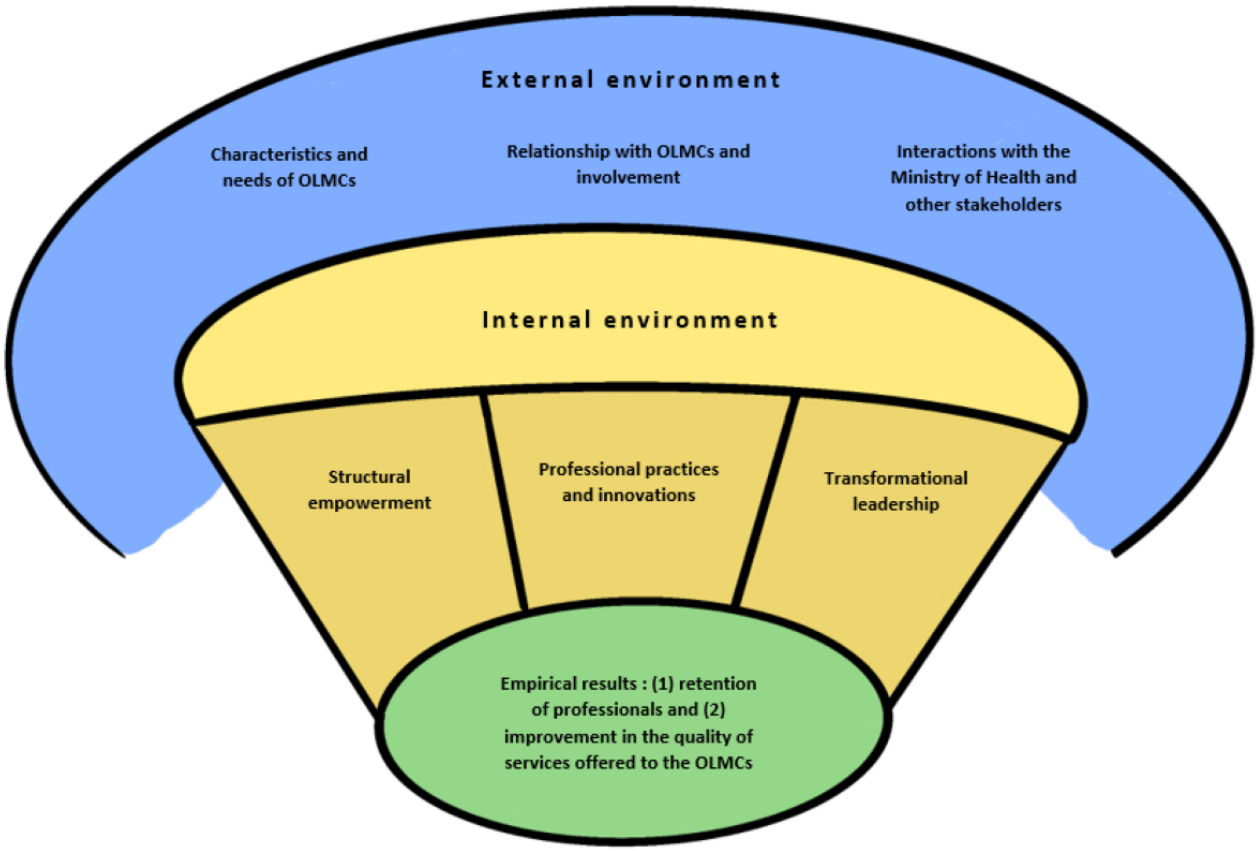
The model [25] in Figure 2 builds on areas that are primarily part of the work environment: (1) transformational leadership (ie, "magnet" managers at all organizational levels), (2) exemplary professional practices (eg, the ethic of caring), (3) structural empowerment (eg, decentralized decision-making), (4) new knowledge, innovation, and improvements (eg, research- and evidence-based decision-making), and (5) empirical outcomes (eg, quality of care and organizational goals) [25,26]. These components cannot be separated from the overall context, relating to, for example, the global pandemic, and all have implications for employee retention, optimal service delivery, and quality of clinical care [27,28].

Shortage of Health Care Professionals and Access to Health Care in OLMCs

The shortage of registered nurses and physicians is particularly acute in rural areas, where are concentrated OLMCs [1,3]. These regions have difficulty attracting and retaining professionals who generally do their training and start working in urban settings [29]. Also, a preference for acute care clinical settings in urban areas and the mobility of professionals make recruitment and retention challenges difficult to overcome by rural and remote OLMCs [30].

A study [30] has shown that one of the factors affecting the retention of professionals in OLMCs is the quality of the work environment. For example, the quality of social ties, the sense of belonging, the diversity of the environment, both ethnic and

XSL•FO
RenderX



linguistic, and the working conditions influenced their desire to remain in their position [30].

For OLMCs, a shortage of registered nurses and physicians can lead to inadequate access to health services and negatively impact initiatives to meet their health needs, such as those in prevention and promotion [31,32]. The provision of quality and safe health care services to OLMCs is, in other words, linked to the availability of competent professional resources [33]. Furthermore, studies have shown that the challenges to offering services to the linguistic minority group are due to the lack of professionals who are able to provide these services within OLMCs [34,35]. The smaller pool of bilingual professionals can thus have consequences on the health of these communities [36-38].

Conceptual Framework and Research Questions

The conceptual framework presented in Figure 3 shows that varied factors in the internal and external environment influence the retention of registered nurses and physicians. The "Magnet Hospital" model provides key work environment components for understanding the retention capacities of these health professionals that are also essential to quality patient care, whereas the "Making it Work" concept helps us analyze the retention factors through the lens of strategic elements crucial to accessing high-quality health services in rural and remote environments.

Figure 3. Factors influencing the retention of Registered Nurses and Physicians Working in OLMCs. OLMCs: Official Language Minority Communities.

The internal environment of the health organization (in yellow in Figure 3) has three components: (1) structural empowerment, (2) professional practices and innovations, and (3) transformational leadership. *Structural empowerment* refers to a structure that is decentralized and debureaucratized [39]. This component includes recognition measures such as awards or scholarships for innovative projects [40] and employee satisfaction with salary, workload, and work-life balance. It also considers other vital elements such as competitive pay, adequate staffing, a sense of control over decision-making and practice, and perceived stress levels [15,24].

Professional practices and innovations are associated with a philosophy of excellence in care that emphasizes evidence-based skills and best practices, a focus on quality improvement through innovative approaches, and the value placed on professional development [15,39]. This component indicates the importance of ensuring that resources are available to new employees like mentorship, access to advice, and other resources to help with their integration. A collaborative relationship between registered nurses and physicians and autonomy based on professional standards are all part of this component [15,27]. Ethical values in caring and transparency are linked to better care for people needing health care and services while helping with their self-fulfillment [24].

Transformational leadership refers to close supervision that is characterized by a manager who is visionary, respectful, attentive to their collaborators, stimulating, and mobilizing [24,41]. To counteract burnout, the caring approach to management prioritizes social ties and team cohesion as well as dialogue and trust [41]. In addition, the practice of supportive

XSL•FO
RenderX

management must take place in a stimulating work environment to be effective.

The external environment of the health organization (in blue in Figure 3) is made up of three main dimensions: (1) the characteristics and needs of OLMCs; (2) the relationship established between the health organization and the OLMCs, and their involvement in attracting and retaining professionals; and lastly (3) interactions with the Department of Health and other relevant actors (such as training institutions).

The *characteristics and needs of OLMCs* focus on the particularities of the populations served by the health organization. In New Brunswick, the territory served by the Network is composed primarily of Francophone and Acadian populations, many of which are in rural areas. These citizens are generally more disadvantaged in terms of socioeconomic status and are older than elsewhere in the province or the country [42]. The health needs of the OLMCs served by the Network differ from one health zone to another and even from one city to another and must be reevaluated on an ongoing basis. A service model that does not meet the needs of rural and remote communities can lead to burnout and job dissatisfaction for its employees [14].

The *involvement of OLMCs* in efforts to counter the departure of health professionals is reported in the literature on the "Making it Work" concept [13,14]. While the involvement of rural and remote communities is crucial when recruiting health care professionals [14], policies that encourage their active and ongoing participation are also essential to ensure the retention and stability of medical personnel [43].

The interactions with the *Department of Health and other relevant actors* go hand in hand with the involvement of OLMCs, as it is linked to the relational dynamics in the planning stage between the health organization and other key players, particularly the Department of Health, training institutions, and nongovernmental organizations. Decisions made by actors of the external environment, sometimes outside the control of the Network, can affect the intention to stay of professionals. Furthermore, without adequate investments, such as in professional development, efforts remain focused on solving urgent problems (vacancies) at the expense of an ongoing strategy to ensure the stability of the skilled workforce [17].

Finally, the empirical results (in green in Figure 3) are influenced by “what’s going on” in the environment (internal and external) of the health care organization. Factors emanating from these 2 spheres affect the commitment and retention of registered nurses and physicians responsible for improving the quality of services offered to OLMCs.

Main and Specific Objectives

The overall objective of this study is to support one of New Brunswick health networks in identifying and implementing concrete strategies that take into consideration its environment to promote physician and registered nurse retention.

Two specific objectives are derived from the general research objective: (1) to identify current staffing trends and examine the turnover rate in each geographical zone of the Network to determine where the most significant challenges are with recruitment and retention; (2) to identify and understand the factors that affect the retention of physicians and registered nurses (a) at the operational level, to determine the factors that make the Network’s environment (internal and external) attractive, such as the working and living conditions of professionals, and (b) at the strategic level, to make concrete and valuable recommendations to our main partner, the Network.

Methods

Methods Overview

This study will use a sequential mixed methods design that combines quantitative and qualitative approaches [44]. This design offers a more comprehensive technique to better understand phenomena and nuance data interpretation [45].

Initially, secondary data will be compiled within existing sources to identify current organizational trends and inform our qualitative data collection strategy. In other words, the quantitative analysis of secondary data will guide the qualitative approaches’ recruitment process. Specifically, we will assess job vacancy and turnover rates for nurses and physicians to target the more problematic geographical zones and departments concerning retention. Turnover rates are commonly evaluated as an indicator of retention of hospital staff, and it is especially used for nurses [46-48]. When turnover rates are chronically high, it may indicate that staff working in that hospital unit are not satisfied at work [46] or that the work environment is not favorable to psychological well-being [48]. Research on turnover rates indicates average annual turnover rates for nurses are between 14% and 27% in Canada [49]. This finding is supported by data worldwide that found the average turnover rate for nurses to be between 15% and 36% [50,51]. For this study, we will use job turnover rates as a guide to target the areas that are more or less successful with retention.

As a secondary indicator for retention, vacant positions will also be analyzed for nurses and physicians within the Network. Using a similar strategy, the job vacancy rate will be assessed as an indicator for retention [52]. The 2 indicators, the turnover and job vacancy rates, will be analyzed together to target areas within the Network that are doing well with retention and areas with retention challenges.

We will then target these areas to recruit participants for individual and group discussions as described in section “Qualitative Approach: Data Collection and Analysis.” For physicians, position turnover rates are less reported, and researchers generally use the intention to leave as a proxy for turnover rates [53]. Of the little data available, the average turnover rate for physicians is between 4% and 25% [54].

Quantitative Approach: Data Collection and Analysis

Component 1 (quantitative secondary data analysis): to achieve specific objective 1, secondary data from the Network will be used to illustrate the proportions and the tendencies in physician and registered nurse vacancies by zone in the Network. It will also measure the extent of the current shortage and determine if there are significant differences between regions and sectors (eg, psychiatry and obstetrics) to identify those that are more

XSL•FO
RenderX

successful than those that are less successful. The data from the past 5 years related to age and gender, the number of years of service in the Network at the moment of departure, family status, type of professional (specialist vs generalist), hospital unit or service area, and geographic area will be analyzed. Information on turnover rates for physicians and registered nurses for the past 5 years will be compiled and analyzed from the Regional Plan of Physician Workforce descriptive data collected by the Network's Medical Services. To supplement this information, data from the Network's Human Resources Department regarding medical and nursing staff who have left their positions will be used. From these data, a profile of professionals who have left the Network can be created to tailor retention strategies and improve their effectiveness.

Since we plan to use secondary data on job vacancies and turnover rates, we will be limited to the data already collected and may face an information gap. Some team members have used quantitative approaches in their research for several years. Faced with sometimes incomplete databases, the team may have to develop data collection tools to collect more quantitative data to supplement the secondary data provided by the Network. At this time, the approach considered is a web-based survey to target employees (nurses and doctors) working at the Network and people (nurses and doctors) who have left. If a survey is used, validated questions will be used to measure factors that impact job satisfaction and intention to leave the current workplace [55-57]. The survey design will be multiple choice questions with a 7-point Likert scale to maintain validation from previous studies.

The statistical analysis for specific objective 1 will be discussed first. Next, we will conduct bivariate and multivariate correlational analyses to assess the influence of the factors comprised in our conceptual framework over health professionals' intention to stay. Considering that participants' sociodemographic characteristics (ie, sectors, gender, age, education, and years of service) may influence the relationships between the variables under study (ie, factors comprise in our conceptual framework), analyses will be conducted to determine the magnitude of their effect [58].

Qualitative Approach: Data Collection and Analysis

Component 2 (qualitative data): to achieve specific objective 2, qualitative data will be collected through semistructured interviews, focus groups, and a document review, including gray literature such as media reports.

Semistructured Interviews

The interview guides were developed to take into consideration the factors listed in the conceptual framework (Figure 3). Participants will be asked to share their views on topics such as job satisfaction, autonomy in decision-making, leadership, and language used at work. The first set of semistructured interviews (approximately 30) will be conducted with physicians and registered nurses who have left the Network in the past 5 years. The second set of semistructured interviews (approximately 30) will be conducted with these same 2 types of professionals the Network currently employs. In sum, the data will be used to understand whether the reasons for retention and departure are more related to the external environment or whether they result from the internal environment. The specific number of semistructured interviews and focus groups is subject to change, depending on data saturation, that is, when the ability to obtain additional new information has been attained, and further coding is no longer needed [59]. If necessary, we will adjust our recruitment efforts to ensure gender participation that represents diversity in the work environment, considering that the proportion of women is higher than men in the health sector. The interviews will be completed on the web or in person to respect certain COVID-19 prevention strategies and enhance a better understanding of the current retention realities across the province (ie, rural and urban regions). There are 2 exclusion criteria for our study: physicians and registered nurses who have left the Network for more than 5 years and those who have retired.

Focus Groups

The focus groups, which will also allow the achievement of specific objective 2, will be held with 5 to 10 participants in 4 different groups and with 2 distinct types of participants: leadership team and Board of Directors and Network managers. Participants will be asked about retention challenges in the workforce, strategies for retaining physicians and registered nurses, relationships with the Health Department and other stakeholders, and the involvement of OLMCs in retention efforts. The focus groups will be conducted at 3 different times (beginning, mid-term, and end of the study). The first focus group will be conducted at the very start of the project with key informants (leadership team, the executive team, and members of the governance team) to enhance the understanding pertaining to the factors responsible for past and current staff shortages. The last focus group, held at the end of our study with the same key informants, will be to mitigate and discuss retention strategies to enhance workplace satisfaction among nurses and physicians. In contrast, the 2 midpoint focus groups will target the Network's management staff, more specifically: the first group in a service area where retention rates have been identified as low and the second group in a service area where retention rates have been identified as high. The information gathered in these latter 2 focus groups will be used to better understand the factors that influence physician and nurse retention in particular areas.

Document Review

A document review is another strategy that complements our data collection. Thus, documentary sources will allow us to corroborate the information obtained through our interviews and focus groups. We believe the document review will also be used to mark key retention milestones for the Network (province announcements, new internal regulations, procedures, etc). Different types of governance or administrative documents will be analyzed: Network and Department of Health annual reports, action plans, regulations, bills, etc. Since the Network does not have total control over the external and internal factors of its environment and since these can influence the retention of professionals, we consider it worthwhile to conduct a media review to understand their impact. The period for the document

XSL•FO
RenderX

and media analysis is from March 2008, when the Network was created, to December 2022, when our data collection ended.

In terms of qualitative analysis, the data analysis approach used in the study is descriptive, where an initial analysis emerges from the respondents' words, using a thematic approach to analysis [44,60]. Coding will be done iteratively in collaboration with other members of the research team using a predeveloped codebook. The team will code the same transcripts and then compare initial findings to help ensure intercoder reliability. Braun and Clark [60] approach to thematic analysis will be used to explore the current state of retention. The approach will also rely on a direct thematic analysis based on the "Magnet Hospital" model and "Making it Work" framework.

Ethics Approval

The project was approved by both ethical research boards: the Vitalité Health Network (101574) and the Université de Moncton (2122-105). A detailed consent form will be explained orally and in writing to all participants. Informed consent will be obtained for all participants before taking part in the individual interview and focus groups. The importance of privacy and confidentiality protection for the research team will also be expressed to all participants, as one of our research partners is their current or past employer. Thus, each participant will be given a numerical code to preserve their anonymity. The code will be kept in a locked cabinet that only the 2 primary researchers can access. As for result reporting, such as in publication or recommendation reports, it will be done so the participants cannot be identified.

Recruitment

Participants in the current workforce will be identified using a "snowball" technique [61]. Initial meetings with physicians and registered nurses associated with the Network should allow us to identify additional participants from these 2 disciplines who can inform us about the shortage of professional resources within the organization. A research team member will contact potential participants by phone or email to explain the research project and solicit their participation.

For respondents who have left the Network, we will seek the Network's Human Resources support to identify potential candidates. Human Resources Department will then send an email to them, including the invitation to participate and specifying that the research is independent of the employer and that the latter will not have access to the data. The study details and the information on how to join the research team will be included in this invitation message. This procedure will ensure that no confidential employee information will be transferred to the research team. A CAD $20 (US $14.68) gift card will be offered to interview and focus group participants.

Results

This study was funded in February 2022 by the Canadian Institutes of Health Research. Active enrollment and data collection started in the spring of 2022. A total of 56 semistructured interviews were conducted with physicians and nurses who are currently working for the network or have left in the past 5 years. The data collection for both quantitative and qualitative is intended to end by February 2023. Summer and fall 2023 is the anticipated period to disseminate the results locally, nationally, and internationally.

Discussion

According to the World Health Organization, there is a global shortage of more than 7 million health professionals [62]. The uneven distribution of professional resources contributes to significant health disparities between rural and urban communities [62,63], and may be associated with economic stagnation and social decline in communities located in rural areas [64,65]. The province of New Brunswick is no exception to this situation, and the Network needs to effectively address its health workforce staff shortages as it may affect its viability.

Through the application of the "Making it work" and "Magnet Hospital" frameworks outside of urban settings, this study will contribute globally to the current reflection on the professional resources shortages within OLMCs [1]. The results of this study will help our partner (the Network) in identifying and implementing concrete strategies to promote physician and registered nurse retention by considering the particularities of its environment. It will allow the Network to replenish its strength and vitality by questioning issues such as autonomy [66], job satisfaction [40,67], and attachment to the community [42,68].

The results of this study will be published in a peer-reviewed open-access journal to increase public dissemination of the findings. The different knowledge dissemination activities will raise awareness among coresearchers and decision makers on the importance of addressing professional shortages in rural areas, especially within OLMCs.

The main limitation of this research is the availability of physicians and registered nurses due to pandemic fatigue and shortages in staffing. A second limitation to be considered in this study, pertaining to organizational systems and retention among physicians and nurses, is social desirability. Although confidentiality and anonymity will be respected and always enforced during the study, there is the potential and willingness to answer questions in a manner that will be viewed favorably by others (social desirability bias) [69]. A third limitation is related to the secondary data on job vacancies and turnover rates and the fact that we are constrained by the information that is already collected by the Network.

Abstract

Background: Cerebral palsy is the most common brain injury in the pediatric population. Patients with cerebral palsy present different affectations such as decreased muscle strength, gait deviations, impaired proprioception, and spasticity. Isokinetic strengthening programs combined with intensive rehabilitation may improve muscle strength and therefore gait efficiency.

Objective: The primary aim of this randomized controlled trial is to compare the effect of an intensive rehabilitation combined with a nonfunctional isokinetic progressive strengthening program to an intensive rehabilitation alone on gait parameters and muscle strength in patients with cerebral palsy. Another goal of this study is to determine whether adding an isokinetic program to intensive rehabilitation is more effective than intensive rehabilitation alone at decreasing spasticity and improving joint position sense in patients with cerebral palsy.

Methods: A total of 30 adolescents with spastic diplegia cerebral palsy (Gross Motor Function Classification System levels I to III) will be randomized, by an independent researcher, into a 3-week intensive rehabilitation and isokinetic progressive strengthening group or an intensive rehabilitation control group. Gait parameters, muscle strength, spasticity, and knee joint position sense will be assessed. These variables will be evaluated at baseline (T0) and at the end of the intervention (T1). The intensive rehabilitation will consist of physiotherapy sessions twice a day and hydrotherapy and virtual reality gait training once a day. The isokinetic training group will have a total of 9 supervised isokinetic strength training sessions focusing on knee flexors and extensors with different execution speeds.

Results: The protocol has been accepted by the French National Ethics Committee in October 2022. The inclusion of patients will start in November 2022.

Conclusions: The combination of intensive rehabilitation with an isokinetic program on knee flexors and extensors has not been studied yet. The findings of this study may determine if an isokinetic strength training program of knee flexors and extensors is beneficial for the improvement of gait parameters, muscle strength, spasticity, and joint position sense in adolescents with spastic diplegia.

Introduction

Background

Cerebral palsy is considered the most common brain injury in the pediatric population [1]. Motor impairments are commonly observed in adolescents with cerebral palsy [2]. Sensory impairments, cognitive disorders, epilepsy, and nutritional deficiencies are also often found in patients with cerebral palsy [2]. Cerebral palsy prevalence ranges from 1.5 to 2.5 cases per 1000 births and does not differ within different western countries [3]. Spasticity is regularly described as the most common motor impairment in the cerebral palsy population and is characterized by an increased stretch reflex. Spasticity is movement dependent, increasing with a higher velocity [4]. Spasticity is often measured through an isokinetic dynamometer to passively stretch the targeted muscles [4-6].

Muscle strength is commonly decreased in adolescents with cerebral palsy. Quadriceps and hamstring muscles are important to perform daily activities such as standing, walking, and climbing stairs [7]. Knee extensor strength is described as a good indicator of total lower limb muscle strength. Isokinetic dynamometry is the gold standard to measure muscle strength [6]. Isokinetic dynamometry has been described as a reliable tool to measure quadriceps and hamstring muscle strength in children with cerebral palsy [6]. Isokinetic dynamometry can also be used within a reeducation program to increase muscle strength in children with cerebral palsy [6]. An isokinetic strength training program focusing on knee flexors and extensors has shown some promising results in improving muscle strength in children with cerebral palsy [8]. MacPhail and Kramer [8] did not find any improvement in gait parameters in patients with cerebral palsy after an isokinetic program focusing on knee flexors and extensors. However, they did not implement such a program within an intensive rehabilitation program. A recent systematic review has shown that an isokinetic strength training program focusing on knee flexors and extensors improves muscle strength, mobility, and gait in patients with stroke [9]. Functional power training has been shown to be effective training to improve muscle strength, walking capacities, and resting somatosensory cortical activity in children with cerebral palsy [10-12]. Power training exercises such as walking, sit-to-stand, and side-walking should form part of an intensive rehabilitation program. Medium-speed concentric and eccentric isokinetic training is considered strength training, whereas low-speed isokinetic training produces hypertrophy [13]. Finally, high-speed isokinetic training is described as power training [13].

Gait deviations are frequently observed in adolescents with cerebral palsy due to motor impairment. Gait speed, stride length, step width, and stance time are important factors for an effective gait [14,15]. Lower limb muscle fatigue is commonly observed in patients with cerebral palsy and drastically affects their gait abilities and distances [16,17]. Usually, patients with cerebral palsy receive physiotherapy treatment for long periods; however, decreased muscle strength of the lower limbs has been shown to be associated with impaired gait function in children with cerebral palsy. Therefore, treatment for patients with cerebral palsy should focus on strengthening lower limb muscles to improve gait parameters [15,18].

Proprioception has been defined as the ability of an individual to integrate sensory signals from mechanoreceptors, allowing him to determine the position of a joint in space and its movement [19]. Knee proprioception is provided by afferent signals that are located inside or around the joint [19,20]. Its functions are to protect the knee joint against excessive injurious movement, stabilize the knee during static postures, and coordinate complex movements [19-21]. Wingert et al [22] have shown that children with cerebral palsy who present with gait disturbances have poorer proprioception than typically developing children. Over the last decade, 2 different proprioception assessment techniques have been described in the literature [21]: joint position sense and joint motion sense. Strength training has been described as an effective intervention to improve proprioception in children with cerebral palsy [23].

Intensive rehabilitation has been shown to be an effective program to improve functional motor outcomes in children with cerebral palsy [7,24-26]. A recent practice guideline to improve physical function in children with cerebral palsy has shown that a high enough dose of practice is required in order to improve motor abilities [26]. Jackman et al [26] have shown that intensive blocks of therapy were better than low-dose regular therapy in order to improve motor abilities in patients with cerebral palsy. Elgawish and Zakaria [27] have shown that intensive physiotherapy is more effective than standard physiotherapy in improving gross motor function in children with spastic diplegia. Bleyenheuft et al [24,25] have shown that an intensive training protocol including upper and lower extremities was effective in improving lower extremity function in children with unilateral and bilateral spastic cerebral palsy. In a meta-analysis, Moreau et al [28] have shown that gait training is an important component of rehabilitation to improve gait parameters, such as gait speed, in children with cerebral palsy. In their clinical guideline, Jackman et al [26] have shown that 30 to 40 hours of practice are required to improve motor abilities. Combining intensive rehabilitation with an isokinetic strengthening program has not been studied yet.

Objectives

The primary aim of this randomized controlled trial is to compare the effect of intensive rehabilitation combined with an isokinetic progressive strengthening program to intensive rehabilitation alone on gait parameters and muscle strength in patients with cerebral palsy. Another goal of this study is to determine whether adding an isokinetic program is more effective than just intensive rehabilitation in decreasing spasticity and improving joint position sense in patients with cerebral palsy.

Methods

Study Design

This study will be a prospective randomized controlled trial. Adolescents with spastic diplegia cerebral palsy will be randomized by an independent researcher through a computer-based method into an isokinetic training group (IG)

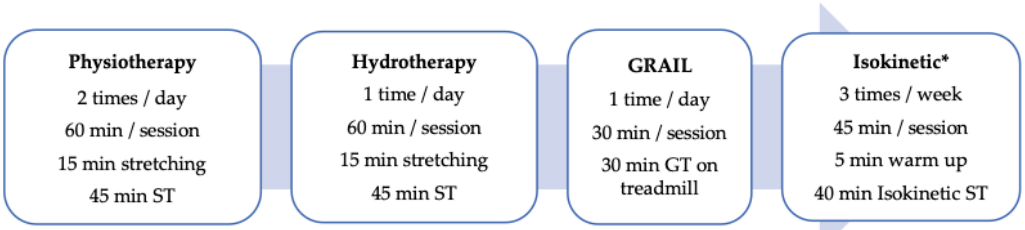
XSL•FO
RenderX

or a control group (CG). The block randomization method will be used to keep the number of subjects in each group equal. The IG will receive a 3-week isokinetic strengthening program together with intensive rehabilitation, and the CG will only follow the intensive rehabilitation. Patients will not be informed if they are part of the intervention or the CG. Outcome measures will be done at baseline (T0) and at the end of the intervention (T1). The protocol has been accepted by the French National Ethics Committee (IDRCB: 2022-A00431-42).

Sample Size

Sample size calculation was realized using G*POWER statistical programming (version 3.1.9.2; Franz Faul): power ($1-\alpha$ error P)=.85, α=.05, effect size=1.1, with a 2-tailed for a comparison of 2 independent groups. This calculation was based on the results of a pilot study based on ratio improvement following 2 specific interventions in patients with cerebral palsy. It will take 15 participants in each group to complete this study.

Participants



A total of 30 pediatric patients will be recruited from the Institut St Pierre, France. The inclusion criteria for this study will be adolescents aged from 11 up to 18 years with a diagnosed spastic diplegia cerebral palsy, patients with walking abilities (Gross Motor Function Classification System levels I to III), the ability to activate knee flexors and extensors voluntarily, and cognitive abilities to understand the instructions. The exclusion criteria for this study will be cardiovascular disorders; fractures of any type; history of hip subluxation, dislocation, or important scoliosis (>40° of curvature); surgery of the lower limb within the last year; botulinum toxin injection within the last 3 months; significant contracture of the knee flexors and extensors (less than 90° of knee active range of motion [ROM]); and insufficient understanding of the French language. All the participants and their legal tutor will be informed of the study procedures in agreement with the ethical standards of the Helsinki Declaration and will sign an informed consent.

Intensive Rehabilitation

The intensive rehabilitation will be conducted over a 3-week period. All participants will follow the intensive rehabilitation. Physiotherapy will be performed twice a day. Hydrotherapy and virtual reality gait training will be performed on a daily basis. During the 3 weeks of rehabilitation, the IG and CG will practice for a total of 59 and 52 hours, respectively. The hourly repartition can be found in Figure 1.

Physiotherapy sessions are expected to last for 60 minutes and will include lower limb stretching exercises and strengthening of the lower extremities (Table 1). All exercises realized during a typical physiotherapy session are described in Table 2. Hydrotherapy sessions will last for 60 minutes and will include stretching exercises, aerobic exercises, and strengthening of the lower extremities (Table 3). Hydrotherapy exercises are realized with water up to the patient's belly. All exercises realized during a typical hydrotherapy session are described in Table 2. The virtual reality gait training will last for 30 minutes in total and will focus on improving different gait parameters with video games. Another aim of the virtual reality training will be to perform balance exercises. Perturbations will be added to challenge participants. All exercises realized during a Gait Real-time Analysis Interactive Lab (GRAIL) session are described in Table 2. The same video games will be performed for every adolescent (Table 4). A summary of all exercises performed during the intensive rehabilitation is presented in Figure 2.

Figure 1. Rehabilitation program with the total amount of training. During the 3 weeks of rehabilitation, the isokinetic training group and control group will respectively perform a total of 48 hours and 41 hours of active training. *Only performed by the isokinetic training group. Table 2. Description of intensive rehabilitation sessions performed by adolescent in both groups.

Interventions and exercises	Description	Resistance added
Physiotherapy		
Stretching		
Triceps surae	Patient in supine position. PT[a] is pushing the patient foot in dorsiflexion with the knee extended as much as possible	N/A[b]
Quadriceps	Patient in prone position. PT is bending the patient knee and maintaining the patient hip against the table	N/A
Hamstrings	Patient in supine position. PT is maintaining the patient knee extended and adding as much hip flexion as possible. The opposite leg must stay extended on the table	N/A
Iliopsoas	Patient in supine position on the lower part of the table. PT is maintaining a hip extension with a knee flexion. The opposite leg is placed on the chest of the PT	N/A
Strengthening		
Foot plantar flexion	Patient in supine position with knee extended. Ankle placed in dorsiflexion. Elastic band placed around the ball of the foot and help by the patient	Resistance band of various resistances
Foot dorsiflexion	Patient in supine position with knee extended. Ankle placed in plantar flexion. Elastic band placed around the instep of the foot and held by the PT	Resistance band of various resistances
Sit to stand	Patient seating on a chair and push with his feet on the ground to stand	Dumbbells from 5 kg to 10 kg
Knee flexion	Patient in prone position with knee extended. Elastic band is placed around patient ankle and held by the PT	Resistance band of various resistances
Hydrotherapy		
Stretching		
Triceps surae	Patient standing against the pool. One lower limb in front of the other. Both feet on the ground with the back foot in maximal dorsiflexion	N/A
Quadriceps	Patient standing against the pool. Holding one lower limb and bending toward knee flexion while the other hand is stabilizing against the pool.	N/A
Iliopsoas	Patient kneeling against the pool. One knee against the ground and the other one bended. Pushing his gravity center forward	N/A
Strengthening		
Forward walking	Patient standing and walking forward at high intensity inside the swimming pool with water up to the belly.	Resistance band
Backward walking	Patient standing and walking backward at high intensity inside the swimming pool with water up to the belly.	Resistance band
Side walking	Patient standing and walking from side to side at high intensity inside the swimming pool with water up to the belly	Resistance band
Calf raises	Patient standing against the pool with water up to the belly. Pushing against the ground toward maximal plantar flexion and going back to the ground slowly	Water resistant weight
Squat	Patient standing against the pool with water up to the belly. Squatting up to 90 degrees of knee flexion and back to the initial position	Water resistant weight
GRAIL[c]		
Gait training		
Rope bridge	Patient standing on a treadmill. 4 markers are placed on posterior and anterior superior iliac spine. A self-paced mode is used to let the patient walk at a comfortable speed	Sway: level 1 to 3; pitch: level 1 to 3; encounters: level 1 to 3
Step on it	Patient standing on a treadmill. 2 markers are placed on both lateral malleoli. Treadmill speed is set based on gait analysis assessment.	Increasing step length and decreasing step width
Balance		
Perturb	Patient is standing on the treadmill. Anteroposterior and mediolateral stimuli are produced from the treadmill.	Automatic mode starting from level 1 to 5

Figure 2. Images of the guidelines for the intensive rehabilitation program and the isokinetic strength training program. Both groups will follow the exact same intensive rehabilitation program. Only the isokinetic training group will follow the isokinetic strength training program. *Knee flexors and extensors are trained at various speeds in concentric and eccentric modes with different intensities depending on the training week.

Isokinetic Training Intervention

The IG will also receive a total of 9 supervised isokinetic training sessions over 3 weeks based on given guidelines for isokinetic training [29-31]. Adolescents will train between 70% and 80% of the maximal value in Newton-meter reached during the test at the different speeds (Table 5). A visual feedback will be displayed to the participants, with a frame range showing the target strength to reach for every set. A rest time of at least 24 hours between sessions will be observed for every participant. Based on MacArdle et al's [13] findings, 1 single training session will consist of 3 sets of 5 repetitions at a speed of 30 degrees/s concentrically, 3 sets of 8 repetitions at 120 degrees/s concentrically, and 3 sets of 3 repetitions at 30 degrees/s eccentrically. Therefore, strength, hypertrophy, and power will be performed. One repetition consisted of a complete knee extension and flexion, based on the ROM reached during the first assessment. A 90-second rest will be respected between each set. Every session will be preceded by a 5-minute warm-up and followed by a 5-minute cooldown. All exercises realized during isokinetic sessions are shown in Figure 2. One session is expected to last for approximately 45 minutes [29,30,32]. A summary of the exercises performed in the isokinetic strengthening program is presented in Figure 2.

Table 5. Isokinetic strengthening program for the intervention group.

Weeks	Sets, n	Intensity, %[a]	Contraction type
1 and 2	3	70	CON[b] and ECC[c]
3 and 4	3	75	CON and ECC
5 and 6	3	80	CON and ECC

[a]Percentage from maximal reached value at each speed.

[b]CON: concentric.

[c]ECC: eccentric.

Primary Outcomes

Strength

Muscle strength will be assessed with an isokinetic dynamometer (CON-TREX, MJ Multijoint module, Medimex, CMV AG). Patients will be installed as described previously. Patients will perform an aerobic warm-up for 5 minutes and stretching of the quadriceps and hamstring prior to the test. The ROM will be set based on the extension abilities of the patients. Knee flexors and extensors will be assessed in a concentric mode for 3 repetitions at a speed of 30 degrees/s, 5 repetitions at a speed of 120 degrees/s, and for 8 repetitions at a speed of 180 degrees/s; in an isometric mode at 45° of knee flexion for

XSL•FO
RenderX

5 seconds; and in an eccentric mode for 3 repetitions at a speed of 30 degrees/s. The isokinetic equipment is shown in Figure 2.

Between the 2 concentric, the isometric, and the eccentric tests, 90 seconds of recovery will be allowed. Verbal encouragement will be provided for all participants during the entire test. The highest value in Newton-meter, the maximum reached speed in degrees/s, and the total work produced in joules will be considered for data analysis.

A recent meta-analysis from Muñoz-Bermejo et al [6] showed good to excellent levels of reliability of isokinetic dynamometer in measuring knee extensors and knee flexors strength in children with cerebral palsy, with an interclass correlation coefficient (ICC) ranging from 0.7 to 1 in the dominant and the nondominant lower limb.

Gait Assessment

Patients will perform a walking test on the GRAIL (Motekforce Link). The GRAIL technology consisted of a split-belt treadmill with integrated force plates, an incurved virtual reality screen, and a 3D motion capture system (VICON). The treadmill is built with a self-paced mode, allowing patients to walk at a comfortable speed during the entire test.

Spatiotemporal parameters such as gait speed, stride length, step width, and stance time will be recorded during the walking test. Gait speed (m/s) is defined as the average speed recorded during the entire test after removing the first and last seconds to undo the acceleration and deceleration phenomena. Stride length (cm) is defined as the average anteroposterior distance between heel strikes of the same lower limb. Step width (cm) is defined as the average mediolateral distance between both feet. Stance time (s) is defined as the time between heel strike and toe-off from the same lower limb.

Kinematics data will also be collected through the 3D motion capture system. A total of 22 markers will be placed on patients' lower limbs following the human body model, which has been described as a valid method to measure kinematics [33]. Hip, knee, and ankle ROM will be captured during the entire gait assessment in the sagittal, transversal, and horizontal planes. Electromyography activity will be recorded for both lower limbs using surface electrodes on 2 important muscles. The rectus femoris and biceps femoris will be recorded. These 2 muscles are important for knee function, including extension and flexion.

A 6-minute walking test (6MWT) will also be performed on the GRAIL. The treadmill will be set to the self-paced mode. Patients will be asked to walk during the entire test. The total distance reached during the test will be registered for data analysis. Performing the 6MWT on the GRAIL technology has shown good construct validity and reproducibility [34,35]. The Borg scale will also be measured before and after the 6MWT for every patient as an indicator of the level of exertion perceived during the test [34,35].

Secondary Outcomes

Spasticity

Spasticity within knee flexors and extensors will be assessed with an isokinetic dynamometer (CON-TREX, MJ Multijoint module, Medimex, CMV AG) by applying a passive movement at a speed of 180 degrees/s to stretch the muscles. Patients will be installed on the isokinetic seat with 80° of hip flexion, 90° of knee flexion, and no restriction within the ankle joint. The mechanical axis of the dynamometer will be aligned with the lateral epicondyle of the femur. The tibial pad will be placed 3 cm above the lateral malleolus. The trunk and the thigh of the patients will be stabilized with belts. Both limbs will be assessed for 10 consecutive times from 90° to 25° of knee flexion and back to 90°. A 60-second rest break will be respected between each movement. The patient will receive the instruction to rest as much as possible during the entire movement. Prior to the spasticity test, a filter for gravity correction will be applied based on the patient's limb weight. The isokinetic dynamometer will record the forces, angles, and speed during the entire movement. The first and last 5° of each movement will be excluded from the data analysis to avoid errors from the effect of inertia [24]. The test will be interrupted if the force, in Newton, applied to the dynamometer is greater than half the patient's body weight. Patients will be instructed to stop the test if they feel any pain or are scared [36].

The peak resistive torque will be calculated at baseline and after a 3-week intensive training program within both groups. In the knee, the peak resistive torque has shown good relative reliability at a speed of 180 degrees/s, with an ICC of 0.86 for knee extensor peak torque and an ICC of 0.80 for knee flexor peak torque [36].

Knee Joint Position Sense

Knee JPS will be assessed with an isokinetic dynamometer (CON-TREX, MJ Multijoint module, Medimex, CMV AG). Patients will be installed as described previously. The patient's resting position will be set to a preselected joint angle of 45° of knee flexion. Knee JPS will consist of the position-reposition angle difference of the dominant leg. The angular speed for the repositioning task will be set at 2° per seconds as described by El Shemy [37]. Prior to the test, every adolescent will participate in a practice session to become familiar with the task. For the test, the patient's limb will first be placed at a knee angle of 45° for 10 seconds, and then the lower limb will go back to 90° of knee flexion. Finally, the dynamometer will move the lower limb through extension at the same speed. Once patients feel that they have reached the target position again, they will press the button and stop the test. Patients will be blindfolded, and the test will be performed in quiet surroundings to eliminate visual and auditory stimuli. The test will be performed 3 consecutive times, and the mean will be calculated for data analysis.

Data Analysis

Descriptive statistics will be used to describe gender, age, and Gross Motor Function Classification System. Primary and secondary outcomes will be analyzed in the same way. The assumption of normality will be checked by visual inspection

XSL•FO
RenderX

of the q-q plot and the box plot of the data within groups. A Shapiro-Wilks test will also be performed on the data within groups. The homogeneity of variance will be checked using Levene test.

If the data are normally distributed, an independent *t* test will be carried out for each variable to see if there are differences between the experimental and control groups. The 95% CI for the mean differences will be determined. Pearson *r* will be used to calculate the effect size.

If the data are not normally distributed, a Wilcoxon rank-sum test will be used for each variable to determine if there are any significant differences between groups. Pearson *r* will be calculated as a measure of effect size.

The data analysis will be performed using SPSS (25.00, IBM Corp). For the data analysis, the researchers will use a 95% CI, considering all those variables with a *P* value of less than .05 to be statistically significant.

Ethics Approval

This research is promoted by the Institut St-Pierre, France. A parent or legal tutor together, with participants, will fill out a written consent. All participants will join this study voluntarily and will be informed that they can stop their participation at any time. Full data will be available only to members of the research team, and anonymization of the data will be done prior to publication. Written observation reports will be registered during the entire trial by the investigators. Adverse events will be reported to the medical practitioner and the trial sponsor. Unexpected serious adverse events will be transferred to the ethical committee within 15 days. Trial results will be published in academic journals and presented at conferences worldwide. Participants, their families, and health care professionals will have the option to receive a summary of the study results. The study will be conducted in accordance with the Declaration of Helsinki, and the protocol has been approved by the Comité de protection des personnes Sud-Méditerranée II (CPP 222 B21) IDRCB 2022-A01790-43. The date of approval was October 3, 2022.

Results

The protocol was accepted by the French National Ethics Committee in October 2022. The inclusion of patients will start in November 2022. Data collection is expected to be completed in June 2024. The results of the trial are expected to be available by the end of 2024.

Discussion

Principal Findings

This study will evaluate the effects of intensive rehabilitation combined with an isokinetic progressive strengthening program on gait parameters, muscle strength, spasticity, and joint position sense. Both groups will receive the same intensive rehabilitation, and the intervention group will also have an isokinetic program. The findings of this study may determine if an isokinetic strength training program of knee flexors and extensors is beneficial to improve gait parameters, muscle strength, spasticity, and joint position sense in adolescents with spastic diplegia. Positive findings are expected for this clinical trial. If this is the case, isokinetic strength training programs should be considered as a complementary intervention for patients with cerebral palsy.

It has been decided to measure and strengthen knee flexors and extensors, as they have been described as good indicators for total lower limb muscle strength [6,38]. Strength training programs have been designed and tested on children with spastic diplegia [30,39,40]. Aye et al [40] have shown an improvement in muscle strength, gait parameters, and gross motor function measure after a strength training program for hip and knee extensors. In their study, MacPhail and Kramer [8] have shown that an isokinetic strength training program focusing on knee flexors and extensors could significantly improve strength in patients with cerebral palsy. MacPhail and Kramer [8] did not find significant improvement in gait parameters following an isokinetic strength training program. However, they did not implement such a program within an intensive rehabilitation program.

Limitations

The intensive rehabilitation program could not be longer than 3 weeks due to school, and a longer period of time might be important to improve gait functions and muscle strength in patients with cerebral palsy.

The total amount of training was not kept equal for both groups due to the isokinetic training program, and this might have an influence on the results.

Conclusions

Nowadays, there is missing information about the effects of an intensive rehabilitation program combined with an isokinetic strength training program on gait parameters. The combination of intensive rehabilitation with an isokinetic program on knee flexors and extensors has not been studied yet. Positive findings of this study may suggest that an isokinetic strength training program should be implemented within the traditional treatment of children with spastic diplegia.

Data Availability

The data are not publicly available, as they have not been collected yet. The data will be uploaded to publish this paper.

Abstract

Background: Obsessive-compulsive disorder (OCD) is a psychiatric syndrome characterized by unwanted and repetitive thoughts and repeated ritualistic compulsions for decreasing distress. Symptoms can cause severe distress and functional impairment. OCD affects 2% to 3% of the population and is ranked within the 10 leading neuropsychiatric causes of disability. Cortico-striatal-thalamo-cortical circuitry dysfunction has been implicated in OCD, including altered brain activation and connectivity. Complex glutamatergic signaling dysregulation within cortico-striatal circuitry has been proposed in OCD. Data obtained by several studies indicate reduced glutamatergic concentrations in the anterior cingulate cortex, combined with overactive glutamatergic signaling in the striatum and orbitofrontal cortex. A growing number of randomized controlled trials have assessed the utility of different glutamate-modulating drugs as augmentation medications or monotherapies for OCD, including refractory OCD. However, there are relevant variations among studies in terms of patients' treatment resistance, comorbidity, age, and gender. At present, 4 randomized controlled trials are available on the efficacy of memantine as an augmentation medication for refractory OCD.

Objective: Our study's main purpose is to conduct a double-blind, randomized, parallel-group, placebo-controlled, monocenter trial to assess the efficacy and safety of memantine as an augmentative agent to a selective serotonin reuptake inhibitor in the treatment of moderate to severe OCD. The study's second aim is to evaluate the effect of memantine on cognitive functions in patients with OCD. The third aim is to investigate if responses to memantine are modulated by variables such as gender, symptom subtypes, and the duration of untreated illness.

Methods: Investigators intend to conduct a double-blind, randomized, parallel-group, placebo-controlled, monocenter trial to assess the efficacy and safety of memantine as an augmentative agent to a selective serotonin reuptake inhibitor in the treatment of patients affected by severe refractory OCD. Participants will be rated via the Yale-Brown Obsessive Compulsive Scale at baseline and at 2, 4, 6, 8, 10, and 12 months. During the screening period and T4 and T6 follow-up visits, all participants will undergo an extensive neuropsychological evaluation. The 52-week study duration will consist of 4 distinct periods, including memantine titration and follow-up periods.

Results: Recruitment has not yet started. The study will be conducted from June 2023 to December 2024. Results are expected to be available in January 2025. Throughout the slow-titration period, we will observe the minimum effective dose of memantine, and the follow-up procedure will detail its residual efficacy after drug withdrawal.

Conclusions: The innovation of this research proposal is not limited to the evaluation of the efficacy and safety of memantine as an augmentation medication for OCD. We will also test if memantine acts as a pure antiobsessive medication or if memantine's ability to improve concentration and attention mimics an antiobsessive effect.

Introduction

Background

Obsessive-compulsive disorder (OCD) is one of the most disabling neuropsychiatric disorders, characterized by repetitive and intrusive thoughts (obsessions) and repeated ritualistic behaviors (compulsions) that are performed by affected individuals to decrease distress [1]. It is estimated that 2.5% to 3% of the general population are affected by OCD [2], which has some sex-related features [3]. Moreover, in the last decade, evidence suggests significant neuropsychological deficits—independent of severity, comorbidity, and medication—in patients with OCD [4,5]. Several studies suggest impairments in executive function, processing speed, sustained attention, and nonverbal memory [6-11].

Prior to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) [12], OCD was included as an anxiety disorder because patients commonly reported anxiety as a symptom [13]. However, in the DSM-5, OCD was moved to its own distinct section—*Obsessive-Compulsive and Related Disorders*—because the condition was considered to be more closely related to other disorders [14].

Typically, OCD is determined by obsessions (irrational beliefs) and compulsions that are rational avoidance responses activated by these irrational beliefs. Recent data [15,16] instead suggest that the mechanism underlying OCD can be found in an interference in the balance between the habit learning system and the goal-directed system. The habit learning system is founded on historical information, independent of past rewards, potentially resulting in behavioral inflexibility even in light of rapid changes in the environment. On the other hand, the goal-directed system applies control over habits in response to changes, including changes in response to the assessment of actions and outcomes. A study conducted by Voon and colleagues [17] found that patients with OCD made choices generally based on a model-free approach (habit learning system) rather than a model based on a goal-directed system.

In the current habit hypothesis of compulsivity, compulsions result from a deficit of goal-directed actions, rather than being driven by irrational beliefs. In line with this much more behavioral account of the disorder, OCD was inserted in the new *Obsessive-Compulsive and Related Disorders* chapter of the DSM-5.

Recurrent circuits that connect the cerebral cortex to the basal ganglia, which are termed *cortico-striatal-thalamo-cortical circuitry* (CSTC) *loops*, are involved in habits. CSTC dysfunctions, as structural abnormalities, alter brain activation and connectivity [18,19] and seem to be implicated in OCD. According to this hypothesis, the hyperactive or hyperconnected CSTC loops are self-exciting in a runaway positive feedback loop [20,21], resulting in the need to perform compulsions, which in turn reinforces habits and increases the urge to perform compulsions [22].

The primary neurotransmitter involved in the CSTC model of OCD is glutamate [23]; it also has a fundamental role in neuronal plasticity, learning, and memory [24]. Excessive levels of glutamate in the brain area can stimulate glutamate receptors, resulting in hyperactivity or even excitotoxicity in neurons; in pathological conditions, glutamate can act as a neuronal excitotoxin, resulting in rapid or late neurotoxicity [25].

In support of this hypothesis, a large mega-analysis and meta-analysis of imaging data found age-related changes in brain structures, suggesting that OCD is underpinned by complex, nonlinear neurodevelopmental mechanisms [26,27].

The pathophysiology of OCD indicates aberrant glutamatergic signaling, with reduced glutamatergic concentrations in the anterior cingulate cortex and increased glutamatergic concentrations in the striatum and orbitofrontal cortex [28]. Moreover, both ionotropic glutamate receptors and metabotropic glutamate receptors are linked in virtually every form of learning in the brain, including habit learning [15,29]; are localized in brain circuitry; and are candidates in the pathophysiology of OCD. Several studies show evidence of altered glutamate homeostasis in OCD, with higher levels of glutamate in the cerebrospinal fluid of patients with OCD compared to those of healthy controls [30,31]. Genetics studies suggest an association between polymorphisms of glutamate-associated genes and the development of OCD [32-34]; in particular, OCD in families has been associated with a polymorphism of the gene that codes for N-methyl-D-aspartic acid receptors [32].

Conventionally, guidelines suggest the use of medications that act on serotonergic pathways, such as serotonin reuptake inhibitors (SRIs) and, in particular, selective SRIs (SSRIs), for OCD. Even if the exact mechanisms of their actions remain mysterious, it seems that SRIs exert their effects by influencing CSTC [35]. Unfortunately, it is estimated that around 30% to 60% of patients with OCD do not attain remission after taking SRIs [5]; even when switching to another SSRI, clomipramine, or an atypical antipsychotic, around 30% of patients remain untreated for refractory symptoms.

Given the role that glutamate appears to play in the dysregulation of OCD, glutamatergic drugs could be potential candidates for an OCD therapy augmentation strategy. Glutamate-modulating drugs seem to be potential therapeutic agents for other psychiatric disorders, such as depression, bipolar

XSL•FO
RenderX

disorder, and suicidality, that have high comorbidity with OCD [36-38].

In light of the new evidence, several authors have focused their interest on the use of glutamate-modulating agents in patients with refractory OCD. Indeed, some studies that used memantine; riluzole; ketamine; or nutritional supplements, such as inositol and N-acetylcysteine, suggested promising benefits for these kinds of patients [39].

Several randomized controlled trials (RCTs) on the effects of glutamate-modulating drugs on OCD were conducted. A review conducted by Marinova and colleagues [39] showed that memantine seems to have a positive effect on refractory symptoms as an augmentation medication for OCD.

Due to substantial differences in treatment resistance, comorbidity, age, and gender among patients [39], at the moment, it is premature to recommend the use of glutamatergic drugs for refractory symptoms, since more studies are needed to confirm the use of this pharmacological approach for OCD augmentation therapy [40]. Moreover, randomized placebo-controlled trials with larger study populations are necessary in order to draw definitive conclusions on the utility of glutamate-modulating drugs for OCD.

Identifying and confirming the efficacy and safety of new therapeutic approaches for OCD could also be very useful for the purpose of early intervention in patients. Even if there are not sufficient data to support a progression of brain changes, it is likely that early intervention could help to reduce damage resulting from neurotoxicity [41].

Objectives

The main purpose of our study is to conduct a double-blind, randomized, parallel-group, placebo-controlled, monocenter trial to assess the efficacy and safety of memantine—a low- to moderate-affinity, noncompetitive N-methyl-D-aspartic acid receptor antagonist [40] that is currently approved for the treatment of Alzheimer disease—as an augmentative agent to an SSRI in the treatment of moderate to severe OCD. The second aim of the study is to evaluate the effect of memantine on the concentration and attention abilities of patients with OCD. The third aim is to investigate if responses to memantine could be modulated by variables such as gender, symptoms subtypes, and the duration of untreated illness.

Methods

This protocol has been reported according to the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) statement requirements (Figure 1). The complete SPIRIT checklist is available in Multimedia Appendix 1.

Trial Design

A double-blind, randomized, parallel-group, placebo-controlled, monocenter trial will be conducted over 52 weeks at the outpatient clinic of the Department of Human Neurosciences, Sapienza University of Rome. The study population will include patients diagnosed with moderate to severe OCD according to the diagnostic criteria of the DSM-5 who consecutively access the OCD outpatient clinic of the Department of Human Neurosciences, Sapienza University of Rome. The investigators

XSL•FO
RenderX

will be academic research assistants and psychiatrists with experience in OCD.

We will enroll patients who meet the diagnostic criteria of the DSM-5 [12] for moderate to severe OCD, and those with a Yale-Brown Obsessive Compulsive Scale (Y-BOCS) [42] score of >21 will be selected for inclusion in the study. The Y-BOCS, which will be used to evaluate treatment efficacy, is a well-validated, 10-item rating scale that is widely used to measure the severity of OCD symptoms. Participants will be rated with the Y-BOCS at baseline and at 2, 4, 6, 8, 10, and 12 months.

During the screening period and T4 and T6 follow-up visits, all participants will undergo an extensive neuropsychological evaluation. We will assess processing speed by using the Wechsler Adult Intelligence Scale, Fourth Edition, Digit Span [43]; attention by means of the Trial Making Test [44]; computerized alertness and go/no-go task memory by using the Digit and Corsi Span [45], a modified version of the Corsi Block-Tapping Test [46], the story recall portion of the Rivermead Behavioral Memory Test [47], and a modified version of the Babcock Story Recall Test [48]; and executive functions by means of the Stroop task [49], a modified version of the Tower of London test [50], and the Modified Five-Point Test [51].

Ethical Considerations

The study will be conducted in accordance with the Declaration of Helsinki and its subsequent revisions. Written informed consent will be obtained from all eligible participants, following the complete description of study details. Participants will be informed about their freedom to withdraw from the trial anytime without any negative effect on their therapy. The study was approved for a grant by Sapienza University of Rome (grant RM11916B7477A1B6), approved by the local ethics committee (protocol number: 0784/2022), and registered on ClinicalTrials.gov (trial number: NCT05015595).

Only patients legally capable of giving their consent can participate in the study. The investigator will be responsible for the correctness of the recruitment procedure and will be asked to use comprehensible verbal communication when providing information to the patients. Before entering the study, patients will be fully informed about the purposes of the research; possible benefits; any potential, personal, reasonable risks or discomforts; and the expected duration of their participation in the trial. The investigator will also clearly inform the patients that they can leave the study at any time and for any reason, without giving an explanation, and that discontinuation would not, in any case, deteriorate the patients' relationship with the physician or the possibility of receiving alternative therapies.

Before recruitment, a copy of the informed consent form and personal data processing consent form will be given to the patients, together with any needed clarification. Sufficient time will be given to enable the patients to decide whether they will participate in the study. Moreover, we intend to also seek approval from the Institutional Review Board of Sapienza University of Rome.

Participants

The inclusion criteria are as follows: a psychiatrist diagnosis of current moderate to severe OCD based on the DSM-5, a Y-BOCS [42] score of >21, an age of 18 to 55 years, patients in therapy with a stable SSRI for at least 3 weeks prior to enrollment, and written informed consent.

The exclusion criteria are as follows: substance dependence, an IQ of <70, comorbid psychiatric disorders, pregnant or breastfeeding women or women who intend to become pregnant during the period of the study, and concomitant treatments (repetitive transcranial magnetic stimulation, cognitive behavioral therapy, or other glutamate-modulating drugs).

Interventions

This is a protocol for a double-blind, randomized, parallel-group, placebo-controlled, monocenter trial in patients with OCD. The trial will include 1 active memantine dose arm and 1 placebo arm.

The trial will consist of the following four distinct periods:

- Screening: the screening period may last up to 4 weeks for each eligible patient.
- A 32-week, double-blind, up-titration treatment period (from T0 to T4): after screening, patients who meet all eligibility criteria will be randomly assigned to 1 of 2 arms (memantine or placebo) in a 1:1 ratio. Following baseline assessments, each patient will receive a daily dose of memantine or the placebo (up to 20 mg/day).
- An 8-week, double-blind, down-titration treatment period (from T4 to T5): at T4, the dose of memantine or the placebo will be reduced to 10 mg per day due to safety reasons, before the end of treatment (T5).
- Follow-up period (from T5 to T6): after the 40-week, double-blind treatment period, patients will be asked to come back for the follow-up visit (T6) 8 weeks after the end of the treatment (T5; Figures 2 and 3).

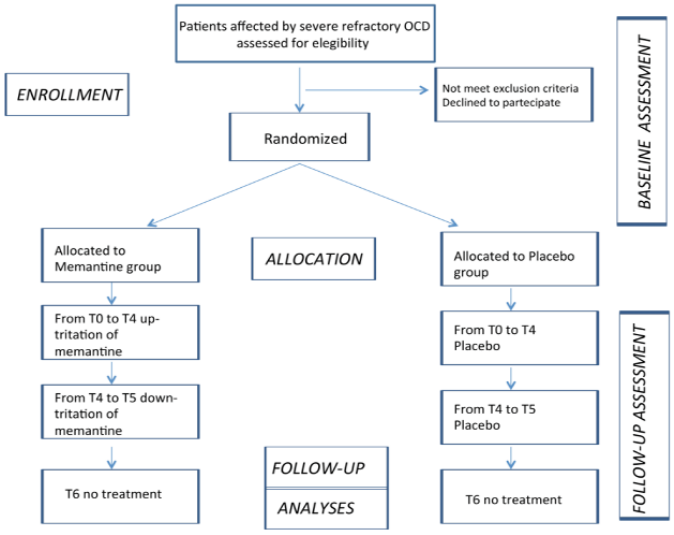
Figure 2. Study Flow-chart.



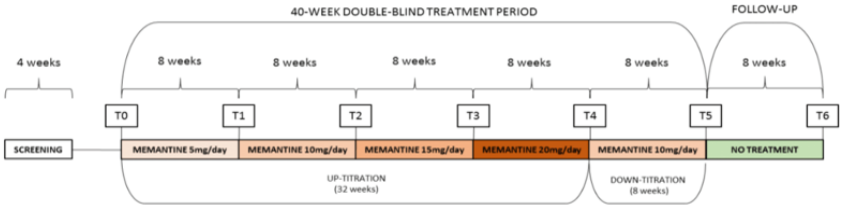


Figure 3. Study Timeline.

Recording of Adverse Events

The investigator will carefully monitor the patients' symptoms and signs, which will be either spontaneously reported or detected, throughout the whole study period up to the last visit scheduled in the study protocol. On a case-by-case basis, a prolonged observation period may be requested.

Adverse events that occur during the clinical trial will be assessed by the investigator in terms of their seriousness and relationship with the investigational product, and the principal investigator will be notified.

As soon as a severe adverse event occurs, an ad hoc form for severe adverse events will be completed, in accordance with the European Union regulation about pharmacovigilance in clinical research [52]. If, for any reason, the disadvantages of participation appear to be significantly greater than those foreseen, the investigator will inform the principal investigator and the bodies providing ethical oversight to evaluate trial discontinuation for the patient.

Sample Size

The sample size was calculated by using the G*Power 3.1.9.2 software (Heinrich-Heine-Universität Düsseldorf) [53]. By using the ANOVA repeated measures test with a within-between group interaction approach (considering changes in Y-BOCS scores as the primary outcome), an α of .5, a power $(1 - \beta)$ of 0.85, 2 groups (SSRI and memantine group vs SSRI and placebo group), and 7 measurements (T0 to T6); and by assuming a correlation of 0.5 among repeated measures and a nonsphericity correction ε of 1, we determined that a total sample size of 20 participants (10 in each group) will be necessary to achieve a moderate effect size (f=0.25).

Randomization and Blinding

Placebo and memantine tablets will be identical in shape, color, weight, and scent. We will prepare in advance a computer-generated random number sequence for random group assignment. Treatment allocation will be concealed from the patients, from the physicians rating the patients, and from the statistician. Separate individuals will be responsible for randomization and the rating of patients.

Data Collection and Quality Control

Patients will be enrolled after the physician in charge and a supervisor check the patient information regarding the inclusion and exclusion criteria. The data of all participants, including those who are discontinued or dropped from intervention protocols, will be collected according to the study protocol. Quality control will be performed by an external data manager (recruited exclusively for this project).

Statistical Methods

Descriptive statistics for baseline characteristics and the measurements at each time point will be calculated. For the primary objective, a repeated measures ANOVA approach will be used to detect between- and within-group differences in Y-BOCS variables. P values of <.05 will be considered statistically significant. Data will be analyzed by using SPSS version 20 (IBM Corp).

Results

Recruitment will start in June 2023, and data collection is expected to end in 2024. Results are expected to be available in January 2025. We also intend to make publications available in 2025, and the results of our trial will also be presented at conferences.

Discussion

Overview

In light of the possible role of glutamatergic signal dysregulation in OCD, it is possible to find, among glutamatergic drugs, candidates for an OCD therapy augmentation strategy.

This has motivated the use of glutamate modulators in patients who are unresponsive to standard pharmacotherapeutic approaches. Several RCTs that used glutamate-modulating agents, such as memantine, riluzole, N-acetylcysteine, and glycine, reported promising benefits [38,54,55]. In particular, 4 RCTs were conducted that used memantine (vs a placebo) as an augmentative agent to SRIs in the treatment of moderate to severe OCD [56].

Marinova and colleagues [39] reported that memantine was the compound that most consistently showed a positive effect, as an augmentation medication, on OCD in their study. A critical letter [40] exposed some concerns on this conclusion and proposed that, in light of some methodological gaps, it is necessary to conduct more studies on the use of memantine as an OCD augmentation therapy.

Limitations

Our outpatient clinic—a center specializing in OCD—is an academic service of the Department of Human Neurosciences, Sapienza University of Rome. This could represent a limitation—patient selection bias—due to patients' access to the center's services. Moreover, our study will use a small sample size due to the limits of service access and the inclusion criteria.

Conclusion

To the best of our knowledge, only 4 RCTs have been conducted in recent years that investigated the effects of memantine in patients with refractory severe OCD; our trial will be the first one of its kind in Italy. The innovation of this research proposal is not limited to the evaluation of the efficacy and safety of memantine as an augmentation medication for OCD. Through slow titration and follow-up, we will also observe the minimum effective dose of memantine and its residual efficacy after drug withdrawal by using an 8-week follow-up procedure. In addition, by measuring potential executive function impairments during the study period, we might confirm whether memory and attention are modulators of overall clinical improvement. In other words, we will test if memantine, being an antiglutamatergic agent, acts as a pure antiobsessive medication or if memantine's ability to improve concentration and attention mimics an antiobsessive effect.

Data Availability

The data generated and analyzed during this study will be available from the corresponding author on reasonable request, following the completion of the trial and publication of the main outcomes paper, and will be included in any published articles.

Authors' Contributions

AM, MP, AT, and CDL contributed to the conception and design of the research. AM and MP will evaluate the patients. ADV and FD will assign the patients to the two groups. AM and MP drafted the manuscript. All authors critically revised the manuscript, agreed to be fully accountable for ensuring the integrity and accuracy of the work, and read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Lung or head and neck cancers are known for their high prevalence and mortality rates. Chemotherapy and radiotherapy are usually recommended as cancer treatment for these malignancies; however, they can negatively impact both the physical and mental status of patients. Hence, it is reasonable to consider resistance and aerobic exercise training to prevent these negative health outcomes. Further, several factors prevent patients from attending outpatient exercise training programs, and, therefore, a semisupervised home-based exercise training program may be seen as a well-accepted alternative.

Objective: The aim of this study will be to investigate the effects of a semisupervised home-based exercise training program on physical performance, body composition, and self-reported outcomes; changes in the initial cancer treatment dose prescribed; number of hospitalizations at 3, 6, and 9 months; and 12-month survival in people with primary lung or head and neck cancer.

Methods: Participants will be randomly allocated to the training group (TG) or control group (CG). The TG will undergo semisupervised home-based resistance and aerobic exercise training throughout their cancer treatment. The resistance training will be performed using elastic bands (TheraBand) twice a week. The aerobic training (ie, brisk walk) will be performed for at least 20 minutes per day outdoors. The equipment and tools used during the training sessions will be provided. This intervention will start the week before treatment commencement, will be performed throughout the duration of the treatment, and will continue for 2 weeks after treatment completion. The CG will undergo usual care (ie, cancer treatment with no formal exercise prescription). Assessments will take place 2 weeks before the beginning of the usual cancer treatment and 2 weeks after treatment completion. The measures of physical function (peripheral muscle strength, functional exercise capacity, and physical activity), body composition, and self-reported outcomes (symptoms of anxiety and depression, health-related quality of life, and symptoms related to the disease and treatment) will be collected. We will report on any change in the initial cancer treatment dose prescribed; number of hospitalizations at 3, 6, and 9 months; and 12-month survival.

Results: In February 2021, the clinical trial registration was approved. Recruitment and data collection for the trial are ongoing (as of April 2023, 20 participants had already been randomized), and findings of this study are likely to be published late in 2024.

XSL•FO
RenderX

Conclusions: This exercise training as a complementary treatment for patients with cancer is likely to promote positive effects on the health outcomes assessed, over and above any change in the CG, and prevent the reduction of initial cancer treatment dose prescribed. If these positive effects are shown, they will likely impact long-term outcomes such as hospitalizations and 12-month survival.

Introduction

Background

Worldwide, lung or head and neck cancers are the most common cancers and the main causes of death each year [1,2]. Because of the direct effect of these cancers on the respiratory system, management and rehabilitation may be substantially similar [3]. The usual cancer treatment options are surgery, chemotherapy, radiotherapy, or a combination of these treatments [4]. Although having positive effects, these treatments also have side effects, such as fatigue [5,6] and a decrease in functional exercise capacity [7], muscle mass [8], and muscle strength [8,9], which will ultimately affect physical activity and health-related quality of life (HRQoL) [10,11]. Therefore, complementary interventions that could minimize these side effects are needed [7].

Studies have demonstrated that exercise promotes benefits to this population [7]. Improvements have been reported in physical function, body composition, psychosocial function, sleep quality, fatigue, HRQoL [12], and muscle strength [7] after completion of an exercise program. When used as a complementary treatment to usual cancer treatment, exercise has been shown to maximize chemotherapy completion in women with breast cancer and men with prostate cancer [13,14].

Exercise training has been shown to be safe and have positive effects on health outcomes in people with lung or head and neck cancer [15]. Taking into account these positive effects [16,17], as well as the fact that exercise is a low-cost treatment modality that attenuates symptoms related to cancer treatment, it is imperative that exercise training is delivered as a complement or adjunct to medical treatment [15-17].

Distance- and travel-related costs are factors that influence the patient's enrollment and attendance to exercise, and home-based exercises seem to be an option that can overcome these barriers. Although being a feasible alternative [18-20], home-based exercises should be semisupervised to ensure safety and adherence, as well as maximize training efficacy. As there is limited data on the effects of a semisupervised home-based exercise program in people with lung or head and neck cancer, this randomized controlled trial aims to investigate the protective effect of semisupervised home-based exercise training on physical function, body composition, and self-reported outcomes in people with primary lung or head and neck cancer. In addition, we will also report on changes in the initial cancer treatment dose prescribed; number of hospitalizations at 3, 6, and 9 months; and 12-month survival.

Hypotheses

We hypothesize that the semisupervised home-based exercise training as a complementary treatment will promote positive effects on physical function, body composition, and self-reported outcomes in these patients during the cancer treatment. It is also expected that the initial usual cancer treatment dose prescribed will be maintained because of the benefits of the exercise training, leading to fewer hospitalizations and greater survival in patients who underwent the exercise training program.

Methods

Study Design

This will be a single-blind (outcome assessor), 2-arm randomized controlled trial. The study will be conducted at a cancer hospital. The study protocol has been developed following the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 checklist guidelines.

Ethics Approval

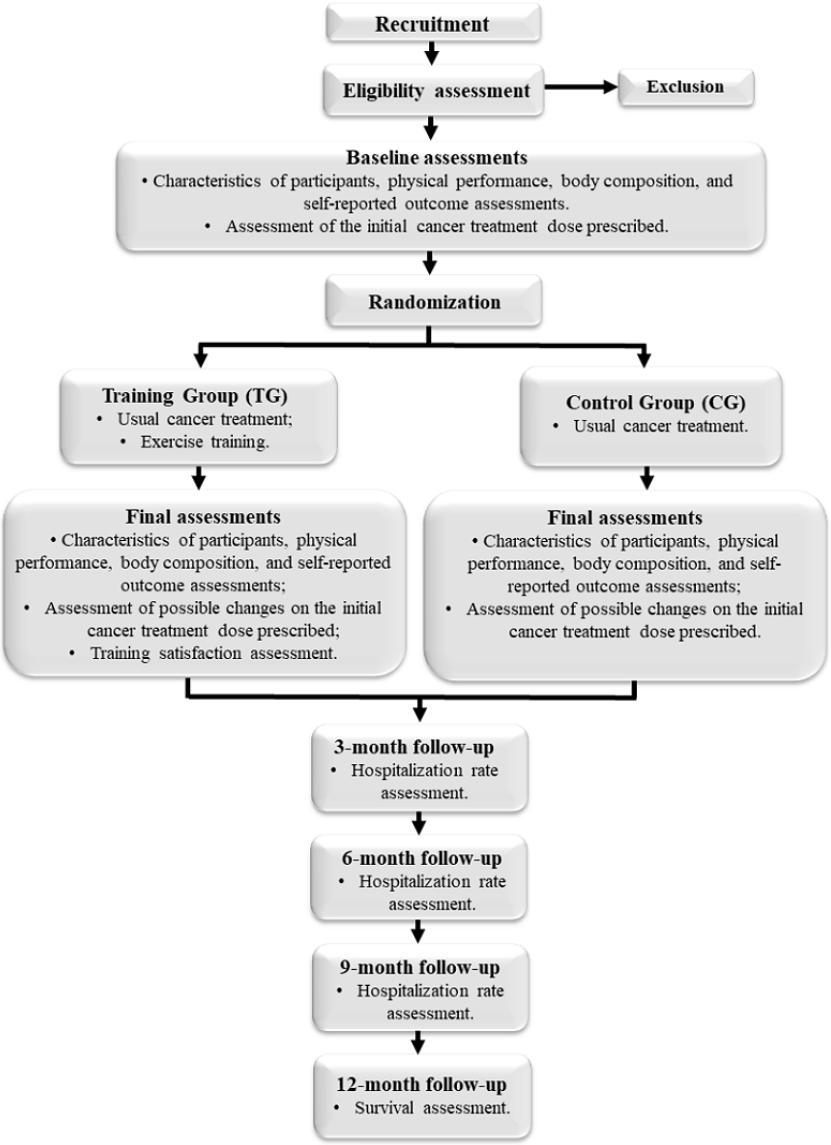
The trial has received approval from the health research ethics committee of the Regional Cancer Hospital of Presidente Prudente (HRCPP; 26123119.5.0000.8247), which complies with the Declaration of Helsinki. Written, informed consent to participate will be obtained from all participants.

Data Collection and Management

The information collected about participants is individually identifiable by members of the research team only. Each participant will be allocated a unique numeric code (ID number) such that all stored electronic data (eg, databases and data files) will not contain identifiable data until the completion of the study. All confidential information is stored in locked filing cabinets, and only deidentified data will be presented or published.

Study Population

Participants will be recruited from the outpatient clinic before cancer treatment commencement. The inclusion criteria will be as follows: diagnosis of primary lung or head and neck cancer;



XSL•FO
RenderX

older than 18 years; referred for cancer treatment including radiotherapy, chemotherapy, or both; Eastern Cooperative Oncology Group performance status score between 0 and 2; life expectancy (physician-rated) of >6 months; and sufficient functional literacy or having a support person who can help with reading the instructions for the home-based exercise program. The exclusion criteria will be as follows: people referred for cancer surgery or palliative care; symptomatic brain or bone metastasis prohibiting participation in exercise training; and unstable metabolic, musculoskeletal, or cardiovascular disease.

Experimental Design

The flow of participants through the study is presented in Figure 1, and the overview of the data collection is given in Table 1. First, people referred to usual lung or head and neck cancer treatment (chemotherapy or radiotherapy) will be assessed on 2 nonconsecutive days. On assessment day 1, participants' characteristics and past medical history will be collected, and data on physical activity, symptoms of anxiety and depression, HRQoL, and symptoms related to treatment and disease will be assessed via validated questionnaires. Subsequently, peripheral muscle strength will be assessed via digital dynamometry. On assessment day 2, measures of body composition (octapolar Inbody 720; Biospace) and functional exercise capacity will be undertaken, including the 6-minute walk test (6MWT), time up and go test (TUG), and 1-minute sit-to-stand test (1STS). After assessment day 2, participants will be randomly allocated to either the training group (TG) or the control group (CG). A third visit will be scheduled for those allocated to the TG, where the exercise training protocol will be explained and demonstrated, and the participants will be familiarized with the training equipment and tools. Participants in the CG group will undergo usual cancer treatment (chemotherapy and radiotherapy) and will be instructed to keep their routine activities during the study period. They will also receive phone calls every 15 days (throughout the course of their cancer treatment) to discuss any issues related to cancer treatment and their participation in the study.

Figure 1. Experimental design of the study.

XSL•FO

Anxiety and depression	HADS[e]	✓		✓		
HRQoL[f]	EORTC QLQ-30[g]/QLQ-LC13	✓		✓		
Symptoms related to the treatment and disease	MSAS-BR[h]					
Cancer treatment dose prescribed	Via the participant's medical records	✓				
Cancer treatment dose completed	Via the participant's medical records			✓		
Hospitalization rate assessment	Via telephone calls				✓	
Survival rate assessment	Via telephone calls					✓

[a]6MWT: 6-minute walk test.

[b]TUG: time up and go test.

[c]1STS: 1-minute sit-to-stand test.

[d]IPAQ: International Physical Activity Questionnaire.

[e]HADS: Hospital for Anxiety and Depression Scale.

[f]HRQoL: health-related quality of life.

[g]EORTC QLQ-30: European Organization for Research and Treatment of Cancer Core Quality of Life Questionnaire.

[h]MSAS-BR: Memorial Symptom Assessment Scale (Portuguese version).

Two weeks after completion of the cancer treatment, participants will be reassessed (ie, repetition of the 2 days of assessments described above). Data on changes in the initial cancer treatment dose prescribed will be collected during the intervention period. Participants (or their support person) will receive phone calls at 3, 6, 9, and 12 months after the reassessment date. The number of hospitalizations at 3, 6, and 9 months as well as 12-month survival will also be recorded.

Randomization, Concealment, and Blinding

The randomization sequence will be generated on a web-based platform [21] and concealed using opaque envelopes. This process will be conducted by a researcher who is not involved with participant recruitment, assessment, or data management and analysis. The assessor will be blinded to group allocation. Assessments and patient recruitment will be blinded to the therapeutics.

Procedures (TG and CG Intervention)

Participants in both groups (TG and CG) will undergo usual cancer treatment that does not include any formal exercise prescription. Those allocated to the TG will perform resistance and aerobic exercises that will be individually prescribed.

TG Intervention

The semisupervised home-based exercise training program will start 1 week before commencement of cancer treatment and will finish 2 weeks after completion of the cancer treatment. Semisupervision will include an exercise diary, daily SMS text messaging, and frequent phone calls. A previous study [22] reported that people who underwent semisupervised home-based exercise training did not have any adverse event during the training program. The resistance and aerobic training will be guided by an exercise diary developed by the research team; see Multimedia Appendix 1 for more details. Participants in the TG will be instructed to complete the diary on a daily basis with information on the exercises they performed. They will also be provided with a pulse oximeter (G-Tech Portable Oled) and the modified Borg scale to assess and record their peripheral capillary oxygen saturation and the Borg dyspnea score, respectively, before and after the exercise training session. Participants will be asked to avoid exercise training if resting oxygen saturation is <90%. Resistance training will be performed twice a week and aerobic training will be performed 7 days a week. Participants will also receive a daily SMS text message reminding them to perform the exercises and will be contacted (via a phone call) every 7 to 14 days.

To ensure participants' safety during the exercise program, blood tests will be performed every second week to monitor

XSL•FO
RenderX

platelet count and hemoglobin levels. Exercise training will be paused when there is fever (>38 °C) [23], infection, hemoglobin level <8 g/dL [24,25], and psychological instability or clinical complications [26].

Resistance Training

Participants in the TG will perform semisupervised home-based resistance training using elastic bands (TheraBand, green color, moderate resistance) [26]. Exercises for the following muscle groups will be included: elbow flexors, knee flexors, and knee extensors (2 sets of 10 repetitions with a 1-minute interval) [27]. The exercise intensity will be adjusted using the modified Borg scale (the participant must maintain dyspnea between 4 and 6, ie, moderate intensity) [22]. Regarding progression of the exercise prescription, if the participant is able to perform more than 2 sets of 10 repetitions and report a Borg dyspnea score <4, an increment of 5 repetitions will be prescribed for the following session using the same elastic band resistance [28]. Subsequently, the intensity progression will be to 3 sets of 10 repetitions and then 3 sets of 15 repetitions. Participants will be contacted via a phone call (or in person, if needed) every 7 to 14 days to assess the need for increased training intensity. This protocol was developed based on previous studies of exercise training in people with cancer [22,26-28] as well as of resistance training with elastic bands in people with chronic obstructive pulmonary disease [29,30].

Aerobic Training

For the aerobic training, participants will perform a brisk walk outside, starting with 20 minutes daily (equivalent to 1.5 km) [28], and will be asked to maintain a Borg dyspnea score between 4 and 6 (moderate intensity) [31]. Therefore, this training will be equivalent to approximately 3.5 metabolic equivalents [28]. Participants will be provided with a pedometer (Power Walk PW-610; Yamax) as a feedback tool for the aerobic training. Participants will be instructed to try to achieve at least 150 minutes of aerobic training weekly. The modified Borg scale will also be used to titrate the intensity of the aerobic training (if symptoms of dyspnea are <4 on the Borg scale, an extra 5 minutes will be prescribed for the following week). If more than 150 minutes of weekly aerobic training is achieved, the participants will be instructed to increase their walking speed but maintain a Borg dyspnea score between 4 and 6. This protocol has been developed based on previous studies of physical training for people with cancer [26,28].

CG Intervention

Participants in the CG will undergo usual cancer treatment with no formal exercise prescription and will be instructed to keep routine activities during the study period. They will also receive phone calls every 15 days to discuss any issues related to cancer treatment and their participation in the study.

Outcome Measures (Assessments)

Characteristics of Participants

Participant characteristics will be collected of age, gender, height, body weight, cancer type and stage, number of cycles per session as well as dose of chemotherapy or radiotherapy prescribed, and self-reported comorbidities.

Primary Outcome

Peripheral Muscle Strength

Peripheral muscle strength will be assessed via the force gauge digital dynamometer (Instrutherm DD-300), and the results will be expressed in newtons. The participants will be instructed to perform elbow flexion (at 180°), knee flexion (at 90°), and extension (at 90°) movements resisted by a steel cable coupled to the dynamometer. The measurement will be repeated 5 times with an interval of 1 minute between attempts, and the highest value among the 3 closest measurements will be recorded [32].

Secondary Outcomes

Functional Exercise Capacity

Functional exercise capacity will be assessed via the 6MWT and the 1STS. The 6MWT will be performed in accordance with the guidelines established by the American Thoracic Society and European Respiratory Society [33]. Two tests will be performed, with at least 30 minutes of rest between them, and the best performance (ie, 6-minute walk distance) will be reported. The reference values developed for the Brazilian population will be used [34].

The 1STS test will also be used to evaluate the functional exercise capacity. Two tests will be performed, with 1 minute of rest between them, and best performance (ie, number of sit-to-stand repetitions) will be reported [35].

Mobility

Mobility and the capacity to perform routine activities will be assessed by the TUG. The TUG has also been used to assess risk of falls, and the performance in the TUG is determined by the time spent to complete the test [36,37].

Physical Activity

The International Physical Activity Questionnaire will be used to assess self-reported physical activity. The variable from the International Physical Activity Questionnaire that will be used is time spent in physical activity [38].

Body Composition

Body composition will be assessed via bioimpedance spectroscopy (octopolar InBody 720; Biospace) following the manufacturer's instructions. Data will be electronically imported to Excel (Microsoft Corp) using the software Lookin'Body (version 3.0; Biospace) [39]. The following variables will be assessed: intracellular water, extracellular water, total body water, basal metabolic rate, protein mass, skeletal muscle mass, bone mineral content, fat mass, and body weight.

Symptoms of Anxiety and Depression

Symptoms of anxiety and depression will be assessed via the Hospital for Anxiety and Depression Scale. This scale comprises 14 questions, divided into 2 subscales: anxiety and depression. The final score indicates probably not anxiety or depression, questionable or doubtful anxiety or depression, and probable anxiety or depression [40].

Health-Related Quality of Life

HRQoL will be assessed using the European Organization for Research and Treatment of Cancer Core Quality of Life

XSL•FO
RenderX

Questionnaire (EORTC QLQ-30) [41]. The specific module for lung cancer (QLQ-LC13) [42] will also be used. Higher scores in physical scales and global health scales indicate greater HRQoL, whereas higher scores in symptoms scales indicate worse symptoms and poorer HRQoL [41].

Symptoms Related to the Treatment and Disease

The Memorial Symptom Assessment Scale (Portuguese version) will be used to assess symptoms related to the treatment and disease. This scale comprises items related to psychological and physical symptoms [43].

Other Measures

Any change in the initial cancer treatment dose prescribed will be investigated via the participant's medical records. Participants (or their support person) will receive phone calls at 3, 6, 9, and 12 months after the reassessment date. The number of hospitalizations at 3, 6, and 9 months as well as 12-month survival will also be recorded. Satisfaction with the semisupervised home-based exercise training program will be assessed using a questionnaire that comprises 2 questions [44]. Participants will rate, on a scale ranging between 0 and 10, their satisfaction with performing the exercise training program and how valuable the exercise training program was for them. Higher scores indicate greater satisfaction.

Sample Size Calculation

The sample size was determined using published data on the effectiveness of exercise training in improving peripheral muscle strength in patients with cancer [45]. Forty participants will be needed to detect a between-group difference of 72 (SD 71) newtons on the specific primary outcome: knee extensors' muscle strength [46] (power of 80%, adopting an α of 5%). This calculation accounts for 30% loss to follow-up.

Data Management and Analysis

The statistical software SPSS (version 23.0; IBM Corp) will be used. The distribution of the data will be assessed by the Shapiro-Wilk test. Continuous data will be expressed as either mean (SD) or median (IQR) according to their distribution. The criteria that define the exclusion of the participant from the final data analysis will be (1) initiation of palliative care or (2) substantial physical impairment due to hospitalization during the intervention period. For data that are normally distributed, both within- and between-group differences will be assessed using the 2-way repeated measures ANOVA. Between-group differences will be reported as the mean difference and 95% CI [47,48]. For data that are not normally distributed, within-group differences will be assessed using the Wilcoxon test, whereas between-group differences will be assessed using the Mann-Whitney *U* test. To evaluate the effect size between groups, the Cohen *d* test will be used. For all analyses, a *P* value of <.05 will be considered significant. The within-group change from baseline to postintervention will be assessed via either a 2-tailed paired *t* test or the Mann-Whitney *U* test. The chi-square test will be used to analyze hospitalization frequency at 3, 6, and 9 months, and the hazard ratio will be used to report on 12-month survival. Analyses will be undertaken according to the intention-to-treat principle.

Results

In February 2021, the clinical trial registration was approved. Recruitment and data collection for the trial are ongoing, and the results of this study are likely to be published late in 2024.

Discussion

Potential Impact and Significance of the Study

This study protocol has been developed after a thorough literature search on exercise training for people with cancer, specifically lung or head and neck cancers. The implementation of this novel exercise training protocol, which will be based on a semisupervised home-based program delivered as a complementary treatment in people with lung or head and neck cancer, will investigate whether the program will promote a protective effect on physical function, body composition, and self-reported outcomes. Further, the study will also explore the effects of the program on any change in initial cancer treatment dose prescribed; hospitalizations at 3, 6, and 9 months; and 12-month survival.

Strengths and Limitations of the Study

This study will be a single-blinded (outcome assessor) randomized controlled trial in which participants allocated to the TG will undergo an individualized home-based exercise program. The study will be the first to include both people with lung cancer and those with head and neck cancer. In addition to reporting the effectiveness of the proposed intervention on important health outcomes, this novel study will also explore the effects of the proposed intervention on any change in the initial cancer treatment dose prescribed; hospitalizations at 3, 6, and 9 months; and the 12-month survival rate. As in any study in the field of exercise training, blinding of participants and personnel is very challenging, and in this case, it is not possible. The study will only be conducted in a single center, which may limit its external validity. However, the robust reporting of our methods will allow replication in future multicenter studies.

Contribution and Clinical Applicability

The proposed complementary semisupervised home-based exercise training program is of low cost. If shown to have a positive impact on the outcomes of interest, the program will likely impact long-term outcomes such as hospitalizations and 12-month survival and is likely to be implemented in routine-practice cancer exercise or pulmonary rehabilitation programs delivered in settings such as outpatient clinics, rehabilitation centers, and community programs.

Conclusions

The proposed exercise training program as a complementary treatment for patients with lung or head and neck cancer is likely to promote positive effects on the physical and mental health outcomes assessed, over and above any change in the CG, and prevent the reduction of initial cancer treatment dose prescribed, which will likely impact long-term outcomes such as hospitalizations and 12-month survival. If shown to be effective at improving outcomes, the semisupervised exercise training

XSL•FO
RenderX

protocol is likely to be implemented in clinical practice across many cancer and pulmonary rehabilitation programs worldwide.

Acknowledgments

This study is supported by the São Paulo State University and Regional Cancer Hospital of Presidente Prudente, which allowed the development of this research and provided structural support. IG is funded by São Paulo Research Foundation (FAPESP; grant 2019/16004-1), National Council for Scientific and Technological Development (470742/2014-3), and CAPES (grant 001). EMCR is funded by FAPESP (grant 2021/06065-3). We highlight that this support did not have any influence on this study's development; also, this study has not undergone peer review by any funding body.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

IG, VC, FFDL, and EMCR contributed to the development of the exercise protocols presented in this study and to the writing and commented on all versions of this study protocol. IG, EMCR, KP, ERMF, DGR, and NI are involved in recruiting and collecting data. IG, VC, FFDL, KP, and EMCR will conduct the analysis. All authors approved the final version of the manuscript.

Abstract

Background: Clinical rehabilitation for brachial plexus injury is difficult in terms of chronic pain and dysfunction. Physiotherapy is considered a routine intervention for rehabilitation. Common physical therapy may require a variety of instruments. One approach that does not need instruments, but belongs to the field of complementary and alternative medicine, is naprapathy. Naprapathy, also called Tuina in China, has been applied in rehabilitation after brachial plexus injury for a long time. Naprapathy can relieve chronic neuropathic pain, promote local blood circulation, and improve body edema. Naprapathy can passively help improve motor functions in patients with peripheral nerve injury. However, the efficacy of naprapathy in improving rehabilitation after brachial plexus injury is unclear.

Objective: This study aims to evaluate the additional value of naprapathy when combined with conventional physical therapy for the treatment of brachial plexus injury.

Methods: This will be a single-center randomized controlled trial. A total of 116 eligible patients with brachial plexus injury will be randomly divided into an experimental group (naprapathy plus physical therapy group) or a control group (physical therapy group). The participants will be followed up for 4 weeks of treatment. Observation outcomes will include the visual analog scale score, upper limb index, electromyography findings, and adverse reactions, among others. The measuring points for outcomes will be the baseline and the completion of treatment. In addition, a quality control group independent from the research team will be set up to control the quality of the trial. Finally, the data will be analyzed using SPSS software (version 21.0; IBM Corp).

Results: The study is recruiting participants. The first participant was enrolled in September 2021. As of January 2023, a total of 100 participants have been enrolled. The trial is expected to be completed by September 2023. The study protocol was approved by the Ethics Review Committee of Yue Yang Hospital affiliated with the Shanghai University of Traditional Chinese Medicine (2021-012).

Conclusions: One limitation of this trial is that we will be unable to achieve strict double-blinding because of the features of naprapathy. The trial aims to contribute reliable evidence for decision-making in naprapathy for treating brachial plexus injury.

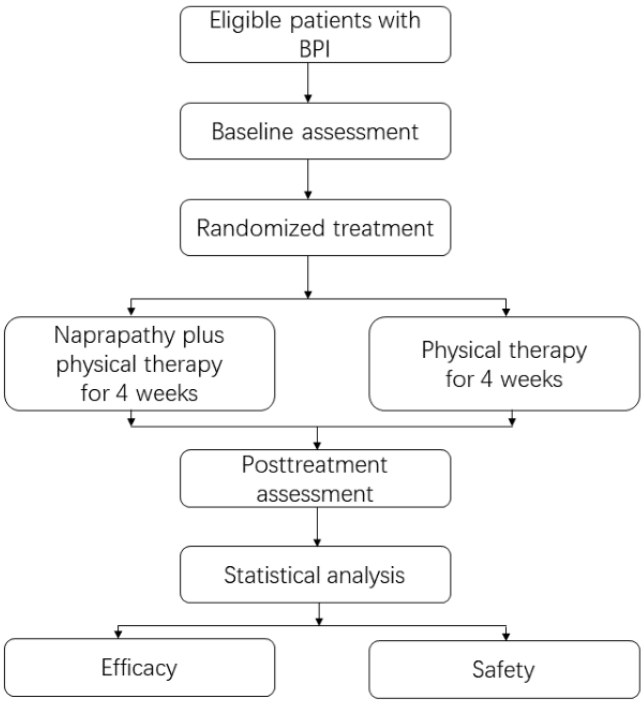
Introduction

Brachial plexus injury (BPI) is one of the most challenging problems in modern medicine because of its high disability rate, surgical difficulty, and complex sequelae [1]. It is mostly caused by injuries such as a motorcycle accident, birth injury, bruising, puncture injury, fracture, dislocation, and lung apex tumor resection [2-5]. Sensory impairment or muscle paralysis and atrophy, which cause partial or complete upper limb motor and sensory dysfunction, may place a great burden on the patient's life and mental health [6,7]. With the development of microsurgical technology in recent decades [8], great progress has been made in the treatment of BPI, especially in terms of surgical treatments [9,10], allowing good conditions for the functional recovery of patients' limbs to be provided. There are also some rehabilitation methods, such as medium-frequency electrical stimulation, infrared irradiation, ultrasound therapy, and so forth, but the effects are not satisfactory [11,12].

The ability of an injured nerve to regenerate is closely related to the repair time, with 1 to 3 months after injury being considered the “golden period” for nerve repair [13]. However, with a delayed diagnosis, the prognosis is poor. Surgical repair is only performed in preparation for the treatment of BPI; rehabilitation is the beginning of treatment and is necessary after surgery [14]. Due to differences in the condition of patients with BPI, physical therapy should be used to relieve pain, eliminate swelling, prevent scar adhesion, and joint contracture; promote nerve regeneration; and prevent muscle atrophy and joint stiffness [15,16].

At present, physical rehabilitation therapies commonly used after BPI, such as neuromyoelectric stimulation, intermediate frequency electrotherapy, and hand function training [17-19], have certain effects on upper limb function, but the effect of rehabilitation on hand function remains limited.

Naprapathy (also called Tuina therapy in traditional Chinese medicine) [20] consists of physical stimuli acting on the human body through manipulation to cause physiological responses in tissue fibers. Through the regulation of nerve reflexes and body fluids, therapeutic effects on damaged areas can be achieved. Naprapathy can promote capillary dilation, increase blood circulation, and improve muscle blood circulation such that the condition of damaged tissue can be improved and the tissue will be repaired [21]. Swelling and cramping can also be reduced or alleviated. Our previous study showed that naprapathy can improve the pain threshold in rats with neuropathic pain caused by BPI, increase the expression of β-endorphin and gamma-aminobutyric acid in the reward circuit in the brain [22], and relieve chronic neuropathic pain in rats. These findings may represent one of the neurological mechanisms of naprapathy. Naprapathy not only exerts an analgesic effect but also provides a certain comfort for patients. Patients with BPI are also willing to undergo naprapathy in the clinic. However, there is a lack of clinical research on naprapathy in the treatment of BPI. Therefore, we designed this randomized controlled trial (RCT) to evaluate the additional effects of naprapathy when combined with conventional physical therapy on pain and hand motor function in patients with BPI.



Methods

Study Design

This clinical trial will be an open-label RCT designed to compare naprapathy plus physical therapy and physical therapy in treating BPI. This protocol has been registered on the Chinese Clinical Trial Registry (2100043515) and will be performed in accordance with the Declaration of Helsinki. The study flowchart is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Study flowchart. BPI: brachial plexus injury.

Study Setting of Recruitment

Recruitment will be carried out at Yue Yang Hospital affiliated with the Shanghai University of Traditional Chinese Medicine. A total of 116 participants with BPI will be enrolled. Recruitment will be carried out through social platforms and outpatient departments. The study team will educate physicians about the study, focusing on those who do the surgery for patients with BPI. If the patients meet the inclusion criteria and are willing to participate in the trial, they will be asked to provide written informed consent. Then, they will be randomized into the naprapathy plus physical therapy group (group A) or the physical therapy group (group B) by LZ and BP.

Ethics Approval

The study protocol was approved by the ethics review committee of Yue Yang Hospital affiliated with the Shanghai University of Traditional Chinese Medicine (2021-012). Any changes including eligibility criteria, outcomes, and so forth should be reported to the Ethics Review Committee. The ethics committee of Yueyang Hospital affiliated with the Shanghai University of Traditional Chinese Medicine will audit the whole procedure during the clinical trial conducted independently from investigators and the funder. The participants signed the informed consent and agreed to the primary and secondary analyses of their data without additional consent. All the study data are deidentified. This trial has also been registered in the Chinese Clinical Trial Registry (2100043515). The results of the preliminary study will be published in a professional journal.

Patient and Public Involvement

Patients and the public are involved in the design of the study. They reviewed the study proposal and attended the design meetings. Patients and the public will be included in all research communications.

The inclusion criteria are as follows: (1) aged 18 to 70 years; (2) BPI diagnosed by history, physical examination, electromyography, or surgical exploration more than 2 weeks after nerve surgery; (3) agreement to provide written informed consent.

The exclusion criteria are as follows: (1) concurrent damage to major organs, such as the heart, kidneys, liver, and so forth; (2) severe cardiovascular or cerebrovascular disease, liver or kidney dysfunction, metabolic disease, or mental illness; (3) chronic illness, physical discomfort, frailty, severe neurosis, or pregnancy; (4) primary brachial plexus pain or brachial plexus neuritis; (5) brachial plexus pain due to cervical spondylosis, tennis elbow, carpal tunnel syndrome, frozen shoulder, biceps tenosynovitis, thoracic outlet syndrome, or other secondary causes.

The participants will be withdrawn if they have the following: (1) missing or incomplete patient treatment records, which would affect the final data analysis; (2) treatment with other methods at the same time; (3) any severe adverse reactions or other emergent symptoms during the treatment (such as aggravation of disease or severe depression and the need for special treatment).

Randomization

In this clinical trial, a total of 116 participants with BPI will be randomly assigned to either group A (naprapathy plus physical therapy) or group B (physical therapy) at a 1:1 ratio. The random sequence will be generated using SAS software (version 9.3; SAS Institute, Inc). The coauthors randomizing the participants are not linked to any statistical work.

Interventions

The treatment plan of this trial is based on naprapathy in clinical rehabilitation for the treatment of BPI. Participants in group A

XSL•FO
RenderX

will receive naprapathy in addition to physical therapy, while participants in group B will receive physical therapy only. Treatment in both groups will last 4 weeks. The interventions in this trial involve rigorous naprapathy and physical therapy schedules. To ensure the compliance of naprapathy practitioners and physical therapists with their schedules, they will be asked to undergo pretrial training, after which they will be required to pass an entrance examination to participate in this trial. All included naprapathy practitioners and physical therapists will have at least 5 years of practical experience in clinical rehabilitation.

Physical Therapy

All participants will receive physical therapy, such as neuromyoelectric stimulation by a transcutaneous electrical nerve stimulator (TENS 21, Homer Ion), medium-frequency electrotherapy by a medium-frequency electrical stimulator (ES-521, Ito), and continuous passive motion by an upper limb continuous passive motion joint rehabilitation device (2029, DJO), once each day for 5 continuous days in a week. Each therapy session will last for 40 minutes and will be performed 5 times a week (from Monday to Friday) for a total of 20 sessions in 4 weeks.

Naprapathy

For patients with total BPI, the patient will take a sitting position. The naprapathy practitioner will stand on the affected side and first apply Yizhichan (one-finger Zen) (Figure 2) pushing manipulation and press-kneading manipulation at Fengchi (GB 20, affected side), cervical Jiaji points (EX-B2, affected side), Jianjing (GB 21, affected side), Jianyu (LI 15, affected side), Quchi (LI 11, affected side), Waiguan (SJ 5, affected side), and Hegu (LI 4, affected side). Then, the practitioner will apply rolling manipulation (Figure 3) from the affected shoulder to the upper limb and grasping manipulation (Figure 4) on the neck, shoulder, and upper limb. Finally, the hand-shoulder shaking (Figure 5) method will be applied to help soothe the joints. Within the allowable safety range of the affected limbs, the joints of the upper limbs will be passively moved.

For patients with upper trunk BPI, the naprapathy practitioner will apply Yizhichan pushing and press-kneading manipulations at Fengchi (GB 20, affected side), Yunmen (LU 2, affected side), Quchi (LI 11, affected side), Shousanli (LI 10, affected side), Hegu (LI 4, affected side), Yangxi (LI 5, affected side), Sanjian (LI 3, affected side), Yuji (LU 10, affected side), and Laogong (PC 8, affected side). The other methods will be the same as above.

For patients with lower trunk BPI, the naprapathy practitioner will apply Yizhichan pushing and press-kneading manipulations at Tianzong (SI 11, affected side), Jianzhen (SI 9, affected side), Waiguan (SJ 5, affected side), Yangchi (SJ 4, affected side), Jianwaishu (SI 14, affected side), Xiaohai (SI 8, affected side), Yanglao (SI 6, affected side), Yanggu (SI 5, affected side), and Houxi (SI 3, affected side). The other methods will be the same as above.

The duration of each naprapathy session will be 20 minutes and will be performed 5 times a week (every Monday to Friday) for a total of 20 sessions in 4 weeks. If there are any adverse events, the treatment will be suspended, and the investigator will decide whether to terminate the treatment.

All the acupoints used in this study are shown in Figures 6 and 7.

Outcomes

Primary Outcome Indicator

The primary outcome measure will be the change in visual analog scale score relative to baseline at 4 weeks.

Secondary Outcome Indicators

The secondary outcomes will include the upper limb motor function score according to the Brunnstrom functional assessment and electromyography findings.

Time Points of Outcome Measurement

Outcomes will be evaluated at 2 time points: baseline and at the completion of treatment. An overview of the outcomes measured at the different time points is shown in Table 1.

Table 1. Case data collection timetable.

Time point	Baseline	Posttreatment

Safety analysis		✓

[a]VAS: visual analog scale.

[b]EMG: electromyography.

Assessment of Safety and Adverse Events

According to clinical experience and the literature, naprapathy may cause several kinds of adverse events, such as subcutaneous hematoma, edema, skin bruising, local pain, and fainting. Among these adverse events, subcutaneous hematoma and edema are the most common. Naprapathy-related safety and adverse events will be carefully recorded using case report

XSL•FO
RenderX

forms. Adverse events should be reported to the ethics committee of Yueyang Hospital affiliated with the Shanghai University of Traditional Chinese Medicine. The Ethics Committee has the right to stop the intervention of the participant.

Data Collection and Management

All our measures will be free of charge to ensure complete participation in the follow-up evaluation. Case report forms will be completed in paper form and stored by the Shanghai University of Traditional Chinese Medicine. Data will be collected according to Table 1 by investigators, and personal information about the enrolled participants will be kept in Yueyang Hospital in order to protect confidentiality in the whole trial. The ethics committee of Yueyang Hospital affiliated with the Shanghai University of Traditional Chinese Medicine will audit the trial every 12 months and will establish a data monitoring committee, which is independent from the funder and has no competing interests. The data will be stored in the clinical trial public management platform and ready for public inquiry after the trial. A quality control group independent from the research team will be set up to control the quality of this study.

Sample Size

Our previous study indicated that 58.5% of patients with BPI showed improvements in upper extremity function and muscle strength [23]. In this clinical trial, the rate of upper extremity function recovery is expected to be 75% in the naprapathy group and 55% in the physical therapy group. With α=.05 and β=.01, a total of 52 participants will be needed, as calculated using SPSS software (version 21.0; IBM Corp). According to the previous study, a 10% withdrawal rate will also be considered; therefore, each group will include at least 58 participants.

Statistical Analysis

All data will be analyzed by researchers using SPSS (version 21.0) software. Data will be expressed as the mean (SD) or median (IQR). First, the data will be tested for normality and homogeneity of variance; if the data meet the requirements for a normal distribution, the homogeneity of variance will be analyzed by the *F* test. In the case of heterogeneity, the corrected *t* test will be used. If the requirements for normality and homogeneity of variance are not satisfied, the rank-sum test will be used. If the sphericity test yields a *P* value less than .05, indicating that the assumption of sphericity is violated, we will perform multivariate analysis. A statistically significant result (P<.05) for the time factor will indicate that the measurements show a trend of changing over time. A statistically significant (P<.05) interaction between time and group will indicate that in addition to the effect of time, there are differences between the groups. If a *P* value is less than .05, the difference will be considered statistically significant, indicating a difference in the results between the two groups. If a *P* value is greater than .05, then the difference will not be considered statistically significant, indicating no difference in the results between the two groups. Cohen *d* (sample size) will also be used to compare differences between groups, and the generalized linear model will be applied to explore differences in outcomes between groups.

For safety analysis, adverse event data are generally expressed as the number of events and the percentage of cases involved in the adverse event.

Results

This study was funded by The National Natural Science Foundation of China and the Shanghai Health Commission. Yue Yang Hospital affiliated with the Shanghai University of Traditional Chinese Medicine approved the study protocol in February 2021. The first participant was enrolled in September 2021. As of January 2023, a total of 100 participants have been enrolled. The trial is expected to be completed by September 2023.

Discussion

Due to methodological design problems, the quality of currently available clinical studies on naprapathy for BPI is relatively low. Therefore, this study is designed as an RCT to evaluate the additional effects of naprapathy when combined with physical therapy on BPI in terms of pain and upper extremity motor function.

Additionally, this single-center trial will provide reliable data for our future multicenter RCTs. Participants will receive 5 treatments a week, which is the most common frequency for external traditional Chinese medicine treatments for rehabilitation after BPI.

One limitation of this trial is that we will be unable to achieve strict double-blinding because of the features of naprapathy. Other limitations include manpower, material resources and funds, and short follow-up time, and it is expected that the future study will extend the follow-up time. Naprapathy relies on the intervention of the naprapathy practitioner, and future trials could be designed with a sham naprapathy placebo group.

This study aims to provide reliable evidence for naprapathy in the treatment of BPI and will compensate for the lack of related research on clinical efficacy.

Acknowledgments

The authors thanks Yaqi Wang for assistance with the illustrations of anatomical landmarks and Xiaoyi Qu for valuable discussion. Abstract

Background: Dental caries is a serious public health issue globally. It is one of the most prevalent chronic disease in children worldwide. An important public health concern is the existence of one or more decayed, missing, or filled tooth surfaces in any primary teeth of preschool children. Early childhood caries (ECC) can be halted with the use of silver diamine fluoride (SDF) solution. Previous research has indicated that it may have a preventive impact in the treatment of ECC. It is well known that 38% silver diamine fluoride (SDF) is helpful at preventing dental caries. On the other hand, there is not enough evidence on SDF's ability to prevent caries in primary teeth. To date, no well-planned clinical study has been carried out to investigate SDF's impact on caries protection.

Objective: The study's objective is to evaluate and compare the efficacy of 12%, 30%, and 38% silver diamine fluoride in preventing ECC in children aged 24 to 72 months in Mangaluru Taluk.

Methods: This is a single-center, randomized, active-controlled, parallel-group pragmatic trial. Children attending preschool in Mangalore Taluk aged 24 to 72 months will be included in the study. There will be three study groups: group 1 will receive 12% SDF semiannually; group 2 will receive 30% SDF semiannually; and group 3 will receive 38% SDF semiannually. After 6 and 12 months, the principal examiner will conduct a clinical examination of the teeth with a visual and tactile assessment. The effectiveness of the various concentrations of SDF will be determined after 12 months.

Results: The research was funded in September 2020, and data collection started in September 2022. As of February 2023, 150 participants have enrolled in the study. The project is still underway, and it is expected to be completed in December 2023.

Conclusions: Uncertainty surrounds the efficacy of 38% SDF in preventing ECC. Consensus-Based Clinical Case Reporting (CARE) guidelines recommending the use of SDF for ECC prevention will be modified if the findings are as expected. Additionally, since the findings will be broadly disseminated, more nations will implement the use of SDF, easing the burden of ECC on the entire world. Future research on the treatment and prevention of ECC will benefit from the study results. If SDF is successful in preventing caries in a classroom or community context, it will mark an important turning point for preventive dentistry.

Introduction

Background

Dental caries is a complex, bacteria-driven, chronic, site-specific, and significant process brought on by a physiological imbalance between minerals in teeth and the fluid in plaque [1]. It is a progressive condition that results from the demineralization of dental enamel caused by the acids generated during the metabolism of sugars by cariogenic bacteria [2] and is one of the most prevalent chronic childhood illnesses; in developing nations, many decayed teeth go untreated. The World Health Organization (WHO) estimates that there are an average of 2.4 decaying, missing, and filled teeth per person worldwide. Dental caries continues to be a significant problem in the majority of developed nations, impacting 60% to 90% of school-aged children. In many industrialized nations, there have been encouraging trends in the fight against pediatric dental caries. In India, where more than 70% of the population lives in rural areas with few health services and restorative therapy is expensive, parents tend to neglect their children's dental needs, leading to untreated dental caries [1].

The term early childhood caries (ECC) has been used to describe the presence of one or more decayed, restored, or missing primary teeth in a child younger than 6 years [3]. The American Dental Association has classified the presence of one or more decayed, missing, or filled tooth surfaces in any primary tooth in a preschool-aged child as a major public health concern. If ECC is not addressed, it may affect a person's quality of life in terms of dental health, as well as their body weight, growth, attendance at school, and academic achievement. Measures to prevent and treat severe ECC are essential for both general and dental health because it is a major indicator of adult caries [4].

Poor oral health–related quality of life, low BMI, bad scholastic results, and high absenteeism from school are just a few of the harmful impacts of untreated dental caries that can have an impact on physical development. Due to their vulnerability and reliance on their caretakers for both nutritional requirements and mouth cleanliness, children are most at risk of developing dental caries. Dental caries frequently exhibits no symptoms in its early phases, but if left unchecked, it can cause excruciating pain and potentially fatal infections [3].

ECC prevalence varies from population to population. The illness is most prevalent and severe in East Asia, where prevalence rates in children aged 3 years range from 36% to 85%. In India, 44% of children aged between 8 and 48 months have ECC. Despite tremendous advancements in the field of caries control in recent decades, a high prevalence of ECC in young infants has been observed. It is thus a major social concern; disease control can be accomplished if the demographic groups with the greatest needs are identified. The prevalence of ECC overall in India is 49.6% according to an analysis of all included studies. While in Karnataka state, the prevalence of ECC was reported to be 48.79% [5].

The current cost of treating oral diseases, such as dental caries, places a heavy financial burden on both households and health care providers. Additionally, because of the high expense of dental treatment, elderly adults, socially excluded groups, and children living in poverty are more likely to develop oral diseases. Moreover, even if people have access to therapy, the current course of action for children with severe caries includes giving them local anesthesia to ease their pain and worry. Such treatments have been linked to poor oral health, dental anxiety, and a higher risk of dental caries in children's permanent teeth in later life. In order to prevent and manage caries and encourage health and well-being, new, accessible, and equitable methods are required [6].

Nonrestorative intervention is a potential alternative method for treating caries in primary molars. Silver diamine fluoride (SDF) has been used successfully to stop the progression of carious lesions in people who cannot tolerate invasive treatment, including children, the elderly, people with medical conditions, and people who require additional care and support. Even though the mechanism of action of SDF is debatable, SDF treatment has been shown to support tooth desensitization and to arrest carious lesions through dentinal tubule blockage, cariogenic bacterial death, remineralization of the demineralized tooth, and inhibition of dentinal collagen degradation. Hence, SDF is a cost-effective, reliable, secure, and efficient caries-prevention substance [6].

Japan authorized the use of silver diamine fluoride (SDF) as a medication in the 1960s. It has been used for many years to cure dental caries in China, Australia, Brazil, Argentina, and Australia. The US Food and Drug Administration authorized the first SDF product for use in the country in 2014. Since 1969, SDF has been used to prevent tooth decay in young children's primary teeth and pit and fissure caries in developing permanent molars, as well as to treat root caries in geriatric patients. In addition to treating caries, SDF is also used to sterilize infected root canals and treat dental hypersensitivity. It can be applied directly to a carious lesion to arrest the spread of caries or to a caries-prone surface to prevent caries [7].

Although some drawbacks of SDF have been reported, such as staining, its safety has been strongly backed by the fact that not a single untoward event has been connected to its use since it was introduced in Japan. Recent Hong Kong–based randomized controlled studies showed that SDF can decrease carious lesions

XSL•FO
RenderX

among children, if SDF is administered twice a year at a concentration of 38%. This method is advised because it can arrest caries without leading to excessive staining. However, after 6 months, it was discovered that a single application of SDF at a concentration of 38% was effective in halting dentinal caries in the primary anterior teeth of preschoolers [6].

SDF has the ability to prevent discomfort, sepsis, and the requirement for extractions if applied early, when the cavity is evident but has not yet resulted in permanent pulpal injury. A 38% SDF solution is more efficient than a solution with a lower concentration, and biannual application is superior to annual application. The use of SDF encourages participation and community support from parents who do not seek dental consultation for their children. Additionally, silver-modified atraumatic restorative therapy is an appealing option that improves treatment results. SDF can increase accessibility and equity in dental care, particularly for people from low socioeconomic backgrounds [6].

A study done by Fung and colleagues in 2018 [8] compared 12% and 38% SDF and found that decay was more substantially arrested when using the higher concentration. Neither that report nor the clinical trial registry listing provides the details of product origin. Further, the investigators did not independently verify the concentrations, making it impossible to generalize from their findings. More research is required to completely evaluate the efficacy of SDF and identify the most effective concentration in order to set guidelines. This study will add on to existing literature, as the SDF product used in our study has not been trialed before. The procedure can be used in basic care settings and could ease the population's burden of untreated tooth decay. SDF has the potential to play a significant role in comprehensive and successful preventative initiatives to achieve the UN Sustainable Development Goals. We hypothesize that both 12% and 30% SDF will have comparable efficacy with 38% SDF.

Objective

To assess and compare the effectiveness of 12% SDF, 30% SDF, and 38% SDF for treatment of early childhood caries among children aged 24 to 72 months in Mangaluru Taluk.

Methods

Trial Design and Protocol Development

This is a single-center, randomized, active-controlled, parallel-group pragmatic trial. This clinical trial protocol's design and report adhere to the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) declaration. The trial schedule is shown in Figure 1.

Figure 1. Schedule of enrollment, intervention, and assessment of groups that received 38%, 30%, and 12% silver diamine fluoride.

Study Setting

The study is being carried out at preschools of Mangaluru Taluk, South India. The dental examinations are performed after receiving confirmation of participation from preschool teachers or caregivers, and informed consent forms (Multimedia Appendix 1) are sent to the parents of the eligible children. Signed parental consent is collected before the intervention starts.

XSL•FO
RenderX

Participant Selection

Children attending preschools in Mangalore Taluk aged from 24 to 72 months are included. Additional inclusion criteria are as follows: at least one soft caries lesion (ie, cavitated active caries lesion) that is small (less than half of the mesial or distal or less than one-third of the buccal, lingual, or occlusal surfaces). The exclusion criteria are pulpal exposure, history of pain, nonvital teeth, swelling or fistula, silver allergy, arrested caries or inactive lesions, teeth at the period of shedding, restored teeth, secondary caries, fluorosis, enamel hypoplasia, uncooperative behavior, physical or mental disability, and a lack of signed informed consent.

Baseline and Follow-up Oral Examinations

Before conducting the trial, the principal investigator was trained and calibrated by experienced dental public health specialists in the Caries Assessment Spectrum and Treatment (CAST) index. Training and calibration sessions included theoretical aspects and were followed by clinical examination of a group of 10 subjects from the outpatient department. The subjects were reexamined by the principal investigator and the guide (an experienced dental public health specialist) after 1 week. The κ coefficient values for intraexaminer and interexaminer reliability were 0.88 and 0.80, respectively, reflecting a high degree of conformity in the observations.

The examinations in this study are performed by a single examiner with the help of a recording device in preschools in Mangaluru Taluk. The study sample comprises 3 groups of children aged 24 to 72 months. After baseline examination, eligible children are randomly allocated to 1 of the 3 groups using the lottery method. Group 1 receives 12% SDF semiannually, group 2 receives 30% SDF semiannually, and group 3 receives 38% SDF semiannually. Dental caries will be measured using the CAST index [9].

A CAST score of 0 is given to sound teeth (ie, with no visible evidence of a distinct carious lesion); a score of 1 for pits or fissures that are at least partially covered with a sealant material; a score of 2 for cavities that have been restored with a direct or indirect restorative material; a score of 3 for distinct visual change in the enamel only or clearly visible caries-related discoloration, with or without localized enamel breakdown; a score of 4 for internal caries-related discoloration in the dentine, with the discolored dentine visible through the enamel, which may or may not exhibit a visible localized breakdown; a score of 5 for distinct cavitation into the dentine with the pulp chamber showing intact pulp; a score of 6 for involvement of the pulp chamber with distinct cavitation reaching the pulp chamber or with the presence of only root fragments and abscess or fistula; a score of 7 for pus-containing swelling or a pus-releasing sinus tract related to a tooth with pulpal involvement; a score of 8 for teeth that have been removed because of dental caries; and a score of 9 for teeth that do not match any of the above descriptions.

All tooth surfaces, including the buccal, lingual, mesial, distal, and occlusal surfaces for posterior teeth, are evaluated for caries. Miller's criterion is used to assess whether active caries are present; Miller's criterion suggests that a carious lesion is termed active if a blunt University of North Carolina–15 probe can easily enter it; a carious lesion is defined as halted when the dentine cannot be penetrated.

The size of the lesion is categorized as small or large at the tooth-surface level (less than one-third of the buccal, lingual, or occlusal surface, or less than half of the mesial or distal surface).

Intervention

Drug Description

The SDF in this study is Caries Stop (Biodinamica); it was used at product concentrations of 12%, 30%, and 38%. The investigators did not independently verify the concentrations stated by the manufacturer. The product is composed of fluoridric acid, silver nitrate, ammonia hydroxide and deionized water.

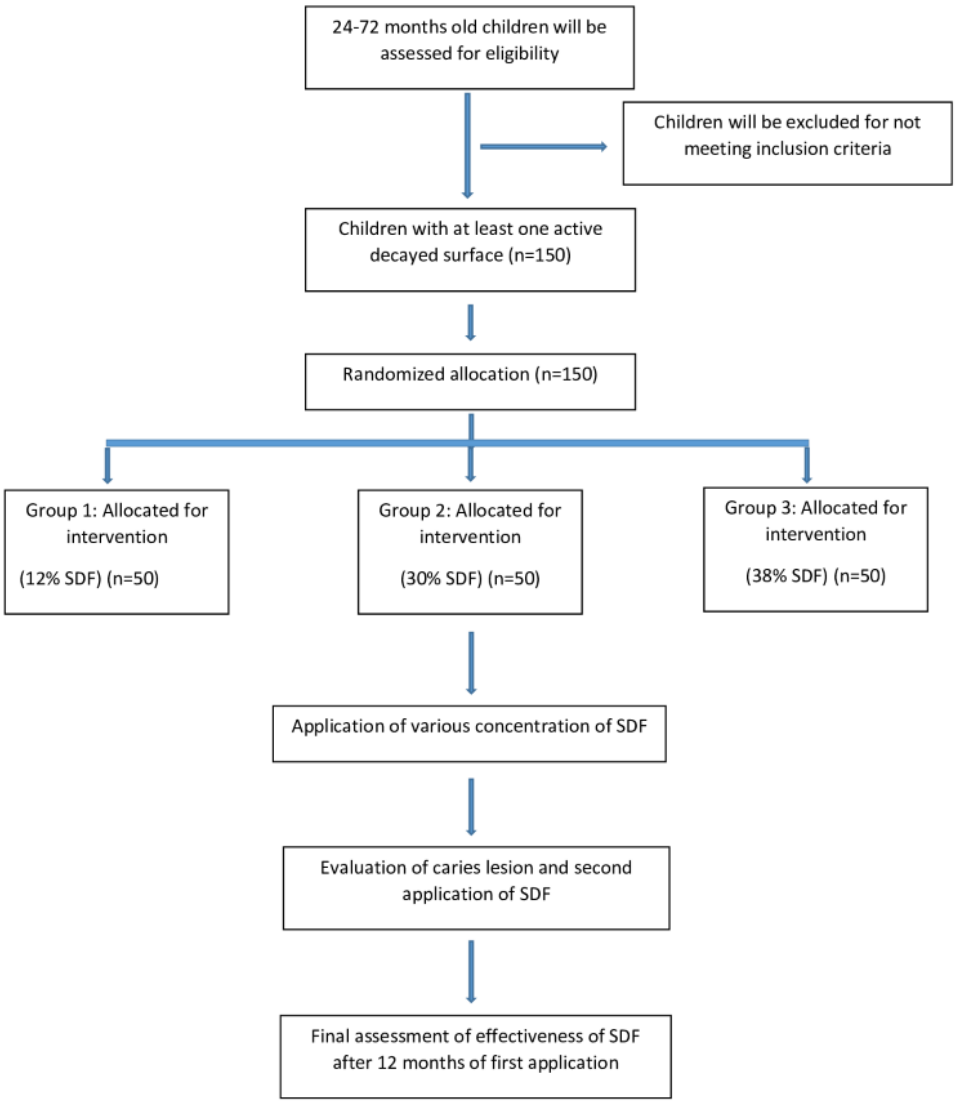
Application of SDF

Primary teeth that have cavities are separated and kept dry using cotton rollers. A plastic dish is prepared that contains 1 drop of SDF. Using a tiny brush, the SDF is administered to the carious lesion for 2 minutes. The excess is eliminated by gently wiping with another cotton pellet. The children are requested to avoid any dietary intake for an hour after application. At 6 months after the first application, a second application will be carried out. After 6 and 12 months, the principal examiner conducts a clinical examination of the teeth with a visual and tactile assessment. After a year, the efficacy of the various SDF concentrations will be evaluated.

Outcome Measure

The primary outcome measure is caries arrest at the twelfth month of application of SDF. The secondary outcome measure is the caries increment (ie, CAST index).

Effect Modification



A parental questionnaire is administered at baseline regarding the children's oral hygiene habits (eg, tooth brushing), fluoride agent use (eg, fluoride toothpaste), dietary habits (eg, bottle feeding), and source of drinking water.

Randomization and Treatment Allocation

The study is being conducted in preschools in Mangaluru Taluk. Multistage random sampling was used to select the preschools, with the following stages: (1) Mangaluru Taluk was divided into north and south zones; (2) preschools in Mangaluru Taluk were divided into government schools, government-aided private schools, and non–government-aided private schools; and (3) children were selected randomly from 437 preschools (n=218 from the south zone and n=219 from the north zone). Children were randomly allocated to 1 of the 3 groups using the lottery method. The study sample comprises 150 students aged from 24 to 72 months attending preschools in Mangaluru Taluk, including 50 students in group 1 (12% SDF semiannually), 50 students in group 2 (30% SDF semiannually), and 50 students in group 3 (38% SDF semiannually), as shown in Figure 2.

XSL•FO
RenderX

Figure 2. Enrollment and allocation of sample. SDF: silver diamine fluoride.

Random Allocation, Concealment, Masking, and Blinding

Allocation concealment was done using the sequentially numbered opaque sealed envelope method. A random code for each participant was put in an opaque package as part of a randomization system. Masking is used for the products, which are indistinguishable in terms of consistency, packaging, and labeling. The researchers applying the products are unaware of what product is being applied. A dentist's aide opens the envelope, and the materials are then prepared after the child's designated actions in accordance with their group allocation. The children and parents are blinded regarding their grouping. The principal examiner, who is blinded to the participating children's group assignment, performs a clinical evaluation of the children at baseline and at semiannual follow-up exams. The dentist's aide is unblinded to the interventions and aids in allocating the participants to the principal examiner. The participant's allocated intervention during the trial will be revealed to the principal examiner only after the follow-up is completed.

Sample Size Estimation

Based on the previous studies, the anticipated proportion of sound occlusal surfaces at baseline that develop into cavitated dentin lesions at the 30-month follow-up is approximately 25% [3].

Sample size calculation was performed with G* Power 3 (Heinrich-Heine-Universität Düsseldorf). Based on a 5% level of significance, power of 80%, effect size of 0.63, and 3 groups, the required sample size is 120, including 40 in each group. Considering a drop-out rate of 20%, the final sample size is 150, as shown by the following equation: final sample size = ND = N / (1 – d), where *N* is the sample size before drop-out, *d* is the expected drop-out rate, and *ND* is the sample size considering drop-out. Thus, ND = 120 / (1 – 0.2) = 120 / 0.8 = 150, and the total sample required for intervention is 150 (50 in each group). The allocation ratio is 1:1:1. The participants are allocated to the 3 groups equally.

XSL•FO
RenderX

Statistical Analysis

Data analysis will be done using SPSS (version 23.0; IBM Corp). Continuous variables will be presented as the mean (SD). Categorical variables will be presented as frequencies and percentages. To confirm normality, the Shapiro-Wilk and Kolmogorov-Smirnov tests will be used. A one-way analysis of variance (ANOVA) statistical test will be used to compare the means of continuous outcome variables if the data follow a normal distribution. Nonparametric tests (ie, the Kruskal-Wallis statistical test) will be used in the data analysis in cases when there is skewed distribution of data. Post hoc tests will be performed with an ANOVA or the Kruskal-Wallis test.

Binary logistic regression will be performed. The dependent variable will be whether the lesion is arrested or not at the 12-month examination, and the independent variables will include the children's oral hygiene habits (eg, tooth brushing), fluoride agent use (eg, fluoride toothpaste), dietary habits (eg, bottle feeding), and source of drinking water.

Ethical Considerations

Ethical approval has been obtained from the Institutional Review Board (Ethics Committee II) of Yenepoya (Deemed to be University) for protocol version 3 (YEC2/175). Research aides will serve as contact people and be involved in all phases of the trial. Parents or legal caretakers of the children are given an information sheet outlining the purpose of the study, the specifics of the research, and the processes after the principals consent to participate in the study. Parents are informed of the side effects of the treatment, notably staining of the tooth. Their queries regarding the side effects are addressed. Before beginning this trial, informed consent is obtained. The participants, including the children and their guardians, are free to withdraw at any time during the study. They are also allowed to pursue additional dental care according to their own decisions and financial means.

Caries assessment is done with aseptic precautions and without any harm to the patient. The application of 12% SDF, 30% SDF, or 38% SDF is also done with aseptic precautions and without any harm to the patient. If any complications take place, the child is treated free of charge by the principal investigator.

The study data will be deidentified for privacy and confidentiality protection. No compensation will be offered to the study participants.

The drugs were sponsored by Biodinamica. This drug company has no role in the research.

The Drug Controller General of India does not normally restrict the use of topically applied drugs. Currently, there are also no official guidelines announced for SDF use by dental professional associations or research bodies [10].

Risks of the Study

There are no major known risks to the study. Minor risks, such as black stains on the carious tooth surface or temporary stains on the skin, will occur. Temporary stains on the skin disappear within 48 hours without treatment.

Withdrawal Criteria

During semiannual applications, clinical examination for caries will be done. If any pulpal involvement or abscess is noticed, appropriate treatment will be provided by the principal investigator. The children will be given the right to refuse or withdraw at any point in time.

Maximum Dose and Safety Margin

The margin of safety for dosing is of paramount concern. The typical lethal dose, 50% (LD 50), for oral administration is 520 mg/kg. One drop (25 µL) contains 9.5 mg SDF and is sufficient to treat 5 teeth. The dose will be 0.95 mg/kg, and assuming that the smallest children with caries weigh between 10 kg and 15 kg, the relative safety margin for administering a whole drop to a child weighing 10 kg is therefore 380 mg/kg LD 50 / 0.95 mg/kg dosage, for a 400-fold safety margin. The actual dose will probably be much lower. One drop (25 µL) per 10 kg per treatment session is the suggested upper limit. The largest applied dose for 3 teeth is 2.37 mg, allowing for more than 400 applications [11].

Adverse Effects

Information on adverse effects of SDF treatment—including tooth or gum pain, gum swelling, gum bleaching (ie, becoming whiter), and systemic toxicity (nausea, vomiting, and generalized discomfort)—is collected through a parental questionnaire within a week of SDF or placebo application at baseline and at 6- and 12-month follow-ups. If there is an acute systemic illness associated with SDF treatment, the parents are asked to immediately contact the principal investigator by telephone. Oral examinations will also be performed at baseline and at 6- and 12-month follow-ups. An examiner will evaluate the hard and soft tissues to establish changes and visible alterations during the clinical examination. All changes will be recorded on a case report form.

Results

The research was funded in September 2020, and data collection started in September 2022. As of February 2023, 150 participants were enrolled in the study. The project is still underway and is expected to be completed in December 2023. The findings of this study will be beneficial for future studies and the management of early childhood caries.

The information obtained from the study will be submitted to the institution and to the concerned authorities. The details of the study will be published in journals and presented at conferences.

Discussion

Principal Aims

The purpose of this single-center, randomized, active-controlled, 3-arm pragmatic trial is to evaluate and compare the efficacy of 12%, 30%, and 38% SDF in preventing early childhood caries in children aged 24 to 72 months. We are using 38% SDF, which is thought of as the standard of care for preventing ECC, in a

XSL•FO
RenderX

positive control group to determine if 30% and 12% SDF are superior.

Our hypothesis is that 38% SDF will have a superior effect compared to 30% and 12% SDF in stopping ECC, because it has a fluoride concentration that is much higher (44,800 ppm) than 30% (35,400 ppm) or 12% (14,100 ppm) SDF. The standard of care will be altered if the results are as expected. Because every child who enrolls in the study should have the right to obtain an efficient preventative strategy, there is no negative control group.

In this study, we evaluate the ability of 12%, 30%, and 38% SDF to arrest ECC. The use of SDF solutions in a clinical setting has been deemed safe, and the application process is noninvasive. Despite the fact that the participants in this study are recruited at a young age, few ethical questions have been raised.

In order to examine the efficiency of 12% and 38% SDF in halting dentin caries in the primary teeth of preschool children, Fung et al [8] undertook a randomized clinical experiment. Other recent research indicates that 38% SDF is more effective than 12% SDF. In a clinical trial, Vollú et al [12] compared the effectiveness of 30% SDF and atraumatic restorative treatment in halting dentine caries in the primary molars of preschoolers. Recent research revealed that 30% SDF could stop caries lesions with effects comparable to those of atraumatic restorative treatment.

The findings of this trial, performed in young children who are in good health, may not be generalizable to other populations of children, such as those who require special medical attention or are older, which is a limitation of this study. It will be necessary to perform additional research on the preventive impact of SDF in individuals with special health care requirements. The generalizability of the study will also be limited by the fact that clinical trials in different countries use different parameters for caries assessment.

The study outcomes will be widely disseminated, which should encourage the adoption of SDF in other nations and lessen the global burden of ECC. SDF may even become a crucial component of comprehensive and successful preventative programs to achieve the UN sustainable development goals.

Conclusions

The findings of this study will be beneficial for future studies on the management and prevention of ECC. If SDF is found to be effective in a school or community setting for caries prevention, it will be a significant milestone for preventive dentistry.

Acknowledgments

This study received financial assistance from the Indian Council of Medical Research Division of Human Resource Planning and Development for MD, MS, DM, McH, and MDS theses in 2020. Funding support for the publication of this article was received from Manipal Academy of Higher Education (MAHE), Manipal, India. Abstract

Background: In the emergency department (ED), medical procedures, such as arterial blood gas (ABG) testing, can cause pain and high stress levels. However, ABG testing is a routine procedure assessing the severity of the patient's condition. To reduce the pain of ABG, several methods have been investigated without significant difference in pain perception. Communication, a key element of care, has shown a significant effect on pain perception. A positive communication strategy, including positive, kind, or reassuring words, can reduce pain perception, while negative words can raise this perception, causing discomfort, known as the “nocebo effect.” Although some studies have compared the impact of verbal attitudes, particularly in anesthesia and mainly with staff already trained in hypnosis, to the best of our knowledge, none have investigated the effect of communication in the emergency setting, where patients may be more suggestible to the words used.

Objective: In this study, we will investigate the effect of positive therapeutic communication on pain, anxiety, discomfort, and global satisfaction in patients requiring ABG compared to nocebo and neutral communication.

Methods: A single-center, double-blind randomized controlled trial (RCT) with 3 parallel arms will be conducted with 249 patients requiring ABG during their ED visit. Patients will be randomly assigned to 1 of 3 groups before receiving ABG: positive communication group, negative communication (nocebo) group, or neutral communication (neutral) group. The communication and the words used by the physicians during hygiene preparation, artery location, and puncture will be imposed in each group. The study will be proposed to each patient corresponding to the inclusion criteria. The physicians will not be trained in hypnosis or in positive therapeutic communication. The procedure will be recorded with audio recorders to test its quality. Intention-to-treat analysis will be performed. The primary endpoint is the onset of pain. The secondary outcomes are patient comfort, patient anxiety, and global satisfaction of the patient with the communication strategy used.

Results: On average, 2000 ABG procedures are performed each year in the EDs of hospitals. In this study, 249 patients are expected to be included. With a projected positive response rate of 80%, we intend to include 25 (10%) patients per month. The inclusion period began in April 2023 and will run until July 2024. We hope to publish the results of the study during the fall of 2024.

XSL•FO
RenderX

Conclusions: To the best of our knowledge, this study is the first RCT assessing the use of positive communication on pain and anxiety in patients undergoing the ABG procedure in the ED. A reduction in pain, discomfort, and anxiety is expected when using positive communication. If the results are positive, this could be useful to the medical community and encourage clinicians to monitor their communication during care.

KEYWORDS

pain; therapeutic communication; nocebo; emergency department; arterial blood gas; anxiety; positive therapeutic communication

Introduction

Pain, defined as a disagreeable sensory or emotional experience, is the most frequent symptom among patients admitted to the emergency department (ED). Karwowski-Soulié et al [1] estimate that this symptom can be observed in almost 80% of patients upon their arrival to the ED. Despite several international recommendations concerning pain management [2,3], pain in the context of an emergency often remains underestimated [4]. Medical procedures, such as venous or arterial blood collection, which are essential for diagnostic management and patient care, can also generate pain and a high level of stress for patients who are already weakened by their underlying condition [5]. This is known as "care-related pain" [6].

Arterial blood gas (ABG) sampling is necessary to assess the gravity of the patient's condition and is a procedure conducted routinely in the ED. In a medium-size hospital (30,000 hospitalizations per year), approximately 1000 ABG tests are conducted annually [7]. However, arterial blood collection is generally associated with pain and patient anxiety [8].

To decrease the perception of pain linked to the collection of arterial blood, several methods have been studied, such as applying a topical anesthetic cream (eg, lidocaine, xylocaine) or administering a subcutaneous injection of lidocaine prior to the procedure [9]. Given that arterial blood collection is often performed in emergency situations and that the anesthetic cream must be applied at least 1 hour before sampling, this method is not adapted to emergency practices. In a previous study, a subcutaneous injection of lidocaine did not allow a significant reduction in pain during radial artery puncture [10]. Similarly, another study using ultrasound guidance for arterial blood sampling did not show any significant decrease in pain, the rate of immediate complications, or physician satisfaction [11].

In addition to the therapeutic tools commonly used, communication is a key element of care [12]. In routine practice, caregivers inform patients that they are going to perform a potentially painful act. However, forewarning a patient that one will perform a painful act increases the perception of pain [13]. It has also been shown that a communication strategy including the use of positive, kind, or reassuring terms ("Let me reassure you…," "Are you comfortable?," "Are you warm enough?") can contribute to decreasing pain [14,15], while conversely, the choice of terms with a negative connotation ("Okay, this might sting," "Do not panic," "Are you in pain?," "Are you cold?") may increase the perception of pain and provoke a sense of discomfort [16]. In the latter case, this is known as the "nocebo" effect [15]. A communication strategy including reassuring terms, perceived by the brain as agreeable information, can reduce the pain perception. The objective of this strategy is that the painful message becomes less present as much as possible and that the patient benefits from a feeling of control. This procedure is widely used in hypnosis communication [17] and is based on a neurobiological rationale [18,19], that is, an increase in the secretion of endogenous opioids [20-25] affecting pain modulation networks [26] decreases transmission in the pain pathways [27,28], thus leading to a release of dopamine in the striatum [29]. This technique has already been shown to be of benefit in patient management [15,30] in various domains, such as anesthesia and pediatrics [15,31].

Arrival to the ED can induce a particular state of consciousness linked to anxiety and a heightened suggestibility of negative communication. Although several studies have compared the impact of verbal attitudes, notably in the domain of anesthesia and mainly with staff already trained in hypnosis, to the best of our knowledge, none have studied the effect of positive communication by caregivers or physicians among a patient population in the ED setting. Given the limited therapeutic options to relieve the pain and discomfort of blood collection performed in the ED, this study will investigate the effect of positive therapeutic communication on pain, anxiety, discomfort, and global satisfaction in patients requiring ABG compared to nocebo or neutral communication.

Methods

Study Design

This study will be a single-center, double-blind randomized controlled trial (RCT) with 3 parallel arms. To minimize bias during the intervention itself, the communication strategy will be clearly defined beforehand. The evaluator (any person [physician/student/other] assessing patient outcomes before and after arterial blood collection but playing no role in patient management in the ED or in the conducting of the procedure and without any knowledge of the study arm assigned to the patient at randomization) will be blinded to the strategy used.

Setting

Patients will be recruited at the adult ED of the Cantonal Hospital of Fribourg (HFR) in Switzerland. On average, 2000 ABG procedures are performed each year in the ED of the HFR.

XSL•FO
RenderX

Population and Sample

The inclusion criteria are as follows:

- Patients over 18 years of age
- Patients scheduled to undergo radial artery blood collection during their visit to the ED in order to pursue routine care
- Free and informed consent obtained from the patient

The exclusion criteria are as follows:

- Patients incapable of judgment
- Patients with conditions that render them unable to participate in the intervention in this study (eg, cognitive impairment, major hearing loss without the use of hearing aids, acute psychiatric disorders, under intravenous or oral sedation)
- Patients with an insufficient understanding of the French language, as defined by self-evaluation
- Patients in critical situation requiring immediate resuscitation
- Local anesthesia (subcutaneous, transdermal patch) at the point of ABG puncture
- Patients already treated with anxiolytics or sedatives during care in the ED

Recruitment and Screening

Potentially eligible patients for inclusion in the study will be identified by residents who will inform the senior physician responsible for triage (triage doctor [TD]) in the ED at the initial stage of patient management if arterial blood collection is required for medical care. The senior TD (triage medical consultant regulating the flow of activity in the ED, who can be a physician investigator) will proceed with recruitment as follows: “We have explained to you that we need to perform a blood gas test on a sample of blood from the wrist artery. At present, we are conducting a study to examine the patient experience with this procedure. In this context, if you accept to participate in our study, another person will ask you some questions before and after sample collection. You are free to participate and to withdraw at any point of time during the study. If you refuse, there will be no modification of your care in the ED. The data collected will be coded, and your name or any other personal information that could identify you will be removed. The entire procedure will be recorded using an audio recorder.”

The study will be proposed to all eligible individuals from among participants available 24 hours a day, 7 days a week. With a projected positive response rate of 80%, we intend to include 25 patients per month. To achieve the desired sample size, we would need 12 months to finalize study inclusion.

Data Collection

The clinician in charge of the patients will determine the indication for ABG testing according to the rules of good practice in emergency medicine (hypotension and shock, dyspnea and respiratory insufficiency, intoxication, metabolic and acid-base disorders, renal insufficiency, polytrauma, convulsions, disorders of the state of consciousness). Patients in critical situations requiring immediate resuscitation will be excluded from the study because of the impossibility of waiting for the time necessary for screening/inclusion/randomization before ABG testing, the immediate vital prognosis being engaged.

Following verification of the inclusion criteria and patient agreement, the patient will be included in the study by the senior MRT. The latter will collect written signed informed consent forms after the procedure, which will be stored in a dedicated file cabinet and locked by 1 of the physician investigators (physicians with a role in the concept, implementation, or organization of the study). The forms will then be filed in a file reserved for this purpose and stored in a secure location by the physician acting as the principal investigator (PI).

Next, the patient will be randomized to 1 of the 3 study arms by an administrative reception agent, who will use Research Electronic Data Capture (REDCap) software (Vanderbilt University) to assign the patient to a randomization arm. To maintain the blinding of those involved in the study, the administrative reception agent will give the participating physician an opaque envelope containing randomization arm details and an audio recorder. The participating physician (resident performing arterial blood collection, who can concomitantly manage the medical aspect of the patient) will only be able to open the envelope once they are in the patient booth in order to maintain the blinding of the senior MRT. They will perform arterial blood collection according to the communication method generated by the randomization arm and will be the only person aware of the patient groups.

The senior MRT will also communicate the patient ID to the evaluator. Data collection, as well as the case report form (CRF), will be completed by the evaluator before the beginning of the recording and after completion of the procedure. Data will be collected with the help of the electronic patient record and the questions asked to the patient before and after the ABG procedure. Thus, the patient will be blinded to the specific intervention status.

Implementation of Arterial Blood Collection

Sample collection will be performed in the patient booth. The booth door will be closed, and the shutter lowered during the intervention to allow noise and visual isolation. Only the physician performing the intervention and the patient will be in the booth during the procedure. At that time, the physician will open the envelope with their back to the patient at the same time as they prepare the material for the arterial puncture. They will then perform arterial blood collection by using 1 of the different standardized communication methods according to the group assigned to the patient: therapeutic positive communication, neutral, or nocebo. The physician assistants participating in the study have not received any training in hypnosis or in-depth instruction in positive therapeutic communication. They will carry out the intervention in all 3 study arms.

Before performing the procedure, the participating physician will switch on the audio recorder and record their conversation with the patient. The recording will start just before sampling. When the collection procedure is terminated, the participating physician will stop recording, place the text and the audio

XSL•FO
RenderX

recorder in the envelope, and give it to the senior MRT. The evaluator will then come to collect the audio recorder and evaluate patient outcomes by using the CRF intended for this purpose.

Arterial blood collection will be conducted in a seated position for all 3 groups. The patient will be in a supine position, with the forearm comfortably placed on a small table. The needle used for blood collection will be a 25-gauge needle without local anesthetic. This method of sampling is identical to the one used in daily practice in the ED of the HFR.

In the event of failure of the first puncture, the physician in charge of the patient will be able to use other terms corresponding to the assigned intervention group. In the event of 2 puncture failures by the participating physician, the patient will be excluded from the study.

Case Report Form

The following data will be collected and included in dedicated CRFs. The paper CRF will contain a first part with the date of the screening, the name of the medical officer who will perform the screening, the inclusion and exclusion criteria, whether the patient has been informed orally, and whether they have provided oral consent. The medical officer will confirm whether the inclusion and exclusion criteria have been met and, if so, indicate the number of the envelope containing the random allocation to 1 of the 3 study arms; this number will be the patient's ID in the study.

Once the patient is included in the study, the assessor will fill in the second part of the paper CRF before the ABG procedure: the name of the assessor, educational level, native language (French/Swiss German/German/Italian/Portuguese/other), tobacco, diabetes, first 3 outcomes, vitals (blood pressure, heart rate, respiratory rate), and time data on the ABG procedure.

After the ABG procedure, the evaluator will fill in the third part of the paper CRF, containing the 5 outcomes, the level of overall satisfaction, the vitals (blood pressure, heart rate, respiratory rate), the number of arterial punctures observed on the skin, and the type of words used by the doctor during the procedure according to the patient.

The fourth part of the paper CRF certifies that the patient has received the complete information about the study, whether the patient has consented, and, if they have consented, whether they have received a copy of the signed informed consent form.

The fifth part of the paper CRF contains the following information extracted directly from the patient's file: age, sex, first and last names of the attending physician, duration of the ED visit (difference between admission and discharge from the ED, difference between admission to the ED and the patient's placement in the cubicle), reason for admission to the ED (Swiss emergency triage scale [U1-U4]), list of emergency reasons, BMI (weight/(height in m × height in m), and the patient outcome after the emergency stay (inpatient/outpatient/death).

The evaluator will confirm the accuracy of the data collected.

Intervention Groups

During each step of the sampling (identification, disinfection, sampling) for the ABG procedure, the physician involved will communicate with the patient with a preestablished speech according to the assigned study arm. Communication sentences for each intervention group are presented in Table 1. In the case of failure of the first puncture, the intervening doctor will be able to use the second set of sentences corresponding to the assigned intervention group (also in Table 1).

XSL•FO
RenderX

Table 1. Study arms.

Study arm	Intervention/treatment
Positive therapeutic communication: Solicit the subconscious mind of the patient by asking questions that are not focused on the ABG[a] procedure. This process allows to divert the attention of the brain to more pleasant information and thus modulate the painful information. This is a standardized intervention with precise phrases.	The positive therapeutic communication group physician will say: • During identification of the arterial blood collection site: "Are you comfortably installed?," "How old did you say you were?," etc • At the time of disinfection: "How did you get to the hospital?," "What day is it?," etc • At the time of puncture: "What is the noise of the lights at your home?," "Does your car still go to the shops?," etc
Nocebo: Use of words with a negative connotation (words used frequently in daily practice in the ED[b])	The nocebo group physician will say: • During identification of the puncture site: "That's where I am going to prick you," "I am looking for the place where I will prick," etc • At the time of disinfection: "Watch out, it is cold," "It is disagreeable," "I am disinfecting the site," etc • At the time of puncture: "Watch out! I am going to prick…1, 2, 3…I am pricking," "Watch out, this is going to hurt, I am pricking," etc
Neutral: Use of words defined as neutral (ie, no negative or positive connotation but based on the description of precise facts)	The neutral group physician will say: • During identification of the site: "I am taking your pulse," "I am identifying the artery," etc • At the time of disinfection: "I am disinfecting the site," "I am cleaning your skin," etc • At the time of puncture: "I am taking the sample," "I am performing the puncture," etc

[a]ABG: arterial blood gas.

[b]ED: emergency department.

Positive Therapeutic Communication Arm

The first 2 sentences allow the gesture to be accompanied by reassuring words and positive words, while the last sentence involves the patient's subconscious by asking a question not focused on the procedure (confusion). This allows the brain to divert attention to more pleasant information and thus modulate the painful perception.

A study of a similar design, "Hypnosis and Communication Reduce Pain and Anxiety in Peripheral Intravenous Cannulation: Effect of Language and Confusion on Pain During Peripheral Intravenous Catheterization" (KTHYPE) [15], has already evaluated the impact of these sentences during the placement of a venous catheter in patients undergoing surgery and demonstrated its beneficial effects.

All the short phrases in this protocol are inspired by the KTHYPE study and have been adapted for the population and context of our study.

Nocebo Arm

The use of words with negative connotations would cause more pain and anxiety [13,18]. Warning a patient that they are going to undergo a potentially painful procedure can potentiate discomfort. In current practice, these are the words most used by emergency teams. The stress associated with the emergency consultation could further amplify the painful experience and the impact of these words by the state of hypersuggestibility that it induces.

Neutral Arm

The use of neutral terms allows precisely describing the procedure to the patient and informing them of the course of the treatment without using words with negative connotations (pain, stinging, unpleasant).

Hypotheses

The principal hypothesis is as follows: Pain perceived during the collection of an arterial blood sample in the ED is lower when it is performed using positive therapeutic communication compared to neutral or nocebo communication.

The secondary hypotheses are as follows:

- Discomfort perceived during the collection of an arterial blood sample in the ED is lower when the procedure is conducted using positive therapeutic communication compared to neutral or nocebo communication.
- Anxiety perceived during the collection of an arterial blood sample in the ED is lower when the procedure is conducted using positive therapeutic communication compared to neutral or nocebo communication.

Outcomes

The primary outcome is pain: self-evaluation of the maximum pain felt by the patient during the collection of an arterial blood sample on the Verbal Rating Scale (VRS: 0=no pain to 10=the worst imaginable pain) just before the beginning of the procedure and during the procedure (question asked during the 3 minutes after the procedure) [14,31,32].

The secondary outcomes are as follows:

XSL•FO
RenderX

- Comfort: self-evaluation of patient comfort using a simple comfort VRS (0=no comfort to 10=the most comfort imaginable) just before the beginning of the procedure and 3 minutes after the procedure [33]
- Anxiety: self-evaluation of patient anxiety using a simple anxiety VRS (0=no anxiety to 10=the worst anxiety imaginable) just before the beginning of the procedure and 3 minutes after the procedure [34]
- Puncture failure: success of the first arterial puncture assessed by the accredited evaluator at the end of the procedure using the number of puncture points visible on the patient's skin (possible response: 1 puncture visible, yes/no)
- Global satisfaction with the communication strategy used: evaluation by the patient at the end of the procedure using a numeric scale of 0-10 (0=extremely dissatisfied to 10=extremely satisfied)

Statistical Analysis

Sample Size Calculation

With a significance level of .05, a power of 0.9, a difference in pain on the VRS of 1.5 (generally accepted as clinically significant) with an expected SD of 2.5 [35], and an attrition of 20% on the basis of a group-independent *t* test (a specific case of linear mixed effects models [LMMs]), we must include 83 patients in each group to show the efficacy of the intervention on pain by applying the Bonferroni correction (ie, a total of 249 patients).

Statistical Analysis Plan

First, descriptive statistics (frequencies and percentages for categorical data; means, SDs, medians, and IQRs for quantitative data) will be run for each measure of time for each group and the overall study sample. In addition, an analysis of nonresponses and patient dropouts will be conducted. Second, bivariate associations will be calculated to compare the groups at baseline (Pearson chi-square test, Fisher exact test, *t* test, and the Mann-Whitney test according to the distribution of variables). Third, to test the impact of the intervention on the different outcomes (hypotheses 1, 2, and 3), LMMs with patients, groups and physicians as a random effect will be performed to analyze changes over time. The participation of approximately 25 physicians is foreseen in this study. The models will be tested on all available data.

The effects of time, groups, and their interaction will be tested by controlling for sociodemographic characteristics and variables linked to health status. An intention-to-treat (ITT) analysis, per protocol (PP) and based on the analysis of communications (ie, the respect of the quality of the defined communication according to the protocol; see the next section), will be conducted. The Pearson chi-square test comparing the allocation defined in the protocol and the allocation following the analysis of communications will be performed. If necessary, a generalized LMM will also be used to explore the differences between the available measured variables (physicians having performed the ABG procedure, pain, etc). Statistical analysis will be performed on available data, and no imputation of missing data will be conducted. Given that our study will be conducted on a 1-to-1 basis with a member of the research team and on the basis of previous experience, we expect that the number of missing values will be low. Statistical analyses will be performed using the R (R Core Team and the R Foundation for Statistical Computing) and STATA version 12 (StataCorp); the level of significance will be set at P=.05.

Analyses of Communications

All communications will be recorded. We will listen to 30 communications at a time to evaluate the quality of each communication and to ensure that the communication corresponds to the defined study arm defined at the time of randomization. This evaluation will be performed until less than 10% of incorrect rankings are obtained. A physician external to patient management will reassign the patient groups based on a list of preselected keywords. This same physician will then (re)classify the patients into 1 of the following 3 arms: therapeutic positive communication, nocebo, or neutral.

The classification will be performed with the help of a list of 10 keywords provided to the external physician. Each list of 10 keywords will be associated with 1 of the 3 arms and will correspond to standardized phrases related to each arm. Thus, if the external physician finds 1 keyword associated with the nocebo arm, the patient will then be reclassified into the nocebo arm; if the external physician finds 1 keyword associated with the therapeutic positive communication arm but without any keywords associated with the nocebo arm, the patient will be classified into the therapeutic positive communication arm. If the physician does not find any keywords associated with these 2 arms, the patient will be classified into the neutral arm.

This classification will be conducted in parallel by 2 persons for the first 30 patients to evaluate the interrater reliability using Cohen κ. If $\kappa>0.90$, only 1 coder will continue to code the audio recordings. If not, 2 coders will continue to evaluate the communications; in the case of disagreement, a third coder will make the final decision.

The keywords associated with the nocebo group are as follows:

- Pain
- Cold
- Prick
- Do not panic.
- Are you in pain? I am going to prick.
- This is going to sting.
- Do not move, it won't be long.
- Do not be frightened.
- How do you feel?

The keywords associated with the therapeutic positive communication group are as follows:

- Be reassured.
- Are you comfortable?
- Are you relieved?
- I am going to place the drip.
- Have confidence.
- Take it easy.
- It will be fast.
- Do you feel well?

XSL•FO
RenderX

These lists are likely to be adapted based on the audio recordings.

Ethical Considerations

Research Ethics Approval

The study protocol was approved by the Human Research Ethics Committee of the Canton of Vaud, Switzerland (no. 2022-00685).

All participants will receive an information letter presenting the study, its objectives, and its risks. Sufficient information will be provided to allow an informed decision to be made concerning their participation in the study. The senior TD responsible for recruitment will be at the disposal of patients to respond to any eventual questions that may arise. Given the specific context of medical care in the emergency setting, a reflection time of 15 minutes will be allocated to allow each participant to make a decision. Particular focus will be given to the primacy of the medical indication for arterial blood sampling and to the fact that this study is solely concerned with the patient perception of this procedure. In this context, we consider that the time of reflection is sufficient to allow free and informed consent. Following signature of the consent form and verification of the eligibility criteria, the patient will be included in the study. As the patient will be blinded to the intervention, the information letter will only explain our hypothesis concerning the importance of communication on the emotional level during a care episode, and no information will be provided on the 3 verbal attitudes or any other details, which might influence the patient's judgement.

In the event of the inability of a patient to provide informed consent in writing before the ABG procedure (eg, severe respiratory distress preventing them to write), verbal consent will be sufficient before inclusion and will be notified in writing on a consent sheet by the senior TD. Written consent will then be requested later after emergency care.

Data Monitoring

No data related to the research foreseen will be obtained via laboratory tests or invasive procedures. The sources of materials are as follows:

- Data of quantitative interviews, heteroadministered by the evaluator using a paper CRF. The data will then be entered into REDCap.
- Patient screening data collected by the senior TD.
- Data of audio recordings collected during the ABG procedure with the use of an audio recorder. Recordings will be transcribed for analysis in Microsoft Word.
- Patient information letters as well as the consent forms to be completed will be stored in a dedicated secure box for the study in the ED.

As this is a low-risk study, the following monitoring activities will be carried out by a person independent of the study and trained in good clinical practices and the protocol:

- A qualification visit will be conducted prior to the start of the study.
- The initiation visit will be conducted in the HFR ED in the presence of the PI and the research team.
- A follow-up visit after the inclusion of the first 3 participants will be carried out and if necessary repeated in the case of major problems encountered.
- Regular monitoring (minimum once every 3 months) will be carried out to (1) check that all patients have provided oral consent before inclusion and written consent after the procedure, (2) check that documents are stored according to the protocol (consents, paper CRFs, etc), (3) verify paper CRF data extracted from the patient records (at least 20% of data randomly selected), (4) verify the concordance of the information in REDCap and the information in the paper CRFs (at least 20% of the randomly selected data), and (5) verify the adequacy of the caregivers' communication with the allocation arm for the first 30 patients included. Control visits will be conducted if the actual communication differs from the allocation arm in more than 10% of cases.

Data Confidentiality

Data concerning the trial and the participants will be treated with the greatest-possible confidentiality and will only be accessible to authorized staff who need the data to fulfil their role within the context of the study. Participants will only be identified on the CRFs and other specific study documents by their unique IDs.

The production, transmission, storage, and analysis of personal health data in the context of this study will strictly respect current Swiss legal requirements concerning data protection and will be conducted in conformity with Ordonnance ClinO Art. 18. All lists of names (or other identifying information), personal IDs, and consent forms will be stored in a locked office at the HFR in the offices of the PI. Access to the initial lists and signed informed consent forms will be limited to the physician investigators (authors CLT, YG, and TS).

All electronic data will be recorded using only personal IDs in REDCap.

Quantitative interview data will be collected using paper CRFs. All participants will be identified only by study IDs. The list corresponding to identifying information and the study IDs will be stored in a file protected by a password and only be accessed by the physician investigators.

Data of physician communication during the ABG procedure will be recorded using a numeric recording machine. Audio files will be labelled only with the ID number and transferred to computers protected by a password to be stored electronically. Interviews will be transcribed in Word files containing only the ID number and then stored electronically on computers protected by a password and on secure servers at HFR. Following verification of the transcripts, the audio files will be erased.

Retention and Destruction of Study Data

All the study data will be archived for 10 years after termination of the study or premature termination. The signed informed consent forms will be kept at the HFR and immediately placed in secure locked cupboards. All paperwork (including printed data) will be archived for a minimum of 10 years after the end

XSL•FO
RenderX

of the study in locked cupboards at the HFR. Participants who withdraw their consent or express the wish to end the research interview will be excluded from the study. Data collected until that time will be analyzed so as not to compromise the validity of the study, unless they request the deletion of their data.

Results

On average, 2000 ABG procedures are performed each year in the ED of the HFR. Recruitment for this RCT began in April 2023. In total, 249 patients are expected to be included. The inclusion period will run from April 2023 to July 2024.

Discussion

Summary

To the best of our knowledge, this is the first RCT that will investigate the effect of a positive communication over a routine procedure, such as ABG testing, in an emergency setting. Considering the KTHYPE study [15], a reduction in pain, anxiety, and discomfort can be expected when using positive communication.

Two of the ethical values in the medical field are beneficence and the objective to do no harm to the patient. However, although the nocebo effect of language is acknowledged today in specialties, such as anesthesiology, negative communication continues to be used daily in the ED, a particularly stressful setting with vulnerable patients. This makes it all the more important to study language tools in this environment, with the aim of standardizing and protocolizing caregivers' communication.

ABG testing is an investigation required in certain medical situations. The global experience of this procedure has often been described as disagreeable and can be improved [8]. The comfort and anxiety before and after sampling can be demonstrated. Today, no risk linked to the communication strategy has been documented, except for the usual inherent risks of arterial blood collection. The nocebo arm is nowadays commonly used in routine practice. If communication can lead to decreased pain, anxiety, and discomfort during this standard investigation, it will lead to changes in current practice. This method is easily used by even the most inexperienced doctors, and we hope that this will reduce their stress during the procedures.

Our study will also assess patient comfort and anxiety. These elements are of primary importance, as pain is frequent in emergencies and frequently underestimated (80% of patients [1]). The patient's anxiety and comfort level contribute to this pain, even if it has not been well documented. To interpret the results, we may compare the comfort and anxiety scores before and after the procedure. This will allow us to control for patients with chronic pathologies (eg, depression).

Strengths and Limitations

The main strengths of the study are its originality, the ease of implementation, and the rigorous methodological design, the last being based on a previously published study [15].

However, this study also has some limitations. First, the received communication policy may be different from the one intended to be used. To limit this bias and avoid any contamination of the arms due to inappropriate communication, all procedures will be recorded and replayed to verify whether the attributed group and the received communication scheme correspond. Second, this is a single-center study. The experience of the physicians performing the ABG procedure, although similar, is quite limited, which could interfere with the communication, as these inexperienced physicians may focus more on the correct technical execution of the ABG procedure than on the communication. In addition, nonverbal communication during the interview will not be studied. Third, other uncontrolled confusing factors could affect the results (eg, a long wait in the waiting room for the patient and overloaded service for the doctor), but we hypothesize that these factors may be similar in each group due to randomization and will thus limit the potential bias.

Conclusion

The Positive Therapeutic Communication on Pain (POPAIN) trial is an RCT assessing the effect of positive communication on pain, discomfort, and anxiety in patients undergoing ABG testing compared to neutral and nocebo communication. A reduction in pain, discomfort, and anxiety is expected when using positive communication. These results could be useful to the medical community and encourage clinicians to monitor their communication to reduce pain and anxiety in care. This method, if successful, could be easily implemented in other emergency departments.

Acknowledgments

This study was funded by the Cantonal Hospital of Fribourg. The authors gratefully acknowledge Pr Helene Beloeil (University Hospital of Rennes, France). She provided the protocol for the KTHYPE (Hypnosis and Communication Reduce Pain and Anxiety in Peripheral Intravenous Cannulation: Effect of Language and Confusion on Pain During Peripheral Intravenous Catheterization) study, which inspired the creation of our study. She also gave us advice on going to the Ethics Commission.

Data Availability

Once data are collected and ready for publication, they will be comprehensively presented in the manuscript. The results will be distributed in national and international scientific conferences and medical peer-reviewed journals.

XSL•FO
RenderX

Authors' Contributions

TS had the idea for the study and was responsible for study design, and funding. CLT was responsible for drafting the protocol, writing it and obtaining ethics committee approval. Both TS and CLT contributed equally as first coauthor. YG, TS, CLT, and KI wrote and prepared the manuscript for publication. KI provided knowledge and input for statistical measures and outcome analyses. TS, CLT, YG, VR, and KI provided significant feedback on the manuscript and aided in the development of content.

Conflicts of Interest

None declared.

Abstract

Background: Nephrotic syndrome that is resistant to steroid therapy is termed refractory nephrotic syndrome (RNS), a condition that is associated with an increased risk of end-stage renal disease. Immunosuppressants are used to treat RNS; however, prolonged use may lead to significant adverse effects. Mizoribine (MZR) is a novel agent used in long-term immunosuppressive therapy, which has few adverse effects, but data on its long-term use in patients with RNS are unavailable.

Objective: We propose a trial to examine the efficacy and safety of MZR compared with cyclophosphamide (CYC) in Chinese adult patients with RNS.

Methods: This is a multicenter, randomized, controlled interventional study with a screening phase (1 week) and a treatment phase (52 weeks). This study has been reviewed and approved by the Medical Ethics Committees of all 34 medical centers that are participating. Patients with RNS consent to participation, and are enrolled and randomized to an MZR group or a CYC group (1:1 ratio), with each group receiving tapering doses of oral corticosteroids. Participants are assessed for adverse effects, and laboratory results are collected at 8 visits during the treatment phase (weeks 4, 8, 12, 16, 20, 32, 44, and 52 [exit visit]). Participants are able to withdraw voluntarily, and investigators are required to remove patients when there are safety concerns or deviations from the protocol.

Results: The study started in November 2014 and was completed in March 2019. A total of 239 participants from 34 hospitals in China have been enrolled. Data analysis has been completed. The results are being finalized by the Center for Drug Evaluation.

XSL•FO
RenderX

Conclusions: This study examines the safety and efficacy of MZR as a long-term treatment approach for Chinese adults with RNS. It is the longest lasting and largest randomized controlled trial to examine MZR in Chinese patients. The results can help determine whether RNS should be considered as an additional indication for MZR treatment in China.

KEYWORDS

refractory nephrotic syndrome; mizoribine; cyclophosphamide

Introduction

Patients with nephrotic syndrome (NS) have the following classic triad of symptoms: heavy proteinuria, edema, and hypoalbuminemia [1]. Additional complications in these patients, such as venous thromboembolism, infection, and, less commonly, acute renal failure, can lead to catastrophic outcomes [2]. Patients with NS who are resistant to or dependent on corticosteroids for more than 4 to 6 months are considered to have refractory nephrotic syndrome (RNS), also referred to as steroid-resistant nephrotic syndrome, although RNS is a complex condition and there have been differences in how this term is used [3,4]. Almost all patients with NS who have proteinuria eventually progress to end-stage renal disease (ESRD) [3,5]. Because prednisone therapy often fails to provide complete remission of proteinuria, immunosuppressants may also be used to prevent or treat RNS [6]. Although several immunosuppressants (eg, cyclophosphamide [CYC], azathioprine, cyclosporine, and rituximab) can effectively treat proteinuria in patients with RNS [7,8], prolonged use of these drugs can lead to severe adverse effects (SAEs), such as sexual dysfunction, tumorigenesis, and renal dysfunction, and patients may also experience recurrence after discontinuation [9]. A novel immunosuppressant therapy that causes fewer side effects and that is suitable for long-term therapy is therefore needed for the treatment of RNS.

Mizoribine (MZR) was originally isolated from an ascomycete, *Eupenicillium brefeldianum*. Initial studies reported it had weak activity against *Candida albicans*, and subsequent studies confirmed it suppressed lymphocyte proliferation, and humoral and cellular immunity [10-12]. Other studies had examined its immunosuppressive effects and its use with other immunosuppressants for preventing rejection after kidney transplantation. Japan has approved MZR for the treatment of lupus nephritis, rheumatoid arthritis, and primary NS. Previous studies showed that MZR led to fewer SAEs, such as myelosuppression and hepatotoxicity, than other immunosuppressants [10,12]. Several clinical trials confirmed the clinical efficacy of MZR when it was used as a long-term therapy for the treatment of certain autoimmune diseases, such as lupus nephritis, rheumatoid arthritis, and primary NS [10,12]. Kawasaki et al [10] also reported that MZR was superior to corticosteroids in reducing proteinuria in patients with RNS and that the adverse effects (AEs) were similar in MZR and control groups. However, due to its relatively low efficacy, there is only limited data regarding the effect of MZR in patients with RNS, especially in adults with complex etiologies.

We propose a randomized, multicenter, controlled study to evaluate the efficacy and safety of MZR compared with CYC for the treatment of adults with RNS.

Methods

Ethical Considerations

This clinical trial is performed in accordance with the principles in the latest versions of the Declaration of Helsinki and Chinese Good Clinical Practice, and applicable clinical trial regulations. This study has been approved by the Medical Ethics Committee of the Chinese People's Liberation Army General Hospital on September 15, 2014 (C2014-042-01). Documents describing the study protocol, informed consent, safety monitoring policy, AEs, and management policies have been reviewed and approved with minor modifications by the Medical Ethics Committee. Approval of this trial has also been granted by appropriate Ethics Committees and the Center for Drug Evaluation (CTR20130299). Written informed consent for publication has been obtained from all participants.

Overview

This multicenter, randomized, controlled, open-label clinical study assesses the efficacy and safety of MZR in comparison with CYC for the treatment of RNS in adult patients. This clinical trial is performed at 34 centers in 27 cities in China.

The principal investigators at the 34 different sites receive patients from inpatient and outpatient settings who are referred and might be good candidates for participation. All potential candidates are carefully screened according to the inclusion and exclusion criteria. Those who qualify are approached by investigators for study enrollment. Study details, potential benefits, and potential risks of participating are explained in detail to all patients and to family members (if present), and all questions are answered. Patients who express full understanding and are willing to participate sign the informed consent documents, and these are co-signed by the investigators who recruit them. Each eligible and enrolled participant is offered US $15 as compensation for transportation expenses. The participants pay for all concomitant medications. The sponsor pays for the study medications and tests. The clinic visits and laboratory procedures are free of charge. The medical care needed for any AEs is also covered by the sponsor. All data are deidentified to protect patient confidentiality. The protected health information of all participants is entered by authorized staff or investigators into the electronic case report form in an electronic database that is managed by Tigermed Data

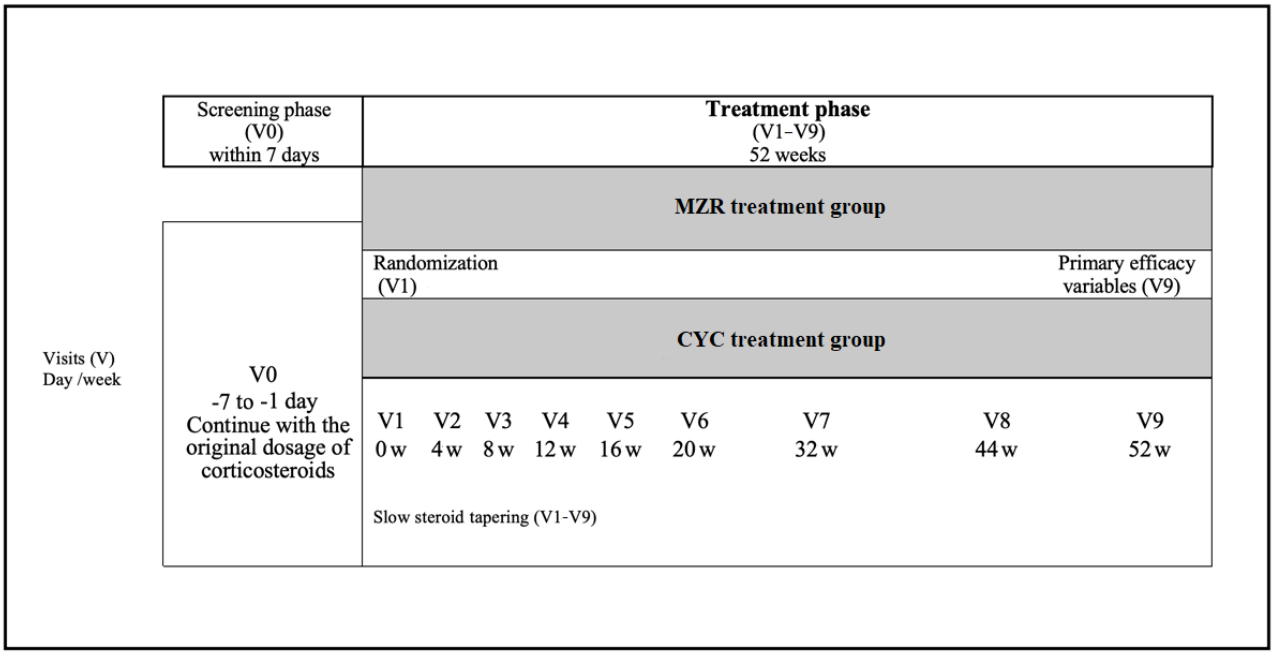
XSL•FO
RenderX

Management. Any access to the system records or change of data in the electronic case report form after the original entry is automatically recorded, and each patient's protected health information is secured. All paper documents, such as consent forms, are collected and locked in the investigators' offices.

Key Study Objectives

The primary objective is to compare the therapeutic effect of MZR with CYC (the current standard therapy) for the treatment of RNS by analyzing overall and total remission rates in the different groups.

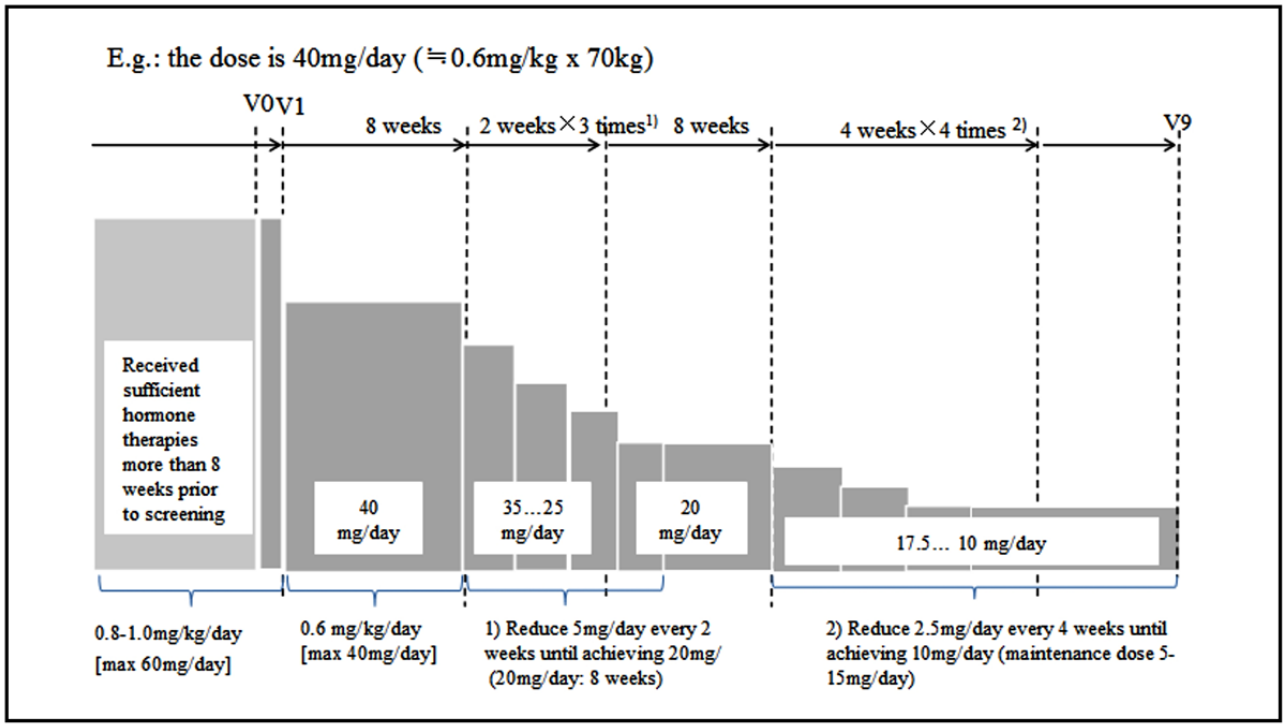
The secondary objective is to evaluate the efficacy and safety profiles of MZR for the treatment of RNS, including but not limited to clinical remission rate, progression rate, treatment failure rate (not achieving partial remission), 24-h urine protein, serum albumin, serum creatine, and estimated glomerular filtration rate (eGFR) as endpoints.



The exploratory objective is to evaluate the changes in high-sensitivity C-reactive protein (hs-CRP) levels in patients who receive MZR.

Trial Design

The specific aim of this study is to assess the hypothesis that MZR is not inferior to CYC for the treatment of RNS. This study consists of a 1-week screening phase followed by a 52-week treatment phase (Figure 1). Signed informed consent agreements are collected upon patient enrolment. The investigators have identified 238 eligible participants during the screening phase (visit 0; V0) according to the inclusion and exclusion criteria. Baseline information, including medical records, are obtained at this time. All enrolled participants are then randomized to an MZR group or a CYC group (1:1 ratio).



There are 9 visits (V1-V9) by each participant during the treatment phase, during which examinations are performed, AEs are evaluated, and samples are collected for laboratory tests performed at a central laboratory (Figure 2). Each visit is within 7 days of the scheduled date. All participants from both groups receive tapering oral corticosteroid therapy during the entire treatment phase (Figure 2). Patients in both groups receive specific doses of the treatment drugs in addition to corticosteroids. AEs and symptoms are closely monitored and documented. Participants are able to withdraw voluntarily, and investigators are required to remove participants when there is any concern regarding safety, according to the withdrawal protocol.

Figure 1. Study timeline. Randomization is performed on day 1 of V1. CYC: cyclophosphamide; MZR: mizoribine; V: visit.

XSL•FO
RenderX

Figure 2. Plan for corticosteroid dose tapering. This example is for a dose of 40 mg/day (0.6 mg/kg x 70 kg). V: visit.

Eligibility Criteria

Inclusion Criteria

Patients are eligible for inclusion if they meet all of the following criteria: (1) Documentation of a confirmed diagnosis of NS; (2) Receipt of a renal biopsy within 1 year prior to screening, with a confirmed pathologic diagnosis of minimal change disease, immunoglobulin (Ig) A nephropathy, mesangioproliferative glomerulonephritis, membranous nephropathy (MN), or focal segmental glomerulosclerosis (FSGS), so that a planned subgroup analysis can be performed for these different pathological classifications; (3) Receipt of an adequate dosage of corticosteroids (0.8-1.0 mg/kg/day prednisolone or equivalent dose of another corticosteroid for more than 8 weeks [more than 12 weeks for FSGS]) based on the pathologic diagnosis mentioned in "inclusion criterion 2" before screening; (4) 24-h urine protein of 2.0 g or more at screening; (5) Male or female gender and age from 18 to 70 years upon signing the informed consent agreement; (6) Body weight between 40 and 80 kg at screening; and (7) Capacity and willingness to sign the informed consent document.

Exclusion Criteria

Patients are excluded if they have any of the following conditions: (1) NS caused by primary diseases other than those listed in "inclusion criterion 2" (eg, membranoproliferative glomerulonephritis); (2) NS from a secondary cause (eg, diabetic nephropathy, anaphylactic purpura nephritis, lupus nephritis, type B hepatitis-related nephritis, and renal amyloidosis); (3) History of allergy to MZR or CYC; (4) Receipt of an accumulated dosage of more than 3 g CYC during the 1 year before screening; (5) Receipt of immunosuppressants or any Chinese traditional medicine with immunosuppressive effects within 30 days before screening; (6) Receipt of disallowed therapeutic medications within 30 days before screening; (7) Receipt of plasma exchange therapy or immunoadsorption therapy within 30 days before screening; (8) Need for pentostatin or a live vaccine (not including the flu vaccine); (9) Receipt of renal replacement therapy; (10) Receipt of kidney transplantation; (11) Malignancy; (12) Severe hypertension (systolic blood pressure >160 mmHg or diastolic blood pressure >100 mmHg) that is not effectively controlled; (13) Low white blood cell count ($<3\times10^9$/L); (14) Elevated serum creatinine (SCr; >176.8 μmol/L [2 mg/dL]); (15) Elevated levels of liver enzymes (aspartate transaminase or alanine transaminase 3 times higher than the upper limit of normal); (16) Hepatitis B, hepatitis C, or HIV infection; (17) Other infections based on chest computed tomography; (18) Unsuitability to participate according to the investigators because of uncontrolled diabetes, central nervous system lupus, lupus encephalopathy, active psychosis, osteonecrosis of the femoral head, fulminant hepatitis, peptic ulcer, etc; (19) Pregnancy, breast feeding, or planning to become pregnant; and (20) Any other disease that may affect the evaluation of medication efficacy and safety.

Premature Withdrawal Criteria

Any participant who has signed the informed consent form and has initiated the study can be withdrawn prior to the last visit for any of the following reasons: (1) Withdrawal by the participant (the participant decides to withdraw during the screening or interventional phase); (2) Screening failure (the participant does not satisfy all inclusion criteria or meets one of the exclusion criteria at V0 and V1 [randomization visit]); (3) Protocol violation (the participant has a serious violation of the inclusion or exclusion criteria after the first dose of medication, uses a prohibited medication or prohibited therapy before the last planned visit, or has another major violation); (4) Pregnancy; (5) Poor compliance with the study medication

XSL•FO
RenderX

(the participant has poor compliance with the protocol, including refusal of follow-up, laboratory tests, or treatments); (6) Investigators' decision (the investigators decide the participant has a medical condition, including those listed in the exclusion criteria, or has personal circumstances during the interventional phase that might cause substantial risk on continuing treatment; or the professional evaluations and decisions of the investigators do not allow the participant to follow the study protocol); (7) AE (the participant has any clinical AE or SAE according to the investigators' professional judgment; if an AE is not considered to be clinically related to the study medications or if the benefits of continuing treatment outweigh the risks, the treatment is continued at the discretion of the investigators; a low white blood cell count [$\leq 3\times10^9$/L] or an elevated aspartate transaminase or alanine transaminase level [>5 times the upper limit of normal] necessitates withdrawal); (8) Loss to follow-up (the participant fails to visit the study site for any reason before the last planned visit or by the end of the study); (9) Reaching an endpoint (progression to ESRD or doubling of SCr) at any time during the study; and (10) Others (difficulty for the participant to continue the study based on judgment of the principal investigator or co-investigators).

Randomization Strategy

Eligible participants are randomized to an MZR group or a CYC group in a 1:1 ratio using the Interactive Web Response System (IWRS) on day 1. A unique subject number is assigned to each participant. Stratification is according to pathological classification. When a participant who fails the screening is deemed eligible after rescreening by the investigators, the participant is allowed to enter the randomization before the end of enrollment.

Interventions

Study Medications

MZR

Participants in the MZR group start receiving MZR at V1. The oral dose is 50 mg per tablet, 3 times per day, corresponding to a total daily dose of 150 mg. Administration continues until V9 (Figure 1).

CYC

Participants in the CYC group start receiving CYC at V1. The dose is calculated as 0.5 to 1.0 g/m^2 body surface area, with a maximum dose of 1.0 g/day. Administration occurs from V1 to V8 (Figure 1).

Corticosteroids

All participants receive oral corticosteroid therapy (0.8 to 1.0 mg/kg/day prednisolone or an equivalent dose of methylprednisolone) during the screening phase. A dose of 0.6 mg/kg/day for 8 weeks begins at V1, and the maximum daily dosage is 40 mg. Starting from V3, the corticosteroid dose is tapered gradually, with a dose reduction of 5 mg every 2 weeks until the daily dose is 20 mg/day (if tolerated). Prednisolone (20 mg/day) or an equivalent dose of methylprednisolone is continued for 8 weeks. The dose is tapered by 2.5 mg every 4 weeks until the maintenance dose of 5 to 15 mg/day is attained at V9 (Figure 2).

Screening Period (V0)

The investigators obtain written informed consent from all participants prior to any intervention, and all participants are registered in the IWRS. During the screening period, participants are screened by the investigators for collection of relevant information. This information includes medical history, medications and previous therapies, and AEs (if any). Height, body weight, and vital signs are measured, and a 12-lead resting electrocardiogram (ECG) is obtained. Blood is collected for laboratory tests, including complete blood count (CBC), biochemistry, eGFR, hepatitis B surface antigen, hepatitis C virus antibody, HIV, IgG, and hs-CRP. A routine urine test for 24-h protein is performed. Women of childbearing age are tested for pregnancy (Multimedia Appendix 1).

Treatment Period (V1-V9)

V1 (Randomization Visit)

Each participant's laboratory results, physical examination results, medical history, medication history, and pathology reports are reviewed for evaluation of eligibility according to the inclusion and exclusion criteria before enrollment and randomization. Participants are then registered in the IWRS. If they qualify and are enrolled, appropriate doses of the study medication are dispensed, and the investigators provide information on how to take the medication and appropriate storage. The investigators also emphasize the importance of compliance, and request the return of all unused medications (Multimedia Appendix 1).

V2-V9

During this phase, all women of childbearing age return to the study center for pregnancy tests whenever they think there is a possibility of pregnancy. All participants are logged in to the IWRS when they visit the study center. Appropriate doses of the study medications are dispensed, and the investigators reinforce the importance of appropriate dosing and storage. The importance of compliance and the return of unused medications is also addressed, and detailed information regarding AEs is recorded. Pregnancy tests are routinely performed in all women of childbearing age. Laboratory tests, including CBC, biochemistry, eGFR, routine urine test, pregnancy test for women of childbearing age (V6 and V9), IgG, 24-h urine protein, and hs-CRP, are performed. Body weight and vital signs are measured at each visit, and a second ECG is performed at V9 (Multimedia Appendix 1).

Unscheduled Visit

Study participants who come to the study site for an unscheduled visit are documented as such. The reason for any unscheduled visit is documented in detail. Laboratory tests are performed if necessary, and vital signs, body weight, ECG, etc are assessed as needed. An urgent or emergent situation, such as potential pregnancy or disease progression, is evaluated and addressed by the study investigators.

XSL•FO
RenderX

Premature Withdrawal From the Study (End of Study)

Any participant who is prematurely withdrawn from the study after confirmation receives an examination within 1 week from the withdrawal date, and this event is documented. The examination consists of necessary tests and other procedures that are recommended by the investigators and accepted by the participant.

The study design and items collected at all visits are summarized in Multimedia Appendix 1.

Outcome Measures

Primary Efficacy Variables

The primary efficacy variable is the total remission rate (%) and is based on data collected from each group at V9. The total remission rate is calculated as the sum of the complete remission rate (%) and the partial remission rate (%). Complete remission is defined as 24-h urine protein less than 0.3 g, and partial remission is defined as 24-h urine protein decline of more than 50% from baseline (V0) and value of less than 3.5 g.

Secondary Efficacy Variables

The secondary efficacy variables are the complete remission rate and partial remission rate of each group at V9; remission rate at V3, V6, V7, V8, and V9; treatment failure, defined as not achieving partial remission; and 24-h urine protein, serum albumin, SCr, eGFR (using the Chronic Kidney Disease Epidemiology Collaboration [CKD-EPI] formula), and blood urea nitrogen values. The endpoint events are progression to ESRD or doubling of the SCr relative to baseline.

Exploratory Variables

The exploratory variables are the hs-CRP levels in each group at the different visits.

Safety Assessment

The safety of participants is actively monitored during the study. All events, including unplanned pregnancy, are documented and properly managed. The reportable events include but are not limited to SAEs (including death), pregnancy, important treatment-related AEs (granulocytopenia, infections, hemorrhagic cystitis, liver function impairment, hyperuricemia, malignancy, amenorrhea, alopecia, nausea, and vomiting), and AEs leading to study discontinuation.

Safety is monitored by asking participants about symptoms, and by assessment of physical examination results and laboratory test results (CBC, blood biochemistry, IgG, hs-CRP, pregnancy test, routine urine test, body weight, vital signs [blood pressure, pulse, and body temperature], chest computed tomography, and 12-lead ECG).

Statistical Plans

The sample size calculation is based on a noninferiority comparison of the MZR and CYC groups regarding the total remission rate after treatment, and is to be calculated using SAS (SAS Institute). Studies of RNS assumed the total remission rate in each group was 60% [13,14] and the risk ratio of MZR to CYC was 1.0. Thus, we include 119 participants in each group based on the following assumptions: total remission rate of 60% for each group, noninferiority difference ratio of 0.674, power of 80%, 1-sided significance level of 2.5%, and dropout rate of 20%.

The full analysis set (FAS) includes all participants who are randomized and treated with at least one dose of the study medication and who have received at least one posttreatment efficacy assessment. The per-protocol set (PPS) includes all FAS participants who have no major protocol violation. The safety set includes all randomized participants who receive at least one dose of the study medication and have at least one safety assessment.

The primary and secondary efficacy outcomes are assessed and analyzed. A noninferiority test of total remission is performed in the PPS population by comparing the 2 groups at V9, and relative risk ratios and 2-sided 95% CIs are calculated. A secondary analysis of the primary efficacy variable is performed in the PPS at the end of the study and in the FAS at V9. The number of participants who achieve total remission in the PPS is calculated in each group at each visit. The secondary efficacy variables are analyzed using descriptive statistics. The safety assessment is performed in the safety set population. The incidences of AEs in the 2 groups are compared. Subgroup analysis is performed as necessary, such as exploratory outcome analysis using hs-CRP and other variables.

Results

The study began in November 2014 and was completed in March 2019. A total of 239 participants from 34 hospitals in China were enrolled. Data analysis has been completed. The results are being finalized by the Center for Drug Evaluation.

Discussion

NS is caused by abnormally increased protein leakage from the kidneys into the urine [15]. In adults, proteinuria greater than 3.5 g/1.73 m^2 per day is considered nephrotic. The incidence of NS in the general population is about 1 per 100,000 [16]. The manifestations of NS are more complex in adults than children, because adults experience a wider variety of primary and systemic diseases, making management more difficult.

MN, FSGS, and minimal change disease are the most common causes of idiopathic RNS in adults [17-20]. Diabetes mellitus is the most common cause of secondary NS, and other causes include systemic lupus erythematosus, hepatitis B or C, amyloidosis, and multiple myeloma [2]. The pathogenesis of secondary NS differs from that of primary NS in that treatments for primary NS focus on the primary disease. Steroid hormone regimens and immunosuppression strategies also differ for primary and secondary NS. Thus, we exclude patients with secondary NS from this study. A potential limitation of this study is that the pathologic types of RNS may be concentrated in a few common pathologic types in Chinese patients, such as MN.

RNS remains poorly understood but is currently considered immune mediated because many patients respond to immunosuppressive drugs [21]. The immune mechanisms

XSL•FO
RenderX

underlying the pathophysiology of RNS may include systemic T- or B-cell dysfunction [22]. In particular, cytokines produced by T cells are thought to act on the slit diaphragms of renal podocytes and increase protein permeability [23]. Alkylating agents, such as CYC, can inhibit T cells and B cells, have a wide range of applications in RNS, and are often used as positive controls in clinical studies. However, CYC and other traditional alkylating agents can cause myelosuppression, infertility, bladder cancer, leukemia, skin cancer, and hemorrhagic cystitis [24]. The optimal regimen to be used for immunosuppression in patients with RNS is uncertain, and many clinical trials are evaluating different therapeutic schedules for patients with different pathological types of RNS. Calcineurin inhibitors mainly inhibit T cells and can induce remission, but there is nearly a 50% risk of relapse after cessation of calcineurin inhibitors in patients with idiopathic MN [25]. Rituximab is a B-cell–depleting agent, and when used alone, it can induce disease remission and can cause few SAEs [26].

MZR was originally isolated as an antibiotic agent that had activity against *C. albicans*, and subsequent studies reported it had strong immunosuppressive activity in various animal experimental models [11]. MZR is an imidazole nucleoside, and its metabolite, MZ-5-P, selectively inhibits inosine monophosphate synthetase and guanosine monophosphate synthetase, resulting in the complete inhibition of guanine nucleotide synthesis without incorporation into nucleotides. MZR also has selective inhibitory effects on inosine 5-monophosphate dehydrogenase, an enzyme that functions in de novo purine nucleotide synthesis. MZR thus suppresses cell-mediated and humoral immune responses by suppressing T- and B-lymphocyte proliferation via the inhibition of guanosine monophosphate synthesis [27,28]. This mechanism is similar to that of CYC, but MZR is associated with fewer AEs. Two previous small head-to-head trials of specific agents compared the relative effectiveness and safety profiles of MZR and CYC in adult patients with MN [29,30]. Both studies showed that MZR reduced albuminuria and had a good safety profile.

Accordingly, this clinical trial evaluates the efficacy and safety of MZR in comparison with CYC for the treatment of RNS in Chinese adults with glomerular diseases. It is a multicenter, randomized, controlled trial, and we assess the efficacy of MZR based on changes in total proteinuria, eGFR, and AEs.

There is no universal treatment regimen used for adults with primary NS, although corticosteroids are beneficial in pediatric patients. Adults with NS usually receive conservative management and steroid treatment when conservative therapies fail [16,31]. However, the long-term use of immunosuppressants for the treatment of RNS may lead to SAEs, with unclear benefits. MZR appears to cause less severe AEs and provides good outcomes when used to treat other immune-related conditions, such as lupus nephritis, disorders after kidney transplantation, and primary nephritic syndrome [10,12,32,33]. However, there is currently insufficient evidence regarding its efficacy and safety for the treatment of RNS.

The proposed study examines the efficacy and safety of MZR as a long-term treatment approach for adults with RNS. It is so far the largest randomized controlled trial to examine MZR in China. The trial lasted about 1 year, and frequent follow-ups have been used to monitor efficacy and AEs. Confirmation of the efficacy and safety of MZR could lead to the improved management of adults with RNS and could improve our understanding of the pathology of RNS caused by different renal diseases.

Acknowledgments

We are grateful to Kiyoshi Horie and Hua Wang from Asahi Kasei Pharma Beijing for support with drug dispensing and to Osamu Matsuki, Rika Oishi, and Seika Yamaguchi from Asahi Kasei Pharma Corporation for providing literature support. The protocol has been implemented by the study group at 34 clinical centers in China. The network database has been designed by the executive committee from the Department of Nephrology, First Medical Center of Chinese PLA General Hospital. Tigermed Contract Research Organization Service Group provided support through clinical research associates. This study was sponsored by Asahi Kasei Pharma Corporation, Tokyo, Japan.

Data Availability

The data sets generated during this study are not publicly available due to the incomplete clinical analysis but will be made available by the corresponding author on reasonable request.

Authors' Contributions

ZD, JZ, ZX, ZN, YH, HL, GJ, XS, LZ, and XC discussed and designed the trial. ZD drafted the manuscript. XC and LZ are the principal investigators. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The hormone cortisol plays important roles in human circadian and stress physiology and is an interesting target for interventions. Cortisol varies not only in response to stress but also as part of a diurnal rhythm. It shows a particularly sharp increase immediately after awakening, the cortisol awakening response (CAR). Cortisol can be affected by medication, but it is less clear whether it can also be affected by learning. Animal studies have consistently shown that cortisol can be affected by pharmacological conditioning, but the results in humans have been mixed. Other studies have suggested that conditioning is also possible during sleep and that the diurnal rhythm can be conditioned, but these findings have not yet been applied to cortisol conditioning.

Objective: The objective of our study was to introduce a novel avenue for conditioning cortisol: by using the CAR as an unconditioned response and using scent conditioning while the participant is asleep. This study investigates an innovative way to study the effects of conditioning on cortisol and the diurnal rhythm, using a variety of devices and measures to make measurement possible at a distance and at unusual moments.

Methods: The study protocol takes 2 weeks and is performed from the participant's home. Measures in week 1 are taken to reflect the CAR and waking under baseline conditions. For the first 3 nights of week 2, participants are exposed to a scent from 30 minutes before awakening until their normal time of awakening to allow the scent to become associated with the CAR. On the final night, participants are forced to wake 4 hours earlier, when cortisol levels are normally low, and either the same (conditioned group) or a different (control group) scent is presented half an hour before this new time. This allows us to test whether cortisol levels are higher after the same scent is presented. The primary outcome is the CAR, assessed by saliva cortisol levels, 0, 15, 30, and 45 minutes after awakening. The secondary outcomes are heart rate variability, actigraphy measures taken during sleep, and self-reported mood after awakening. To perform manipulations and measurements, this study uses wearable devices, 2 smartphone apps, web-based questionnaires, and a programmed scent device.

Results: We completed data collection as of December 24, 2021.

Conclusions: This study can provide new insights into learning effects on cortisol and the diurnal rhythm. If the procedure does affect the CAR and associated measures, it also has potential clinical implications in the treatment of sleep and stress disorders.

Introduction

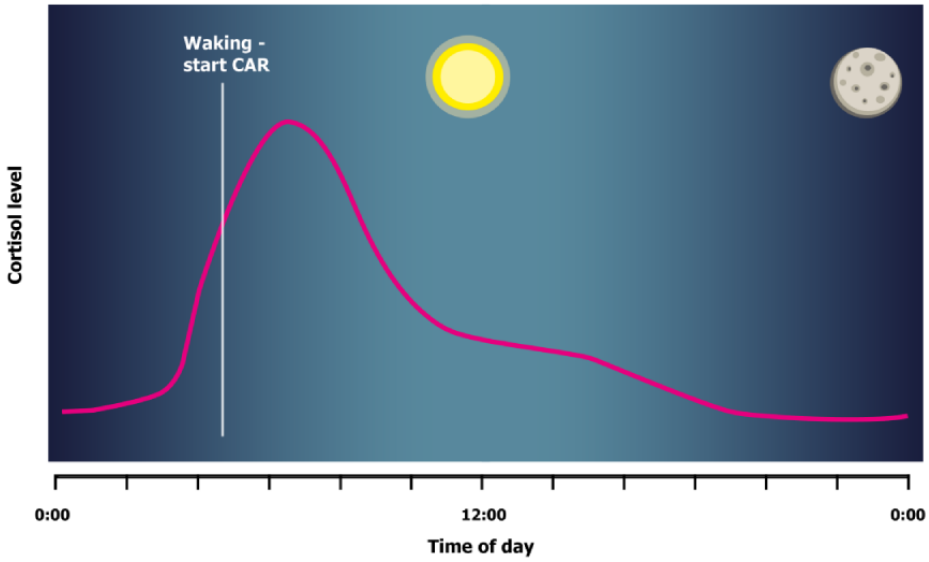
Background

The hormone cortisol has far-reaching effects throughout the body, mainly influencing metabolism but also being involved in systems as varied as the immune system [1], memory [2,3], and the sleep-wake cycle [4]. Cortisol is secreted from the adrenal gland as the end product of the hypothalamic-pituitary-adrenal (HPA) axis, a system of cascading secretions that originate in the hypothalamus. Cortisol is perhaps best known for its role in the stress response [5], and thus is often called the "stress hormone" in everyday parlance. However, cortisol does not just fluctuate in response to stress; it also follows several rhythms, including a diurnal rhythm. Cortisol levels are highest in the early morning and decline throughout the day and evening, with levels increasing again in the second half of the night [6]. A visual representation of a typical rhythm is shown in Figure 1. The onset of pulsatile secretion varies, but a strong peak is seen in cortisol increase in the period immediately after awakening in most participants [7]. This peak is referred to as the cortisol awakening response (CAR). The CAR has been extensively studied and has been shown to be generally consistent in size within an individual [7,8] but also influenced by situational variables [9], such as sleep duration in the preceding night [10]. Befitting the role of the stress hormone, the most reliable of the situational variables are stress-related [11]. Reviews of relevant studies suggest that the CAR is partially responsible for preparing the body in anticipation of the events and challenges of the day ahead [9,10]. Anticipation of a stressful and challenging day may lead to an increased CAR [12], while an intervention that reduces stress showed a corresponding decrease in the CAR [13]. Meanwhile, patients with severe amnesia, presumably not expecting anything from the coming day, seem to show no CAR at all [14].

Apart from stress and diurnal rhythms, cortisol levels can also be influenced more directly by medical interventions, whether intentionally or as a side effect. For example, sumatriptan is a serotonin receptor agonist taken to help with migraines, but it also reduces serum levels of adrenocorticotropin, and will reduce cortisol levels as a result [15]. Corticosteroids, such as dexamethasone, are a synthetic form of natural cortisol and can be used as cortisol replacement or to treat inflammation. Because cortisol is one part of an interconnected system, these types of medication can have indirect effects. Increased serum cortisol levels will normally trigger negative feedback to the hypothalamus and pituitary, the first links in the HPA axis, which leads to serum cortisol levels decreasing [16]. Corticosteroids trigger the same mechanism, which means that taking them lowers cortisol levels in the long term. Thus, it is always important to consider the timeframe and downstream effects when estimating the effect of any form of medication on cortisol levels.

Once the body is familiar with the effects of cortisol-affecting medication, learning processes can modulate their effects. These generally arise through the process of classical conditioning. Classical conditioning occurs when a natural reaction, the unconditioned response, which is normally caused by a stimulus termed the unconditioned stimulus (UCS), is repeatedly paired with a different, traditionally neutral stimulus. Once an association is established, the paired stimulus, known as the conditioned stimulus (CS), may evoke a response even when the UCS is not present; in this case, the response is known as the conditioned response [17]. These principles can be applied to cortisol-affecting medication. After repeated pairings, the CS will "remind" the body of the UCS and evoke either the cortisol change produced by the medication or a compensatory feedback mechanism [18,19]. A review of human and animal studies [20] found that this type of pharmacological conditioning was effective in animals, with 13 out of 15 studies finding the expected effect but less often tested and not as effective in humans. Of the human studies performed on this topic, 2 used medication that indirectly affects cortisol levels as a UCS: Benedetti et al [21] used sumatriptan, which reduces cortisol levels, while Petrakova et al [22] used corticotropin-releasing hormone, an upstream factor in the HPA axis. In the study by Benedetti et al [21], participants were injected with sumatriptan on 2 consecutive days, and on the third day, they received a saline injection presented as a 50/50 chance of sumatriptan or saline. Cortisol levels on the third day decreased in response to the injection in this group, while no effect was observed in the group that received the same injection without the previous 2 days of conditioning. Petrakova et al [22] used 2 conditioning trials 3 days apart, where participants received a distinctly flavored and colored drink combined with an injection of corticotropin-releasing hormone. After another 3 days, the participants were tested with a saline (placebo) injection on 2 subsequent days. Compared with a control group that also received saline injections in the conditioning phase, the participants showed an increase in cortisol during conditioning, but not in response to saline.

Two other studies relied on a direct increase in cortisol. Sabbioni et al [23] used dexamethasone, a glucocorticoid, while Tekampe et al [19] used hydrocortisone. In both cases, the CS was a strongly flavored drink combined with oral intake of the UCS on 3 occasions during the conditioning period. The results here are mixed again. Both studies indicate that cortisol increased after conditioning, but the results are inconclusive because of low power or group differences at baseline, respectively. On the basis of the 4 studies investigating this topic, it remains unclear to what extent and in what situations cortisol levels are



XSL•FO
RenderX

subject to classical conditioning in humans. It may be worthwhile to test cortisol conditioning in other situations.

Association learning is generally performed while the learner is fully conscious, but a line of studies suggests that it is also possible during sleep. A series of studies by the same research group [24-26] have shown that associations between a scent and another stimulus can be formed during sleep. While these stimuli are relatively subtle, they can lead to relevant behavioral effects; 1 study found that coupling the scent of smoke with an aversive stimulus for one night led to a modest reduction in smoking for several days afterward [25]. Odors seem to be particularly suited for this type of learning, because they do not wake sleeping individuals but seem to reduce arousal and wakefulness [27] and seem to function as a strong memory stimulus in general [28]. This idea is supported by other exploratory studies suggesting that presenting a scent during sleep can reactivate memories. For example, 1 study had participants perform a problem-solving task in the evening and simultaneously present a scent. On the subsequent night, some participants were reexposed to the scent, and these participants imagined and applied more creative solutions to the problem the next day compared with participants who received a different or no scent [29]. The authors suggest that this effect was the result of reactivating memory of the task during sleep. Another study [30] similarly presented a scent during sleep that was also present during a task performed the evening before, in this case using a visual memory task. In addition, while the scent was presented, functional magnetic resonance imaging measures were taken to examine brain activity. The results showed that the presentation of the scent activated the hippocampus, known for its role in declarative memory, and improved memory performance the following day, suggesting that scents presented during sleep can reactivate memories and influence objective outcomes.

Two animal studies have indicated that this type of learning may apply not only to associations relevant outside of sleep but also to the workings of the diurnal rhythm itself. In 1 study, a CS that was previously associated with light exposure was found to be able to trigger behavioral awakening patterns and awakening-related activity in the suprachiasmatic nucleus [31]. In another study, a stimulus linked to light deprivation was able to trigger increased melatonin levels related to the start of sleep [32]. To our knowledge, these results have not been replicated in humans. However, 1 publication suggests that the diurnal pattern of cortisol concentration can be influenced by learning [33]. When participants were informed that they would be awoken 3 hours before normal, they showed an anticipatory increase in adrenocorticotropin several hours before awakening. This response was not present when the participants were not given any warning, regardless of whether they were awoken 3 hours before normal or simply allowed to keep sleeping. This suggests that the human diurnal rhythm may be subject to learning effects just as it is in animals.

Figure 1. Stylized representation of a typical change in cortisol levels over a 24-hour period. CAR: Cortisol Awakening Response.

Objective

This study builds on these separate lines of evidence by investigating whether the CAR can be conditioned during sleep and moved to an earlier point in the night. Manipulation of the CAR could help evoke the benefits associated with a high CAR, such as a more alert and prepared awakening on busy days, or a low CAR, such as a more restful awakening. The association between cortisol and the diurnal cycle may indicate that such effects could be helpful in normalizing the sleep-wake cycle when it has been disturbed, as seen in conditions such as seasonal affective disorder [34] or delayed sleep phase disorder [35]. These effects are especially valuable considering that they could be evoked without the use of medication and the associated side effects.

Owing to the interindividual reliability and strength of the CAR, it has the potential to be an effective unconditioned response. By exposing participants to a distinctive odor in the half hour before awakening, we expect that an association can be created between the cortisol increase in this period and the distinctive scent. According to the principles of classical conditioning, the scent alone should also be able to evoke an increase in the CAR

XSL•FO
RenderX

and potentially accompanying feelings of wakefulness, even when administered hours before the regular time of awakening.

Methods

Ethics Approval and Dissemination

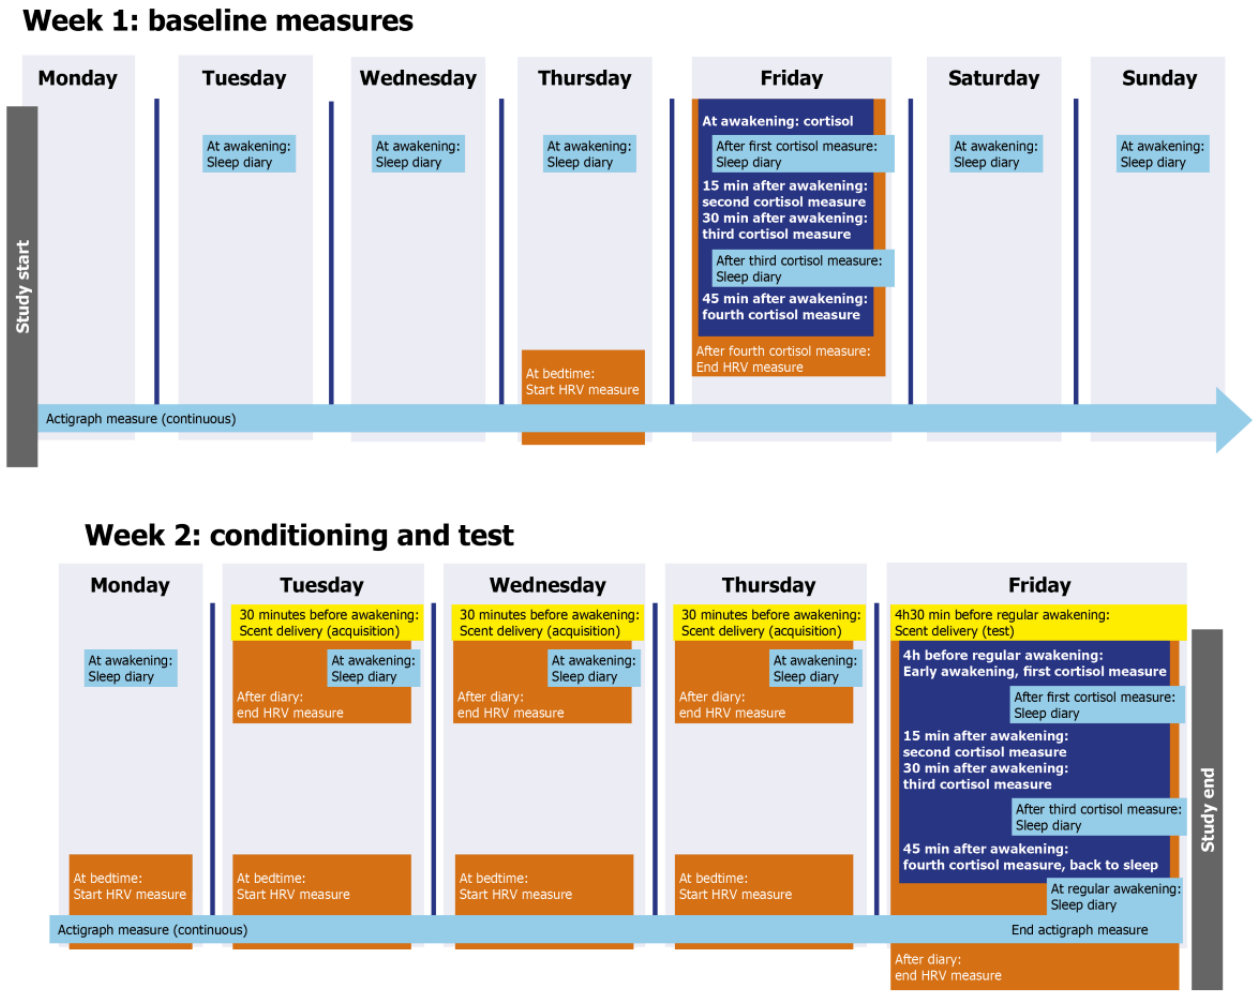
The study was approved by the Medical Ethics Committee of the Leiden University Medical Centre, Leiden, the Netherlands (case NL62812.058.017), who will be notified of major changes. The study is performed in accordance with the principles of the Declaration of Helsinki and Dutch Medical Research Involving Human Subjects Act (WMO). The study was preregistered at the Dutch trial register [36]. The results will be disseminated in peer-reviewed journals, international conferences, and the PhD thesis of the first author.

Participants

Participants are recruited from the local Dutch population and compensated with €100 (US $110.25) for participation. Flyers displaying a summary of the study inclusion criteria and procedures as well as the compensation amount are disseminated on social media through word of mouth by students and teachers, in university buildings, and in local student housing. Owing to the novel and exploratory nature of the study design, no sufficiently similar studies are available to form the basis of a power analysis. Studies on similar topics have used different outcome measures and statistical analyses and thus do not offer a usable comparison. Therefore, it was decided to run a pilot study and include as many participants as possible within the grant-permitted timeframe, which resulted in 50 inclusions and 42 participants completing the full protocol. It should be noted that the most similar studies available use a comparable number of participants [24,25,37].

To avoid confounding in the measurement of the CAR by menstrual cycle or age [38], only male individuals between the ages of 21 and 34 years are included, and participants are excluded if their answers during screening indicate obesity (defined as BMI >30 kg/m^2), brain damage, or HPA axis–related endocrine disorders (Cushing disease or Addison disease). Participants currently taking medication (including glucocorticoid medication) or who have a habit of heavy drinking or recreational drug use are also excluded. Participants are screened for severe somatic or psychiatric conditions that would interfere with the study protocol using the Mini-International Neuropsychiatric Interview Plus (MINI-Plus) [39]. To ensure a regular sleep pattern, participants are screened using the Pittsburgh Sleep Quality Index (PSQI) [40] and excluded if they experience jetlag or participate in shift work up to 1 week before participation. To ensure that participants are able to properly detect the scents used in the study, they are excluded if they indicate that they have olfactory impairments. Participants are also excluded if they report allergies or sensitivity to perfume or similar substances that might indicate an adverse reaction to the scents used in the study or if they show an allergic reaction to the scents in the course of the study.

Ongoing health and stress are checked at several points from 1 week before participation up to the conclusion of the study, and participants are encouraged to report any changes between these points. Participation is stopped if a participant uses glucocorticoid medication, has high levels of stress, or falls ill during the study period. The participants are asked to refrain from alcohol and drug use for the duration of the study. Caffeine use is permitted for consistency with existing habits but is monitored. They note their regular awakening time and are requested to set their alarm at exactly the noted time and maintain a steady sleep rhythm for the duration of the study. All participants sign an informed consent before participation.



Upon inclusion, participants are randomized to the experimental or control group through a pregenerated random number list, set to randomize in blocks of 4. Owing to procedural constraints (see the *Procedure* section), the study is single-blinded. Participants are not informed about the existence of a control group or the purpose of the study until the debriefing at the end of the study; instead, they are told that the study examines the effect of certain scents on sleep.

Design

The study design is summarized in Figure 2. Participants follow a 2-week protocol, with all measurements taking place in their own homes. The first week functions as a baseline measure. In the second week, the scent conditioning takes place on Tuesday through Thursday morning. Participants are exposed to a scent half an hour before awakening, with the aim of conditioning the scent to the CAR. The 30-minute interval was chosen to match the CAR in length and to increase the chance that the participant is still asleep for the length of the scent presentation, while still clearly preceding the CAR and minimizing the time between CS and CAR. It is presupposed that the CAR naturally functions as an unconditioned response to daylight and other zeitgebers that set the diurnal rhythm that serves as the UCS. The final night of the study functions as the test phase. To test whether conditioning has taken place, participants in the experimental group are asked to set their alarm 4 hours earlier than normal, and the scent device releases the trained scent half an hour before this time. This way, the CS is present, while the UCS is not. Participants in the control group wake up at the same time, but for them, the scent has surreptitiously been replaced the previous day with a different, novel scent, so that neither the CS nor the UCS is present. We expect that in the experimental group, the scent (CS) will evoke the CAR and lead to an increase in cortisol levels. While the process of awakening may lead to an increase in cortisol levels in both groups, the presence of the CS would cause this increase to be more pronounced in the experimental group.

Measurements

Scent Delivery System and Scents Used

Scents are delivered using the Air/Q-100 and Air/Q-160 devices and accompanying scent cartridges (Prolitec Inc). The scents used in the study were “Blue Wood” (Prolitec reference 9083) and “Marsala” (Prolitec reference 9141), with the latter used as the control scent during the last night for the participants in the control group and the former for all other instances. The scents were previously piloted to ensure that they were sufficiently distinctive. The devices release the scent at intervals of approximately 2 minutes every 9 minutes. The exact length of the delivery was dependent on the settings of the device, which were adjusted to the size of the participant’s bedroom based on the manufacturer’s suggestions. Custom-made containers were used to muffle the noise generated by the scent delivery devices.

Physiological Measures

Cortisol Awakening Response

Participants take saliva measures themselves on 2 consecutive Fridays of the experiment to measure cortisol levels. A total of 4 samples are taken each week: immediately after awakening, 15 minutes after awakening, 30 minutes after awakening, and 45 minutes after awakening. Participants are instructed not to eat, brush their teeth, smoke, exercise, shower, or drink anything other than water between awakening and taking the final sample to avoid any contamination of the samples or confounding of cortisol values [38]. Saliva is collected using sealed swabs designed for cortisol collection (Salivettes; Sarstedt AG and Co). Cortisol is assessed in saliva with a competitive electrochemiluminescence immunoassay using a Modular Analytics E602 immunoanalyzer (Roche Diagnostics). Cortisol activities are measured and expressed in nmol/L. Participants track the times when they take the saliva measures in a smartphone app, using a phone that they receive from an experimenter and use throughout the study to allow the researchers to verify that they were awake and took the required samples at the correct time. Because cortisol samples remain stable at varying temperatures for up to 5 days [41], participants were not required to cool or freeze the samples once collected. Samples were retrieved by a researcher and frozen on the same day they were collected.

The cortisol measure requires participants to be awake, but the scent conditioning procedure operates for half an hour before the participant wakes. To investigate whether the conditioning procedure has an effect before awakening, heart rate variability

XSL•FO
RenderX

and actigraphy measures are included that operate throughout the night. These measures also allow for an additional check for whether the participant did indeed awake at the scheduled time.

Heart Rate Variability

Heart rate is measured using Polar H7 and H10 heart rate sensors (Polar Electro Oy) connected to the Heart Rate Variability Logger smartphone app [42] using the same phone as the one required for registering cortisol measures. Participants equip themselves with the heart rate monitor before going to bed on the first Thursday and every day of the second week, so that it stays on throughout the night. On days when they perform the saliva measures, the monitor is kept on until the end of those measures (ie, 45 minutes after awakening) so that any changes in heart rate that accompany the change in cortisol levels during this period can also be measured.

Actigraphy

Actigraphy is performed using Motionwatch 8 wearable motion detectors (CamNtech Ltd). Measures are taken over the entire 2-week period with 1-minute epochs.

Questionnaires

All questionnaires used have previously been found to have adequate validity and reliability.

For screening, the participants complete the PSQI [40]. Scores of 5 or higher indicate poor sleep and are used as an exclusion criterion. In addition, participants are screened for mental disorders using the MINI-Plus [39,43] and excluded if they meet the criteria for any disorder.

Several personality characteristics are measured upon inclusion, to check for possible interaction with the main outcome. Specifically, the questionnaires used are the extraversion and neuroticism scales of the Eysenck Personality Questionnaire [44,45] to measure extraversion and neuroticism, the Depression Anxiety Stress Scale-21 (DASS-21 [46]) to measure symptoms of depression and anxiety, the Life Orientation Test–Revised [47] to measure optimism, the Perceived Stress Scale [48] to measure general appraisal of stress, and the Morningness-Eveningness Questionnaire [49] to measure chronotype.

Every day of the study, immediately after awakening or after the first saliva measure, participants complete a web-based diary on their phone or PC, which includes several questionnaires. To measure positive and negative affect, the Positive and Negative Affect Schedule (PANAS [50,51]) is used. Stress is measured using a custom-made Numerical Rating Scale (NRS) asking participants to score themselves between 0 (“not at all”) and 100 (“very much”) on 7 stress-related words [19,52]. Vitality is measured using the Subjective Vitality Scale (SVS [53]), and fatigue using the fatigue subscale of the Checklist Individual Strength (CIS [54]) adjusted to measure the current state of fatigue.

The sleep diary also includes custom-made daily questions about habits that indicate or may influence sleep quality and patterns. Participants are asked about their meal times; their intake of caffeine, alcohol, tobacco, medication, and recreational drugs; sporting activities; the time at which they fell asleep the previous night and the time at which they awoke in the morning; any nighttime awakenings; and their perceived sleep quality.

Procedure

An experimenter screens interested applicants through a telephone interview consisting of questions about relevant exclusion criteria (*Participants* section) and vocal administration of the PSQI (no data are saved). If participants meet the criteria, a follow-up screening session at Leiden University is scheduled to obtain written informed consent, perform a more elaborate check of mental and physical health, and to further explain the procedure and schedule meetings. This screening session consists of several questions about sleep, stress, and health and the Mini-International Neuropsychiatric Interview (MINI) plus international psychiatric interview. Participants who pass the screening also complete the Eysenck Personality Questionnaire – Revised Short Scale, Life Orientation Test–Revised, DASS-21, Perceived Stress Scale, and Morningness-Eveningness Questionnaire in this session. To ensure that the participants know how to take a sample of their saliva, they practice using the swabs used in the study under the supervision of a member of the research team.

The procedure of the actual experiment takes place over a period of 2 weeks, always starting on a Monday and ending on the second Friday. All measurements are performed at the participants’ homes; an experimenter visits the participants at several points to deliver and take equipment, check on participants’ health and stress, offer instructions on study procedures, and check whether all measurements have been completed successfully. Participants indicate their regular time of awakening before the experiment starts and instructed to set their alarm for this time for every day of the study. They are instructed to try to fall back asleep if they wake earlier than the indicated time. However, if they are fully awake, they should start all measurements at the earlier time of awakening.

The measures begin once an experimenter delivers the equipment on Monday of the first week. Participants are checked for exclusion criteria, instructed in the procedure for the coming days, and put on the actograph watch. The (waterproof) actograph watch will be worn continuously until the study ends, barring special circumstances such as high-contact sports or interactions with sensitive equipment where the watch could cause an issue, in which case it can be removed for the duration of the activity. Up until the evening of Thursday of week 1, participants fill in the web-based diary each morning at awakening and indicate their wake and sleep times on the actograph. Thursday evening, they put the heart rate monitor around their chest and wear it for the following night. On Friday morning, when waking up at their regular time of awakening, the first saliva measure is taken. Participants then complete the morning’s sleep diary, followed by another saliva measure 15, 30, and 45 minutes after awakening. An additional diary, where the PANAS, Stress NRS, SVS, and CIS-fatigue are completed again, is taken after the third saliva measure. After the last saliva measure, the participants remove the heart rate monitor. An experimenter arrives later in the day to take saliva measures for analysis.

XSL•FO
RenderX

During the weekend and on the morning of the following Monday, participants only complete the web-based sleep diary and indicate their sleeping times on the actograph. On Monday, an experimenter arrives to install the scent delivery system. This device has been preprogrammed to deliver the distinctive scent 30 minutes before the participant's regular awakening time. Participants continue to complete the diary and use the actometer in the second week, and starting Monday evening, they also wear the heart rate monitor every night. An experimenter comes by again on Thursday to reset the scent delivery system to go off 4 hours earlier than previously, that is, 4 and a half hours before regular awakening. The experimenter also checks the participant's experience with the scent device at this time and notes if the participant had any unexpected reactions or has woken up early. Unbeknownst to the participant, if the participant is in the control group, the cartridge containing the scent is also switched for a different cartridge containing a different scent. The participant is instructed to set their alarm 4 hours earlier than normal and perform saliva measures at the new time of awakening and 15, 30, and 45 minutes later. They also use the web-based diary to complete the PANAS, Stress NRS, SVS, and CIS-fatigue directly after the first and third saliva measures. After the final saliva measure, the participants are allowed to return to sleep. They awake at a time of their choosing the following morning and only at that point remove the heart rate monitor. Their only remaining activity that day is a final diary filled in at a time of the participant's choosing. Later that day, an experimenter picks up the saliva samples and all equipment, including the actometer that the participant can at that point remove, and debriefs the participant about the true aim of the study and their group assignment.

Data Management

Self-reported data will be entered electronically by participants and checked for completion throughout the study at each experimenter visit. These data will be stored on a secure server that produces daily backups. Saliva samples are stored securely in a freezer at Leiden University Medical Center until study completion. All data are handled in compliance with the Leiden University Data Management Policy (available at request). Personal data are kept separate from the research data, and the file connecting the 2 is secured and only accessible to the study staff. Owing to low risk, external monitoring was deemed unnecessary by the ethical review committee, but a department data manager will monitor the data during the study and check the data package for completeness at study completion. Data will be stored locally for a period of 15 years after study completion and will be uploaded to the Data Archiving and Networked Services database to be accessed at request.

Statistical Analysis

The data will be checked for outliers and all relevant assumptions. If cortisol values deviate strongly from normality, a log transformation will be performed. An α level of .05 will be used for all analyses, and an effect size (Cohen *d* or partial eta squared, as appropriate) will be calculated for all effects.

Sensitivity analyses will be performed to investigate the effect of including participants who do not show a CAR in week 1 (defined as an increase of at least 2.5 nmol/L above baseline [8]) and the effect of including participants with incomplete data.

A conditioned effect on cortisol values can be defined in 2 ways: by a higher increase in the CAR from baseline (first week) to evocation (second week) for the experimental group (same scent on evocation) than the control group (different scent on evocation), and by a higher increase in the initial cortisol value (first measure of the CAR) from baseline (first week) to evocation (second week) in the experimental group than in the control group. Therefore, 2 separate analyses will be performed. For the first definition, cortisol levels over each day will be transformed into a single score by computing the area under the curve with respect to the first value (area under the curve with respect to increase [7]). We will then perform a linear mixed-model analysis with week (baseline vs evocation) and group (experimental vs control) as fixed factors. For the second definition, we will again perform a linear mixed-model analysis, replacing the area under the curve with respect to increase value with the first cortisol value after awakening. To check for confounding variables, sociodemographic and personality variables will be included as random factors in both the analyses.

Linear mixed models are also used to analyze the secondary outcomes. Heart rate variability measures 30 minutes before awakening and 45 minutes after awakening will be analyzed separately. In both cases, week (baseline vs evocation) and group will again be fixed factors. For the secondary psychological outcomes affect, stress, vitality, and fatigue, the measurement time (0 vs 30 minutes after awakening) is added as an additional fixed factor.

Finally, multivariate regression will be used to explore the possible moderating or mediating role of psychological variables (affect, personality, and perceived stress) on the effects of conditioning.

Results

Data collection started on June 24, 2019, and we encountered difficulties owing to the COVID-19 pandemic. Data collection was closed on December 24, 2021, with 50 inclusions and 42 participants completing the full 2-week protocol. The results will be published separately at a later date when the data analysis is completed.

Discussion

The design of this study is intended to classically condition the CAR by repeatedly presenting a scent in the half hour immediately before awakening, immediately before the CAR normally occurs. If the conditioning is successful, participants should respond to the CS with higher cortisol levels even when it appears in the middle of the night, when cortisol levels are normally far below the morning levels. The outcomes of this study could offer more insight into learning during sleep, learning influences on physiological processes, and manipulating the diurnal rhythm. These findings may also aid in the treatment of sleep rhythm and cortisol disorders.

XSL•FO
RenderX

This study uses a novel design that combines the finding that conditioning is possible during sleep [24,25] with the idea that the diurnal rhythm itself could be conditioned [31,32]. While other studies have investigated whether cortisol levels are subject to classical conditioning [19,21-23], all of them have used an external UCS to adjust cortisol levels rather than relying on changes brought upon by the natural diurnal rhythm. Even animal studies that relied on less invasive stimuli kept the animals under artificial lighting conditions that are impossible to replicate in daily human life [31,32]. Should the alternative approach of this study be successful in conditioning the CAR, this could indicate that it is not necessary to rely on medication or highly demanding procedures to influence cortisol levels.

Should the conditioning procedure used in this study be successful in affecting subjective wakefulness measures, then a similar conditioning procedure has potential use in the treatment of sleep disorders. The primary target group would likely be those patients who do not respond to or cannot participate in existing behavioral therapies. Pharmacological therapies currently prescribed for this purpose are not always ideal solutions; many, such as benzodiazepines, do more to deregulate than help the sleep cycle and feature unpleasant side effects and risks of dependence [55].

On the other hand, the conditioning procedure could fail to affect cortisol. This may be due to the novel aspects of the study design. For example, using the stimuli associated with the diurnal rhythm may prove to be less reliable than inducing effects on cortisol through medication; the existing animal studies that relied on this [31,32] may not generalize to humans. Timing the test phase in the middle of the night will hopefully expose the effect because the CAR is not present in the control group, but there are indications that cortisol will still show an increase around an earlier time of awakening as long as the participants are aware that they will awake at the earlier time [33]. There is also the risk that the presence of the scent, the knowledge of having to wake, or the sound of the scent device would cause participants to wake up before the predetermined time. This would cause the scent and CAR to overlap, potentially affecting the conditioning procedure. If the participants do wake up, they could also consciously process the scent. While the debate on the role of consciousness in conditioning is ongoing and beyond the scope of this paper [56], what exactly is learned under these conditions is no doubt different than when asleep. Even if the conditioning procedure still led to an increase in cortisol, the conditioning might not be unconscious or physiological. Therefore, we endeavored to reduce the chances of this occurrence by selecting good sleepers as participants and reducing the noise as much as possible. If the participants do wake up, actigraphy and heart rate variability measures should show this.

Apart from factors specific to this study's design, a null result may indicate that pharmacological conditioning of cortisol levels in humans may not be feasible in general. The mixed results in existing studies might be the result of underlying confounds or sample fluctuations; several early studies rely on relatively small samples or groups [21,23] or suffer from unexpected baseline differences [19]. We hope that this study will avoid these issues and offer more clarity. The difficulties so far could also indicate that any effect of conditioning on cortisol is small and easily overshadowed by confounds. If the effect is too small or unreliable to be of use in clinical applications, further investigations may not be warranted.

Allowing participants to perform all measures themselves at home will invariably lead to a loss of control over the measurement situation, resulting in overall noisier data and an increased likelihood of missing or inaccurate measurements compared with a laboratory environment. Testing in a laboratory would have also allowed us to perform more continuous measures, such as daily cortisol sampling. However, such a setting would also highly increase participant burden, and sleep in a controlled medical environment has been shown to affect sleep measures in a way that does not occur for at-home measurements [57]. Therefore, we chose to focus on a home setting with fewer measurement points, relying on the reliability of the CAR [9] and stringent participant selection to still provide reliable data. Allowing measures to be taken at home also ensures that the results of the study are generalizable to real-life situations in a way that laboratory measures are not, thus ensuring maximal external validity.

Only healthy young men are included in this study. This selection is performed to prevent possible confounding effects of the menstrual cycle, gender, age, stress, and illness. However, it should be noted that the effects of some of these confounds are small [38] and the findings are often heterogeneous. For example, while some studies find differences in CAR in different phases of the menstrual cycle [58,59], others do not [60,61], and even when there are effects, they are limited to 1 phase differing from all others. Those few studies that cover a large age range show mixed results regarding the effect of age [8,60]. The effect of smoking is similarly equivocal [7,60,62,63]. Because this study uses a novel procedure and the exact size of the expected effect is uncertain, and because testing in the home environment is already going to produce additional noise, precautions have been taken to exclude any additional sources of interference. Thus, we have chosen to control for these factors, even if their effects may be small. However, should the current design produce the expected effect, broadening the type of participants in follow-up studies will greatly help generalizing the results. Extending the design to women may be especially valuable, not only because this is the largest excluded group but also because the CAR tends to be larger in women [7,8,64], which may make it easier to evoke through conditioning.

In conclusion, an innovative study design has been presented to investigate whether the CAR can be classically conditioned during sleep. The design of this study offers a unique first look at the potential of using natural diurnal changes in physiological conditioning. The results of this study will provide clarification on the currently murky topic of the conditioning of cortisol levels and, if positive, can inspire future additive treatment for sleep disorders.

Abstract

Background: Among doctors in the United Kingdom, there is growing sentiment regarding delaying specialist training, emigrating to practice medicine abroad, or leaving the profession altogether. This trend may have substantial implications for the future of the profession in the United Kingdom. The extent to which this sentiment is also present in the medical student population is not well understood.

Objective: Our primary outcome is to determine current medical students' career intentions after graduation and upon completing the foundation program and to establish the motivations behind these intentions. Secondary outcomes include determining which, if any, demographic factors alter the propensity to pursue different career paths available to a medical graduate, determining which specialties medical students plan on pursuing, and understanding current views on the prospect of working in the National Health Service (NHS).

Methods: The Ascertaining the Career Intentions of Medical Students (AIMS) study is a national, multi-institution, and cross-sectional study in which all medical students at all medical schools in the United Kingdom are eligible to participate. It was administered via a novel, mixed methods, and web-based questionnaire and disseminated through a collaborative network of approximately 200 students recruited for this purpose. Both quantitative and thematic analyses will be performed.

Results: The study was launched nationally on January 16, 2023. Data collection was closed on March 27, 2023, and data analysis has commenced. The results are expected to be available later in the year.

Conclusions: Doctors' career satisfaction within the NHS is a well-researched topic; however, there is a shortage of high-powered studies that are able to offer insight into medical students' outlook on their future careers. It is anticipated that the results of this study will bring clarity to this issue. Identified areas of improvement in medical training or within the NHS could be targeted to improve doctors' working conditions and help retain medical graduates. Results may also aid future workforce-planning efforts.

Introduction

Background

In the United Kingdom, medical degrees typically last for 5 or 6 years, depending on whether one elects to pursue an additional year in the awarding of an intercalated degree. Alternatively, for previous degree holders, there is a 4-year accelerated medicine course. Upon the completion of their medical degree, graduates are provisionally registered with the General Medical Council (GMC). Graduates then enter the mandatory 2-year United Kingdom Foundation Programme (UKFP), consisting of rotations in various settings and specialties. After the first year of the UKFP, graduates are awarded full medical registration with the GMC. Doctors who have completed the UKFP are then able to pursue further training, which may be in very specialized fields, for example, ophthalmology or neurosurgery, or broader pathways such as general practice or internal medicine training [1].

Historically, the vast majority of UKFP graduates pursued specialty training immediately after completing their foundation program; for instance, in 2010, the proportion of graduates entering further training upon completing Foundation Year 2 was 83.1%. However, the UKFP Office career destination report revealed that this number had fallen to only 34.9% of doctors in 2019 [2]. The UKFP Office has not repeated the survey since, so it is difficult to surmise how these statistics may have changed in the interim.

In comparison to most other Organization for Economic Co-operation and Development countries, the United Kingdom has fewer doctors per capita [3]. One of the ways the British government has attempted to combat this issue is through the opening of new medical schools as well as increasing student capacity in existing medical schools [4,5]. The aim of the Ascertaining the Career Intentions of Medical Students (AIMS) study is to understand the effectiveness of this approach: are the factors encouraging graduate doctors to seek alternatives to medicine in the United Kingdom, or in its entirety, also present in the undergraduate population?

AIMS also endeavors to investigate the reasons behind students' intentions to both enter and leave the standard training pathway and attempt to identify any demographic and background information that might increase the propensity to leave training.

A British Medical Association survey of 8000 senior doctors determined that 44% of National Health Service (NHS) consultants in England plan to leave or take a break from working in the NHS over the next year [6]. Similarly, a recent survey of 4553 junior doctors in the NHS reported that 4 in 10 plan to leave the NHS, with 33% of these wanting to immigrate to another country to work [7]. Broader literature supports these findings, with a 40-year survey series of junior doctors highlighting that the desire to remain in UK medical practice was lower in 2015 than had ever been recorded [8]. Additionally, in 2021, nearly 10,000 doctors relinquished their license to practice in the United Kingdom, making up nearly 1 out of 10 of the total UK doctor workforce [5,9]. We aim to determine if this trend, found in both junior and senior doctors alike, may also manifest in the intentions of medical students yet to even enter the profession.

The study invites participants to share their views on many aspects of working in the NHS and how the prospect of working in the NHS could be improved. Data collected from this study could prove helpful in addressing some of the concerns of those making up the future of the profession. In Australia and New Zealand, a questionnaire is distributed each year where the medical deans of medical schools in the country survey final-year medical students and collect data on their background, medical school experience, and any early geographical and specialty preferences for their future career [10]. The information gained has had a lasting positive impact on curriculum development and future medical workforce planning. Additionally, it has assisted in workforce distribution and helped to plan specialist training pathways to meet the career interests of trainees and the public's health needs.

The AIMS study is a national, multi-institutional, and cross-sectional study. AIMS endeavors to understand the factors involved in medical students' decision-making around their future careers. Specifically, we are interested in students' current career plans and why they may or may not intend to pursue specialty training or a medical career in the United Kingdom. We are also hoping to understand current views on the prospect of working in the NHS.

Study Objectives

Primary Objectives

This primary objectives are to determine current medical students' career intentions after graduation and upon completing the foundation program and to ascertain the motivations behind these intentions.

Secondary Objectives

Secondary objectives are as follows:

- To characterize the backgrounds of medical students intending to:
  - emigrate to practice abroad
  - leave medicine permanently
  - undertake further study or a career break
  - not going into further medical training immediately after degree completion or foundation training
- To determine which specialties medical students plan on pursuing
- To analyze medical students' views on how the prospect of working in the NHS could be improved

Methods

Study Design

AIMS is a national, multi-institutional, and cross-sectional study of medical students. Participants' responses will be recorded via a web-based survey platform. The survey contains 71 items, but participants will not view all of them as their visibility depends on their previous answers. The shortest question sequence involves 30 items, and the longest involves 43 items. Questions are structured using a combination of Likert scale

XSL•FO
RenderX

matrices, multiple-choice options, and free-text entry to broaden the capture of sentiment nuance and improve precision in the data. Data collection began on January 16, 2023, and was completed on March 27, 2023. A full project timeline can be found in Table 1. This timeline will be approached with a level of flexibility, such as for centers with logistical obstacles to data collection.

Table 1. Project timeline.

Dates	Activity
December 12, 2022, to January 9, 2023	Recruitment of collaborators throughout all UK medical schools via social media and communication with medical schools and societies
January 10, 2023, to January 15, 2023	Training of collaborators
January 16, 2023, to March 27, 2023	Study runs nationally for approximately 2 months
March 28, 2023, to June 1, 2023	Data analysis and manuscript preparation

The survey consists of multiple sections. Section 1 of the survey involves a background and demographic section, which all participants will answer. Consent is also obtained in this section. Section 2 focuses on participants' career intentions immediately after graduation and after foundation training (for those entering it). Section 3 invites participants to explore the factors behind their decision-making. Section 4 surveys which specialties the participants are currently inclined to pursue. The final section includes a free-entry text box where participants are invited to articulate how the prospect of working in the NHS could be improved and a question to obtain consent for follow-up studies.

The complete 71-item questionnaire can be found in Multimedia Appendix 1.

To identify gaps in knowledge and inform the aim of the project, a review of existing literature was conducted, including similar questionnaires and qualitative studies on students' and doctors' perspectives. Feedback from senior clinical staff was also obtained. Questions were revised based on the comments received, aiming to ensure they were as nondirective and comprehensive as possible while remaining unencumbering so as to maximize the number of responses for statistical power.

The survey will be hosted on the Qualtrics survey platform (Qualtrics XM), a General Data Protection Regulation (GDPR)–compliant web-based survey platform that supports both mobile and desktop devices. The survey will be distributed through university mailing lists, student society social media pages, conferences, and personal and medical school social media platforms (such as Facebook, Instagram, LinkedIn, and Twitter). To maximize distribution across the United Kingdom, a national network of approximately 200 AIMS Collaborative members was recruited, representing all medical schools in the United Kingdom. Each member will be asked to liaise with their medical school dean to distribute the survey through official channels and advertise it at regular intervals over the collection period from January to March.

Study Population

All current students in all years at UK medical schools recognized by the GMC and the Medical Schools Council are eligible to participate in the study. A list of eligible medical schools and approved programs can be found in Multimedia Appendix 2. It is worth noting that we have excluded schools that, although approved by the GMC, have not yet admitted their first cohort of students since they have no medical students to participate.

Data Collection

The survey will be disseminated primarily through medical student collaborators recruited prior to the study launch. These collaborators will ensure that their medical school is formally engaged at an early stage of this study and will be primarily responsible for disseminating this questionnaire among students at their medical school.

Ethics Approval

Ethical approval was granted by the University of Cambridge Research Ethics Committee (reference PRE.2022.124) on January 5, 2023.

To obtain informed consent, a participant information sheet (Multimedia Appendix 3) will be made available to all participants. This information sheet will explain the rationale and purpose of the study, emphasizing its voluntary nature and the anonymity and confidentiality of participants. It will be made clear on the study materials and on the first page of the questionnaire that submitting responses provides consent for data usage. Additionally, the first question of the survey will obtain consent, and it will be mandatory to complete. Consent can be withdrawn at any time, during or after completing the questionnaire, by contacting the study lead. Email addresses will only be collected and stored for participants who provide explicit consent to this in the final question of the survey. Email addresses will be kept separate from the responses to survey questions, ensuring anonymity.

The anonymous responses will be collected and stored on the secure web-based server, Qualtrics. Survey data will be extracted from Qualtrics and stored in a password-protected Microsoft Excel (version 16.71; Microsoft) file accessible only to the central study team. The University of Cambridge standards for data handling will be followed for all data management and record-keeping.

Participants will not receive compensation for completing the questionnaire. However, participants who provide their contact information will be entered into a prize draw, with one randomly selected individual receiving a cash prize of £300 (US $370.10) at the time of prize draw, at the end of data collection.

Data Analysis

A sample size calculation was performed, and it was determined that a minimum of 8026 participants are needed to have a confidence level of 95% that the results of the survey are within 1% representation of the total medical student population. This calculation used a population size for UK medical students acquired via a Freedom of Information request to the GMC.
