Subsequently, training progression and personalization are carried out based on three factors: (1) a progression algorithm integrated into the software adapting the level of difficulty in each game in real time, (2) an objective progression criterion (performance plateau, defined as <5% performance increase from 1 week to the other [34]), and (3) a subjective rating of the level of difficulty by the participants based on the Borg Ratings of Perceived Exertion Scale [35] indicating whether a game was too exhausting or too easy. If, in the context of progression, new games are implemented in the training plan, the participants are informed accordingly by written messages sent via the rehabilitation cockpit.

With our training plan, we aim to follow the findings of previous systematic reviews that suggest that to be effective, a combined motor-cognitive training approach should be applied for a minimum of 8 weeks, 2 to 4 times a week, and should be based on tailored intensity monitoring and progression [10,11,36].

Usual Care and Choice of Comparator

Both IG and CG participants continue their usual care throughout the study. In pragmatic trials, usual care is difficult to define and could theoretically include a large range of interventions [37]. It could be argued that CG participants should receive 1 specific predefined treatment, but "patients in usual care control group should be confronted with the heterogeneity of treatments available in real, daily practice, rather than receiving a treatment chosen by the researchers" [37]. For this reason, we aim to administer the content of the usual care programs as precisely as possible through training logs.

Criteria for Discontinuing or Modifying Allocated Interventions

The criteria for which a participant is withdrawn from the study are (1) the withdrawal of informed consent, (2) acute hospitalization, (3) the occurrence of events or diseases listed in the exclusion criteria, and (4) the occurrence of any intervention-related major safety issues. In case of the last-named criterion, the study will be discontinued.

Strategies to Improve Adherence to Interventions

During the home-based training period, regular telephone calls (4 times) and personal visits (2 times) are made, which are expected to improve the participants' adherence. In addition, written motivational and feedback messages can be sent to the participants via the rehabilitation cockpit.

Relevant Concomitant Care Permitted or Prohibited During the Trial

There is no relevant concomitant care or intervention that is specifically permitted or prohibited during the intervention.

Outcomes and Outcome Measures

Primary Outcome

The primary outcome of this study is the feasibility of a home-based exergame training program with the Senso Flex in older adults. Thus, we follow the phases defined in the updated framework for developing and evaluating complex interventions commissioned jointly by the Medical Research Council and the National Institute for Health Research and recommended for the development of complex interventions [27]. For this purpose, we assess adherence, attrition, and perceived enjoyment in IG participants (Table 1).

The adherence rate is determined by calculating the duration of completed training sessions as percentages of the recommended duration of training. Furthermore, the attrition rate in both groups is calculated as the percentage of dropouts during study participation.

Perceived enjoyment while playing the exergames is measured with the Exergame Enjoyment Questionnaire, developed to assess enjoyment of the physical activity aspect in exergames together with enjoyment of the gaming elements [38]. The questionnaire comprises 20 items that are rated on a 5-point Likert scale, resulting in a minimum possible score of 20 and maximum possible score of 100. Considering the results of previous literature [38] and of a preliminary study testing the usability of this motor-cognitive training approach [29], an average Exergame Enjoyment Questionnaire score of 70 points (out of 100) can be deemed as *acceptable*.

However, the criteria for trial success are solely based on adherence and attrition rate measures. A 70% adherence rate was defined as being "adherent to the training program" [46,47]. According to a systematic review [47], an attrition rate of ≤10% is *acceptable* for RCTs. However, because this study is a pragmatic RCT, we deem an attrition rate of ≤20% as *acceptable*.

Secondary Outcomes

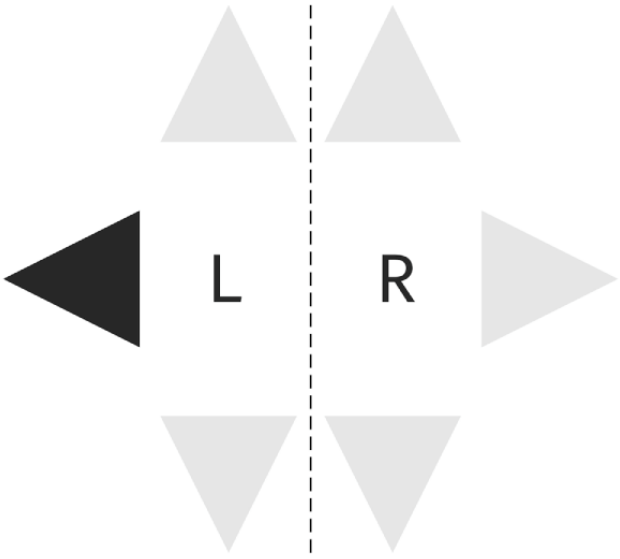
Overview

Several other feasibility measures are assessed as secondary outcomes (Table 1). The National Aeronautics and Space Administration Task Load Index [39] is used to assess the subjective workload during exergaming. It consists of 6 subscales: mental demand, physical demand, temporal demand, performance, effort, and frustration. Each subscale is rated on a 20-point Likert scale ranging from 0=very low to 20=very high. The raw National Aeronautics and Space Administration Task Load Index scores are calculated by multiplying each subscore by 5.

In addition, after the intervention, participants will be asked about their willingness to continue a similar home-based exergame training program after the end of the study (as a proxy for training satisfaction), and agreement will be determined on a 5-point Likert scale. Finally, during the whole home-based intervention period, the number and types of additional instructions as well as help instructions are noted.

Furthermore, a series of physical and cognitive functions as well as balance confidence are assessed before and after the home-based intervention as secondary outcomes to obtain first indications regarding the effectiveness of the home-based exergame intervention (Table 1).

Cognitive Assessments



The cognitive assessments are mainly based on the standardized and validated *Test for Attentional Performance* (TAP) developed by Zimmermann and Fimm [40], a collection of reaction time tasks with tasks consisting of “simple and easily distinguishable stimuli that the patients react to by a simple motor response” [48], and are conducted using the Dividat Senso.

The reaction time test measures psychomotor speed. Six triangles are presented on the display. When a triangle turns dark, the participants are asked to react as fast as possible by taking a step in the corresponding direction (Figure 1). The arrows also indicate with which foot the step must be taken. The average reaction time (ms) and errors will be included in the analysis of effectiveness.

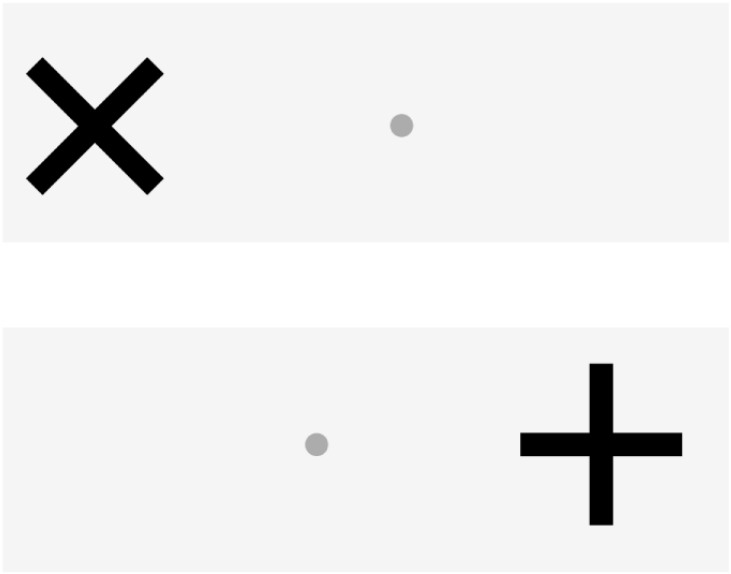
The go-no-go test was developed based on the go-no-go test from the TAP assessment battery [40] and measures selective attention and inhibition. More precisely, it evaluates the ability to suppress a response in the presence of irrelevant stimuli as well as the response latency during stimulus selection. Participants are asked to react as fast as possible when a cross (x) is presented on the screen. However, in case the stimulus is a plus sign (+), they must remain still (Figure 2). The average reaction time (ms) will be included in the analysis of effectiveness, and errors will be described descriptively.

The flexibility test is based on the flexibility test from the TAP battery [40] and aims to assess the flexibility of focused attention. Participants are instructed to react by taking a step toward the rounded figure and then toward the angular figure in an alternating manner (Figure 3). The average reaction time (ms) and errors will be included in the analysis of effectiveness.

Figure 1. Reaction time test.

XSL•FO
RenderX

Figure 2. Go-no-go test.



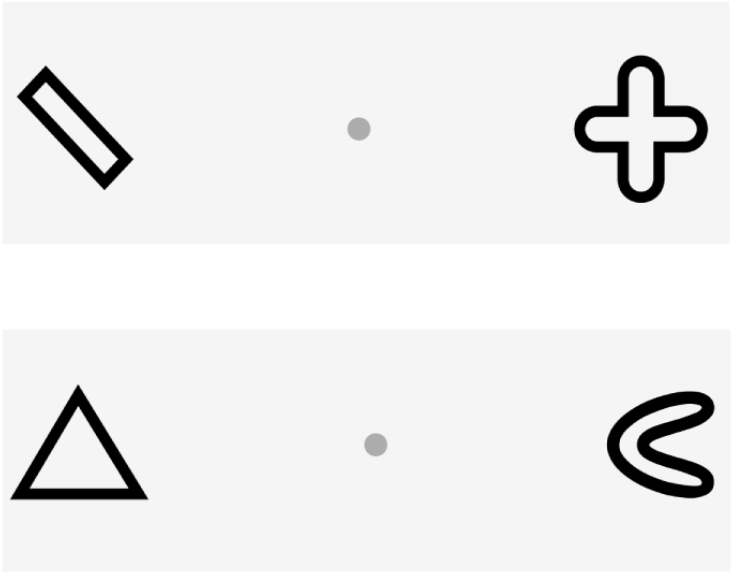


Figure 3. Flexibility test.

Balance

The sway test is based on the Romberg test [49,50] and is conducted on the Senso. The participants are instructed to stand as still as possible for 30 seconds. Meanwhile, postural sway, which is the movement of the center of pressure, will be recorded. The sway path length (mm) will be used for further analyses.

The coordinated stability test serves to measure dynamic balance. At the beginning, the participants are instructed to stand with their feet hip width apart on the middle plate and keep their arms crossed in front of their chest for the entire duration of the assessment. The task is then to follow a figure shown on the screen by shifting their center of pressure without lifting their feet. The output metrics, which will be included in the analysis of effectiveness, are the difference from the ideal path (mm) and the completeness of the path (percentage).

The timed up-and-go test [42] is a measure of mobility and functional balance and requires the participant to “rise from a standard armchair, walk to a line on the floor 3 meters away, turn, return, and sit down again” [42]. The timed up-and-go dual task (DT) complements this motor task (as the primary task) with a secondary task—here a cognitive task. For the cognitive task, participants are instructed to count backward from 90, subtracting 7 successively. This simultaneous execution of motor and cognitive tasks reflects real-life conditions better, considering the fact that in older adults, gait is not only a motor activity but also involves cognitive demands [51]. Two attempts without DT and 2 attempts with cognitive DT are conducted. In both cases, the time until the patient is fully seated again is recorded, and the best attempts are used for further analysis. DT cost is calculated by determining the percentage at which the secondary task interfered with the test performance:

XSL•FO
RenderX

DTC [%] = 100 × (DT score − simple task score) / simple task score **(1)**

where "DTC" is the DT cost [52].

Leg Power

The 30-second chair-stand test [43] is used to assess lower limb power and short-term endurance. The participants start seated on a chair; after a countdown, they must stand up straight and sit down again as many times as possible within a time frame of 30 seconds. Meanwhile, the number of times the patient fully stands up from a seated position is counted.

Balance Confidence

The Activities-Specific Balance Confidence Scale measures the fall-associated self-efficacy of a person in different activities and situations (eg, stair climbing and walking on icy pavements). The scale is able to detect the loss of balance confidence in highly functioning older adults too [44].

Quality of Life

Participants are asked to rate their overall quality of life and satisfaction with their health. Both assessments use a 5-point Likert scale (ranging from 1=very poor or very dissatisfied to 5=very good or very satisfied).

Other Outcomes

In addition, every 2 weeks, all participants are queried by a study investigator regarding the dose (frequency and time) and content (intensity and type) of their usual care as well as their daily cognitive and physical activities, and the training times of the IG participants are collected.

At baseline, the following demographic information is collected to describe the study population: age, sex, years of education, living situation (living with another person or alone), body weight and height, reason for therapy prescription, number of falls, and comorbidities (Charlson Comorbidity Index) [45].

Assessment Time Points and Duration

Assessments are performed in a standardized order at study entry (T1), before intervention period 2 (T2), and after the intervention (T3; Tables 1 and 2). Depending on group allocation, the T1 assessment takes 30 to 60 minutes and mainly serves to collect demographic data, randomize participants, and, in the case of IG participants, assess the functional status to subsequently create their training plan. The T2 and T3 assessments represent pre- and postintervention measurements for the evaluation of the home-based intervention's effectiveness. Both measurements take approximately 90 minutes to complete.

Participant Timeline

Overview

Table 2 displays the time schedule of enrollment, interventions, and measurements for IG and CG participants, as well as the respective data collected at each time point.

Sample Size

An intended sample size of 180 is based on recommendations from Whitehead et al [53], who stated that, in pilot clinical trials, for an extra small standardized effect size (≤0.1) and 90% power, 75 participants per group are required. We are expecting a 20% dropout rate, which is why we aim to recruit 90 participants per group; thus, in total, 180 participants (n=60, 33% at each trial site).

Recruitment

In Switzerland, participants are recruited through VAMED Rehabilitation Centre Zürich Seefeld, through an advertisement in the University of the Third Age of the University of Zurich, through announcements to various senior centers and organizations, and through university newsletters. Furthermore, participants of previous studies on older adults are contacted. Participants in Italy are recruited via convenience sampling, and in Cyprus, older adults who are members of existing networks are contacted, and collaborations with multifunctional

XSL•FO
RenderX

centers for older adults are used. Besides, an open invitation to the general public has been published.

Assignment of Interventions

Sequence Generation, Allocation Concealment, and Implementation

Participants are randomly allocated to either the IG or the CG with a 1:1 allocation ratio using permuted block randomization to avoid group size imbalances as well as allocation predictability. Blocks of 4, 6, and 8 were randomly generated. The allocation list was created with the web-based randomization tool Sealed Envelope [54] and uploaded on REDCap by a study investigator not involved in the enrollment, assessment, and randomization of participants. Randomization is then run in REDCap after baseline assessments. This allows a careful allocation concealment, and the investigators responsible for recruitment and baseline assessments are unaware of the group to which a participant will be allocated.

Blinding

Given the nature of a pragmatic RCT, neither the investigators nor the participants are blinded. The investigators will be responsible for supervising the interventions as well as for conducting the measurements, and participants cannot be blinded because the CG participants do not receive any intervention (other than usual care).

Data Management and Analysis

Data Management

All investigators received theoretical and practical trainings about all study procedures, including data collection and entry. Besides, written instructions have been created to ensure standardized conduction and reproducibility of the study protocol. These trainings were documented noting date, training time point, trainer name, trainee names, and training content.

All data of all study participants are kept strictly confidential. Data are coded, and the key remains password protected in a secure network folder.

REDCap, an electronic data capture system that meets the requirements of Good Clinical Practice, is used for electronic data entry. To ensure data quality, ranges for data values have been prespecified in REDCap, which will give a warning sign if the entered data lie outside these ranges. In addition, all data entered are double-checked by an investigator not involved in specific data collection who then confirms data accuracy with their signature.

Statistical Analysis

Baseline data of IG and CG participants will be compared with independent, 2-tailed *t* tests to validate the comparability of the 2 groups. The feasibility measures will be analyzed in a descriptive way. Besides, qualitative reports will be created based on the notes of the investigators regarding the kind of help requests and additional instructions, as well as other observations.

A generalized linear mixed model will be built to analyze changes in the measures of effectiveness for the IG participants compared with the CG participants (time × group interaction to indicate whether change differs between the groups). Thus, the explanatory variables include time (T2 and T3), group (IG or CG), and the interaction between time and group. To estimate the size and direction of effects, effect sizes (Pearson correlation coefficient *r*) and CIs will be calculated [55].

Per-protocol analysis will be conducted including data of only those participants who underwent the whole study procedure, with a training adherence of at least 70% of the training at home.

In case of missing data, a missing value imputation method will be used.

Monitoring

Overview

An internal monitoring visit was conducted at ETH Zurich before the inclusion of the first participants. Further monitoring visits will be conducted after the inclusion of the first participants, throughout the whole study period to track the study progress, and at closeout, which will ensure data quality and the early detection of possible mistakes. Moreover, the clinical trial unit of the Don Carlo Gnocchi Foundation as well as the chief scientist of Materia are monitoring this study. Furthermore, there are regular meetings with the whole study team for the principal investigator to check on and manage the accuracy of the study procedures at all trial sites.

Adverse Event Reporting and Harms

In case of an adverse event, we will investigate whether it was caused by the study intervention. Furthermore, a severity assessment of the event as mild, moderate, or severe will be made. If necessary, a report will be sent to the local ethics committees.

Auditing

The ethics committees may conduct a quality assurance audit of this study.

Dissemination Plan

The study results will be disseminated to academic groups and the public through publications, conference presentations, and social media.

Results

Data collection started in February 2023 and is still ongoing. As of May 2023, we enrolled 77 participants. Final measurements are expected to be performed in January 2024, and results are expected to be published in spring 2024.

Discussion

Study Rationale

This pragmatic RCT will provide new knowledge on the feasibility and effectiveness of an exergame-based telerehabilitation program in older adults.

Despite the promising results of previous studies investigating telerehabilitation and exergames in older adults, the feasibility and effectiveness of a combination of both have not yet been

XSL•FO
RenderX

sufficiently demonstrated. Furthermore, the combined provision of both approaches (motor-cognitive training) performed in a home setting and independently by older adults is another novel, underexplored, and fertile research area tapped by this study. To the best of our knowledge, previous research has either investigated telerehabilitation approaches that rely on the consecutive conduction of motor and cognitive training [56], or, in the case of approaches that rely on exergames, these have often limited their focus to specific populations (eg, survivors of stroke [57-60]; patients with Parkinson disease [61,62]; and older adults with cognitive impairment [63], subsyndromal depression [22], or lower limb amputation [64]) or healthy older adults [65-67]. However, exergame-based telerehabilitation should be feasible and effective in a broader population of both healthy and recovering older adults. It should especially target those without long-term access to traditional rehabilitation interventions and should accompany them to full recovery.

For this reason, and given the nature of a pragmatic RCT, in this study, the inclusion and exclusion criteria are formulated in a rather broad way to analyze the feasibility of a motor-cognitive telerehabilitation intervention in a diverse population of older adults to mirror or reflect real-life conditions and usual clinical practice as best as possible. Therefore, only participants who are clearly unable to perform a step-based motor-cognitive training program owing to physical and cognitive limitations must be excluded (another reason for exclusion: they cannot be regarded as future targets of such intervention approaches).

Concerning the study design, pragmatic RCTs have a limited internal validity, but they provide real-world evidence as well as generalizability to many real-world settings and therefore high external validity. Thus, they are “becoming a major tool in the evaluation of complex interventions and services” [68].

Conclusions

The Cocare system is complex and innovative in terms of 4 aspects. First, it includes an assessment system comprising cognitive as well as physical assessments that are based on the validated TAP battery [40]. Second, it introduces in a home environment an exergame-based training approach that has previously been proven to be effective in inpatient rehabilitation of patients classified as geriatric [31]. This seems promising, given decreasing access to conventional supervised interventions owing to the demographic change. Third, the training program can constantly be monitored and managed by health care professionals who can also communicate with the participants directly through the system (eg, send them motivational or feedback messages). Finally, and most importantly, the system has been developed in an iterative user-centered design process, which previous system developers have failed to do [69,70]. Thus, after being adapted based on a focus group study and a usability study, the Cocare system is ready to enter phases 2 and 3 of complex intervention research, and an acceptable feasibility and effectiveness can be expected.

Acknowledgments

This work was funded by the European Union and the involved national funding authorities (Innosuisse, the Swiss Innovation Agency; the Italian ministry of health; and the Cyprus Research and Innovation Foundation) as part of the AAL Association joint program (aal-2020-7-145-CP). Open access funding was provided by ETH Library (ETH Zurich).

Data Availability

Pending approval by the responsible local ethics committees, all data will be publicly available on Zenodo. Otherwise, data will be available to researchers upon reasonable request.

Authors' Contributions

JS was responsible for conceptualization, methodology, data curation, formal analysis, and writing the original draft. EG was responsible for conceptualization, methodology, supervision, and writing the original draft. EDdB was responsible for the trial sponsor, methodology, and cosupervision. IC, MF, SI, SM, FR, and ES were responsible for methodology, data curation, and reviewing and editing the manuscript. All authors revised the manuscript and approved the version submitted for publication and agree to be accountable for all aspects of the work.

Conflicts of Interest

EDdB was a cofounder of Dividat GmbH, the spin-off company that created and developed the Cocare system. However, no revenue was paid (or promised to be paid) directly to EDdB or his institution. All other authors declare no other conflicts of interest.

Abstract

Background: The medical community is beginning to recognize that retinitis pigmentosa (RP), due to its disabling progression, eventually leads to a reduction in the patient´s quality of life, a direct economic impact, and an increase in the burden on the health care system. There is no curative treatment for the origin of the disease, and most of the current interventions fail in reducing the associated negative psychological states, such as anxiety and depression, which lead to increased variability of vision and pose a continuous threat to the patient's independence.

Objective: The aim of this study is to assess the effect of oral melatonin (OM) administration alone and combined with short-wavelength light (SWL)–blocking filters on patients with RP and test their effectiveness in improving the level of stress and sleep problems in many of these patients.

Methods: We have developed a low-cost therapy protocol for patients with RP with sleep disorders and negative psychological stress. Patients will be randomized to receive a combined intervention with SWL-blocking filters and OM, SWL-blocking filters alone, or OM alone. There will also be a nonintervention arm as a control group. This study will be conducted across 2 retinal units in patients with RP with sleep disorders and high perceived stress and anxiety score reports. Patients will be assessed in the preintervention period, weekly during the 4 weeks of intervention, and then at 6 months postintervention. The primary outcomes are the differences in changes from baseline to postintervention in hormone release (α-amylase, cortisol, and melatonin) and sleep quality, as measured with the visual analog scale. Secondary outcome measures include clinical macular changes, as measured with optical coherence tomography and optical coherence tomography angiography; retinal function, as measured using the visual field and best-corrected visual acuity; sleep data collected from personal wearables; and several patient-reported variables, such as self-recorded sleep diaries, quality of life, perceived stress, and functional status.

XSL•FO
RenderX

Results: This project is still a study protocol and has not yet started. Bibliographic research for information for its justification began in 2020, and this working group is currently seeking start-up funding. As soon as we have the necessary means, we will proceed with the registration and organization prior to the preliminary phase.

Conclusions: In this feasibility randomized clinical controlled trial, we will compare the effects of SWL blocking alone, administration of OM alone, and a combined intervention with both in patients with RP. We present this study so that it may be replicated and incorporated into future studies at other institutions, as well as applied to additional inherited retinal dystrophies. The goal of presenting this protocol is to aid recent efforts in reducing the impact of sleeping disorders and other psychological disorders on the quality of life in patients with RP and recovering their self-autonomy. In addition, the results of this study will represent a significant step toward developing a novel low-cost therapy for patients with RP and validating a novel therapeutic target.

Introduction

Background and Rationale

Retinitis pigmentosa (RP) is the most frequent form of inherited retinal dystrophy (IRD) and the main cause of hereditary blindness, with more than 1.5 million patients affected worldwide and a prevalence of 1:4000 people [1]. The term was coined by Donders in 1857 [2] and compounds a group of heterogeneous diseases characterized by a progressive degeneration of photoreceptors, starting with rods and eventually affecting cones as well. This is the mechanism responsible for the progressive loss of vision function [3].

RP can have bilateral or, less frequently, unilateral involvement and can occur isolated or as part of a syndrome [1,4,5]. It is caused by more than 3000 mutations in over 70 genes, creating a wide heterogeneity among patients with RP [6].

RP affects mainly the outer retina, but in the final stages of the disease, atrophy and damage ultimately affect the inner retina, including retinal ganglion cells [7]. Intrinsically photosensitive retinal ganglion cells (ipGCs) constitute a special type of photoreceptors within the retina that contain the melanopsin photopigment [8,9]. Although they represent less than 10% of the total ganglion cells, they play a key role in regulating the pupillary reflex, circadian photoentrainment, mood, and diverse cognitive functions [9-16]. Alterations in circadian rhythms, partially dependent on ipGC integrity, have been previously reported in different ocular diseases and blindness [17-22]. These patients usually do not properly receive light signals that ordinarily synchronize their internal circadian clock to the 24-hour day, causing sleep-wake cycle abnormalities and recurring blocks of days with severe insomnia and excessive daytime sleepiness [21]. This circadian clock impairment could ultimately affect the quality of life due to sleep disorders and could also involve cardiovascular problems or emotional disorders or trigger or accelerate the pathology progression in neurodegenerative diseases [7,23,24].

The few therapeutic options for patients with RP currently available in daily clinical practice just retard disease progression and are limited. There is no therapy nowadays that restores vision, so the prognosis is poor [3]. Because of the chronic nature of this disease and its disabling progression, there has been great interest in the development of new strategies to help patients cope with the social and psychological impacts of blindness.

Among nonpharmacological strategies aimed at slowing down the degenerating process are those that are based on light protection. Some pieces of evidence indicate that some hereditary pigmentary retinopathies are partly light dependent [25,26]. Violet (400-440 nm) and blue (440-500 nm) light constitute the lower wavelength of the visible spectrum, which carries the highest amount of energy per photon [27]. The possible role of short-wavelength light (SWL) in the photochemical damage to retinal tissue and retinal pigment epithelium (RPE) cells has been studied, with high-energy SWL (415-455 nm) being the most harmful to the eye (the second type of phototoxicity or blue-light hazard) [28-30]. Blue-violet light could cause oxygen-dependent retinal injury, acting on specific chromophores, and *N*-retinylidene-*N*-retinylethanolamine (A2E) is considered the most important target molecule. Reactive oxygen species (ROS) initiate the activity of cysteine-dependent proteases, ultimately leading to apoptosis and cell death [28,31-34]. Mitochondria from photoreceptors, retinal ganglion cells, and RPE cells are the main targets of blue light–associated oxygen free radicals [35-37]. Moreover, photophobia, a common unpleasant symptom in patients with RP, has been described to be caused primarily by SWL in its interaction with S-cones from the retina [38]. In addition, in experimental RP models, limiting SWL exposure by the application of optical filters has been demonstrated to slow retinal degeneration [39].

However, some studies have shown that longer blue wavelengths of the visible spectrum (465-495 nm) are essential for the circadian rhythm, pupillary reaction, color discrimination, and night vision [7,23,24,40-43]. Numerous studies have demonstrated their close association to circadian rhythm regulation, alertness, memory, and cognition [44,45]. Therefore, blue-light exposure could regulate the secretion of melatonin

XSL•FO
RenderX

in the pineal gland through the retinal–suprachiasmatic nucleus (SCN)–pineal axis, modulating cortisol expression through the hypothalamic–pituitary–adrenal (HPA) axis or the autonomous nervous system [7,23,24,44]. These responses are driven primarily by intrinsically photosensitive retinal ganglion cells (ipGCs), which are more sensitive to 480 nm SWL and remain functional in late stages of the disease [7]. In contrast, melatonin suppression has a peak sensitivity of roughly 460 nm in humans, the same spectrum that has been shown to reset the circadian pacemaker and directly enhance alertness [46].

In consequence, evening SWL exposure in daily life may affect sleep, hormone release, and the circadian rhythm in patients with RP. In fact, it has been reported that wearing SWL-blocking glasses that virtually eliminate SWL is effective in improving sleep, the circadian rhythm, and mood. Three randomized controlled trials (RCTs) have demonstrated that SWL-blocking glasses bring about significant improvement in sleep quality in participants with insomnia [42,43,47].

Among pharmacological interventions, the trophic and antioxidant effects of vitamins or nutritional supplements have been evaluated in patients with RP to demonstrate a protective action on cone death [48-50]. Accumulating evidence indicates that melatonin therapy is a promising approach in the treatment of various ocular degenerative disorders (eg, age-related macular degeneration, diabetic retinopathy, and RP) since it can exert a protective effect against damage to RPE cells evoked by ROS, but it has also been reported to increase ROS-induced damage to photoreceptors and RPE cells [51-55].

Melatonin is an endogenous hormone that has been implicated in a variety of biological processes, including antioxidant, anti-inflammatory, and neuroprotective activities [56,57]. Melatonin is released from the pineal gland in a circadian fashion, which is controlled by the SCN. However, many other tissues and organs also synthesize melatonin. In the retina, it is mainly synthesized by photoreceptors and is involved in the modulation of neuronal activities. Its circadian production results in a high concentration at night and a low level during the day, although its amount is small compared to its pineal counterpart [7,51,58].

Oxidative damage has been proposed to be an important contributor to cone death in RP, and antioxidants may prevent cone damage in RP by reacting with free radicals produced during light absorption [59]. Melatonin behaves like synthetic mitochondria-targeted antioxidants, which are concentrated in the mitochondria at relatively high levels [51,58]. It exerts its antioxidant actions in the eye via several mechanisms, including direct ROS scavenging, stimulating antioxidant enzymes, improving the functioning of the mitochondrial electron transport chain (ETC), reducing the extent of electron leakage from the mitochondrial complexes, and improving the efficacy of other antioxidants. As mentioned before, mitochondria from photoreceptors, retinal ganglion cells, and RPE cells are the main targets of ROS produced by the ETC, and thus, melatonin may prevent mitochondrial damage in patients with RP [7,51,58,60,61].

However, it has also been demonstrated that daily administration of appropriately timed melatonin can synchronize the circadian clock [62-66] in patients with sleep disorders; its use is even recommended by the Standards of Practice Committee of the American Academy of Sleep Medicine [67]. The phase-shifting effects of melatonin are essentially opposite to those of light. It can phase-shift the endogenous circadian clock and, in the absence of light, entrain the sleep-wake and neuroendocrine rhythms (cortisol) [61]. Therefore, it is likely that OM may also be effective in sleep and circadian rhythm management in patients with RP. However, to the best of our knowledge, no previous RCT has investigated the potential additive benefits of adjunctive SWL-blocking glasses plus OM in improving sleep, perceived stress, and the circadian rhythm in patients with RP.

The aim of this study is to assess the efficacy of OM combined with SWL-blocking filters in patients with RP who have sleep disorders and stress compared to any intervention alone or no intervention. We hypothesized that both interventions would improve their sleep quality, reduce their perceived stress levels, and shift their circadian rhythm to morningness.

Need for a Trial (Innovation Aspect)

RP is the commonest of inherited retinal disorders, with a great economic impact and poor associated quality of life [68]. In addition, there is a lack of standard treatment with a good level of efficacy data, which brings a fruitful opportunity to add new knowledge and pursue evidence-based interventions.

The innovation in this study is based on a noninvasive approach—SWL-blocking filters combined with OM. This treatment protocol might represent a better option for patients with RP, especially those with moderate or severe RP, who present with greater functional disability, glare symptoms, and variations in cortisol, salivary α-amylase (sAA), and melatonin levels.

Although a few trials have assessed the efficacy of different vitamins and melatonin in visual and sleep pattern anomalies in patients diagnosed with RP, none of them used a similar combined therapy and even fewer focused on variations in cortisol, sAA, and melatonin levels or determined the impact of these interventions on psychological factors. This study aims to fill this gap in the literature by enhancing the level of evidence with a double-blind RCT that evaluates the benefits that OM combined with SWL-blocking filters may bring to patients with moderate or severe RP.

Significance/Impact of the Study

RP is accompanied by significant disability, greater dependency, and a decrease in the health-related quality of life, with increased rates of admission to institutional facilities [68-70]. It is also considered a public health issue and a primary cause of headaches, sleep disturbances, and increased rates of depression [71]. Patients with RP also face difficulties in performing daily activities and increased risk of cardiovascular, metabolic, and psychiatric disorders [68-70]. Productivity losses for patients with visual impairment are likely to be amplified in patients with RP because of the early age at onset, vision challenges at school, and loss of visual function without some type of rehabilitation during prime working years [68-70].

XSL•FO
RenderX

The annual cost of adult vision problems for the National Health Service (NHS) is around US $51.4 billion. Among adults with retinal diseases, the annual total health care costs were estimated to be US $7317 higher per patient with RP, increasing the community costs by around 2.5 times because of the number of years of blindness experienced [72].

SWL-blocking filters and OM have been playing an important role in the treatment of several kinds of retinal conditions and sleep disabilities [42,43,47,60,61,73]. Unlike other expensive treatments for sleep disorders, anxiety, and depression, SWL-blocking filters or OM may provide effective control of the human circadian clock through changes in the HPA axis or the retinal–SCN–pineal axis, which could be positively correlated with improvement in the quality of life and visual function disability.

Some studies suggest a multidisciplinary treatment program that includes specialists from different areas of expertise [74]. This program provides a combination of drug treatment and SWL-blocking filters with an adequate assessment of the grade of severity (via clinical assessment) and biochemical stress (by analyzing biomarkers) and determines the impact of psychological factors on patients with RP. It could be considered a good alternative for patients with moderate and severe RP who have not benefited from expensive therapies (eg, bionic eye or genetic therapy) individually. Therefore, in this study, we suggest mimicking a multidisciplinary treatment by combining treatments and analyzing the impact of biochemical and psychological factors on anxiety and sleep disability.

Choice of Comparators

To date, therapeutic approaches for RP are restricted to slowing down the degenerative process; treating ocular complications, such as cataracts and macular edema; and helping patients cope with the social and psychological impacts of blindness. In addition, the evidence from RCTs on the visual protective effects of vitamins and nutritional supplementations in patients with RP is limited and in some cases contradictory. Moreover, as mentioned before, few studies on the effects of blocking SWL on visual discrimination capacity in patients with RP have been reported. In addition, in clinical practice, there is insufficient experience to recommend the use of optical absorbing filters, since their potential effects on regulating the human internal circadian (24-hour) clock in patients with RP are yet unknown.

For this reason, the intervention groups will consist of SWL blocking alone (SWL group), OM therapy alone (OM group), and SWL blocking plus OM therapy (SWL+OM group) in order to determine whether there is any summative effect. No intervention has been chosen for comparison to avoid performance bias and other biases related to loss of blinding in the trial. Therefore, as several treatments have been proposed to slow down the degenerative process and the current evidence from their results is still limited, no intervention as the control group is justified for this study.

Methods

Overview

This parallel-group RCT will be performed at a single institution, which is a tertiary referral hospital with an affiliated research institute (Institute of Applied Ophthalmobiology [IOBA], University of Valladolid). The retinal units in both institutions are highly specialized to manage inherited retinal dystrophies and other related retinal eye diseases. Additionally, the IOBA has a clinical trial unit that could help with the local ethical requirements for running a clinical trial and any oversight or external auditing of data that is needed.

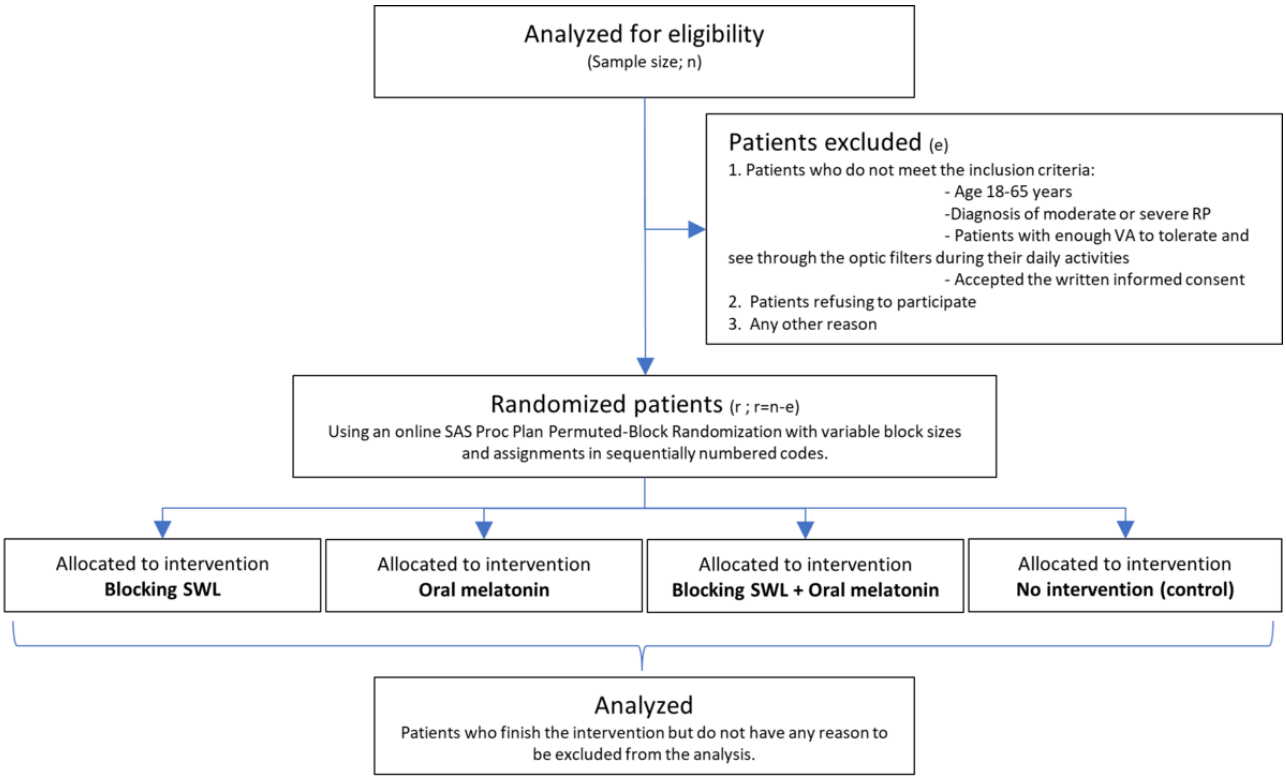
There will be 4 parallel groups of patients. Recruitment will be facilitated by a local foundation for patients with retinitis pigmentosa called the Retina Castilla y León (ReCYL) and will be tightly supervised by an ophthalmologist with specialization in retinal degenerations. Figure 1 provides a summary of the clinical pathways.

A draft intervention protocol will be developed for each group, covering preintervention, intervention, postintervention, and discharge settings based on the literature. A steering committee comprising ophthalmologists, opticians, nurses, psychologists, and the research team will be created to develop these protocols. Additionally, 2 ophthalmology residents will be included. Finally, 1 patient with RP, who is the current president of the Federation of Inherited Retinal Dystrophies' Associations, will be included in the steering committee. The steering committee members are experts in their respective fields and have used the existing literature (summarized in the *Background and Rationale* section) to inform the inclusion of the different interventions in the protocols. The draft intervention protocols are presented in Table 1. Although the choice of each intervention in these protocols will be informed by the literature [7,28,30,36,51,57,67,75-82] and expert consensus of the steering committee, the study will assess the efficacy of combined interventions in sleep disorders and stress control in a large group of patients with RP. Before the intervention period, all patients will be asked to complete sleep diaries for 2 weeks. In addition, patients in the intervention groups (SWL, OM, SWL+OM) must complete them during the intervention period (30 days). Patients from the SWL and SWL+OM groups will wear SWL-restricting goggles in bright-light conditions and when using light-emitting diode (LED) electronic devices for the 30 days of intervention. Patients from the OM and SWL+OM groups will take 3 pills of Circadin 2 mg (OM) every evening at 10:00 P.M. with a margin of 30 minutes before and after.

A preintervention time of 1.5 years will be necessary for recruitment, informed consent, eligibility screening, and baseline data collection. Next, patients will be randomized to 4 groups in a 1:1 ratio. The treatment groups will include SWL with or without the use of OM. The control group will include patients who are eligible for the study but not willing to be randomized to an intervention sleep and stress management pathway. When the intervention phase (4 weeks) is over, all patients will be followed up for 6 months via standard monitoring. Figure 2 provides a summary of the RCT timeline.

XSL•FO
RenderX

Figure 1. Flow diagram illustrating the study protocol. At the allocation to interventions, the number of patients who receive the intervention will be registered, as well as those who do not receive it (together with the reason it was not applied) and those who get lost in the follow-up or discontinue the intervention. In addition, unbearable side effects and SUSARs would be appropriately notified and registered. e: patients excluded; r: randomized patients; RP: retinitis pigmentosa; SUSAR: suspected unexpected serious adverse reaction; SWL: short-wavelength light; VA: visual acuity.



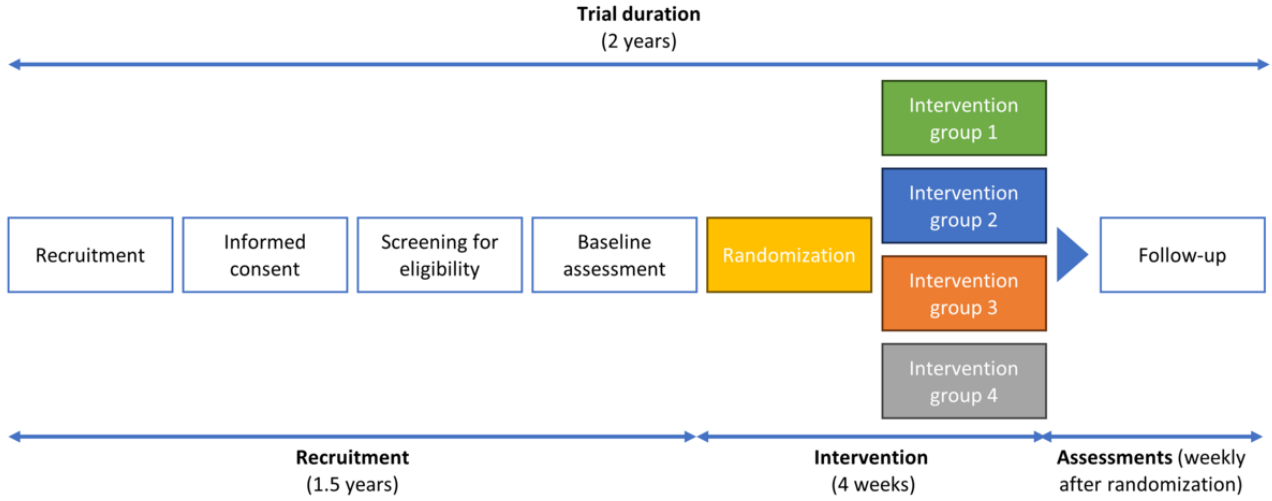


Table 1. Protocols of the intervention.

Group	Preintervention period (2 weeks)	Intervention period (30 days)
SWL[a]: optical SWL filters	Sleep diary	Sleep diary, goggles
OM[b]	Sleep diary	Sleep diary, OM
SWL+OM: optical SWL filters and OM	Sleep diary	Sleep diary, goggles, OM
Control: no intervention	Sleep diary	None

[a]SWL: short-wavelength light.

[b]OM: oral melatonin.

Figure 2. RCT timeline. RCT: randomized controlled trial.

XSL•FO
RenderX

Study Population

The study population will comprise patients aged 18-65 years with a history of moderate or severe RP with a grading severity scale score of >1 point according to Iftikhar et al's [83] scoring criteria. Eligible patients who provide written informed consent will be randomized to 1 of the 4 study groups. Outcomes will be assessed at multiple time points: at baseline in the preintervention period; then at 1, 2, 3, and 4 weeks of the intervention period; and then at 6 months postintervention.

Patient Selection, Recruitment, Randomization, and Blinding

Eligibility

Eligibility will be determined based on the inclusion and exclusion criteria listed in Table 2. Eligible participants will be identified after initial evaluation by a staff ophthalmologist, determined to satisfy 1 of the qualifying procedures, and approached for informed consent by the ophthalmologist and research staff. At this time, patients will watch an introductory video explaining the purpose of the clinical trial. The physician also will lead an in-depth preintervention discussion explaining each approach to stress and sleep disability (SWL and OM vs control) and postintervention expectations. If patients decline to participate in the RCT, they will be presented with the option of enrolling in the control group (no intervention). There will be no restrictions on patient care due to enrollment in the study.

Table 2. Inclusion and exclusion criteria at screening.

Inclusion criteria	Exclusion criteria
• Age 18-65 years, from ReCYL[a] • Diagnosis of moderate or severe RP[b] (grading severity scale score>1 point) • Visual function enough to tolerate and see through the optic filters during daily activities • Written informed consent provided	• Underwent any ocular surgery within the previous 6 months • Involvement in any other ongoing clinical trial • Pregnancy and lactation or under hormonal treatment • Allergy or hypersensitivity to melatonin • Previous or current therapy with melatonin • Autoimmune diseases • NSAID[c] and others anti-inflammatory drug treatment • Psychiatric disorders or under any psychotropic medication

[a]ReCYL: Retina Castilla y León.

[b]RP: retinitis pigmentosa.

[c]NSAID: nonsteroidal anti-inflammatory drug.

Recruitment

Screening Visit

Patients will undergo an initial screening visit that includes a semistructured interview, a series of questionnaires, a complete ophthalmic examination, and laboratory assessment. Eligible patients will be provided with a verbal description of the trial and presented with a comprehensible informed consent form.

Semistructured Interview

All patients will undergo a semistructured interview to collect medical (signs and symptoms, personal and family records, coexisting pathology, previous or current medication, etc), demographic (age, gender, ethnicity, etc), socioeconomic (relationship status, educational attainment, employment status, etc), and lifestyle (physical exercise, consumption of drugs, use of hair dyes, BMI, etc) data.

Ophthalmic Examination

All patients will undergo a complete ophthalmological examination, which will include the best-corrected visual acuity (BCVA) with the Early Treatment of Diabetic Retinopathy Study (ETDRS) letter score, a slit lamp examination, intraocular pressure measurement, fundoscopy, contrast sensitivity with a CSV-1000 chart (Vectorvision), and a glare test with the MonPack 3 device (Metrovision).

Ancillary Tests

Visual field impairment (VFI) will be assessed using a Humphrey 750i visual field analyzer (Carl Zeiss) and the central 30-2 SITA fast strategy protocol. Only tests that met the criteria (low [<20%], false positive, false negative, and fixation loss parameters) were evaluated [84].

Optical coherence tomography (OCT) images, assessing the central retinal thickness (CRT), macular ganglion cell–inner plexiform layer (GCIPL) thickness, and retinal nerve fiber layer (RNFL), will be performed using Cirrus HD-OCT 5000 with AngioPlex OCT-A (Carl Zeiss Meditec V.10.0) and cube scans. Only images with a signal strength of >6 with no movement artifact will be included in the study.

Two consecutive optical coherence tomography angiography (OCTA) images will be obtained by a single skilled examiner. A foveal centered scan area of a 3×3 mm^2 pattern will be used, and all scans will be analyzed using en face OCTA images generated automatically with the optical coherence tomography microangiography (OMAG) algorithm in Angioplex software (ZEISS). The foveal avascular zone (FAZ) area will be manually outlined and expressed as square millimeters.

The vascular density (VD) will be measured automatically by the software, which will quantify the VD of a local region of tissue according to the ETDRS subfields. We will analyze the VD of each ETDRS sector, the inner ring, and the full area in

XSL•FO
RenderX

3×3 mm^2 rings and exclude OCTA images with a signal strength of <7 [12].

The axial length will be calculated using an IOLMaster 500 optical biometer (Carl Zeiss Meditec) to be used as a correcting variable in the analysis, if necessary.

Questionnaires and Diaries

The State-Trait Anxiety Inventory (STAI), the Epworth Sleepiness Scale (ESS), the Pittsburgh Sleep Quality Index (PSQI) questionnaires and a sleep diary will be used to ask patients about their level of sleep quality, perceived stress, and anxiety.

Sleep Diary

During the 2-week period before trial commencement and the 4-week period of the intervention, patients will fill a daily self-recorded sleep diary at home. The sleep diary will record parameters such as bedtime, wake time, sleep onset, and sleep offset time.

State-Trait Anxiety Inventory

STAI is designed to assess the degree of state and trait anxiety in research participants (in this study, patients with moderate and severe RP) and takes about 10 minutes to complete. It is a reliable, valid, and responsive questionnaire consisting of 20 items for assessing state anxiety and 20 for trait anxiety. Higher scores (maximum score of 40) are positively correlated with higher levels of anxiety [85]. To evaluate the magnitude of any treatment effect, the minimum clinically important difference (MCID) will be regarded as a 30% reduction from baseline [86]. This magnitude represents a "small" effect in the behavioral sciences.

Epworth Sleepiness Scale and Pittsburgh Sleep Quality Index

The ESS and the PSQI are both sleep quality questionnaires. The ESS is widely used in the field of sleep medicine as a subjective measure of a patient's sleepiness. The overall score ranges from 0 to 24. The scale estimates whether the patient is experiencing excessive sleepiness that possibly requires medical attention [87]. The PSQI is a self-reporting questionnaire that assesses sleep quality over a 1-month time interval. The global PSQI score is calculated by adding the 7 component scores, providing an overall score ranging from 0 to 21, where lower scores denote a healthier sleep quality [88].

As determination of the MCID in the sleep quality questionnaires remains controversial, with no consensus on methodology, we will estimate the minimum clinically important improvement in the ESS and PSQI to lie between −2 and −3 for this trial [88-92].

Laboratory Assessment

All patients will undergo a salivary and hair draw to confirm eligibility. Sample collection will be carried out between 9:00 A.M. and noon to minimize potential errors associated with diurnal variations in neuroendocrine parameters. Samples will be collected in the same room, and temperature and humidity will be recorded. After collection, samples will be frozen at –20 °C until analysis. When analyzing results, in female subjects, menstrual cycle phases will be considered.

Salivary α-Amylase, Cortisol, and Melatonin levels

Salivary samples will be collected by patients using the passive secretion drooling method. Two samples of saliva from each patient will be collected in 24 hours. At least 1 mL is required for analysis. The putative salivary indicators will be assayed with enzyme-linked immunosorbent assay (ELISA): cortisol (DRG Salivary Cortisol ELISA, DRG Instruments GmbH) and melatonin (DRG Instruments GmbH). Salivary α-amylase (sAA) will be determined with an α-amylase kit (Salimetrics) [93].

Cortisol Levels in Hair Samples

Three single 3-cm-long locks of hair will be collected from each patient to measure hair cortisol levels in a 3-month period (assuming an average growth rate of 1 cm per month). After collection, each hair sample will be wrapped in aluminum foil to protect it from light and humidity until analysis. The cortisol level in each sample will be measured using the Cortisol Hair ELISA kit (Alpco Diagnostics) with phosphate-buffered saline (PBS) at pH 8.0.

Randomization

All patients who provide written informed consent for participation and meet the eligibility criteria will be randomized and assigned using the online SAS Proc Plan permuted-block randomization with variable block sizes and assignments in sequentially numbered codes provided by the central randomization service on its website [94]. The randomization code will not be released until the patient has been recruited into the trial after baseline measurements have been completed.

An administrative assistant not otherwise involved in the study will provide the next treatment code in the sequence and will record the assignment in a confidential log.

Blinding

In our double-blinded trial, the principal investigator and statistician will be blinded to treatment allocation. Staff responsible for recruitment and grading severity will not be allowed to receive information about the group allocation. Raters will not be present during the lab analysis. Randomization will be conducted by the central randomization service to keep the principal investigator and statistician blind to the data management and study condition.

In the event of a SUSAR (suspected unexpected serious adverse reaction), if requested by the Data Safety Monitoring Committee (DSMC), or if a medical emergency occurs where knowledge of the blinded treatment is necessary, unblinding will be performed independently of the group allocation. The reporting of all SUSARs needs to be expedited.

Intervention

All patients will be provided with a leaflet with clear instructions at the baseline visit, and they will be asked to follow the guidelines throughout the 4-week follow-up period.

XSL•FO
RenderX

Optical Filters for Blocking SWL

Patients will be provided with SWL-restricting goggles to wear during the daytime, in indoor bright-light conditions, and when using LED electronic devices in order to prevent the suppression of melatonin for at least 30 days. Optical filters will allow selective exclusion of less than 480-nm-wide wavelengths, while maintaining relatively good contrast sensitivity and a visual light transmittance of 70%-75% [95].

Oral Melatonin (6 mg)

Patients will be asked to intake a 6 mg melatonin dose orally once a day for 30 days in the evening (22:00 P.M. with a margin of 30 minutes before and after) to activate its sleep-promoting effects approximately 2 hours after intake, avoiding fatigue and sleepiness during the daytime [96-99].

Although the chosen dose is safe to obtain the desired effect, patients will be prompted to report any possible side effects, if present, during the intervention period [79,81,82,100]. If they experience unbearable side effects, they will have to discontinue the OM intervention. If they wish, they can participate in the SWL-blocking intervention and will be evaluated over the 4-week follow-up period.

SWL Blocking + Oral Melatonin (6 mg)

Participants in this combination arm will receive both interventions—filter goggles and OM—at the same time under the same conditions as the SWL and OM groups and for the same 30-day period.

No Intervention

The purpose of this arm is to serve as the procedural control, so patients in this group will be asked to fill their sleep diaries at home only for the first 2-week period after trial commencement. They will be chosen as comparator to avoid performance bias and other biases related to loss of binding in the trial.

Adherence

Adherence monitoring will be performed to find new strategies to avoid attrition during the study and to look for unexpected problems that may prevent patients from attending the sessions. Patients will receive weekly phone calls to confirm appointments and obtain educational instructions about the study protocols to reassure them of the importance of adherence. Upon discharge, patients will be provided with instructions to contact their physician for unacceptable levels of sleep disability or perceived stress to receive an outpatient prescription of antianxiety medications and lifestyle techniques. Additionally, if a patient deviates from the intervention protocol assigned to them, they will not be considered a study failure. Instead, we will continue to follow the patient through study completion and continue to track patient-reported outcomes.

Data Collection and Outcome Measures

Baseline Assessments and Frequency of Follow-Up Assessments

A full list of assessments obtained at each time point is summarized in Table 3.

We will obtain baseline assessments during each patient's screening visit. These measures will include, but will be not limited to, demographics, comorbidities, subjective sleep quality and perceived stress rating, ophthalmic and laboratory outcomes, and patient-reported outcomes specific to the planned intervention.

Initial follow-up assessments will be obtained at 1, 2, 3, and 4 weeks after the start of the intervention. Patients will also be asked to return for postintervention follow-up visits 6 months after the intervention. These visits will be scheduled at the beginning of the study. Patients unable to attend any in-person visit will be asked to at least provide all subjective patient-reported outcomes over the phone or via an electronic survey for that visit in order to facilitate retention and optimal follow-up.

Sleep quality level, laboratory outcomes, ophthalmic clinical outcomes, questionnaire patient-reported outcomes, and potential complications will be gathered during these visits.

XSL•FO
RenderX

Table 3. Assessments and follow-up.

Clinical and laboratory event	V_{-1}[a] (–4 weeks)	V_0 (0 weeks)	V_1 (1 weeks)	V_2 (2 weeks)	V_3 (3 weeks)	V_4 (4 weeks)	V_F (6 months)

[a]V: visit; V_{-1}, screening visit, when inclusion and exclusion criteria will be checked; V_0, visit to assess baseline characteristics; V_1-V_4, visits during the intervention period (every week); and V_F, final visit after 6-month follow-up.

[b]✓: applicable.

[c]Not applicable.

[d]STAI: State-Trait Anxiety Inventory.

[e]ESS: Epworth Sleepiness Scale.

[f]PSQI: Pittsburgh Sleep Quality Index.

Primary Outcome Measures

The primary outcomes are the differences in changes from baseline to postintervention in hormone release (sAA, cortisol, and melatonin levels in salivary and hair samples) and sleep quality, as measured by the ESS and the PSQI.

Intra-Assay Variations

To evaluate the reproducibility of each salivary and hair biomarker, the within-subject standard deviation (Sw) will be calculated by obtaining the square root of the sum of the within-subject variance and the error variance estimated in a linear random-effects model. The mean intra-assay coefficients (ICCs) will be determined for each biomarker and interpreted as follows: 0 (SD 0.2), poor agreement; 0.3 (SD 0.4), fair agreement; 0.5 (SD 0.6), moderate agreement; 0.7 (SD 0.8), strong agreement; and >0.8, almost perfect agreement.

Secondary Outcome Measures

Secondary outcome measures include any clinical macular changes or retinal function measured with the ETDRS scale, CSV-1000 chart, and ancillary tests, such as the VFI, OCT, and OCTA. In addition, several patient-reported variables, such as self-recorded sleep diaries, perceived stress, and functional status will be recorded.

Covariates and Confounders

Several variables will be measured as potential covariates, including preintervention sleep quality scores, concomitant procedures, medical comorbidities, alcohol use, antianxiety medications or other nonprescribed medications used to help with insomnia and anxiety relief, tobacco use, and nonsteroidal anti-inflammatory drug (NSAID) and others anti-inflammatory drug treatment. In addition, basic demographic information will be obtained.

Ethical Considerations

The protocol was reviewed by the local Institutional Review Board of the East Health Area of Valladolid (CASVE 21-520) and will be registered with ClinicalTrials when a start date is decided.

Informed consent will be obtained from each patient in the preintervention period, which must be signed, thumb-imprinted, or recorded by the patient and collected by a coached research assistant, when necessary.

Privacy and confidentiality will be guaranteed for each patient, and the study will be conducted in accordance with the principles of the Declaration of Helsinki.

Data Management, Analysis, and Additional Information

Data Management

In the clinical trial, data handling will be managed by a third-party agency. The investigators, patients, and clinical staff rating or applying therapies will not have access to information until the data analysis is completed by predetermined statisticians. They will also not be aware of the allocation of patients in the trial. Data entry into the virtual system will also be managed by the third-party agency.

Patients' information will be encrypted in a virtual database, secured, and password-protected. Only the data monitoring committee (DCM) will have access during the trial. Data coding will begin at randomization; SAS will generate an alphanumeric code for each block. An ID number will be assigned to each patient. If a major adverse effect occurs, it will be identified by the ID number.

The software will record any changes made by any person involved in the functioning of the program. The user ID will identify people who make any changes to the system, and this

XSL•FO
RenderX

information will be used for the purpose of auditing the trial. During a regulatory audit, the auditors can verify any changes that occur in the system and data. All data will be regularly backed up to a password-secured database.

Data Monitoring

The DCM will comprise a data manager, a database programmer/designer, a medical coder, a clinical data coordinator, a quality control associate, and a data entry associate. A member of the DCM can have 1 or more duties. The DCM will be established according to the Spanish Agency of Medicines and Medical Devices (AEMPS) rules. According to Royal Decree 1090/2015, of December 4, the AEMPS is the regulatory authority responsible for clinical trial oversight, approval, and inspections in Spain and is attached to the Ministry of Health. The Institutional Ethics Committee will review and approve the clinical trial applications prior to the AEMPS initiating its review and approval process.

Data monitoring will take place in a pre-established room, with easy access to data, inside the institution but not in the same room where the trial is performed.

Interim Analysis

The clinical trial will have 4 major evaluation time points of interventions, that is, every week after V_0 and 4 weeks and 6 months postintervention. In each visit for application of the intervention, the patient's personal diary will be reviewed by the clinical staff. They have the responsibility to notify the DMC about eventual minor or major adverse effects.

Adverse events will be recorded from the start of stimulation through the end of the study. All adverse events regardless of attribution to OM and any unexpected adverse event due to the optical filters will be recorded using standard adverse event forms. Adverse events will be measured in several areas: seriousness, severity, length of duration, and any causal relationship, if any, with the intervention. Serious adverse events will be defined as those that are life threatening/disabling, require hospitalization, or result in death.

Patients who develop any adverse effect will be followed up. The DCM will have unblinded access to all patient data and will discuss the adverse events at a meeting. The decision of allowing a patient to withdraw from the study will be made by a majority consent of 50% or more.

Statistical Analysis

Sample Size Calculation

A sample size estimation of 48 patients (n=12, 25%, per group) was calculated for a target power of 80% and considering an α (probability of rejecting a true null hypothesis) of 5% and an actual power of 80.02%. Cohen d was 1.2 [101]. Due to the possible overestimation of the effect size in pilot studies, an effect size of 0.6 (medium-high) was chosen for this study. We calculated a total sample size of 60 participants (a total of 15, 25%, patients per group), adding approximately 20% (3 more patients per group than before) to manage possible dropouts [102-105].

Statistics

A linear mixed effect regression model will be applied to compare intervention arms against the control at baseline and stimulated measures for the HPA axis or the retinal–SCN–pineal axis comprising cortisol, melatonin, and sAA [106]. Baseline characteristics of patients from each group will be compared applying independent *t* tests, 2-way repeated-measures ANOVA, and the Fisher exact test. To grade the RP severity (by quantifying clinical features, the ETDRS score, and visual field deviation) and the primary outcomes, we will consider both to be continuous variables and apply a multiple linear regression model. For secondary outcomes, normally distributed variables will be statistically assessed via parametric tests, such as the *t* test or ANOVA, while nonnormal distributed variables will be assessed with nonparametric tests, such as the chi-square test or the Fisher exact test and the Mann–Whitney U test. A chi-square or Fisher test will be performed to compare STAI, PSQI, and ESS scores among groups.

Statistical associations between covariates and outcomes will be evaluated using the appropriate statistical methodology, as previously described. Multivariable linear regression models will be appropriately fitted to continuous data based on the distributions of those data. Multiple logistic regression models will be fitted for all dichotomous outcome variables. Appropriate variable selection methods and model fit statistics will be used to determine the best-fitting model to determine the effects of treatment after adjusting for significant effects of covariates.

Finally, any protocol amendment will be first submitted to the Institutional Review Board for approval. If the amendment changes anything about what is reported

on ClinicalTrials, then the study's registration on ClinicalTrials will be updated accordingly.

Modification/Discontinuation

If patients experience unbearable side effects related to melatonin, they must leave their intervention group. If they wish, they can continue participating in the study as part of the SWL group being evaluated over the 4-week follow-up period. To reflect these changes at the end of the study, an intention-to-treat analysis will be conducted.

Missing Data

Dropouts and missing facts are known as missing data. A dropout rate of 5%-10% is expected based on recent OM clinical trials [99,107]. An intention-to-treat analysis, regardless of the treatment administered, will be carried out for every primary and secondary endpoint. A preprotocol analysis will also be conducted with those who complete the trial, since secondary outcomes could be more affected by uncensored withdrawals. Both analyses must be favorable for the intervention to be considered better than standard. To deal with missing data, imputation techniques will be applied.

Dissemination

Once the study enters the data reporting phase, the data sets used and analyzed during the study will be available from the corresponding author upon reasonable request. The protocol and results will be released on the ClinicalTrials website, as

XSL•FO
RenderX

required upon study completion. Final study results will be published in a peer-reviewed, PubMed-indexed journal to reach health care professionals. The authors will also seek to present the study findings at relevant ophthalmic subspecialty society meetings. The Federación de Asociaciones de Retinosis Pigmentosa de España (FARPE) website will describe this project. Final findings and results will be published on this website for the general public, as well as disseminated through the FARPE social networking channels.

Results

This work is a clinical trial protocol that has not yet been launched. The bibliographic research for information for its justification began in 2020, and this working group is currently seeking start-up funding. As soon as we have the necessary means, we will proceed with the registration and organization prior to the preliminary phase.

Discussion

Summary of Findings

The aim of the implementation of this clinical trial is to find an innovative strategy that allows a holistic approach for patients with RP, focusing on slowing down the progression of the disease, if possible, and improving their quality of life, especially their mood problems as well as their sleep-wake rhythm disorders.

The use of optical filters blocking SWL in the daylight was chosen as an intervention because of its nature as a noninvasive strategy as well as its protective potential against retinal neurodegeneration and melatonin suppression, both of which are relevant in these patients.

One of the main known sources of blue light is sunlight, but the widespread use of high-brightness lights with LED technology had made an increasing contribution in the past decade. A significant part of the LED emission spectrum peaks at 450 nm, within the wavelength range of blue light. Thus, with the increasing popularity of blue-rich LED-blacklight display devices, such as smartphones and tablets, computer screens, and other commonly used devices, our eyes are exposed to more blue light than they were in the past [28,36,75,108].

In addition, shorter-wavelength blue light has been reported to play a pivotal role in glare disability, especially in patients with retinal dystrophies [38,76]. Photophobia occurs because RPE cells appear to be defective with regard to absorbing light and because a lack of photoreceptors makes the adaptation to different lighting levels difficult [38,76]. Several studies have shown that patients with RP present higher values of intraocular scattering and, therefore, a decreased visual discrimination capacity in comparison to healthy people [77,109-111].

However, although excessive blue light is theoretically harmful, some studies have shown that longer blue wavelengths of the visible spectrum (465-495 nm) are essential for the circadian rhythm, pupillary reaction, color discrimination, and night vision [7,23,24,40-43]. Therefore, optical SWL filters may offer interesting advantages in having a positive effect on the visual discrimination capacity and decreasing glare disability in patients with RP. Finally, they could also help in circadian rhythm regulation and modulate the spectral transmittance of SWL, protecting injured eyes from potential additional photochemical damage.

We have selected melatonin as an intervention because of its close relationship with and involvement in the regulation of circadian cycles and its antioxidant and anti-inflammatory potential.

Melatonin's functions are either receptor dependent or receptor independent. The former includes circadian rhythm control and sleep regulation. There is a considerable body of evidence of melatonin regulating sleep in various sleep disorders [7,62-66]. In fact, melatonin appears as one of the most effective drugs for treating circadian rhythm sleep-wake disorders [67]. Aging, the presence of certain diseases (eg, primary degeneration of the autonomous nervous system and diabetic neuropathy, some types of neoplasms, Alzheimer disease), and certain drugs (eg, β-blockers, clonidine, naloxone, and NSAIDs) abolish the nocturnal production of melatonin and are associated with impaired sleep [7,61,79,81].

Melatonin acts via its own receptors (MT1, MT2) present at the SCN, which are members of the G protein–linked receptor family [61]. The phase-shifting effects of melatonin are essentially opposite to those of light. In humans, its sleep-promoting effects become significant about 2 hours after intake, similar to the physiological sequence at night. However, administration of melatonin during the daytime (when its endogenous levels are minimal) results in induction of fatigue and sleepiness in humans [79,81].

Thus, melatonin administration appears to be one of the most promising approaches, with long-term benefits, for circadian rhythm sleep disorders because it simultaneously treats sleep and wake state problems and, in addition, synchronizes other bodily rhythms so as to maintain the body's internal temporal order and prevent internal desynchronization [67,79,81].

Although the receptor-independent functions of melatonin include the detoxification of ROS and other reactive molecules, the antioxidant action of melatonin can also be expressed by increasing the efficacy in preventing oxidative DNA damage [7,51,58,60,61].

In addition to its pleiotropic actions, melatonin possesses an advantage over other possible candidates due to its amphiphilic character, which enables it to enter any fluid, cells, or subcellular structures, including mitochondria. Conversely, melatonin exhibits poor pharmacokinetic properties (eg, limited oral bioavailability and short plasma half-life) and low subtype receptor selectivity [79,81]. The effective doses reported are between 0.5 and 10 mg without a clear dose-response relationship (Multimedia Appendix 1). This mainly reflects the large interindividual variability in melatonin bioavailability, which is well known in the published literature and is attributed to differences in first-pass metabolism (Multimedia Appendix 1).

The acute toxicity of melatonin, as seen in both animal and human studies, is extremely low [82]. Melatonin may cause

XSL•FO
RenderX

minor adverse effects, such as headache, insomnia, rash, diarrhea, and nightmares [82]. In animals, a lethal dose for 50% of the subjects (LD50) could not be established; even 800 mg/kg body weight (high dose) was not lethal [100]. Studies on human subjects given varying doses of melatonin (1-6.6 g/day) for 30-45 days and followed with an elaborate battery of biochemical tests to detect potential toxicity have concluded that in addition to drowsiness, all findings were normal at the end of the test period [79,81,82].

In the same line as the previous Spanish RCT (EudraCT no: 2012-002436-82) with OM and patients with RP, we have considered that 6 mg of OM for 30-40 days will be a safe dose to reach the desired effects without causing side effects in our target population. In general, a dose between 0.2 and 10 mg has been considered a safe starting dose in most of the previous studies with OM [67,79,81,82].

Accumulating evidence indicates that melatonin has a protective effect against various ocular disorders, such as uveitis, diabetic retinopathy, glaucoma, and even optic neuritis, through different mechanisms of action [60,61,73,112-115]. The multifaceted role of melatonin in neuroprotection might imply that melatonin may possess the capacity to attenuate the harmful effects that occur in degenerative retinal diseases, such as RP. Daily administration of melatonin has been shown to delay the photoreceptor apoptotic loss in RP mice [53,116]. This evidence supports that a clinical trial using melatonin to at least delay cell loss in RP in humans might be beneficial. In this context, a Spanish RCT (EudraCT no: 2012-002436-82) with 6 mg of OM and patients with RP is ongoing. Thus, therapeutic treatments of eye diseases using melatonin alone or in combination with other strategies deserve serious investigation.

The possibility of synergy between the 2 strategies stems from the common point between them—their involvement in circadian rhythms. Glucocorticoid hormones, particularly cortisol, participate in the body's homeostasis and stress responses and follow a circadian rhythm, exhibiting a predictable peak in the morning, with a typically sharp elevation 30 minutes to an hour after awakening [117-119], although one that is apparently more complex than the melatonin rhythm.

The sAA enzyme has been used as a marker for the sympathetic nervous system response [118,120,121] and, like cortisol, has been shown to respond to psychosocial stress [118]. As with melatonin and cortisol, sAA production exhibits a regular circadian pattern [118]. Under normal, steady-state conditions, high levels of cortisol tend to be associated with low levels of sAA and vice versa.

Synthesis of melatonin is affected by SWL, whereas cortisol production and sAA levels are modulated by both short- and long-wavelength light. Since light is a well-known stimulus for suppressing the synthesis of the hormone melatonin at night, it was considered important for this study to also understand how blocking SWL in bright-light conditions may prevent the suppression of melatonin, which could affect perceived stress, sleep quality, and the quality of life of patients with RP.

Limitations

The limitations that may be encountered in the application of this clinical trial are likely to be related to the large phenotypic and genotypic variability found among patients with RP; the difficulties in recruiting patients who meet the eligibility criteria, especially those with enough visual acuity that allows them to use the filters; and the subjective nature of the results of the questionnaires. However, this could be overcome by a good baseline study that allows for proper analysis that considers possible confounding variables. However, a sleep-monitoring device could be used, such as second-generation multisensory sleep trackers, but their price would increase the cost of the study and there is still no validated device for this purpose, so for the time being, they have not been included in the study protocol [122].

Conclusion

Preservation of vision in retinal degeneration is one of the priorities of the World Health Organization Vision 2020 program. Clinical trials of melatonin in the context of controlling RP, for example, warrant serious consideration. Furthermore, positive results of such studies would not only benefit patients with various ocular disorders but also be particularly helpful in countries where the treatments are expensive and not easily accessible.

This protocol for a double-blind RCT aims to shed light on the benefits that OM combined with SWL-blocking filters might have for patients with moderate or severe RP in terms of disease progression and quality of life. The goal is that this protocol be replicated for future studies, applied to additional inherited retinal dystrophies, and potentially incorporated into clinical practice. Should this study demonstrate the superiority of the combined intervention versus no intervention, its findings may also help reduce the impact of sleeping disorders and negative psychological disorders on the quality of life of patients with RP and help them recover their self-autonomy.

Acknowledgments

We thank the patients from the Retina Castilla y León (ReCYL) and healthy subjects for their participation in the study. No artificial intelligence tool was used in the elaboration process of this paper. This study was supported by a grant from the Gerencia Regional de Salud de Castilla y León (GRS 1932/A/19).

Data Availability

All data sets generated and analyzed during this study are included in this published paper and Multimedia Appendix 1. Once the study enters the data reporting phase, the data sets will be available from the corresponding author upon reasonable request.

Abstract

Background: Cannabis use is highly prevalent in young people with first-episode psychosis (FEP). Most report cannabis use and are often diagnosed with a cannabis use disorder upon admission to specialized services for psychosis. Cannabis use in this population is associated with worse clinical and psychosocial outcomes, rendering it an important clinical target. Despite this,

XSL•FO
RenderX

few cannabis-specific interventions have been developed for FEP and empirically evaluated through randomized controlled trials. Most evaluated interventions have targeted cannabis abstinence, with limited efficacy, but none have centered on harm reduction outcomes for people with FEP who use cannabis. Early intervention services (EIS), the standard of care for FEP, have not successfully addressed problematic cannabis use in people with FEP either. Clinical trials are needed to explore the potential of harm reduction strategies, although these should be preceded by robust pilot studies to establish optimal design and approaches.

Objective: Recognizing the need for harm reduction strategies for individuals with FEP who use cannabis and based on research on patients' preferences supporting harm reduction interventions, we developed a mobile app–based cannabis harm reduction intervention for this population. This intervention is called Cannabis Harm–reducing Application to Manage Practices Safely (CHAMPS). Here, we describe the protocol for a multicenter, 2-arm, parallel group, randomized pilot trial evaluating the acceptability of CHAMPS for people with FEP who use cannabis and the feasibility of conducting a full-scale trial in this population using CHAMPS. The impact on key clinical outcomes will also be explored.

Methods: This pilot trial aims to recruit 100 young people with FEP using cannabis from 6 Canadian EIS clinics. Participants will be randomized in a 1:1 ratio to CHAMPS+EIS or EIS-only. CHAMPS acceptability will be assessed using completion rates for the intervention arm. Trial feasibility will be assessed using a retention rate for randomized participants. Secondary outcomes will explore tendencies of change in the use of protective behavioral strategies and in motivation to change strategies. Exploratory outcomes include cannabis use–related problems, other substance use, the severity of dependence, psychotic symptoms, and health care service use.

Results: Recruitment began in December 2021. Data collection and analysis are expected to be completed in early 2024. Study results describing CHAMPS acceptability and trial feasibility will then be submitted for publication in a peer-reviewed journal.

Conclusions: CHAMPS uniquely combines evidence-based approaches, patient perspectives, and mobile health technology to support harm reduction in people with FEP who use cannabis. Attaining adequate acceptability and feasibility through this trial may justify further exploration of harm reduction tools, particularly within the context of conducting a larger-scale randomized controlled trial. This pilot trial has the potential to advance knowledge for researchers and clinicians regarding a feasible and user-acceptable research design in the cannabis and early psychosis fields.

Introduction

Background

Cannabis use is widespread in young people with psychosis, with 60% of young people with first-episode psychosis (FEP) reporting cannabis use at admission into specialized mental health services such as early intervention services (EIS) [1]. Compared to individuals with FEP not using cannabis, people with co-occurring cannabis use are susceptible to worse short- and long-term clinical and mental health outcomes, including persistent psychotic symptoms, more frequent relapses and hospitalizations, and worse psychosocial functioning [1-7]. Given the increased risk of worsened prognosis, it is necessary to deploy evidence-based interventions that target problematic cannabis use (including cannabis use disorder [CUD]) in people with FEP. However, relatively few cannabis-specific interventions have been developed for and tested in people having FEP and those studied have mainly focused on achieving abstinence, showing overall limited efficacy [8-10]. A minority of individuals will recover from CUD without any cannabis-specific treatments [11], and only about half of people with FEP will recover from CUD within 2 years of regular EIS treatment [1]. For many individuals who continue to use cannabis, including those who do not wish to participate in cannabis cessation interventions, more research is needed to determine effective therapeutic options that can reduce potential cannabis use–related harms.

In response to this challenge, there is a growing interest in innovative harm reduction interventions to help individuals with FEP and persistent cannabis use [12-14]. Cannabis harm reduction is an approach that has been endorsed in public health or government reports, as well as by clinicians and young people using cannabis [15-19]. Harm reduction in a drug use context shifts the focus away from the all-or-nothing goal of abstinence and instead focuses on improving the health or quality of life of individuals by targeting the reduction of harmful drug–related consequences [20]. Harm reduction approaches often leverage motivational interviewing techniques to augment motivation to change drug use habits [20]. Motivation to change use habits reportedly represents a major barrier to successful cannabis intervention implementation for young adults with FEP [18]. Harm reduction approaches, especially when using motivational interviewing, may thus be well suited as an alternative to people who are ambivalent or reluctant to reduce their cannabis use but who may be ready to modify their cannabis use practices. Examples of such modifications might include reducing the

XSL•FO
RenderX

number of times they use cannabis before work to avoid work problems, avoiding cannabis use while using other substances to reduce compounded deleterious physical or mental health harms, and so forth.

Although used to address problems related to other substances for many years [20], harm reduction initiatives for cannabis are only just emerging [21-23]; few trials (in nonclinical populations [24]) have evaluated their effectiveness, but initial findings are promising. However, there are, so far, no cannabis harm reduction interventions that have been specifically designed and evaluated for people with FEP who use cannabis [8]. This population is characterized by distinct clinical features, such as impaired attention and memory, and cognitive deficits [25], which must be considered when designing or recommending interventions. More research is needed to evaluate whether harm reduction interventions could benefit people with FEP and continued cannabis use, who are at risk of experiencing related harms.

Study Aims

Our team developed a novel harm reduction intervention for individuals with FEP who are interested in reducing their cannabis use–related harms, called the Cannabis Harm–reducing Application to Manage Practices Safely (CHAMPS), which is delivered through a smartphone app. The development of CHAMPS was informed by related projects in cannabis use and psychosis conducted by our team [8,18,26] and co-designed in collaboration with clinicians, patient-partners, and experts in cannabis and psychosis (see intervention description in the Study Arms section). To our knowledge, the CHAMPS intervention represents the first psychosocial mobile health intervention aiming to reduce cannabis use–related harms in people with FEP. Our team is also currently working on a psychosocial mobile health intervention that addresses CUD in people with FEP and focuses on decreasing cannabis use or cessation [27].

Due to the paucity of cannabis harm reduction research in this population, a preliminary assessment of trial feasibility and intervention acceptability as well as an initial assessment of key clinical outcomes were necessary before conducting a large-scale randomized controlled trial (RCT) of CHAMPS [28]. As EIS represent the mainstay of treatment for FEP [29], we opted to evaluate this novel intervention as an adjunctive clinical tool to existing services. We will thus evaluate CHAMPS+EIS versus EIS-only in a multicenter, 2-arm, parallel group, open-label, randomized pilot study. The primary objectives of our study are to assess whether it is feasible to conduct a future RCT of the CHAMPS intervention in people with FEP who use cannabis and want to modify their cannabis behaviors and determine if CHAMPS is an acceptable intervention for this population. Secondary objectives aim to descriptively determine whether CHAMPS+EIS influences the use of protective behavioral strategies (PBS) and motivation to change PBS, compared to EIS only, in young people with psychosis who use cannabis. Exploratory objectives aim to descriptively estimate the effect of the intervention arm on cannabis-related problems, quality of life, cannabis and other substance use, severity of dependence, psychotic symptoms, and health care service use. We hypothesize that CHAMPS will be acceptable to those randomized to the CHAMPS+EIS intervention arm and that the pilot trial will demonstrate adequate feasibility, with a minimum trial retention rate of 60%.

Methods

Participants and Recruitment

This study will involve 100 young adults (50 per arm) who meet the study's eligibility criteria. Briefly, the inclusion criteria are having a diagnosis of psychosis, being 18 to 35 years old, having recent cannabis use, and being treated at an EIS (see Textbox 1 for detailed inclusion and exclusion criteria). Participants will continue their usual pharmacological and psychosocial interventions offered at the EIS, including taking any medication prescribed for their psychosis or other health concerns while participating in this study; these will be recorded in the patient study file.

If the CHAMPS intervention is considered clinically relevant for a potential participant, a clinician approaches this person, briefly explains the intervention, and asks about any interest in meeting the research team to learn more about the trial. If the person agrees, the referring psychiatrist or clinician collects screening and medical eligibility information. In other words, participant recruitment will use purposive sampling. The research staff then schedules a full screening visit, where eligibility is confirmed, and informed consent is obtained from interested participants (Figure 1; Multimedia Appendices 1 and 2). For study visits conducted via telepsychiatry, e-consent and verification of comprehension are documented using the Research Electronic Data Capture (REDCap; Vanderbilt University) web-based data entry system [30].

Clinicians will assist participants as needed, as they download the CHAMPS app from the Apple Store or the Google Play Store. If potential participants do not own a smartphone, the research staff will loan them a smartphone for the study duration. All participants will receive a compensation of CAD $30 (US $22.14) for participating at each visit (eg, screening, baseline, and follow-up assessment visits), with a maximum of CAD $150 (US $110.69) per participant. In addition, participants randomized to the EIS-only arm are offered CHAMPS access after their trial completion; these data will not be collected for research purposes.

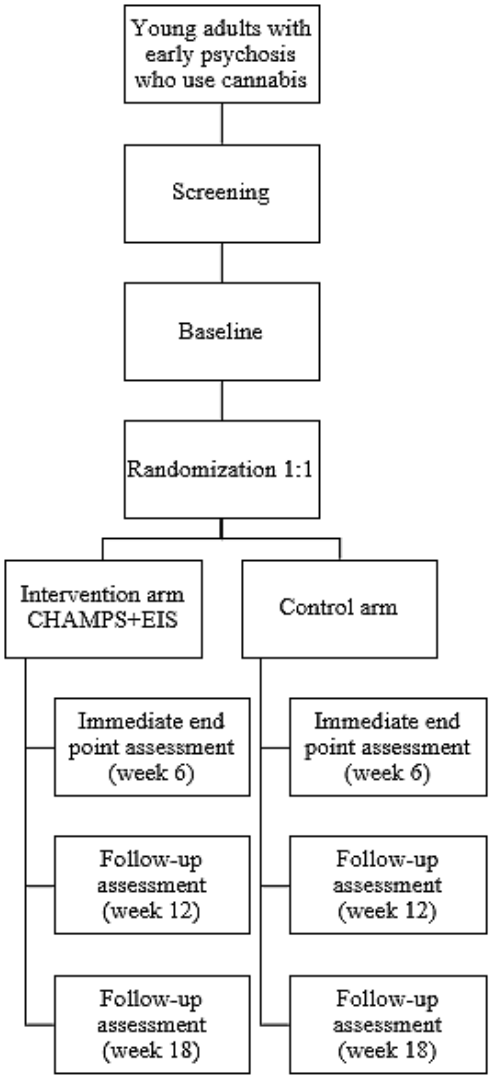
Textbox 1. Inclusion and exclusion criteria for participants and recruitment sites.

Inclusion criteria



- Participants
  - Young adults (18 to 35 years of age)
  - Diagnosis of a psychotic disorder (including primary psychotic disorders, mood disorders with psychotic features, substance-induced psychosis, etc)
  - Receiving care for psychosis at early intervention services for at least 2 months
  - Recent cannabis use (in the last 30 days)
  - Interest in changing cannabis-related practices
  - Provide informed consent
  - Comply with study procedures
  - Read French or English
- Recruitment sites
  - Specialized early intervention services for the treatment of people with early-phase psychosis
  - Demonstrate capacity to provide early intervention services for psychosis
  - Agree to offer Cannabis Harm–reducing Application to Manage Practices Safely alongside early intervention services
  - Have sufficient patients to achieve enrollment targets
  - Have a sufficient psychiatrist and clinician availability and acceptance of the study to refer patients
  - Adhere to trial procedures

Exclusion criteria for participants

- Participation in another cannabis-focused intervention or treatment
- Currently seeks cannabis use disorder treatment

XSL•FO
RenderX

Figure 1. Study flowchart. CHAMPS: Cannabis Harm-reducing Application to Manage Practices Safely; EIS: early intervention service.

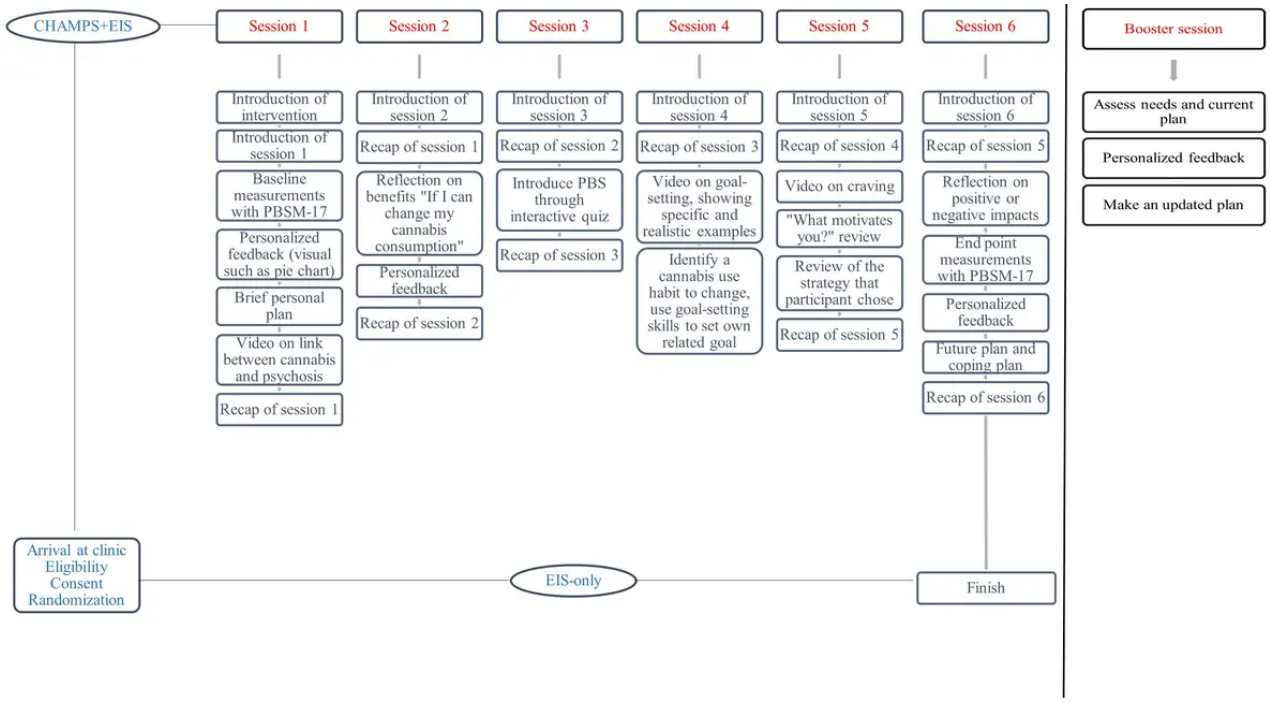
The lead site is located at the Centre Hospitalier de l'Université de Montréal (CHUM). Recruitment takes place at 6 EIS clinics in Nova Scotia and Quebec, Canada, which have varying clinical and sociogeographical contexts. See Textbox 1 for inclusion criteria for EIS. Each local site has a similar structure that includes clinicians (eg, case workers and psychiatrists), research staff, a research coordinator, and site principal investigators (PIs). With the assistance of local site PIs, our research team conducts a project presentation for clinicians working with this population at collaborating sites. Clinicians who are available to recruit and can adhere to CHAMPS trial procedures and requirements recruit participants for this study. Local site investigators responsible for local study oversight are invited as study coauthors. Clinicians contribute to recruitment and support using the CHAMPS app. Research staff and coordinators contribute to data collection, assist with recruitment, and conduct follow-up assessments. Local site PIs oversee research ethics board processes, recruitment, staff training, and coordination with the lead site. The lead site additionally oversees any potential study implementation challenges, ensures the quality of the data collection and databases, and monitors study progress.

Randomization and Blinding

Participants are randomized in a 1:1 ratio to either arm (EIS-only and EIS+CHAMPS). Randomization is stratified by sex and CUD status using random permuted blocks. The CHUM Center for Integration and Analysis of Medical Data generates the allocation sequence. Access to the randomization code is strictly controlled by the data management team. Individual participant codes can be broken without unblinding the sequence allocation of other participants. Due to the nature of the intervention, clinicians and research staff collecting data cannot be blinded; however, the research staff conducting data analysis are blinded to group assignment. Participants are not able to switch arm assignments.

Study Arms

EIS-only (ie, "Control") offers EIS to all participants as per the standard of care at participating sites. Many EIS international and national guidelines are available and typically followed by these programs [31-33]. Most EIS offer similar services, including integrated treatments such as psychopharmacology and psychosocial interventions (eg, case management, family interventions, cognitive behavioral therapy, motivational interviewing, vocational recovery interventions, and outreach



XSL•FO
RenderX

interventions) [29]. Regarding substance use services, a survey found that the majority of English-speaking Canadian EIS reported offering informal and general substance use services to patients (eg, individual psychoeducation), and only 12% reported offering cannabis-specific formal interventions [34]. A similar survey of 28 of 33 EIS in Quebec found that only 16 of 28 EIS offered group or individual substance use services [35]. The Quebec EIS framework explicitly states that substance use is important to address, ideally using motivational interviewing and cognitive behavioral strategies, although no formal harm reduction–focused interventions are recommended [33]. Practices may differ between EIS across Canada; we can expect at least some EIS to offer an unstructured, nonspecific, informal substance use intervention. Most EIS use a case management model, where a clinician takes the central role of treating a patient [29]. Any visits and services offered (eg, in person or via teleconsultation) at EIS will be considered "usual care."

CHAMPS+EIS (ie, "Intervention") arm offers participants access to EIS usual care in addition to the CHAMPS intervention. CHAMPS is a psychosocial intervention that aims to promote positive behavioral changes and a reduction of cannabis use–related harms, using motivational interviewing, psychoeducation, skills training, and personalized feedback strategies. CHAMPS is self-guided and delivered through a smartphone app; this delivery mode was guided by previous studies signaling an acceptability of and preference for technology-based interventions [36,37]. The CHAMPS protocol recommends accompanying clinicians to provide support using CHAMPS if participants request it as well as to encourage its use. If the participant consents, accompanying clinicians can also access the participant dashboard, which shows high-level app data, such as how many modules they have completed, as well as participant responses in the CHAMPS intervention (eg, goals they have set during module 4, reasons for changing cannabis use stated in module 2). No additional participant data will be shared with accompanying clinicians.

There are 6 modules in the intervention and a booster session module 4 weeks after the last module (see Figure 2). Each module is expected to take up to 15-20 minutes to complete. In essence, CHAMPS informs participants about cannabis use and its effects on people with FEP, offers strategies to reduce related harms (inspired by harm reduction tools), and guides participants to set their own cannabis harm reduction-related goals to help improve their well-being. Suggested goals can target participants' physical or mental well-being, social relationships, or even cannabis use itself; however, no goal will be imposed, and participants will decide which goals they would like to work on. Table 1 provides a detailed description of each module, and Textbox 2 provides examples of harm reduction strategies and goals from CHAMPS.

Figure 2. CHAMPS intervention detailed description. CHAMPS: Cannabis Harm-reducing Application to Manage Practices Safely; EIS: early intervention service.

XSL•FO
RenderX

Table 1. Detailed CHAMPS[a] module descriptions.

Week	Module	Description
1	Module 1	Measures baseline cannabis protective behavioral strategies (PBS[b]) and automatically provides participants with personalized feedback on their cannabis practices, as well as suggestions on what cannabis practices they could improve
2	Module 2	Explores what is important to participants and the possible benefits of adopting safer cannabis use strategies
3	Module 3	Exposes participants to various evidence-based cannabis PBS using interactive psychoeducational techniques
4	Module 4	Introduces participants to goal setting and asks them to set their own cannabis-focused goals, which they can immediately implement in their lives
5	Module 5	Helps participants reflect on their goal progress and offers help to the participant in either revising their current goal or adopting a new goal
6	Module 6	Reassesses cannabis PBS and encourages participants to continue improving their cannabis practices
10	Booster session	Four weeks postintervention, participants will receive a booster session, also lasting between 15 and 20 minutes. The purpose of this booster session will be to review the main components of the intervention, remind participants of what they explored about their cannabis use as well as goal setting during the intervention, and revise it as needed

[a]CHAMPS: Cannabis Harm-reducing Application to Manage Practices Safely.

[b]PBS: protective behavioral strategies.

Textbox 2. CHAMPS harm reduction strategies and sample goals.

Limit the amount of cannabis you smoke in one sitting

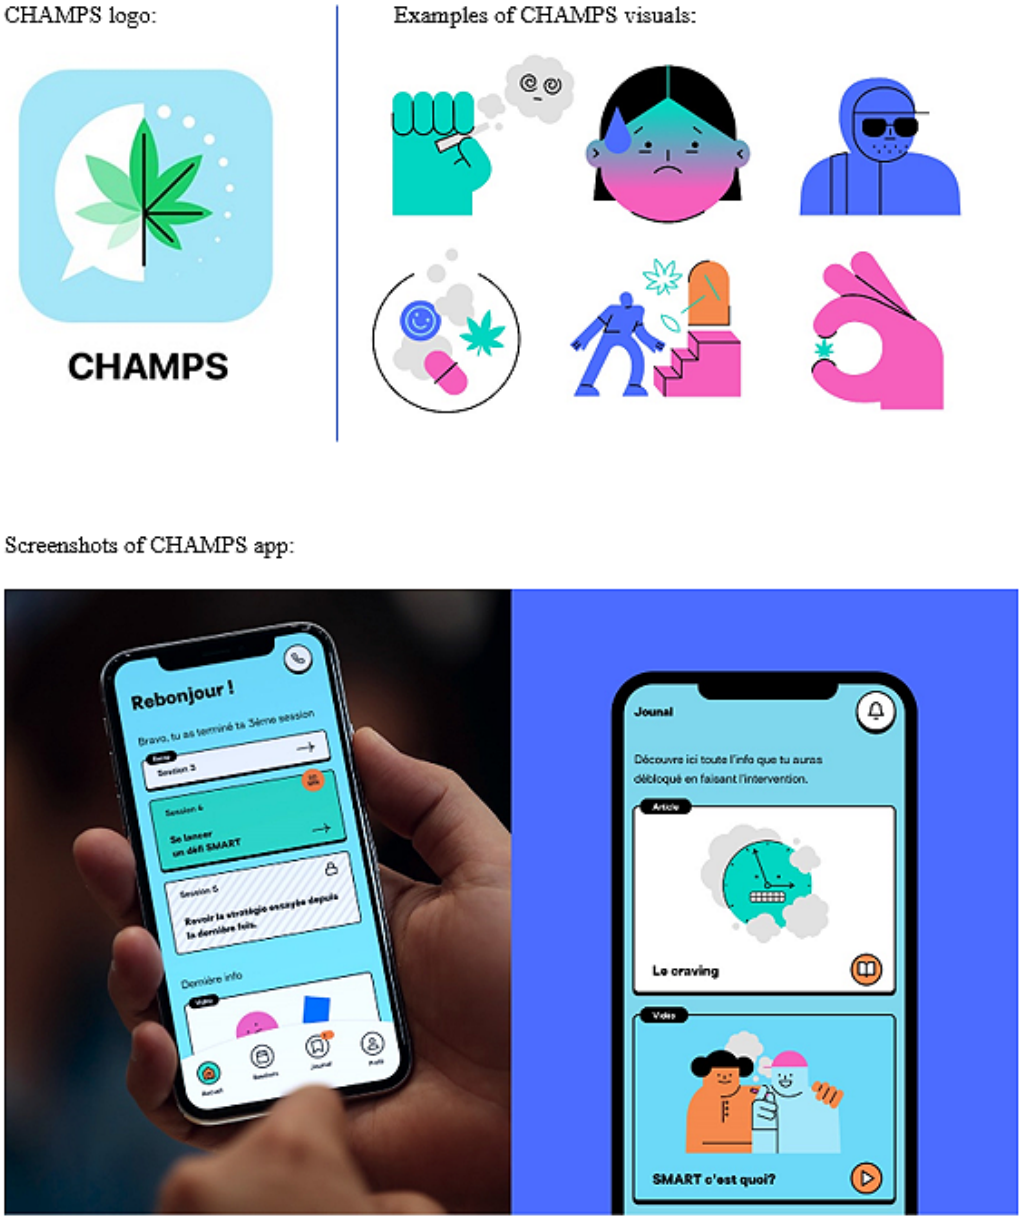
"I will put a quarter of the amount of cannabis I usually put in my joints for a prespecified period of time."

Avoid mixing cannabis with other drugs

"I will avoid using alcohol and cannabis at same time during a pre-specified period of time"

Avoid using cannabis to help cope with emotions such as sadness, depression, anxiety, and fear

"Instead of using cannabis, I will practice using alternate and healthier coping strategies (eg, trying a new sport, calling a friend) the next time I feel negative emotions"



CHAMPS Intervention Development

The CHAMPS intervention was inspired by the Behavioral Change Wheel theoretical framework, which has been used to design behavioral interventions in various settings including for young people at ultra-high risk for psychosis [38,39]. The CHAMPS intervention uses the following behavior change techniques detailed in this framework: feedback on behavior, brief action planning, modeling of behavior, reflection of health, social and environmental consequences, instructions on how to perform a behavior and behavioral experiments, review behavioral goals, and behavioral rehearsal and practice. The findings of our qualitative study outlining barriers and facilitators in a variety of cannabis-focused interventions according to young adults with FEP who use cannabis and to accompanying clinicians also helped guide the CHAMPS intervention development [18]. This study supported the use of harm reduction for people who used cannabis and lacked motivation for more intensive cannabis-focused treatments and reported openness to technology-based interventions, citing potential benefits such as quicker intervention access for patients, decreased clinician workload, and so forth. The modalities of CHAMPS were informed by our preference study for cannabis harm reduction interventions, which surveyed 89 young adults with FEP using cannabis. This survey, which featured a quantitative discrete choice experiment design, found that respondents significantly preferred interventions with shorter durations and sessions, technology-based interventions, and brief booster sessions (personal communication by SC-M and DJ-A, September 2023 on patient preference survey results; associated manuscript submitted for publication).

The design of CHAMPS used a participatory approach, where people with lived experience were integrated into different facets of the study. We created the CHAMPS patient advisory committee comprising young individuals who used cannabis, had FEP, and attended EIS. This committee consulted on and helped co-design CHAMPS. For example, this committee contributed to the selection of the visuals we used, the tones and language of our CHAMPS content, the phrasing, the frequency and content of add-ons such as notifications, and so forth (see Figure 3 for examples of CHAMPS app visuals). Some patient-partners were also involved in the content creation, as they coproduced video testimonials of their experience with changing their cannabis use habits. Additionally, 1 patient-partner was involved in knowledge dissemination related to this project, copresenting on the protocol at a scientific conference and detailing the involvement of the patient advisory committee.

RenderX

Figure 3. Examples of CHAMPS app. CHAMPS: Cannabis Harm-reducing Application to Manage Practices Safely.

Outcomes and Data Collection

Participant Characteristics

Sociodemographic data are collected at baseline using a questionnaire on sociodemographic outcomes that include gender identity, sex, ethnicity, educational attainment, vocational status (eg, employment), income, and housing status.

Primary Outcomes

The feasibility of conducting a future RCT will be determined through the trial's retention rate. The retention rate will be calculated by dividing the number of participants who completed all end point assessments (week 6) by the number of total randomized participants at baseline. As discussed, there are so far no other harm reduction–oriented studies in this population to guide our study design. Therefore, to establish an adequate minimum retention rate, we looked at related trials of (1) psychosocial mobile health interventions in populations with psychotic disorders, which had retention rates ranging from 76% to 100% [40-43] and (2) RCTs of face-to-face cannabis interventions for people with FEP, which had retention rates ranging from 52% to 96% [44-47]. The mobile health intervention trials either did not include comparison groups, did not focus specifically on individuals with FEP who used cannabis, or did not evaluate cannabis-focused interventions. The face-to-face interventions all focused on cannabis use in people with psychosis, but the delivery method precluded generalization to our trial. Given our intervention characteristics, we expect our retention rate will be on the lower end of these spectrums. We believe a 75% retention rate is a conservative estimate, but we are setting the minimum threshold for retention rate at 60%, which we believe represents a clinically important retention rate for our population.

Acceptability of the CHAMPS intervention will be assessed using the CHAMPS completion rate. This rate will be calculated by dividing the number of participants who completed at least

XSL•FO
RenderX

the first 4 modules of CHAMPS by the number of total participants randomized to CHAMPS. We selected this completion threshold as the first 4 modules represent the core of the intervention, exposing participants to psychoeducation, motivational interviewing, personalized feedback, and skills training.

Secondary Outcomes

The efficacy of CHAMPS will be described by examining the change in participants' use of PBS, using the Short Form Protective Behavioral Strategies-Marijuana measure [21]. This is a 17-item self-report measure that includes evidence-based strategies that promote safer cannabis experiences. The marginal reliability of the short-form measure is high (0.93) [21].

The efficacy of CHAMPS will also be estimated by measuring the change in participants' motivation to change PBS, which is assessed using the Readiness to Change Questionnaire (RCQ) modified for cannabis use [48,49]. The RCQ is a 12-item clinician-administered measure based on Prochaska and DiClemente stages-of-change model and assesses 3 stages of change: precontemplation, contemplation, and action [49]. The internal consistency is satisfactory; the 3 stages of change scales have acceptable internal consistency, ranging from Cronbach α=.73 to α=.85 [48].

Exploratory Outcomes

Cannabis use–related physical, psychological, social, and functioning problems will be assessed using the Marijuana Problems Scale, a 19-item self-report instrument that measures changes in problems related to cannabis use over time [50,51].

Cannabis and other drug use in the past 2 weeks will be assessed using the Timeline Follow-back. This tool has high test-retest reliability and has been validated using other measures of drug-related problems or in clinical populations [52,53]. This tool has previously been used in a trial of people with psychosis who use cannabis [54]. This tool assesses the self-reported days of cannabis use per week, as well as the type of cannabis products, quantity, and dose or concentration of cannabinoids. The main end point for this outcome will be the number of days per week of cannabis use. The frequency of other drug use in the past 2 weeks will also be assessed using this tool.

Psychotic symptoms will be measured using the Positive and Negative Syndrome Scale-6, which is easily administered and has good psychometric properties [55,56]. The scale consists of 6 items: delusions, conceptual disorganization, hallucinatory behavior, blunted affect, passive or apathetic social withdrawal and lack of spontaneity, and flow of conversation.

Severity of cannabis dependence will be measured using the Severity of Dependence Scale [57]. This is a short, easily self-administered instrument developed to provide a brief measure of the psychological aspects of dependence experienced by users of various types of illicit drugs. It is a measure of compulsive use. This scale has good internal consistency (Cronbach α ranging from .80 to .90) [57,58] and has previously been used in trials with people with FEP [5,59].

Health service use data are collected via participant self-report and are confirmed as needed through patient medical record abstraction and contact with the clinician, gathering information on the total number of past-month emergency visits and days of hospitalization.

Data relating to the reception of EIS, CHAMPS usage data, and participant satisfaction will be used to complement data on CHAMPS acceptability and trial feasibility. We collect data on participants referred, screened, considered eligible, recruited, and consented; participants who initiated the intervention; and participants who completed baseline assessments. We will calculate the control group completion rate by dividing the total participants randomized to the control group by the number of participants who, at week 12, are still participating in EIS treatment.

Understanding of CHAMPS acceptability by study participants will be complemented by an evaluation of participant satisfaction with CHAMPS, using the Client Satisfaction Questionnaire-I, which is a modified version of the Client Satisfaction Questionnaire-8 and which measures global satisfaction with a web-based intervention [60]. This measure has an adequate internal consistency, as represented by Cronbach α=.93 for the 8-item scale [60,61]. Those randomized to EIS-only will receive the Client Satisfaction Questionnaire-8 and accompanying instructions to evaluate the cannabis-related treatment components of EIS using this questionnaire.

Data Collection and Management

Participation in the trial lasts up to 22 weeks, including up to 4 weeks between screening and randomization, 6 weeks of active CHAMPS intervention (immediate end point assessment), a booster session 4 weeks after the end of active CHAMPS intervention, and follow-up assessments conducted at weeks 12 and 18 (Table 2). Assessments are conducted either in person, over the phone, or using videoconferencing platforms. Communication and contact can be done digitally, over the telephone, or during in-person visits (only if confidentiality can be strictly maintained). All interactions are recorded in the patient study file. Furthermore, sites track participant interactions and collect information on recruitment, ineligibility reasons, and nonparticipation reasons. The research team uses these data to refine the recruitment strategy during the trial if needed.

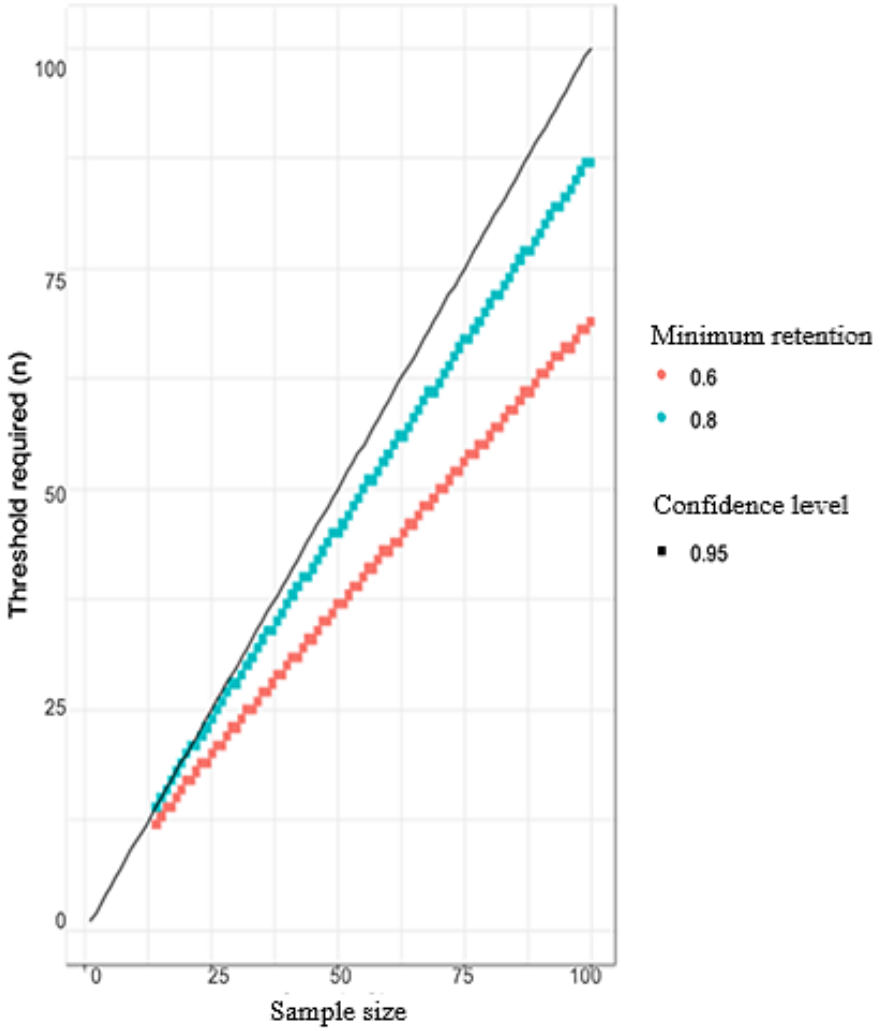
Data are entered into REDCap by site research staff or directly by the participant (through the CHAMPS app). The data dictionary will be built on REDCap and will be available upon request to the corresponding author. Final data quality assurance checks will be conducted by the data management team, and the study database will be locked, prohibiting further modification. The REDCap system was developed and implemented by the Center for Integration and Analysis of Medical Data to ensure that guidelines and regulations surrounding the use of computerized systems in clinical trials are upheld.

Participants are attributed a unique numeric study identifier to anonymize data, and data are password-protected on computerized databases and kept strictly confidential. Records are accessible only to research staff. Intervention arm participants are provided with detailed information regarding their data usage and protection (Multimedia Appendix 3). The final analysis data set will be kept on the secure server at the CHUM in Montreal, Québec, for 10 years, in line with *Fonds de la recherche en santé du Quebec* and CHUM research ethics board requirements.



An independent data and safety monitoring board examines accumulating data to ensure the protection of participants' safety during the study. This board determines whether there is ground for trial continuation; evidence that study procedures require modifications; or whether the trial should be halted for participant safety, intervention efficacy issues, or inadequate trial performance reasons.

Sample Size

The sample size for pilot trials is typically not driven by power calculations but rather by convenience or precision estimates [62], both of which we used to inform our sample size. Using a precision-based approach, we estimated the number of participants we would need to retain in this trial to detect with 95% confidence the true retention rate for a future trial. As aforementioned, based on related literature and our current context, we deemed 60% a clinically significant retention rate for this trial [40-43]. As seen in Figure 4, if we recruit 100 participants and retain at least 69 participants at the end of the study, we would have 95% confidence that the true (ie, population-level) retention rate is above 60%. Regarding convenience, our existing partnerships with Canadian EIS clinics and experience recruiting relatively large samples from this population [63] lead us to believe that recruiting 100 eligible individuals is feasible for this trial.

Figure 4. Diagram of trial retention rates.

Statistical Analysis

We will be analyzing primary outcomes using univariate analyses. The trial retention rate will be measured in terms of the percentage of randomized individuals retained in the intervention at end point assessment and will include a 1-sided 95% confidence interval to estimate the lower bound of the retention rate. CHAMPS acceptability will be reported using univariate analysis. We will also conduct exploratory analyses to test whether belonging to either study arm influenced EIS completion rates.

To describe sociodemographic and clinical variables at baseline, trial parameter data, and secondary and exploratory outcomes, we will conduct univariate analyses. We will use multivariable statistical methods to explore the following outcomes: participant satisfaction, use of cannabis PBS, and motivation to change cannabis PBS. To compare satisfaction between groups, we will use a hierarchical linear regression. The first regression model will insert the intervention arm as the independent study variable; the second model will insert other covariates. We will also conduct a hierarchical linear regression exploring the use of cannabis PBS over time as the outcome; the first regression model will insert study arms as the independent variable, and the second model will insert baseline PBS scores and other relevant covariates. To look at motivation to change, analyses will be done as with cannabis PBS, using hierarchical models that look at RCQ scores as the outcome and control for RCQ scores at baseline.

In multivariable models, we will include sites as random effects and will include certain covariates of interest that differ at baseline. These covariates may include age, sex, gender, study site, education status, employment, housing status, social support, and baseline clinical characteristics including cannabis use and CUD severity. Sensitivity analyses will explore key outcomes in subgroups of participants (eg, location-based subgroups), as well as the use of different thresholds to determine whether participants have completed CHAMPS.

Missing data will be handled issuing guidance of the missing data treatment for each instrument. The proposed analyses will include all participants with at least 1 nonmissing visit. Our analysis plan includes both intention-to-treat and per-protocol analyses.

Ethical Considerations

Ethical approval for the proposed study was obtained from the CHUM research ethics board (#20.433). Prior to initiating the study, local approval to conduct the study at each respective location was also obtained. This study will be conducted in accordance with the ethical principles outlined in the Declaration

XSL•FO
RenderX

of Helsinki, the International Conference on Harmonization Good Clinical Practice Guidelines, and all other applicable regulatory requirements. This pilot trial protocol was developed in accordance with the extension of the Consolidated Standards of Reporting Trials statement for randomized pilot or feasibility trials [64] (Multimedia Appendix 4).

Site PIs will ensure that the trial is conducted according to good clinical practice guidelines and may perform quality assurance audits for protocol compliance. The local research ethics board may inspect research records for verification of data, compliance with federal, provincial, and local guidelines on human participant research and to assess participant safety. Adverse events reported by the participant will be recorded electronically by study staff and reported to the site PI, study nurse, and study clinician for assessment and referral as appropriate. Site PIs will review each adverse event and assess the possible relatedness of any adverse event to the study intervention or other study procedures. Each of the sites has established practices for managing medical and psychiatric emergencies, and the study staff will use these procedures.

Results

Enrollment took place from December 2021 to June 2023. Data collection and analysis are expected to be completed by early 2024, and study results will be submitted for publication in peer-reviewed scientific journals thereafter. For participants who opt to receive the results, we will apply various knowledge transfer tools (eg, health cards, summaries with charts and graphics, video clips accessible on the web or through social media) in English and French to effectively translate our findings. Furthermore, we will leverage our networks to relay study findings in a format that is tailored to this population. We have designed an ancillary qualitative study that will explore CHAMPS pilot trial participants' and accompanying clinicians' experiences regarding the CHAMPS intervention and its implementation in EIS. This ancillary study will serve to further understand the barriers and facilitators of CHAMPS and its implementation and can inform future trials of similar interventions.

Discussion

Principal Findings

This mobile health and harm reduction intervention is the first of its kind to be evaluated in the context of reducing cannabis use–related harms for this population. We consider that CHAMPS was strengthened by its unique development process, using preference research to shape the intervention and involving individuals with lived experience as CHAMPS coproducers. Despite potential barriers to coproduction research, such as a high turnover rate of clinicians or researchers and stigma toward patients [65], our patient-partners anecdotally reported that the coproduction process was successful in building healthy relationships between coresearchers and patient-partners and provided opportunities for personal growth. Feedback from our co-researchers also highlighted the benefits, including the production of a well-informed intervention that valued the knowledge of all contributors.

Another strength of this pilot trial is its rigorous and carefully crafted design, considering the limited literature on cannabis use–related harm reduction in people experiencing FEP and the use of mobile health technology in this context. The CHAMPS trial design, as a multicenter, randomized pilot study, will enable rigorous assessment of the feasibility of running a full-scale RCT with CHAMPS and of the acceptability of the CHAMPS intervention for this population. Furthermore, we are collecting data exploring how CHAMPS may potentially influence harm-related outcomes. The results of this pilot trial and its ancillary qualitative study may offer valuable insights for future trials assessing similar psychosocial interventions.

Mobile health interventions like CHAMPS may contribute to the alleviation of strained health care systems by improving accessibility for participants and providing an independent tool to aid clinicians in delivering optimal care to their patients [66]. Surveys and personal communication by SC-M and DJ-A on September 2023 on patient preference survey results (associated manuscript submitted for publication) demonstrate the theoretical acceptability of and preference for mobile health interventions to target CUD or cannabis use by people with FEP [36,37]. However, the implementation of a novel mobile health intervention or concerns around data confidentiality may hinder the potential acceptability of this intervention. More research piloting the use of new technologies, such as CHAMPS, to address existing mental health challenges in individuals with FEP needs to be undertaken before recommending these initiatives in clinical contexts.

Limitations

The present trial has limitations and may face a variety of possible challenges. Previous data suggest that continued cannabis use predicts persistently poor treatment adherence for people with psychosis [67]; if such patterns also translate to psychosocial intervention adherence, then this may lead to retention challenges for our trial. We are recruiting participants from Quebec and Nova Scotia provinces, which differ in their sociocultural and clinical contexts from each other and other provinces. To explore the potential impact of these differences, we will be doing sensitivity analyses to explore possible site-specific effects on outcomes. On the other hand, our potentially heterogeneous sample may provide researchers with insights regarding the effectiveness of CHAMPS in multiple real-world contexts, facilitating generalization to other settings. The context-specific adaptations that occurred as a result of the ongoing COVID-19 pandemic (eg, transitioning to telehealth services) and which our participants may have experienced may influence the results of our study. For example, tightening restrictions may have resulted in less frequent in-person clinical consultations. These tightened restrictions may also have particularly impacted people with psychosis, who are likely to be single and have limited social networks [68], and resulted in higher levels of isolation and emotional distress for certain participants. It is possible that these changing regulations and societal restrictions may have influenced the reception, effectiveness, satisfaction, or other related outcomes of our intervention and EIS. The role of this particular context must be considered during our analyses and may limit the generalizability of our study findings. Finally, while we

XSL•FO
RenderX

consulted the literature to determine best practices for data protection and confidentiality strategies while designing CHAMPS, concerns around data protection and privacy have previously been a hindrance to the acceptance of mental health–related apps [66]. It is thus still possible that we will face confidentiality and privacy issues or that risk perception by participants may impact our capacity to recruit and engage them in the intervention.

Conclusions

CHAMPS uniquely combines evidence-based approaches, harm reduction strategies, patient perspectives, and mobile health technology to address cannabis use–related harms in young people with FEP and persistent cannabis use, potentially addressing an unmet need in this population. Our study findings have the potential to advance knowledge in the cannabis and psychosis fields. To gain a better understanding of harm reduction interventions, future research should prioritize conducting robust, large-scale RCTs. Preliminary studies, like the present pilot trial, are urgently required to refine optimal design and approaches for these interventions.

Acknowledgments

The authors would like to acknowledge the invaluable contributions of all patient-partners in the development of CHAMPS. Further, they would like to express their gratitude to all participants, clinicians, and research staff for their ongoing contributions to this study. The authors would like to acknowledge the contribution of Navdeep Kaur in the conceptualization of this intervention. They would also like to extend gratitude to Jill Fikowski and the Changemark team, as well as Laurie Argourd, Anita Abboud, and Alice Gauchet for their ongoing support of this study. This work was supported by the Quebec Ministry of Health and Social Services (Public Health Division). The authors would like to acknowledge support from Fonds de Recherche du Québec en Santé (DJ-A), the University Institute on Addictions (SC-M), and the Vanier Canada Graduate Scholarship (SC-M). The funding sources have no input in the study design, data analysis, or interpretation of findings.

Authors' Contributions

SC-M wrote the initial manuscript draft, tables, and figures. SC-M, AA-B, JC, DC, SD, BF, PL-T, TL, SL, CO-P, M-AR, OT, PT, MV, AW, and DJ-A contributed to the study conceptualization, critically reviewed, and edited the manuscript. AA-B, DC, SD, TL, SL, CO-P, M-AR, PT, MV, and DJ-A contributed to the data acquisition. DJ-A obtained funding and supervised the study’s development and conduct. All authors approved the manuscript.

Conflicts of Interest

BF has held research grants and contracts in the areas of substance use, health, and policy from public funding and government-related agency (ie, public only) organizations and has consulted as a scientific expert with such entities in different countries. DJ-A received investigational products (2022-23) from Cardiol Therapeutics for a clinical trial funded by the Quebec Ministry of Health and Social Services. DJ-A received study materials from Cardiol Therapeutics and Exka for clinical trials funded by Quebec government.

Abstract

Background: Endometriosis-associated deep dyspareunia is associated with reduced sexual quality of life, lower self-esteem, and impaired sexual function.

Objective: The primary objective is to assess the acceptability of a phallus length reducer (brand name: Ohnut [OhnutCo]), which is a buffer worn over the penis or a penetrating object to reduce endometriosis-associated deep dyspareunia, and the feasibility of a definitive randomized controlled trial (RCT). The secondary objective is to obtain estimates of the effectiveness of the buffer. An embedded substudy will explore the acceptability and the preliminary validity and reliability of a vaginal insert for the self-assessment of deep dyspareunia.

Methods: Ours is an investigator-initiated, 2-arm RCT. We will recruit 40 patient participants with diagnosed endometriosis between the ages of 19 and 49 years, as well as their sexual partners. The participating couples will be randomized in a 1:1 ratio into the experimental arm or the waitlist control arm. The length of the study period will be 10 weeks, during which time all participants will record deep dyspareunia severity following each episode of sexual intercourse. In weeks 1 to 4, all patient participants will record deep dyspareunia severity at each sexual encounter. In weeks 5 to 10, participants in the experimental arm will use the buffer during vaginal penetration; participants in the waitlist control arm will continue engaging in vaginal penetration as usual. Participants will complete questionnaires for assessing measures of anxiety, depression, and sexual function at baseline, at 4 weeks, and at 10 weeks. In the substudy, patient participants will self-assess dyspareunia by using a vaginal insert on 2 occasions, at least 1 week apart. The primary outcomes—the acceptability and feasibility of the buffer—will be assessed with descriptive statistics, and the secondary outcome—phallus length reducer effectiveness—will be assessed by using an analysis of covariance–based approach. For the vaginal insert, we will assess acceptability, test-retest reliability, and convergent validity via correlation analyses comparing the use of the insert to clinical examination in terms of dyspareunia assessment outcomes.

Results: Our pilot will provide initial data on the acceptability and effectiveness of the buffer and the feasibility of the study methodology. The results from our study are expected to be submitted for publication by the spring of 2023. As of September 2021, we have consented 31 couples into the study.

Conclusions: Our study will provide preliminary evidence for the self-assessment and management of endometriosis-associated deep dyspareunia. The findings will inform the decision to proceed to a definitive RCT.

Introduction

Endometriosis is the presence of endometrial-like glands and stromata that abnormally grow outside the uterus [1]. This disease affects approximately 1 in 10 women and can cause various types of pain, including dysmenorrhea; chronic pelvic pain; and deep dyspareunia, which is defined as pain with deep vaginal penetration [1,2]. Deep dyspareunia is often neglected due to its intimate nature and reservations among both patients and clinicians in discussing sexual health [3,4]. People with endometriosis and deep dyspareunia have been shown to have significantly reduced sexual quality of life [5], lower self-esteem [6], and impaired sexual function [7]. Qualitative research has shown that many people with deep dyspareunia feel guilty about their pain and often continue to engage in penetrative activity even when the pain is severe [6].

Endometriosis-associated deep dyspareunia is multifactorial and can result from the endometriotic lesions themselves and other factors, such as myofascial pelvic pain and central nervous system sensitization [1,2,8]. A subset of patients do not experience improvements in deep dyspareunia after standard care, such as hormonal or surgical interventions for endometriosis [7-11], indicating an important need for self-management approaches. One self-management option is a phallus length reducer (PLR; brand name: Ohnut [OhnutCo])—a buffer that is worn externally over the penis or a penetrating object to reduce the depth of penetration [9]. Conceptually, this should reduce deep dyspareunia by limiting contact with deep pelvic structures; however, this intervention has not been empirically tested.

The assessment of deep dyspareunia for clinical and research purposes is challenging; pelvic examination in the clinical context may not reliably reflect sexual activities, particularly for patients who have experienced trauma [12], while questionnaire-based measurement is limited by recall bias that may be exacerbated for patients who have become abstinent as a result of dyspareunia. A study that investigated superficial dyspareunia among people with vulvodynia found that the Tampon Test—a self-administered test involving the insertion and removal of a tampon—was reliable and demonstrated good construct validity [13]. The study showed 95% adherence, providing evidence that participants found the test to be an acceptable method of assessing superficial dyspareunia [13]. Similarly, the self-assessment of endometriosis-associated deep dyspareunia by using a vaginal insert may be an acceptable, ecologically valid approach to assessing this symptom.

In our pilot randomized controlled trial (RCT) protocol, the primary objective is to assess the acceptability of a PLR and the feasibility of a definitive RCT. The secondary objective is to obtain estimates of the effectiveness of the PLR, which will be compared to those of a waitlist control for reducing endometriosis-associated deep dyspareunia. An embedded substudy will explore the acceptability, reliability, and preliminary validity if a vaginal insert for the self-assessment of deep dyspareunia.

Methods

Trial Design

Our study is a pilot study of a parallel-group, 1:1 RCT of the PLR, which will be compared to a waitlist control. An embedded substudy will investigate the use of a vaginal insert (brand name: Soul Source Rigid Plastic Vaginal Dilator Size #P1 [Soul Source Therapeutic Devices Inc]) [14] for the self-assessment of deep dyspareunia.

This protocol was developed by using the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist [15], the CONSORT (Consolidated Standards of Reporting Trials) extension for randomized pilot and feasibility trials [16], and published guidance for the reporting of protocols of pilot and feasibility trials [17]. This protocol describes the study rationale, proposed methods, organization, and ethical considerations.

Study Setting

The study is being conducted at a tertiary care center for endometriosis within a large urban center in western Canada. Our research team manages a prospective patient registry called *Endometriosis and Pelvic Pain Interdisciplinary Cohort* (EPPIC; ClinicalTrials.gov trial number: NCT02911090) [18]. Baseline data collected in EPPIC are derived from patient-reported questionnaires and clinician-reported data from clinic consultations. The variables that are included in this prospective registry have been described previously [18]. New or rereferral patients at the center are invited to participate in the registry and can consent to being contacted about further research. In our study, all procedures will be conducted by the participants at home.

Eligibility Criteria

Eligible patient participants will be new or rereferred patients in EPPIC who attended a clinic visit between January 1, 2018, and December 31, 2020; those who consented to being contacted for future research; and those who have a history of surgically confirmed endometriosis. Details of the inclusion and exclusion criteria are listed in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for the patient participants and their partners.

Patient participants

- Inclusion criteria
  - 19 to 49 years of age
  - Birth-assigned female
  - Monogamous sexual relationship
  - Sexually active or not currently sexually active due to deep dyspareunia
  - Self-reported deep dyspareunia score of ≥4 (out of 10)
  - Sexual partner who consents to participating in the study
  - Willing to engage in penetrative sex at least once during the duration of the study
- Exclusion criteria
  - Self-reported superficial dyspareunia score of ≥4 (out of 10; this is a potentially confounding variable, as the phallus length reducer is not expected to affect introital pain)
  - Severe anxiety or depression symptoms in the last 2 weeks (Generalized Anxiety Disorder-7 or Patient Health Questionnaire-9 score of ≥15)
  - Confirmed "yes" to question "In the last 2 weeks, have you had intense fear/anxiety in anticipation of, during or as a result of vaginal intercourse?"
  - Current use of a phallus length reducer
  - Inability to complete English-language questionnaires

Partners

- Inclusion criteria
  - 19 years of age or older
  - Any sex and gender
- Exclusion criteria
  - Current use of a phallus length reducer
  - Inability to complete English-language questionnaires

Sample Size

A sample size for a pilot study is often recommended to be at least 12 per group [19]. Given potential dropout and the uncertainty around the variance in acceptability, we will aim to recruit 20 participants and their sexual partners per group (ie, 40 couples or 80 total study participants).

Recruitment

Individuals will be selected from a list of potential participants and will be telephoned and emailed about the study by a study coordinator. Interested individuals will be asked a series of screening questions to confirm that they meet the eligibility criteria. An important inclusion criterion listed in Textbox 1 is that participants must have a self-reported deep dyspareunia score of ≥4 (out of 10). This criterion was established to exclude patients who may have undergone surgery or other interventions that reduced deep dyspareunia symptoms. If the inclusion criteria are met and no exclusions are identified, patient participants and their partners will be emailed the consent form to review. The study coordinator will then review the consent forms with both the patient participants and their partners in a second telephone call and address any questions that the patient participants or their partners may have. Participants will give their consent to participate electronically, using an e-consent form.

Interventions

The PLR (brand name: Ohnut) is made of a Food and Drug Administration–approved body- and skin-safe polymer blend. The blend is a thermo-set material that does not contain bisphenol A, phthalates, and latex and can be used with either silicone lubrication or water-based lubrication [20]. The PLR is a buffer that is worn externally over the penis or a penetrating object to limit the depth of penetration.

The vaginal insert is made of polyurethane and is stable from −40 to 70 °C. It will be self-inserted by the patient participants to self-assess the tenderness of pelvic structures implicated in deep dyspareunia that are typically assessed by a clinician during a pelvic examination. This is a novel, off-label use of the device.

To support the use of the vaginal insert and PLR, the study team developed patient-centered study booklets, which include instructions for the use of each tool (Multimedia Appendix 1).

XSL•FO
RenderX

The instructions were developed with a gynecologist specialized in the assessment of dyspareunia, a pelvic floor physiotherapist with expertise in guiding patients to use vaginal inserts, and a clinical psychologist with experience in coaching patients and their partners to integrate the PLR in penetration. A medical illustrator was engaged to create diagrams for guiding the use of the vaginal insert.

Outcomes

Primary Outcomes

The primary outcomes are the acceptability of the PLR and the feasibility of study methods. Details of the specific outcomes are listed in Textbox 2.

Textbox 2. Primary outcomes of the feasibility and acceptability of the phallus length reducer (PLR).

Outcomes and explanations

- Response: the number of individuals who responded divided by the total number of individuals contacted
- Refusal: the number of individuals who refuse to participate divided by the number of individuals who responded
- Screen fail: the number of individuals who did not meet the inclusion criteria divided by the number of individuals who responded
- Recruitment rate: the number of participants enrolled divided by the length of the recruitment period (months)
- Retention: the number of participants who complete the study divided by the number of participants enrolled
- Adherence: the number of sexual events completed with the PLR divided by the total number of sexual events reported
- PLR acceptability: a 34-item, built-for-purpose questionnaire (adapted from a previously published measure for assessing the acceptability of female condoms [21]), with a response scale ranging from 1 to 5, will be completed by participants in the experimental arm in week 10 (Multimedia Appendix 1)

Secondary Outcomes

The secondary outcome is the effectiveness of the PLR, which will be determined by comparing changes in outcomes reported from week 4 to week 10 by patient participants in the experimental arm to those reported by participants in the control arm. Details of these outcomes are listed in Textbox 3.

Textbox 3. Secondary outcomes of the effectiveness of the phallus length reducer.

Outcomes and explanations

- Deep dyspareunia: an 11-point numeric rating scale, wherein 0 corresponds to no pain and 10 corresponds to the worst pain, will be used to measure deep dyspareunia intensity (using an item previously published by our team [18]); mean dyspareunia scores from weeks 1 to 4 will be compared with those from weeks 5 to 10 in the control and experimental arms
- Sexual function: total score on the Female Sexual Function Index, a 19-item self-report measure that captures information on sexual desire, arousal, lubrication, orgasm, satisfaction, and pain over the past 4 weeks [22]
- Sexual distress: total score on the Female Sexual Distress Scale-Revised, a 13-item self-report measure that captures sex-related personal distress over the past 4 weeks [23]
- Anxiety: total score on the Generalized Anxiety Disorder-7, a 7-item questionnaire validated for monitoring the severity of general anxiety [24]
- Depression: total score on the Patient Health Questionnaire-9, a 9-item questionnaire validated for monitoring the severity of depression [25]

Substudy Outcomes

The substudy will explore the acceptability and the preliminary convergent validity and test-retest reliability of a vaginal insert for the self-assessment of deep dyspareunia. The vaginal insert acceptability substudy outcome is based on an 18-item, built-for-purpose questionnaire adapted from a previously published measure for assessing the acceptability of female condoms [21] on a response scale ranging from 1 to 5. This questionnaire will be completed by all patient participants by week 4 (Multimedia Appendix 1).

Participants will use the vaginal insert to palpate various pelvic organs and structures (ie, to palpate the bladder anteriorly, the pelvic floor laterally, the pouch of Douglas posteriorly, and the cervix at the apex of the vagina) that have been previously associated with deep dyspareunia [26], and they will indicate whether they feel pain (“yes” or “no”) and the severity of the pain (11-point numeric rating scale wherein 0 corresponds to no pain and 10 corresponds to the worst pain). The number of tender sites for each participant will be calculated based on the self-reported number of tender anatomic sites that the participants identify when using the insert. Data on clinically assessed tenderness (“yes” or “no”) for each participant were previously collected through digital pain mapping, which was completed by a clinician. Data for clinically assessed tenderness are stored in EPPIC. These pain-related variables will be used to assess the convergent validity and test-retest reliability of the vaginal insert.

Assignment of Interventions

The study coordinator will use a REDCap (Research Electronic Data Capture; Vanderbilt University) extension package called *randomization* to randomly assign consented participants in a 1:1 ratio to 1 of 2 study arms; the experimental PLR arm will receive the PLR, and the waitlist control arm will receive the

XSL•FO
RenderX

PLR once the study has concluded. Both arms will receive the vaginal insert for the substudy.

Participant Timeline

Throughout the study, all participants will continue concurrent endometriosis treatments and treatments for other conditions as usual. At the start of the study, both arms will complete baseline demographic, psychological, and sexual function questionnaires. In weeks 1 to 4 of the study, patient participants in both arms will engage in sexual activity as usual and be asked to record a daily diary of all sexual events and the severity of deep dyspareunia (score: range 0-10). Psychological and sexual function questionnaires will be repeated at the end of week 4. In week 5, participants in the experimental arm will receive and begin to use the PLR. Participants in the waitlist control arm will not receive the PLR and will continue to record deep dyspareunia severity at each sexual encounter. At the end of week 10, all patient participants will repeat the psychological and sexual function questionnaires, and participants in the experimental arm will indicate the acceptability of the PLR. At the conclusion of the study period, participants in the waitlist control arm will receive the PLR.

For the substudy, during weeks 1 to 4, all patient participants will self-assess deep dyspareunia by using the vaginal insert on weeks 2 and 3 of their menstrual cycle or on another two occasions (1 week apart) in the absence of regular bleeding. At the end of week 4, all patient participants will indicate the acceptability of the vaginal insert. The participant timeline is depicted in Table 1.

Confidentiality

The list of potential participants is password protected and stored on a secure server at the study site, and it will only be available to select members of the research team. Upon enrollment to the study, each participant will be given a unique study ID number that does not correlate to any personally identifying information. All reports, data collection sheets, and administrative forms will be identified by this number to maintain confidentiality. This ID number can only be decrypted by a password-protected linking file, which is stored separately on the secure server at the study site; similarly, it will only be available to select members of the research team.

Data Management

Study materials, such as the instruction booklet, the daily diaries, and the PLR, will be mailed to the participants, depending on their study arm allocation. The study coordinator will follow up with each participant to collect the daily diaries of the control and intervention group participants upon the completion of the study. We will not blind the research team to the study arm allocations. Once the participants have completed the study, a research team member will extract the data from the daily diaries and upload the data onto a Microsoft Excel (Microsoft Corporation) sheet. The data will be stored on a secure server at the study site, and they will only be available to select members of the research team. Details of the data management procedures can be found in the study's research ethics board application, which can be provided upon request. We do not anticipate any adverse events with the use of the PLR, and as such, we will not need a data monitoring committee. If any adverse events occur, the participants can record them in the daily diary, and they will have the contact information of the study team to debrief such cases.

Statistical Methods

Descriptive statistics for demographic data and outcome variables will be presented by using means and SDs for continuous variables that are normally distributed, medians and IQRs for continuous variables that are not normally distributed, and frequency tables for the categorical variables of each study arm and the whole sample. Baseline measures will be compared to assess balance between the two arms, using Fisher exact tests for categorical variables and Kruskal-Wallis tests for continuous variables. With regard to our analytic approach for missing data.

Acceptability of the PLR and Vaginal Insert

For the PLR and vaginal insert, an overall acceptability index will be calculated by summing the acceptability questionnaire item responses and dividing the sum by the total possible score. The index will be characterized by using means and SDs, and individual items will be reported by using medians and IQRs. For the PLR, results that are stratified by participant type (patient or partner) will be reported.

Effectiveness of Using a PLR to Reduce Deep Dyspareunia

For the experimental and waitlist control arms, the difference in deep dyspareunia scores from week 4 to week 10 between the two arms will be assessed by using an analysis of covariance (ANCOVA)–based approach [27]. We will compare mean scores from weeks 5 to 10 between the two arms, using preintervention (weeks 1-4) mean scores as covariates in the model. Similar ANCOVA modeling will be used for the Female Sexual Distress Scale-Revised, Female Sexual Function Index, Generalized Anxiety Disorder-7, and Patient Health Questionnaire-9 scores. If the assumptions of the ANCOVA model are not met by the data set, then we will consider conducting other appropriate statistical analyses, such as the ANOVA-based approach, 2-tailed *t* tests, linear regression modeling, and nonparametric approaches for the ANCOVA model.

Validity and Reliability of the Vaginal Insert for the Self-assessment of Deep Dyspareunia

Tenderness at each pelvic anatomic site, as assessed via the vaginal insert test, as well as the highest score across all anatomic locations, will be correlated with the mean deep dyspareunia score, highest deep dyspareunia score, and lowest deep dyspareunia score. The self-assessed tenderness scores will be correlated with self-reported deep dyspareunia scores, using the Spearman rank correlation test. Participants without sexual events during weeks 1 to 4 will be compared to participants with ≥1 sexual event.

The results of assessments of tenderness ("yes" or "no") from the most recently performed clinical pelvic examinations, if applicable (these data are collected in EPPIC), will be correlated with self-assessed tenderness, as measured with the vaginal insert (score: range 0-10), by using a 2-tailed *t* test or Mann-Whitney *U* test.

To evaluate test-retest reliability, self-assessed tenderness scores for each anatomic site from the first assessment will be correlated with self-assessed tenderness scores from the second assessment to determine if the two sets of vaginal insert data are reproducible over time. This will be done by using scores (0-10) to calculate the intraclass correlation coefficient, as well as by categorizing tenderness ("yes" or "no") and using the McNemar test.

With regard to our analytic approach for missing data, if the maximum amount of missingness in any variable is <5%, we will exclude cases with missing data via pairwise exclusion. Otherwise, if the maximum amount of missingness is >5%, multiple imputation via chained equations will be used to impute the missing values. Results from imputed data sets will be pooled to provide final results.

Ethics Approval

The research presented in this protocol was approved by the Children's and Women's Research Ethics Board of the University of British Columbia (approval number: H19-00294). The study is also registered on ClinicalTrials.gov (trial number: NCT04370444). Any subsequent modifications to the study protocol will be reviewed by the Research Ethics Board of the University of British Columbia for approval, submitted to ClinicalTrials.gov, and communicated to the study participants.

Results

The results from our study are expected to be submitted for publication by the spring of 2023. As of September 2021, we have recruited 31 couples into the study.

Discussion

Deep dyspareunia affects approximately 50% of people with endometriosis and has significant impacts on their sexual and mental health [5-7]. One gap in the care of endometriosis-associated deep dyspareunia is the lack of evidence-based self-management tools. A second gap is the lack of validated self-assessment tools that patients can use for objective measurements of deep dyspareunia that can supplement patient-reported outcomes of pain severity. In this protocol, we propose a pilot RCT for evaluating the feasibility and acceptability of, and obtaining estimates of effectiveness for, a PLR (brand name: Ohnut), which is a buffer that limits the depth of penetration and can be used as a self-management tool for deep dyspareunia. Embedded in our pilot RCT is a substudy that will evaluate a vaginal insert for objectively self-assessing anatomic sites associated with deep dyspareunia.

Potential feasibility issues pertain to the recruitment rate, retention, and adherence. Both the PLR and vaginal insert will be used in vaginal penetrative activities. The vaginal insert will be used on 2 occasions (in order to test reproducibility), and the PLR will be used during sexual encounters involving vaginal penetration over 6 weeks. Moreover, pain scores will be prospectively recorded for each sexual encounter during the 6 weeks. These intensive procedures and prospective data collection activities may reduce the recruitment rate, retention, and adherence. Acceptability issues may include impacts on the sexual function of the partners and how the placement of the PLR on the penis or a penetrating object affects the sexual response cycles of the participants. We also aim to estimate the potential effectiveness of the PLR in reducing deep dyspareunia by comparing it to a waitlist control.

The strengths of the protocol include having a randomized design, taking prospective pain measurements at each sexual encounter, and supplementing the trial by embedding the vaginal insert as a potential novel self-assessment tool. One limitation of the protocol is that it is not placebo controlled; however, it would be difficult to design a placebo for the PLR. Another limitation is that we will be comparing the vaginal insert to clinical examinations that are done at entry into the registry, which may be conducted several months before enrollment into the trial. In a future study, a pelvic examination can also be performed at recruitment. Furthermore, a limitation of the pilot trial is that we will not control for variables like age and BMI, which are potential confounders that may affect the use of the vaginal insert or PLR.

In summary, the PLR may be a noninvasive self-management tool for people with endometriosis-associated deep dyspareunia. The results of our pilot RCT will inform a future full-scale RCT of both the PLR and the vaginal insert test. The results from our study will be reported in peer-reviewed journals, in conference presentations, and to the study participants and the public through plain-language knowledge translation strategies. Ultimately, these innovations will contribute to the body of work on the rigorous investigation and evidence-based management of endometriosis-associated deep dyspareunia.

Acknowledgments

We would like to thank the participants for their involvement in this study, as well as the clinicians and the patient partners from the Endometriosis & Pelvic Pain Laboratory. This project was funded by the University of British Columbia D A Boyes Memorial Research Award and an International Society for the Study of Women's Sexual Health Research grant. These organizations had no role in the design of the study or writing of the manuscript. Ohnutco has provided a discount for purchase of the phallus length reducer (PLR) device utilized in the protocol, and had no role in the design of the study or writing of the manuscript.

Data Availability

We do not have institutional ethics approval to publicly share the data sets in our study.

Authors' Contributions

Abstract

Background: Among people with serious mental illness (SMI), obesity contributes to increased cardiovascular disease (CVD) risk. The Achieving Healthy Lifestyles in Psychiatric Rehabilitation (ACHIEVE) randomized controlled trial (RCT) demonstrated that a behavioral intervention tailored to the needs of individuals with SMI results in clinically significant weight loss. While the research team delivered the ACHIEVE intervention in the trial, community mental health program staff are needed to deliver sessions to make scale-up feasible. Therefore, we adapted the ACHIEVE-Dissemination (ACHIEVE-D) curriculum to ease adoption and implementation in this setting. Designing and testing of implementation strategies is now needed to understand how to support ACHIEVE-D delivery by community mental health program staff coaches.

Objective: This study aims to conduct a pilot trial evaluating standard and enhanced implementation interventions to support the delivery of ACHIEVE-D in community mental health programs by examining effects on staff coaches' knowledge, self-efficacy, and delivery fidelity of the curriculum. We will also examine the effects on outcomes among individuals with SMI taking part in the curriculum.

Methods: The trial will be a cluster-randomized, 2-arm parallel pilot RCT comparing standard and enhanced implementation intervention at 6 months within community mental health programs. We will randomly assign programs to either the standard or enhanced implementation interventions. The standard intervention will combine multimodal training for coaches (real-time initial training via videoconference, ongoing virtual training, and web-based avatar-assisted motivational interviewing practice) with organizational strategy meetings to garner leadership support for implementation. The enhanced intervention will include all standard strategies, and the coaches will receive performance coaching. At each program, we will enroll staff to participate as coaches and clients with SMI to participate in the curriculum. Coaches will deliver the ACHIEVE-D curriculum to the clients with SMI. Primary outcomes will be coaches' knowledge, self-efficacy, and fidelity to the ACHIEVE-D curriculum. We will also examine the acceptability, feasibility, and appropriateness of ACHIEVE-D and the implementation strategies. Secondary outcomes among individuals with SMI will be weight and self-reported lifestyle behaviors.

Results: Data collection started in March 2021, with completion estimated in March 2023. We recruited 9 sites and a total of 20 staff coaches and 72 clients with SMI. The expected start of data analyses will occur in March 2023, with primary results submitted for publication in April 2023.

XSL•FO
RenderX

Conclusions: Community mental health programs may be an ideal setting for implementing an evidence-based weight management curriculum for individuals with SMI. This pilot study will contribute knowledge about implementation strategies to support the community-based delivery of such programs, which may inform future research that definitively tests the implementation and dissemination of behavioral weight management programs.

Introduction

The prevalence of obesity is significantly elevated in people with serious mental illness (SMI) [1,2]. Obesity is a leading cause of preventable death in this population, both directly through its effects on cardiovascular disease (CVD) and indirectly by contributing to other CVD risk factors [3-6]. In general populations, behavioral weight loss interventions have been demonstrated to improve CVD risk by reducing blood pressure and glucose, as well as improving lipid profiles [7]. However, behavioral interventions targeting changes in diet, exercise, and weight loss need to be tailored to the particular needs of people with SMI, such as memory impairment and limited executive function [8,9]. The National Institute of Mental Health (NIMH)–funded Achieving Healthy Lifestyles in Psychiatric Rehabilitation (ACHIEVE) randomized controlled trial (RCT) tested a behavioral weight-loss intervention for individuals with SMI who attended community-based psychiatric rehabilitation programs [10]. The ACHIEVE RCT demonstrated clinically and statistically significant weight loss [11]. ACHIEVE included group and individual weight-management sessions and group exercise sessions, which were led by trained study interventionists. Given the obesity epidemic in persons with SMI, there is an urgent need to disseminate ACHIEVE.

We posited that the ACHIEVE intervention might be ideal for dissemination by training and supporting community mental health program staff to deliver the sessions [12]. In the ACHIEVE RCT, the interventionists were study staff that received substantial onboarding and ongoing in-person training, as well as performance feedback with particular emphasis on motivational interviewing (MI) skills [10,11]. Time and other logistical constraints prevent community mental health program staff from participating in such intensive training. By leveraging novel strategies that incorporate advances in training and feedback modalities (eg, web-based training and web-based training environments), we could train community mental health program staff to facilitate the real-world implementation of the ACHIEVE program. We used the enhanced Replicating Effective Programs (REP) Framework for translating evidence-based interventions into community settings [13,14]. This model has 4 stages: preconditions, preimplementation, implementation, and maintenance. Preconditions identify needs, effective interventions, and implementation barriers to draft an intervention package. Preimplementation adapts and pilot tests implementation strategies for the community. Implementation focuses on training, support, evaluation, and refinement. Maintenance supports sustained implementation and dissemination.

We completed the REP preconditions stage for ACHIEVE by adapting the intervention to facilitate implementation by community mental health program staff while retaining core elements [15]. We modified the schedule and format to support efficient, staff-led delivery but retained the core messages and behavioral strategies. We previously evaluated this adapted curriculum in a proof-of-concept study at a community mental health program (NCT03999892) [16], which informed further refinements based on feedback from staff observers and participating individuals with SMI. Table 1 outlines this modified weight management curriculum, ACHIEVE-Dissemination (ACHIEVE-D), which will be used in the REP preimplementation stage.

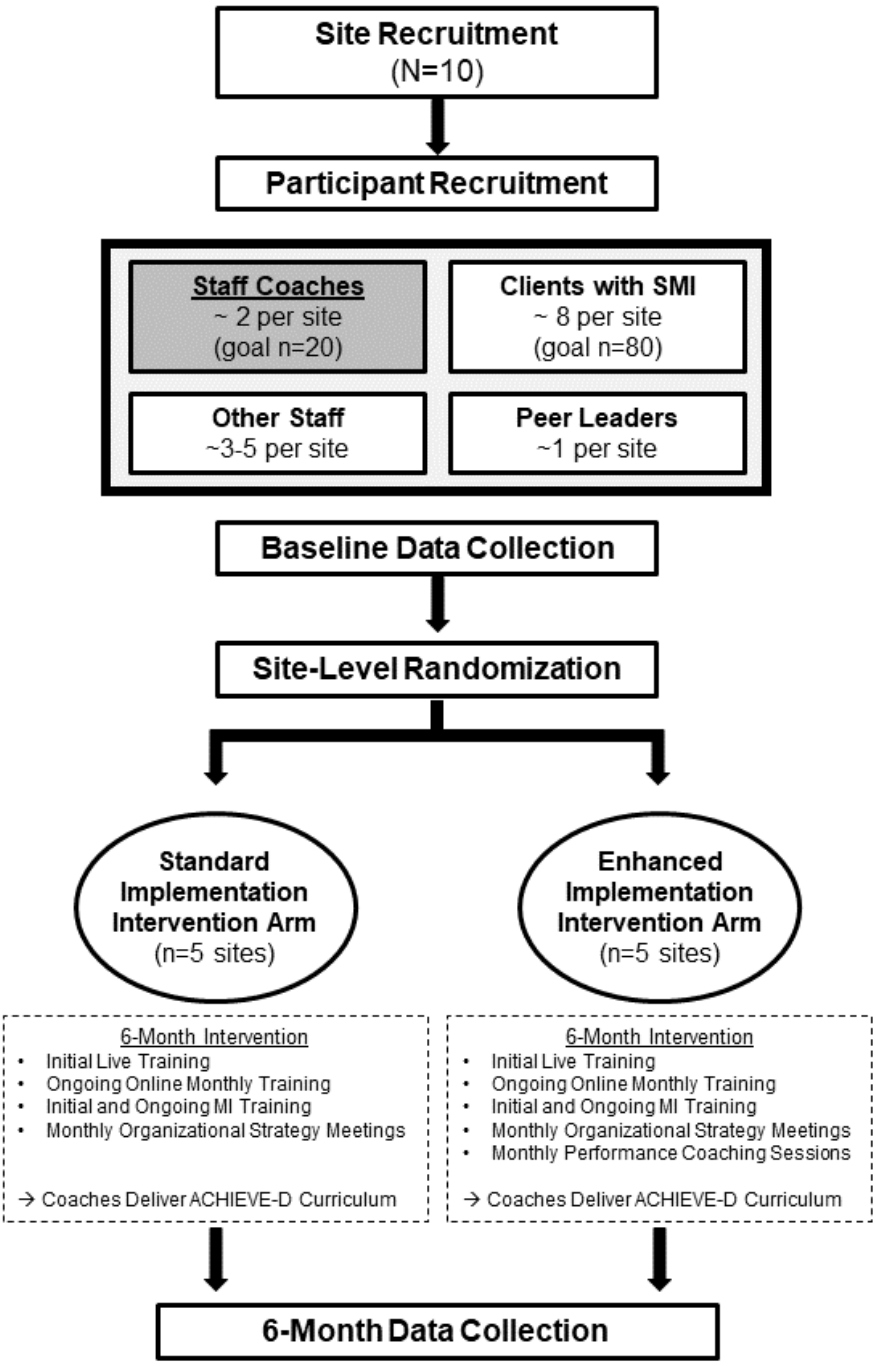
Table 1. Overview of the ACHIEVE-Dissemination curriculum adapted for delivery by community mental health program staff.

	ACHIEVE-Dissemination curriculum[a]
Duration	• 6 months
Group sessions	
1 group type	• Multipurpose group weight management and exercise: 45-minute class, 3 times a week with weigh-ins (17 minutes of weight management, 20 minutes of moderate intensity exercise, and 8 minutes for weigh in)
Individual sessions	• None
Total time	• ~540 minutes per month
Delivery modality of components	• Weight management: led by staff member assisted with short videos and facilitator guide • Exercise: video-assisted
Facilitators	• Trained staff member and peer leader
Behavioral messages	
6 messages	• Weight loss success • No sugar drinks • No junk food • Eat smart portions • Eat more vegetables • Putting it all together
Goal	• 5-lb weight loss in 6 months[b] • (tailored to individual)

[a]ACHIEVE: Achieving Healthy Lifestyles in Psychiatric Rehabilitation trial.

[b]Goal of a 5-lb weight loss at 6 months was based on results from the ACHIEVE trial [11] and adult obesity guidelines [7].

We describe the protocol for a pilot RCT comparing standard and enhanced implementation interventions that train and support community mental health program staff as coaches delivering the ACHIEVE-D weight management curriculum. This study represents our REP's preimplementation stage. Our primary outcomes will be knowledge, self-efficacy, and delivery fidelity to the ACHIEVE-D curriculum among staff coaches. Both implementation interventions will include multimodal staff training and organizational strategy meetings. The staff coaches in the enhanced intervention will also receive performance coaching. We hypothesize that both implementation interventions will lead to increased knowledge of the ACHIEVE-D curriculum, self-efficacy for delivering the program, and fidelity for ACHIEVE-D delivery and that the enhanced intervention will have improved outcomes as compared to the standard intervention. To prepare for REP implementation and dissemination stages, we will use a mixed methods approach to examine acceptability, appropriateness, and feasibility, as well as compare differences in implementation and process measures to guide further refinements of both the ACHIEVE-D curriculum and implementation interventions. Secondarily, we will examine outcomes among individuals with SMI who participate in the curriculum, in particular self-reported lifestyle behaviors and measured weight.



Methods

Study Design

The design will be a cluster-randomized, 2-arm parallel pilot RCT comparing standard and enhanced implementation intervention at 6 months within community mental health programs. We will aim to randomly assign 10 programs in Maryland to either the standard or enhanced implementation intervention arms. Figure 1 provides an overview of the study. Multimedia Appendix 1 contains the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist for RCTs [17].

XSL•FO
RenderX

Figure 1. Overview of the study design. This diagram shows the planned study steps in this pilot randomized controlled trial. The gray shaded box indicates our primary study participant group who will take part in the implementation interventions. ACHIEVE-D: Achieving Healthy Lifestyles in Psychiatric Rehabilitation-Dissemination; SMI: serious mental illness.

Overview of the ACHIEVE-D Curriculum

The ACHIEVE-D program is a 6-month curriculum comprised of structured group sessions incorporating behavioral weight management lessons along with group exercise. Groups will last approximately 45-60 minutes and occur at least once a week. Groups may be delivered in person or remotely. Table 1 outlines the components of the ACHIEVE-D curriculum, and Multimedia Appendix 2 includes a detailed description of the ACHIEVE-D curriculum. The curriculum has been previously tested in other studies [11,16]. As such, this study will focus on testing implementation interventions to support the delivery of the curriculum by community mental health program staff.

Site Eligibility Criteria

We will aim to recruit 10 community mental health programs as study sites. Site inclusion criteria include (1) an adult psychiatric rehabilitation program (PRP) within Maryland, (2) a willingness for at least 2 staff to be trained as coaches and implement the ACHIEVE-D curriculum, (3) a willingness for leaders and staff to participate in monthly organizational strategy meetings, and (4) the anticipated ability to recruit clients with SMI to participate. Site leadership will indicate their agreement

XSL•FO
RenderX

to fulfill these criteria with study staff and complete a reliance agreement for the study with the Johns Hopkins Institutional Review Board. At each site, we will recruit participants from three different study populations: (1) staff to serve as coaches; (2) clients with SMI to take part in the curriculum; and (3) other staff and peer leaders—we describe the eligibility criteria, recruitment, and measures separately for each group of study participants in the sections below.

Coaches

Eligibility and Recruitment

To be included, the person must be ≥18 years old, staff at an enrolled PRP, and willing to complete all training activities, deliver all components of the ACHIEVE-D curriculum, and complete data collection procedures. We will exclude staff that plans on leaving their position or taking a leave of absence from the program. Site leadership will identify potential staff to serve as coaches, and the research team will approach these individuals to discuss the study and obtain a waiver of documentation of consent. We will aim to recruit 20 coaches (at least 2 per site).

Measures

Table 2 describes the assessment schedule for the primary outcomes and implementation measures for coaches. Multimedia Appendix 3 describes other measures that we plan to collect among coaches. The following will be the primary outcome and implementation measures for coaches.

Table 2. Assessment schedule for coaches: primary outcomes and implementation measures.

[a]M: month.

[b]Postperiod will be approximately 6 months after completion of the intervention.

[c]ACHIEVE-D: Achieving Healthy Lifestyles in Psychiatric Rehabilitation-Dissemination.

Primary Outcomes

ACHIEVE-D Curriculum Knowledge, Self-Efficacy, and Fidelity

We will assess knowledge about key curricular elements using 2 measures at baseline and 6 months: a 22-item ACHIEVE-D Curriculum Weight Management Knowledge measure and a 16-item ACHIEVE-D Curriculum Exercise Knowledge measure. The research team created these questions using the best practices recommended by the National Board of Medical Examiners for item writing [18]. We will assess self-efficacy to deliver key curricular elements at baseline and 6 months using a 31-item ACHIEVE-D Curriculum Self-Efficacy measure. The research team used principles from confidence rulers in creating this measure [19], where participants rate their confidence to deliver each element on a 10-point scale. To determine fidelity, each coach will video-record their delivery of an ACHIEVE-D group session once a month. Two research team members will view each recording and use the ACHIEVE-D Curriculum Fidelity rating tool to assess performance on key elements. The research team created this tool to evaluate how a coach implements key ACHIEVE-D curriculum elements, including a counseling style consistent with MI techniques (eg, open-ended questions and affirmations) [20], within each segment (before the session, group exercise, weigh-in, focus on weight loss, role model video, commitment to high-impact behavior). Each item will be scored as absent (0) or present (2) or on a 3-point scale of absent (0), below expectations (1), or meets expectations (2). Quarterly meetings will be conducted to ensure alignment between coders. Table 3 displays example items from instruments used for the primary outcomes.

XSL•FO
RenderX

Table 3. Samples of included items in primary outcome measures.

Primary outcomes	Sample questionnaire items
ACHIEVE-D[a] Curriculum Weight Management Knowledge	
Example 1	• An evidence-based weight loss program includes which of the following? • Uses solid scientific evidence to drive recommendations[b] • Promises results that sound too good to be true • Has evidence from personal testimonials about weight loss success • Don't know
Example 2	• Jessica is taking part in ACHIEVE. She wants to say "no" to junk foods, but needs help identifying foods that she eats that are considered junk foods. Which of the following things that she eats would be considered a junk food in the ACHIEVE program? • Orange slices • Chocolate bars[b] • Cheese • Don't know
ACHIEVE-D Curriculum Exercise Knowledge	
Example 1	• What should you do if a client has arthritis in their knees and cannot keep up with the class choreography? • Tell the client with the arthritis that they must do a different exercise move • Choose slower music for the entire class so that all clients can keep up • Remind all clients that they can choose a lower intensity[b] • Don't know
Example 2	• Joy is 45 year old woman with obesity. She is sedentary (does not exercise). If Joy starts going for a 20 minute brisk walk every morning, she will: • Start losing weight • Will not lose weight, because exercise doesn't help with weight loss • May not lose weight, but will get benefit from exercising[b] • Don't know
ACHIEVE-D Curriculum Self-Efficacy[c]	
Example 1	Use a leader's guide along with any other needed materials, props, visual aids, videos, or lesson presentations for the class.
Example 2	Communicate with clients how their diet, activity and other behaviors aligns with weight change.
ACHIEVE-D Curriculum Fidelity[d]	
Example 1	• Asks about success with high impact behavior. • 0: Does not ask participants about progress on high impact behavior • 1: Asks some participants about progress on high impact behavior • 2: Asks all participants about progress on high impact behavior
Example 2	• Ensures session remains focused on main topic as per leaders guide. • 0: Did not focus on the main topics in the leaders guide for this module • 1: Some topic elements covered, but a major deviation from a main topic occurred • 2: All topic elements covered with minor acceptable deviations

[a]ACHIEVE-D: Achieving Healthy Lifestyles in Psychiatric Rehabilitation-Dissemination.

[b]Indicates correct responses. Complete measures are available from the authors upon request.

[c]Participants indicate how confident they are that they can currently perform the listed task during a behavioral weight loss program for a group of adults with serious mental illness.

[d]All items have a numerical value, and we will sum key items to create a composite score.

XSL•FO
RenderX

Implementation Measures

We will determine the perceived acceptability, feasibility, and appropriateness of the implementation interventions (eg, coach training) and the ACHIEVE-D curriculum. We adapted these assessments from previously validated measures [21]. We will also assess motivation and implementation climate using adapted, validated instruments [22,23]. At 6 months, we will conduct focus groups with staff coaches to elicit feedback on the following: acceptability, appropriateness, and feasibility of the implementation intervention and ACHIEVE-D curriculum; barriers to implementation; strategies to overcome barriers; and suggestions for further refinement. We will conduct a second series of focus groups or interviews at each site approximately 6 months after the conclusion of the intervention to determine whether and how the ACHIEVE-D curriculum was sustained and the challenges experienced.

Clients With SMI

Eligibility and Recruitment

Clients with SMI will participate in the ACHIEVE-D weight management program delivered by the staff coaches. To be included, the person must be ≥18 years old, a client with SMI at an enrolled PRP, BMI ≥25 kg/m^2 (ie, overweight or greater), and willing to make lifestyle changes to lose weight and participate in all ACHIEVE-D activities at least once a week. We will exclude individuals with contraindications to losing weight (eg, history of anorexia, liver failure, and pregnancy), who have conditions that require medically supervised weight loss (eg, myocardial infarction in the last 6 months and insulin-dependent diabetes mellitus), who plan to pursue other obesity treatments (eg, antiobesity medication and bariatric surgery), who plan to leave the PRP or move out of the geographic area within 12 months, or who are unwilling to complete all data collection procedures. Staff at each site will identify potential clients to participate who may meet the eligibility criteria; the research team will approach these individuals, on a first-come, first-served basis, to discuss the study, screen individuals, and obtain a waiver of documentation of consent. We will aim to recruit 80 clients with SMI (~8 per site).

Measures

Table 4 describes the assessment schedule for individuals with SMI. Multimedia Appendix 3 describes other measures that we plan to collect among individuals with SMI. In other studies, we have successfully used all selected measures among individuals with SMI. Similar to our prior studies, study staff will be available to assist clients with SMI complete measures, if needed. The following will be the secondary outcome and process measures for individuals with SMI.

Table 4. Assessment schedule for individuals with serious mental illness: secondary outcomes and process measures.

	Baseline	Follow-up	
		During	6M[a]
Secondary outcomes			
Weight[b]	✓		✓
CARDIA[c]/EARLY[d] Q[e]—sedentary behavior	✓		✓
Block Dietary Fat Q	✓		✓
Block Dietary Fruit or Vegetable Q	✓		✓
EARLY Eating Away from Home Q	✓		✓
EARLY SSB[f] Consumption Q	✓		✓
Process measures			
Consumer Satisfaction and Helpfulness Q			✓
Attendance		✓	
Participation in group session		✓	

[a]M: month.

[b]If weight measurement cannot be done in person, due to COVID-19 restrictions, participants will self-measure weight on a scale that the study provides to them.

[c]CARDIA: Coronary Artery Risk Development in Young Adults.

[d]EARLY: Early Adult Reduction of Weight through Lifestyle Intervention.

[e]Q: questionnaire.

[f]SSB: sugar-sweetened beverage.

XSL•FO
RenderX

Secondary Outcomes

Weight and Lifestyle Behaviors

Study staff will measure weight to the nearest 0.1 lb. on a high-quality digital scale with participants wearing light indoor clothes without shoes at baseline and 6 months. We will assess several lifestyle behaviors at baseline and 6 months. Study staff will administer the Coronary Artery Risk Development in Young Adults (CARDIA)–Early Adult Reduction of Weight through Lifestyle Intervention (EARLY) sedentary behavior questionnaire [24]. For diet, we will administer the block fat, fruit, vegetable, and fiber screener questionnaires [25,26]. We will also administer the EARLY eating away from home and sugar-sweetened beverage questionnaires [27,28]. These measures have been recommended by the National Institutes of Health Accumulating Data to Optimally Predict Obesity Treatment (ADOPT) Core Measures for Obesity Studies [29].

Process Measures

We will adapt prior measures to assess the helpfulness of the behavioral weight loss intervention component [30] and satisfaction with the ACHIEVE-D curriculum and staff coaches [31]. We will collect attendance and participation information for each enrolled client.

Other Staff: Eligibility, Recruitment, and Measures

We will recruit 2 groups of other staff: program leaders (ie, program directors or coach supervisors) and general staff members. Program leaders will participate in monthly organizational strategy meetings with the coaches. General staff members will not participate in training or meetings. To be eligible as other staff, the person must be ≥18 years old, staff at an enrolled PRP, and willing to complete data collection procedures. After site leadership facilitates contact with other staff, the research team will approach these individuals to discuss the study and obtain a waiver of documentation of consent. All other staff will complete baseline demographics as well as motivation for implementation and implementation climate [22,23] measures at the baseline and 6-month follow-up. Program leaders will be in the aforementioned end-of-study focus groups with the coaches.

Peer Leaders: Eligibility, Recruitment, and Measures

When possible, we will recruit a peer leader for each site. To be eligible, the individual must be a person with SMI who is ≥18 years and interested in helping staff coaches with the ACHIEVE-D curriculum. Staff at each site will identify potential clients to participate as peer leaders; the research team will approach these individuals to discuss the study and obtain a waiver of documentation of consent. The study will proceed at sites without peer leader support if no candidates are identified. Peer leaders will participate in the following: training with the staff coaches, assisting staff coaches in the delivery of the ACHIEVE-D curriculum to clients, modeling behavior by participating in group exercises, and completing data collection (same measures as coaches except for ACHIEVE-D curriculum fidelity).

Implementation Interventions

Overview

The study team's prior research and experience with ACHIEVE informed our selection of components that will comprise the implementation interventions for the standard and enhanced arms. Both arms will use multimodal training in combination with organizational strategy meetings with site leadership to support the implementation of the ACHIEVE-D group sessions. In the enhanced arm, staff coaches will also receive performance coaching from research team members with expertise in weight management and MI.

Multimodal Coach Training—Both Arms

Table 5 provides an overview of all coach training that will be conducted by the research team during the 6-month intervention period. Multimodal training will include real-time initial training via videoconference, ongoing monthly virtual training, and web-based avatar-assisted MI practice for coaches [32,33]. This training approach will provide interactive opportunities for coaches to practice the skills needed to implement the ACHIEVE-D curriculum—a more effective strategy than didactic education [34]. All coaches will receive initial training in real-time delivered via videoconferencing (approximately 14 hours in total). The initial training will include an introduction to MI, highlighting the effectiveness of this counseling style for weight management. Ongoing monthly training will be offered through a digital platform with the goal of orienting coaches to upcoming content (less than 30 minutes per month). The coaches will also have access to a web-based avatar module to review and practice MI techniques when discussing weight management with a simulated client avatar. The research team developed this module in partnership with a health care simulation company. Coaches will receive reminders to complete the monthly web-based training and avatar modules.

XSL•FO
RenderX

Table 5. Overview of ACHIEVE-Dissemination trainings for coaches.

Type and training components	Approximate length
Initial training (synchronous, videoconference, and research team–delivered)	
Overview of the ACHIEVE[a] program and introduction to behavior change for weight loss	2 hours
Components of an ACHIEVE group and observing research staff deliver a group lesson	2 hours
Introduction to Module 1: Weight Loss Success	45 minutes
Weight management practice session	60 minutes
MI[b] techniques for weight loss	4 hours
Common challenges that may come up when running a weight loss group and how to address them	60 minutes
Exercise in the ACHIEVE program	20-60 minutes
Introduction to Module 2: Say No to Sugar Drinks	50 minutes
Resources for implementing the ACHIEVE program	20 minutes
Overview of performance coaching	40 minutes
Ongoing training (asynchronous, digital, and self-paced)	
Didactic training for each core and seasonal module with real-world examples of how to deliver the content in groups	15-20 minutes per month
Avatar simulations to practice using motivational interviewing skills when discussing weight management with a consumer	15 minutes per month

[a]ACHIEVE: Achieving Healthy Lifestyles in Psychiatric Rehabilitation.

[b]MI: motivational interviewing.

Organizational Strategy Meetings—Both Arms

Programs targeting frontline staff, like ACHIEVE-D, are more effective when supplemented with implementation interventions that successfully engage organization leaders [35]. Therefore, to enhance curriculum uptake and increase engagement from site leadership [36], we will hold monthly organizational strategy meetings (30-60 minutes each month). Research team members, coaches, and site supervisors or leadership will be encouraged to attend. These meetings will support the development, adoption, and sustainment of organizational strategies needed for implementation and provide opportunities to problem-solve barriers encountered (eg, changing the class schedule to maximize attendance).

Performance Coaching—Enhanced Arm Only

At sites randomized to the enhanced intervention arm, coaches will take part in monthly performance coaching. Performance coaching is an implementation strategy where coaches "learn by doing" and receive feedback on their ACHIEVE-D delivery [37]. Performance coaching may be particularly beneficial when evidence-based practice is new to the implementers, as is the case with ACHIEVE-D [38-40]. The performance coach will be a research team member with extensive knowledge of the ACHIEVE-D curriculum, behavioral weight loss, and MI. Each month, the performance coach and staff coach will meet to review the staff coach's monthly video-recorded group session (see the video recording described in coach measures above). The performance coach will share their evaluation of the video, identifying areas of strength, opportunities for improvement, and a performance improvement plan (1.5 hours each month). Performance coaching feedback will be grounded in evidence-based behavioral weight loss principles and core ACHIEVE-D messages, mirror a MI style, and promote skill development and high-fidelity curriculum delivery. Of note, the study staffs who deliver performance coaching will be different from the study staff rating the video-recorded sessions for fidelity.

Pilot Trial Sample Size

This pilot trial will provide useful information on protocol feasibility and parameter estimates for designing a future confirmatory trial but will not necessarily be powered to detect differences in outcomes. With 5 sites per arm and 2 coaches per site, we will have 80% power to detect large changes in effect size in our primary coach-level outcomes from baseline to 6 months between arms (1.5-1.6 in units of outcome SD). We assume an intracluster correlation coefficient of 0.05-0.2 and a within-coach correlation of 0.5 between outcomes at baseline and 6 months, using a 2-sided alpha of .05.

Randomization and Blinding

Following recruitment and baseline data collection, sites will be randomized to the standard or enhanced arm. The randomization sequence will be generated in the block size of 2 using computer software by the trial biostatistician, and assignments will be delivered to the eligible sites by the research coordinator. Due to the nature of the intervention, both staff coaches and some research team members will be aware of the assignment. For our primary outcomes of knowledge and self-efficacy, staff coaches will self-complete specific questionnaires, which may reduce the risk of bias. For our primary outcome of fidelity, study team members who rate the video-recorded sessions will be masked to study arm assignment, which may also reduce the risk of bias. Individuals with SMI

XSL•FO
RenderX

taking part in the curriculum and other staff will not be aware of the assignment.

Statistical Analysis

Quantitative Analyses

We will assess the effects of the implementation intervention on coaches' knowledge, self-efficacy, and fidelity to the ACHIEVE-D curriculum, as well as client outcomes, using generalized linear mixed-effects models under the intent-to-treat approach. The mean models will include a binary intervention group indicator, time indicators, and intervention-by-time interaction terms. The time indicator coefficients estimate time-specific mean outcome changes in the standard arm, and the interaction coefficients estimate the between-arm differences of time-specific outcome changes from the baseline. The linear combination of these time-specific coefficients captures the time-specific mean outcome changes in the enhanced arm. Site differences will be assumed to follow a normally distributed random effect, while an unstructured variance-covariance matrix will be used for the repeated outcome measurements over time within individuals. For our implementation measures, we will use descriptive statistics to analyze survey measures of perceptions of acceptability, feasibility, and appropriateness of the implementation intervention and ACHIEVE-D curriculum. Point estimates and corresponding 95% confidence intervals will be obtained.

Qualitative Analyses

Focus groups will be audio- or video-recorded, and recordings will be transcribed. Given that we are seeking to understand experiences across sites and participants, we will use thematic analysis [41,42], which can serve as a standalone analytic method. We will use a 6-step process, which includes data familiarization, initial code generation, searching for themes (ie, repeated patterns), reviewing themes, defining or naming themes, and producing a report. The first 3 steps will be conducted by 2 research team members, and the larger research team will be involved in the final steps.

Ethics Approval

The Johns Hopkins University School of Medicine Institutional Review Board approved this study (IRB00247344). Consent will be obtained from all participants using a waiver of documentation of consent.

Results

This trial was funded by an ALACRITY center grant from the NIMH (funding started in August 2018). We started recruitment and data collection in March 2021. We estimate all data collection will be completed in March 2023. We recruited 9 sites and a total of 20 staff coaches and 72 clients with SMI. We expect to start data analyses in March 2023, with primary results submitted for publication in April 2023. We will also communicate the results with participating sites after the study through a presentation with leadership or a report.

Discussion

Principal Findings

Addressing inequities in CVD risk among persons with SMI is needed to meet current public health objectives of improving cardiovascular health for all persons [43]. Given the prevalence of obesity among adults with SMI and its associated increased CVD risk, it is critical to implement effective behavioral weight loss interventions tailored to this population in real-world settings. The ACHIEVE trial demonstrated the efficacy and safety of such a behavioral weight loss intervention [11], which has been translated into the ACHIEVE-D weight management curriculum appropriate for delivery by community mental health center staff [16]. We are applying the Enhanced Replicating Effective Programs Framework to increase the acceptability and feasibility of implementing the ACHIEVE-D curriculum in community settings [13,14]. In this pilot trial, we will compare an enhanced implementation intervention to a standard intervention on community mental health program staff coaches' knowledge, self-efficacy, and fidelity to the ACHIEVE-D curriculum.

We will use a mixed methods approach [44], where the design will be primarily quantitative with a sequential supplementary qualitative component among staff coaches. The quantitative component will determine whether the staff coaching approach is a feasible one, while the qualitative component will be key to understanding staff experiences as coaches and leadership experiences with having ACHIEVE-D at their site. We anticipate that we will identify patterns of facilitators and barriers common across staff and sites through the focus groups, and we will use these findings to guide further refinements in the ACHIEVE-D curriculum and implementation interventions.

There are several potential strengths in this study. We are training community mental health program staff to deliver the curriculum, which may have numerous advantages when considering dissemination. Staff members already have an established rapport with clients, which may be helpful when addressing sensitive topics such as weight. The ACHIEVE-D curriculum is a turnkey product with coach guides and videos for staff to use, which may minimize work burden and increase confidence in providing safe, evidence-based recommendations to clients. In addition, we created an adapted and abbreviated strategy for remotely delivered training to program staff, which may address potential time and logistical constraints [12]. Asynchronous web-based training will be brief, which may enhance coach uptake and completion of this training as this approach meets the needs of staff with competing priorities. Since training alone is often insufficient to adopt new interventions [45-48], this trial will incorporate organizational strategy meetings to engage leadership and test the addition of performance coaching in the enhanced arm. Finally, we anticipate recruiting diverse program staff with varying years of experience, education, and profession (eg, counselors and nurses) and diverse organizations with varying staffing models, geographic locations (eg, urban, suburban, and rural), and delivery models (eg, in-person and remote). This diversity may provide novel lessons relevant for dissemination. Overall, these

XSL•FO
RenderX

strengths may help support testing of future REP stages of implementation and maintenance of the ACHIEVE-D curriculum in community mental health settings through a hybrid effectiveness-implementation trial approach [49].

Limitations

Our pilot trial will have limitations and challenges. Our study sites will be limited to community mental health programs in Maryland, specifically psychiatric rehabilitation programs. Other states may not offer such programming, and billing practices may differ, which may limit generalizability. This trial may be impacted by the high staff turnover rates that are common in community mental health programs. In anticipation of this challenge, we plan to recruit at least 2 staff coaches for each site and have the flexibility to train replacement coaches if needed. This study is a pilot trial, and as such, our sample size is small. The COVID-19 pandemic will present several challenges, as this trial will be recruiting and conducting the study during this period. First, community mental health program staff turnover may be even higher, which may negatively impact staff engagement in the study due to increased workload. Second, PRP may experience changes related to COVID-19 restrictions, such as format (in-person versus remote) and the number of clients permitted on-site. These factors may affect delivery and client attendance at ACHIEVE-D sessions. Third, sites might experience closures due to COVID-19, which would result in gaps in ACHIEVE-D delivery. As consistency and repetition are key elements for clients with SMI, such gaps may affect client engagement and participation, as well as weight and behavioral outcomes. Finally, we will be unable to blind coach participants or interventionists to study arm allocation due to the nature of the intervention in this pilot trial; however, we will mask the study assignment of study team members to determine fidelity. Future studies should consider blinding data collectors and analysts to study arm allocation.

Conclusions

This trial aims to provide key information on implementation strategies to increase community mental health program staff coaches' knowledge, self-efficacy, and fidelity to deliver the ACHIEVE-D weight management curriculum for persons with SMI. Our results may inform future research that definitively tests the implementation and dissemination of behavioral weight management programs. Unless effective weight management interventions are disseminated into real-world settings, obesity and CVD disparities among persons with SMI will likely persist.

Acknowledgments

This research was funded by a grant from the National Institutes of Mental Health (P50MH115842). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. The web-based avatar module on motivational interviewing was developed by the research team in partnership with Kognito. SG, GJJ, and KG are major contributors to writing the manuscript. NYW designed the quantitative statistical analysis plan and critical revision of the manuscript. All authors participated in the trial protocol design and read and approved the final manuscript.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study. Future data collected as part of the study described in this protocol will be made available from the corresponding author upon reasonable request.

Conflicts of Interest

KG serves as the medical director for the American Board of Obesity Medicine, has a research grant from Novo Nordisk, and is a paid consultant to Eli Lilly. All other authors declare that they have no competing interests.

Abstract

Background: Poor sleep, defined as short-duration or poor-quality sleep, is a frequently reported condition with many deleterious effects including poorer cognitive functioning, increased accidents, and poorer health. Melatonin has been shown to be an efficacious treatment to manage symptoms of poor sleep. However, the treatment effects of melatonin on sleep can vary greatly between participants. Personalized, or N-of-1, trial designs represent a method for identifying the best treatment for individual participants. Although using N-of-1 trials of melatonin to treat poor sleep is possible, the feasibility, acceptability, and effectiveness of N-of-1 trials using melatonin are unknown. Using the National Institutes of Health Stage Model for Behavioral Intervention Development, a stage IB (intervention refinement, modification, and adaptation and pilot testing) design appeared to be needed to address these feasibility questions.

Objective: This trial series evaluates the feasibility, acceptability, and effectiveness of a series of personalized interventions for remote delivery of melatonin dose (3 and 0.5 mg) versus placebo supplements for self-reported poor sleep among 60 participants. The goal of this study is to provide valuable information about implementing remote N-of-1 randomized controlled trials to improve poor sleep.

Methods: Participants will complete a 2-week baseline followed by six 2-week alternating intervention periods of 3 mg of melatonin, 0.5 mg of melatonin, and placebo. Participants will be randomly assigned to 2 intervention orders. The feasibility and acceptability of the personalized trial approach will be determined with participants' ratings of usability and satisfaction with the remote, personalized intervention delivery system. The effectiveness of the intervention will be measured using participants' self-reported sleep quality and duration and Fitbit tracker–measured sleep duration and efficiency. Additional measures will include ecological momentary assessment measures of fatigue, stress, pain, mood, concentration, and confidence as well as measures of participant adherence to the intervention, use of the Fitbit tracker, and survey data collection.

Results: As of the submission of this protocol, recruitment for this National Institutes of Health stage IB personalized trial series is approximately 78.3% complete (47/60). We expect recruitment and data collection to be finalized by June 2023.

Conclusions: Evaluating the feasibility, acceptability, and effectiveness of a series of personalized interventions of melatonin will address the longer term aim of this program of research—is integrating N-of-1 trials useful patient care? The personalized trial series results will be published in a peer-reviewed journal and will follow the CONSORT (Consolidated Standards of

XSL•FO
RenderX

Reporting Trials) extension for N-of-1 trials (CENT 2015) reporting guidelines. This trial series was approved by the Northwell Health institutional review board.

Introduction

Sleep health is understood to be a multidimensional construct influenced by dimensions such as duration, satisfaction, timing, efficiency, and alertness, and it is a partially subjective experience that should be assessed in the context of the individual. In recent years [1], the prevalence of self-reported difficulty sleeping has increased, and population studies have shown increasing trends toward shorter sleep duration [2]. A recent study of US workers found the prevalence of short sleep duration to be 37.6% and associated poor sleep quality to be 19.2% [3]. Deleterious effects of poor sleep include a heightened stress response; pain; depression; anxiety; and deficits in cognition, memory, and performance [4]. Short sleep duration or poor-quality sleep is also associated with health outcomes including obesity [5], diabetes [6], hypertension [7], cardiovascular disease [7], higher productivity loss [8], reduced quality of life [9], depression [9], and mortality [8]. The causes of poor sleep, defined by short sleep duration and the commonly associated poor-quality sleep [10], can be complex and diverse. These include personal factors such as sex, mental health status, and BMI [8]. Lifestyle factors such as smoking, poor diet, and low physical activity (less than 120 minutes) also predict short sleep duration [8]. Further, environmental factors including financial concerns, children, marital status, irregular work hours, and a long commute can also influence sleep quality and duration. Finally, discrete sleep disorders such as obstructive sleep apnea, insomnia, and restless leg syndrome may also affect sleep [11]. The complex etiology of sleep duration and quality means that not all individuals suffering from poor sleep have comparable presentations. The widespread and increasing nature of poor sleep and the gravity of its effects support the need for innovative treatments. Furthermore, the diversity of factors contributing to poor sleep warrants treatment that accounts for individual differences among participants. Poor sleep has been determined as high priority for a personalized trial approach by previously interviewed clinicians and patients [12].

Exogenous melatonin supplements are widely used to treat insomnia and sleep disorders as well as to adjust altered sleep schedules related to jet lag [13]. Doses of melatonin available over the counter range from 0.3 mg to a maximum of 10 mg, but they typically fall within the range of 0.3 to 3 mg [14]. Because melatonin is naturally occurring within the brain and external food sources such as fish, eggs, milk, nuts, and seeds [15], it is considered a dietary supplement, therefore warranting less regulation before distribution than a typical drug [16]. As such, research evaluating the efficacy of melatonin across populations is still developing. However, various clinical trials have been conducted demonstrating the efficacy of exogenous melatonin in treating sleep disorders regardless of the etiology of the disorder [17-20].

Functionally, endogenous melatonin secretion is governed by the suprachiasmatic nucleus (SCN) of the hypothalamus, which is the primary circadian pacemaker in mammals [21]. In addition to its endogenous activity, the SCN responds to retinal light exposure to help regulate circadian rhythms, which impact significant processes relevant to survival, including sleep, wake, appetite, mood, hormone secretions, and behaviors. During the daytime, the SCN, reinforced by external light patterns, activates processes that maintain wakefulness, attention, and cognitive capacity. Melatonin, secreted by the pineal gland primarily during darkness or nighttime in response to a signal from the SCN, is thought to facilitate sleep in part by inhibiting processes associated with wakefulness [21]. Therefore, exogenous melatonin supplements are thought to promote increased sleep duration by signaling to melatonin receptors that day has, in fact, shifted into night [22]. As such, melatonin has been found to be particularly useful in facilitating sleep initiation and increased sleep duration for individuals with disrupted circadian rhythms resulting from, for example, overnight shift work, jet lag, or sleep-wake disorders [23]. Melatonin has also been indicated in improving sleep efficacy and daytime sleepiness in healthy volunteers [24].

Importantly, clinical trials of melatonin therapy for sleep have found that not all participants benefit equally from treatment with melatonin. Several meta-analyses assessing the efficacy of melatonin therapy found evidence for significant heterogeneity in the effectiveness of melatonin interventions, particularly for outcomes including sleep onset latency, total sleep duration, and sleep efficiency [25,26]. Furthermore, the authors of a recent systematic review assessing melatonin's effect on these sleep dimensions across 23 clinical trials identified significant between-study heterogeneity, which they attributed to differences in participant health status [27]. Participants with respiratory diseases, metabolic disorders, and sleep disorders saw greater sleep improvement from melatonin therapy than participants with a variety of other health concerns, including mental disorders, neurodegenerative diseases, and breast cancer [27]. Authors across meta-analytic publications additionally cite concerns regarding the heterogeneity of treatment dosage between studies; without consistent dosage information, the authors could not draw robust conclusions regarding overall treatment efficacy or minimum and maximum dosage recommendations for different populations [26,28].

XSL•FO
RenderX

These findings suggest that not all participants benefit equally from treatment with melatonin.

Because of this variability in treatment provision and response, participants taking melatonin may benefit from a personalized (N-of-1) trial approach [29,30]. Personalized trials are a research approach that helps participants to select which treatments work best for them individually. Participants in a personalized N-of-1 trial receive a multiple crossover trial with continuous collection of objective outcome data throughout the trial. Interventions are delivered in alternating time periods of treatment, alternative treatment, and placebo therapies, usually in randomized blocks [31,32]. At the completion of the personalized trial, the effect of each intervention is evaluated and the trial participants are able to select which intervention works best for them. Personalized trials are designed to provide patients with high-integrity, evidence-based information uniquely relevant to the outcomes and values important to them so they may identify efficacious treatments [33]. Despite the potential of personalized trials, N-of-1 personalized designs are not often used in clinical practice [31,34-36]. In surveys that examined attitudes about personalized trials, hesitancy to engage in personalized N-of-1 trials was attributed to the cost and effort required for implementation [31,34,36].

In the context of melatonin therapy, personalized trials would elucidate gaps in previous research by helping to identify the optimal melatonin treatment for participants despite a variety of demographic, health-related, and environmental factors. However, given prior issues with implementing personalized N-of-1 trials, it is important to evaluate the feasibility of this type of intervention for feasibility and acceptability from a participant perspective and the effectiveness of melatonin delivered in a personalized N-of-1 trial. On the basis of guidelines in the National Institutes of Health Stage Model for Behavioral Intervention Development [37], we will conduct a stage IB (ie, intervention refinement, modification, and adaptation and pilot testing) design trial to address these feasibility questions.

This study evaluates the feasibility, acceptability, and effectiveness of a series of personalized interventions for remote delivery of higher dose melatonin at 3 mg, lower dose melatonin at 0.5 mg, and a placebo supplement in 60 participants with self-reported poor sleep. By using new wearable technologies (such as Fitbit devices), commercially available supplements (such as melatonin produced by Pure Encapsulations), and commercially available medication adherence devices (such as Nomi by SMRxT), the current protocol allows for remote assessment of outcomes and thereby also continuous data collection. Further, remote delivery of the intervention allows each participant to receive the intervention and be assessed for poor sleep in their own home with limited disruption. Results from this study will determine whether remote delivery of these interventions is feasible and acceptable for participants with self-reported poor sleep and will allow clinicians to identify whether remote delivery of melatonin can effectively allow patients to manage their sleep.

Methods

Study Design

The study is a series of 60 randomized personalized N-of-1 trials examining the effects of 3 mg of melatonin and 0.5 mg of melatonin versus placebo for poor sleep. The intervention will be delivered remotely to participants residing in the United States over the course of 14 weeks. Participants will be provided with a Fitbit Charge 5 device, all necessary supplements, and 3 Nomi by SMRxT medication adherence devices. Nomi by SMRxT is a smart pill bottle that monitors medication-taking behavior in real time to collect adherence data without active participant input (see Figure 1).

Figure 1. The Nomi pill bottle by SMRxT.

XSL•FO
RenderX

The first 2 weeks of the study will be a baseline assessment period. Participants will not take any melatonin or placebo pills during this time. During baseline assessment, each study participant will be asked to both engage in their usual methods of managing sleep and wear their Fitbit device at all times, including during sleep. Participants will also be asked via SMS text messaging to rate an ecological momentary assessment (EMA) of their fatigue, pain, concentration, stress, mood, and confidence at 3 random times throughout the day. Each morning, participants will answer a survey questionnaire assessing their sleep quality from the previous night. Every other Sunday evening, participants will complete a longer survey measure asking them to reflect on their sleep quality over the past 2 weeks. Participants will be encouraged to wear their Fitbit devices day and night, asked to sync their device with the Fitbit application on their phone at least every 2 days, and asked to charge their Fitbit device at least every 4 days.

After successfully completing the baseline period, participants will be randomized into 2 arms with six 2-week intervention blocks of 3 mg of melatonin, 0.5 mg of melatonin, or placebo pills. During the intervention, participants will be discouraged from taking additional melatonin or using other sleep treatments outside those provided during the study. Within 3 months of the end of the 14-week trial, each participant will be provided with a report containing their analyzed data and asked to complete a satisfaction survey. After the satisfaction survey is completed, study coordinators will reach out to each participant to interview them about their experience with the personalized trial. Study recruitment began in April 2022, and the study completion is anticipated to occur by June 2023.

Study Population

Participants in this study will be volunteer subjects from across several states within the United States. This will include the approximately 77,000 employees of the Northwell Health System [38]. Digital recruitment of potential participants will include email blasts and advertisements in newsletters circulated to the Northwell Health team member population. To expand beyond the Northwell Health system, recruitment will also target web and social media; Facebook and Google ads for the study will be published in users' web feeds and searches. Additionally, web posts to communities on platforms such as Reddit, Craigslist, and LinkedIn will also be used to appeal to individuals with sleep issues. With 93% of US adults reporting using the internet, 69% reporting ever using Facebook, and 18% reporting using Reddit, use of digital recruitment methods significantly broadens the potential span of our outreach [39].

All potential participants will be required to self-identify as having a minimum threshold of poor sleep for at least 4 weeks using the Insomnia Symptom Questionnaire (ISQ). Poor sleep for this study was defined by self-reported difficulty in falling asleep, staying asleep, and feeling refreshed by sleeping 4 to 7 times per week for a period of at least 4 weeks. Participants must also report 1 or more sleep symptoms that bother them "quite a bit" or "extremely." Potential sleep symptoms on the ISQ include disrupted work, irritability, and feeling fatigued. An example of the ISQ measure used to assess sleep disruption can be found in Multimedia Appendix 1. Because of the high prevalence of poor sleep [3] and wide reach of our recruitment methods [39], we anticipate a large pool of potential participants from which to recruit.

Recruitment and Consent

Participants for this study will be recruited via advertising and social media posting on Facebook, Instagram, Google, Craigslist, LinkedIn, and Reddit. Posting and advertisement will comprise multiple formats of information (including videos, images, and text posts). Additional recruitment methods will include Northwell Health team member email listserves, word of mouth, recruitment emails to individuals who previously expressed interest in personalized trials, and the Northwell Health Clinical Trials Listing.

Interested individuals who respond to any of the above recruitment methods will be directed to an digital information screen with details about the pilot study and asked to complete screening measures containing questions regarding study inclusion and exclusion criteria (Textbox 1). This information will be reviewed by study staff to determine participant eligibility before consent. If a potential participant is deemed ineligible or is wait-listed due to high demand, study staff will reach out to the participant to notify them within 2 business days. Upon completion of screening, eligible individuals will be provided with a link to an electronic consent form and a short video explaining details of the study protocol and consent form. If individuals wish to speak with a staff member regarding details of the study or consent, they will be offered a 30-minute informational phone call with study staff to review key points within the consent form and any questions the potential participant has about the study. A study staff member will confirm the scheduled time for this call with the participant within 2 business days. After the phone call, the study staff will send the eligible participant a message containing the electronic consent form, the explanatory video, and a 4-question screening measure assessing participant understanding of the protocol and consent process.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

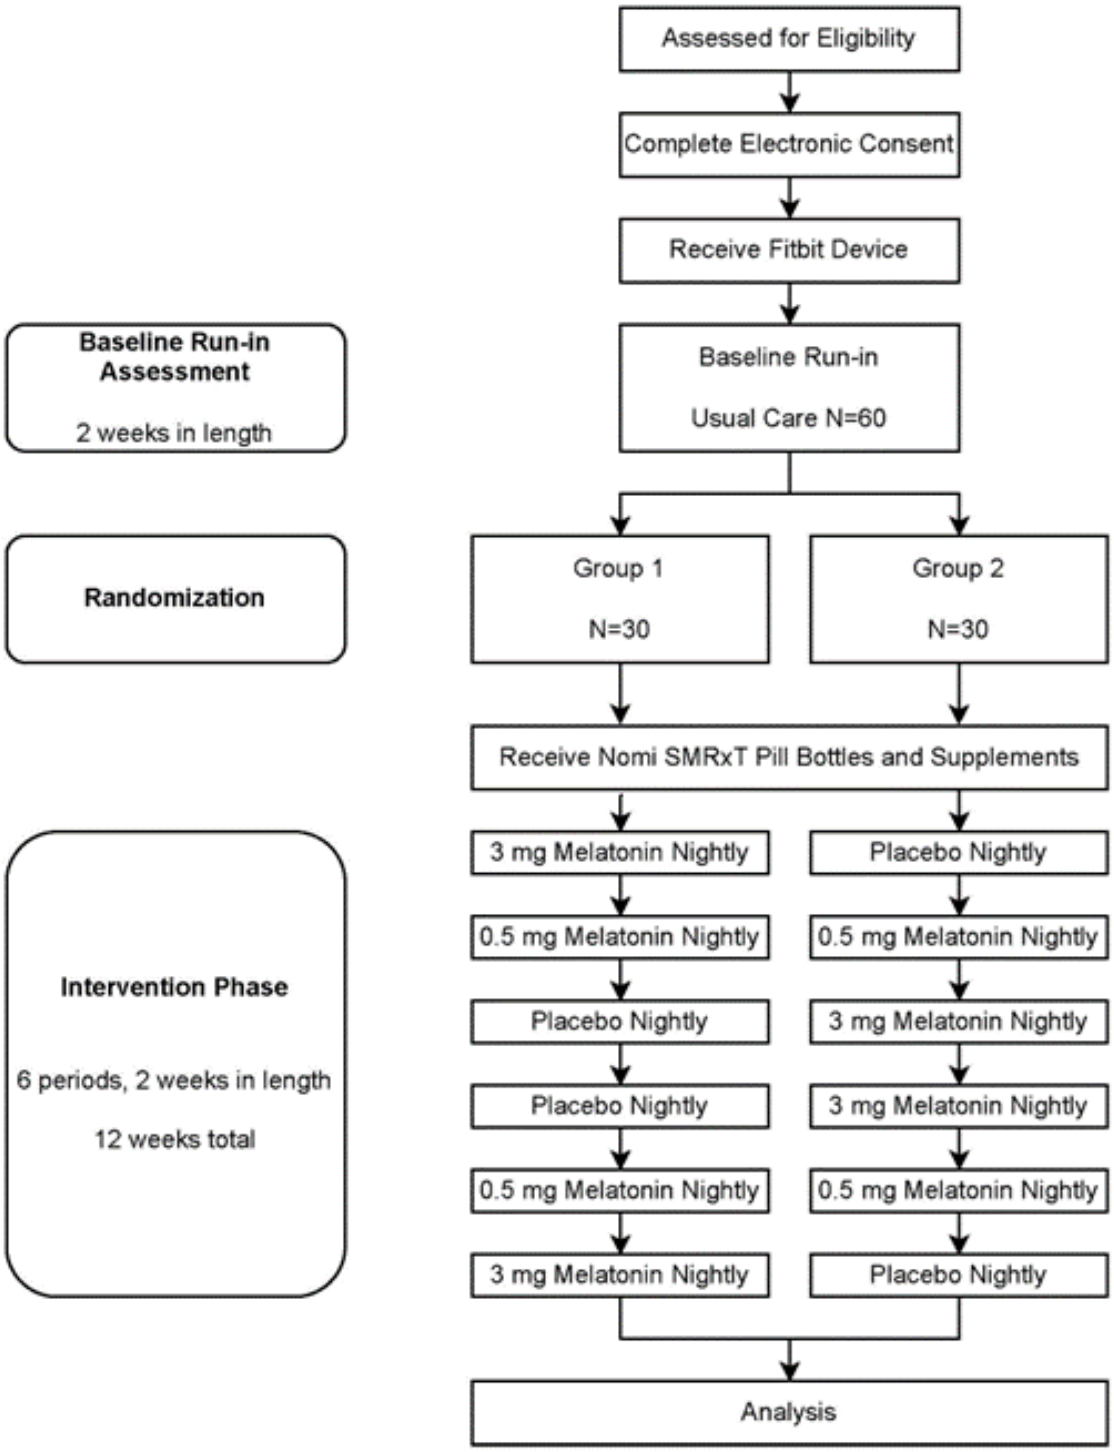
- Aged ≥18 years
- Fluent in English
- Able to take melatonin and a placebo
- Self-report of poor sleep symptoms using the Insomnia Symptom Questionnaire
- Own and can regularly access a smartphone capable of receiving SMS text messages
- Owns and can regularly access an email account
- Lives in the United States
- Agrees to adhere to lifestyle considerations including wearing a Fitbit device day and night and potentially adapting their current melatonin routine to fit the protocol throughout the study duration

Exclusion criteria

- Aged <18 years
- Pregnant or breastfeeding
- Diagnosed with depression, seasonal affective disorder, schizophrenia, autoimmune disease, or asthma
- Take monoamine oxidase inhibitors or corticosteroids
- Diagnosed with low blood pressure
- Clinically diagnosed with a sleep disorder (eg, narcolepsy, circadian rhythm sleep-wake disorders, periodic limb movement disorder, restless leg syndrome, obstructive sleep apnea, etc)
- Deemed unable to complete the study protocol due to cognitive impairment, severe medical or mental illness, or active or prior substance abuse
- Participate in shift work (evening/night shifts, early morning shifts, rotating shifts, etc)
- Frequently travel across time zones (eg, pilots or flight attendants)
- Receive specialty mental health care for insomnia (eg, cognitive behavioral therapy for insomnia and medications for insomnia)
- Advised by a doctor or health care provider that taking melatonin is unsafe
- Do not own or cannot regularly access a smartphone capable of receiving SMS text messages
- Do not possess or cannot regularly access an email account
- Lives outside of the United States
- Scheduled for planned surgery within 6 months from the study start date

Persons who are eligible to participate after screening and who opt out of the educational phone call will receive a message from study staff containing an electronic copy of the consent form and an explanatory video. These potential participants will also receive the same 4-question screening measure to assess their understanding of the consent form and study protocol.

Consent will be obtained electronically. Participants will receive a copy of the institutional review board (IRB)–approved consent form, a copy of their signed consent form, and a copy of their signed HIPAA (Health Insurance Portability and Accountability Act) authorization form via an encrypted message. Signed consent and HIPAA authorization forms will be stored electronically on a HIPAA-compliant, Northwell Health–approved shared drive accessible only to the IRB-approved study staff. The example study consent form can be found in Multimedia Appendix 2.



After consent, participants will be able to choose a study start date during their enrollment process from a provided list of dates. No more than 20 potential participants will begin their baseline period on the same day. Study enrollment will continue until 60 participants have been randomized after the baseline assessment.

Assignment of Interventions

Each treatment was assigned a letter with A=3 mg of melatonin, B=0.5 mg of melatonin, and C=placebo. Of those participants who are enrolled in the study, approximately 30 will be randomized by the study statistician to receive the protocol in the following order of 2-week treatment periods: 3 mg of melatonin, 0.5 mg of melatonin, placebo, placebo, 0.5 mg of melatonin, 3 mg of melatonin (ABCCBA). Approximately 30 more participants will be randomized in the following order of 2-week treatment periods: placebo, 0.5 mg of melatonin, 3 mg of melatonin, 3 mg of melatonin, 0.5 mg of melatonin, placebo (CBAABC). This randomization pattern can be viewed in the participant time line in Figure 2.

XSL•FO
RenderX

Figure 2. Participant Timeline.

Interventions

Once a participant successfully completes baseline and is randomized into the study, they will be mailed 3 Nomi pill bottles (see Figure 1). Each bottle will contain 28 pills of 3 mg of melatonin, 0.5 mg of melatonin, or placebo labeled “A,” “B,” or “C.” The doses of 3 and 0.5 mg of melatonin were selected to compare high and low doses of melatonin, respectively. Previous studies have classified doses of 0.3 to 1 mg as low doses of melatonin, which may still be effective [40]. Higher doses of melatonin (ranging between 2 mg and 6 mg) have been found to be effective for treating sleep disruption [41,42]. In this study, 3 and 0.5 mg of melatonin were selected because they are provided by the manufacturer, and color- and size-matched placebos are available. Both the 3 and 0.5 mg of melatonin pills are presented in the same type of capsule (ie, same size and appearance) but with different concentrations of melatonin. The placebo pill is an identical capsule filled with

XSL•FO
RenderX

a glucose solution. The melatonin and placebo doses provided for this study are prepared by Pure Encapsulations LLC, a National Sanitation Foundation Good Manufacturing Practices–registered laboratory that exceeds United States Pharmacopeia standards for supplement manufacturing. This laboratory has a 50-year history of producing products for clinical research [43-45]. Participants will receive a treatment schedule that indicates which pill bottle of medications is assigned to each week of the intervention. During intervention weeks, participants will receive nightly SMS text message reminders an hour before their self-reported bedtime, instructing them to take a pill from their assigned pill bottle depending on where they are in the randomization time line. Participants will be asked to refrain from taking additional melatonin for the duration of the study. During all treatment periods, participants will be asked to wear the Fitbit device 24 hours a day and answer up to 5 survey measures sent to them via SMS text messaging daily.

Participant Time Line

Figure 2 illustrates the participant time line.

Adherence

During the baseline period, the study team will assess participant adherence to the protocol. Adherence will be evaluated using the Fitbit tracker and survey completion. Participants wearing the Fitbit for 12 or more hours per day, including at least 180 minutes of sleep time, will be defined as adherent [46,47]. During the 14 days of the baseline period, participants who do not achieve a minimum of 80% adherence to Fitbit tracker wear and study measures (including EMA and survey measures) will be withdrawn from the study before randomization. Those participants with 80% adherence or higher by the final day of the baseline period will be randomized to the intervention phase. To encourage adherence, participants will be provided with short educational videos and protocol reminders via SMS text messaging, and they will be encouraged to contact study staff with concerns by phone, email, or secure portal message.

Participant Report

Participants who complete the intervention portion of the trial will have generated a 15-page personalized report summarizing their trial results and showing the impact of 3 mg of melatonin, 0.5 mg of melatonin, and placebo on their Fitbit-recorded sleep duration. The goal of the report is to display participants' sleep duration averaged across each study intervention with the goal of helping participants to select which treatment works best for them. The participant report also presents summaries and results for other sleep- and wellness-related outcomes that are both Fitbit-recorded (such as sleep efficiency, average time spent in sleep stages, and average number of steps) and self-reported (such as daily sleep quality and EMA fatigue). This report is not to be interpreted as medical advice. Participants are encouraged to seek a medical professional's opinion if they have any questions or concerns about the data displayed in their report. A similar version of the participant report in a series of personalized trials for chronic lower back pain is described and displayed in further detail elsewhere [48].

Results for the participant report are generated by comparing the effectiveness of 3 mg of melatonin and 0.5 mg of melatonin relative to placebo for each of the outcomes measured in the study. The participant report contains information about the magnitude of the difference for each outcome between each treatment period. Participants will be provided information about whether the difference was statistically significant (defined as $\alpha \leq .05$) in generalized least-squares (GLS) regression analyses. They will also be provided with estimates of their adherence to the intervention, Fitbit device, and survey measures.

After automated generation by the study data team, each participant report will be individually reviewed for accuracy, consistency, and comprehensibility by several study team members before delivering the report to the participant as a printable PDF file via a secure web portal. Personalized participant reports will be delivered to the participants within 3 months of their intervention completion, and they will be given the option to review their report along with a study team member. Participants will have an opportunity to provide their feedback on their report in the satisfaction survey and follow-up study interview.

Patient and Public Involvement Statement

Pilot data with participants and internal use testing were used to help determine which medication adherence device to select for this trial. We did not directly involve participants in any other elements of the design of this trial.

Ethics Approval

This study underwent ethics review and was approved by the Northwell Health IRB (IRB #21-0239). All amendments to the protocol will be submitted for approval to the ethics committee and Northwell Health IRB.

Data Monitoring

A Data and Safety Monitoring Board (DSMB) will be assigned to periodically assess for participant safety, scientific integrity, and the trial's progress. This DSMB will include 4 members who will have varying areas of scientific expertise including statistics and medicine. The DSMB conduct periodic reviews of study data for accuracy, completeness, and timeliness of submission. The study DSMB will also assess for evidence of potential harms, including adverse treatment events and loss of confidentiality. Following these reviews, the DSMB will be responsible for making recommendations regarding the continuation, modification, and termination of the project in reports provided to the study principal investigator. Regular collaboration between the study team and the DSMB will ensure access to study data for monitoring and regulatory inspection.

Treatment Adverse Events

Melatonin poses a low risk of physical harm to subjects, as it has a very low side effect profile and limited evidence of habituation and tolerance. A 2015 review on the safety of melatonin supplements indicated that only mild side effects were reported in various short-term studies that involved adults, surgical patients, and critically ill patients [49]. Some of the mild side effects that were reported in the studies included

XSL•FO
RenderX

headache, dizziness, nausea, and sleepiness [49]. Less common side effects include short-lasting feelings of depression, mild tremor, mild anxiety, abdominal cramps, irritability, reduced alertness, confusion or disorientation, and abnormally low blood pressure. The chances that participants could experience these side effects during the trial are low given the duration and dosing proposed for this research [50]. Participants document any side effects they experience that may be related to the supplements to the study team daily in the morning survey. Participants are informed that they may discontinue supplement dosing at any point during the trial.

The exclusion criteria for this study were used to prevent participants who are at greater risk of harm from participating in the study. Protocol adherence is monitored throughout the trial, and participant re-education is conducted as needed.

Loss of Confidentiality or Privacy

A risk that may be incurred by participating in the trial is a loss of privacy or confidentiality. The participant is made aware of all the data collected and the companies and devices employed to collect the data via the consent process. All identifying information of participants is stored in a secure, password-protected, Northwell Health–approved, HIPAA-complaint database, and personal and identifying information is not stored on any devices used in the study. Using the devices employed in this trial as part of this study as compared with using the devices as a consumer presents no additional risk. Once participants complete their study involvement, identifying information will be destroyed. All research team members with access to identifiable and deidentified data are trained and included on the IRB submission for approval. Regular meetings will occur with the principal investigator and other study team members to ensure protocol adherence and data accuracy.

Costs

This pilot study is funded by the National Institutes for Health (R01LM012836). All study-related equipment, devices, procedures, melatonin, and placebo supplements will be provided to participants at no cost, and participant insurance will not be billed. This study uses SMS text messaging to deliver notifications, reminders, and study questionnaires, which may include standard message and data rates from the participants' wireless carrier. Study participants will not be compensated for any costs related to data usage or sending or receiving SMS text messages by the study or by members of the study team.

Compensation

After completing all components of the study (ie, successful completion of a research team–approved intervention period, submission of a satisfaction survey, and returning the Nomi devices), study participants will be mailed a US$ 100 payment card (ClinCard). Additionally, as a thanks to study participants for their participation, they will be allowed to keep their Fitbit Charge 5 (a value of US$ 150.00).

Primary Outcome

The primary outcomes of this study will be feasibility as measured by the mean usability score evaluated using the 10-item System Usability Scale (SUS) [51] and acceptability as measured by an 18-item satisfaction survey. The SUS is a validated questionnaire that asks users to score each item on a Likert scale from "strongly disagree" (1) to "strongly agree" (5) [52,53]. Individual item scores are multiplied by 2.5 and summed to generate a total score ranging from 0 to 100, with higher scores indicating a greater level of usability. This measure has been used and validated in multiple contexts [52,53]. The SUS will be presented to the participants as addressing the ease of use, complexity, and consistency of the personalized trial system as a whole. Satisfaction will be measured using a 6-item satisfaction survey. The survey will assess participant satisfaction with elements of the trial, including explanatory resources, the Fitbit device, the personalized trial design, survey assessment measures, and the participant report. Participants will be asked to rate their satisfaction on a scale of 1 ("not very satisfied") to 5 ("very satisfied").

The satisfaction survey will also include a 7-item series of questions regarding the participant's experience in the personalized trial as a whole. Satisfaction with aspects of the trial including the onboarding process and ease of trial adoption will be rated on a scale of 1 ("strongly disagree") to 5 ("strongly agree"). Finally, satisfaction with the personalized report will be assessed through 5 questions on a scale of 1 ("strongly disagree") to 5 ("strongly agree").

Secondary Outcomes

The secondary outcomes in this study will include Fitbit device–recorded nightly sleep duration, self-reported sleep quality using a modified version of the Consensus Sleep Diary (CSD), EMA self-reported fatigue ratings, EMA self-reported pain ratings, adherence to use of the Fitbit device, and adherence to each of the interventions (3 mg of melatonin, 0.5 mg of melatonin, and placebo).

Nightly sleep duration and daily steps will be assessed using non–Near Field Communication, Fitbit Charge 5 devices. During baseline assessment (2 weeks) and all intervention weeks (12 weeks), participants will be asked to wear their Fitbit device each day and night (for a total of 14 weeks overall). All enrolled participants will be provided with a Fitbit device and Fitbit account that the research team has created with no identifying information for use in the study. A file linking the Fitbit account identifier to the study participant will be housed in a Northwell Health–approved drive to store protected health information. It will be accessible solely to members of the study team listed in the IRB application. Participant Fitbit data will be retrieved using N1Thrive and Fitabase, both secure web portals. Participants' study Fitbit accounts will be linked to an identification number in the N1Thrive and Fitabase systems. No identifying information will be stored in the Fitabase data set. Fitabase and N1Thrive will stop tracking participant Fitbit data at the end of the trial. As an added security measure, participants will be instructed to remove the Fitbit study account from their smartphone device to keep the Fitbit.

The CSD is a daily instrument used to assess and track intervention effects on sleep symptoms, quality, and satisfaction [54]. Three versions of the CSD were originally put out by its authors: the core CSD containing 9 items, an expanded morning

XSL•FO
RenderX

version with optional additional items to be completed upon arising, and an expanded evening version with separate morning and evening items to be optionally completed. This study uses a modified version of the core CSD, asking participants about perceived sleep quality (via a Likert scale), sleep onset latency, the time at which the participant believes sleep onset occurred, duration of nighttime awakenings, final rise time, and a multiple-selection question asking if any of 10 (or an optional "other" selection) listed factors directly impacted the participant's sleep. The CSD will be sent to participants within an hour of their self-reported wake time each day of the study to assess and monitor patient-reported outcomes regarding sleep quality throughout each intervention period of the trial. Data observed through the CSD will be reported back to participants via the personalized participant report.

Daily self-reported fatigue and pain ratings will be assessed via EMA using a measure adapted from the Numeric Pain Rating Scale [55]. These assessment measures are single-item assessments administered 3 times daily via SMS text messaging asking participants to rate their fatigue and pain in the current moment on a scale of 0 to 10. The timing of the SMS text messages will be randomized between a participant's self-reported wake and sleep times. For fatigue, ratings of 0 indicate no feeling of fatigue, with scores of 1 to 3, 4 to 6, 7 to 9, and 10 respectively indicating a little, somewhat, quite a bit, and very much feeling fatigued. Interpretations of scores remain the same for pain. EMAs are collected daily via surveys using the secure study platform N1Thrive, a Northwell Health–approved and HIPAA-compliant system used for patient engagement and collecting and storing research data. A workflow was constructed for this study to include automated messaging pathways delivered via SMS text messaging directly to the participant's smartphone via the platform.

Participant adherence to the intervention and time of melatonin or placebo use will be measured using the Nomi smart pill bottle. The Nomi system includes a smart bottle that is designed to look just like a typical prescription pill bottle. The bottle comes equipped with a sensor that measures patient adherence using weight, time, movement, and temperature. The data are then made available to health care providers via a cellular connection to the SMRxT cloud. Below the sensor is a light that flashes when it recognizes that a dose has been taken, the device's battery is low, or the device is unable to connect to the network. From the digital Nomi dashboard, study team members will remotely assign treatments to patients, create treatment schedules, and monitor medication usage. No patient information or identifying data will be stored on the device or within the Nomi adherence dashboard—only unique study IDs will be used to collect data. The bottle serial number and the unique study ID will be linked to subjects in REDCap, a secure data management system managed only by research staff. The Nomi system will also be integrated with the study platform to deliver automated SMS text message reminders in cases of deviation from assigned supplement dosing.

Exploratory Outcomes

The exploratory outcomes in this trial will include self-reported sleep disturbance measured using the Insomnia Severity Index (ISI), participant self-reported side effects, EMA self-reported pain ratings, EMA self-reported mood ratings, EMA self-reported concentration ratings, and EMA self-reported confidence ratings. We will also measure participant adherence to survey measures and EMA assessment measures. The ISI is a brief patient-reported outcome insomnia instrument assessing the severity of nighttime insomnia and related daytime impairment [56]. It comprises 7 items, each scored using a 5-point Likert scale, which summate to a total score. Lower ratings on the scale equate to less disturbance (0=no problem) and higher ratings of more disturbance (4=very severe). This overall score can function as a diagnostic of the severity of clinically significant insomnia or subclinical sleep disturbances. The ISI will be sent to participants as a biweekly survey every other Sunday evening (ie, at the end of baseline and the end of each intervention block), and it will ask them to reflect on their sleep disturbance symptoms for the past 2 weeks (or the past study block). This instrument will therefore be the key data point to solicit participants' self-reported sleep disturbance on a retrospective basis for an intervention period as a whole. ISI data will be reported back to the participants in the participant report.

Patient self-reported side effects will be assessed daily using a survey measure. EMA measures of stress, mood, confidence, and concentration will be assessed in using single-item assessments administered 3 times daily via SMS text messaging asking participants to rate how they feel in the current moment on a scale of 0 to 10. Delivery and assessment of these measures will be identical to the methods used for EMA fatigue and pain described above. Participant adherence to survey measures (including the sleep diary and ISI) and EMA check-in measures will also be tracked.

Results

Recruitment Status

As of the submission of this protocol, recruitment for this pilot is approximately 78.3% (47/60). We expect recruitment and data collection to be finalized by June of 2023.

Sample Size Calculation

The sample size of 60 participants was chosen to ensure a sufficient number to obtain a preliminary assessment of the feasibility of this series of personalized trials of melatonin therapy for sleep. The feasibility for this study is determined using scores from the SUS, which is administered at the completion of the trial. With 60 participants receiving the intervention and use of a single sample binomial test with α set to 2.5% significance, we will have approximately 90% power if 70% of participants complete the trial. With 60 randomized participants—and an expected trial completion rate of 70%—we anticipate SUS data to be available in approximately 42 participants, thus giving a standard error no greater than 8% in estimating the rate of SUS ≥85, an exceptional level of usability [57]. Individual participant responses will be reported so that individual-level heterogeneity can be assessed and evaluated [58].

XSL•FO
RenderX

Primary Analysis

The primary analysis will be based on usability ratings submitted by all enrolled participants (n=60) on the SUS. These usability ratings will be summarized using descriptive statistics including means, medians, SDs, and IQRs and visualized via a histogram. If the trial receives a score of 70 or greater, it will be judged to have "acceptable" levels of feasibility, whereas scores of 80 or greater are interpreted as "excellent" [57]. The SUS has been used and validated for use in multiple programs and trials [52,53].

We will also analyze participant self-reported levels of satisfaction. Self-reported satisfaction levels will be reported for each component of the trial (eg, interventions and design) using means and SDs. Participant responses to each satisfaction item will also be depicted graphically to show the distribution of participant responses from "not very satisfied" to "very satisfied." This satisfaction measure has previously been used to evaluate acceptability of personalized trials [47].

Secondary Analyses

Means and SDs for Fitbit device–recorded nightly sleep duration, self-reported sleep quality using a modified version of the CSD, EMA self-reported fatigue ratings, and EMA self-reported pain ratings will be reported for the baseline assessment period (2 weeks) and each intervention period (6 blocks of 2 weeks) and depicted graphically. Proportion of days adherent to the Fitbit device and adherence to the intervention will be reported using mean proportions and SDs for the study overall. We will also calculate mean and SD values for each secondary outcome across intervention periods for 3 mg, 0.5 mg, and placebo. For example, we will sum all outcome measures for both the 2-week intervention periods to derive an overall mean value for the 3 mg melatonin period. The same process will be followed for the 0.5 mg melatonin and placebo periods. As the timing of melatonin doses may influence the effect of melatonin on sleep [59-61], the time of dose relative to sleep onset will be examined in sensitivity analyses.

Finally, the effects of each intervention (3 mg of melatonin, 0.5 mg of melatonin, and placebo) on the secondary outcomes will be examined using generalized linear mixed models with an autoregressive, AR(1), model. This model accounts for possible autocorrelation and linear trends between fatigue ratings across time. We will consider week as a linear term and factor in the mixed model to explore the nonlinear time effects of each treatment. This will generate estimates of each intervention on each of the secondary outcomes for the overall sample. In addition, we will conduct analyses to evaluate the effects of each intervention on the secondary outcomes at the level of the individual participant. Using GLS analyses with an AR(1) model, we will be able to generate estimates of the effect for each intervention for each participant for each of the secondary outcomes. This level of individual-level analyses is essential for personalized trials.

Exploratory Analyses

Exploratory outcome measures, including ISI, participant self-reported side effects, EMA self-reported pain ratings, EMA self-reported mood ratings, EMA self-reported concentration ratings, and EMA self-reported confidence ratings, will be reported using means and SDs overall and by the study period. Similar to analyses of secondary outcomes, the effects of each intervention on the exploratory outcomes will be evaluated with generalized linear mixed model analyses using autoregressive models in the overall sample and with GLS analyses using autoregressive models with individual participants. Exploratory adherence measures (adherence to surveys and EMA measures) will be represented using proportions for the overall study and by the study period. Comparisons between the 2 treatment orders (ABCCBA and CBAABC) will also be conducted to identify potential confounding effects due to treatment order.

Discussion

This study represents an advancement in the process of developing feasible, acceptable, and effective personalized interventions for a variety of health conditions. Widespread use of personalized N-of-1 designs has been hampered by difficulties in the feasibility of creating them, with many researchers and clinicians feeling that personalized N-of-1 trials are not the worth the effort needed to conduct them [62]. In assessing the feasibility and acceptability of our developing personalized N-of-1 platform, which has been previously implemented to treat chronic lower back pain [47] and fatigue [46], we hope to continue refining a programmatic template for using personalized N-of-1 designs for other health conditions and other interventions. Further, we hope the use of digital enrollment, consent, intervention delivery, and outcome assessment will make personalized N-of-1 trials more feasible in research and clinical practice.

Potential limitations for the current trial include potential issues with representativeness of the participant sample and with doses of melatonin selected in the trial. Although our recruitment efforts are directed to identify a diverse sample for enrollment in the current trial, inaccurate sampling of participants with disrupted sleep is possible. For example, using digital recruitment methods may oversample individuals who have disrupted sleep due to excess internet usage time or exposure to blue light. For evaluations of effectiveness, this is not a concern since the goal of a personalized N-of-1 trial is to assess treatment effectiveness in each individual participant. However, the primary goal of this trial is to evaluate the feasibility and acceptability of personalized trials for poor sleep. Failing to recruit a representative sample of participants with poor sleep may limit our conclusions regarding the feasibility and acceptability of personalized N-of-1 trials of melatonin for sleep. In addition, individual participants may respond more optimally to other doses of melatonin than those examined in the current trial (namely 0.5 and 3 mg). Although these doses are representative of lower and higher doses of melatonin used in previous sleep interventions, assuming that some individuals may respond optimally to higher doses of melatonin (eg, 6 mg) or to doses not examined in the current trial (eg, 1 mg) is reasonable. In addition, some research suggests that depending on how melatonin supplements are prepared, the dose within each supplement may also vary [63]. Further, it is possible that dose duration may influence findings, as longer duration melatonin treatments have been associated with increased sleep

XSL•FO
RenderX

duration [25]. For example, a participant may have responded better to a longer duration (eg, a 4-week block of melatonin rather than a 2-week block). However, the current goal of this trial is to identify the feasibility and acceptability of personalized N-of-1 designs rather than to select the ideal treatment for each individual participant. Another potential limitation for the current trial is the lack of information about participants' habitual melatonin levels before beginning the trial. Prior research suggests that individuals with lower endogenous melatonin secretion may benefit more from receiving melatonin replacement [64]. Therefore, the cause of participants' self-reported poor sleep may not be influenced by melatonin.

Despite these potential limitations, this trial represents a significant step forward in the design of digital, remote, personalized trials. If it is found to be feasible and acceptable among individuals dealing with poor sleep, revision of the design of the intervention to evaluate alternative formulations of the current treatment (such as longer dose durations or different strength doses of melatonin) or multiple alternative treatments (such as behavioral interventions for sleep hygiene and exercise) in comparison to melatonin is possible. Further, if these personalized trials are found to be feasible as prior series of trials have been [47], we will be able adapt the platform used in this intervention for other health conditions and hopefully integrate personalized N-of-1 trials into clinical practice.

Acknowledgments

We are grateful for the contributions and support of the Northwell Health System, Pure Encapsulations, and Nomi by SMRxT for providing the investigators with the support and tools for the development and implementation of this trial. This work was supported by the National Library of Medicine of the National Institutes of Health (grant R01LM012836). The funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; or decision to submit the manuscript for publication. The views expressed in this paper are those of the authors and do not represent the views of the National Institutes of Health, the US Department of Health and Human Services, or any other government entity.

Data Availability

Data archives containing the raw study data and data dictionaries for this study are available on the Open Science Framework platform [65].

Dissemination

The trial results will be published in a peer-reviewed journal. All publications resulting from this series of personalized trials will follow the CONSORT extension for N-of-1 trials (CENT 2015) reporting guidelines [66]. Trial results will be reported to study collaborators and participants after study completion.

Authors' Contributions

KWD, SD, AS, and Y-KC contributed to the development of the trial idea. KWD, SD, AP, JR, DM, and Y-KC contributed to the development of the trial protocol. MJB drafted the manuscript and all authors contributed to its revision and gave final approval. TC and Y-KC provided statistical expertise.

Abstract

Background: Psychological factors such as stress, anxiety, mood, emotions, cognitive functioning, and pain behavior are relevant to the onset of pain and its continuation in the transition to chronic conditions. Subacute low back pain (LBP), a precursor to chronic LBP, is particularly poorly understood, and its relationships with psychological factors are understudied.

Objective: We will conduct a study aiming to prevent the chronicity of subacute LBP by altering the emotional response to pain using an interoceptive exposure technique (IET). Considering the recent increase in knowledge about psychological risk factors, as well as recent findings in cognitive neuroscience regarding emotional and cognitive background factors in the LBP chronicity process, efforts should be made to discover effective preventive methods.

Methods: We present a novel method aiming to prevent the transition from subacute to chronic back pain by altering the emotional response to pain using an IET. In this pilot randomized controlled trial, participants who are at a higher risk of LBP chronification due to the presence of a biomarker (ie, functional connectivity between the medial prefrontal cortex and nucleus accumbens) will be randomly assigned to the IET intervention group or control group A (treatment as usual). Participants who do not present with the biomarker will be assigned to control group B (treatment as usual) to assess how well this biomarker predicts the chronification of subacute LBP in this study population. Questionnaires measuring the pain experience and psychological distress will be used before the intervention, after the intervention (at 3 months), and at the 12-month follow-up.

Results: This research project will combine 2 novel methods: a biomarker as the inclusion criterion and an IET as the intervention. The comparative study design enables evaluation of the efficacy of the IET, as well as replication of the biomarker's validity as a possible clinical screening method.

Conclusions: If found to be useful, the IET would offer a cost-effective and reasonable way to develop treatment for acute and subacute back pain conditions. Potential benefits include increased pain management and quality of life for the individual patient with the addition of a potentially useful functional pain management method at the societal level.

Introduction

Overview

As low back pain (LBP) has been shown to be highly prevalent and hence a major problem throughout the world, preventing LBP from becoming chronic can be considered a major challenge in pain medicine [1]. LBP prevalence rates between 3.9% and 20.3% have been reported [2], with the highest prevalence among female individuals and those aged between 40 and 80 years [3].

Although LBP episodes and associated disability usually improve within weeks, pain and disability typically continue, and recurrences are common [4]. The predictive power of biomarkers for chronic LBP has so far proven to be insufficient [5]. Risk factors for LBP may be genetic, acquired, or due to an individual's interaction with the environment [6]. In a review of prospective studies, Linton [7] concluded that psychological variables such as stress, distress, anxiety, mood, emotions, cognitive functioning, and pain behavior were relevant to the onset of pain and its continuation in the transition to chronic conditions. The transition from acute localized LBP into chronic widespread LBP has shown relationships with the progression of both peripheral and central sensitization [8]. Furthermore, patients with chronic LBP might develop maladaptive behavioral strategies [9].

Recent brain imaging studies have further supported the role of emotional factors in the LBP chronification process, revealing mental factors influencing pain conditions [10]. Even in acute pain states, emotional factors seem to directly influence neural pain processing, as shown in the brain imaging study by Orenius et al [11], in which a valence-independent emotion interacted with the pain processing in the secondary somatosensory cortex. Functional and emotional nonadjustment factors have been identified in the acute LBP chronification process [12], with emotional nonadjustment relating to helplessness and hopelessness. Furthermore, chronification does not simply implicate the presence of enduring pain symptoms; it signifies a complex process associated with alterations in cortical structure and function. Vachon-Presseau et al [13] emphasized the importance of the emotional brain (ie, the cortico-limbic system) in the modulation of acute pain and in the prediction and amplification of chronic pain. A functional magnetic resonance imaging (fMRI) study showed that chronification of LBP shifts brain representation from nociceptive to emotional neural circuits [14]. These findings indicate the pivotal role that the neural structures involved in emotional learning play in the chronification of back pain [15]. Furthermore, the strength of synchronicity (ie, functional connectivity) between the medial prefrontal cortex (mPFC) and nucleus accumbens (NAc) was predictive (with >80% accuracy) of individuals who would subsequently transition from subacute pain to chronicity at a 1-year follow-up [15].

Neuroimaging studies have shown that cognitive behavioral therapy can change anxiety-related dysfunctions (phobia, traumatic stress, obsessive-compulsive disorder, and panic) of the nervous system [16]. Brain regions associated with attention, interoception, and sensory processing, including the prefrontal cortex and right anterior insula, are thicker in meditation participants than in matched controls, with the thickness of 2 regions correlating with meditation experience [17]. It has also been shown that mindfulness-based stress reduction techniques (a subcategory of cognitive behavioral therapy) produce macroscopic cortical plasticity in the adult human brain, demonstrating a dynamic relationship between behavioral state and cerebral anatomy [18]. Stress reduction correlated with structural changes in the amygdala after an 8-week mindfulness-based stress reduction intervention, demonstrating an association between neuroplastic changes and corresponding improvements in a psychological state variable [19]. An anatomical likelihood estimation meta-analysis showed that 8 brain regions were consistently altered in meditators, including areas key to meta-awareness, exteroceptive and interoceptive body awareness, memory consolidation and reconsolidation, self-regulation and emotion regulation, and intra- and interhemispheric communication [20]. Therefore, psychological interventions can produce both objective structural changes and alterations in the neural processing of emotions.

The treatment of chronic LBP has not primarily focused on removing an underlying organic disease but rather, within a biopsychosocial framework, on identifying the underlying mechanisms driving the disorder and thus enabling treatment to favorably influence the outcome [21]. Psychological methods targeting therapeutic processes relate to attention, cognition, emotions (including emotion regulation), and overt pain behaviors [22]. Despite a growing knowledge of relevant background factors in the transition from acute to chronic LBP [23], insight into preventive psychological methods applicable to subacute (4-12 weeks) LBP, a precursor to chronic LBP, is still particularly scarce. Insufficient theoretical guidance and integration in the design, selection, and delivery of methods that precisely target known dysfunctional behavioral processes have been presented as plausible shortcomings [24]. A recent systematic review showed that psychological interventions aiming to prevent chronification of subacute LBP had an insignificant preventive impact on pain measures [25].

Aims and Objectives

There is a shortage of studies on interventions to prevent the chronicity of subacute back pain [25]. Considering the recent increase in knowledge about psychological risk factors, as well as recent findings in cognitive neuroscience regarding emotional and cognitive background factors in the LBP chronicity process, efforts should be made to discover effective preventive methods. Therefore, we will conduct a study aiming to prevent the chronicity of subacute LBP by altering the emotional response to pain using an interoceptive exposure technique (IET).

The aims of this study are as follows:

1. A pilot study will address the efficacy and feasibility of IET in preventing the chronicity of subacute pain. Participants who are found to have a higher risk of pain chronification due to the presence of a biomarker (functional mPFC-NAc synchronicity) will be randomized to the intervention group (n=7) or control group A (n=7; treatment as usual). To assess how well this biomarker predicts LBP chronification, participants who are not found to have the

XSL•FO
RenderX

biomarker will be assigned to control group B (treatment as usual) without a defined number of participants.

2. A full-scale study (intervention group: n=20; control group: n=20) will address the efficacy and feasibility of the IET in the prevention of subacute LBP chronicity with the same parameters as in the pilot study.

Methods

Participant Selection and Sampling Strategy

All participant recruitment will take place through the pain clinic at the Orton Orthopaedic Hospital and another private occupational health center. All study participants will be outpatients at the pain clinic and the private occupational health center. They are working-aged Finnish citizens who speak Finnish as their first or second language. A health care professional will diagnose the participants' back pain and assess them based on the inclusion and exclusion criteria.

The inclusion criteria approximately correspond to those of Baliki et al [15]: pain intensity >40/100 on the numeric rating scale (NRS) [26] and back pain duration <16 weeks. Deviating from the abovementioned criteria, we limit the pain duration time more precisely (ie, to 4-10 weeks) to enable commencement of the IET before exceeding the valid 12-week time limit for pain chronicity. Additionally, it will be implied that participants experience at least occasional back pain when lying on their backs. Exclusion criteria resemble those of Baliki et al [15]: other chronic painful conditions, systemic disease, history of head injury, psychiatric diseases, or more than mild depression (score >19), as defined by Beck Depression Inventory-II (BDI-II) [27]. As an addition, exclusion criteria also include self-reported earlier diagnosed prolonged LBP episodes and longer sick leaves due to LBP.

A health care professional (physician or physiotherapist) will ask patients with subacute back pain if they are willing to participate in the study. When a patient is willing to participate, the research secretary will contact the patient and check that he or she meets the research criteria. Then, the health care professional will provide the patient with information about the study procedure and deliver the information and a consent form to the patient, who will sign the consent document. The patient will be told that he or she has the right to stop his or her participation at any time without having to explain the reason. The participant, accompanied by the research secretary, will undergo an fMRI scan and fill out the questionnaires. The feedback from the lumbar magnetic resonance imaging (MRI) will be given to the participants by the clinician. If necessary, proper further examinations and treatments will be provided, and the participants will be excluded from the study.

Neuroimaging and Data Acquisition

All participants will undergo an fMRI measurement at the Advanced Magnetic Imaging Centre, Aalto University, Espoo, Finland, to determine if they meet the criteria for the biomarker (mPFC-NAc synchronicity), according to the study by Baliki et al [28]. The fMRI is done only in the initial stage, and no post-IET measurement is done to demonstrate possible effects on the biomarker.

The fMRI data will be collected with a 3T Magnetom Skyra whole-body scanner (Siemens Healthineers) and a standard 32-channel head coil. Anatomical T1 magnetization prepared–rapid gradient echo images will be acquired with the following parameters: orientation=sagittal; repetition time (TR)=2530 ms, time to echo (TE)=33 ms; 176 slices, slice thickness=1 mm, gap=50%; phase encoding direction=A-P; field of view=256 mm; and flip angle=7°.

Next, fMRI images will be acquired with a T2* weighted echo planar imaging sequence with the following parameters: orientation=transversal; TR=1570 ms, TE = 30 ms; 38 interleaved slices with no gap, slice thickness=3 mm; phase encoding direction=R-L; field of view=220 mm; flip angle=70°; base resolution=74; and 400 time points/volumes. A total of 4 dummy scans will be acquired for signal stabilization.

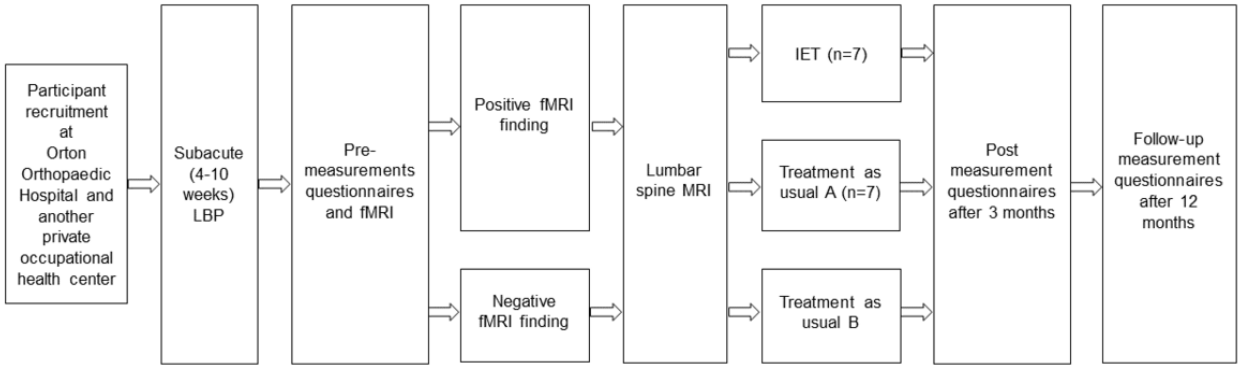
We will collect 1 anatomic MRI and 1 fMRI series for each participant. Throughout the fMRI acquisition, the participants will be asked to rate their LBP on a sliding cursor from "no pain" to "worst imaginable pain" (0-10). Participants will be given the following instructions (in Finnish): "Continuously rate the intensity of your low back pain. Indicate the intensity of your low back pain and changes in it by adjusting the cursor to the location corresponding to the intensity of your pain." Participants will give their answer with a handheld 2-button device. Participants' answers will not be recorded.

Functional Connectivity Analysis and Participant Grouping

The functional mPFC-NAc connectivity of each participant will be analyzed with data processing assistant for resting-state fMRI [29]. Slice timing correction will be performed using the first acquired slice (slice number 2) as the reference slice. Images will be realigned, and normalization will be completed using a new segment and the diffeomorphic anatomical registration through exponentiated lie (DARTEL) algebra algorithm [30]. Images will be smoothed by DARTEL using a Gaussian kernel of full width at a half-maximum of 5 mm. Nuisance covariate regression will be performed with the Friston 24-parameter model. White matter signals and cerebrospinal fluid signals will be used as covariates. A 0.01 to 0.1 Hz filter will be applied. The functional region of interests, defined according to the criteria of Baliki et al [28], are spheres with a 10-mm radius. Talairach seed coordinates for the mPFC (x=2, y=52, z=–2) and right NAc (x=10, y=12, z=–8) will be transformed into Montreal Neurological Institute coordinates before calculating mPFC-NAc synchronicity. Participants with $z(r) \geq 0.25$ will be classified as having an increased risk for LBP chronification.

Participants who are found to have a higher risk of pain chronification due to the presence of a biomarker (mPFC-NAc synchronicity) will be randomized to the intervention group (IET) or control group A (treatment as usual). To assess how well this biomarker predicts the chronification of LBP, participants who are not found to have the biomarker will be assigned to control group B (treatment as usual).

Participants who fit the inclusion criteria (based on fMRI) will undergo a lumbar spine MRI examination (1.5 Tesla) to rule out specific causes of the low back symptoms (ie, tumors,



XSL•FO
RenderX

evidence of ankylosing spondylitis) or other conditions requiring special attention. Furthermore, the lumbar MRI ensures the homogeneity of the study population. The feedback from the MRI examination will be given to the participants by the clinician briefly in the style of "no specific causes or special factors to be taken into account," after which the participants will participate according to the protocol. If necessary, proper further examinations and treatments will be provided, and the participants will be excluded from the study.

Study Procedure

The study procedure is outlined in Figure 1. All participants will complete the study questionnaires before the fMRI, 3 months after completing the IET, and 12 months after the fMRI. Questionnaires will be presented in paper form. Post-IET questionnaires will be sent to participants by paper mail. Questionnaires will be pseudonymized.

Figure 1. The study procedure. fMRI: functional magnetic resonance imaging; IET: interoceptive exposure technique; LBP: low back pain; MRI: magnetic resonance imaging.

Participants at risk for LBP chronification will be classified and categorized within 48 hours after fMRI. High-risk participants will be further pseudo-randomized into the intervention (IET) or control group (A), whereas low-risk participants will form the treatment-as-usual group (B). Participants will be provided with group-specific instructions on the remaining study procedures by email and telephone. Participants in the intervention group will begin practicing the IET within a week after neuroimaging.

Study Setting

The IET to be used in this study is a modified version of the IET used by Flink et al [31]. The original Swedish version used in the original study was translated into Finnish with small adjustments to the IET without departing from the structure and scope of the original exercise. At the beginning of the study procedure, the participants will be given brief information about the IET. The participants will access the IET through a web-based platform secured by a personal password and a username. The platform can be accessed on a mobile phone or a home computer with internet access. The participants will then be told to perform the 8 minutes and 26 seconds–long IET exercise 3 times a week (Monday, Wednesday, and Friday) in as serene a setting as possible. During the IET, the participants will be asked to relax and calmly focus their attention on the sensation of pain. They will be told to focus on the pain with an open and nonjudgmental attitude and to feel the pain as much as possible without trying to change it or block it. If their attention wanders from the pain, they will be asked to return their focus to the pain sensation. The web-based exercise platform will keep track of the participant's activity. Platform visits and the time spent committing to the IET will be recorded. In this way, the research team can contact the participant if he or she is not logging on to the platform or if the IET is not carried out completely. The participant will be reached by phone to investigate the problem with attendance. If the participant misses 3 consecutive training sessions (ie, 1 week's training), he or she will be excluded from the study. The IET intervention is designed to take 12 weeks. The IET exercise (in Finnish) is presented in Multimedia Appendix 1.

Outcome Assessment and Measurements

The questionnaires used in the study will address conditions of pain experience and psychological distress. All measures are standardized and commonly used in pain research.

For all visits, participants will complete the short form of the Finnish version of the McGill Pain Questionnaire (MPQ), abbreviated as the FPQ [32]. The main component of the MPQ consists of 12 sensory and 4 affective descriptors, which are used to compute the sensory and affective scores, respectively. Radiculopathy scores are quantified from pain locations, which patients shade in with pencil on the MPQ form 15. Depression scores are assessed using the BDI-II [27]. All questionnaires will be given on the same day before brain scanning. The questionnaires are presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. Behavioral measures and corresponding questionnaires to be used in the study, with abbreviations in brackets.

Measures and corresponding questionnaires

- Pain intensity: Numeric Rating Scale (NRS) [26]
- Pain experience: the Finnish Version of the McGill Pain Questionnaire (FPQ) [32]
- Pain-related anxiety: Pain Anxiety Symptoms Scale (PASS-20) [33]
- Anxiety symptoms: State-Trait Anxiety Inventory (STAI) [34]
- Fear of movement: Tampa Scale of Kinesiophobia (TSK) [35]
- Depression: Beck Depression Inventory-II (BDI-II) [27]

Pain intensity will be estimated with the numeric rating scale (NRS), with a pain intensity ranging from "no pain" to "worst pain" (1-10) according to the conventional use of the NRS [26]. The subjective unpleasantness will be measured analogously on the NRS, ranging from "not unpleasant" to "extremely unpleasant." The primary outcome will be pain intensity on the NRS. Secondary outcomes will be pain experience [32], pain-related anxiety [33], state and trait anxiety [34], fear of movement [35], and depressive symptoms [27] (Textbox 1).

Data Collection and Statistical Analysis

Data will be obtained before the fMRI, 3 months after completing the IET, and 12 months after the fMRI. Data will be compared between the groups (IET vs treatment as usual in control groups A and B). The data will be analyzed using a repeated-measures analysis (mixed models).

Ethics Approval

This study has obtained ethical approval from the ethical committee at Helsinki and Uusimaa Health District (HUS/2435/2017). Good research ethics practices will be maintained in the study according to the Declaration of Helsinki.

There will be no inclusion of vulnerable groups (ie, children, prisoners, individuals with mental disorders). No participant reimbursement will be provided to prevent economic factors from impacting the recruitment process. No specific physical health risks can be seen to be involved in participating in the study. Participants will be physically checked with a handheld metal detector before entering the scanner. However, the procedure could cause slight stress for participants and might even provoke pain. The fMRI and MRI procedures could cause some distress for some participants. The IET training might test participants' motivation.

Anonymity and confidentiality will be ensured by using numerical codes for the participants. Only the research group members will know the participants' names. Data protection and storage security will be ensured by storing the participant information and questionnaires in a locked cabinet at Orton. Data will be stored behind electronic passwords securely on Orton's server.

For the duration of the fMRI measurements, all participants will have patient insurance against possible injuries.

Results

This research project will consist of a pilot randomized controlled trial in which 2 novel methods will be combined: a biomarker as the inclusion criterion and an IET as the intervention. The comparative study design enables evaluation of the efficacy of the IET as well as replication of the biomarker's validity as a possible clinical screening method. This study will yield valuable new information about both the neural processes driving pain to chronicity and a specific and promising intervention to modulate that process.

As of September 2023, we have not enrolled any participants.

Discussion

Principal Findings

The principal finding will be pain intensity. Secondary findings will be pain experience, pain-related anxiety, state and trait anxiety, fear of movement, and depressive symptoms.

Strengths and Limitations

This study will combine neuroscience and psychology in a novel and innovative way. The study's strengths will be precise diagnostic criteria, objective selection criteria with measurement methods, and behavioral metrics that have been found to be reliable. Furthermore, the comparative design with 3 groups can be considered a strength.

The small number of participants in the pilot phase can be considered a weakness, as can the completion of the IET at home without objective supervision, which could become a possible source of error.

Study Significance and Feasibility

The first step of this project was to write a systematic review. It was registered with PROSPERO (Prospective Register of Systematic Reviews; CRD42019053580) and published in 2022 [25]. This study has also been registered at ClinicalTrials.gov (NCT05450263). We have (adjusted to our research design) followed the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials)-2013 recommendations for clinical trial protocols and related documents [36].

This study will yield valuable new information about both the neural processes driving pain to chronicity and a specific and promising intervention to modulate that process. In addition,

XSL•FO
RenderX

this study will offer new insight into the use of mindfulness meditation in pain management. If found to be useful, the IET would offer a cost-effective and reasonable way to develop treatment for back pain. The potential benefits are improved pain management and quality of life for the individual patient, with the addition of a potentially useful functional pain management method at the societal level.

Acknowledgments

The authors would like to thank Ida Flink, PhD, at the Center for Health and Medical Psychology (CHAMP) at Örebro University, Sweden, for giving her permission to use a modified version of the interoceptive exposure technique (IET). We would also like to thank Tuukka Raij, MD, PhD, for his valuable help in structuring the methods and defining the functional magnetic resonance imaging (fMRI) parameters. We are very grateful to Emma Stickler, MSc, who has actively helped us throughout the writing of the protocol and in clarifying the use of fMRI parameters.

This study is funded by Orton research grants from the Ministry of Social Affairs and Health, Finland (A2500/483).

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors made substantial contributions to the conception or design of the study; the acquisition, analysis, or interpretation of data for the study; the drafting or critical revision of the manuscript for important intellectual content; final approval of the version to be published; and agreement to be accountable for all aspects of the study in ensuring that questions related to the accuracy or integrity of any part of the study are appropriately investigated and resolved.

Conflicts of Interest

None declared.

Protocol

Model Clinic to Increase Preventive Screenings Among Patients With Physical Disabilities: Protocol for a Mixed Methods Intervention Pilot Study

Abstract

Background: People with physical disabilities often experience premature multimorbidity and adverse health events. A tailored primary care approach for this vulnerable population that also accounts for social and functional risk factors could promote healthier aging and more equitable health care.

Objective: This project will evaluate the implementation of a health program designed for people with physical disabilities. The proposed evaluation result is to generate the first best-practice protocol focused specifically on developing primary care to help reduce preventable causes of morbidity and improve functioning among people with physical disabilities.

Methods: We will design and implement a pilot health program for people with physical disabilities at a primary care clinic within Michigan Medicine. The health program for people with physical disabilities will be an integrated intervention involving a tailored best practice alert designed to prompt family medicine providers to screen and monitor for common, preventable health conditions. The program will also collect social and functional status information to determine the patient's need for further care coordination and support. Adult participants from this clinic with identified physical disabilities will be targeted for potential enrollment. To create a quasi-experimental setting, a separate departmental clinic will serve as a control site for comparison purposes. A quantitative analysis to estimate the treatment effect of implementing this health program will be conducted using a difference-in-differences approach. Outcomes of interest will include the use of preventative services (eg, hemoglobin A_{1c} for diabetes screening), social work assistance, and emergency and hospital services. These data will be extracted from electronic health records. Time-invariant covariates, particularly sociodemographic covariates, will be included in the models. A qualitative analysis of patient and health care provider interviews will also be completed to assess the effect of the health program. Patient Health Questionnaire-9 and Generalized Anxiety Disorder 7-item scores will be assessed to both screen for depression and anxiety as well as explore program impacts related to addressing health and functioning needs related to physical disabilities in a primary care setting. These will be summarized through descriptive analyses.

Results: This study was funded in September 2018, data collection started in September 2021, and data collection is expected to be concluded in September 2023.

Conclusions: This study is a mixed methods evaluation of the effectiveness of an integrated health program designed for people with physical disabilities, based on a quasi-experimental comparison between an intervention and a control clinic site. The intervention will be considered successful if it leads to improvements in greater use of screening and monitoring for preventable health conditions, increased social worker referrals to assist with health and functioning needs, and improvements in emergency and hospital-based services. The findings will help inform best practices for people with physical disabilities in a primary care setting.

KEYWORDS

clinical decision support; electronic health records; mixed methods; people with physical disabilities; primary care

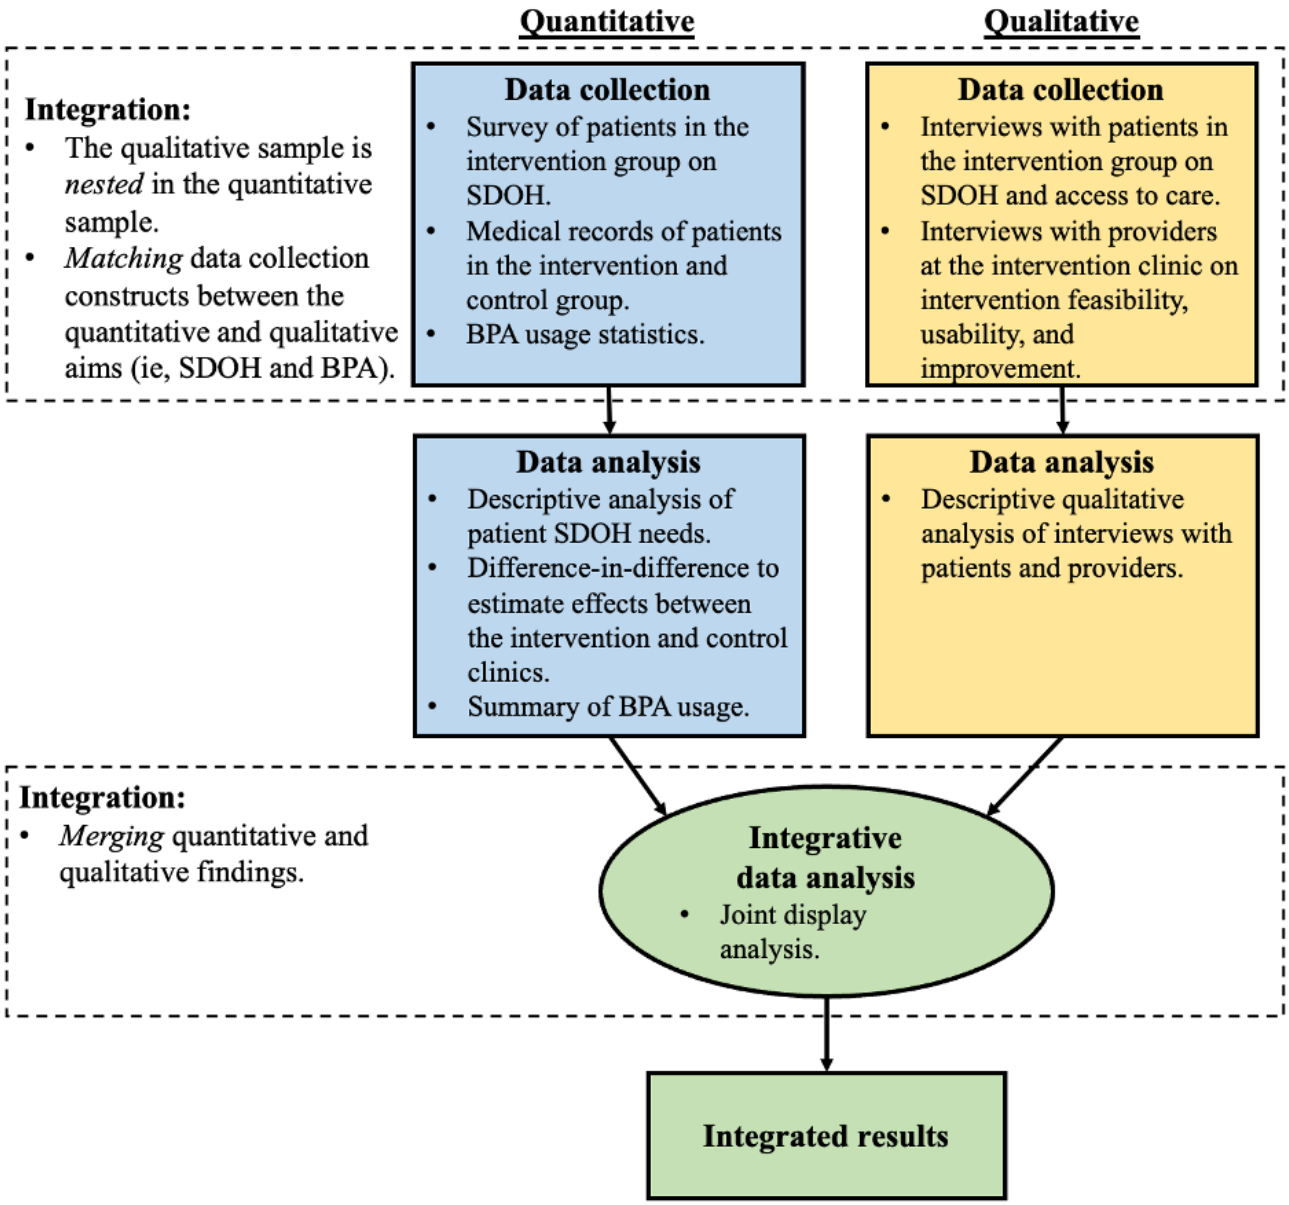
Introduction

People with disabilities make up approximately 26% (54 million) of the adult population in the United States [1]. Among this population, the most common disabilities are those that impact mobility [1]. Premature multimorbidity and adverse health events are more common among people with physical disabilities compared with the population norm [2-5]. Research shows that healthy aging is strongly influenced by patients' social, behavioral, and environmental variables [6-8]. However, patients' information on social and functional status factors is not systematically collected in health care, and therefore, these factors are not considered in medical decision-making aiming to promote healthy aging among this priority population.

There is evidence that primary care generates the largest ability to reduce illness and premature death, as well as providing more equitable health care in populations [9], yet little is known on how this can be achieved effectively for people with physical disabilities [10,11]. The Centers for Disease Control and Prevention (CDC), following the Forman-Hoffman et al [12] report, has provided suggested recommendations to address the existing gaps for individuals with disabilities. These actions include (1) providing a system in which people with physical disabilities at risk for adverse health events, including premature death, can be identified to proactively provide the care and social services that may be needed; (2) tailoring health care services, including health education and prevention, for people with physical disabilities whose needs differ from people without a disability [9]; (3) improving the inclusion of behavioral health interventions for people with physical disabilities; and (4) providing care management for people with physical disabilities by health care staff trained to work with this population [12].

This study aims to explore how care for people with physical disabilities can be fostered and improved through the implementation and comprehensive evaluation of a pilot integrated health program, which will include social support services. To do this, we will (1) design, pilot, and evaluate an accessible, integrated health program for people with physical disabilities at a primary care clinic within Michigan Medicine (ie, Briarwood Family Medicine), scalable for other integrated health centers, and (2) assess how the systematic collection of social and functional status information and use of this information by care managers may reduce adverse health events and improve the social and functional status of people with physical disabilities. Ultimately, our goal is to develop a protocol that provides guidance to other primary care clinics in need of improving the delivery of health care to people with physical disabilities. To our knowledge, this would be the first tailored best practice advisory (BPA) and health care-initiated social intervention designed for people with physical disabilities.

Methods



Study Design

Overview

This is a pilot intervention study using a convergent mixed methods design. For the quantitative analysis, we will use a quasi-experimental approach, enrolling participants from an intervention site into an integrated health program and using a control site with patients not enrolled in such a program for comparison purposes. Both the intervention and control sites will be separate ambulatory care clinics managed by Michigan Medicine's Department of Family Medicine. Both sites are located in Southeast Michigan. We will use qualitative methods to better understand social determinants of health among the patient cohort, as well as the perspectives of health care providers on the feasibility and usability of the proposed intervention. An overview of the study design is shown in Figure 1.

XSL•FO
RenderX

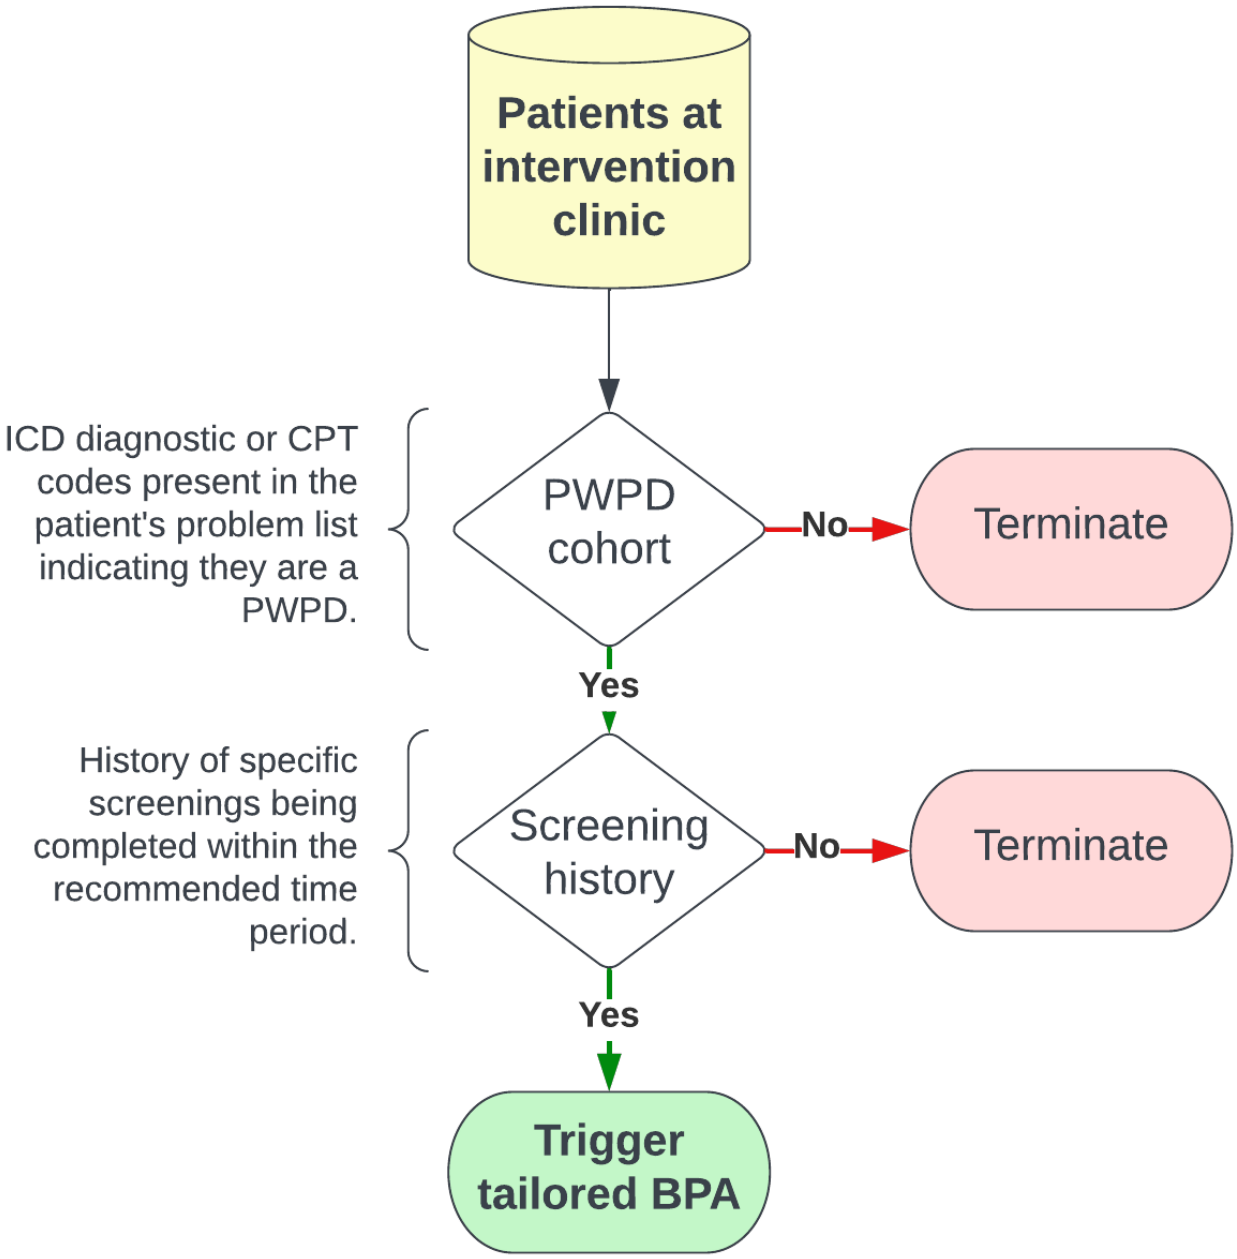
Figure 1. Overview of the pilot intervention study of an integrated care clinic for patients with physical disabilities. BPA: best practice advisory; SDOH: social determinants of health.

Intervention

The intervention is based on the paradigm of integrated health programs, which are designed to improve collaboration among primary care providers, social workers, and behavioral health specialists. The co-location of these health professionals at the same clinic allows for higher levels of patient care collaboration; for example, through primary care providers regularly having regular consultations with clinical social workers. This collaboration parallels institution-wide efforts at Michigan Medicine to improve service delivery and integrate medical, social, and behavioral health in a single clinic. This model has been successfully implemented to address significant behavioral health gaps for deaf and hard-of-hearing patients in the Michigan Medicine Family Medicine clinics [13,14].

The intervention has multiple components: (1) development and implementation of an electronic health record (EHR)–based alert to improve preventive screenings among people with physical disabilities; (2) training of providers on how to improve care for people with physical disabilities; and (3) inclusion of a specialized social worker with disability health training.

Clinical Decision Support Alert



We will use tailored BPAs in the EHR to provide clinical decision support to primary care providers of people with physical disabilities. This was based on a previously completed study using BPA that increased the rate of hearing screenings and audiology referrals at primary care clinics [15]. BPAs are a type of clinical decision support tool available in Michigan Medicine's Epic medical record software called MiChart. BPAs are activated in a patient's medical record when a patient meets eligibility criteria based on factors including diagnostic codes, procedure codes, quality indicators, or laboratory results. BPAs can be used by health care providers to more efficiently order or be reminded about screenings or immunizations. These tools can also aid in documenting medical decision-making. When this BPA is activated, the primary care provider will be

XSL•FO
RenderX

prompted to engage the patient to determine the applicability of the BPA by selecting one of the recommended actions or dismissing the alert.

The BPA for this intervention is designed to prompt preventive and screening services for which there are well-documented disparities for people with physical disabilities [16-18]: hemoglobin A_{1c}, bone density DEXA scan, lipid panel, laboratory panels (eg, basic metabolic panel), renal ultrasound, referral to a nutritionist, and referral to a specialized social worker with disability health training. A description of the BPA trigger conditions is available in Figure 2.

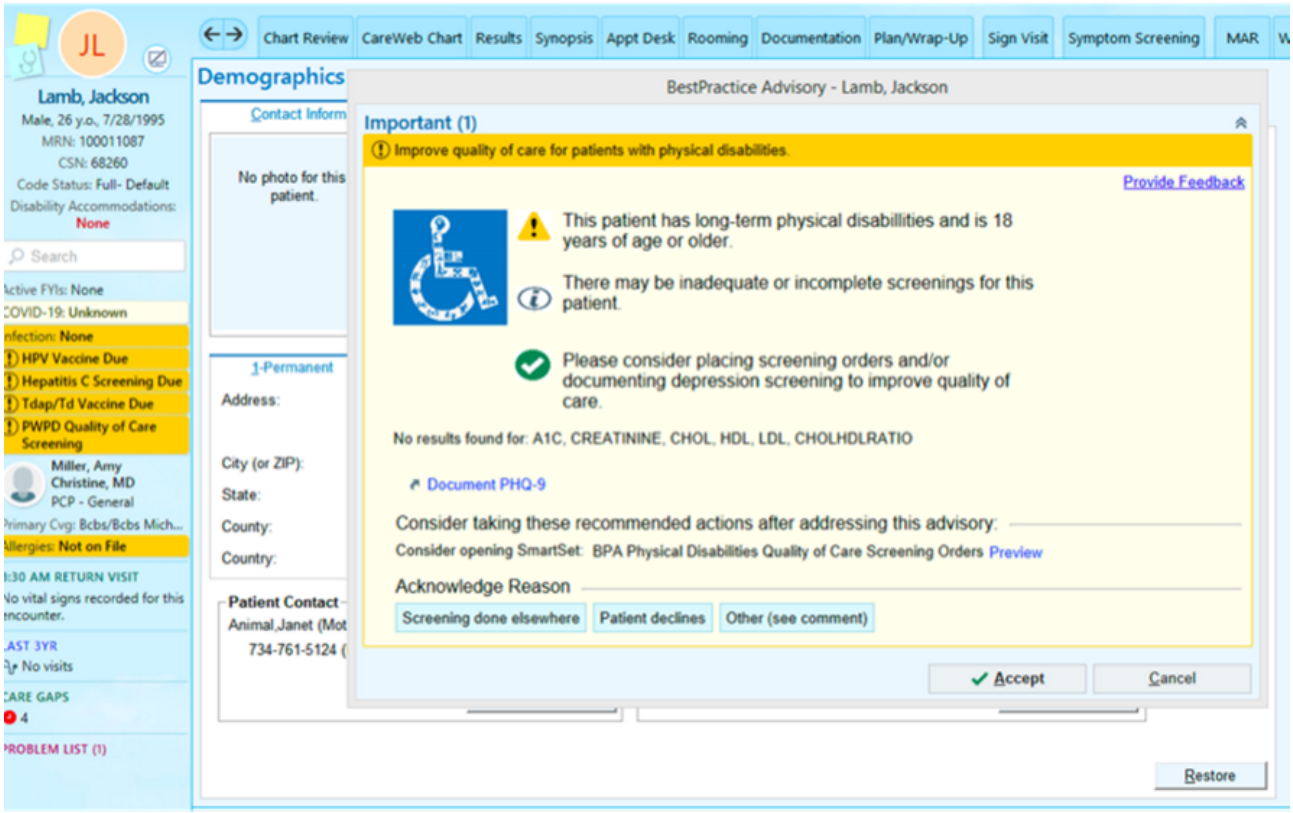


Figure 2. Flowchart of best practice advisory (BPA) activation triggers to improve preventive care for people with physical disabilities (PWPD). CPT: Current Procedural Terminology; ICD: International Classification of Disease.

When the BPA is activated for a specific patient, the alert will appear in their medical record in a yellow alert box on the main screen, along with the patient summary (left column; Figure 3). This alert remains active until it is acted on or dismissed by the provider. Available actions are “act on any of the suggested alerts,” “dismiss with an explanation” (eg, patient declines or already completed elsewhere), and “ignore.” Based on the provider’s recommendation and discussion with the patient, the provider can accept the SmartSet proposed by the BPA. The BPA will be pilot-tested by an Epic programming analyst with Michigan Medicine, TGJ, and MM before activation.

XSL•FO
RenderX

Figure 3. Screenshot of the best practice advisory to improve preventive care for people with physical disabilities (mock patient).

Provider Training and Communication

Primary care providers at the intervention clinic will be initially trained in intervention design to help reduce preventable causes of morbidity and improve functioning among people with physical disabilities. This training will be done before the implementation of the intervention and will be led by a family medicine clinician-scientist who is an expert in disability health. In addition, throughout the intervention, the research team will meet with the clinic director and other providers to communicate feedback and updates about the intervention.

Social Worker

Social work theory posits that an individual's health may be influenced by organic processes as well as by psychosocial factors in the environment [19]. Therefore, social workers at Michigan Medicine have historically been well integrated with clinics [14], providing case management services, advocacy, care management for maintenance of chronic health conditions, psychotherapy, and additional social support. The social worker for this intervention will work closely with the intervention clinic's primary care providers to provide additional support in addressing the health, behavioral, functional, and social needs of people with physical disabilities. Patients without any current identified needs will be monitored for any changes with annual BPA prompts.

Patients to be contacted by the social worker will be identified in two ways. Survey participants will complete the seven-item Generalized Anxiety Disorder Scale (GAD-7) and the Patient Health Questionnaire-9 (PHQ-9; Multimedia Appendix 1). The social worker will contact those who indicate moderate to severe anxiety or depression and assess the patient's need for mental health resources and psychotherapy. A MiChart referral to social work will be created and prepopulated with the following common reasons for referral: caregiver support; durable medical equipment and community referrals; grief and loss; guardianship and advance directives; home modifications; long-term planning; mental health and substance abuse concerns; safety concerns; violence and abuse; and other (with a comment field). Social work interventions will mostly be completed by phone.

Patient Cohort

People with physical disabilities will be identified using the International Classification of Disease, Ninth Revision (ICD-9) and International Classification of Disease, Tenth Revision (ICD-10) diagnostic and procedure codes from patients' problem lists in MiChart (Multimedia Appendix 2). The patient cohort at the intervention clinic will be patients who are identified as people with physical disabilities and who are patients at the intervention clinic (Briarwood Family Medicine). To create a quasi-experimental setting for our intervention, another primary care clinic in the same department will serve as a control clinic (Dexter Family Medicine).

Eligibility Criteria

All patients with identified physical disabilities, aged 18 years and older, will trigger the BPA. Using conservative estimates (eg, ICD-9 and ICD-10 codes with strongly associated physical disabilities in Multimedia Appendix 2), we identified 284 patients who were seen in the past 12 months before BPA implementation at the intervention clinic. The characteristics of the patients that were seen in the past 12 months at the intervention clinic were 166 (58.4%) female, 51 (18%) Black,

XSL•FO
RenderX

57 (20.1%) Medicaid insured, and 137 (48.2%) Medicare insured. A similar number of people with physical disabilities is anticipated to be identified in the control clinic.

Data Sources

Overview

This study will use multiple quantitative and qualitative data sources. The alignment of variables and constructs between quantitative and qualitative aims is provided in Textbox 1.

Textbox 1. Quantitative and qualitative data sources and related variables and constructs.

Michigan Medicine electronic health record

- General patient demographics
- Best practice advisory usage

Patient questionnaire

- General patient demographics
- Social needs
- Activities of daily living
- Depression and anxiety

Patient in-depth interviews

- General facilitators and barriers to accessing primary care
- Patient-provider communication
- Social needs

Provider in-depth interviews

- Implementation factors related to using the best practice advisory

Michigan Medicine Electric Medical Record (MiChart)

We will download structured clinical data, patient demographics, health care visits, diagnoses, procedures, laboratory orders, and results using the data warehouse at Michigan Medicine. We will also be able to capture the specific use of the BPAs for each patient. Textbox 2 summarizes the important domains that we will use in our analyses. Further, we will use an existing search algorithm [20] in the Electronic Medical Record Search Engine [21], to work with free-text and unstructured clinical documents in electronic medical records in order to identify influential social factors.

XSL•FO
RenderX

Textbox 2. Patient-related domains and variables in structured electronic medical record.

Sociodemographic

- Age
- Race and ethnicity
- Insurance and payor category
- Disadvantage and affluence index (derived from National Neighborhood Data Archive [21])

Most common comorbidities

- Driven based on International Classification of Diseases (Ninth Revision before October 2015 or Tenth Revision after October 2015) coding algorithms for Elixhauser comorbidities (29 conditions) from inpatient, outpatient, or emergency visits during the previous 12 months

Medication count

- 1-5
- 6-10
- 11-20
- >20

Use of agents

- Antithrombics
- Chemotherapeutics
- Hypoglycemics
- Insulins
- Narcotics
- Opioids, etc

Abnormal biomarkers

- High-density lipoprotein
- Hemoglobin A_{1c}
- Lactate dehydrogenase, etc

Patient Questionnaire

A short questionnaire (“Partners in Health”) will be prospectively collected from people with physical disabilities who meet our inclusion criteria at the time of the BPA implementation. The collected data are related to basic social needs (eg, ability to pay and social and family support; Multimedia Appendix 1).

Patient In-Depth Interviews

To understand barriers and facilitators to accessing primary health care among people with physical disabilities, we will recruit people with physical disabilities who complete the aforementioned patient questionnaire and consent to being recontacted for a one-hour interview. The interview will be semistructured, guided by an interview guide (Multimedia Appendix 3), and implemented by the intervention social worker (LC) or mixed methods methodologist (TGJ).

Provider In-Depth Interviews

Provider interviews will be conducted to understand usability, feasibility, and implementation constructs related to the use of the BPA alert. The interview guide (Multimedia Appendix 4) is informed by the Consolidated Framework of Implementation Research (CFIR) [22]. These interviews will be conducted by MM, a family medicine clinician-scientist, to aid in establishing rapport and trust.

Quantitative Analysis

Preliminary Analyses

Before being analyzed, the data will be explored to identify any missingness, which will be handled appropriately (eg, using imputation techniques or keeping complete cases only), based on its extent, impact on the sample size, and missing data pattern.

The characteristics of patients in the intervention group will be summarized using descriptive statistics. We will compare the characteristics of the intervention clinic with those of the control clinic and test for relevant associations using Student's *t* test or Wilcoxon signed-rank test for continuous variables and chi-square or Fisher exact tests for categorical variables as appropriate.

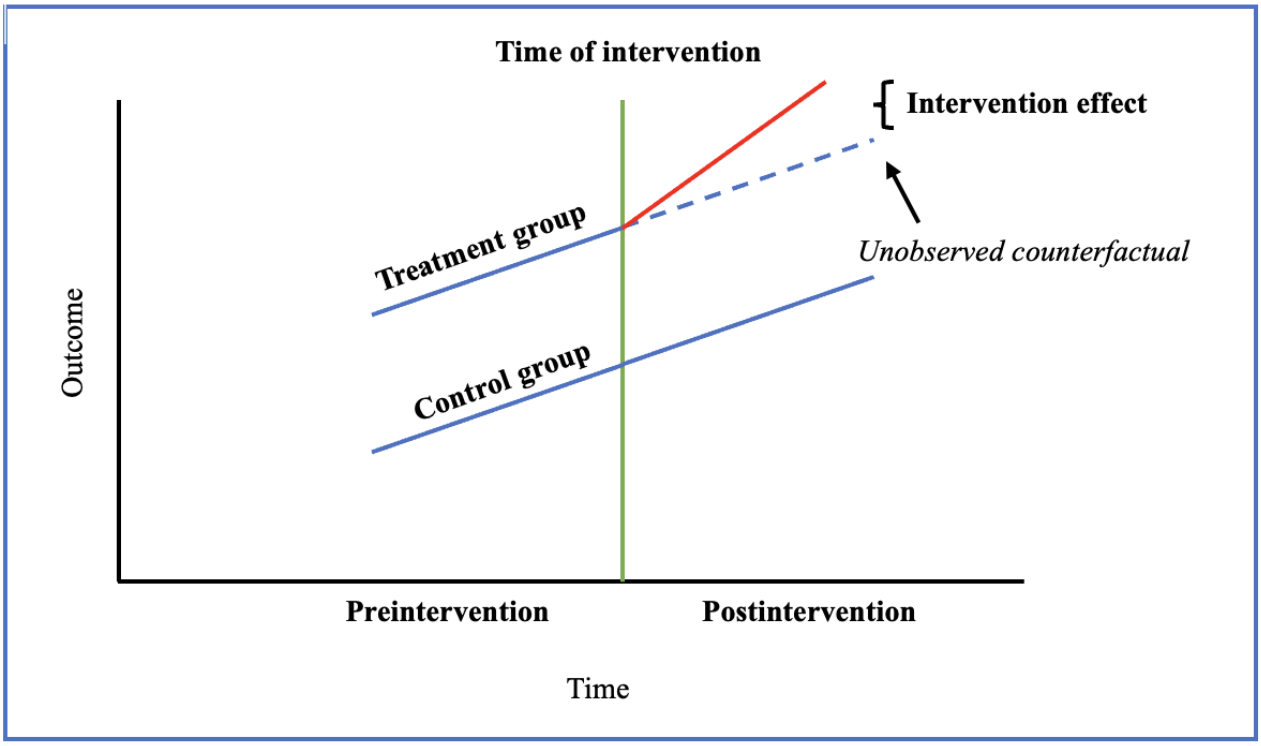
If this preliminary exploration of the full sample shows a lack of balance between the groups, we will apply inverse propensity

XSL•FO
RenderX

weighting to calculate a weight defined as the inverse probability of observing the given sample [23-25].

To verify the comparability of the intervention and the control sites, which is a key requirement for our quantitative intervention effectiveness analysis, we will also analyze data on the main outcomes of interest dating back to three years before the launch of the intervention.

In addition, preliminary analyses will also include summarizing the patient questionnaire data, mental health scores (GAD-7 and PHQ-9 overall scores), and BPA usage data. The questionnaire data will be described and may be merged with EHRs to be further used in qualitative analyses. The BPA usage data analysis will be used to investigate the (1) provider type acting on the BPA, (2) type of appointment when the BPA is firing, and (3) what actions were taken with respect to the BPA order.



Difference-in-Differences (DD) Intervention Effectiveness Analysis

The primary health–based outcomes assessed will be used for preventative services (eg, diabetes and lipid screening rates and hemoglobin A_{1c}) and the number of emergency room or hospital visits. The primary behavioral outcomes will be based on the changes in the PHQ-9 and GAD-7 overall scores before and after the intervention (after one month).

In order to evaluate the effect of the integrated health program on these outcomes, we model these outcomes using a DD approach [26]. DD is a statistical technique applied to longitudinal data that attempts to find a causal effect between an intervention and a control group in a quasi-experimental setting before and after a certain intervention is implemented. It assumes that, if the groups were similar based on observable characteristics and preintervention trends, any differences between them with respect to the outcomes of interest can be attributed to the intervention itself, rather than to systematic, preexisting differences. The average change in the outcome in each group is compared to estimate an average intervention effect for the intervention group (known as the average treatment effect for the treated).

The key assumption DD relies on is, thus, the presence of parallel trends; in the absence of the intervention, the treatment and control groups would continue to follow analogous trends with respect to the outcomes of interest. The postintervention, parallel trend in the intervention group would be an unobserved counterfactual path. Additionally, in the context of DD, particular attention to meeting the stable unit treatment value assumption is also required; the composition of treatment and control groups should remain stable over time to avoid spillover effects [9]. Figure 4 provides a simple graphical representation of the intervention effect and the parallel trend assumption.

Figure 4. Graphical representation of difference-in-differences approach's intervention effect and parallel trend assumption.

In the simple case of 2 time periods (1 pre- and 1 postintervention period), DD involves building a regression model with the following key predictors: a binary time covariate (before and after the intervention), a binary intervention covariate (treatment and control group), an interaction term between the 2 variables (ie, the DD estimator), and any time-varying covariates that may affect the outcome's trend over the observed time period without being themselves affected

XSL•FO
RenderX

by the intervention. Table S1 in Multimedia Appendix 5 outlines the list of outcomes and related models.

All statistical analyses will be performed using the software RStudio [27].

Qualitative Data Analysis

Qualitative data will be collected from the semistructured interviews with people with physical disabilities and primary care providers at the intervention clinic. Interviews will be audio-recorded to facilitate transcription by a Health Insurance Portability and Accountability Act (HIPAA)–compliant transcription service. Transcriptions will be imported into MAXQDA 2022 (Verbi Software) to conduct qualitative analysis.

The research team will code patient and provider interviews separately, as the codes that are developed will be different; provider interview questions are based on an implementation framework, while the patient interview questions are focused on quality of life and clinic access. The overarching qualitative strategy that will be used in this study is the qualitative description, as described by Sandelowski [28,29]. In qualitative description, the researchers seek to keep the analysis closely grounded in the participants' words while also using theory and conceptual models as appropriate.

A preliminary codebook will be developed through multiple members of the research team open-coding the same transcript from each group and meeting to discuss coding decisions. This process encourages a collaborative process of developing codes and code definitions across multiple coders who will independently code the transcripts. In addition, transcripts from the provider group will be coded using codes aligned with the CFIR [22]. Additional codes may be added to the codebook as the analysis progresses; in this case, the qualitative analysis team will meet to discuss the appropriateness of developing a new code, the name of the code, and its definition. Previous transcripts will be rereviewed to ensure the same codebook is applied to each transcript. Throughout the analysis, coders will be encouraged to memo transcripts with overarching thoughts, theme development, and other analytic insights [30].

Themes will be developed after the coding is complete. The research team will review the developed memos, code segments, and code relations, in addition to "focusing strategies" as described by Saldana [30]. For example, we will use the "touch test" to ensure that the developed themes are conceptually relevant and not just a description of a code.

Ethical Considerations

This study was approved by the University of Michigan institutional review board (HUM00189835). The project was given an exemption from the institutional review board because the information obtained from the survey is recorded in such a manner that the identity of the survey participants cannot readily be ascertained. The consent form included a statement that deidentified participant information may be shared in publications or for research purposes. There was a hybrid informed consent process. Paper consent forms and surveys were sent to all potential participants, which could be returned through an included envelope. Participants were also given the option to complete an electronic consent form and survey through Research Electronic Data Capture (REDCap). An incentive of US $2 cash was included with the mailed paper survey. Interview participants were given a gift card worth US $10 for their participation.

Results

The BPA was activated in the intervention clinic's EHR on September 16, 2021. The research team has had monthly meetings with the clinical director and the Department of Family Medicine's Director of Medical Informatics since implementation. The intervention patient cohort was sent the survey on May 5, 2022, and data collection for this source was completed on November 1, 2022.

Questionnaire data, including anxiety and depression overall scores (ie, GAD-7 and PHQ-9), and basic needs access (ie, "Partners in Health"; Multimedia Appendix 1), as well as BPA usage data, will be explored through descriptive statistics in the fall of 2023. Preliminary analyses to test assumptions about the comparability of the intervention and the control clinics will be conducted in late 2023 using data from the EHR, provided by the Michigan Medicine Data Office for Clinical and Translational Research. Interviews with people with physical disabilities were completed in December 2022, and formal data analysis will begin in the fall of 2023. During the spring and summer of 2023, we will meet with health care providers at the intervention clinic to conduct the semistructured interviews.

The results from our quantitative and qualitative analyses will be combined using mixed methods integrative data analysis [31,32]. These integrated results will be used to advance knowledge of best practices in the area of primary care and well-being for people with physical disabilities and pave the way for a more comprehensive and equitable approach to care for people with physical disabilities. Our findings will be submitted for publication in peer-reviewed journals once the study is completed.

Discussion

Overview

The quantitative results from the primary aim of this study, which is to measure the effectiveness of a pilot model clinic designed for people with physical disabilities, will advance knowledge on best practices for caring for a population that is disenfranchised in health care. Supplementing the primary findings with the aid of qualitative methods, our secondary focus on social support will allow us to explore the full extent of the role that an integrative approach can have in improving the health and well-being of people with physical disabilities. The integration of different data points will help determine if the intervention can be successfully implemented into a primary care setting. Second, it will help inform whether the intervention leads to (1) an improved use of tailored screening and monitoring needed for this population; (2) an increased social worker referral to assist with health and functioning needs related to their physical disabilities; and (3) reduced preventable

XSL•FO
RenderX

causes of morbidity and improved functioning among people with physical disabilities. Thus, the merit of a combined quantitative and qualitative approach in the particular context of researching and improving care for people with physical disabilities is that together these methodologies will allow us to explore both the measurable, physical impact of an integrated approach to care for people with physical disabilities and the less measurable, nuanced social, behavioral, and environmental factors, which are better captured in questionnaires and interview settings than chart abstraction.

The mixed methods findings of this study will be used to improve the proposed clinical model and identify further opportunities to develop a comprehensive protocol for primary care clinics to improve the care of people with physical disabilities. In line with previous literature observing the key impact of primary care and of people with physical disabilities' social, behavioral, and environmental factors on the health of people with physical disabilities [9], our uniquely integrated intervention has the potential to significantly advance care and preventive practices for people with physical disabilities. Integrated findings will also be used to improve the BPA. This protocol will also provide a framework for the actions recommended by the CDC to address the existing health care gaps for individuals with disabilities. The overarching clinical model, with recommended improvements, may be tested in future clinical trials.

Some of the major strengths that we anticipate for this study are the presence of a similar number of eligible patients with physical disabilities in the intervention and control sites, the sites being part of the same health group and based in the same geographic area, which facilitates comparisons and monitoring to prevent spillover effects, and the presence of all health professionals involved in the integrated health program within each site, which enables close collaboration during the implementation period.

Despite the considerable benefit of the knowledge gained from this study and the noted strengths, this study presents some possible limitations. DD, the main approach adopted to test intervention effectiveness, will allow us to estimate a causal effect only if its assumptions are satisfied. The assumptions that could represent the biggest threat to validity in our case are low between-group similarity, parallel trends preintervention, and stable group composition pre-post intervention (including, ideally, during the follow-up period). If required, we will attempt to address a lack of balance with respect to the covariates of interest through inverse propensity weighting and any potential failure to meet other DD assumptions by adopting alternative modeling methodologies.

In addition, the sample size in the qualitative aim is a potential risk. Adequate sample size, prolonged engagement, and participant trust are pivotal to ensuring the credibility of results [33]. To help address these factors, medical providers will be interviewed by a medical provider (MM), while interviews with patients will be conducted by a trained clinical social worker (LC) and a community-engaged, mixed methods research methodologist (TGJ).

Finally, because this is a pilot study, we are limiting its implementation to one intervention and one control site. While having more sites would provide us with a larger sample size and a stronger claim for external validity, trialing the intervention on a smaller, local scale will allow us to follow the program closely and develop it optimally, with the aim of expanding its scope in the future and working on a more extensive analysis.

Overall, this study will integrate findings from multiple data sources to best assess the feasibility and potential effectiveness of the proposed model clinic for primary care tailored to people with physical disabilities. Our findings will inform health care services for people with physical disabilities and lead to a more equitable paradigm with respect to primary care for people with physical disabilities.

Conclusions

Currently, there are no formal guidelines to ensure that people with physical disabilities, a particularly vulnerable population, receive appropriate, tailored care for their needs and susceptibility to premature multimorbidity and adverse health events. This is aggravated by the lack of available data on the social and functional context (known factors that contribute to healthy aging) of people with physical disabilities. Research that links all these aspects and tests effective solutions that can be feasibly scaled is crucial to changing this and establishing best practices. The results and protocol generated from this quasi-experimental study aim at achieving this in a robust manner, providing a contribution to the literature as well as making an impact on the national health system.

Acknowledgments

No artificial intelligence or generative language model was used to aid the development of this study or the preparation of this paper. This study is supported by funding from the National Institute on Disability, Independent Living, and Rehabilitation Research, under the Administration for Community Living of the US Department of Health and Human Services (award 90RTHF0001-01-00). Abstract

Background: Indigenous Australian children and adolescents experience profound levels of preventable dental disease. The application of silver fluoride (AgF) to active dental caries is a noninvasive alternative to traditional dental treatment approaches. There is particular utility among Indigenous children and young people with dental fear, who may not have access to timely or culturally safe dental service provisions.

Objective: The aims of this study are to: (1) assess levels of active dental caries among Indigenous children and young people in 6 Australian states and territories; (2) determine if an AgF intervention reduces levels of active disease over 12-24 months; (3) measure the impact of improved oral health on social and emotional well-being (SEWB) and oral health-related quality of life; and (4) calculate the cost-effectiveness of implementing such an initiative.

Methods: The study will use a 2-arm, parallel cluster randomized controlled trial design. Approximately 1140 Indigenous children and youth aged between 2 and 18 years will be recruited. Each state or territory will have 2 clusters. The intervention group will receive the AgF intervention at the start of the study, with the delayed intervention group receiving the AgF intervention 12 months after study commencement. The primary outcome will be the arrest of active carious lesions, with arrested caries defined as nonpenetration by a dental probe. Secondary outcomes will include SEWB, oral health-related quality of life, and dental anxiety, with covariates including dental behaviors (brushing and dental visits). Effectiveness measures for the economic evaluation will include the number of children and young people managed in primary oral health care without the need for specialist referral, changes in SEWB, the numbers and types of treatments provided, and caries increments.

Results: Participant recruitment will commence in May 2023. The first results are expected to be submitted for publication 1 year after a 24-month follow-up.

Conclusions: Our findings have the potential to change the way in which active dental disease among Indigenous children and young people can be managed through the inclusion of specifically tailored AgF applications to improve dental health and SEWB delivered by Indigenous health care workers. Desired impacts include cost savings on expensive dental treatments; improved SEWB, nutrition, social, and learning outcomes; and improved quality of life for both children and young people and their caregivers and the broader Indigenous community. The AgF application could be easily implemented into the training program of Indigenous health workers and yield critical information in the management armamentarium of health and well-being recommendations for Australia's First Peoples.

Introduction

Young Indigenous Australian Oral Health

Indigenous Australian children and adolescents experience profound levels of preventable dental disease [1]. These have an impact on Indigenous children's and young people's ability to eat, speak, socialize, and learn. It is a leading cause of child malnutrition, poor quality of life, and nonoptimal social and emotional well-being (SEWB) [2]. Trajectories of dental disease among Indigenous children and adolescents are increasing at a rate far greater than for non-Indigenous children and adolescents, with severe cases requiring care under a hospital-based general anesthetic [3]. Poor oral health in childhood is the leading cause of poor oral health in adulthood [4] and has associations with other systemic conditions, including diabetes, cardiovascular disease, and chronic kidney disease [5].

Dental Treatment Under General Anesthesia

Provision of dental care to young children can pose many challenges because of their emotional and physical development and lack of cooperation in the dental chair. The issues are multiplied for Indigenous children in rural and remote locations, where access to dental care is severely limited. Hospital-based treatment under general anesthesia is becoming an increasingly used mode of dental care for Indigenous children, with Australian Institute of Health and Welfare statistics showing that the rate of Indigenous Australian child admissions for dental treatment is twice that of non-Indigenous children [6]. However, dental treatment under general anesthesia does not prevent the occurrence of new dental decay, with children frequently readmitted for hospital-based dental general anesthesia after initial treatment [7]. Recent reports also suggest that oral rehabilitation under general anesthesia does little to alleviate dental fear or change noncooperative behavior and may, in fact, heighten these characteristics [8,9]. Moreover, comprehensive dental care under general anesthesia is not without risk, including the potential for long-term adverse neurodevelopmental effects [10-12]. Dental general anesthetics are extremely expensive for the taxpayer, the Australian health care system, and the community more broadly, and require considerable time and financial investments from carers (to transport the child to the hospital, stay overnight, ensure fasting before the operation, etc). The estimated mean cost of dental general anesthetics for Indigenous children is substantially higher than the cost of care for non-Indigenous children [10]. Treatment and preventive approaches that can be undertaken in Indigenous primary care settings to reduce the number of Indigenous children undergoing dental general anesthetics are thus urgently required.

Interventions to Improve Indigenous Children's Oral Health

In the past decade, there have been 4 published interventions aimed at reducing the burden of dental caries among Indigenous Australian children. Slade and colleagues [13] conducted a cluster randomized controlled trial of a dental health program that included the application of fluoride varnish to the teeth of Indigenous children aged between 18 and 47 months and dental education in 30 remote communities in the Northern territory. Although the study team reported reduced experience of dental disease among the intervention group compared with the control group, overall levels of dental disease at 2-year follow-up were extremely high, with 94% of children having experienced caries. Jamieson et al [14] conducted an early childhood caries intervention among Indigenous children and their families in South Australia, commencing during pregnancy and when children were aged 6, 12, and 18 months old. The intervention comprised dental care during pregnancy, fluoride varnish application to the teeth of children, anticipatory guidance, and motivational interviewing. At 5-year follow-up, children in the immediate intervention group had significantly less decay than those in the delayed intervention group (who received intervention at ages 2 to 3 years), but 47% of children still had experience of dental disease (Jamieson et al [14]). Smith et al [15] tested the effectiveness of a dental education program among young Indigenous children and their families from 8 Aboriginal Community Controlled Health Organizations (ACCHOs) in New South Wales. They reported that children in the education program had fewer dental caries at age 30 months than a comparator group drawn from the community, but the study did not follow standard randomization processes, meaning the conclusions are weakened (Smith et al [15]). Roberts-Thomson et al [16] used a silver fluoride (AgF) intervention among remote-dwelling Indigenous children and reported that children exposed to the intervention had less dental pain, dental extractions, use of antibiotics for dental infections, and fillings than children not exposed to the intervention. AgF was reportedly well accepted, easy to use, and at least as effective as conventional dental care (fillings and extractions). There were limitations, however, including a lack of robust randomization, only 2 trial sites included, only primary molar teeth included, a large loss to follow-up, and outcome measures not including specific assessments of dental caries or any patient-reported outcome measures such as oral health-related quality of life (OHRQoL), SEWB, and dental anxiety. As such, it has not been able to influence policy. A study that has more rigor (ie, is properly randomized), has a larger number of study sites (ie, more power in a statistical sense), uses explicit measures of dental caries (such as tooth surfaces with active dental decay), includes all present teeth, and comprehensively measures changes to SEWB, quality of life, and anxiety is urgently needed. Only then can we realistically expect policy

XSL•FO
RenderX

changes, with the ultimate goal being to introduce the treatment for adults as well.

What is Silver Fluoride and How Does it Prevent Dental Caries?

AgF is a cariostatic agent clinically applied to manage active dental caries to prevent further progression of disease. The fluid comprises 2 key therapeutic ingredients: silver and fluoride. The fluoride helps replenish the fluoride reservoir in the enamel (the outermost surface of the tooth) to ensure a robust crystalline structure and to promote the remineralization of carious lesions. Formulations of AgF at 38% present the highest concentration of fluoride (44,800 ppm F) among the available remineralizing agents—nearly twice the concentration of professionally applied fluoride varnish (22,600 ppm F) [17]. The silver acts as an antimicrobial agent, altering the composition of cariogenic biofilm within the dentine tubules of treated lesions (Sulyanto et al [18]). In contact with decalcified dentine, AgF forms insoluble silver microwires that block dentine tubules and contribute to the increased hardness of tissues [19]. AgF also has an inhibitory effect on matrix metalloproteinases involved in the degradation of collagen [20]. Unlike other modes of treatment for active dental caries, AgF may be applied by nondentally qualified staff, meaning the cost-benefit ratio is substantial [21]. Although it has been around for at least fifty years, the uptake of AgF has been limited because, under the old formulation, the active ingredient (silver) stained decalcified soft dentine black. However, the application of a potassium iodide solution immediately after the placement of AgF has been reported to reduce staining and improve aesthetic outcomes [22,23]. The World Health Organization has recently included AgF on the list of essential medicines for children [24].

Why is Economic Evaluation Important?

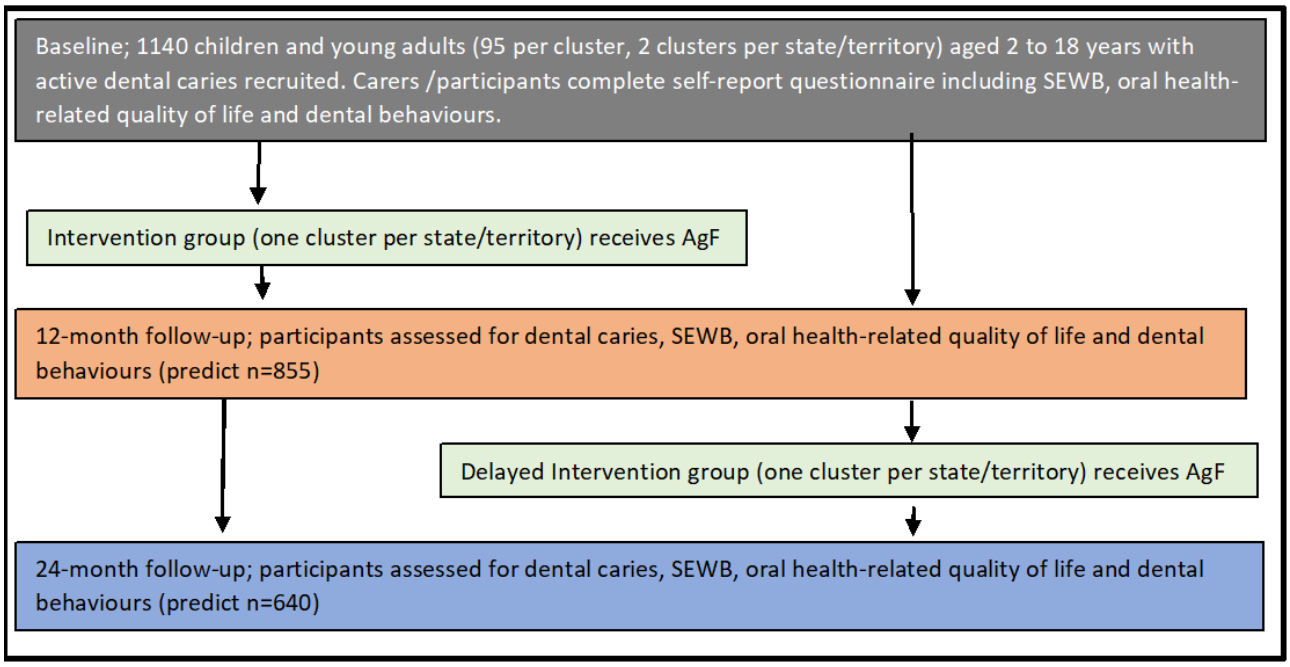
In Australia, the Pharmaceutical Benefit Advisory Committee and Medical Services Advisory Committee require evidence of cost effectiveness for their reimbursement decisions. As such, it is important to conduct an economic evaluation for any health intervention to ensure financial sustainability in addition to clinical effectiveness. Moreover, to convince state and federal health services to sustain the funding of a new health intervention, it is imperative to prove the cost-effectiveness of the program. In the broader scientific community, there is now an expectation that clinical trials evaluating medicines and procedures should additionally assess the economic value of such interventions [25]. This expectation reflects both interest in economic information for new technologies and the regulatory and reimbursement regimes that require evidence of economic value along with clinical efficacy before implementing policy change. Nowhere is this more critical than in the field of young Indigenous Australian dental care. Indigenous Australians experience a disproportionate burden of disease, which translates into a 30% higher cost of health care delivery per capita for Indigenous populations compared to the general population [26]. Any demonstration of the cost-effectiveness of a dental care intervention over standard care is going to be of benefit to not only Indigenous children receiving the intervention but also to taxpayers contributing to the health care budget. To the best of our knowledge, there have been few evaluations of the cost-effectiveness of child dental caries interventions. The only one within the Indigenous child dental space was evaluated by Kularatna et al [27], with economic evaluations of dental health interventions per se being scarce.

Most ACCHOs in regional and remote locations in Australia are unable to provide dental care, yet they recognize that these services are critically important [28]. AgF can be applied by nondental personnel in home environments with minimal cost and equipment. This means AgF implementation, uptake, and cultural acceptability are superior to many other expensive health service models delivered by non-Indigenous staff.

The aims of this study are to (1) assess levels of active dental caries among Indigenous children and young people in 6 Australian states and territories; (2) determine if an AgF intervention reduces levels of active disease over 12-24 months; (3) measure the impact of improved oral health on SEWB and OHRQoL; and (4) calculate the cost-effectiveness of implementing such an initiative.

Methods

Overview



This is an Indigenous-led project conducted in partnership with ACCHOs across 6 states or territories in Australia. Meaningful and respectful engagement with ACCHOs ensures Indigenous self-determination and culturally appropriate research practices for the context of each Indigenous community throughout all stages of the study.

Study Design

The study will use a 2-arm, parallel, matched-paired cluster randomized controlled trial design with 2 study sites (clusters) in each partnering state and territory (Figure 1). The intervention group will receive the AgF intervention at the start of the study, with the delayed intervention group receiving the AgF intervention 12 months after study commencement.

XSL•FO
RenderX

Figure 1. Study plan schema. AgF: silver fluoride; SEWB: social and emotional well-being.

Inclusion Criteria

Indigenous children and young adults aged between 2 and 18 years with active carious lesions (nonpulpally involved) in the primary or permanent dentition residing in selected study clusters will be eligible. Caregivers or participants who are unable to provide written informed consent, participants with a history of allergy to silver, or those presenting oral ulceration will be excluded. At the tooth level, symptomatic or pulpally involved teeth (pulp exposure, presence of an abscess or fistula, obvious discoloration indicative of pulp necrosis, or premature hypermobility) will be excluded from receiving the intervention.

Randomization

The randomization schedule will be developed by biostatisticians at the Australian Research Centre for Population Oral Health, who will not be involved in the trial, using a computer-generated block-randomized algorithm. The random allocation will be 1:1 per state and territory; that is, 1 cluster per state or territory will be randomly allocated as the intervention site, leaving the other cluster to be the delayed intervention site. Randomization will be done before baseline fieldwork. Field staff will have no access to the randomization algorithm, thus allowing the randomization process to be audited.

Participant Recruitment

We will adopt recruitment strategies that have been successfully applied in our wide body of research with Indigenous communities across Australia and that build upon the extensive community consultation processes that have already been undertaken for the proposed study. We will employ local Indigenous people as research assistants to continue to facilitate community engagement and participant recruitment. These research assistants will, in turn, be guided by senior Indigenous project officers. All participants at baseline will receive a clinical dental examination by a calibrated dental examiner, with participants aged 15 years or older or caregivers asked to complete a baseline questionnaire containing items on SEWB, oral health-related quality of life, dental behaviors, and sociodemographic characteristics. Participants in the delayed intervention cluster will be able to access standard dental care during the first 12 months of the study at their own volition.

Reimbursement for Time

As per our standard procedures for participants involved in health research projects, all participants will receive an Aus $20 (US $15) gift voucher as a reimbursement for their time at both the initial recruitment and 12- and 24-month follow-ups. Each participant will additionally receive a sample bag of oral and general health-related items at baseline, including fluoridated toothpaste and toothbrushes.

Intervention

After cleaning teeth with dry gauze and drying the cavities with cotton pellets, dentally qualified research officers will apply 38% AgF (Riva Star Aqua Step 1, Southern Dental Industries Ltd) to sites of active caries in the primary and permanent dentition using a microbrush applicator and keeping the solution in contact with the lesion for 60 seconds. No attempts will be made to remove soft dentine. Potassium iodide (Riva Star Aqua Step 2, Sothern Dental Industries Ltd) will be applied immediately after Riva Star Aqua Step 1 until the white precipitate is clear, signaling that all free silver ions have reacted with the potassium iodide. Petroleum jelly will be applied to the lips and gingival mucosa to avoid direct contact of AgF with soft tissues. Participants will be instructed to refrain from drinking, eating, or rinsing their mouths for at least thirty minutes. A single AgF application will occur at the baseline visit for the immediate intervention clusters and at the 12-month follow-up for the delayed intervention clusters. Any participants requiring additional dental treatment at the baseline, 12-month,

XSL•FO
RenderX

or 24-month follow-ups will be referred for standard dental care to the local dental service provider.

Outcomes

The primary outcome will be the arrest of carious lesions in the dentition, with arrested caries defined as nonpenetration by a dental probe. Secondary outcomes will include SEWB, OHRQoL, dental anxiety, and dental behaviors. A SEWB measure has been developed by our team based on community consultation, item polling, and a theoretical framework that identified six core SEWB domains for Indigenous Australian youths: (1) feeling empowered; (2) feeling strong in my body; (3) feeling loved and safe; (4) feeling resilient; (5) feeling strong in my mind; and (6) feeling strong in my identity. OHRQoL will be assessed using the Caries Impacts and Experiences Questionnaire [29], which we have validated and successfully implemented in other studies involving Indigenous Australian children [30]. Dental anxiety will be assessed using the Child Dental Anxiety and Scale [31], modified to capture anxiety from adolescent participants, which we have also validated and implemented in studies involving Indigenous children [30]. Behaviors will be assessed using items from the 2012-2014 National Child Oral Health Survey [1]. These will include participant age when commenced tooth brushing, tooth brushing frequency, use of fluoride toothpaste, last time participant saw an oral health care provider, usual reason for participant to visit an oral health care provider, and consumption of sugar-sweetened beverages and foods.

Effectiveness measures for the economic evaluation will include the number of children and young people managed in primary oral health care without the need for specialist referral, changes in SEWB, the numbers and types of treatments provided, and caries increments. A cost-utility analysis will be undertaken using the recently developed dental caries utility index for adolescents [32] and ECOHIS-4D to measure the utility values of the health states experienced by children and young people [33].

Oral Epidemiological Examinations

Caries experience will be collected through standardized oral epidemiological examinations by calibrated dental examiners. Didactic and clinical training for the examination teams will be conducted before baseline data collection, with refresher sessions provided during the fieldwork phase. Examinations will be in participants' homes, ACCHOs, schools, or wherever the caregiver, child, or young person feels most comfortable. All examiners will be tested in the field against the senior trainer to estimate interexaminer reliability. Intraclass correlation coefficients for caries assessment scores will be used to assess reliability.

Sample Size Calculation

Based on the literature, in which approximately 81% of carious lesions were estimated to have been arrested with AgF [34], the community intracluster correlation was calculated as 0.09. Using these parameters at 80% power, α=.05, and 12 clusters available (6 clusters per treatment arm), the estimated sample size required is 320 in each arm. Allowing for a 25% loss to follow-up each year, the estimated sample size is 570 per arm, or 95 children and adolescents per cluster (rounded up). Sample size estimations were undertaken on STATA 15 (StataCorp) using the commands for cluster randomized trials for proportions of caries arrest.

Data Analysis

The trial has been registered in the Australian and New Zealand Clinical Trials Registry (ACTRN12622001066774p). All analysis will be reported according to CONSORT (Consolidated Standards of Reporting Trials) guidelines. Data analysis will use intention-to-treat approaches, with standard imputation measures used to manage missing data. The analysis plan for each aim is as follows.

Aim 1 (severity of dental disease in young Indigenous Australians): the severity of dental disease will be calculated using the decayed, missing, and filled tooth surface index (dmfs/DMFS) for the primary and permanent dentition. The 2014-2016 National Child Oral Health Survey will enable comparison with both general and Indigenous population-level estimates [1]. General analysis will comprise the chi-square and 1-tailed Student *t* tests within the study sample and a nonoverlapping 95% CI when comparing with population estimates.

Aim 2 (changes in dental disease following AgF intervention): the trial will be analyzed on an intention-to-treat basis according to group allocation. Generalized linear mixed models will be performed to determine differences in the primary outcome (arrest in dental caries) between the 2 groups and over time when the outcome is continuous. For binary outcomes, general estimating equations with the log binomial family will be used [35].

Aim 3 (economic evaluation of the intervention): the cost-effectiveness of the intervention will be estimated using standard approaches from a health provider perspective. Effectiveness measures will include quality of life and utility indicators. A literature review will inform long-term cost savings to the health system by improving Indigenous children's and young people's experiences of dental disease. The usual method of determining the cost effectiveness of a health intervention is by estimating the incremental cost effectiveness ratio, the ratio between the incremental cost and the incremental outcome. Incremental cost is the cost difference between the intervention and usual care, while incremental outcome is the outcome difference between the intervention and usual care. The economic evaluation will compare any incremental costs of the intervention (costs accrued in the intervention arm compared to those in the delayed intervention arm) to the full list of incremental primary and secondary outcome endpoints, all expressed in their natural units of measurement. Costs will be measured from activity data with pathway analysis to fully specify all activities in both the immediate and delayed intervention arms. Resource use will be obtained from research and provider records. Measured resource use will be valued using both existing estimates of the costs of each unit of resource use from market prices and the Medicare fee rates. Intervention costs will exclude research project costs. Standard discounting will be applied to both costs and outcomes, with uncertainty in these data subjected to sensitivity analyses.

XSL•FO
RenderX

Ethical Considerations

Ethics approval (number 04-22-1013) has been obtained from the Aboriginal Health Council of South Australia Human Research Ethics Committee, the University of Adelaide Human Research Ethics Committee, the Human Research Ethics Committee of the Northern Territory Department of Health and Menzies School of Health Research, the Far North Queensland Human Research Ethics Committee, the Aboriginal Health and Medical Research Council of New South Wales Human Research Ethics Committee, the Australian Institute of Aboriginal and Torres Strait Islander Studies Human Research Ethics Committee, and the Western Australian Aboriginal Health Ethics Committee. Before being recruited, all participants will be required to sign an informed consent form, which includes consent for the authors to publish the findings in the peer-reviewed scientific literature. All authors are named investigators on the project; they all contributed to the intellectual input of the study design and in writing this protocol.

Results

Participant recruitment for this study commenced in May 2023, and up until September 2023, around 540 children and young adults have been recruited. We anticipate the first results to be submitted for publication 2 years following initial recruitment.

Discussion

What are the Views of the Indigenous Community About the Study?

Feedback from multiple Indigenous participants in our current studies reveals that poor access to dental services is a key barrier to achieving optimal health. Many participants should be in the prime of their lives, yet ongoing concerns about their oral health are impacting important life decisions (eg, shame about poor oral health prevented one from singing in a television documentary, while embarrassment about bad breath prevented another from attending a job interview). These inequities begin in early childhood, with Indigenous children as young as 2 years old in some communities requiring all teeth to be removed under a hospital-based general anesthetic because of advanced dental decay.

Why is This Study Important?

Despite the unacceptable poor oral health experienced by many Indigenous children and young people in regional and remote locations, there have been few interventions developed using culturally safe methodologies for improving oral health using low-cost approaches that are non–resource-intensive. Consequently, the management arsenal available to reduce the incidence of active dental decay among Indigenous children and young people that does not involve extensive restorative care (needles, drilling, and filling) is limited. The proposed study will investigate a novel use (AgF) for a potentially widely available public health service with which every health professional can become familiar. Currently, AgF is the only nonsurgical therapeutic option for the management of active dental caries. Our results may provide evidence for decision makers to make informed resource allocations in Indigenous oral health, which impacts both SEWB and health-related quality of life. This is especially necessary in the ACCHO sector.

Strengths and Limitations

This study will test the hypothesis that Indigenous children and young people in 6 Australian states and territories can be provided with appropriate dental care in local Indigenous settings using the AgF approach without specialist intervention and avoiding the need for treatment under hospital-based general anesthesia. This study has six major strengths: (1) it will evaluate the and severity of dental disease in Indigenous children and young people in 6 states and territories; (2) it will test the efficacy of a simple and culturally safe AgF initiative, which could be easily implemented into the training program of Indigenous Health Workers to be included in their remit of care; (3) we will have capacity to comprehensively assess the cost-effectiveness of the intervention, meaning uptake into clinical guidelines will be much swifter than if no cost-effective analysis was undertaken; (4) the intervention will likely lead to SEWB improvements in Indigenous children and young people; an important strategic priority given current commitments to improving child health and well-being, with the Australian Government launching, in October 2021, the world's first National Children's Mental Health and Well-Being Strategy [36]; (5) we have engaged and consulted considerably with participating ACCHOs, using their feedback to shape the research questions and; (6) our researchers are world-class experts in their respective specialties and have experience working with Indigenous child and adolescent populations. Limitations include operationalizing a national-level trial while COVID-19 is still present and assessing active dental caries by clinical examination only (no use of radiographs). Conducting a clinical trial in challenging contexts and following the cultural protocols of local Indigenous communities prevents us from blinding study participants.

In conclusion, our findings have the potential to change the way in which the oral health of Indigenous children and young people is managed, with desired impacts including cost savings on expensive dental treatments, improved SEWB, nutrition, social, and learning outcomes, and improved quality of life for both children and young people and their caregivers and the broader Indigenous community. This study addresses priorities raised in the National Aboriginal and Torres Strait Islander Health Plan 2013-2023 [37], particularly in regard to increasing understanding of Indigenous health issues at a community level, improving public health measures that address Indigenous health, and facilitating the collection of Indigenous health data.

Acknowledgments

This study's funding is from a National Health and Medical Research Council project grant (APP2016532). LMJ is supported by a National Health and Medical Research Council research fellowship (APP1102587).

Abstract

Background: Though rates of tobacco smoking have decreased consistently over the past 3 decades, cigarette use remains the top preventable cause of premature death in North America. The Clinical Effort Against Secondhand Smoke Exposure (CEASE) is a medical clinic-based intervention that systematically screens parents for tobacco use and offers them direct access to evidence-based smoking cessation services. While the effectiveness of CEASE for parents who smoke has already been demonstrated in the United States, the CEASE model has not yet been tested in Canada, among parents who use e-cigarettes, or among adolescents who use cigarettes and e-cigarettes.

Objective: We aim to demonstrate the feasibility and evaluate the preliminary effectiveness of the CEASE program for parental smoking cessation and its adapted version for adolescent smoking cessation and adolescent and parental vaping cessation.

Methods: We will approach parents or guardians of children aged between 0 and 17 years, as well as adolescent patients aged between 14 and 17 years, from a tertiary care pediatric hospital in Montreal, Quebec, Canada, for participation in this single-blinded, pilot randomized controlled trial. Eligible participants are those who report using tobacco cigarettes or e-cigarettes at least once in the last 7 days and present to an outpatient pediatric clinic for a scheduled appointment. Our recruitment target is 100 participants: 50 parents or guardians of children aged 17 years or younger, and 50 adolescents aged between 14 and 17 years. The feasibility of implementation of the CEASE model will be measured by recruitment and retention rates for all 4 participant groups (stratified as follows: parents who use cigarettes, parents who use e-cigarettes exclusively, adolescents who use cigarettes, and adolescents who use e-cigarettes exclusively). Parent and adolescent participants within each group are randomized to the intervention and control groups using a 1:1 ratio through a computer-generated randomization list. Preliminary effectiveness outcomes include self-reported smoking and e-cigarette cessation, use of cessation resources, changes in smoking and e-cigarette use, motivation to quit, and quit attempts among participants. Participants complete electronic questionnaires on a tablet in the clinic at baseline as well as electronic follow-up questionnaires at 1, 3, and 6 months. Individuals reporting successful quit attempts are invited to provide a urine sample for cotinine testing to biochemically confirm quit. Analyses include descriptive statistics as well as exploratory trajectory analyses of smoking, e-cigarette use, and motivation to quit.

XSL•FO
RenderX

Results: Research activities began in June 2022. Participant enrollment and data collection began in February 2023 and are expected to be completed in 15 months.

Conclusions: There is a strong need for effective and cost-effective smoking and vaping cessation interventions for parents and adolescents. If successful, this study will help inform the preparation of a fully powered randomized controlled trial of CEASE in Canada in these populations.

Introduction

Tobacco use is the single greatest preventable cause of morbidity and mortality in Canada, accounting for 48,000 deaths and CAD $16.2 billion (US $11.9 billion) in attributable health-related costs annually [1,2]. Smoking is a significant risk factor for multiple cancers [3] as well as cardiovascular diseases [4], thus shortening the life expectancy of smokers who initiate during adolescence by more than 10 years [4]. Despite parental smoking being an important risk factor for child initiation of tobacco (children of parents who smoke have 4-fold greater odds of becoming smokers when compared with children of nonsmoking parents) as well as for the development of several illnesses, such as bronchiolitis, asthma exacerbations, and pneumonia [5], about 15% of Canadian children are still exposed to household secondhand smoke [6]. Parents are thus an important target for smoking cessation interventions to improve their own health and protect that of their children and future generations. Given that 90% of smokers start smoking before the age of 18 years [7], adolescence represents a critical period to intervene in the fight against smoking [8].

Smoking among adolescents and young adults remains common despite rates decreasing over the past 3 decades, and adolescent use of nicotine-containing e-cigarettes (hereafter referred to as e-cigarettes) has shown a worrying increase over the past 10 years [9]. Most adults who use e-cigarettes (e-cigarette use is referred to interchangeably with vaping) do not have a history of tobacco use; however, once vaping has been initiated, the risk of subsequent tobacco, alcohol, and drug use increases [9]. Commonly used e-cigarettes usually contain high concentrations of nicotine, and while potentially effective for adult smoking cessation [10], they are not effective for youth smoking cessation and should not be recommended in this population [11].

In 2019, more than half of smokers in Canada (57.9%) reported seriously considering quitting in the next 6 months, and 26.9% were considering doing so in the next month [12]. Similarly, the majority of adults and adolescents who use e-cigarettes report that they intend to quit vaping [13,14]. Individuals trying to quit without behavioral support or smoking cessation medication (eg, nicotine replacement therapy [NRT]) can face great challenges due to nicotine's addictive nature and severe psychological and physical withdrawal symptoms [3]. Several evidence-based smoking cessation interventions exist, including behavioral and pharmacological treatments that can be used alone or in combination [15], which greatly increase the odds of successfully quitting [16], and even more so when behavioral and pharmacological (NRT) interventions are combined [17]. Behavioral support traditionally refers to counseling; however, newer modalities, such as SMS text messages and app-based interventions, have shown promise [16] and would provide individuals with personalized, accessible behavioral support in quitting at low to no cost.

Health care providers can enhance the success of quit attempts by offering assistance and facilitating access to smoking cessation interventions [18]. Through their regular contact with families, pediatric health care providers are in a unique position to assist parents and adolescents in quitting smoking and vaping. However, studies and clinical experience show that pediatric health care providers rarely capitalize on this opportunity [19]. Lack of time, lower perceived priority of smoking or e-cigarette cessation relative to other care, fear of upsetting families, and lack of perceived efficacy are among the reasons why this type of intervention is rarely provided [20]. Digital preappointment screening questionnaires to identify individuals who smoke or vape and connect them with existing resources are a promising avenue to deliver cessation interventions in pediatric clinics [21]. This approach is well-accepted by patients and health care providers [21].

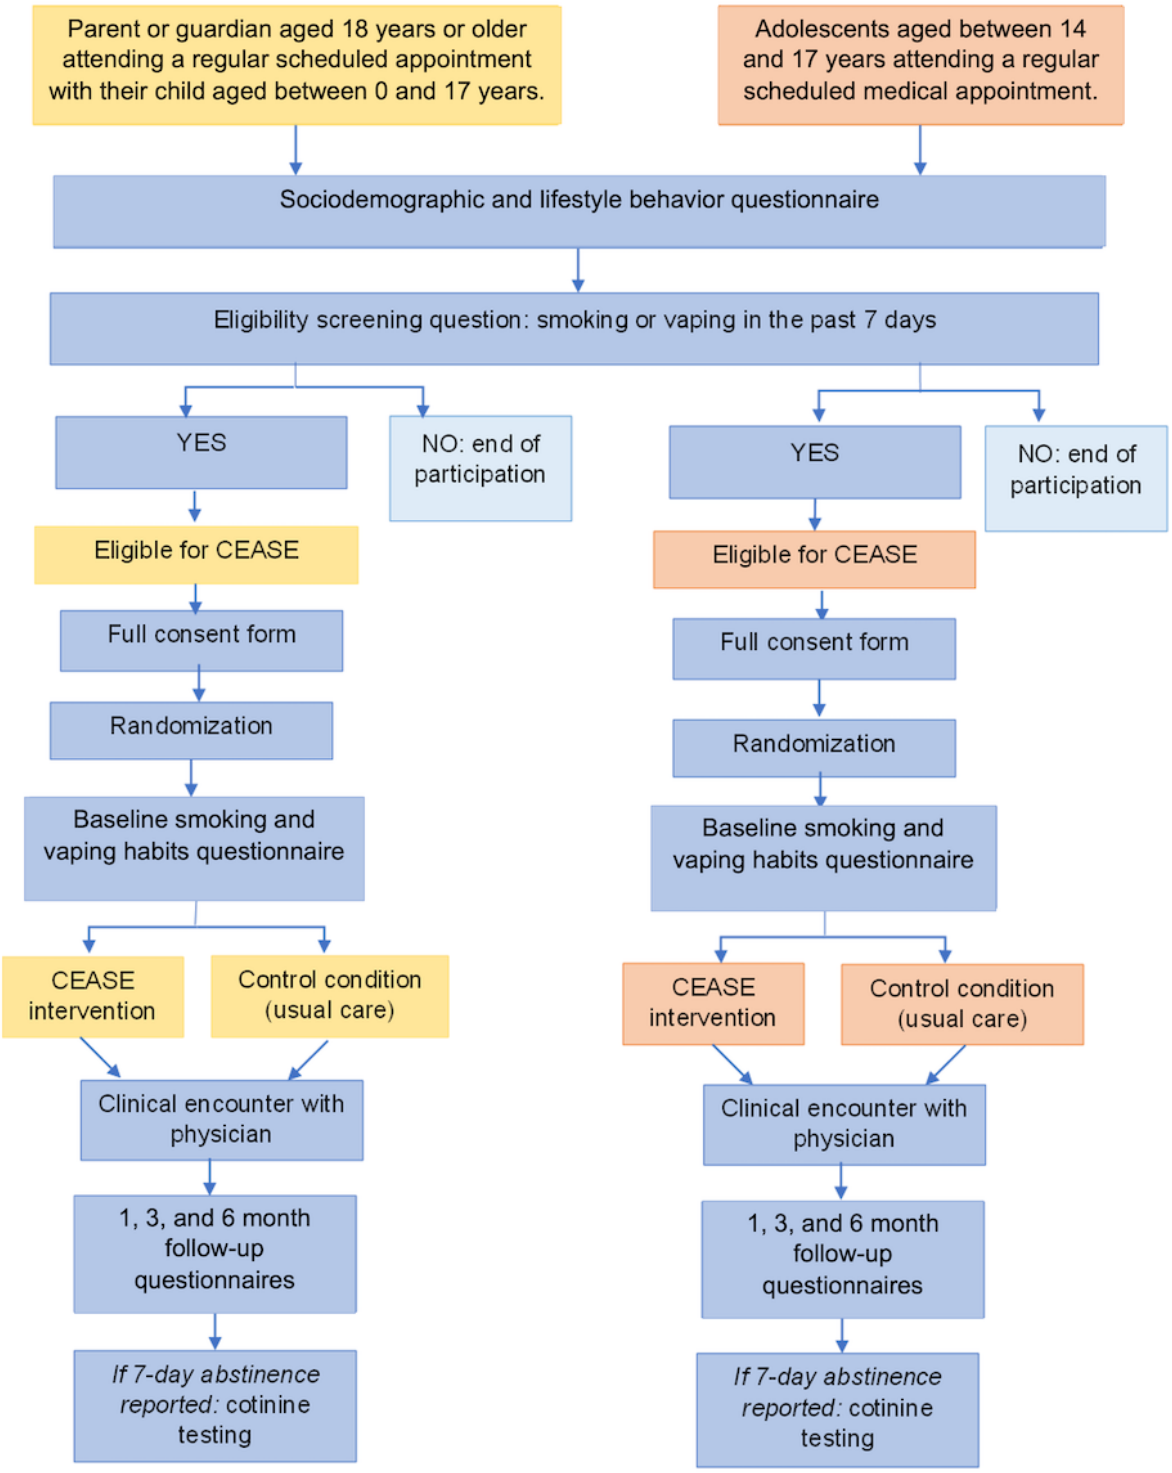
The Clinical Effort Against Secondhand Smoke Exposure (CEASE) intervention is an effective and cost-effective medical clinic-based intervention that systematically screens parents for tobacco use and offers them direct access to evidence-based smoking cessation services [22,23]. The model has been studied in the United States with promising results. A cluster randomized trial showed a 3.7% decrease in smoking prevalence between the intervention and control groups over a 2-year observation period (2.7% decrease in smoking rates in the intervention group vs 1.1% increase in the control group; difference –3.7%, 95% CI –6.3% to –1.2%; [23]). Cost-effectiveness data from Drouin et al [22] also showed that the incremental cost per quit (among adult participants who smoked) was US $1132 compared with usual care, a much lower figure than other clinical care-based smoking cessation interventions.

The primary objectives of this pilot randomized controlled trial of CEASE are to demonstrate the feasibility and preliminary effectiveness of CEASE for adults who smoke tobacco and its adapted version for parents with e-cigarette use and adolescents

XSL•FO
RenderX

with cigarette and e-cigarette use in Canada. This pilot trial seeks to accomplish the following three aims: (1) evaluate the feasibility and effectiveness of the CEASE model in the Canadian setting, which differs from the United States in pediatricians' scope of practice, financial incentives for physicians, and insurance coverage for NRT [24]; (2) address the gaps in knowledge regarding vaping cessation, for which many professional societies recommend using similar cessation tactics, strategies, and resources as with regular tobacco cigarettes [11,25]; and (3) validate the feasibility of recruiting participants in proposed sites of care (hospital-based pediatric clinics) and obtaining data on quit interest and intent in this population.

This pilot randomized controlled trial of CEASE in Canada aims to answer these questions by recruiting parent and adolescent participants from hospital-based pediatric clinics and randomizing them to the CEASE program or usual care.



Methods

Study Design, Setting, and Participants

This is a single-center, pragmatic, single-blind, pilot randomized controlled trial comparing the CEASE intervention to usual care (control condition). Participants will be recruited over a 9-month period and followed for 6 months (15-month study period). Figure 1 shows the study flow diagram. This study is being conducted in various clinics within the Sainte-Justine University Hospital Centre, (Montreal, Quebec, Canada), including the general pediatrics clinic, the adolescent medicine clinic, and the orthopedics and sports medicine clinics.

XSL•FO
RenderX

Figure 1. Study flow diagram illustrating participant trajectory through study of a brief digital screening and intervention tool for parental and adolescent tobacco and electronic cigarette use. CEASE: Clinical Effort Against Secondhand Smoke Exposure.

The recruitment target is 100 individuals who report using tobacco or e-cigarettes (either tobacco or e-cigarettes alone, or both tobacco and e-cigarettes) in the 7 days before responding to the study questionnaire. A minimum of 50 parents and 50 adolescents will be recruited.

The study will be reported according to the Strengthening the Reporting of Observational Studies in Epidemiology Statement: Guidelines for Reporting Observational Studies [26].

Recruitment

The appointment schedules of participating clinics will be reviewed the week before by the research team, and a recruitment schedule will be made according to the clinical volume of each clinic to maximize the number of potential patients approached. At the time of registration for their scheduled appointment, parents or legal guardians (hereafter referred to as parents) of children aged between 0 and 17 years

XSL•FO
RenderX

as well as adolescents aged between 14 and 17 years are approached by a research assistant in the clinic waiting room to complete the screening survey on an electronic tablet. The survey is preceded by an abbreviated consent form. This approach is similar to that which was successfully used in CEASE studies in pediatric primary care in the United States [23]. Parents and adolescents are asked sociodemographic, smoking, and e-cigarette screening questions (see "Inclusion and Exclusion Criteria" section). Participants who respond "yes" to at least 1 of the 2 screening questions are invited to participate in the CEASE pilot study and have access to the full consent form. These forms are available in the Multimedia Appendix 1. During the entire study period, research assistants keep a detailed recruitment log, including information on participant screening, eligibility, recruitment, randomization, and retention in the study.

Inclusion and Exclusion Criteria

Inclusion Criteria

Parents of children aged between 0 and 17 years who smoke cigarettes or use nicotine-containing e-cigarettes. Users are defined as those who answer "yes" to at least 1 of the 2 screening questions: (1) Have you smoked a single cigarette, even a puff, in the past 7 days? (smoking), and (2) Have you used an e-cigarette or vaping device containing nicotine, even a puff, in the past 7 days? (vaping).

Parents are eligible if (1) they are aged 18 years or older, (2) their child is aged between 0 and 17 years, (3) they are attending a regular scheduled medical appointment, and (4) they are sufficiently proficient in either French or English to be able to read and answer a written questionnaire. Informed consent is obtained before data collection.

Adolescent users are defined as those who answer "yes" to at least 1 of the above screening questions.

Adolescents are eligible if they are aged between 14 and 17 years, meet the aforementioned 3rd and 4th criteria, and have provided informed consent (in Québec, adolescents aged 14 years can provide consent).

Exclusion Criteria

Adolescents whose parents (if present) are not agreeable to their participation and families presenting to the clinic for an urgent medical issue will be excluded.

In each age category, a total of 2 participant groups are formed: "smokers," defined as all users reporting past 7-day use of traditional combustible cigarettes, with or without e-cigarette use, and "e-cigarette-only users," who report exclusive use of e-cigarettes. E-cigarettes include any electronic nicotine delivery systems, for example, vape pens, e-pens, e-cigars, e-pipes, or vaporizers containing nicotine. This division was created on the basis that the CEASE model has only been tested in individuals who report cigarette use (with or without e-cigarette use) but has not yet been tested in individuals using exclusively e-cigarettes [22].

Intervention

The CEASE Intervention

The CEASE intervention is an evidence-based parental smoking cessation intervention delivered in pediatric practices, leveraging existing health care and community resources [23]. In this project, CEASE is delivered through electronic tablets in pediatric clinic waiting rooms. It integrates evidence-informed tobacco (cigarette) and vaping (e-cigarette) product use screening and cessation assistance into routine visits to pediatric clinics. This workflow, used by Winickoff et al [19] in the United States, requires less than 10 minutes to complete, does not disrupt clinic flow, can be sustained over a 2-year period, and is acceptable to families and health care providers. CEASE is based on the 5As (ask about smoking, advise to quit, assess readiness to quit, assist with a quit plan, and arrange follow-up) model of smoking cessation. Given that CEASE is a 1-time intervention, "arrange" is removed, and the fourth step "assist" is divided into 2 parts: (1) providing behavioral support (in-person, phone, SMS text message, or app quit support) and (2) providing pharmacological support (access to NRT). Specifically, CEASE includes the following steps:

1. Ask (routine, systematic identification of smokers and e-cigarette users)
2. Advise (brief motivational intervention)
3. Assess (self-assessment of readiness and quitting preferences)
4. Assist (support to quit for those interested)
    - Behavioral support
    - Pharmacological support (NRT)

Ask: Routine, Systematic Identification of Smokers and E-Cigarette Users

Families with a scheduled appointment are approached by a research assistant and prescreened for eligibility using a brief anonymous survey on the secure REDCap (Research Electronic Data Capture; Vanderbilt University) platform. Eligible participants are randomized to either (1) the intervention (CEASE) or (2) the control (usual care condition).

Advise: Brief Motivational Intervention

Brief motivational interventions have been shown to improve quit rates and may include goal setting, setting a quit date, secondhand smoke education (shown to increase acceptance of services), and enlisting social support. After collecting data on participant smoking and vaping behaviors (a baseline questionnaire delivered through an electronic tablet), CEASE will automatically include brief motivational messages describing the main short- and long-term health benefits of smoking cessation to increase participant engagement and acceptance of services [23].

Assess: Self-Assessment of Readiness and Quitting Preferences

Next, participants are invited to indicate whether they are interested in trying behavioral (eg, in-person, phone, SMS text message, or app-based) or pharmacological (ie, NRT) interventions to help them quit or cut down.

XSL•FO
RenderX

Assist: Support to Quit for Those Interested—Behavioral Support

In-person or phone quit line support is offered through the government-funded and evidence-based smoking cessation internet platform "J'Arrête (I Quit Now)," provided by the Conseil Québécois sur le Tabac et la Santé (CQTS). Interested individuals can sign up for cessation services directly on the website [27]; study participants have the opportunity to do so directly on the electronic tablet. The Canadian Cancer Society's (CCS) Short Messages Against Tobacco [28], available from the J'Arrête (I Quit Now) website, is also presented as an option for participants who are interested in receiving SMS text messaging support to help them quit. Participants are offered to sign up to the "J'Arrête (I Quit Now)" web-based app, which provides a platform for the creation and realization of their smoking quit plan, as well as a dashboard to track their progress, trophies, tricks, and a variety of exercises to help overcome smoking cravings. In the week following the completion of the baseline questionnaire, interested participants receive an email or SMS text message reminder with information on how to access the behavioral resources they selected. All in-person, web-based, and SMS text messaging services are available in French and English for both adults and adolescents who smoke and use e-cigarettes. After signifying their interest in signing up for either of these services, participants are asked to consent to their information being transferred to the CCS or to the CQTS, which may contact them in the future and offer them additional smoking or vaping cessation resources.

Assist: Support to Quit for Those Interested—Pharmacological Support

CEASE automatically generates a written recommendation for NRT [23], to be discussed with a community pharmacist, including for those cutting down to quit as recommended in the latest national and international guidelines [29]. Since the best practice for NRT is to provide both a long- (ie, patch) and short-acting form (eg, gums or lozenges), a recommendation for 2 forms of NRT is automatically populated and printed in the clinic, provided to the participant, and sent to the participant by email. Given that pharmacists can now prescribe NRT in Quebec, the recommendation is written as detailed instructions for the pharmacist to prescribe NRT for a period of 3 months (the time period covered by public medical insurance in Quebec) and adjust the dosage based on the participant's reported use of tobacco or e-cigarettes. Study investigators remain available to support community pharmacists as needed.

The role of the provider in this intervention is adjunctive and not necessary to trigger intervention delivery. As such, CEASE is a standalone intervention and can take place without any provider involvement.

Control Condition

The control condition is care as is usually delivered in participating clinics. Current practice at those sites does not currently include routine provision of assistance for parental nor adolescent smoking and e-cigarette cessation (eg, referral to quit lines and NRT prescription). Participants in the control conditions will complete the same questionnaire as those in the intervention group; however, they will not be presented with a list of resources at the end of the questionnaire. While completing the final 6-month follow-up questionnaire, participants in the control group will be offered the option to receive a 1-time direct linkage to CEASE smoking and vaping cessation resources (behavioral supports and NRT recommendation).

Data Collection and Compensation

After consenting to the study, participants are asked to fill out a baseline questionnaire on an electronic tablet. Participants randomized to the intervention group have the option of receiving direct access to the CEASE evidence-informed cessation resources (if interested) after completing their questionnaire, while those randomized to the control group are only offered access to these resources at the end of the 6-month follow-up period (see "Control Condition" section). Participants in both groups are followed for 6 months following recruitment, with data collection at 1, 3, and 6 months (and the possibility of obtaining direct access to evidence-informed resources at each time point, if interested, for participants in the intervention group). Data collection tools (questionnaires) are available upon reasonable request to the corresponding author. Participant confidentiality is protected by limiting the collection of identifying information to an email address and phone number; date of birth, name, or participant address will not be collected. All data are stored on the secure web-based REDCap platform and in study logs on the Sainte-Justine University Hospital Centre server without participant-identifying information. Only the study investigators will have access to this data set at the end of the study period.

At each time point, participants are contacted by the study team by email, phone, or SMS text message (based on their preference) with a notification to complete the follow-up survey through REDCap, a secure web-based platform. If participants declare an abstinence of 7 days or more and consent to undergoing urine cotinine testing, they are contacted to arrange for biochemical confirmation of smoking cessation (cotinine testing) [30]. Data for confirmatory smoking or vaping cessation testing (urinary cotinine testing results) is sent directly to the study coordinator (to maintain investigator blinding) using a secure web-based portal. Participants will be called by research assistants and sent reminder emails or SMS text messages (based on their preference) to bolster the completion of follow-up questionnaires. They will receive CAD $10 (US $7.31) in compensation for each survey completed and an additional CAD $20 (US $14.62) per urine sample provided for cotinine testing.

Recruitment is expected to last a period of 9 months, with an additional 6 months required for follow-up with all recruited participants to complete data collection. The data analysis will begin with the end of recruitment and is expected to be completed in the 9 months following the final participant follow-up, for a total of a 24-month study period.

Allocation

This study aims to recruit an equal number of parent and adolescent users. Parent and adolescent participants are randomized to the intervention and control groups using a 1:1

XSL•FO
RenderX

ratio. Parent and adolescent participants are stratified into 2 subgroups: those who smoke traditional combustible cigarettes (with or without e-cigarette use) and those who report exclusive use of e-cigarettes. A computer-generated randomization list created by a biostatistician external to the study team is used to randomize participants within each group.

Blinding

This is a single-blinded study in which investigators will be blinded to the participant's group allocation, and data analysis is blinded, but participants and research assistants remain unblinded. Pediatricians may decide to discuss smoking and vaping with families as part of their usual care, and participants may mention the CEASE intervention during the encounter with the provider. As such, participants and physicians will not be blinded. Participant data is anonymized using individual participant codes. No participant identifiers (eg, birth date and hospital number) are included in the database.

Outcomes

The capacity of CEASE to provide cessation assistance for parental and adolescent smoking and e-cigarette use is assessed using a series of outcomes detailed in Tables 1 and 2. Table 1 includes all clinic-level outcomes, while Table 2 includes all patient-level outcomes. Each table includes details and a summary of each outcome measure, their operational definition, as well as the suggested time line for data collection and feasibility threshold when applicable. Outcomes were based on Winickoff's previous experience conducting CEASE feasibility and effectiveness trials in the United States [23].

Feasibility thresholds of 50% of potential participants screened for eligibility, 15% clinic-level smoking and vaping prevalence, 20% enrollment rate, and 3 participants (total) recruited per week (at least 6 parents and 6 adolescents recruited per month; primary outcome for this study) have been set (Table 1). Given an average of 250 patients seen per week across all 4 clinic recruitment sites, we anticipate that these thresholds will allow for 100 participants to be recruited over 36 weeks (9 months). Similarly, a feasibility threshold for baseline and follow-up questionnaire completion has been set at 90% and 80%, respectively, as shown in Table 2.

Data are obtained directly from participants through baseline and follow-up questionnaires, as well as from recruitment logs, biochemical assay results, and key informant interviews with clinic staff (eg, clinical nurse, front desk staff, and medical director) to inform about the potential impacts of the study on clinic flow. The key informant semistructured interview template is presented in Multimedia Appendix 2.

Table 1. Clinic-level outcomes of a pilot randomized controlled trial evaluating the feasibility and preliminary effectiveness in Canadian pediatric clinics of a brief digital screening and intervention tool for parental and adolescent tobacco and electronic cigarette use.

Outcome	Operational definition and details of measure	Timeline	Data collection	Feasibility threshold
Recruitment				
Clinic flow	Number of potential participants (parent and adolescent) per month for each clinic	Throughout	Recruitment log	N/A[a]
Proportion screened	Proportion of potential participants screened for eligibility	Throughout	Recruitment log	>50%
Clinic-level smoking and vaping prevalence	Self-reported smoking and vaping rates among parents and adolescents screened	Throughout	Recruitment log	>15%
Eligibility rate	Number of eligible parents and adolescents per month for each clinic	Throughout	Recruitment log	N/A
Enrollment percentage	Proportion of eligible participants approached who are enrolled	Throughout	Recruitment log	>20%
Reason for declining	Reasons for declining participation in the study	Throughout	Recruitment log	N/A
Recruitment rate (primary outcome)	Total number of participants recruited per month (parents and adolescents)	Throughout	Recruitment log	>3 participants, total, per week; >6 adolescents and >6 parents per month
Feasibility of the intervention				
Interest in smoking or vaping cessation	Proportion of eligible participants per category (parents and adolescents) who declare interest in smoking or vaping cessation	End of study	Baseline and follow-up questionnaires	>5%
Interest in smoking or vaping cessation services	Proportion of eligible participants (parents and adolescents) who want to be connected with smoking or vaping cessation services (quit lines, etc)	End of study	Baseline and follow-up questionnaires	>5%
Interest in obtaining NRT[b]	Proportion of eligible participants in each category who want to receive NRT	End of study	Baseline and follow-up questionnaires	>5%
Impact on clinic workflow				
Clinic staff evaluation	Key informant semistructured interview template (Multimedia Appendix 2) based on a number of references, including the CFIR[c] interview guide [31] and RE-AIM[d] [32]	End of study	Key informant interviews	N/A
Patient flow	Pre- and postrecruitment average weekly and monthly patient volumes in each clinic	End of study	Key informant interviews	<10% change

Power Calculations

The most recent Statistics Canada data show prevalence rates for daily or occasional smoking that are higher among males (17.3%) than females (12.3%), though this gap is narrowing [33]. In Québec, where the study is conducted, smoking prevalence is slightly higher (17.0%) than the Canadian average (14.8%) [33]. Among adults, especially adults aged older than 25 years, smoking rates remain significantly higher than vaping rates, as only 3.2% of adults aged older than 25 years report past-month use of a vaping device, and a significant proportion of adult e-cigarette users report dual use of cigarettes and vaping devices [34].

The latest provincial statistics report an 18% vaping prevalence among youth aged between 15 and 17 years [35] in Quebec, which is 4.5 times higher than the smoking prevalence (4%) in this age group, though the majority of adolescents who smoke also report past use of an electronic cigarette [34].

Considering recent epidemiological trends, a conservative 15% prevalence estimate is expected for the combined use of cigarettes and vaping devices among both parents and adolescents, resulting in a potential participant pool of approximately 1 in 7 parents or adolescents presenting to the clinic. With average clinic volumes of 250 patients per week and the screening and enrollment rates mentioned above, we anticipate attaining targeted recruitment rates of 3 participants per week.

To estimate the retention rate, using a sample size of 50 participants per age group (parents and adolescents) will allow for a 95% CI within 15% of the estimate obtained. As such, if a study completion rate of 60% is observed, the 95% CI would be 44.2%-75.8%. Other research groups have reported

XSL•FO
RenderX

challenges in recruiting teenagers for vaping cessation research studies [36]. As such, recruitment and retention rates are expected to differ between adult and adolescent participants; enrolling 50 parents and 50 adolescents for this pilot study will provide the 2 participation rate estimates.

Analyses

Clinic-level outcomes will be evaluated using descriptive statistics (recruitment and feasibility) and qualitatively (key informant interviews). Participant-level outcomes will also be evaluated using descriptive statistics, both overall and stratified by participant type (parents vs adolescents), nicotine product used (cigarettes with or without vaping vs vaping only), and clinic where recruitment occurred. Recruitment outcomes will be compared by participant gender. Given that this is a pilot trial with insufficient power to formally test the effectiveness of CEASE, exploratory analyses comparing smoking and vaping cessation, use of cessation resources, and motivation to quit smoking and vaping between intervention and control participants will be performed to identify potential trends and signals of effectiveness in all 4 participant groups.

Ethical Considerations

This study was reviewed and approved by the Institutional Review Board of the Sainte-Justine University Hospital Research Centre (2023-4237) and has been registered on ClinicalTrials.gov (NCT05366790). Any modifications or deviations from the protocol or adverse events will be recorded in the study logs on REDCap and reported immediately (within 48 hours) to the Institutional Review Board of the Sainte-Justine University Hospital Research Centre.

Results

This study obtained funding in April 2022. Research activities for this study began in June 2022. Participant enrollment and data collection began in February 2023 and are expected to be completed in 9 months (October 2023). As of September 30, 2023, a total of 115 participants—61 parents and 54 adolescents—have been recruited and have completed all baseline data. Data analysis will begin once all participants have been recruited and follow-up measures (1, 3, and 6-month follow-up) are in progress. The primary results of this study are expected to be available in the first months of 2025.

Discussion

Potential

This is the first study to test the feasibility and preliminary effectiveness of the CEASE intervention in Canada, as well as with adolescents and individuals with exclusive e-cigarette use. If shown feasible by reaching the feasibility recruitment threshold of 6 parent and 6 adolescent participants per month, this study could allow for the planning of a full-scale randomized controlled trial testing CEASE's effectiveness in Canada in these populations.

Strengths and Limitations

This study includes several strengths. First, it builds on the CEASE intervention, which has previously been demonstrated to be effective and cost-effective. Second, the electronic format of the screening and intervention will facilitate the integration of the tool in clinic workflow without any required intervention from clinical staff and will help with scale-up to additional sites. Finally, the study leverages existing cigarette and e-cigarette cessation resources, foregoing the need for additional costs for resource development. This also means that those resources can evolve and improve over time without affecting the design or feasibility of the study.

This study has certain limitations. Given the pilot nature of the study and the small sample size, this study does not have the statistical power to evaluate the effectiveness of the CEASE intervention. This study is also being conducted exclusively in an urban tertiary care hospital, which may not be reflective of pediatric clinics in community hospitals or other primary care clinics. Nonetheless, as recruitment is taking place in both general pediatric and adolescent medicine clinics as well as several specialized pediatric clinics, it allows for testing of the CEASE model in a diverse parent and adolescent patient group. Given this diversity of participants and recruitment clinics within a single center, we elected to randomize at the participant level rather than following the cluster-randomization protocol previously used to evaluate CEASE [23]. This decision does, however, pose a risk of contamination, wherein participants in the control group learn of the intervention and choose to seek out these publicly available smoking cessation resources themselves. While this may result in a decreased effect size of "The Clinical Effort Against Secondhand Smoke Exposure–Canada" (CanCEASE) in this study, all participants are offered access to these resources at the end of the study period, and the CanCEASE questionnaire itself may prompt individuals wishing to quit smoking or vaping to seek out these publicly available resources themselves during the study. Furthermore, cluster randomization would have been impractical in the context of this pilot study, as a larger sample size is required.

Logical next steps for our work will be to consider expanding CEASE recruitment to other clinic settings, including primary and secondary care clinics as well as rural settings, and conducting a full-scale cluster randomized controlled trial.

Conclusions

Cigarette smoking and nicotine vaping remain highly prevalent among parents and adolescents. Pediatric clinics represent an underutilized opportunity for the promotion of healthy lifestyle behaviors. This study tests the feasibility and preliminary effectiveness of a simple approach to smoking and vaping cessation. If successful, it could pave the way for a large-scale randomized controlled trial testing the effectiveness of this approach for adolescents and parents who smoke and vape in a Canadian setting. It also has the potential to inform clinicians and researchers about preferred cessation tools for parents and adolescents who use cigarettes and e-cigarettes, which remains an understudied area.

XSL•FO
RenderX

It is anticipated, based on previous implementation of CEASE in the United States, that CEASE will be feasible, as determined by a satisfactory recruitment rate as well as high proportions of participants interested in cessation, referral to cessation services, and NRT. As such, the data obtained through this study will help inform the design and implementation of a fully powered randomized controlled trial of CEASE in Canada.

Acknowledgments

This study is supported by a bridge grant from the Canadian Institutes of Health Research (CIHR). OD and NC are supported by Clinician Scholar Awards from the Fonds de recherche du Québec-Santé. MPS is supported by a Junior 2 Clinician Scholar Award from the Fonds de recherche du Québec-Santé.

These funding sources had no role in the design of this study and will not have any role during its execution, analyses, interpretation of the data, or decision to submit results.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

NC and OD conceived of the study and study design and prepared the initial study protocol. TP and AAS implemented the study design. TP managed study data and adherence to protocol. MPS and JO provided statistical expertise; JPW oversaw study design and provided guidance in study oversight. ED is conducting the primary statistical analysis. All authors contributed to the refinement of the study protocol and approved the final manuscript.

Conflicts of Interest

JPW has served as an expert witness in litigation against the tobacco industry.

Abstract

Background: Approximately 75% of people with pancreatic cancer experience pain, and >50% of them have cachexia (weakness and wasting of the body). However, there is considerable uncertainty regarding the management of these distressing symptoms.

Objective: Our primary objectives are to compare the relative benefits and harms of different interventions for pain in people with unresectable pancreatic cancer and for prevention and treatment of cachexia due to pancreatic cancer, through systematic reviews and network meta-analysis. Our secondary objectives are to develop an evidence-based clinical care pathway to manage pain and prevent and treat cachexia in people with pancreatic cancer through surveys and focus groups involving patients, carers, and health care professionals.

Methods: We will perform 2 systematic reviews of the literature related to pain and cachexia in people with pancreatic cancer using searches from Cochrane Library, MEDLINE, Embase, Science Citation Index, and trial registries. Two researchers will independently screen for eligibility and identify randomized controlled trials (no language or publication status restriction), comparing interventions for pain or cachexia based on full-texts for articles shortlisted during screening. We will assess risk of bias in the trials using the Cochrane risk of bias tool (version 2.0) and obtain data related to baseline prognostic characteristics, potential effect modifiers and outcome data related to overall survival, health-related quality of life, treatment-related complications, and resource utilisation. We aim to conduct network meta-analysis on outcomes with multiple treatment comparisons where possible, otherwise, meta-analysis with direct comparisons, or narrative synthesis. We will perform various subgroup and sensitivity analyses. Using information obtained from both systematic reviews, we will conduct 2 surveys: one directed to patients or carers to assess acceptability of interventions, and the other to health care professionals to assess feasibility of delivery in the National Health Service. Four mixed focus groups will be conducted to evaluate findings and foster consensus in the development of the care pathway.

XSL•FO
RenderX

Results: Funding was awarded from April 2022 (NIHR202727). Both systematic review protocols were prospectively registered on PROSPERO in May 2022. Formal searches began thereafter. Approval by the University College London Research Ethics Committee (23563/001) was received in December 2022. Data collection began in January 2023; data analysis will begin in May 2023 (completion expected by October 2023).

Conclusions: This study will comprehensively encompass major interventions for management of pain in people with unresectable pancreatic cancer, and prevention and treatment of cachexia in people with pancreatic cancer. Key stakeholders will facilitate the development of an evidence-based care pathway, ensuring both acceptability and feasibility. The project ends in April 2024 and published results are expected within 12 months of completion. We aim to present the findings through patient group websites, conferences, and publications, irrespective of the findings, in a peer-reviewed journal.

cachexia; pain relief; palliative care; pancreatic cancer; quality of life; systematic review

Introduction

What Is the Problem Being Addressed?

In the United Kingdom, 11,700 people were diagnosed and 10,000 people died from pancreatic cancer in 2020 [1]. The incidence of pancreatic cancer is increasing in the United Kingdom and in many other countries worldwide [2-9]. If the trend continues, it is likely to become the third-most common cause of cancer death in the United Kingdom by 2030 [10]. Surgical resection remains the only treatment with the potential for long-term survival and cure. However, only about 10% to 20% (n=~61,203) of patients are suitable for resection [8,11-13]. In people who do not undergo resection, the main options are chemotherapy, chemoradiotherapy, and treatment of symptoms [13-18]. The major symptoms related to pancreatic cancer, particularly in those with unresectable cancers, are pain, cachexia, and jaundice. In this work, we will be looking at the evidence for the management of pain and cachexia.

Pain

Pancreatic cancer can cause severe pain. It is estimated that 70% to 80% of people with pancreatic cancer seek medical help for the treatment of abdominal or back pain [19,20]. The 2 major mechanisms of pain are pancreatic ductal obstruction and pancreatic neuropathy (increased activation of pain nerve fibers) [20]. The main treatment options evaluated for pancreatic cancer pain include nonopioid analgesics such as nonsteroidal anti-inflammatory drugs (NSAIDs), opioid analgesics such as morphine, corticosteroids, neuropathic pain medications such as gabapentin or pregabalin, palliative radiotherapy, thoracoscopic splanchnicectomy (severing the splanchnic nerves), celiac plexus nerve blocks or neurolysis, and other treatments include pancreatic duct stenting, acupuncture, and hypnosis [20-24]. Review 1 is a systematic review focusing on the benefits and harms of the different pain control strategies in people with unresectable pancreatic cancer. There are no previous network meta-analyses (NMA) on the topic. Head-to-head comparison systematic reviews included comparison of celiac plexus nerve block plus analgesics with analgesics alone [23,25,26] and videothoracoscopic splanchnicectomy [27], stereotactic radiotherapy [28], various ablative therapies [29], kanglaite (Chinese medicine) in addition to chemoradiotherapy versus chemoradiotherapy alone [30]. The current clinical guidelines on the management of pain in pancreatic cancer are based on the World Health Organization's 3-step ladder for cancer pain [31]. The National Institute of Health and Care Excellence (NICE) suggests nonpharmacological treatments such as coeliac plexus blocks when the pharmacological treatment fails or is unacceptable because of adverse events [32], a recommendation that has been questioned [21]. The NICE acknowledged the uncertainty in the recommendation [32].

Cachexia

Cancer cachexia is a multifactorial syndrome defined by an ongoing loss of skeletal muscle mass (with or without loss of fat mass) that cannot be fully reversed by conventional nutritional support and leads to progressive functional impairment [33]. An estimated 55% to 85% (n=~170) of people with pancreatic cancer have cachexia [34,35]. The major proposed mechanism for cachexia of pancreatic cancer is decreased appetite, decreased production and increased lysis of lipids, increased protein lysis, decreased liver function, fat malabsorption, and decreased muscle mass due to increased cytokines and tumor-derived factors [34,36,37]. Mechanical intestinal obstruction due to the cancer, pancreatic exocrine insufficiency, and nutritional deficiency because of the combination of the above factors are other potential mechanisms [34,36,37]. Interventions evaluated for the prevention and treatment of cachexia include pancreatic enzyme replacements, increased calorie intake, ketogenic diet, amino acid supplementation, nutritional supplements, appetite stimulants, corticosteroids, NSAIDs, progesterone analogues such as megestrol acetate, cytokine inhibitors such as melatonin, omega-3 fatty acids, and exercises to improve muscle mass [37-39]. Review 2 is a systematic review of the prevention and treatment of cachexia in people with pancreatic cancer. There are no previous NMAs on the topic. The existing systematic reviews on the topic are different from this study because of the types of studies included [40,41], types of interventions included [40-42], risk of bias assessment [40-42], and the type of outcome measures studied [40-42]. The NICE guideline on pancreatic cancer does not recommend anything specific for cachexia [32]; however, only nutritional interventions (for cachexia) were evaluated.

Why Is This Research Important to Patients and Health and Care Services?

Increased pain decreases the health-related quality of life [43]. Cancer cachexia can lead to decreased health-related quality of life and may increase treatment complications, health care costs, and deaths [44]. Low performance status due to cachexia may preclude patients receiving more toxic but effective treatments such as the combination chemotherapy FOLFIRINOX [45]. The research questions included in this study are among the top 10 research priorities of the James-Lind Alliance Priority Setting Partnership on pancreatic cancer therapy involving people with pancreatic cancer in Germany, their carers, and clinicians treating them [46,47], that is, "How can the best treatment for each individual patient with pancreatic cancer be identified?" and "Does nutrition influence the survival or quality of life of patients with pancreatic cancer?" Furthermore, the use of evidence-based clinical care pathways in the National Health Service (NHS) helps to streamline care and avoid health care inequities and therefore would be beneficial for the management of pain and cachexia in people with pancreatic cancer.

Aims and Objectives

The overarching aim of this study is to answer the following research question: "What is the best treatment and NHS care pathway to decrease pain and cachexia and improve health-related quality of life in people with pancreatic cancer?"

The primary objectives include the following:

- To compare the benefits and harms of different treatments for pancreatic cancer pain through network meta-analyses, and to generate rankings of the different treatments according to their safety and efficacy.
- To compare the benefits and harms of different interventions in the prevention and treatment of pancreatic cancer cachexia through a systematic review (and meta-analysis when possible).

The secondary objectives include the following:

- To identify the gaps in the existing research that cause uncertainty in decision-making (based on the systematic review and NMA).
- To develop an evidence-based pathway for the management of pain and for the prevention and treatment of cachexia (using evidence collected as part of primary objectives), through surveys and focus group discussions with patients, carers, and NHS clinicians.

Methods

The bulk of the study is contained within work package 1, in which we will complete 2 comprehensive systematic reviews and meta-analyses on the management of pain and cachexia in pancreatic cancer. Work package 2 forms a smaller part of the overall study, yet it will involve surveys and focus groups of patients, carers, and health care professionals, leading to the development of a proposed evidence-based clinical care pathway for the management of pain and cachexia in people with pancreatic cancer.

Work Package 1: Systematic Reviews and NMA

We will perform two systematic reviews:

- Management of pain in people with unresectable pancreatic cancer: a systematic review of randomized controlled trials and NMA (review 1).
- Prevention and treatment of cachexia in people with pancreatic cancer: a systematic review of randomized controlled trials (review 2).

We will register the protocols in PROSPERO (International Prospective Register of Systematic Reviews) and conduct and report the systematic review according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement and its extension for NMA [48,49] (Table 1).

XSL•FO
RenderX

Table 1. Eligibility criteria for systematic reviews.

	Review 1	Review 2
Title	Management of pain in people with unresectable pancreatic cancer	Prevention and treatment of cachexia in people with pancreatic cancer
Type of studies	All randomized controlled trials regardless of the publication status, year of publication, and language of publication	All randomized controlled trials regardless of the publication status, year of publication, and language of publication
Setting	Primary, secondary, tertiary, or community care	Primary, secondary, tertiary, or community care
Types of participants	People with unresectable pancreatic cancer	People with pancreatic cancer regardless of whether the tumor was resectable or not
Types of interventions		
	NSAIDs,[a] opioid analgesics, neuropathic pain medications, thoracoscopic splanchnicectomy, celiac plexus blocks or neurolysis, splanchnic nerve blocks or neurolysis, radiotherapy, pancreatic duct stenting, acupuncture, and hypnosis	Pancreatic enzyme replacements, increased calorie intake, ketogenic diet, amino acid supplementation, nutritional supplements (oral or parenteral), appetite stimulants, corticosteroids, NSAIDs, progesterone analogues, cytokine inhibitors, omega-3 fatty acids, and exercises to improve muscle mass
	Within each review, the above interventions will be considered if used either alone or in combination with other interventions listed and compared with another intervention (or combination of interventions) listed above.	Within each review, the above interventions will be considered if used either alone or in combination with other interventions listed and compared with another intervention (or combination of interventions) listed above.

[a]NSAIDs: nonsteroidal anti-inflammatory drugs.

Outcomes

The choice of outcomes is based on the Core Set of Patient-Reported Outcomes in Pancreatic Cancer (ie COPRAC) study that involved patients with pancreatic cancer and health care professionals involved in their care [50]. We will collect all outcomes at 3 time points: until 3 months from randomization or intervention, 3 to 12 months from randomization or intervention, and beyond 12 months.

The primary outcomes include the following:

1. Overall health-related quality of life (any validated scale)
2. Pain (however defined by authors) (this will be secondary outcome for review 2)
3. Cachexia (however defined by authors) (this will be secondary outcome for review 1)

The secondary outcomes include the following:

1. Consumption of analgesics (drug, quantity, and frequency) (review 1 only)
2. Change in body weight (total amount and percentage of body weight) (review 2 only)
3. Death from any cause (all-cause mortality)
4. General health (any validated scale)
5. Physical ability (any validated scale)
6. Ability to work and do usual activities (however defined by authors)
7. Satisfaction with services and care organization (any validated scale)
8. Relationship with partner and family (any validated scale)
9. Serious adverse events (ICH-GCP [51] or any other definitions used by authors)
10. Number of hospital attendances and hospital admissions
11. The total length of hospital stays (planned admissions related to all components of treatments and admissions related to observation or treatment of complications)

Search Strategy

The following electronic databases will be searched to retrieve all eligible studies: The Cochrane Central Register of Controlled Trials (CENTRAL) in the Cochrane Library; MEDLINE (OvidSP); Embase (OvidSP); and Science Citation Index Expanded (Web of Knowledge); Conference Proceedings, from inception to date of search using free text and controlled vocabulary terms; ClinicalTrials.gov and the World Health Organization International Clinical Trials Registry Platform [52], which searches various trial registers, including ISRCTN and ClinicalTrials.gov. The search strategies are provided on the web-based published study registration records on PROSPERO (CRD42022333239 and CRD42022333241).

Additionally, we will search the references of the identified trials and the existing recent major systematic reviews on the topics to identify additional trials for inclusion. We will also contact the study authors to identify further trials and obtain aggregate data from unpublished studies.

Data Collection and Management

Selection of Studies

Two review authors will independently identify trials for inclusion by screening the titles and abstracts and make the final selection for inclusion based on the full-text articles (after translation if required) selected during screening. We will resolve any discrepancies through discussion and arbitration. The process will be documented to enable the completion of the PRISMA flowchart.

Data Collection

Two review authors will independently extract the following data using a prepiloted data extraction form:

1. Intervention and control details (including who delivers it, dose, how long and how frequently it is delivered, and compliance as appropriate)

XSL•FO
RenderX

2. Outcome definition, scale, and data
3. Data on potential effect modifiers: both reviews: age, performance status; review 2: presence of pancreatic exocrine insufficiency; resectable versus unresectable pancreatic cancer
4. Length of follow-up
5. Information to assess risk of bias
6. Other data include year and language of publication, country and setting, ethnicity of participants, recruitment period, and inclusion and exclusion criteria.

Assessment of Bias

We will use the Cochrane risk of bias tool version 2.0 to assess the risk of bias in the included randomized controlled trials [53]. We will assess reporting bias by the completeness of search.

Meta-analysis of Clinical Effectiveness

Measures of Treatment Effect

For binary outcomes, we will calculate the odds ratio with 95% credible interval (CrI). For continuous outcomes, we will calculate the mean difference (if trials used same scale) or standardized mean difference (if trials used different scales) with 95% CrI. For count outcomes, we will calculate the rate ratio with 95% CrI. For time-to-event data, we will calculate hazard ratio with 95% CrI.

Data Synthesis

We will conduct NMA on all outcomes with multiple treatment comparisons wherever possible. We will obtain a network plot to understand the network geometry and ensure that the trials are connected by interventions. We will report only the direct pairwise meta-analysis for comparisons that are not connected to the network. We will summarize the population and methodological characteristics of the trials included in the NMA in a table based on pairwise comparisons and ensure that the transitivity assumption is reasonable. If there are concerns about the transitivity assumption, we will perform only direct comparisons. We will conduct a Bayesian NMA by using the Markov chain Monte Carlo method in OpenBUGS 3.2.3 as per the guidance from the NICE Decision Support Unit (NICE DSU) documents using study-level data and appropriate likelihood, and link functions [54]. We will calculate the additive main effects, 2-way interaction, and the full-interaction models [55] to capture the effect of a component, interactions between the components and the overall effect of a combination of components. We will use the model fit to guide the selection of the model to be reported, when we perform a component NMA. We will use the standard of care as the reference group.

We will perform a fixed-effect model and random-effects model for the NMA, and report the more conservative model. The codes that we use for the analysis will account for the correlation between the effect sizes from the studies with more than 2 groups [54]. We will use a hierarchical Bayesian model using "vague" priors and 3 different sets of initial values (to ensure convergence of values), using the codes provided by NICE DSU. We will estimate the probability that each intervention ranks at one of the possible positions by using the NICE DSU codes. We will obtain the surface under the cumulative ranking curve (cumulative probability) and rankogram [56,57].

Presentation of Results

We will present the effect estimates with 95% CrI for each pairwise comparison calculated from the direct comparisons and NMA. We will also present rankograms and surface under the cumulative ranking curve [58,59]. We will present "Summary of Findings" tables for each of the primary and secondary outcomes using the methods described by the GRADE Working Group for presenting the Summary of Findings for NMA [60].

Dealing With Missing Data

In the first instance, we will endeavor to contact trial investigators to obtain missing data. We will perform an intention-to-treat analysis, whenever possible [61]; otherwise, we will use the data available to us. We will conduct best-worst case and worst-best case scenario analyses as sensitivity analyses for binary outcomes, whenever possible. For continuous outcomes, we will impute the mean and SD from median and *P* values according to the guidance in the Cochrane Handbook if the data seem to be normally distributed [62].

Alternatives to Meta-analysis

For outcomes where meta-analysis is not possible (eg, where the data were not normally distributed), we will present the studies in a table and report the median and quartiles of the differences. When it is inappropriate to perform a meta-analysis because of major differences in the types of participants included in the studies, we will summarize the information in a table and perform only a narrative synthesis. For the narrative synthesis, we will present the results systematically by the comparisons for each outcome and will report the findings according to "Synthesis Without Meta-analysis" guidelines [63].

Assessment and Investigation of Heterogeneity and Inconsistency

Heterogeneity

We will assess clinical and methodological heterogeneity by carefully examining the characteristics and design of the included trials. The potential sources of clinical heterogeneity include age, performance status, presence of pancreatic exocrine insufficiency; resectable versus unresectable pancreatic cancer, baseline risk (may be related to when the trial was conducted reflecting improvement in supportive care), variations in the intervention, different definitions used for outcomes, different scales used for assessment of outcomes, and period of follow-up.

We may encounter a diverse range of outcome measures, that is, for pain and health-related quality of life, using different scales. To account for this we will convert the available data into standardized mean difference and the SE that can be directly used in the NMA applying the standard WinBUGS codes available from the NICE DSU documents [54], that is, we will use the codes for combining "treatment differences." We may also encounter cases in which pain may be reported as "pain response" in some trials, but reported as continuous outcomes in other trials. In these cases, we will convert the available data

XSL•FO
RenderX

into standardized mean difference using the methods provided in the Cochrane Handbook (version 6.3, Section 10.6) [62] for the conversion of odds ratio to standardized mean difference (and its SE). Once converted into standardized mean difference, this can be used in the same way as above in the NMA. We will consider this variation in the way that outcomes are reported as a source of heterogeneity and address this by meta-regression and subgroup analysis, as appropriate.

Investigation of Heterogeneity

We will assess statistical heterogeneity by comparing the results of the fixed-effect model meta-analysis and the random-effects model meta-analysis, between-study variance, and by calculating NMA-specific I^2 [64]. If we identify substantial, clinical, methodological, or statistical heterogeneity, we will explore and address the heterogeneity in subgroup analysis and meta-regression by using the methods and codes described in the NICE DSU documents [65].

Inconsistency

We will evaluate the plausibility of transitivity assumption by looking at the inclusion and exclusion criteria in the studies and limit the NMA to a subset of trials, where transitivity assumption is reasonable.

We will assess inconsistency (statistical evidence of the violation of transitivity assumption) by fitting both an inconsistency model and a consistency model. We will use the inconsistency models employed in the NICE DSU manual [59], as we will use a common between-study SD. In addition, we will use the design-by-treatment full interaction model and inconsistency factor plots to assess inconsistency [56,66]. If there was evidence of inconsistency, we will identify areas in the network where substantial inconsistency might be present in terms of clinical and methodological diversities between trials and, when appropriate, limit NMA to a more compatible subset of trials.

Sensitivity Analysis

In addition to the best–worst case scenario and worst–best case scenario sensitivity analyses mentioned above, we will also perform a sensitivity analysis excluding the trials in which mean or SD or both were imputed and use different imputed SDs.

Work Package 2: Development of the Clinical Care Pathway

The information from work package 1 (both systematic reviews and NMA) will be supplemented by surveys and focus group discussions involving patients, carers, and health care professionals. We aim to engage these key stakeholders in a discussion about the acceptability and feasibility of interventions toward developing an evidence-based clinical care pathway for the management of pain and cachexia in pancreatic cancer.

Surveys

Two web-based surveys will be performed: one directed to patients or carers and the other to health care professionals. Both surveys will address pain and cachexia symptoms in turn and will precede the focus group discussions. Both surveys will include a question asking respondents whether they would be willing to participate in a focus group to further discuss the acceptability and feasibility of the different treatments toward the development of a care pathway for pancreatic cancer pain and cachexia. In this way, we will recruit members for the subsequent focus group discussions. The surveys will be hosted via a web-based survey platform using REDCap software. We will also offer a word-processing version, as well as paper surveys with stamped return envelopes, to increase participation. There will be an appropriate mix of closed questions to allow for quantitative analysis and open questions enabling free-text, qualitative responses. The survey templates are available from the researchers upon request. We will use the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) when formally reporting the results of the surveys for publication [67].

First Survey

For the sample frame, people with pancreatic cancer and their carers are identified through the Pancreatic Cancer UK patient network.

We expect approximately 50 responses for this survey. Although we recognize the importance of gaining views directly from people with pancreatic cancer, we have included carers due to the nature of this severe illness meaning people with pancreatic cancer and symptoms of the pan and cachexia may be too unwell to answer for themselves, and thus carers could provide valuable insights and views on behalf of people with pancreatic cancer.

The first survey aims to direct the focus group discussions toward deciding on the acceptability of the interventions (identified from the systematic reviews). We will provide the details of the procedure (what the procedure involves in plain language), and the effectiveness and complications of the procedures (again in plain language). Patients and carers will be asked to rank the treatments in the order of their preference or acceptability, according to how acceptable or tolerable they consider the treatment to be. We will summarize the acceptability (after stratification by symptom) in bar charts and pie charts.

Second Survey

For the sampling frame, health care professionals in NHS are identified through the Pancreatic Cancer UK clinical network.

We will also use the National Cancer Research Institute Upper Gastrointestinal Group (Pancreatic cancer Workstream) to publicize and increase the outreach of the survey. We expect around 50 responses for this web-based survey.

The purpose of the second survey will be to help inform the focus group discussions to understand the feasibility of performing the above interventions (identified in the systematic reviews) in the NHS and where best to deliver the intervention (ie, community, primary care, secondary care, specialist centers, hospice, etc). Health care professionals will be asked to score each intervention on a scale of 1 to 10, according to how feasible or realistic they consider for it to be delivered in NHS. We will summarize the feasibility of the treatments (after stratification by the category of the health care professional) in bar charts and pie charts.

RenderX

Focus Group Discussions

We will conduct focus group discussions involving patients, their carers, and health care professionals to develop a care pathway using the information from the systematic reviews (work package 1) and the surveys described above. Having a rich, mixed focus group (50% patients and carers and 50% health care professionals) will enable all participants to discuss their respective opinions and comments regarding the acceptability and feasibility of treatments, thereby enabling a consensus to be reached.

We will present the evidence from the systematic reviews and meta-analysis, and acceptability of treatments for each of pain and cachexia in two ways:

- ordered by the number of people who ranked an intervention as the most acceptable treatment
- ordered by their weighted ranking score using weights applied in reverse, for example, if there were 5 interventions, the most acceptable intervention will get a weight of 5, the second most acceptable intervention a weight of 4, the third most acceptable intervention a weight of 3, and so on.

Similarly, we will then present the feasibility of treatments in the NHS for each of pain and cachexia in 2 ways:

- ordered by the number of people who ranked an intervention as the most feasible treatment
- ordered by the average feasibility score.

After the presentation of the results of the surveys, the focus group will begin in-depth discussions to review the findings. The focus group discussions will focus around areas of contention—that is, interventions that are acceptable to patients but not very feasible to deliver in NHS or vice versa, or interventions that are highly acceptable but limited efficacy is found in the systematic review. Additionally, further discussions will take place regarding the most appropriate site of delivery of interventions. The templates for the focus group discussions are available from the researchers on request. We anticipate 2 focus group discussions (involving 8 to 12 participants each) covering each symptom (ie, 2 focus groups for pain interventions and 2 focus groups for cachexia interventions). Each round will be iterative, in that findings from the first focus groups in each symptomology will feed into each of the second focus group discussions. Each focus group's meeting is expected to last from 60 to 90 minutes. We plan to conduct the focus group meetings in-person; however, we have the flexibility to conduct the meetings on the web via Microsoft Teams or using a hybrid model, if preferable for participants. We will record all focus group discussions and use General Data Protection Regulation–compliant transcription services for transcribing the discussions for analysis. The transcript will not contain any identifiable participant details.

The focus group discussions will be analyzed using the Framework method [68], using a preliminary logic model developed following Phase 1 of the study to inform the development of the analytical framework. This logic model will describe the theory underlying a potential care pathway for the management of pain and cachexia and will use a Situation (*pain, cachexia*)–Inputs (*resources*)–Outputs (*activities*)–Mechanism –Outcomes (*short and longer terms*) configuration [69,70]. The focus group data will be coded and mapped onto this framework and further themes and subthemes will be developed and used to modify the logic model as required. Regular research team discussions will be held to ensure that the coding scheme reflects the data. We will use the Standards for Reporting Qualitative Research when formally reporting the results of the focus group discussions for publication [71].

We anticipate the development of a proposed care pathway in further iterative communications among the research team and relevant additional health care professionals (depending upon the intervention) identified through National Cancer Research Institute Upper Gastrointestinal Group (Pancreatic cancer Workstream), thus reaching a final agreement via email or teleconferences.

Patient and Public Involvement

The research team includes a patient representative who was involved in the preparation of the grant project proposal and determined that this research was important to patients. The patient representative will be part of the research oversight committee for the project and will help to facilitate the focus group discussions.

Ethics Approval

This study was approved by the University College London Research Ethics Committee (Ethics number: 23563/001).

Results

The funding for this study has been awarded from April 2022 to April 2024. The actual project start date occurred on schedule in April 2022. Immediately, prior to any study selection or formal searches, both systematic review protocols were prospectively registered publicly on the PROSPERO database in May 2022, along with the formal search strategies (CRD42022333239 and CRD42022333241). Formal searches and subsequent study screening began shortly thereafter. Data collection began in January 2023. Ethical approval (with regard to the surveys and focus groups pertaining to the second part of the project) was received in December 2022, and hence the full project protocol was prepared for publication in January 2023. Data collection began in January 2023 and data analysis is due to begin in May 2023 (expected to be completed by October 2023). Surveys and focus groups will run thereafter. The project ends in April 2024 and results are expected to be published within 12 months of project completion.

Discussion

Strengths and Limitations of This Study

This study will provide comprehensive coverage of all the major interventions for the management of pain in people with pancreatic cancer not suitable for pancreatic resection, and for the prevention and treatment of cachexia in people with pancreatic cancer regardless of whether they are suitable for pancreatic resection. It will also be the first time for network meta-analysis to be used for the systematic review on the

XSL•FO
RenderX

management of pain in people with unresectable pancreatic cancer, which has several advantages in terms of evaluating multiple treatment comparisons, and enabling calculation of additive main effects, 2-way interactions, and the full interaction models, which allow us to find out if there are any interactions between different combinations of treatments. However, the main limitation of the study is that sufficient outcome data may not be available from the randomized trials to enable network meta-analysis to be performed.

Nevertheless, this study will identify the gaps in the existing research that cause uncertainty in decision-making in the management of pain and cachexia in people with pancreatic cancer. A further strength is that the study will consult key stakeholders in the development of an evidence-based care pathway for pain and cachexia in pancreatic cancer, ensuring acceptability for patients and carers and feasibility for delivery in the NHS.

Dissemination

The team will disseminate the findings of the research through patients group websites, social media groups, conferences, and publish the findings in peer-reviewed journals.

Acknowledgments

The authors used the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols checklist when writing their report [72]. This work is funded by the National Institute for Health and Care Research (NIHR) Research for Patient Benefit Programme (Project Ref: NIHR202727). This protocol is based on the grant application that was submitted, peer-reviewed, and accepted by the funder; however, the funder was not involved in the preparation of this manuscript. The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care.

Data Availability

For the systematic reviews in work package 1, all the data will be available from the published report. Regarding data generated from the surveys and focus group discussions in work package 2, we will provide summary data only, in line with the data management plan that was ethically approved.

Authors' Contributions

DAR and KG wrote the manuscript. The manuscript was critically revised by EW, CM, YK, SP, APS, EP, JS, MHG, and BD. DAR is the guarantor of this manuscript.

Conflicts of Interest

KG is the co-lead applicant for the grant from NIHR which provides funding for this report. Their promotions and salary depend upon peer reviewed journal publications. The clinical practice of the clinicians in the project (DAR) may be altered by the findings of the review.

Abstract

Background: The current literature identifies several potential benefits of artificial intelligence models for populations' health and health care systems' efficiency. However, there is a lack of understanding on how the risk of bias is considered in the development of primary health care and community health service artificial intelligence algorithms and to what extent they perpetuate or introduce potential biases toward groups that could be considered vulnerable in terms of their characteristics. To the best of our knowledge, no reviews are currently available to identify relevant methods to assess the risk of bias in these algorithms. The primary research question of this review is which strategies can assess the risk of bias in primary health care algorithms toward vulnerable or diverse groups?

Objective: This review aims to identify relevant methods to assess the risk of bias toward vulnerable or diverse groups in the development or deployment of algorithms in community-based primary health care and mitigation interventions deployed to promote and increase equity, diversity, and inclusion. This review looks at what attempts to mitigate bias have been documented and which vulnerable or diverse groups have been considered.

Methods: A rapid systematic review of the scientific literature will be conducted. In November 2022, an information specialist developed a specific search strategy based on the main concepts of our primary review question in 4 relevant databases in the last 5 years. We completed the search strategy in December 2022, and 1022 sources were identified. Since February 2023, two reviewers independently screened the titles and abstracts on the Covidence systematic review software. Conflicts are solved through consensus and discussion with a senior researcher. We include all studies on methods developed or tested to assess the risk of bias in algorithms that are relevant in community-based primary health care.

Results: In early May 2023, almost 47% (479/1022) of the titles and abstracts have been screened. We completed this first stage in May 2023. In June and July 2023, two reviewers will independently apply the same criteria to full texts, and all exclusion motives will be recorded. Data from selected studies will be extracted using a validated grid in August and analyzed in September 2023. Results will be presented using structured qualitative narrative summaries and submitted for publication by the end of 2023.

XSL•FO
RenderX

Conclusions: The approach to identifying methods and target populations of this review is primarily qualitative. However, we will consider a meta-analysis if quantitative data and results are sufficient. This review will develop structured qualitative summaries of strategies to mitigate bias toward vulnerable populations and diverse groups in artificial intelligence models. This could be useful to researchers and other stakeholders to identify potential sources of bias in algorithms and try to reduce or eliminate them.

health equity; health disparity; algorithms; artificial intelligence; primary care; rapid review; systematic review

Introduction

Background

There is growing interest in artificial intelligence (AI) in medical research and clinical practice. Judicious use of algorithms could potentially improve the quality of care and accessibility to health services [1,2]. AI in health care is mostly used for training supervised models on previously collected data [1,3]. Some health specialties benefit from these tools that allow the application of AI models safely with a controlled risk of bias. For instance, the use of AI in medical imaging allows an improvement in the detection of some anomalies [4,5], and initiatives in radiology seem to improve efficiency and health outcomes [6]. Similarly, AI models could potentially have a positive impact on populations in vulnerable situations who access the health care system through primary care [1,7]. Unfortunately, AI remains poorly integrated into primary and community health services [8].

A potential use and implementation of AI models in the primary health care context could be in citizen portals by promoting health-oriented behaviors and preventing the onset of chronic diseases [8]. As elsewhere in Canada and worldwide, such portals are currently implemented in some electronic medical records in the province of Québec and serve as an interface between clinicians and patients [9]. These portals can provide access to laboratory results, reports of health questionnaires, or communication with health care professionals.

Citizen portals with integrated AI could lead to virtual assistance throughout the health care system or in situations where vulnerable populations do not have direct and rapid access to physicians' advice (eg, remote, isolated, vulnerable, and stigmatized populations) [1,2]. However, since these AI models are deployed in communities and vulnerable populations are concerned, there are risks of biases affecting patient care quality and safety, and their sources must be explored and identified prior to implementation [10]. We need to take a specific interest in medical and ethical parameters to ensure user quality and safety, as these models may be biased especially by ethnicity, sex, or gender [11-14]. Moreover, inequitable access to resources and recommendations could potentially put some users at risk [10].

Community-Based Primary Health Care

As defined by the Canadian Institutes of Health Research, community-based primary health care (CBPHC) "covers the broad range of primary prevention (including public health) and primary care services within the community, including health promotion and disease prevention; the diagnosis, treatment, and management of chronic and episodic illness; rehabilitation support; and end of life care" [15]. The current literature identifies several potential benefits of AI to develop and integrate clinical tools for population health, care team well-being, and efficiency of the CBPHC system [1,16-18]. Integration of AI technologies into CBPHC could help in many ways especially "to help people to get the care (including prevention) they need" [15]. However, there is a lack of understanding on how the risk of bias is considered in the development of these AI models and to what extent they perpetuate or introduce potential biases toward groups that could be considered vulnerable in terms of their characteristics (eg, sex, gender identity, sexual orientation, race, ethnicity, socioeconomic status) [16,19]. In response to this concern, the US Food and Drug Administration recently "calls for efforts to develop a methodology to develop devices to be well suited for a racially and ethnically diverse patient population" [1,16].

In a recent scoping review with the objective to "assess the nature and extent of the body of research on AI to primary care," the authors concluded that AI "is at an early stage of maturity (...) and more evaluation studies are needed" [7]. To the best of our knowledge, no reviews are available on methods to assess risk of bias and health inequity in primary care algorithms. We recently found a scoping review protocol aiming "to summarize the extent to which AI systems in primary care examine the inherent bias toward or against vulnerable populations and appraise how these systems have mitigated the impact of such biases during their development" [20]. Unless we are mistaken, the results of this protocol have not yet been published, and we still lack an overview of bias mitigation interventions and the characterization of groups and subgroups to which they are applied in CBPHC.

The aim of this rapid qualitative systematic review is to identify relevant methods (eg, frameworks, tools, checklists) for a risk of bias assessment for vulnerable or diverse groups in the development or deployment of algorithms in CBPHC and identify mitigation strategies deployed to promote and increase equity, diversity, and inclusion in CBPHC algorithms.

XSL•FO
RenderX

Review Questions

The research questions are:

- Which strategies have been suggested for consideration when assessing the risk of bias in CBPHC algorithms toward vulnerable or diverse groups?
- What methods assessed the risk of bias for vulnerable and diverse groups in CBPHC algorithm applications?
- Which mitigation interventions are deployed and (if applicable) what are the quantitative results?

Methods

Overview

This protocol follows the Cochrane Collaboration guidance for rapid reviews [21] and the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines [22,23]. PRISMA-P guidelines recommend the use of PICO (Participant, Intervention, Comparator, and Outcome) to frame the review question and develop a search strategy [22,23]. However, other options are available depending on the review objective. For a scoping review, the Joanna Briggs Institute recommends the PCC (Population or Participant, Concept, and Context) search framework [24]. Although we are not in a scoping review process, the PCC search framework [25] seems more appropriate and consistent with our open-ended qualitative research question (Table 1).

Table 1. PCC (Population or Participant, Concept, and Context) framework used for the search strategy[a].

PCC elements	Definition (per JBI Reviewer's Manual Ch 11)	PCC elements applied in this review
Population	"Important characteristics of participants, including age and other qualifying criteria" (11.2.4)	Any vulnerable populations or diverse groups
Concept	"The core concept examined by the scoping review should be clearly articulated to guide the scope and breadth of the inquiry. This may include details that pertain to elements that would be detailed in a standard systematic review, such as the 'interventions' and/or 'phenomena of interest' and/or 'outcomes'" (11.2.4)	Strategies or methods to assess risk of bias in algorithms (artificial intelligence)
Context	"May include...cultural factors such as geographic location and/or specific racial or gender-based interests. In some cases, context may also encompass details about the specific setting."	Community-based primary health care

[a]PCC framework [25]. Topic: risk of bias assessment methods developed/used in community-based primary health care algorithms. Primary review question: Which strategies can assess the risk of bias in community-based primary health care algorithms toward vulnerable or diversity groups?

Search Strategy

In November 2022, an information specialist developed a search strategy based on the main concepts of our primary review question and adapted it to the most relevant databases (PubMed, CINAHL, Web of Science, and PsychINFO). We used five relevant articles to test the sensitivity, and the search covered the last 5 years (2017-2022) aligned with the concept's emergence time frame. The database search strategies can be found in Multimedia Appendix 1.

Data Collection

We include all studies on methods developed or tested to assess risk of bias in algorithms that are relevant in CBPHC. In December 2022, all citations were exported to the web-based collaborative tool Covidence (Veritas Health Innovation) [26] where 581 duplicates were removed by the automated function. Since February 2023, two reviewers have independently screened the titles and abstracts of the identified records (N=1022) and assessed the inclusion and exclusion criteria (Table 2). Conflicts on study selection are resolved by consensus, and the opinion of a senior researcher is sought if required. At the full-text assessment step, two reviewers (and the information specialist if required) will search and obtain all the full texts of the selected references, and they will import the PDF files into Covidence.

Table 2. Inclusion and exclusion criteria.

PCC[a] elements [25]	Inclusion criteria	Exclusion criteria
Population	• Any vulnerable populations or diverse groups targeted by CBPHC[b] interventions	• Any populations targeted by hospital or specialized care interventions
Concept	• All the methods, tools, recommendations, or any intervention used to assess the risk of bias in CBPHC algorithms • All mitigation strategies deployed to promote and increase equity, diversity, and inclusion in CBPHC algorithms	• Methods or interventions not CBPHC related • CBPHC interventions that do not include any algorithm/AI[c] system
Context	• Include all the CBPHC algorithms (AI) applications that can perpetuate/introduce potential biases toward groups that could be considered as vulnerable in terms of their characteristics	• Algorithms used by primary health care providers for support in administrative tasks and for operational aspects, rather than for clinical decisions

[a]PCC: Population or Participant, Concept, and Context.

[b]CBPHC: community-based primary health care.

[c]AI: artificial intelligence.

Data Extraction

Team members will complete the extraction on a structured prespecified grid in Covidence, and the data will be reviewed and pretested by the research team. We will extract descriptive data (title, year of publication, authors, country), study type (published, study design), and population data (populations targeted by the intervention, number of participants). Characteristics of populations will be mainly extracted to our prespecified grid according to the PROGRESS (place of residence, race/ethnicity/culture/language, occupation, gender/sex, religion, education, socioeconomic status, and social capital) framework [27]. This framework addresses "health inequalities and unfair differences in disease burden," and these characteristics "that stratify health opportunities and outcomes" are "place of residence, race/ethnicity/culture/language, occupation, gender/sex, religion, education, socioeconomic status, and social capital" [27]. We will add to that list the "Plus" in the acronym PROGRESS-Plus, referring to the "1) personal characteristics associated with discrimination (e.g. age, disability) 2) features of relationships (e.g. smoking parents, excluded from school) 3) time-dependent relationships (e.g. leaving the hospital, respite care, other instances where a person may be temporarily at a disadvantage)" [28].

We will also extract concept data: identification and characteristics of the assessment method used/developed; identification and characteristics of the algorithm, including purpose (eg, diagnosis- or prognosis-related, used for disease detection or surveillance), type (eg, machine learning, natural language processing, expert systems), and any other available detail (eg, input information/parameters, outcomes); and context data, including details about the specific settings (ie, identification of potential biases for vulnerable or diverse groups) and the results of the intervention (eg, bias mitigation data).

Quality Assessment

We will appraise the quality of empirical studies included based on experiment, observation, or simulation (randomized controlled trial, quasi–randomized controlled trial, prospective cohort study, pre-post study, observational study, mixed methods study, qualitative study) by applying the Mixed Methods Appraisal Tool (MMAT) [29].

Data Synthesis

We will synthesize data using structured narrative summaries around our main concept/context and provide a list of available methods. The development process and main features of the methods (eg, potential sources of bias/items covered, signaling questions, differences and similarities, strengths and weaknesses) will be described. Furthermore, we will present mitigation strategies deployed with these methods (eg, algorithm parameter adjustments, mitigation or elimination of bias).

Ethics Approval

We obtained approval by the Ethics board of the "Comité d'éthique de la recherche sectoriel en Santé des Populations et Première Ligne du CIUSSS de la Capitale-Nationale" for the Protecting and Engaging Vulnerable Populations in the Development of Predictive Models in Primary Health Care for Inclusive, Diverse and Equitable AI (PREMIA) project (#2023-2726).

Results

We completed the search strategy in December 2022, when 1022 sources were identified and 581 duplicates were removed by the automated function of Covidence. In early May 2023, a total of 479 out of 1022 (46.9%) titles and abstracts have been screened. This first screening step was completed in May 2023. In June and July 2023, two reviewers will independently apply the same inclusion and exclusion criteria to full texts. Data from the selected studies will be extracted using a validated grid in August 2023. The quality of studies will be appraised along with the data extraction by applying the MMAT [29] in August 2023. Data will be analyzed in September 2023, and the results will be presented using structured qualitative narrative summaries. We plan to complete this review and submit a final manuscript by the end of 2023.

XSL•FO
RenderX

Discussion

Principal Findings

We anticipate structured narrative summaries of identified bias mitigation methods would be useful to researchers, data scientists, ethicists, and other CBPHC providers. We also anticipate that identification and documentation of these methods would be particularly relevant for multidisciplinary teams: "AI initiatives should have two main goals: they should be designed and utilized in a manner that does not create or maintain health disparities currently experienced by vulnerable groups, and they should address and remove existing health disparities" [1]. We hypothesize that giving methods and tools to multidisciplinary teams, with the participation of vulnerable populations in the entire process, would be useful to achieve inclusive AI when applied to health. We also expect that few studies will present quantitative bias mitigation data and results. Nevertheless, we will present these data in qualitative structured summaries.

Comparison to Prior Work

Other reviews generally focused on a few specific population characteristics. In a recent study on hospital readmission rates, the authors focused on racial and socioeconomic status biases in algorithms due to an increased risk in these groups [19]. In another example, the authors explored the source of age-related bias in AI systems [30]. There are many other "subgroups or unprotected groups" that can be considered to address "health inequalities and unfair differences in disease burden" [31]. We expect that our focus on primary health care will offer a different insight and that the PROGRESS-Plus framework will be helpful to identify potential interventions to mitigate health inequalities [27,28]. We anticipate listing and describing which vulnerable or diverse groups are considered (and which could be considered).

Strengths and Limitations

The main strength of our review is that we are applying an equity lens [27,28] to describe mitigation strategies in primary health care AI models. However, this review has three main limitations. First, its rapid nature implies that we limit our search to the last 5 years and to 4 databases only. Some relevant studies might not be included. However, given the recent interest in AI in primary care, this is unlikely. Second, we will consider all types of health conditions and various types of populations, which could bring important heterogeneity in the results and limit the possibility of synthesizing this information. Finally, applying the findings of this review to existing AI-based algorithms could present challenges because of the different contexts and populations in which they were developed.

Future Directions and Dissemination Plan

This rapid review is the first step of the larger PREMIA project. This work will be presented to key stakeholders, and we will conduct qualitative data collection to identify and evaluate biases in one AI model. Giving a voice to diverse groups [32,33] at the development or deployment stages of CBPHC AI-based algorithms could have a substantial impact on this review. Recommendations will be implemented into tools able to guide developers, researchers, and decision makers on strategies to reduce the risk of bias in AI primary health care programs and services, with the objective to protect vulnerable groups and not further exacerbate inequalities.

Conclusion

Identifying methods developed and deployed to mitigate biases toward vulnerable populations is needed to develop equitable primary health care. AI models can have many benefits for patients, but factors that stratify health opportunities and outcomes need to be addressed to mitigate inequalities toward members of vulnerable or diverse groups. To our knowledge, no reviews are currently available to identify risk of bias mitigation strategies in CBPHC AI algorithms. This rapid review will contribute to providing comprehensive structured narrative summaries of risk of bias assessment methods. This knowledge could be useful to CBPHC researchers and other stakeholders to identify potential sources of bias in AI algorithm development and eventually try to reduce or eliminate them.

Acknowledgments

The Protecting and Engaging Vulnerable Populations in the Development of Predictive Models in Primary Health Care for Inclusive, Diverse and Equitable AI (PREMIA) project is funded by the International Observatory on the Societal Impacts of AI and Digital Technology (OBVIA).

Data Availability

The database search strategy data is available in Multimedia Appendix 1. All data generated or analyzed during this study (including the PRISMA [Preferred Reporting Items for Systematic Reviews and Meta-Analyses] flow diagram) will be included in the results manuscript submission as multimedia appendix files. Databases created in the data extraction process can be provided upon reasonable request.

Authors' Contributions

MS is the corresponding author and guarantor of the review. MPG is the leader of Predictive Models in Primary Health Care for Inclusive, Diverse and Equitable AI (PREMIA) project administration and funding acquisition. All authors, except SO and FB, contributed to the whole PREMIA project design. MS and MPG equally contributed to the design, methodology, and review of

XSL•FO

Abstract

Background: Health measurement guides policies and health care decisions are necessary to describe and attain the quintuple aim of improving patient experience, population health, care team well-being, health care costs, and equity. In the primary care setting, patient-reported outcome measurement allows outcome comparisons within and across settings and helps improve the clinical management of patients. However, these digital patient-reported outcome measures (PROMs) are still not adapted to the clinical context of primary health care, which is an indication of the complexity of integrating these tools in this context. We must then gather evidence of their impact on chronic disease management in primary health care and understand the characteristics of effective implementation.

Objective: We will conduct a systematic review to identify and assess the impact of electronic PROMs (ePROMs) implementation in primary health care for chronic disease management. Our specific objectives are to (1) determine the impact of ePROMs in primary health care for chronic disease management and (2) compare and contrast characteristics of effective ePROMs' implementation strategies.

Methods: We will conduct a systematic review of the literature in accordance with the guidelines of the Cochrane Methods Group and in compliance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines for its reporting. A specific search strategy was developed for relevant databases to identify studies. Two reviewers will independently apply the inclusion criteria using full texts and will extract the data. We will use a 2-phase sequential mixed methods synthesis design by conducting a qualitative synthesis first, and use its results to perform a quantitative synthesis.

XSL•FO
RenderX

Results: This study was initiated in June 2022 by assembling the research team and the knowledge transfer committee. The preliminary search strategy will be developed and completed in September 2022. The main search strategy, data collection, study selection, and application of inclusion criteria were completed between October and December 2022.

Conclusions: Results from this review will help support implementation efforts to accelerate innovations and digital adoption for primary health care and will be relevant for improving clinical management of chronic diseases and health care services and policies.

KEYWORDS

systematic review; patient-reported outcome measure; primary healthcare; health care; implementation science

Introduction

Primary health care is essential, comprehensive, and universally available to a community [1]. For most of the Canadian population, primary health care represents the first contact with the health care system, and in 2016, overall, 88.5% of the Canadian population had access to a family physician attached to a primary health care service [2]. Mostly managed in primary health care, chronic diseases affect 3 out of 5 Canadian adults, significantly impacting their quality of life, and account for approximately 80% of disability and 70% of deaths in Canada [3]. Primary health care management of chronic diseases remains a challenge at the core of the health care system.

Health measurement guides policies and health care decisions and is necessary to describe and attain the quintuple aim of improving patient experience, population health, care team well-being, health care costs, and equity [4]. In the primary care setting, health measurement allows outcome comparisons within and across settings and helps improve the clinical management of patients [4,5]. However, for these outcomes to be informative, researchers, key stakeholders, clinicians, and patients must codevelop a measurement framework integrating the perspectives of end users [5,6] and for outcome measurement to deliver on the promise of addressing the quintuple aim [5].

Patient-reported outcome measures (PROMs) are health reports of patients' conditions, capturing their perception of their own health, without clinician input [5]. PROMs enable patients to report on their quality of life, daily functioning, symptoms, and other aspects of their health and well-being [5]. A body of evidence shows that effective use of PROMs in the clinical context reduces consultation time [7], improves patient-provider communication [8], identifies patient needs and allows for a patient-centered practice [9], decreases symptom severity, increases survival, and decreases emergency department visits [10,11].

The development of integrated digital solutions to care pathways is essential for PROMs to have a clinical impact [8,12,13]. It has been reaffirmed in the 2021-2026 Canadian Institutes for Health Research's strategic plan that researchers must accelerate digital transformation of health care systems for efficient health measurement and data analysis [4]. Electronic PROMs (ePROMs) can bring several benefits to the use of pen-and-paper PROMs: higher motivation to complete the task of self-reporting, lower rates of missing data and errors, improved chronology on historical patients' data [14], remote and quick data collection, integrated data analysis, and availability of reports for care teams [15].

However, ePROMs are still not adapted to the clinical context of primary health care, which is an indication of the complexity of integrating these tools in this context [16,17]. The effectiveness of including ePROMs in routine clinical care has been studied in contexts of specialized care among homogenous patient groups based on diagnoses such as cancer [18-24]. Whereas successful ePROMs implementation in Canada has been noted (eg, Cancer Care Alberta), unfortunately, there are additional implementation challenges specific to primary health care, including the heterogeneity of the patient population [25]. There are also significant disparities among patients regarding their ability to understand and use digital tools [26]. The development of ePROMs is expected to increase the existing digital divide and reduce the ability to self-report outcomes among certain populations [26]. Understanding the extent to which ePROMs provide outcomes for clinicians and patients and prioritize the adaptation of additional ePROMs in this context is critical to present exhaustive evidence of what works and how to implement ePROMs in primary health care. Consequently, to address these abovementioned critical needs and challenges, we must gather evidence of the impact of ePROMs on chronic disease management in primary health care and understand the characteristics of effective implementation.

With the goal of accelerating the integration of ePROMs to optimize the delivery of primary health care and bring about rapid and meaningful benefits to patients, we will conduct a systematic review to identify and assess the impact of ePROMs implementation in primary health care for chronic disease management.

Our objectives are to (1) determine the impact of ePROMs in primary health care for chronic disease management and (2) compare and contrast the characteristics of effective ePROMs implementation strategies. We expect that our results will directly contribute to providing decision makers with high-quality, timely, accessible, and relevant evidence to inform policies and practices.

XSL•FO
RenderX

Methods

We will conduct a systematic review of the literature in accordance with the guidelines of the Cochrane Methods Group and in compliance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for its reporting [27,28]. We have registered the study protocol to the PROSPERO systematic review registry (CRD42022333513) [29].

Conceptual Underpinnings

This review will be grounded in the integrated knowledge translation approach to pursue its objectives [30]. According to this approach, knowledge users (KUs) will be involved in all aspects of the research process to enhance its relevance and usability in practice. The Strategy for Patient-Oriented Research framework for patient engagement will be used to complete integrated knowledge translation in promoting a respectful climate between researchers and KUs, including decision makers and patient partners [31].

Synthesis Questions

The following questions will be addressed: (1) what are the outcomes of ePROMs in primary health care in chronic disease management? (2) What are the effective strategies to implement ePROMs in primary health care? (3) What are the challenges, barriers, and facilitators to successful implementation of ePROMs in primary health care?

Eligibility Criteria

We will address all types of evidence matching the Population, Intervention, Comparison, Outcomes, and Setting/context criteria [28]. *Participants* include all studies reporting on the implementation of an ePROM among adults for chronic disease management. We have no restrictions regarding the *Interventions/phenomena of interest*; we will include all types of implementations, theoretical models, structures or PROMs. We have no restrictions regarding the *Comparator*; we will consider all outcomes reported in the studies. We will seek outcomes related to patients, caregivers, health care providers, policy makers, barriers, facilitators, acceptability, feasibility, adoption, fidelity, morbidity, mortality, quality of life, satisfaction, cost and cost-effectiveness. Regarding *Setting*, we will only include studies taking place in primary health care settings in any geographical setting and extract information regarding implementation. All types of studies will be included (ie, those using qualitative, quantitative, and mixed methods), which were published in French, English, or Spanish.

Search Strategy

We will develop the search strategy under the leadership and guidance of an experienced information specialist (FB). An iterative process of revision by the research team members and a revision by another experienced information specialist will be carried out (per the PRESS [Peer Review of Electronic Search Strategies] checklist) [32]. All relevant comments will be integrated in the final version of the search strategy. Specific search strategies will be formulated for the following databases: Cochrane Database of Systematic Reviews, MEDLINE (Ovid), CINAHL (EBSCO), Embase, PsycINFO (Ovid), Web of Science, and ProQuest Dissertations & Theses. Considering the recent nature of the topic, a time limit of 20 years will be applied to the search strategies. No restriction on language will be applied. We will develop and include a gray literature search strategy. We will perform an internet search in the following sources and search engines: Google, Google Scholar, Canadian Evaluation Society, EuroScan, OpenGrey, Grey Literature Report, GreyNet, and Grey Matters. Since innovation implementations are often conducted by government entities or large health care systems, we will search within the websites of key governmental agencies (eg, US Agency for Healthcare Research and Quality's studies on health care systems [eg, Kaiser Permanente]). Furthermore, we will perform backward citation searches of included studies and recent literature reviews for additional relevant references.

Data Collection and Screening

We will export all citations in the web-based collaboration tool Covidence, where duplicated entries will be removed with the automation function [33]. Titles and abstracts will be screened independently by pairs of reviewers. A pilot testing to validate the screening process will be completed on 5% of a random sample of all studies. Variability in reviewer assessment will be documented using the Cohen κ statistic [34]. Ambiguous or incomplete abstracts will be retained to be reviewed in full and additional information could be obtained from the authors. We will search and obtain all the full texts of the selected references and will import the PDF files in Covidence. Pairs of reviewers will independently apply the inclusion criteria using the full texts following a pilot testing using the process outlined above. At any moment in the overall screening process, a third reviewer will help resolve any discrepancy. All the reasons for exclusion will be recorded in Covidence. A PRISMA flowchart will be used to describe study identification, screening, inclusions, and exclusions [35].

Data Extraction and Appraisal

We will codevelop the extraction form with all KUs and team members to ensure that we are capturing relevant information (ie, what matters the most for them). Pairs of reviewers will independently complete data extraction following a pilot testing (see above). We will extract descriptive data (title, year of publication, authors, funding, conflicts of interests, and country), study types (published or gray literature), methodological data (design, sample size, measure constructs, and name of the instrument), setting data (clinical setting, type health professionals, and patient population), implementation data (description of implementation activities, facilitators, and barriers), outcomes (patient health, providers workflow, and cost), and outcome types (qualitative and quantitative). The quality of the included studies will be evaluated using the mixed methods appraisal tool [36]—a tool adapted to systematic reviews synthesizing data from qualitative, quantitative, and mixed methods studies.

Data Synthesis

We will use the RE-AIM (reach, effectiveness, adoption, implementation, maintenance/sustainability) framework as a

XSL•FO
RenderX

data analysis framework. The RE-AIM framework has been developed to evaluate the public health impacts of interventions and has been used in systematic reviews to help structure the assessment of the different implementation factors at play in complex contexts and settings [37,38]. This framework includes 5 dimensions: reach (how willing the targeted population is to participate in the intervention; ie, ePROMs), efficacy (what is the impact of the intervention on outcomes?), adoption (can this be adopted by new groups with ease and minimal changes?), implementation (what are the special issues and barriers?), and maintenance (can the intervention be maintained and its impact sustained?). The use of the RE-AIM framework will enable us to provide an overview of the parameters strengthening (review questions 2 and 3) the efficiency (review question 1) of ePROMs' integration in primary health care and its impact on outcomes associated with the quintuple aim.

We will use a 2-phase sequential mixed methods synthesis design (ie, conduct a qualitative synthesis) and use its results to perform a quantitative synthesis [39]. In phase 1 (qualitative), we will use a thematic synthesis procedure [40] wherein we will summarize and describe methods and approaches designed to implement and integrate ePROMs in primary care. The qualitative data synthesis will produce structured narrative summaries of main themes of data in accordance with the RE-AIM framework. In phase 2 (quantitative), for each phase 1 theme, we will synthesize quantitative data with study subgroups centered around the theme in a descriptive manner when statistics and calculation methods are available. We will summarize study characteristics and methodological differences and similarities to highlight the following points: strengths and weaknesses of each implementation method, main outcomes of implementation, main conclusions regarding the relationship between methods and outcomes, main resources used and their impacts, and whether any trade-offs are described and their effect on the results of the study. If data are available in the primary studies, sex and gender similarities and differences (eg, adoption and satisfaction) will be included in our synthesis. The diversity in team expertise, clinical background, and gender will contribute to the orientation of the synthesis and choices that could lead to inclusive recommendations for clinical choices and policies. This study will also follow the Canadian Institutes for Health Research's SAGER (Sex and Gender Equity in Research) for study design and reporting of the results. If needed, we will also provide training in sex and gender equity for the trainees and the patient partners on the team [41].

Results

The study was initiated in June 2022 by assembling the research team and the knowledge transfer committee. The preliminary search strategy was developed and completed in September 2022. The main search strategy, data collection, study selection, and application of inclusion criteria were completed between October and December 2022. Data analysis will be completed and reports, briefs, and papers will be written from January to September 2023. The knowledge translation committee meets throughout the study period, once every 2 months, but more actively, from January to March 2023.

Discussion

In order to not only impact but also document the extent of success toward the abovementioned quintuple aim, health measurements must include patients' self-evaluation of health, well-being, and behaviors that contribute to care quality, service comparability, provider performance, patient engagement, and general patient status. Effective implementation of relevant ePROMs in primary health care is necessary to orient chronic disease management that is patient-centered and personalized in a contemporary and modern context of care. This study aims to synthesize the learning from using ePROMs in primary health care organizations. This information will be useful in supporting the adoption of PROMs in clinical settings. Optimal implementation of PROMs in primary health care would improve perceived relevance and adoption by health care providers and patients. Results from this review will orient the delivery, accountability, effective implementation, and contextualized usefulness of PROMs for the implementation of ePROMs in clinical settings. Optimal implementation of ePROMs in primary health care would improve perceived relevance and adoption by health care providers and patients. Results from this review will orient the delivery, accountability, effective implementation, and contextualized usefulness of PROMs. The patient-centered approach facilitated by PROM use will greatly improve health equity for populations needing a personalized care approach of primary health care.

Results from this review will help support implementation efforts to accelerate innovations and digital adoption for primary health care and will be relevant for improving clinical management of chronic diseases, health care services, and policies. Efficient ePROM implementation has a direct impact on the quintuple aim of improving patient experience, improving health, improving health professionals experience, improving care value, and advancing health equity.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Adolescents are a large proportion of the population in sub-Saharan Africa and face multiple risks to their health and well-being. Prior systematic reviews have focused on specific adolescent sexual and reproductive health outcomes such as teen pregnancies, HIV/AIDS, and sexually transmitted diseases. A comprehensive synthesis of the influential factors that shape different aspects of adolescent sexual and reproductive health can inform health policy and program development for this important segment of the population.

Objective: This paper presents the protocol for an umbrella review that aims to synthesize the existing knowledge in the literature on the associations among individual, family, and societal factors and sexual and reproductive health outcomes among adolescents in sub-Saharan Africa.

Methods: We will include systematic reviews that identify factors associated with sexual and reproductive health outcomes among adolescents, 10-19 years of age, in sub-Saharan Africa. Reviews can include quantitative and qualitative primary studies with or without meta-analysis. Academic and gray literature searches will identify reviews from PubMed, Scopus, CINAHL, Cochrane Database of Systematic Reviews, ProQuest, Google, and Google Scholar. Two reviewers (MZG and KO) will independently carry out title, abstract, and full text screening, assess methodological quality, and extract data. We will assess the methodological quality of the included studies using the Joanna Briggs Institute standard forms. The review will present findings in narrative form and in tables and will follow PRISMA (the Preferred Reporting Items for Systematic Reviews and Meta-Analyses) reporting guidelines.

Results: A preliminary search in April 2023 found 1351 articles to be screened.

Conclusions: This umbrella review will permit a comprehensive and high-level understanding of the various factors that influence adolescent sexual and reproductive health in sub-Saharan Africa.

KEYWORDS

adolescents; youth; sexual health; reproductive health; sexually transmitted infections; pregnancy; sub-Saharan Africa

Introduction

Adolescence is the transition phase between childhood and adulthood that serves as a window of opportunity for development and growth. Different exposures help adolescents establish patterns of behaviors related to diet, physical activity, substance use, and sexual activity. These behaviors and influences, especially related to adolescent sexual and reproductive health (ASRH), can either protect or put at risk their health and the health of others around them now and in

XSL•FO
RenderX

the future [1]. During the past 25 years, following the International Conference on Population and Development in Cairo (Egypt), there has been improvement in ASRH outcomes globally [2]. However, progress is unequal between and within countries and in different regions, such as Sub-Saharan Africa [3]. Adolescent girls in sub-Saharan Africa face an elevated risk of early marriage [4], teenage pregnancies [5], and exposure to unsafe abortions [6], leading to a high rate of maternal deaths among this group [7]. Lack of knowledge about safe sexual and reproductive behaviors and practices [8,9] exposes adolescents to HIV and sexually transmitted infections [10]. The risks are higher among rural girls who are poor and uneducated [4]. Multifaceted barriers at the individual, family, community, service, and policy levels still impede ASRH policies and programs in the provision of comprehensive information and services to adolescents [11-13]. Attitudes of peers, parents, family members, and service providers influence adolescents' access to ASRH information and services [14]. In many settings, discussion about ASRH and the use of related services, especially by unmarried adolescents, is stigmatized.

To improve ASRH and address inequalities, policy makers and planners need to set priorities based on robust evidence. Historically, statistics about adolescents have often been merged with children or adults even in national databases [15,16]. There has been a steady growth in published evidence, including systematic reviews, about ASRH in sub-Saharan Africa. However, studies and reviews focus on specific ASRH outcomes (such as the use of contraceptives [17], teen pregnancies [18,19], transactional sex [20], HIV/AIDS [21], and other sexually transmitted diseases [STDs]) or interventions [22]. There remains a need for a comprehensive and overarching review of factors associated with the range of ASRH outcomes. In our search of the 3 main systematic review registries (the PROSPERO [International Prospective Register of Systematic Review], Joanna Briggs Institute Systematic Review Register, and Open Science Framework Registries), we did not find any umbrella review registered on this topic.

This umbrella review will identify and summarize evidence on the factors associated with the range of ASRH outcomes in sub-Saharan Africa. The aim is to identify and synthesize existing knowledge on the associations between individual, family, and societal factors and ASRH outcomes. The research questions are (1) what are the overlapping and unique factors associated with a broad range of ASRH outcomes (including teen pregnancies, transactional sex, sexual abuse, gender violence, HIV/AIDS, and other STDs)? (2) What are the research gaps in the literature around ASRH in sub-Saharan Africa? The intention is to cover a wide range of ASRH outcomes, using previously synthesized evidence in systematic reviews. The review will form part of the evidence considered in a larger study to co-design strategies to promote and protect ASRH in Bauchi State, Nigeria [23].

Methods

Study Design

The umbrella review [24] will examine the documented associations between ASRH outcomes including teen pregnancy, transactional sex, sexual abuse, gender violence, HIV/AIDS, and various STDs, and individual, family, and societal factors. There are many preexisting reviews of factors related to specific ASRH outcomes; we will not conduct a review of primary studies. The unit of search and data analysis will be systematic and scoping reviews, with or without meta-analyses [25]. By using an umbrella review approach, we can cover a wide range of ASRH outcomes. An umbrella review will permit a more comprehensive and higher-level analysis of the various factors that influence ASRH in sub-Saharan Africa. We seek to synthesize the available evidence about factors associated with each ASRH outcome. We will examine whether the results and conclusions of individual reviews of factors related to specific ASRH outcomes are consistent or contradictory. This review will provide an overarching view of current knowledge about the multifaceted issue of ASRH and will identify research gaps in the literature.

Search Strategy

A comprehensive search strategy included both peer-reviewed articles and gray literature. We searched for peer-reviewed articles in PubMed, Scopus, CINAHL, and Cochrane Database of Systematic Reviews on April 11, 2023. The search matrix included a combination of controlled vocabulary and keywords to represent reviews, adolescents, sexual and reproductive health outcomes, and sub-Saharan Africa. We used a similar search matrix in the gray literature database ProQuest to search for relevant theses or dissertations. The gray literature search also used the Google and Google Scholar search engines with the search terms such as adolescent sexual reproductive Africa review. We included the first 10 search results from Google and Google Scholar in the initial screening. The initial searches considered published articles and gray literature irrespective of date of publication.

Eligibility Criteria

The review will include systematic and scoping reviews of both quantitative and qualitative primary studies, with or without meta-analyses. All included reviews must describe a reproducible and systematic search strategy, well-defined inclusion and exclusion criteria and outcome, and risk of bias assessment of included primary articles. We will include academic and gray literature in English or French, irrespective of the date of publication. The population of interest is adolescents, 10-19 years of age, in sub-Saharan Africa. This includes studies irrespective of gender, place of residence (urban and rural demographics), and educational attainment (students and out-of-school youth). We will include reviews that include children, adults, or countries outside of sub-Saharan Africa if they present disaggregated data on youth (10-19 years of age) and sub-Saharan Africa. We will exclude studies of specific subpopulations, such as athletes or orphans. Textbox 1 describes the inclusion and exclusion criteria for this umbrella review.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for an umbrella review of factors related to adolescent sexual and reproductive health in sub-Saharan Africa.

Inclusion criteria

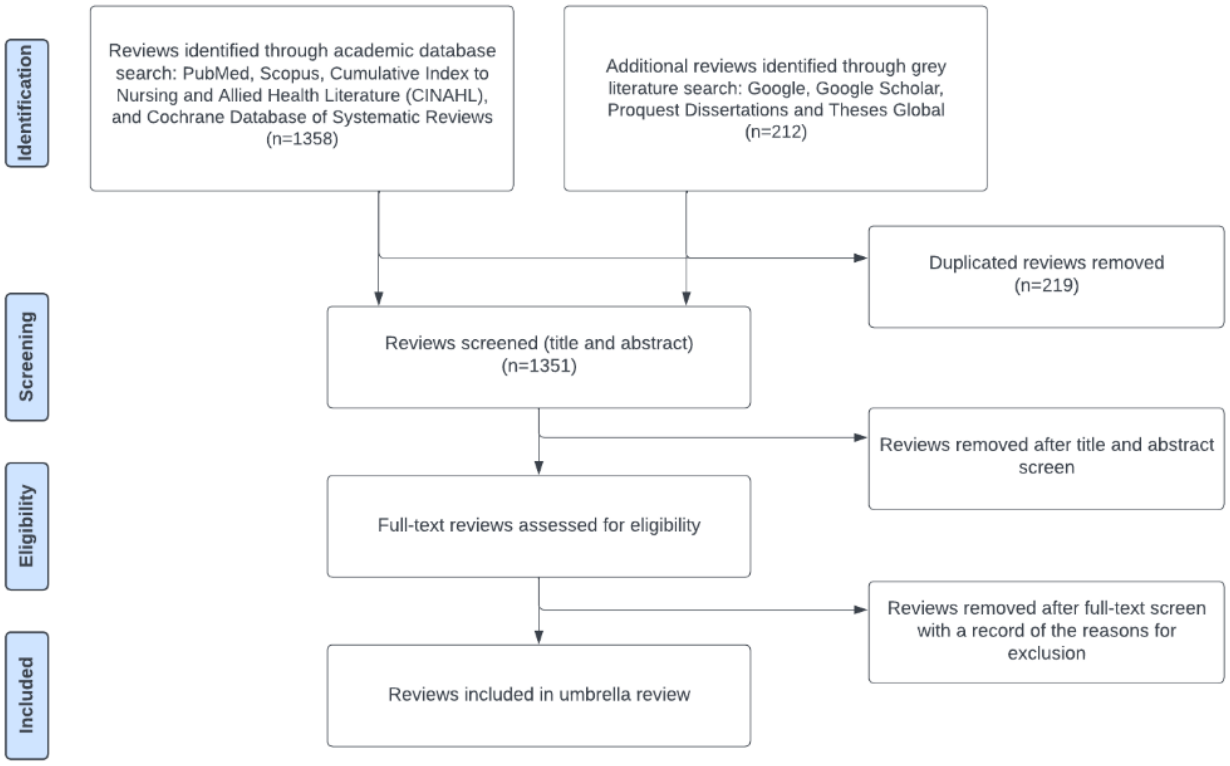
- Reviews published in peer-reviewed journals, thesis manuscripts, and reports
- All reviews irrespective of date of publication and date range of search
- Articles written in English or French
- Quantitative and qualitative reviews. Scoping and systematic reviews, with or without meta-analyses. Reviews must include a reproducible and systematic search strategy, well-defined inclusion and exclusion criteria and outcome, and risk of bias assessment of included primary articles
- The review should include male and female adolescents, 10-19 years of age, or present disaggregated data for adolescents
- The review should include studies from sub-Saharan Africa or present disaggregated data from a country or countries in sub-Saharan Africa
- The domain under investigation is adolescent sexual and reproductive health. Adolescent sexual and reproductive health outcomes include issues around teen pregnancy, transactional sex, gender violence, sexual abuse, and the transmission of HIV and other sexually transmitted diseases. This review will consider any outcome that the authors explicitly state is related to adolescent sexual and reproductive health

Exclusion criteria

- Blogs, websites, and conference papers
- Reviews without a systematic and reproducible methodology for article identification, such as well-defined eligibility criteria and outcome of interest
- Reviews that do not provide the list of included primary studies
- Reviews concerned with specific populations such as adolescent athletes or patients

Outcome

The primary domain of interest is outcomes related to ASRH. ASRH refers to more than the absence of disease. It also includes the physical, mental, and social well-being of adolescents such as the ability to access sexual health services, the prevention of unintended pregnancies, safe abortion, the prevention of STDs including HIV/AIDS, and all forms of sexual violence and coercion. This umbrella review will consider any outcome that has been explicitly defined by the authors as being related to ASRH. All included reviews will describe the individual, family, or societal factors associated with an ASRH outcome. Reviews may include studies of interventions to address ASRH outcomes such as school-based sex education initiatives, behavior change interventions, programs, and policies.



Study Selection

We will combine reviews identified in the academic and gray literature searches and remove duplicates. Two reviewers (MZG and KO) will independently screen all articles. In the first round of study selection, 2 reviewers (MZG and KO) will independently read titles and abstracts and select potentially eligible articles. They will discuss and resolve disagreements on selection, with articles retained if there is no agreement.

In the second round of study selection, 2 reviewers (MZG and KO) will screen full-text articles of the remaining reviews from the first round, according to the eligibility criteria described above. The 2 reviewers will agree on whether to include or exclude each article and on the primary reason for exclusion. They will discuss and resolve disagreements, if necessary involving a third reviewer (AC). The study selection process is depicted in Figure 1.

XSL•FO
RenderX

Figure 1. Flow diagram illustrating the study selection process of review articles in an umbrella review of the determinants of adolescent sexual and reproductive health in sub-Saharan Africa.

Data Extraction

Reviewers will extract data from eligible articles with the use of a systematic review management software called Covidence (Veritas Health Innovation Ltd). The research team will develop a data extraction template to capture the items such as study information, study participants' characteristics, characteristics of included primary studies, how the ASRH outcomes of interest are defined, factors associated with the outcomes of interest, and intervention models used (if relevant) and their influence on ASRH outcome. Factors under consideration include but are not limited to age, sex, marital status, schooling level, employment status, wealth, religion, knowledge about ASRH-related topics, age of sexual initiation, various behaviors such as the use of contraception or engagement in transactional sex, rural versus urban dwelling, parental care and communication, parental education, media influence, gender and cultural norms, and policies. For each included article, 2 reviewers (MZG and KO) will independently complete an extraction template, documenting all responses in Covidence. A third reviewer (AC) will resolve any disagreements about data extraction.

We will assess the methodological quality of the included articles using the Joanna Briggs Institute Critical Appraisal Checklist for Systematic Reviews and Research Syntheses, which covers both quantitative and qualitative research. Two reviewers will conduct the assessments independently and in pairs, and a third reviewer will resolve disagreements. The umbrella review will report the findings of the risk of bias assessment.

Data Synthesis

The umbrella review will present a narrative synthesis of a range of ASRH outcomes and their associated factors. We will not attempt a meta-analysis of quantitative findings. We will organize the data by ASRH outcome—including pregnancy, HIV/AIDS transmission, intimate partner violence, and others—and synthesize the factors that have been explored in systematic reviews for each outcome. The review will also present subgroup analyses about associations of factors such as sex, age, school attendance, and rural versus urban dwelling with ASRH in sub-Saharan Africa.

Ethical Considerations

This protocol follows the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines [26]. The review is registered with PROSPERO (CRD42023394512). The review will exclusively use data from secondary sources and will not involve interactions with human subjects. Ethical clearance is not required. The findings will form part of the evidence to be discussed in a larger project to co-design strategies for improving ASRH in Bauchi State, Nigeria. The research team will also disseminate findings in conference presentations and publications.

Results

The initial academic and gray literature search started in April 2023 and has resulted in a total of 1358 and 212 articles, respectively. After the removal of duplicates, 1351 articles remain to be screened. We expect to publish the review findings before the end of 2023.

XSL•FO
RenderX

Discussion

Summary

This is the first umbrella review within the sub-Saharan African context to assess comprehensively ASRH outcomes and the factors associated with them. By systematically reviewing both academic and grey literature, we aim to identify, synthesize, and critically evaluate existing research evidence on factors related to ASRH outcomes within the region. Existing systematic reviews focus on specific aspects of ASRH, but these are often intertwined so a broad overview across different outcomes is timely. By synthesizing the findings from multiple systematic reviews, this review will identify gaps in the existing evidence base. This can guide future research to fill these gaps.

The literature about ASRH in sub-Saharan Africa is diverse and complex, covering a range of outcomes, associated factors, and interventions. Many systematic reviews have synthesized the literature relating to different outcomes; our preliminary search strategy resulted in 1351 articles to be screened. An umbrella review is timely to synthesize existing systematic reviews and meta-analyses and will provide a comprehensive overview of the available evidence. Sub-Saharan Africa has limited human and financial resources. An umbrella review can guide the efficient allocation of scarce resources by identifying the most robust and relevant evidence, minimizing duplication of effort, and identifying areas where further research or interventions are needed.

Anticipated limitations of this review include the diversity and varying quality of the included reviews. We will consider the quality of the included reviews in our interpretation of the findings of our umbrella review. Another limitation is the potential overlap of original articles between the reviews included within our umbrella review. Ignoring potential overlap might lead umbrella reviews to overstate certain results and conclusions. We will identify overlaps in our synthesis report.

Conclusions

This umbrella review of factors related to ASRH outcomes in sub-Saharan Africa is timely. It will provide a comprehensive overview of the landscape of studies on ASRH outcomes and potential determinants in sub-Saharan Africa. It will identify gaps in the evidence base and guide future research on the topic.

Acknowledgments

This work was supported by the Canadian Institutes of Health Research grant number (CIHR PJT-178066). Generative artificial intelligence was not used in any portion of the manuscript writing.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study.

Authors' Contributions

All authors contributed to and approved the final manuscript. MZG and KO performed the initial systematic literature searches and drafted the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Amid all public health measures to contain COVID-19, the most challenging has been how to break the transmission chain. This has been even more challenging in low- and middle-income countries (LMICs). A public health emergency warrants a public health perspective, which comes down to prevention. Rapid mass testing has been advocated throughout the pandemic as a way to promptly deal with asymptomatic infections, but its usefulness in LMICs is yet to be fully understood.

Objective: The study objectives of this paper are to (1) investigate the impact of the different rapid mass testing options for SARS-CoV-2 that have been delivered at point of care in LMICs and (2) evaluate the diagnostic safety (accuracy) of rapid mass testing for SARS-CoV-2 in LMICs.

Methods: This review will systematically search records in PubMed, EBSCOhost, Cochrane library, Global Index Medicus COVID-19 Register, and Scopus. Records will be managed using Mendeley reference manager and SWIFT-Review. Risk of bias for randomized controlled trials will be assessed using the RoB 2 assessment tool, while nonrandomized interventions will be assessed using the tool developed by the Evidence Project. A narrative approach will be used to synthesize data under the first objective, and either a meta-analysis or synthesis without meta-analysis for the second objective. Tables, figures, and textual descriptions will be used to present findings. The overall body of evidence for the first objective will be assessed using the Grading of Recommendations Assessment, Development, and Evaluation–Confidence in the Evidence from Reviews of Qualitative research (GRADE-CERQual) approach, and for the second objective using GRADE.

Results: The screening of records has been finalized. We hope to finalize the synthesis by the end of February 2023 and to prepare the manuscript for publication by April 2023. The study will be reported in accordance with standard guidelines for the reporting of systematic reviews. Review results will be disseminated through conferences and their peer-reviewed publication in a relevant journal.

Conclusions: This review highlights the role of a preventive approach in infection control using rapid mass testing. It also flags the overriding need to involve users and providers in the evaluation of such tests in the settings for which they are intended. This will be the first review to the best of our knowledge to generate both qualitative and quantitative evidence regarding rapid mass testing specific to LMICs.

Introduction

Background

The real challenge of COVID-19 containment is to break the transmission chain by preventing individuals from getting infected and preventing those infected from transmitting to others [1]. The gold standard of COVID-19 containment has shifted to mass vaccination, with the belief that vaccines will break the chain of transmission. It is reported that current vaccines are close to 100% effective in reducing hospitalizations and deaths [2]. These significant efficacy results from conducted studies may however be limited given that these are just 2 of the endpoints of vaccine effectiveness. In reality, the effectiveness of available vaccines in preventing *infections* is yet to be fully understood in many countries. The duration of immunity of current vaccines is also a critical yet unanswered question [3]. It becomes even more challenging to measure the above endpoints amid emerging new variants [4-8] since this requires constant knowledge renewal on viral genomic epidemiology [9]. New variants of SARS-CoV-2, including B.1.1.7, B.1.351, and P.1, have been reported in the United Kingdom, South Africa, and Brazil, respectively. The emergence of these new variants—when the global economy is yet to recover from the devastating effects of the previous variants still in circulation—is particularly challenging. More so, the fact that these new variants of concern [10,11] are not only more transmissible but appear to be more asymptomatic and resistant to polymerase chain reaction detection, flags the overriding importance of waiting time in the detection of those infected. Transmissibility of the virus appears to vary by context as factors reported to determine transmission include the capacity for the virus to replicate, the exhibition of symptoms (cough), and the individual associated environmental factors (including behavior) [12].

It is reported that a major factor that can contribute to up to 50% of infected persons being overlooked during symptom screening is the inability to detect the virus during the asymptomatic stage by programs designed to diagnose cases when the disease is quite advanced [13]. Apart from a group of people who deliberately might not declare they have symptoms, the first 2 days of the 12-day infectious period of the virus, during which infected persons do not show any symptoms, remain an important proportion in the transmission mechanism of a deadly disease. The inability to effectively manage the transmission mechanism in low- and middle-income countries (LMICs) due to limited resources prompts the need for low-cost rapid tests in these countries. While some remain skeptical about the diagnostic safety and effectiveness of rapid tests [14,15], others believe that the currently available rapid tests are equally accurate enough in detecting some of the new variants [16-18]. The current evidence of what these different tests are and their diagnostic safety [19] within the context of LMIC is limited. In addition, standard guidelines for their use [20,21] seldom exist in these settings, making their effective deployment more challenging.

Key questions to ask when planning to identify infections promptly include, among others, the following: (1) When to test? (2) Where to test? (3) When to get the results? (4) How safe? and (5) How regular? As the global economy learns to cope with the more silent new variant infections, it is apparent that low-cost regular rapid mass testing might assume an important role [22,23], but their diagnostic safety [24] may be an issue particularly in LMICs. According to a 2020 report by the World Bank, low-income countries are those with a gross national income per capita of ≤US $1045, and middle-income countries are those with a gross national income per capita of US $1046 to US $12,695 [25]. About 500 million tests have been estimated to be needed in LMICs in 2021 [26], and the adoption of low-cost rapid tests might lead to up to 50% cost savings [27,28]; however, their fitness for purpose in these countries is yet to be fully understood. This study seeks to systematically review the evidence-based rapid mass testing options for SARS-CoV-2 that can be delivered at point of care in LMICs.

Specific Objectives

The specific objectives of this study are as follows: (1) to investigate the impact of the different rapid mass testing options for SARS-CoV-2 that have been delivered at point of care in LMICs and (2) to evaluate the diagnostic accuracy of rapid mass testing for SARS-CoV-2 in LMICs.

Research Questions

Given that our review was geared toward going beyond a quantitative evidence synthesis, the research questions were framed following the Perspective, Setting, Phenomenon, Environment, Comparison, Timing, and Findings (PerSPEcTiF) framework to incorporate the (1) setting, (2) time, and (3) place [29] for objective 1, and using the population, intervention, comparison, outcome (PICO) approach for objective 2 [30].

Objective 1

From a preventive health perspective in a LMIC, what do rapid tests for SARS-CoV-2—in an environment of limited resources with silent transmissions from infection up until diagnosis—mean to patients, health personnel, and the general public?

Objective 2

What is the diagnostic accuracy of near-the-patient rapid mass testing options for SARS-CoV-2 implemented, irrespective of symptoms in LMICs?

Methods

Study Design

This is a systematic review of both qualitative and quantitative evidence synthesis. A qualitative approach will take the form

XSL•FO
RenderX

of a metasynthesis while the quantitative approach will take the form of a meta-analysis.

Eligibility Criteria

Searched records will be screened using the inclusion and exclusion criteria. Given the important role played by both contextual variables and time in the detection of SARS-CoV-2 to break the transmission chain, we believed that rapid mass testing interventions were complex ones [31], not only following a systems approach but underpinned by both contextual variability and time scale [29]. The eligibility criteria for the first objective follows the PerSPEcTiF framework, while that for the second objective follows the PICO framework, as seen in Table 1.

Table 1. Inclusion and exclusion criteria.

Objective	Inclusion	Exclusion
Objective 1 (PerSPEcTiF[a])		
Perspective	Preventive care [32,33] and public health [21,34] perspective	Diseased population
Setting	Point of care or near the patient [35,36], including GP[b] surgeries; physician offices; community (population); walk-in or drive-through testing sites; primary care centers; nursing; and long-term care facilities, hospital wards, clinics, prisons, pharmacies, schools, workplaces, sports centers, and border testing sites	Lab-based testing
Phenomenon	Non–lab-based rapid and point of care test [37]; they are highly accessible, applied irrespective of symptoms, easily transported, and inexpensive, and should provide results in 1 visit [38].	Serology tests, lab-based tests, and non–point of care tests
Environment	In low- and middle-income countries [25]	High-income countries
Comparison	N/A[c]	N/A
Timing	Time during which infection remains asymptomatic; results delivered in 1 visit	Time of diagnosis includes symptoms; if time to results is more than 24 hours
Findings	Impact of rapid tests including the knowledge, attitude, and perception of patients, health care providers, and the public	Studies not evaluating the impact of rapid tests on the public
Objective 2 (PICO[d])		
Participants	Asymptomatic patients with COVID-19 and close contacts of index cases	COVID-19 or symptomatic patients
Intervention	Rapid antigen and point-of-care tests	Lab-based tests
Comparison	Lab-based reverse transcription–polymerase chain reaction [39-41]; the test could miss up to 30%-40% of infections [42,43]	Tests other than reverse transcription polymerase chain reactions
Outcome	Diagnostic test accuracy	Nondiagnostic test accuracy studies
Other		
Studies	Qualitative and mixed methods studies for objective 1; RCTs[e], non-RCTs, and cross-sectional cohort studies for objective 2	Longitudinal cohort, case-control, case-control cross-sectional, and all prognostic and predictive DTA[f] studies

[a]PerSPEcTiF: Perspective, Setting, Phenomenon, Environment, Comparison, Timing, and Findings.

[b]GP: general practitioner.

[c]N/A: not applicable.

[d]PICO: population, intervention, comparison, outcome.

[e]RCT: randomized controlled trials.

[f]DTA: diagnostic test accuracy.

Information Sourcing

Electronic Databases

The literature search will be performed in PubMed, EBSCOhost (CINAHL Plus), Global Index Medicus COVID-19 register, Cochrane (library and COVID-19 register), and Scopus. Gray literature from MedRxiv, BioRxiv, AiXiv, and other preprint servers will be ensured through the inclusion of the Global Index Medicus database. No restriction will be set on language. The search for records will follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) [44]. A PRISMA flow diagram will be used to present the workflow of how studies were included.

Manual Search

The search for useful articles will be conducted in Google scholar using the keywords of included articles, for objective 1, and the Cochrane COVID-19 Study Register for objective 2.

XSL•FO
RenderX

We will also search manually through professional networks and other sources.

Citation Search

We hope to locate useful studies through the reference list of identified records by searching them online using their digital object identifiers in Crossref, DOI resolver, or through the journals in which they were published. Articles will also be identified through the reference list of suitable systematic reviews in the Cochrane Special Collections for COVID-19 Infection Control and Prevention.

Alerts and Generic Sources

Wherever necessary and possible, we will (1) set up email alerts in the electronic databases searched, (2) screen the citation manager's generic suggestions as well as those from databases, and (3) screen database suggestions for similar articles.

Search Strategy

Electronic Search Terms

Search terms will include "Qualitative"[Mesh], "Qualitative Study"[tiab], "Mixed-method"[tiab], "Interview"[Mesh], "Attitude"[Mesh], "Knowledge[Mesh]", "Practice"[Mesh], "KAP"[tiab], "Acceptance"[Mesh], "Public Perception"[tiab], "Public Acceptance"[tiab], "Public Attitude"[tiab], "Compliance"[Mesh], "Adherence"[Mesh], "Qualitative Research"[Mesh], "Explor*"[tiab], "COVID-19 Testing"[Mesh], "COVID-19 Nucleic Acid Testing "[Mesh], "Rapid Diagnostic Testing"[tiab], "Lateral Flow Tests"[tiab], "Nucleic Acid Testing"[Mesh], "Rapid test"[Mesh], Lateral Flow[tiab], "Mass Testing"[Mesh], "Mass Screening"[Mesh], "Diagnostic Test"[tiab], "Diagnostic Performance"[tiab], "Test Accuracy"[tiab], Test Performance"[tiab], "Universal Testing"[Mesh], "Universal Screening"[Mesh], "Point-of-Care Testing"[Mesh], "Point-of-Care"[tiab], "Point-of-Care Screening"[Mesh], "POC Testing"[Mesh], "Community Testing"[tiab], "Asymptomatic Infections"[Mesh], "Asymptomatic"[tiab], "Carrier State"[Mesh], "Asymptomatic Diseases"[Mesh], "COVID-19"[Mesh], "SARS-CoV-2"[Mesh], "2019-nCoV"[Mesh], "SARS-CoV-2 Variants"[Mesh], "VOC"[Mesh], "SARS-CoV-2 Variants"[Supplementary Concept], "RT-PCR"[tiab], "PCR"[Mesh], and "Molecular"[tiab]

Electronic Search Strategy

Records will be searched in databases highlighted under the electronic databases subsection. A date limit will be applied using electronic filters of search engines and set to 2020 and beyond. Searches will constantly be updated throughout the research period. A detailed search strategy in PubMed can be found in the study protocol [45]. The search strategy for each database can be seen in Table 2.

Search Peer Review

Search terms will be performed and verified by a second person to ensure search reproducibility. Both results were then compared, and any differences were resolved by modifying and rerunning the searches.

Study Records

Data Management

Mendeley reference manager (Elsevier) and SWIFT-Review (Sciome) will be used to manage search records. SWIFT-Review workbench will be used to deduplicate, screen records, and code [46]. Data analysis will be conducted with the help of the SWIFT-Review and Stata package (Stata Corp).

Screening Process

We will start by identifying and removing duplicates in the first phase followed by the screening of titles and abstracts in the second phase, following the outlined inclusion and exclusion criteria. Screening of titles and abstracts will be conducted by 2 independent reviewers (PK and KA) while a third reviewer will serve as an arbitrator. If necessary, full articles will be read should it not be possible to screen records by title or abstract alone. The unavailability of full text will lead to exclusion.

Data Extraction

Data extraction for the first objective will be performed by the author leading the protocol development (MM) using SWIFT-Review. This will be done with the help of the SWIFT-Review Tag Browser and manually applied tags. Two reviewers (PK and KA) will independently extract data for the second objective using a customized data extraction template

XSL•FO
RenderX

for RCTs and non-RCTs) [47]. The data form which can be accessed in Multimedia Appendix 1 aligns with the Methodological Expectations of Cochrane Intervention Reviews (MECIR) [48].

Management of References

A reference management software (Mendeley reference manager) will be used to manage records both for citations and for the generation of bibliography.

Data Items

Data items to be extracted will include study title, year, author, country, study objective, conflicts of interest, funding, study design, population (age, sex, and ethnicity), setting, sample size, eligibility criteria, type of test, the time interval between the index and reference tests, the sample collected, statistical analysis, test status, time to results (turnaround time), test accuracy, and study limitations.

Outcomes and Prioritization

The outcome of interest for the first objective is the test impact (patients, health personnel, and the general public). The outcome of the intervention for the second objective based on PICO is the status of SARS-CoV-2/COVID-19, which involves how well the test can identify those with the target condition and reject those without the conditions. Studies comparing the index and reference tests regarding the above will be prioritized.

Risk-of-Bias Assessment

The assessment of the risk of bias of included studies will be conducted using the most relevant tools and based on study design [49]. Randomized controlled trials will be assessed using the revised version of the Cochrane Risk of Bias (RoB 2) assessment tool [50,51]. The items for risk-of-bias assessment using the RoB 2 tool will be organized into 5 domains including (1) bias due to randomization, (2) bias due to deviation from intended intervention, (3) bias due to missing data, (4) bias arising from outcome measurements, and (5) bias in the selection of reported results. Studies will be categorized into "low," "some concerns," and "high" for randomized controlled trials, as shown in Table S1 of Multimedia Appendix 2. Nonrandomized intervention studies will be assessed using the 8-item tool developed by the Evidence Project, suitable for a variety of study designs [52]. This tool assesses the risk of bias under 3 domains, including (1) study design, (2) representation of participants, and (3) comparison group of equivalence. Following the view not to attribute a summary risk-of-bias score for studies evaluated using the Evidence Project tool [52], the risk of bias of nonrandomized studies will be reported based on Table S2 of Multimedia Appendix 2.

Metabias

Publication bias will be reduced through the inclusion of gray literature [53,54]. Additionally, in the event of a meta-analysis, publication bias will be assessed by inspecting the funnel plot. Any indication of missing data through funnel plot asymmetry will be adjusted using the "trim and fill" approach [55]. A positive difference between the corrected and uncorrected diagnostic accuracy values will be indicative of an overestimation of diagnostic accuracy due to missing data.

Data Synthesis

Synthesis Procedure

Our synthesis approach for objective 1 to a greater part will take the form of a narrative synthesis [56,57]. Other studies have been found to use a similar method [58-61]. This will help maintain the contextual nature of the different mass testing options that will emanate from the literature. We will perform a meta-analysis for the second objective. We also anticipate possible heterogeneity in study design, study population, setting, and type of test, which may not make it possible to do a meta-analysis, in which case we will perform a synthesis without meta-analysis. Given the role played by context and system setup, we hope to capture both the quantitative and qualitative nature of diagnostic test studies.

Synthesis Framework

For outcomes under objective 1, the synthesis will follow four elements regarding the implementation of rapid mass testing, including (1) theoretical modeling, (2) preliminary synthesis (3), data interrelatedness, and (4) synthesis robustness [56]. Each of the aforementioned elements will be assessed using the most appropriate technique. An interpretative technique will be used to develop a theory about mass testing in relation to the outcomes of interest. The preliminary synthesis will be done using tabulation, textual description, clustering, and data translation. The relationship between data will be assessed using conceptual triangulation, case description, visual representation, and methodological triangulation. We will do a narrative synthesis to describe the outcomes of interest and other contextual factors. The synthesis robustness will be assessed through a critical reflection on the synthesis performed.

Concerning objective 2, we will perform a meta-analysis using the bivariate hierarchical logistic regression [62,63] in Stata, should there be a reasonable number of similar studies with the possibility of generating 2 x 2 tables. This multilevel model considers the correlation between sensitivity and specificity as well as variations in test performance between studies. If this is not possible, we will use positive and negative outcome events to pool event rates. We will inspect heterogeneity through direct observation of CIs on forest plots, where possible, and other graphs, as well as interstudy variability. The 95% CI binomial exact test will be used to report sensitivities and specificities for tests with single studies.

Data Presentation

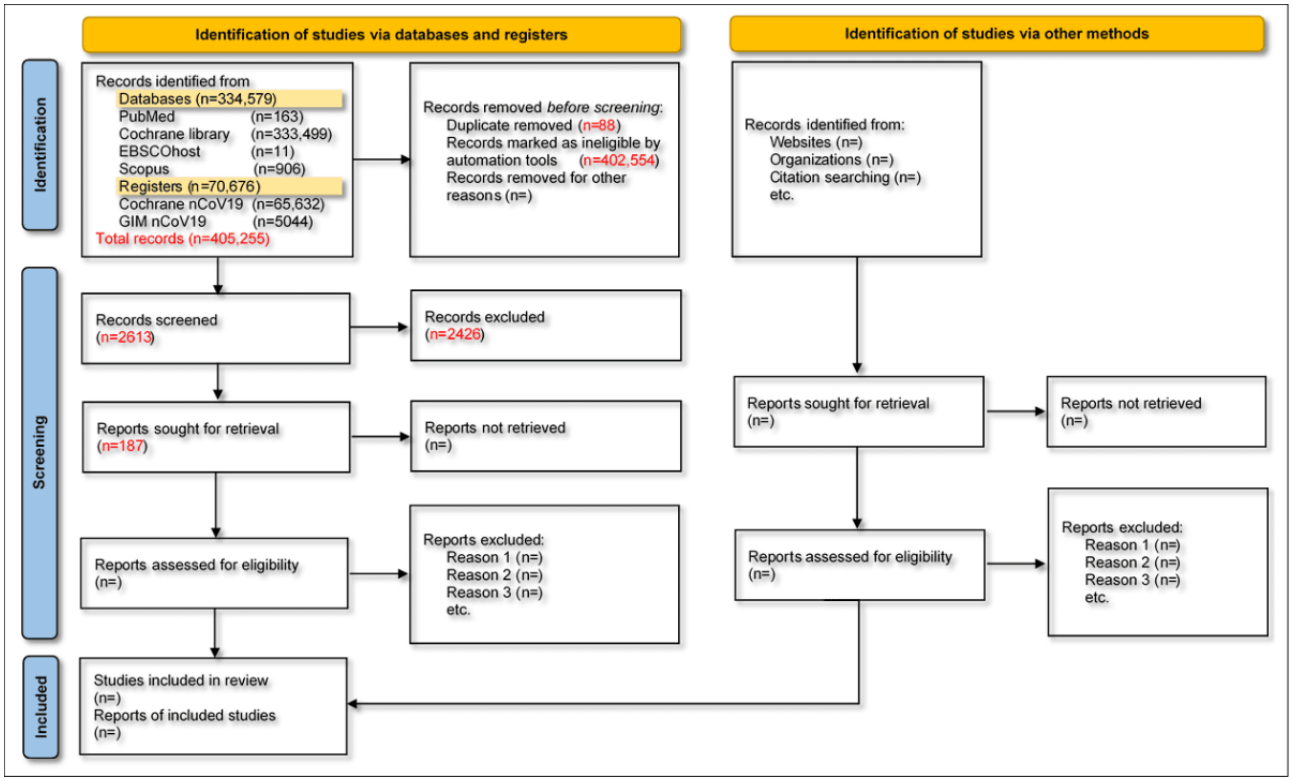
The review findings will be presented using tables, figures, and case descriptions. Risk-of-bias assessment visualizations will be conducted using the robvis web application [64] where possible. Included studies will be organized by point-of-care setting using table rows and by study design, sample size, population, index test, index and reference tests interval, the sample collected, target gene, turnaround time, and accuracy, using table columns. Case summaries regarding outcomes of interest for the first objective (impact on patients, personnel, and the general public) will be summarized and presented according to the World Bank's classification of countries by income for 2021-2022 [65]. Evidence of effect under the second objective will be presented using forest plots where possible.

XSL•FO
RenderX

Quality of Evidence

The search strategy will follow the PRISMA search guidelines [66]. The quality of database search will be improved by searching beyond Medical Subject Headings (MeSH) terms by including "AND" and "OR" strings to the MeSH terms. Retained studies will be assessed for risk of bias using the most appropriate guidelines and checklists. The overall body of qualitative evidence in the first objective will be assessed using a critical reflection as highlighted [56], and the Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) Confidence in the Evidence from Reviews of Qualitative research (GRADE-CERQual) [67]. If applicable, the GRADE will be used to assess the overall body of evidence regarding objective 2 [68,69]. This will consider the risk-of-bias assessments, precision in reported results, consistency, directness, and publication bias.

Ethics and Dissemination



This study does not warrant any ethical approval. This protocol has been registered with the International Prospective Register of Systematic Reviews (PROSPERO; CRD42022283776) [45], in line with the standards for undertaking systematic reviews. Review results will be disseminated through conferences and their peer-reviewed publication in a relevant journal.

Results

This protocol will be in line with the PRISMA protocol checklist [66]. We do not expect to have a reasonably high number of studies for rapid tests performed at point of care in LMICs in this review. Should this be the case, the results will be reported as 2 separate reviews and published in a relevant journal, as it might be unlikely to summarize all results in 1 report that robustly addresses both research questions. Following the above, the results of this review will be reported per (1) RAMESES (Realist and Metanarrative Evidence Syntheses: Evolving Standards) publication standards for meta-narrative reviews [70] regarding objective 1 and (2) the PRISMA checklist [71] or the Synthesis Without Meta-analysis in systematic reviews checklist [72], in the event that a meta-analysis was not possible, regarding objective 2.

The second round of screening has been finalized. Figure 1 shows the search results from the different databases. We hope to finalize the synthesis by the end of February 2023 and to prepare the manuscript by April 2023.

Figure 1. Preliminary PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. GIM: Global Index Medicus; nCoV19: COVID-19.

Discussion

Summary

This protocol is based on the diagnostic usefulness and safety of rapid diagnostic tests in LMICs. A point-of-care test is one that can be delivered at the point of sample collection or near the patient, with results made available almost immediately. By "near the patient," we refer to settings as specified by the Centers for Disease Control and Prevention [36] and the Medicines and Healthcare products Regulatory Agency [73]. A range of rapid tests esteemed to be useful in surveillance has been reported in the literature [18,74,75], broadly categorized into diagnostic, screening, and public health surveillance tests [76]. Moreover, 36 lateral flow devices believed to have the minimum performance requirements have been published by

XSL•FO
RenderX

the UK government [37]. Their usefulness is however yet to be fully understood within the context of LMICs.

Comparison With Prior Work

A search for reviews evaluating rapid point-of-care test against the gold standard on asymptomatic carriers in Cochrane library found 3 reviews [38,77,78]. Only 1 of the reviews [38] evaluated the diagnostic accuracy of rapid diagnostic tests. The review concluded that evidence for the testing of asymptomatic carriers was limited and highlighted the overriding need for the evaluation of rapid tests in the settings for which they are intended. This review will be the first, to the best of our knowledge, to address this knowledge gap in LMICs from a public health perspective.

Although rapid mass testing programs came under serious criticism early in the pandemic [79-82], it is still obvious that the symptom-based testing alone is not comprehensive enough as it failed to bring the virus under control prior to the approval of vaccines; this is partly because even the gold standard reverse-transcription polymerase chain reaction test is also prone to false negatives [83]. One possible way of ensuring that people are detected as soon as they become infected is by making a rapid mass testing regime available at point of care and service points [84].

Strengths and Limitations

This protocol presents many strengths starting with its registration with PROSPERO. It is the first protocol that seeks to investigate both qualitative and quantitative evidence regarding the diagnostic safety of rapid mass tests in LMICs. The protocol's specific objectives, search strategy, and reporting are all in line with the guidelines for the undertaking of systematic reviews.

Conclusions

This review highlights the role of context in infection prevention and control using rapid mass testing. It flags the overriding need to involve users and providers in the evaluation of such tests in the settings for which they are intended. This will be the first review, to the best of our knowledge, to generate both qualitative and quantitative evidence regarding rapid mass testing specific to LMICs.

Acknowledgments

MM is an independent researcher. He can be reached at Alumni Relations, London School of Hygiene & Tropical Medicine.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during the current study.

Authors' Contributions

MM developed and registered the protocol and generated the first draft of the manuscript. PK and KA pilot-tested the data collection form. The manuscript was reviewed and approved by all authors.

Conflicts of Interest

None declared.

Abstract

Background: Mental health has become an increasingly significant issue in the workplace. Non–health care workers are experiencing increased levels of psychological symptoms in their workplaces, especially during the COVID-19 pandemic, which limited social interactions and health service access. These conditions have a negative effect on employees' mental health and may also be associated with work-related outcomes, such as reduced levels of work engagement. Cognitive behavioral therapy (CBT) is one of the most effective methods used for treating workers with mental illness and preventing work-related psychological outcomes. The delivery of internet-based CBT (iCBT) has been established as a result of both technological improvements that have influenced health promotion and prevention components, and limited social contact and health service access.

Objective: The purpose of this systematic review is to synthesize the best available evidence concerning the preventive effect of iCBT on employees.

Methods: A systematic search will be conducted across 12 electronic databases, including a hand search for main journals and reference lists. Randomized controlled trials testing the effects of iCBT on psychological outcomes and work engagement among employees will be eligible. Initial keywords will cover the concepts of employees, workers, non–health care personnel, internet-based, web-based, eHealth cognitive behavioral interventions, stress, depression, anxiety, and work engagement, and then a full search strategy will be developed. Following titles, abstracts and the full text will be screened for assessment against the inclusion criteria for the review. Search results will be fully reported and presented per Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Two independent reviewers will screen and extract data, appraise methodological quality using the Cochrane risk-of-bias assessment tool, and assess overall quality of evidence with the Grading of Recommendations Assessment, Development, and Evaluation approach. A random effects meta-analysis and standardized mean differences using review manager software will be applied to synthesize the effect of iCBT based on similar outcomes.

Results: This protocol was registered in the International Prospective Register of Systematic Reviews in March 2022 and is now an ongoing process. The data will be analyzed in August 2022, and the review process should be completed by December 2022. All included studies will be synthesized and presented to demonstrate the effectiveness of iCBT in decreasing psychological distress and optimizing work engagement outcomes among employees.

XSL•FO
RenderX

Conclusions: According to the findings of this study, iCBT therapies will be used to promote mental health concerns such as depressive symptoms, anxiety, psychological distress, stress, insomnia, and resilience among non–health care professionals. In addition, the results will be used to ensure the policy related to reducing psychological distress and optimizing work engagement in the workplace.

Introduction

Background

The extended COVID-19 pandemic has had an impact on the mental health of both health care workers and non–health care personnel [1]. Previous research has found a significant frequency of depression (34.6%), anxiety (42.3%), and psychological distress (65.1%) among workers during the COVID-19 pandemic [2]. This means that psychological distress has turned out to be more noticeable among employees in the workplace [3] during the COVID-19 pandemic. Psychological distress is the unique, uncomfortable, emotional state experienced by an individual in response to a specific stressor or demand that results in harm, either temporary or permanent, to the person [4]. Employees in various workplaces commonly face stress, anxiety, depression, attention-deficit/hyperactivity disorder, and bipolar illnesses. The symptoms indicate psychological distress involving insomnia, fatigue, difficulty concentrating, etc [5]. Long working periods, inappropriate salaries, job stress, an unhealthy working environment, and several risk factors in the workplace could also have a serious impact on one's mental health [6].

Previous systematic reviews have found that psychological distress such as stress, depression, and anxiety have been endured by a large number of employees around the world [3,5]. Those symptoms could prompt weakened prosperity such as sleep problems, fatigue, burnout, and manifest diseases including the consequence of work engagement outcomes. This not only impacts individuals' psychological well-being and reduces their capacity [6-8] but also leads to a financial burden on companies and governments [3,9]. Work engagement is also an important point among employees because it is linked to job performance and productivity. Work engagement is defined as a good, satisfying state of mind related to work that is characterized by vitality, dedication, and immersion [10]. Work engagement has been related to significant individual and organizational outcomes [11].

To minimize these consequences, a greater understanding of interventions that facilitate the improvement of psychological problems among employees is essential for protecting and promoting the mental health of workers during the prolonged COVID-19 pandemic [1,8,12].

Cognitive Behavioral Therapy Intervention

Cognitive behavioral therapy (CBT) is one of the most effective interventions to not only treat mental illnesses [13] but also prevent work-related psychological outcomes [14,15]. Internet-based CBT (iCBT) is a form of psychotherapy based on CBT principles, which is delivered through the internet by an individual or software that is not physically present with the client [13]. The delivery of iCBT was developed because of today's advanced technology, which has impacted everyday life, including aspects of health promotion and prevention, as well as providing an advantage during the COVID-19 crisis, which limited social interaction and health service access. Internet-delivered programs are named differently as *online interventions*, *web-based interventions*, *e-therapy*, *eHealth*, and *computerized cognitive behavioral therapy* [16]. In recent years, iCBT interventions have yielded techniques, which have been developed and tested in different forms for mental problems including depression and anxiety [13,17-19].

Rationale for Performing a Systematic Review

Previous systematic reviews have suggested that group iCBT interventions enhanced work performance among mental health workers [20]; reduced stress, anxiety, and depression among health personnel [21]; and reduced subsequent sickness-related absenteeism from work among adults with common mental disorders [14]. In addition, several researchers have examined the effectiveness of iCBT in improving outcomes for people with chronic illnesses and chronic mental disorders [18,19,22]. However, all of these existing reviews focused on health personnel and persons with mental health disorders and thus results may not be generalized to healthy workers and non–health care workers. Furthermore, most reviews used anxiety, depression, and insomnia as psychological outcomes but overlooked other work-related variables such as work engagement. Consequently, a comprehensive review and meta-analysis investigating the effectiveness of iCBT interventions on these outcomes among healthy workers is necessary.

A preliminary search of the Cochrane Database of Systematic Reviews, The JBI Database of Systematic Reviews and Implementation Reports, and the previous registration of an ongoing study in International Prospective Register of Systematic Reviews (PROSPERO) found no recent systematic reviews on this topic in progress. Therefore, the aim of this systematic review and meta-analysis is to evaluate the efficacy

XSL•FO
RenderX

of iCBT as a preventive intervention on work engagement and psychological outcomes for nonclinical workers.

Review Objective and Question

An objective of this systematic review is to synthesize the best available evidence concerning the preventive effect of iCBT on employees. Review questions are as follows: (1) in comparison to controls, what is the preventive effect of iCBT in improving psychological outcomes (including stress, anxiety, depression, insomnia, and resilience) among healthy non–health care employees? (2) In comparison to controls, do iCBT interventions, as preventive interventions, enhance work engagement among healthy non–health care employees?

Methods

The proposed systematic review will be conducted in accordance with the Cochrane Handbook for Systematic Reviews of Interventions [23].

Protocol Registration

A summary of the protocol and supplemental data were registered in PROSPERO (CRD42022320589) [24] to provide a methodological outline of this systematic review and meta-analysis.

Eligibility Criteria

Study Selection

This systematic review will admit studies that (1) involved participants who were healthy non–health care workers of any sociocultural background, such as office workers, military personnel, and teachers; (2) examined programs using iCBT or iCBT with co-interventions; and (3) included our primary outcomes, including psychological distress, depression, stress, anxiety, insomnia, and resilience, and examined our secondary outcome—work engagement. Due to logistic issues, we considered studies reported in English without any year restriction.

Exclusion criteria for this systematic review are studies that (1) involved participants who were health care professionals and those with mental disorders or physical illnesses who were different in context from non–health care workers, and (2) tested only face-to-face CBT.

Intervention

For this review, the iCBT program, as a preventive intervention, is defined as a psychotherapy program based on CBT principles such as cognitive restructuring, behavioral activation, and behavioral experiments, delivered via the internet, remotely, or through mobile-based platforms in an individual or group formats. This is in accordance with the aim of this review, which is to test the effectiveness of the core method of iCBT interventions on psychological distresses and work engagement outcomes.

Comparator

This review will consider studies that compare intervention groups with no intervention controls, active controls, placebo controls, and usual-care groups.

Outcomes

The studies that evaluate the effect of iCBT on any aspect of psychological outcomes including depression, stress, anxiety, insomnia, and resilience will be considered primary outcomes. This review will also consider studies of the effect on work engagement, which is operationalized as a good, satisfying state of mind associated with work, characterized by vitality, dedication, and immersion as a secondary outcome.

Types of Studies

This review will consider only randomized controlled trials. Studies reported in English will be included without any year restriction.

Information Sources

The 6 electronic databases to search published studies include PubMed, CINAHL, Embase, Ovid, MEDLINE, Scopus, and IEEE Xplore. Ongoing clinical trials will be searched in the clinical trial registry. Sources of unpublished studies or gray literature to be searched include Google Scholar, ProQuest Dissertations, and Theses Global and Ethos. The date when each database will be last searched is May 2022.

Search Strategies

The search strategy targets published and unpublished studies. The Peer Review of Electronic Search Strategies checklist [25] will be used in the search strategy. An initial limited search of PubMed will be undertaken to identify articles on the topic. Initial keywords will cover the PICO framework [26], which includes *participants* (employees, workers, and non–health care personnel), *intervention* (internet-based, web-based, and eHealth cognitive behavioral interventions), and *outcomes* (such as depression, anxiety, and work engagement; Multimedia Appendix 1). Boolean and proximity operators will be used to combine the search terms. Subsequently, the text words contained in the titles and abstracts of relevant articles, and the index terms used to describe the articles were used to develop a full search strategy for CINAHL, Embase, Ovid, MEDLINE, and Scopus. The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. A librarian will be consulted to ensure the comprehensiveness of the search strategy. The reference list of all included sources of evidence will be screened for additional studies. A hand search for the main journal such as the *Journal of Occupational Health*, the Journal *of* Occupational Health Psychology, and the Journal of Medical Internet Research will be also conducted.

Study Selection

Keywords and Medical Subject Headings terms (ie, *Internet-based cognitive behavioral therapy program* AND *Employees*) were piloted on PubMed. Following the search, all identified citations will be collated and uploaded into EndNote version 9 [27,28], and duplicates will be removed. Titles and abstracts will then be screened by 2 independent reviewers for assessment against the inclusion criteria for the review. The full text of selected articles will be assessed in detail against the inclusion criteria by 2 independent reviewers. Reasons for exclusion of sources of evidence in the full text that do not meet

XSL•FO
RenderX

the inclusion criteria will be recorded. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion or with an additional reviewer. The results of the search will be reported in full in the final systematic review and presented in a Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow diagram [29].

Assessment of Methodological Quality

A pilot test with 6 studies will be undertaken to guarantee consistency between the 2 reviewers responsible for the selection and data extraction process. Then, 2 independent reviewers will assess each eligible study for methodological quality prior to inclusion in the review, using the Cochrane risk-of-bias tool for randomized trials [30]. Potential biases in studies may include a selection bias, performance bias, detection bias, attrition bias, and selective report bias. Each domain will be rated as "Yes," "No," or "Unclear." All included studies will be processed in the next phase regardless of risk-of-bias scores. The study authors will be contacted to obtain information if needed.

The overall quality of evidence will be assessed using the Grading of Recommendations Assessment, Development and Evaluation method. Findings for each outcome will be rated as high, moderate, low, or very low quality. Items include study design, risk of bias, imprecision, inconsistency, indirectness, and publication bias. Any disagreements that arise between the reviewers will be resolved through discussion or with other reviewers.

Data Extraction

Data will be extracted from studies included in the review by 2 independent reviewers. A pilot test will be conducted on 6 studies to ascertain agreement between the reviewers. The data extracted will include specific details about the populations, interventions, comparison, outcomes, findings, and measurement of significance to the review objective. Any disagreements that arise between the reviewers will be resolved through discussion or with a third reviewer. Authors of papers will be contacted to request missing or additional data, where required.

Data Synthesis and Presentation

Outcomes will be analyzed as continuous and dichotomous outcomes whenever possible. Meta-analyses will be performed using the random effects model for outcomes using Review Manager (RevMan) [31] computer software. For continuous outcomes, the standardized mean difference and 95% CIs for the means will be calculated. A P value of less than .05 will indicate statistical significance for the overall effect. Heterogeneity of effect sizes across studies will be determined by significant chi-square values and an I^2 value of >60%. Subgroup analyses will be performed [32]. A Funnel plot will be used to examine publication bias if there are 10 or more studies included in the meta-analysis. An asymmetry funnel plot will substantiate the presence of publication bias. A meta-analysis will be conducted with studies that report on the same outcomes.

Results

This study was supported by the Department of Public Health Nursing, Faculty of Public Health, Mahidol University, Thailand, in January 2022. This systematic review protocol was started in February 2022 and registered in PROSPERO in March 2022. As of August 2022, the data were analyzed, and the final report of the review were completed at the end of December 2022.

The characteristics of the included studies and the description of iCBT interventions will be summarized. The findings from the meta-analysis will show and describe the ability of iCBT to change psychological distress and work engagement outcomes among employees. When quantitative synthesis is not possible, a narrative synthesis of the results will be used.

Discussion

Here we provide a short summary of the main findings related to the aim and hypothesis of this review. The discussion will be motivated by the fact that the iCBT intervention will benefit selected outcomes based on the existing pool effect size of all included studies and how they add new findings to these fields. In addition, here we shall explain why the effective iCBT interventions yielded the results that they did and how they would be supported by the current evidence and comparison to prior work.

There will be strengths and limitations to this review. In contrast to previous reviews, we will concentrate on healthy non–health care workers. The new evidence of preventive psychological and work engagement outcomes is to be included in our review. Only randomized controlled trials were included in the study because they are regarded as the most suitable research designs.

The meta-analysis will be carried out in order to pool the effect size among individual studies for each outcome. This result could predict the evidence supporting the use of iCBT interventions in clinical practice. The limitations to this review will be explained in terms of the possibilities for future research, such as the generalizability of the findings, confirming further results, and clarifying more outcomes in future research.

The findings from this review will provide evidence for clinical and policy implications that internet delivery has the potential to improve the benefits of CBT in terms of reducing psychological consequences and increasing work engagement level. This conclusion will be used to assist in making decisions regarding implementing iCBT techniques as a preventive intervention for healthy non–health care employees in clinical practice, such as the variety of program characteristics, including content and duration, which will be examined for use in enhancing employee outcomes. The efficacy of iCBT will also be used to improve the negative impacts of psychological conditions and support high levels of work engagement in the workplace.

According to the findings of this study, iCBT therapies will become a strategy for promoting mental health issues among healthy non–health care workers, such as depressive symptoms,

XSL•FO
RenderX

anxiety, psychological distress, stress, insomnia, and resilience. The summary of this review will also support future decision-making regarding the adoption of an internet-based intervention to reduce psychological discomfort among employees. Importantly, the findings will be used to ensure workplace policies that aim to alleviate the negative impacts of psychological conditions.

Acknowledgments

This study was supported by the Department of Public Health Nursing, Faculty of Public Health, Mahidol University, Thailand.

Authors' Contributions

WL, PB, and PKY conceived the initial concept for the review. All authors revised and approved the protocol, which was developed by WL. WL and PB will carry out the search strategy, screening, extraction, and analysis of the included studies. WL will draft the final manuscript of this systematic review with contributions and approval from all authors.

Conflicts of Interest

None declared.

Abstract

Background: Precision health is a rapidly developing field, largely driven by the development of artificial intelligence (AI)–related solutions. AI facilitates complex analysis of numerous health data risk assessment, early detection of disease, and initiation of timely preventative health interventions that can be highly tailored to the individual. Despite such promise, ethical concerns arising from the rapid development and use of AI-related technologies have led to development of national and international frameworks to address responsible use of AI.

Objective: We aimed to address research gaps and provide new knowledge regarding (1) examples of existing AI applications and what role they play regarding precision health, (2) what salient features can be used to categorize them, (3) what evidence exists for their effects on precision health outcomes, (4) how do these AI applications comply with established ethical and responsible framework, and (5) how these AI applications address equity and social determinants of health (SDOH).

Methods: This protocol delineates a state-of-the-art literature review of novel AI-based applications in precision health. Published and unpublished studies were retrieved from 6 electronic databases. Articles included in this study were from the inception of the databases to January 2023. The review will encompass applications that use AI as a primary or supporting system or method when primarily applied for precision health purposes in human populations. It includes any geographical location or setting, including the internet, community-based, and acute or clinical settings, reporting clinical, behavioral, and psychosocial outcomes, including detection-, diagnosis-, promotion-, prevention-, management-, and treatment-related outcomes.

Results: This is step 1 toward a full state-of-the-art literature review with data analyses, results, and discussion of findings, which will also be published. The anticipated consequences on equity from the perspective of SDOH will be analyzed. Keyword cluster relationships and analyses will be visualized to indicate which research foci are leading the development of the field and where research gaps exist. Results will be presented based on the data analysis plan that includes primary analyses, visualization of sources, and secondary analyses. Implications for future research and person-centered public health will be discussed.

Conclusions: Results from the review will potentially guide the continued development of AI applications, future research in reducing the knowledge gaps, and improvement of practice related to precision health. New insights regarding examples of existing AI applications, their salient features, their role regarding precision health, and the existing evidence that exists for their effects on precision health outcomes will be demonstrated. Additionally, a demonstration of how existing AI applications address equity and SDOH and comply with established ethical and responsible frameworks will be provided.

Introduction

Overview

Precision health is described as the ability to assess disease risks at an individual level, detect early preclinical conditions, and initiate preventive strategies [1]. Precision health refers to personalized health care based on a person's unique genetic, genomic, or omics composition within the context of lifestyle, social, economic, cultural, and environmental influences to help individuals achieve well-being and optimal health [2]. As a field of research, it is still being delineated in relation to other fields such as precision medicine [3], while at the same time giving rise to other research concepts that it may actually encompass, such as precision public health [4]. In this manner, the scope of precision health is broader than that of precision medicine, by including strategies for health promotion and disease prevention that occur outside the setting of health care institutions, which can be widely adopted [5]. Thus, precision health strives to match promotion, prevention, diagnostic, and treatment interventions with genetic, biological, environmental, and social and behavioral determinants of health in a more person-centered manner [6]. Precision health, in a nutshell, entails shifting the focus from treatment to promoting health and preventing the onset of diseases.

Precision health, an evolution of precision medicine, combines genetic and genomic sequence, protein, metabolite, and microbiome information collectively known as "omics" with lifestyle, social, economic, cultural, and environmental factors [1].

Precision health applications often combine more than one data source to assess risks and diagnose and initiate preventative interventions, including biological, genetic, environmental, social, and lifestyle-related measurements or observations. Although combining clinical- and community-based health data sources has not yet been established as necessary to fall within the realm of precision health, the field does provide the theoretical basis to amalgamate precision medicine and the social determinants of health (SDOH) [7] within the same interventions. This ambitious approach to health includes dynamic linkages between the research and practice of medicine, economics, population health, and public health [6].

Digital technologies such as artificial intelligence (AI) are playing an increasing role in precision health. AI systems are partially or wholly autonomous machine-based systems that can, using statistical and mathematical modeling techniques for a given set of human-defined objectives, make predictions, recommendations, or decisions influencing real or digital environments [8]. A recent review has identified few studies on machine learning techniques that promote behavioral changes and physical or mental health [9]. AI-based health technologies are rapidly entering the precision health domain outside the clinical setting. Examples of such technologies include screening and early detection devices and applications, health tracking applications, and mobile devices that support healthy living and improve chronic diseases management. In many cases, such technologies are integrated into devices where precision health was not the primary function or purpose. This may affect both the reliability and accuracy of, but also access to, precision health strategies. Some scholars have highlighted the potential of AI-based interventions in integrating the SDOH and precision medicine to improve overall population health [6,10].

With the prevalence and rapid development of health AI applications, the World Health Organization (WHO) has released a set of guiding principles for the ethical use and governance of AI in health [11]. Per the WHO guidelines, emphasis should be on (1) protecting autonomy; (2) promoting human well-being, human safety, and the public interest; (3) ensuring transparency, explainability, and intelligibility; (4) fostering responsibility and accountability; (5) ensuring inclusiveness and equity; and (6) being responsive and sustainable during its deployment. These guidelines thereby address a recent discussion of AI's bias [12] and other challenges [13] to its use in health applications. The source of such bias and related challenges may be largely related to a long-entrenched health research focus on specific socioeconomic and demographic populations. A recent review further demonstrated that only 20% of studies include individuals from socioeconomically disadvantaged backgrounds [14]. There is, therefore, considerable risk for bias which should be clearly considered in AI algorithms that steer precision health interventions.

The Organisation for Economic Co-operation and Development has also published 5 complementary values--based principles for the responsible stewardship of trustworthy AI [8]. Three Organisation for Economic Co-operation and Development countries' health regulatory agencies further elaborated upon these values by providing a common set of machine learning best practices for medical device development [15]. A potential challenge with value-based ethical frameworks is their openness to interpretation and lack of enforceability. Health AI technologies' rapid development and focus on individualization may also affect the longevity and scope of guidance for their application, suggesting a need for more tailored assessment than current standards [16], if not stricter regulations. The European Union (EU) Commission has also proposed a legal framework for trustworthy AI based on EU values and fundamental rights

XSL•FO
RenderX

[17], stressing human-centrism, trust, safety and compliance with the law, and fundamental rights.

Several state-of-the-art reviews have been conducted for a broad array of AI-based applications in precision medicine [18], including oncological treatment [19], cardiovascular imaging [20,21], and optimization of clinical workflows [22]. However, similar, timely reviews of AI-based applications within the broader context of precision health are not yet available, and the types and categories of such applications are largely undefined. One summary of state-of-the-art consumer health informatics and education was conducted in 2018 [23] to elucidate opportunities, challenges, and practical implications of AI in these applications, stating that direction and evidence on the benefits of AI to individuals' health were lacking. Since then, the global AI in health care market size is projected to grow from US $8.23 billion in 2020 to US $194.14 billion in 2030, growing at a rate of 38.1% [24].

Review Questions and Objectives

We plan to conduct a state-of-the-art literature review to address research gaps and reduce the knowledge gap regarding novel AI-based applications in precision health. The research questions guiding the review are as follows:

- What novel AI-based applications exist that target precision health and what is their role?
- How are AI-based applications categorized?
- What evidence exists for the effects of AI application on precision health outcomes?
- How do AI-based applications account for ethical and responsible AI principles according to the recent WHO and other guidelines, and if so, how are they operationalized?
- How do AI-based applications for precision health address socioeconomic determinants of health?

The objectives for the review are therefore:

- to identify and categorize novel precision health-related AI applications reported in both scientific and gray literature,
- to summarize the most recent evidence demonstrating effects of AI-based interventions in contributing to precision health outcomes,
- to identify evidence for compliance of AI-based applications in precision health with the WHO principles for ethical AI according to the WHO [11], and
- to assess how AI-based applications for precision health affect health equity in relation to socioeconomic determinants of health [25].

Methods

Overview

This article outlines the protocol for an original state-of-the-art review that will be undertaken and reported according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [26]. State-of-the-art reviews address more current matters and the most current literature in contrast to other kinds of reviews, offering new perspectives on the issue in focus and highlight areas in need of further research [27,28].

The review will encompass applications that use AI as a primary or supporting system or method when primarily applied for precision health purposes in human populations. Any geographical location or setting, including web-based, community-based, and acute, or clinical settings will be included, reporting clinical, behavioral, and psychosocial outcomes, including detection-, diagnosis-, promotion-, prevention-, management-, and treatment-related outcomes. Primary empirical research studies published in scientific or gray literature in the English language will be included for all dates prior to onset of searches.

Textbox 1 describes the planned eligibility criteria for the review based on population, intervention, contexts, and types of studies or evidence.

XSL•FO
RenderX

Textbox 1. Eligibility criteria for the planned state-of-the-art review.

Inclusion criteria

- Human participants of any age, health status, residence and background; and their samples, material, or data related to their health

  *Note: The use of samples, material, or data falls within the inclusion criteria. Fictional or fabricated material will be included as long as the trained models are validated for external previously unseen real populations.*N
- Applications that use artificial intelligence (AI) as a primary or supporting system or method, when primarily applied [1] for precision health purposes
- Any geographical location or setting, including web-based, community-based, acute, or clinical settings
- Clinical, behavioral, and psychosocial outcomes, including detection-, diagnosis-, promotion-, prevention-, management-, and treatment-related outcomes
- Primary empirical research studies published in scientific or gray literature (see information sources)
- English language for scientific and gray literature; those that can be obtained as full texts or reports
- All dates prior to the onset of searches

Exclusion criteria

- Any participants, samples, material, or data not obtained or derived from humans
- AI-based systems or methods that are primarily applied for other reasons, even if they indirectly affect precision health outcomes

  Note: An example of an excluded intervention would be an AI-based application for tailored marketing of services or products, which affects the users' psychological or well-being status.
- Economic or organizational outcomes (eg, cost-effectiveness or organizational efficiency studies)
- Qualitative, nonempirical studies, editorial or opinion pieces, or reviews
- All other languages; articles that cannot be obtained as full texts or reports

Information Sources

Scientific database searches will be conducted from all dates prior to the onset of searches in Medline (EBSCOHost), CINAHL Plus (EBSCOHost), APA PsycInfo (EBSCOHost), Scopus [29], Web of Science [30], IEEE [31], and Cochrane Central Registry of Controlled Trials [32].

Searches in gray literature, or "that which is produced on all levels of government, academics, business and industry in print and electronic formats, but which is not controlled by commercial publishers, i.e., where publishing is not the primary activity of the producing body" [33], will be conducted. The purpose of the gray literature searches is to identify ongoing or completed studies that are not available in the commercial scientific literature databases. Links to such studies may also be found in device registries. The following gray literature sources will therefore be searched:

- Study registries and registers of medical devices:
  - WHO ICTRP [34]
  - ClinicalTrials.gov [35]

Search Strategy

The preliminary search terms and number of retrieved documents are provided in Table 1. The full review will include both free-text and controlled vocabulary, and the search terms will be adapted for each database. The search terms related to the intervention precision health through AI will be divided into 2 blocks. Proximity operators will be used, where possible, to increase the chance of finding relevant references. Searches of gray literature will be simplified to individual terms if required. No date limit will be applied.

XSL•FO
RenderX

Table 1. Example of the search strategy in Medline (EbscoHost, October 17, 2022)

Search #	Search blocks	Retrieved documents, n
1	TI ((genomic* OR precis* OR personali* OR individuali* OR stratif* OR tailo* OR adapt* OR custom* OR predictive) N2 health*) OR AB ((genomic* OR precis* OR personali* OR individuali* OR stratif* OR tailo* OR adapt* OR custom* OR predictive) N2 health*)	18,454
2	(TI "Artificial Intelligence" OR AB "Artificial Intelligence") OR (TI "machine learning" OR AB "machine learning") OR (TI "deep learning" OR AB "deep learning")	104,534
3	(MH "Artificial Intelligence+")	156,342
4	2 OR 3	208,639
5	4 AND 1	571
Limiters	Narrow by Language: English	566

A larger alteration concerning the search block relating to AI is applied based on the recent publication [46]. However, due to complexity, databases such as IEEE and Cochrane Trials are excluded. Yin et al [46] argue that AI is a broadly encompassing term and includes specific AI techniques, such as neural networks, support vector machines, decision trees, and natural language processing. Yet, such studies are highly likely to use "artificial intelligence" or "machine learning" in abstracts or keywords [47].

The final search terms and eligibility criteria (Textbox 1) will be designed to capture a range of precision health research. The search strings are presented in Table 1.

Data Management Plan

All identified records will be entered into EndNote (Version X20, Clarivate Analytics) and duplicates will be removed. Remaining records will then be entered into and managed within the Covidence systematic review software (Veritas Health Innovation Ltd) for the remaining review process.

The PRISMA guidelines for reporting of systematic reviews [27] will be followed. Three researchers will conduct the review process in 4 steps:

1. Initial screening: the titles, keywords, and in some cases abstracts of the obtained records will be screened for relevance by 2 reviewers independently in duplicate and voted upon for relevance for further review. Consensus will result in inclusion or exclusion, with conflicts resolved by a third researcher.
2. Full-text screening: the full text for all studies proceeding to this step will be obtained and read independently by 2 reviewers, who will vote upon inclusion in the next step. Consensus will result in inclusion or exclusion, with conflicts resolved by the third researcher.
3. Citation searching: the cited references for, and citations of, any studies included after the full-text screening step will be searched in the same manner as the source articles, and then follow the steps preceding this in the review process.
4. Data extraction: essential information regarding the study aim, design, conduct, population, intervention, and outcomes, as well as results data for relevant outcomes, will be extracted from each included study by 2 reviewers independently. Consensus will result in the inclusion of the extracted data in the review's summary of findings, with conflicts resolved through dialogue or, failing consensus thereafter, by the third researcher.

Quality Assessment of AI Interventions

Due to the diversity and heterogeneity of existing AI techniques, significant biases are likely to occur, making it difficult to interpret the results and implement these models in practice [48]. AI-based models rely substantially on data, quality, quantity, and type of data to ensure high algorithmic accuracy. Additionally, studies related to AI interventions require high methodological quality and rigorous standards of outcome reporting and representative study participants.

Thus, Quality Assessment of Diagnostic Accuracy Studies 2 (QUADAS-2) will be used to validate the quality of studies in the review [49]. The QUADAS-2 tool includes 4 domains covering flow and timing, reference, standard, and patient selection. Each domain is evaluated for biases and assessed for applicability.

Framework for SDOH

There is no universal standardized method for categorizing SDOH. For example, the WHO's conceptual framework includes micro-, meso-, and macrolevel measures [50]. SDOH is further defined by the Centers for Disease Control and Prevention as "conditions in the environments in which people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks" [51]. Thus, SDOH falls into 5 key categories: health care access and quality, education access and quality, social and community context, economic stability and the neighborhood, and the built environment.

For this review, the framework for SDOH will be based on the sociocultural environment within the framework for digital health equity. This includes social determinants that include downstream and upstream factors at the individual, interpersonal, community, and societal levels [52].

Ethics and Dissemination

This study will not involve human participants and their primary data or unpublished secondary data, thus ethical approval is not required. Findings of the state-of-the-art review will be disseminated through publication in an open-access scientific journal as well as through research networks and journalistic media.

XSL•FO
RenderX

Patient and Public Involvement

The primary and secondary analyses will be presented to representatives of multiple stakeholder groups, including users or patients, professionals, and public purchasers (if relevant). Their input will then be solicited to assist in the secondary analyses regarding anticipated impact and consequences on equity and the SDOH.

Results

Overview

This article is step 1 toward a full state-of-the-art literature review with data analyses, results and discussion of findings which will also be published.

The anticipated consequences on equity from the perspective of SDOH will be analyzed. Keyword cluster relationships and data analyses will be visualized to indicate which research foci are leading the development of the field and where research gaps exist. Results will be presented based on the data analysis plan that include primary analyses, visualization of sources, and secondary analyses. Results from this review will potentially guide continued application and development of AI applications and pinpoint agenda for future research to reduce the knowledge gaps and improve practice related to precision health. New insights regarding examples of existing AI applications, their categorization and role regarding precision health, and the existing evidence for their effects on precision health outcomes will be demonstrated. Additionally, how existing AI-based applications account for ethical and responsible AI principles and address socioeconomic determinants of health will be analyzed.

Primary Analyses

The main statistics in each study relevant to the aims of the review will be reported as well as grouped across studies by target population (eg, older individuals, risk groups, disease state), channel (eg, device, software, or app), setting (eg, home or primary care), area of focus (eg, detection and treatment), and outcome (clinical, behavioral, and psychosocial). Depending on the statistical reporting of the studies, which is often less rigorous in gray literature, further synthesis may be conducted. As this is not a systematic review, the strength of the cumulative body of evidence will not be assessed.

Secondary Analyses

The compliance of the precision health AI interventions or applications with the WHO principles for ethical AI [11] will be assessed and analyzed on quantitative (number of principles) and qualitative (degree or veracity of fulfilment of principles) levels. The anticipated consequences on equity from the perspective of SDOH will be analyzed.

Discussion

Overview

This article is step 1 toward a full state-of-the-art literature review with data analyses, results, and discussion of findings, which will also be published.

Keyword cluster relationships and data analyses will be visualized to indicate which research foci are leading the development of the field and where research gaps exist. Results will be presented based on the data analysis plan that include primary analyses, visualization of sources, and secondary analyses. Results from this review will potentially guide continued application and development of AI applications and pinpoint agenda for future research to reduce the knowledge gaps and improve practice related to precision health. New insights regarding examples of existing AI applications, their categorization, and role regarding precision health and the existing evidence for their effects on precision health outcomes will be demonstrated. Additionally, how existing AI-based applications account for ethical and responsible AI principles and address socioeconomic determinants of health will be analyzed.

This protocol is step 1 in the full state-of-the-art review that intend to provide insights on the evidence-based novel AI applications that promote precision health and how these applications comply with the WHO principles for the ethical use and how they affect health equity in relation to socioeconomic determinants of health.

As per our knowledge, this will be the first review addressing and precision health through lenses of ethics and SDOH. As an example of the search we conducted, search strategy in Medline (EbscoHost, October 17, 2022) indicated a total of 566 retrieved documents. Updated searches will be conducted in the full review.

Primary analyses will include main statistics in each study relevant to the aims of the review as well as grouped across studies by target population, setting, area of focus, and outcome. Visualization of sources will include mapping the existing literature on the use of AI in precision health and will help illustrate what precision health-related AI applications exist.

Secondary analyses will include compliance of the precision health AI interventions or applications with the WHO principles for ethical AI and consequences on equity. Due to the diversity and heterogeneity of existing AI techniques, and the significant biases that are likely to occur, QUADAS-2 will be used to validate quality of studies in the review [49]. This will enable interpretation of the results from the review and address implementation of AI models in practice [48].

Conclusions

This protocol will guide the development of the full review article. Results will potentially guide continued development of AI applications, future research in reducing the knowledge gaps, and improve practice related to precision health. New insights regarding examples of existing AI applications, their categorization and their role regarding precision health, and the existing evidence exists for their effects on precision health outcomes will be demonstrated. Additionally, demonstration of how existing AI applications address equity and SDOH and comply with established ethical and responsible framework will be provided.

XSL•FO
RenderX

Implications for future research and person-centered public health will be discussed in the full review in the light of strengths and limitations.

Acknowledgments

This research is funded by the Mälardalen university special grant for development of health and welfare technology research. The authors would like to acknowledge Julia Harrysson and Per Nyström who contributed to the literature search and to the visualization analyses, respectively.

Authors' Contributions

SWA conceived the project and conceptualized the research idea and is the guarantor of the review. SLS performed the literature search. MXR performed data extraction and data analysis. All authors contributed to the conceptualization and the drafting of this work. Inspirations were collected from previous reviews. All authors approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: With an increase in the number of artificial intelligence (AI) and machine learning (ML) algorithms available for clinical settings, appropriate model updating and implementation of updates are imperative to ensure applicability, reproducibility, and patient safety.

Objective: The objective of this scoping review was to evaluate and assess the model-updating practices of AI and ML clinical models that are used in direct patient-provider clinical decision-making.

Methods: We used the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist and the PRISMA-P protocol guidance in addition to a modified CHARMS (Checklist for Critical Appraisal and Data Extraction for Systematic Reviews of Prediction Modelling Studies) checklist to conduct this scoping review. A comprehensive medical literature search of databases, including Embase, MEDLINE, PsycINFO, Cochrane, Scopus, and Web of Science, was conducted to identify AI and ML algorithms that would impact clinical decision-making at the level of direct patient care. Our primary end point is the rate at which model updating is recommended by published algorithms; we will also conduct an assessment of study quality and risk of bias in all publications reviewed. In addition, we will evaluate the rate at which published algorithms include ethnic and gender demographic distribution information in their training data as a secondary end point.

Results: Our initial literature search yielded approximately 13,693 articles, with approximately 7810 articles to consider for full reviews among our team of 7 reviewers. We plan to complete the review process and disseminate the results by spring of 2023.

Conclusions: Although AI and ML applications in health care have the potential to improve patient care by reducing errors between measurement and model output, currently there exists more hype than hope because of the lack of proper external validation of these models. We expect to find that the AI and ML model-updating methods are proxies for model applicability and generalizability on implementation. Our findings will add to the field by determining the degree to which published models meet the criteria for clinical validity, real-life implementation, and best practices to optimize model development, and in so doing, reduce the overpromise and underachievement of the contemporary model development process.

KEYWORDS

model updating; model calibration; artificial intelligence; machine learning; direct clinical care

Introduction

Background

The ubiquitous application of artificial intelligence (AI) and machine learning (ML) algorithms in health care delivery has increased [1]. Investments in clinical AI and ML algorithms are based on their perceived potential to improve health care quality [1]. These algorithms can automate insights directly from data without using standard computer programming [2]. In addition, they can analyze large data sets with high dimensionality to yield insights and predictions on complex associations without prior assumptions from traditional statistical methods, differentiating AI and ML models from other statistical techniques (interference statistics, classical prediction models, and hypothesis testing) [3,4]. Generally, 2 methods of learning from data exist in AI and ML: supervised and unsupervised learning. Supervised learning involves making predictions based on a set of prespecified input, references, and output variables, whereas unsupervised learning is used to draw inferences from data sets consisting of input data without labeled responses [5].

There has been a paradigm shift in health care stakeholders' goals of quality improvement in recent years, with an emphasis on achieving better outcomes at lower costs, while improving the efficiency of care delivery and prioritizing personalized care [6]. This change, resulting in the use of AI and ML algorithms, has also been driven by regulators and payers demanding high-value care rather than volume-based care, as well as the changing role of patients as consumers [7]. In addition, the unprecedented abundance of data with the advent of electronic health records (EHRs) and other direct consumer wearables allows the application of data-heavy clinical models [8].

Despite these perceived potentials, AI and ML algorithm performance degrades over time, particularly because of model calibration (calibration drift), which refers to the accuracy of risk estimates in terms of agreement between the predicted risks of events and their actual observed frequencies [9]. Calibration drift arises as a consequence of deploying a model in a dynamic environment, with the resulting difference between the population or setting in which the model was trained and that in which it was implemented [10].

Degradation of a model over time can also occur within the same health care system where it was derived [11]. Among other factors, there is a tendency toward a systematic data shift when a model is successfully deployed [12,13]. The downstream characteristics of data change owing to differences in the distribution of outcomes in a prognostic model as users respond to the model prediction. The more effective a predictive model is to improve outcomes, the faster the model will likely degrade [14].

Because of the sensitive nature of patient-level algorithm predictions, consistency and accuracy are critical. Therefore, an appropriate model-updating process is essential across the lifetime of the model [15]. Model updating aims to improve the performance of an existing model by adjusting (recalibrating) its parameters and predictors, either within the same clinical environment in which the model was developed or within an external environment [15,16]. The best practice is to update a clinical model rather than abandon the model, build another, or repeat the selection of predictors, which leads to a loss of the previous scientific information captured [11,17].

The existence of multiple models for the same clinical scenario without model-updating methods declared ab initio leaves clinicians uncertain of which model is appropriate to use, potentially resulting in adverse consequences for patient care [17]. For example, there are more than 80 models for the prognosis of stroke [18], more than 20 models predicting intensive care unit stay after cardiac surgery [19], more than 100 published algorithms for prognosis after neurotrauma [20], and over 50 models to predict outcomes after breast cancer [21].

Peculiarities and Challenges of Model Updating in the Health Care Environment

The health care model updating process faces unique challenges owing to the health care sector's dynamic clinical, environmental, and regulatory ecosystem [22]. Therefore, it is imperative to consider all these issues from the early stages of clinical model development to ensure consistency and accuracy over time [1,23].

Subtle population demographic changes, in addition to changes in health care access and the heterogeneity of health insurance coverage (health disparity), can also deteriorate a model's future output [1,24]. Changes in best practice clinical guidelines, in addition to variations in practice preferences across different health care providers, can also be a source of data shift, resulting in suboptimal model output [1,15,25-29].

Health centers often update or change information systems and digital health tools such as imaging software and EHRs. Models that are not updated based on the data output of new information systems will be suboptimal [1]. In addition, there is a constant change in clinical nomenclature and disease coding, which can also affect the output [23].

The health care regulatory landscape is constantly evolving as well [30,31]. The enactment of the Affordable Care Act, which was associated with many sweeping reforms to health care delivery and redefining value in health care delivery, rendered previous standards of care invaluable [31]. As such, a model built based on those standards will likely be suboptimal.

RenderX

Issues Regarding Health Care Model Input Data

Learning artifacts or bias specific to the sites where training data sets were produced or because of the nature of the data set itself can ultimately result in a data set shift and model degradation over time [1]. Most AI tools are developed based on the nuances of specific local health care workflows and the data they generate. For example, consider an algorithm developed to predict sepsis based on a patient's lactate level. The algorithm will learn to correlate the physician's lactate orders with a high possibility of sepsis. However, model quality would be reduced if there were a policy change requiring more frequent ordering of lactate tests.

Model validation in these circumstances shows reduced performance, as the learned pattern does not generalize across sites and circumstances [24,32]. In addition, there is systemic bias in the geographic distribution of patient cohorts, as algorithms trained on US data were disproportionately trained on patients from just 3 states (New York, California, and Massachusetts) [33].

Label and causality leakage phenomena occur when the model's prediction target is directly or indirectly present in the training data set, rendering the model prediction irrelevant [34]. An example is a model developed to predict hospital mortality in patients admitted to the intensive care unit. An AI model trained naively on all data will learn to correlate extubating and turning off the ventilator with the death of a patient and ultimately produce a near-perfect predictive performance yet with absolutely no clinical utility [34]. Causality leakage in the clinical model can occur in a situation whereby a clinician orders a test based on a high index of suspicion of a clinical outcome that the algorithm is meant to predict; the algorithm then uses the test to generate an alert that results in an action [35].

Overview of Model Updating Methods in Health Care

There are several methods that address the data shift required to update models [1,16,17,23,36]. Although extensive details of these methods are beyond the scope of our analysis, we have highlighted the most important methods here [16,17,23,36]. The least complex method involves adjusting the model intercept to a different prevalence or incidence rate according to the new population (assuming risk factors still confer the same level of risk). Another option is adjusting the population prevalence rate and adding a single adjustment to all risk factors in the model. One or more risk factor relationships may also need to be adjusted, given the changes in relationships over time. A more drastic method involves adjusting both the prevalence and the coefficients and adding new risk factors into the model.

The last option involves refitting the entire model based on a new data sample, either alone or in combination with the addition of new potential risk factors (essentially remodeling the problem from scratch on a new sample). The best options typically depend on the time from initial model development to the time sample sizes are updated [23]. With larger samples or longer time periods since the initial fitting, ideal updates usually involve the prevalence updating option or refitting the model based on the updated sample. With small samples, it is generally advised that no updates are made. With shorter periods of time since the last update, it is generally recommended that the prevalence be updated.

Time and Frequency of Model Updating

A few approaches exist to guide the timing and frequency of model updating, each with its own advantages and limitations. Real-time calibration drift detection and updating is usually the most computationally intensive approach; however, real-time detection provides users with the peace of mind that their models are accurate at the time of use without requiring manual steps [23]. A similar approach is incremental updating, in which models are updated based on new instances as they become available [16,23]. This approach is computationally extensive and requires the same infrastructure to automatically provide near-real-time updates automatically. Fixed and batch updating at specified intervals is another option, with models evaluated and updated at specific intervals; however, if the frequency of the update is not ideal, model drift issues may exist before the update [16,23].

Study Objectives

Our main study objective is to evaluate model updating in AI and ML clinical models and assess model updating practices used in direct patient-provider clinical decision-making. Previously published reviews have established that most clinical AI and ML models do not conduct external validation of their models [5]. In addition, phases of model development pertaining to applicability and reproducibility (model updating, impact assessment, and implementation) have received less attention in the scientific literature [37]. Clinical model-updating processes seek to prevent model deterioration with adverse consequences, such as inaccuracy or lack of practicality in clinical settings; model updating can also impact generalizability and reproducibility [37]. The model-updating processes of clinical algorithms must be determined proactively from the time of initial model development [32,37] to ensure patient safety and quality of care. Understanding the degree to which model updating is prioritized will help inform the validation of future models and guide the modification of best practices in model development.

Our intentions are as follows:

1. To determine if the process of clinical model updating is mentioned or prioritized in the reviewed published clinical AI studies used to support direct patient-provider clinical decision-making.
2. To determine if AI and ML studies in the literature include demographic data and if there are significant geographic distributions of models whose investigators recommended model-updating procedures in their publications.
3. To test correlations between the quality of published AI clinical models and prioritization of the model-updating process.

Methods

Eligibility Criteria: Inclusion and Exclusion

This study protocol is for a scoping review. Our original protocol was developed based on the PRISMA (Preferred Reporting

XSL•FO
RenderX

Items for Systematic Reviews and Meta-Analyses) Protocols [38].

Inclusion Criteria and Rationale

Only AI and ML studies that involve clinically predictive or prognostic modeling used to support specific clinical decisions by medical providers for or against intervention for direct patient care will be included. In addition, only human studies with algorithms applied to organic and emotional and behavioral health domains used directly in addressing clinical problems (by supporting patient-provider decision-making) will be included. Examples of algorithms we will include are those predicting outcomes that affect clinical decisions and treatment (mortality and morbidity and predicting length of hospital stay) and those predicting complications and health improvement.

Algorithms comparing diagnostic modalities and tools with the possibility of affecting clinical decisions also fall under our inclusion criteria. We will include both observational and experimental studies regardless of study methods, as there is a dearth of randomized controlled trials (RCTs) in AI and ML studies owing to the novelty of AI applications in health care [39].

Supervised ML methods, including both classification and regression methods, will also be included. Most supervised predictive model outputs directly impact decisions at the point of use, unlike unsupervised or clustering and semisupervised methods, mostly to generate insights for a predictive problem [40]. Studies will be included without geographic or regional preferences. All studies that were published from March 2018 until March 2021 will be reviewed (Textbox 1).

Textbox 1. Inclusion criteria.

- Inclusion criteria and definition
  - Only artificial intelligence and machine learning studies that involve clinically predictive or prognostic modeling: Diagnostic prediction models calculate an individual's risk of having an illness, whereas prognostic prediction models calculate the risk of certain health conditions that could occur in the future.
  - Study outcome and outcome measures format: Only human studies with algorithms and outcomes in organic and emotional or behavioral health domains. All study outcome measures format will be included as follows: continuous, binary, ordinal, multinominal, and time-to-event.
  - Supervised machine learning technique: Only articles with supervised learning methods will be included, with methods such as regression, ensemble, and decision trees.
  - Study design and data source: Any experimental or observational study that meets our inclusion criteria will be included. These include randomized controlled trials, prospective and retrospective cohorts, case-control studies, and case-cohort studies. All data sources are permitted, including data registries and electronic health record data.
  - Predictors: Articles that use at least two predictor variables in their model development will be included.

Exclusion Criteria

Health care AI models that do not use clinical domains as a primary end point (studies of health care operations, finance, billing, and inventory management) will be excluded.

AI and ML studies whose predictions may not directly support provider-patient clinical decision-making, including the following, will also be excluded.

- Studies of population-based estimates only (incidences, prevalence, and others)
- Patient or provider satisfaction with care
- Studies designed to improve diagnostic tools, such as imaging and genomics
- Imaging biosignal studies that do not directly impact clinical decision-making
- Studies that evaluate health care system quality indicators

Unsupervised and semisupervised learning and clustering studies will also be excluded, as most data mining and unsupervised learning models are used to generate insights into a problem or identify predictive modeling problems [40]. Reviews, articles, commentaries, letters to the editor, conference abstracts, and commentary articles without algorithms will also be excluded.

We will exclude models embedded in proprietary software where the specific ML methods used are not specified. Failure to meet any of the above eligibility criteria will result in exclusion from the review (Textbox 2).

XSL•FO
RenderX

Textbox 2. Exclusion criteria.

- Exclusion criteria and definition
  - Health care artificial intelligence studies that do not involve clinical domains as the primary end point: Studies of health care operations, finance and billing, and inventory managements. These do not fall primarily under patient treatment and care.
  - Purpose and potential of study not directly supporting provider-patient clinical decision-making: Studies that may not impact direct provider decision-making at the point of care, such as population-based estimates only (incidences and prevalence), those designed to improve diagnostic tools, and those that evaluate health care system quality indicators.
  - Unsupervised learning and clustering studies: Those that mostly are used to generate insight into a problem or identify predictive modeling problems.
  - Nonexperimental articles and proprietary models: Reviews, articles, commentaries, letters to the editor, abstracts, commentaries without algorithms, and models embedded in a proprietary software whereby the specific machine learning methods used are not specified.
  - Genomics and advanced genetic algorithms: These articles are usually based on very high dimensional data and unsupervised methods, which are beyond the scope of our analysis.
  - Pathological specimen and image signal studies: Pathological specimen studies mostly seek to improve accuracy at the level of the clinical pathologist. Image signals studies are mostly used to improve the accuracy of an imaging instrument rather than provide a basis for preferred clinical outcomes.

Information Sources

A comprehensive literature search will be conducted using the following databases: Ovid Embase, Ovid MEDLINE, Ovid PsycINFO, Web of Science Core Collection, Scopus, and the Cochrane Library. Searches will be limited to articles published from January 1, 2018, to December 31, 2021.

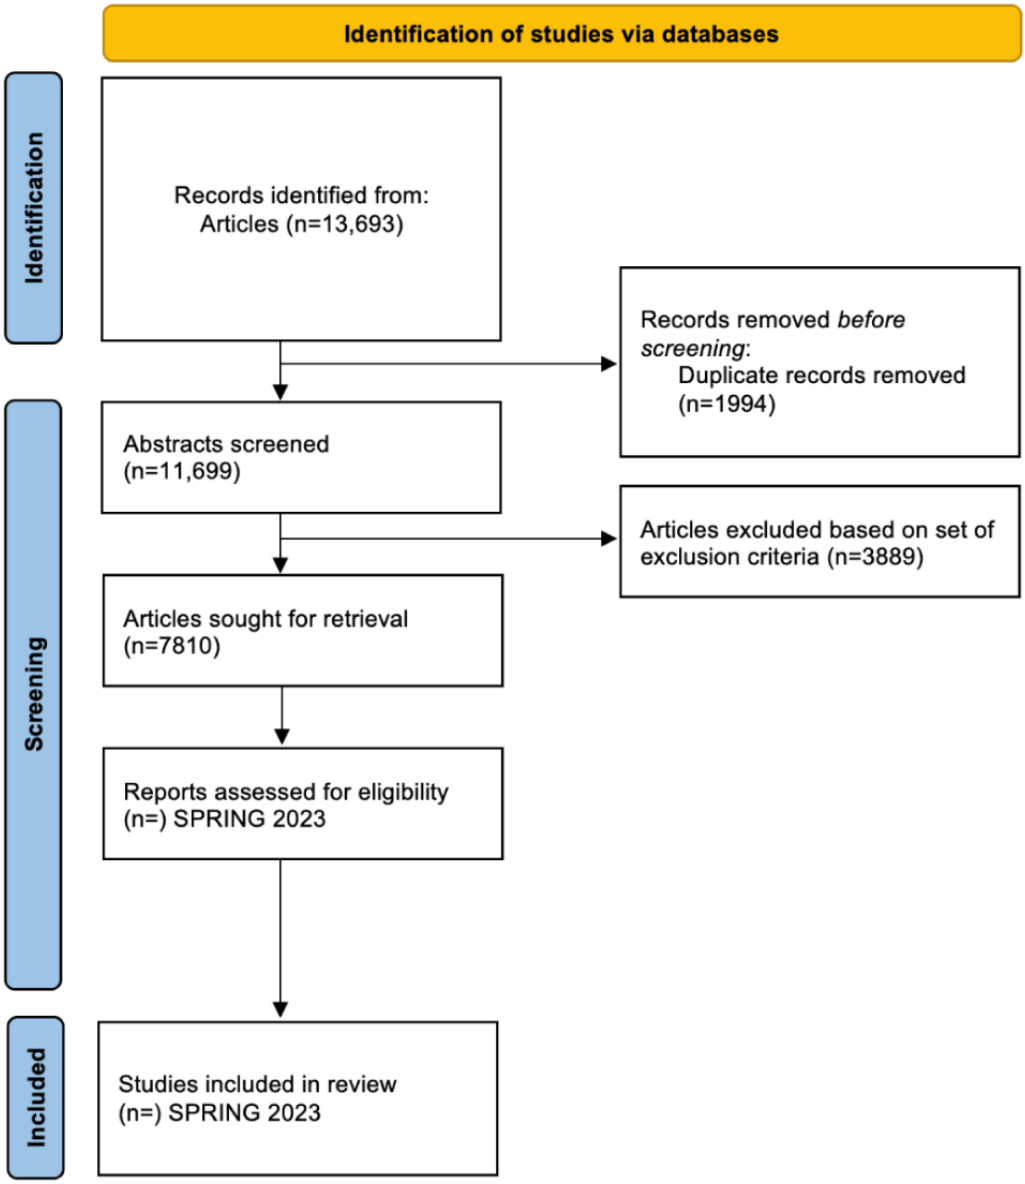
Search Strategy

The search strategy for each database was developed by a medical librarian (SW) in concert with the rest of the team. Each search strategy used a combination of keywords and subject headings related to ML, predictive algorithms, medical diseases and disorders, and study design (Multimedia Appendix 1).

Statistical Analysis

Data Management

All search results will be imported into Covidence software for deduplication and screening [41]. Covidence facilitates a blind review process, and results from multiple databases can be imported, deduplicated, and screened for eligibility. Following the title and abstract screening phase, the full text of all included abstracts will be gathered and imported. Covidence will create a PRISMA flowchart and facilitate the data extraction and quality appraisal phases [42].



Selection Process

Two reviewers will use the Covidence software to independently screen the title and abstract of each article and the full text of all included abstracts. A third-party independent reviewer will resolve disparities. The screening process will be documented and presented using the PRISMA flow diagram like the flowchart in progress in Figure 1.

Before title and abstract screening, the review team will meet to screen a random sample of 50 records to validate the inclusion and exclusion criteria.

XSL•FO
RenderX

Figure 1. PRISMA flow chart.

Data Collection Process

Variables collected from each eligible study will be guided by the CHARMS (Checklist for Critical Appraisal and Data Extraction for Systematic Reviews of Prediction Modelling Studies) [43] and PRISMA checklists [42].

Data Items

Data items will reflect the objective of our study, which is the need to prioritize clinical model updating as an integral part of validating published medical algorithms. Therefore, our data items will pertain to generalizability and applicability.

We will collect general study information, such as the title; first author; year of publication; clinical setting, such as academic, nonacademic, vendor, and governmental agency; disease system of the study; aim of the algorithm (predictive vs prognostic); type of algorithm (traditional ML vs neural network or deep learning); and geographic region. We will also collect data on study type and model type (research vs production model) as well as model-updating methods.

Our preliminary search on geographic clusters of AI adoption and model implementation revealed that AI and ML adoption is mostly clustered in the United States, Canada, the United Kingdom, Australia, the European Union, China, Taiwan, and Israel [44,45]. As these regions account for most of the clinical models created, we will use another category of “Other” to capture models developed in other geographic regions. We will also collect information about the data sources such as EHRs, open registry or open sources, and closed registry or proprietary databases.

In the *Methods* section, we will abstract the data relating to the assessment of study quality (Table 1). Data on handling missing data will also be abstracted, such as sample size, well-defined primary outcomes, and predictors. We will also abstract data on the study limitations considered in the Discussion section of the article in review.

Table 1. Checklist for Critical Appraisal and Data Extraction for Systematic Reviews of Prediction Modelling Studies.

Domains and key items	General	Applicability	Risk of bias
Source of data			
Source of data (cohort, case-control, randomized trial participants, or registry data)		✓	✓
Participants			
Participant eligibility and recruitment methods (consecutive participants, location, number of centers, setting, and inclusion and exclusion criteria)	✓	✓	
Participant descriptions	✓	✓	
Details of treatment received, if relevant		✓	✓
Study dates	✓	✓	
Outcome to be predicted			
Definition and methods for outcome measurements		✓	✓
Determine if the same outcome definition and method for measurement was used in all patients			✓
Type of outcome (single or combined end points)	✓	✓	
Determine if the outcome was assessed without knowledge of candidate predictors (blinded)			✓
Determine if candidate predictors were part of the outcome (in panel or consensus diagnosis)			✓
Time of outcome occurrence or summary of duration of follow-up		✓	
Candidate Predictors (or Index Test)			
Number and type of predictors (demographics, patient history, physical examination, additional testing, and disease characteristics)	✓		
Definition and method for measuring candidate predictors		✓	✓
Timing of predictor measurement (patient presentation, diagnosis, and treatment initiation)		✓	
Determine if predictors were assessed blinded for outcome and for each other (if relevant)			✓
Handling predictors in the modeling (continuous, linear, and nonlinear transformation or categorized)			✓
Sample size			
Number of participants and number of outcomes or events	✓		
Number of outcomes or events in relation to the number of candidate predictors (events per variable)			✓
Missing data			
Number of participants with any missing values (including predictors and outcomes)	✓		✓
Number of participants with missing data for each predictor			✓
Handling of missing data (complete case analysis, imputation, or other methods)			✓
Model development			
Modeling methods (logistics, survival, neural networks, or machine learning techniques)	✓		
Modeling assumptions satisfied			✓
Method for selecting predictors for inclusion in multivariable modeling (all candidate predictors and preselection based on unadjusted association with the outcome)			✓
Methods for selecting predictors during multivariable modeling (full model approach backward or forward selection) and criteria used (*P* value and Akaike Information Criterion)			✓
Shrinkage of predictor weights or regression coefficients (no shrinkage, uniform shrinkage, and penalized estimation)		✓	✓
Model performance			
Calibration (calibration plots, calibration slope, and Hosmer-Lemeshow test) and discrimination (*C*-statistic, *D*-statistic, and log-rank) measures with CIs		✓	
Classification measures (sensitivity, specificity, predictive values, and net reclassification improvement) and whether a priori cut points were used			✓
Model evaluation			

XSL•FO
RenderX

Domains and key items	General	Applicability	Risk of bias
Method used for testing model performance: development data set only (random split of data, resampling methods, bootstrap or cross-validation, or none) or separate external validation (temporal, geographic, different settings, and different investigators)			✓
In case of poor validation, whether the model was adjusted or updated (intercept recalibrated, predictor effects adjusted, or new predictors added)		✓	✓
Results			
Final and other multivariable models (basic, extended, and simplified) presented, including predictor weights or regression coefficients, intercept, baseline survival, and model performance measures (with SEs or CIs)	✓	✓	
Any alternative presentation of the final prediction models (sum score, nomogram, score chart, and predictions for a specific risk subgroup with performance)	✓	✓	
Comparison of the distribution of predictors (including missing data) for development and validation data sets			✓
Interpretation and discussion			
Interpretation of presented models (confirmatory, model useful for practice vs exploratory, and more research needed)	✓	✓	
Comparison with other studies, discussion of generalizability, strengths, and limitations	✓	✓	

Evaluation Outcomes

Primary Outcome

The primary outcome of this scoping review is the percentage of published algorithms that prioritize model-updating methods (model updating is considered prioritized if it is part of the algorithm protocol). We also identify articles that mention model updating but do not apply it to algorithm protocols.

Secondary Outcomes

We will also identify any correlations between prioritizing model updating and geographic region, and quality of studies, as well as temporal correlation and correlation by setting of model development. In addition, we will assess how frequently EHRs are used for model development, given the high incidence of inaccuracies in EHR data [46-48].

As a secondary end point, we will capture the incidence of models reporting the demographic breakdown of their data (ethnic background and gender); this is of particular importance owing to potential societal harm and resulting AI and ML algorithm setbacks because of the use of nonrepresentative data [49].

Quality of Studies and Risk of Bias Assessment

Owing to the overemphasis on model technical validity at the expense of downstream clinical validity in published algorithms, a clinical model that has acceptable, technically valid prediction results during model development with favorable statistical indexes, such as area under the curve, does not automatically translate to model effectiveness when deployed in real-life clinical scenarios [1,50-52]. Rather than the in-depth technical validity of model results, our evaluation of individual model quality will assess a model's ability to attain high real-life clinical validity for generalizability. Our goal is to focus on established factors and best practices that indicate a study's applicability and low risk of bias to ensure generalizability beyond the model's technical output as follows [52-54]:

- Applicability: the extent to which the study fits within the inclusion and exclusion criteria of the review
- Risk of bias: the extent to which any flaws in the study lead to overly optimistic estimates of predictive performance measures (CHARMS article)
- Generalizability: the degree to which the study results are relevant to the larger population
- Reproducibility: the ability to duplicate the study using the same methods used in the original study

Checklist/Evaluation Tools for Study Quality Assessment

Best practices recommend adequate reporting of model development to ensure reproducibility and applicability of models in real clinical settings [2]. To evaluate the quality of reporting of the reviewed published models, we used an adaptation of a verified tool available for model quality assessment [43]. The CHARMS is an 11-item checklist, with each item created to assess the model study on the domains of risk of bias and applicability (Table 1). The checklist is a comprehensive guide created from a combination of 8 other published guides that include both criteria to ascertain applicability and reproducibility with implications for patient safety, as well as technical validity of a model's results, some of which are beyond the scope of our review.

We created our quality assessment tool by extracting the criteria that are more specific to applicability and reproducibility analysis and that have a potential impact on patient safety and quality of care at the level of clinical model deployment, which resulted in our 6-item checklist for study quality assessment (Table 2). A total of 5 items out of our 6-item checklist were adapted from the CHARMS checklist; our last criteria, the model development checklist standard, was obtained from literature review best practices for model development.

[g]PROBAST-ML: Prediction model Risk Of Bias Assessment Tool- Machine Learning.

[h]STROBE: The Strengthening the Reporting of Observational Studies in Epidemiology.

Rationale for Checklist Items

Checklist Items Adapted From the CHARMS Checklist: Study Design and Data Source for Model Development

The data used to develop the algorithm may be sourced from retrospective and prospective cohorts including RCTs and cross-sectional studies. In addition, there is a proliferation of sourcing model data from registries, databases, and EHRs. Although RCTs are considered the gold standard, they also have shortcomings similar to all other methods. Although RCTs are designed to reduce biased outcomes, their findings can lead to impaired generalizability of outcomes in real-life clinical scenarios owing to the rigid eligibility criteria of study participants [43]. Data sources for model development are critical for the predictive accuracy, applicability, and reproducibility of any algorithm [11,12,43,50,51].

- Outcomes: the lack of well-defined study outcomes increases risk of bias and adversely affects model reproducibility in real-life clinical scenarios [43]. For example, 40% of cancer prognostic model studies were found to have poorly defined outcomes [55]. For our quality assessment, a well-defined outcome is considered to occur when the definition and measurement of the outcome events or target disease clearly correspond to the outcome definition of the study objective [43].
- Model testing and evaluation methods: model validation is the process of quantifying model performance in other individuals beyond the training and testing data set used to develop the model [56]. Whenever the predictive performance of a model is estimated using the same data set that was used to develop the model, it is referred to as "apparent performance" [43]. Regardless of which modeling technique is used, apparent performance tends to be biased, as it can overestimate performance relative to the performance of other individuals. It is very important that all models be evaluated in an independent data set (external validation) before deployment [55]. Externally validated models (either temporal or geographic validation) provided the best insights into the usefulness of the model for other individuals, centers or settings, and regions. Several reviews have shown that external validation studies are generally uncommon [5,20,57,58], as most studies are only internally validated by a random split sample of the data into development and validation samples [5]. Because of the higher impact of external validation on model applicability in real-life clinical scenarios, we prioritize these models in

XSL•FO
RenderX

our checklist by allocating 2 stars to any study with externally validated models (Table 1)

- Model updating method recommendation: in the event that an existing model shows poor performance when evaluated in other settings (geographic or temporal), it is best practice to adjust, update, or recalibrate the original model to increase performance [43], as there are well-established methods to achieve successful model updating. It is also best practice that the potential techniques for updating a model on external deployment can be identified before deployment [1,32]. The primary outcome of our review is the proactive determination of possible model-updating methods. As such, we will prioritize any study that proactively suggests a model-updating method as part of its study method by scoring it as 2 stars.
- Model interpretation and generalizability concerns: best practice guidelines for reporting medical studies recommend discussing strengths, weaknesses, and future challenges with regard to the generalizability of the studies [59-61]. For models, these studies should therefore provide insight into the model's applicability, usefulness, and intended users [43]. This discussion also serves as a basis for comparison with other studies. Therefore, our quality checklist will include a score (1 star) for a study that mentions the strengths and weaknesses of their model in the Discussion section.

Other CHARMS Checklist Items

The remaining 6 items in CHARMS were excluded from our assessment tool because they were already considered during the initial screening stage of our review process (participant characteristics and predictors). We also excluded items that focused on technical assessment, as that is beyond the scope of our study objective of real-life clinical applicability (technical process of model development, model performance, results, and sample size). Although the checklist still needs to be validated, our adapted checklist captures the essence of our review.

Checklist Items Based on a Literature Review of Best Practices of Clinical Model Studies: Model Development Reporting Standards

The best practice standards for reporting primary prognostic and predictive model studies exist in the literature [62] and include SPIRIT-AI (Standard Protocol Items: Recommendation for Interventional Trials- Artificial Intelligence), CONSORT-AI (Consolidated Standards of Reporting Trials-Artificial Intelligence), TRIPOD (Transparent Reporting of a Multivariable Prediction Model of Individual Prognosis Or Diagnosis), REMARK (Reporting Recommendations for Tumour Marker Prognostic Studies), and GRIPS (Genetic Risk Prediction Studies) [63-67]. Adhering to these guidelines may ensure study reproducibility and could improve future real-life applications [62,63,68]. Despite the availability of these guidelines, there is poor overall quality of reporting in many published AI models [53,62,68,69]. Therefore, we have included declaring a reporting standard as part of our checklist (reporting standard scores will receive 1 star).

For each checklist item fulfilled by the study reviewed, studies will be scored with 1 or 2 stars as described above, with a maximum score of 10 stars each.

Data Synthesis

After extracting data from the manuscripts, we will conduct a narrative synthesis. Data will be summarized using descriptive statistics, figures, and tables for visualization. Categorical data will be presented through numbers and percentages. The distribution of continuous data such as sample size and the number of predictors will be assessed and described using means and SDs for normally distributed data using median and 25th and 75th percentiles for nonnormally distributed data. The results will be characterized by study design, outcomes, service delivery type, ML techniques, and model-updating properties.

Ethics Approval

On August 13, 2021, our systematic review protocol was registered with the International PROSPERO (Prospective Register of Systematic Reviews) CRD42021245470 [70]. Our protocol was developed based on the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols) 2015 statement [38]. Our study does not require an ethics committee review because our research does not directly involve human subject data and it will be conducted on publicly available data from published articles.

Results

So far, we have conducted a literature search of the specified databases. We are now in the title and abstract screening phase. Our initial literature search yielded 13,693 articles; after removing duplicates, we obtained approximately 11,699 articles. We identified approximately 7810 articles for full article review among the 8 reviewers (Figure 1). We hope to complete the review process and disseminate the review results by spring of 2023.

Discussion

Principal Findings

AI and ML applications in health care are significantly increasing at an estimated 40% compounded annual growth rate [71]. Most models are proliferating because of their perceived potential for increased quality of health care at the point of care by providing real-time clinical decision support, early warning sign systems, clinical documentation, improved administrative workflow, medical device automation, and better imaging analysis [2,71,72]. Their implementation has the potential to move the needle from a reactive to a proactive approach, focusing on health management rather than disease treatment [71]. Despite this potential, there is a lack of adequate external validation and real-life assessment of the applicability of these models [5,36], which can adversely affect the generalizability of clinical models at the point of implementation [5,73]. There is also concern regarding algorithmic bias and worsening health inequity.

Owing to the complex nature of health care environments, clinical algorithms tend to deteriorate over time. Considering

XSL•FO
RenderX

the constantly evolving nature of medical practice in response to new technology, epidemiology, and social phenomena, it appears we will always be chasing a moving target with regard to outcome prediction using an algorithm [72]. Therefore, the relevance of clinical data as predictor factors decays with a half-life of only 4 months [74]. This decay phenomenon reinforces the need for model-updating methods that can adapt to evolving data from the inception of model development [74]. Although there are proposed methods for model updating in the literature [23], a lack of inclusion of these methods in published algorithms can impair a model's applicability and reproducibility. This review aims to highlight and raise awareness of these issues to encourage model developers to improve their protocols.

Limitations

Interpretation of our review should bear some limitations in mind. First, AI and ML implementations in health care are relatively novel and lack standardization across different regions and clinical specialty domains. Although we established our literature search strategy (Multimedia Appendix 1), this lack of standards can impact the scope and sensitivity of our search and render the reproducibility of our review challenging. While the terms "AI" and "ML" are included in our search, terms used to describe models and modeling are not standardized, and therefore, it is possible that our strategy will not capture possible emerging or lesser-known terms. In addition, our search included only English language publications, and, as such, we cannot generalize our findings to publications in other languages. In addition, we did not include book chapters, theses, short papers, editorials, non–peer-reviewed reports, or conference abstracts. Another factor to consider in the interpretation of our results is that the studies we reviewed were published during the global COVID-19 pandemic. The impact of the pandemic on the nature and type of AI and ML studies published during this time is unknown.

Conclusions

In this scoping systematic review, we will review published AI and ML algorithms across all clinical fields and geographic regions to determine how frequently model-updating methods are suggested in published studies. We believe that the AI and ML model-updating methods offered in published models are a proxy for a model's generalizability and implementation reproducibility. We aim to determine the geographic distribution of published models that prioritize model-updating methods and if any correlations exist between the quality of the model reported and the suggested model-updating method. Owing to the faulty evaluation of real-life generalizability and reproducibility of AI systems, recent studies have shown that health care AI and ML performance may be overly optimistic [72]. Although AI and ML applications in health care have potential, some have argued that AI and ML is presently riding atop the peak of "inflated expectations" [72]. We aim to ascertain the degree to which published model results include ethnic and gender demographic data in the light of well-established algorithmic bias in health care.

Our findings will add to the literature on model clinical validation and real-life implementation and help improve best practices for model development by prioritizing updating. We will conduct the scoping review with the hope of moving the needle of contemporary model development away from the peak of "inflated expectations" [72] to the nadir of enlightened reality.

Authors' Contributions

All authors contributed to manuscript writing, revision, data abstraction, and search strategy. In addition, SW formulated and modified the search strategy.

Abstract

Background: In recent years, mHealth has increasingly been used to deliver behavioral interventions for disease prevention and self-management. Computing power in mHealth tools can provide unique functions beyond conventional interventions in provisioning personalized behavior change recommendations and delivering them in real time, supported by dialogue systems. However, design principles to incorporate these features in mHealth interventions have not been systematically evaluated.

Objective: The goal of this review is to identify best practices for the design of mHealth interventions targeting diet, physical activity, and sedentary behavior. We aim to identify and summarize the design characteristics of current mHealth tools with a focus on the following features: (1) personalization, (2) real-time functions, and (3) deliverable resources.

Methods: We will conduct a systematic search of electronic databases, including MEDLINE, CINAHL, Embase, PsycINFO, and Web of Science for studies published since 2010. First, we will use keywords that combine mHealth, interventions, chronic disease prevention, and self-management. Second, we will use keywords that cover diet, physical activity, and sedentary behavior. Literature found in the first and second steps will be combined. Finally, we will use keywords for personalization and real-time functions to limit the results to interventions that have reported these design features. We expect to perform narrative syntheses for each of the 3 target design features. Study quality will be evaluated using the Risk of Bias 2 assessment tool.

Results: We have conducted a preliminary search of existing systematic reviews and review protocols on mHealth-supported behavior change interventions. We have identified several reviews that aimed to evaluate the efficacy of mHealth behavior change interventions in a range of populations, evaluate methodologies for assessing mHealth behavior change randomized trials, and assess the diversity of behavior change techniques and theories in mHealth interventions. However, syntheses on the unique features of mHealth intervention design are absent in the literature.

Conclusions: Our findings will provide a basis for developing best practices for designing mHealth tools for sustainable behavior change.

Introduction

One of the most significant achievements in human health in the past century was the extension of life expectancy from 45 to >75 years, resulting in an expanding, aging global population [1]. Concurrently, lifestyles have changed with industrialization, inducing dramatic shifts in the global disease burden, which is now dominated by chronic diseases [2,3]. Globally, the leading modifiable risk factors for chronic diseases are poor diet, alcohol consumption, smoking, and a lack of physical activity [4]. More importantly, these lifestyle behaviors are also modifiable factors for chronic disease management [5]. Hence, sustaining healthy lifestyle behaviors has been recommended by the World Cancer Research Fund [6], the International Society of Hypertension [7], the International Diabetes Federation [8], and many others [9-12].

Since the 1950s, the harm of smoking has been embedded in medical training with policy support to promote smoking cessation [13]. Coupled with individual behavior change strategies, smoking rates have seen a continuous decline since the 1960s [14]. In sharp contrast, the inclusion of diet and physical activity as topics in medical training was only initiated as recently as the 21st century [15-18]. Unique to quitting smoking, which removes one behavior, initiating and maintaining healthy dietary patterns and an active lifestyle (ie, reducing sedentary behavior and increasing physical activity) requires sustained behavior changes throughout life. Therefore, responsibility for these behaviors ultimately falls on patients, who must self-manage their chronic diseases in the long term, even with the availability of system and policy supports [19].

Theory-based behavior change interventions are highly efficacious in controlled experiments. Multiple behavior change theories have been tested in selected populations (eg, the Theory of Planned Behavior and the Social Cognitive Theory), targeting individual knowledge and cognitive and affective determinants of behavior. To reduce the complexity of using multiple theories, the Theoretical Domains Framework was developed in 2005 by bringing together 33 models of behavior change [20]. In 2011, the Behaviour Change Wheel was created as a causal "behavior system" to guide intervention design through mapping Theoretical Domains Framework–based behavior determinants to the Behaviour Change Technique Taxonomy [21].

Despite high efficacy in experimental settings, the real-world application of behavior theories has had limited effectiveness at the population level in achieving sustainable changes in diet, physical activity, and sedentary behavior [22,23]. For models that emphasize the interaction between individuals and the environment within a social system (eg, the Ecological Model), environmental influences and policy context often become the primary target [24], risking disparities within population subgroups (ie, by creating urban-rural disparities). Human behavior is dynamic, and sustained behavior change following interventions is dependent on the individual's ability to adopt and continuously use behavior change techniques [25-27]. Intervention fidelity (ie, the delivery-receipt-enactment chain) is the key process measure of the mechanism linking intervention to outcome [28]. The process of enactment is the most sensitive to potential breakdowns in the delivery-receipt-enactment chain, occurring when individual-level factors and contextual resources are not properly aligned to support enactment [25]. Hence, real-time personalized interventions are desired to improve self-enactment and fidelity by facilitating the continuous alignment of individual and contextual factors.

The growing computing capabilities of mobile phones have enabled us to monitor and deliver health metrics continuously in real time [29,30]. Therefore, mobile health (mHealth) has the potential to enable personalized, real-time feedback and monitoring of targeted behaviors. The term "mHealth" describes the practice of medicine and public health supported by mobile devices [31]. The World Health Organization has recommended mHealth as a key health promotion strategy to improve global health across low- to middle- and high-income countries [32]. In recent years, mHealth has increasingly been used as a method in behavioral research for disease prevention and self-management through supporting positive changes in diet, physical activity, and sedentary behavior [33].

It is important to note that technology-enabled mHealth tools are twofold, including the active ingredients of behavior change interventions as the intervention content and the mHealth tools themselves as the intervention delivery strategy [34]. The computational power (ie, how fast a system can process data and perform a computational task) of mHealth tools can provide unique functions compared to conventional interventions, such as providing personalized behavior change recommendations and delivering them in real time with the support of dialogue systems. It is also worth noting that mHealth interventions differ from in-person interventions in the resources they deliver. For instance, mHealth interventions may deliver behavior change techniques as an end product with virtual resources [35], whereas conventional interventions may be able to deliver direct physical resources, such as in-person group interventions, exercise equipment, or access to facilities [36]. However, design principles for mHealth interventions to incorporate personalization, real-time functions, and deliverable resources have not been systematically evaluated.

The goal of this review is to identify best practices for the design of mHealth interventions targeting diet, physical activity, and sedentary behavior changes for chronic disease prevention and self-management. We aim to review and identify specific designs in current mHealth tools that feature personalization, real-time functions, and deliverable resources. Our findings will provide a basis for developing best practice guidelines for designing mHealth tools targeting sustained behavioral change.

Methods

Prospective Registration and Reporting Guidelines

This systematic review has been registered with PROSPERO (CRD42021261078), an international database of prospectively registered systematic reviews. Conduct of this review will be guided by the 2022 updated PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [37].

Eligibility Criteria

We will focus on randomized controlled trials that have reported using mHealth tools for interventions targeting diet, physical activity, or sedentary behavior for chronic disease prevention or management purposes among adults aged 18 years or older. The inclusion criteria are as follows: (1) the study must include a behavior change intervention for chronic disease prevention and self-management; (2) the mHealth tool must include a personalization feature (eg, personalized intervention content and dose, delivery process, or feedback) or a real-time feature (eg, real-time behavioral monitoring or a dialogue system); (3) the behavior change need not have been the primary aim of the study or the primary outcome measure of the study, but a specific measure of behavior change must be reported; (4) a deliverable resource does not have to have been included in the mHealth intervention, although we will review and summarize deliverable resources (eg, virtual social support, access to facilities, diet recipes, or exercise videos) in the mHealth tool; (5) the study must be peer-reviewed and must also have an English abstract, even if it is written in a different language. We will screen non-English abstracts for inclusion and leverage international colleagues for full-text screening and data extraction.

Information Sources

Two reviewers will independently search electronic databases, including MEDLINE, CINAHL, Embase, PsycINFO, and Web of Science, for studies published since 2010 that report findings from mHealth interventions. The year 2010 was chosen because it was when several national and international health organizations identified mHealth as a health promotion strategy with funding opportunities [32,38].

Search Strategy

We will use keywords for mHealth, behavior change, interventions, and self-management and combine them using the “AND” term (Multimedia Appendix 1). Literature found with the search will discuss mHealth interventions targeting lifestyle behavior changes for chronic disease prevention and self-management. Next, we will use keywords for diet, physical activity, and sedentary behavior to limit the search to mHealth interventions targeting these behaviors. Finally, we will use keywords for personalization and real-time functions, respectively, to limit the identified interventions to ones that have reported these design features.

Selection Process

The search strategy will be applied to all databases and aggregated in Endnote reference management software (Clarivate LLC). One reviewer will remove obviously irrelevant references by screening the titles and abstracts, with a 5% sample of these decisions being verified by another reviewer. All remaining abstracts will be assessed for inclusion by one reviewer, with all those selected for exclusion being checked by the other reviewers before final exclusion. The full text of all remaining studies will be obtained and assessed independently for inclusion by 2 reviewers, with any discrepancies resolved in discussion with a third reviewer. The process of study selection will be reported in PRISMA flow diagrams [37] and the reasons for exclusion will be noted. Reference lists of the included studies will also be reviewed to further identify relevant studies.

Data Collection Process

The lead reviewer will develop a data extraction form. Two reviewers will independently pilot the data extraction form on 5 studies. Extracted data will be reviewed by the entire review team to refine the data extraction form. At the commencement of data extraction, 2 reviewers will each extract the data from half of the included studies and perform a cross-check to verify the extracted data. Any discrepancies will be recorded and resolved by discussion.

Data Items

The following data will be extracted for each included study: first author name, year of publication, journal, country, setting, and objective; study design and content of the mHealth intervention (ie, the targeted behavior, behavior change theory used, personalization features, real-time functions, and deliverable resources); procedures for defining, recruiting, and sampling from the intervention and control groups; characteristics and sample size of the study population; frequency and duration of follow-up; definition and measures of behavior change; reference group in any statistical modeling and results of any statistical tests reported; and subgroup analyses or any evidence relating to effects on other health outcomes.

Study Risk of Bias Assessment

Study quality will be assessed using the Risk of Bias 2 assessment tool, an update to the original Cochrane risk of bias tool [39]. The Risk of Bias 2 tool evaluates the following domains in randomized controlled trials: randomization process, deviations from the intended interventions, missing outcome data, measurement of the outcome, and selection of the reported result. Two reviewers will assess study quality independently, and their assessments will be compared for agreement, with any discrepancies resolved in discussion with a third reviewer.

Synthesis Methods

Based on our knowledge and findings from an initial search, we expect substantial heterogeneity in the mHealth interventions across the targeted chronic conditions, targeted behavior (ie, diet, physical activity, and sedentary behavior), reported outcomes, and methods (ie, frameworks and technologies) to achieve personalization, real-time functions, and deliverable resources. Hence, meta-analysis is unlikely to be feasible or appropriate. Therefore, we will perform narrative syntheses following the Reporting Guidelines of Synthesis Without

XSL•FO
RenderX

Meta-Analyses [40] guideline for each of the 3 design features of interest.

We will first present detailed descriptions of the included studies in both narrative and tabular formats. This description table will focus on reporting the year of publication, country, setting, study objectives, population, mHealth intervention, comparison group, and outcome measures. Next, the included mHealth interventions will be further evaluated for 3 key design features based on the targeted behavior (ie, diet, physical activity, or sedentary behavior): personalization, real-time functions, and deliverable resources. The study team will develop a separate table for each targeted behavior to map the personalization (ie, personalized intervention content and dose, delivery process, and feedback), real-time functions (ie, the inclusion of technologies to support real-time behavior monitoring and a dialogue system), and deliverable resources (ie, social support, access to facilities, diet recipes, and exercise videos). Finally, the effectiveness of the included mHealth interventions will be presented by showing their unique features, that is, features that they do not share with usual care or nonintervention. A narrative synthesis of the included mHealth interventions will be presented together with an evaluation of study quality (ie, the risk of bias assessment) to provide context for the study findings and support confidence in our evaluation of the state of the field.

Although we anticipate a low likelihood of quantitative synthesis, meta-analyses for outcomes that include a sufficient number of studies will be considered if deemed feasible. We will provide statistical descriptions for behavior change related to the mHealth intervention for specific targeted behaviors and design features, such as personalization and real-time functions. We will estimate the summary effect size and its 95% CI through both fixed and random effects models. Between-study association will be estimated using the I^2 metric; values of 50% are indicative of high heterogeneity, while values above 75% suggest very high heterogeneity [41]. Whenever necessary, we will calculate the evidence of small-study effects (ie, whether small studies have inflated effect sizes compared to larger ones). To this end, we will use the regression asymmetry test developed by Egger and colleagues [42]. A P value of .10 with more conservative effects in large studies in random-effects meta-analyses is considered indicative of a small-study effect.

Results

As of November 10, 2022, we have completed our database search and have begun searching by hand. After removing 607 duplicates, the initial search yielded 2961 studies; the review team will screen the titles, abstracts and full texts. We aim to complete the review by March 2023.

Discussion

This systematic review will provide a comprehensive overview of the literature to better understand the design of mHealth tools and their unique features, such as support for personalization, real-time functions, and deliverable resources, in interventions targeting diet, physical activity, and sedentary behavior. The main contribution of our review will be an understanding of the current methods and technologies used in mHealth interventions. Any amendments or modifications made to the protocol will be reported in the final paper.

Lifestyles and environments have changed in modern society with industrialization, inducing dramatic shifts in the global disease burden, which is now dominated by chronic diseases [43]. As such, now more than ever, we must face the consequences of the massive societal burden of chronic diseases. Importantly, lifestyle behaviors are both a major cause of chronic diseases and the key to effective management of chronic diseases [44]. Therefore, it is critical to develop tools to support positive changes in lifestyle behaviors and to support individuals in adopting environmental resources for sustainable behavior change. To this end, mHealth tools offer promising avenues to deliver personalized interventions in real time, powered by technology and computing capacity. The coverage rate of mobile technology worldwide increased from 87% to 95% from 2011 to 2012 and is expected to rise to 96% by 2026 [45]. However, best practices for designing mHealth tools to support positive behavior change are unclear.

We have conducted a preliminary search for existing systematic reviews and review protocols on mHealth-supported behavior change interventions. We identified several reviews that aimed to evaluate the efficacy of mHealth behavior change interventions in a range of populations [46-48], evaluate methodologies for assessing mHealth behavior change randomized trials [49], and assess the diversity of behavior change techniques and theories in mHealth interventions [35,48]. However, syntheses of features unique to mHealth intervention design, including personalization, real-time functions, and deliverable resources, are lacking in the literature.

Based on the synthesized data, the key outcomes of our review will be (1) identifying gaps in the existing literature and (2) informing future research to improve the design of mHealth interventions and incorporate their unique features to support sustainable behavior change. These findings will be summarized and reported in a peer-reviewed journal.

Data Availability

The data sets generated during and/or analyzed during the current study will be made available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: With the rapid advancement of mobile technology, the scope of mobile health (mHealth) has expanded to include consumer-grade devices such as smartphones and wearable sensors. These solutions have typically been used for fitness purposes; however, due to their ubiquitous capabilities for data collection, they have the potential to bridge information gaps and supplement data from clinical visits. Patient-generated health data (PGHD) can be derived from mHealth solutions and be used by health care professionals (HCPs) as complementary tools in the care process, yet their integration into clinical workflows presents a myriad of challenges. PGHD might be a new and unfamiliar source of information for most HCPs, and the majority of mHealth solutions have not been designed to be used by HCPs as active reviewers. As mHealth solutions become more available and attractive to patients, HCPs may see an increase in the influx of data and related inquiries from their patients. This mismatch in expectations can result in disruptions to clinical workflows and negatively impact patient-clinician relationships. For PGHD to be integrated into clinical workflows, its use should be proven beneficial for both patients and HCPs. However, so far, only limited research has been done on the concrete experiences of HCPs as active reviewers of PGHD from consumer-grade mobile devices.

Objective: We aimed to systematically guide the review of existing literature to identify what types of PGHD from consumer-grade mobile devices are currently being used by HCPs as complementary tools in the care process.

Methods: The PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 was followed for the design of the search, selection, and data synthesis processes. Electronic searches will be done on PubMed, ACM Digital Library, IEEE Xplore, and Scopus.

Results: Preliminary searches have been conducted, and previous related systematic and scoping reviews have been found and evaluated. The review is expected to be completed in February 2023.

Conclusions: This protocol will guide the review of existing literature on the use of PGHD produced by consumer-grade mobile devices. Although there have been previous reviews related to this topic, our proposed approach seeks to understand the specific opinions and experiences of different types of HCPs who are already using PGHD in their clinical practice and the motives for deeming these data useful and worth reviewing. Depending on the studies that will be included, there may be an opportunity to provide a wider understanding of what types of HCPs trust PGHD, despite the possible challenges that its use might convey, potentially contributing with the knowledge to support the design strategies of mHealth tools that could be integrated into clinical workflows.

Introduction

Background

Mobile health (mHealth) refers to the use of mobile technology to obtain data pertinent to wellness and disease diagnosis, prevention, and management [1]. With the rapid advancement of mobile technology in the last decade, the scope of mHealth has expanded to include consumer-grade devices, such as smartphones and wearable sensors, which allow for convenient access to health apps [2], motion sensing, as well as physiological and biochemical tracking. The certification of medical-grade mobile devices is based on clinical evidence, often needing years to bring a device to the market [3]; however, consumer-grade devices are evolving at a more rapid pace, and although they are typically used for fitness purposes, their capabilities for data collection are opening possibilities for their use in the medical sphere as well [4]. Ubiquitous health data collection can theoretically make it possible to monitor and intervene whenever and wherever acute and chronic medical conditions occur [1].

The data created, recorded, and gathered by and from patients, using mHealth tools such as smartphones and wearable devices, are known as patient-generated health data (PGHD) [5]. The PGHD derived from mHealth solutions has the potential to bridge information gaps and supplement data from clinical visits by providing a rich picture of a patient's daily behaviors, environment, lifestyle, and biometric data outside of the clinic.

In the past, mHealth solutions have been mostly designed for general wellness purposes; in recent years, mHealth interventions targeting specific health conditions have been increasing [6]. Likewise, the body of evidence that proves the potential value of mHealth is growing [7]; however, there seems to be only limited evidence of its efficacy [8]. Furthermore, the strength and quality of clinical evidence have been identified as factors that impact the adoption of mHealth tools by health care professionals (HCPs). Although the adoption of HCPs seems to be one of the most influential factors regarding the success of mHealth tools [7], there has not been much research on the role HCPs are expected to play in the implementation process of mHealth tools [3,9].

The use of mHealth tools by patients enables access to electronic PGHD by HCPs; however, access does not equate to active use. Furthermore, the integration of PGHD into clinical workflows presents a myriad of challenges, including data security and privacy, data standardization, difficult and time-consuming interpretation, and interoperability, among others [5,10].

In regular clinical workflows, patients often interact with HCPs with different medical specialities, who might have different approaches and goals when collecting data from their patients, depending on their role in the care process. A scoping review by Nittas et al [9] identified that there are 2 roles that HCPs can take when integrating PGHD into the care process: the supporter and the reviewer. In the supporter role, the HCP mostly motivates patients and oversees the use of PGHD. In the reviewer role, the HCP analyzes PGHD to personalize advice, conduct remote monitoring, and complement medical data [9]. PGHD can encompass diverse data sets that come from both passive sensing (through mobile and wearable devices) and active sensing (through mHealth apps) [1]; therefore, PGHD might be a new and unfamiliar source of information for most HCPs [11]. Considering that the reviewing tasks imply a more active stance from HCPs, it is reasonable to assume that not all of them might be interested or confident in becoming PGHD reviewers.

mHealth solutions are becoming increasingly available and attractive to patients, with many integrating mHealth apps and tracking devices into their everyday life as ways to improve their health and well-being [12]. A recent scoping review identified 31 studies that evaluated mHealth interventions for self-management of chronic conditions [3], of which over a third required or encouraged patients to share data with their health care providers. However, only 2 of those studies described mHealth solutions that were meant to be used by HCPs as active reviewers. This sort of mismatch in expectations from patients and HCPs can result in disruptions to existing clinical workflows and negatively impact patient-clinician relationships [13].

For PGHD to be effectively integrated into clinical workflows as a complementary tool to bridge information gaps and supplement data from clinical visits, their use should prove beneficial for both patients and HCPs. However, so far, little research has been done on the concrete experience of HCPs as active reviewers of PGHD from consumer-grade mHealth solutions.

Objectives

The main objective of our review will be to systematically analyze existing literature to try to identify the profile of HCPs who are using PGHD from consumer-grade mobile devices as complementary tools for their clinical practices.

The secondary objective will include the identification of the types of PGHD, produced by consumer-grade mobile devices and mHealth apps, that HCPs might deem useful and worth reviewing.

To attain these objectives the research questions to be addressed by the review are as follows:

- How are the PGHD from consumer-grade mobile devices used by HCPs in the clinical workflow?
- Which types of HCPs are actively reviewing PGHD in their clinical practice?
- What kind of PGHD from consumer-grade devices do HCPs find useful?

XSL•FO
RenderX

Methods

Design

For the design of this protocol, the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 [14] was followed. For the design of the search, selection, and synthesis processes, the guidelines for performing systematic literature reviews in software engineering [15] were also consulted.

For the review design, we will use a convergent design for systematic mixed studies reviews [16]. The systematic review will adhere to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [17].

Search Strategy

Eligible studies will be identified through comprehensive literature searches conducted in the bibliographical databases that focus on health and biomedicine, information technology domains, or encompass journal articles and conference proceedings from multiple disciplines. The selected sources are PubMed, ACM Digital Library (including the ACM Guide to Computing Literature), IEEE Xplore, and Scopus. The advanced search methodologies and limitations of each source were revised in advance to standardize the final search terms and resulting search string, which will be used in all sources without alterations to maintain consistency.

The search strategy was constructed iteratively to ensure that relevant articles were more likely to be identified. After a pilot search in PubMed, it was deemed that the searches should be delimited by 3 key topics: “patient-generated health data,” “health personnel,” and “mobile technologies.” Considering that the key aspects of this review will be more relevant to the medical context than to the technological context, the Medical Subject Headings will be used to search for literature.

Terms comparable to “patient-generated health data,” “health personnel,” and “mobile technologies” were added to the search string using AND operators. To avoid overlooking relevant articles by excluding terms and to prevent retrieving an excessive number of irrelevant results, exact phrases were used with some of the terms. To identify the most appropriate phrases, trial searches were performed in Google Scholar, using possible variations identified in the literature. The final search string was validated by a research librarian from the University of Oulu (Table 1).

Additional filters will be used in all sources to limit the results to articles published in scientific peer-reviewed journals or conferences, written in English, with a publication date between January 2013 and May 2022, and with topics related to medical disciplines or the field of information technologies.

Once the electronic searches have been completed, a supplementary hand search of studies will be performed within previous systematic literature reviews and scoping reviews related to the topic PGHD that were identified in the pilot searches.

Table 1. Search string to be used in the electronic searches.

Concept	Search string	Definition
“Patient-generated health data”	“Patient-generated health data” OR “patient health data” OR “patients health data” OR “patient-generated data” OR “person-generated data” OR “person-generated health data” OR “patient-reported data” OR “patient self-reported data” OR “patients self-reported data” OR “patient-generated clinical data” OR “patient-generated medical data” OR “self-reported patient data” OR “self-generated patient data” OR “personal health data” OR “mHealth patient data” OR “patient collected data” OR “patient-collected health data” OR “self-collected health data” AND	MeSH[a] terms introduced in 2018 to refer to health-related data created, recorded, or gathered (outside of clinical settings) by patients, family members, or caregivers to help address a health concern [18].
“Health personnel”	“Health personnel” OR “care professionals” OR “medical professionals” OR “health care professionals” OR “health professionals” OR ”health care providers” OR “health providers” OR “medical providers” OR “health care worker” OR “health care workers” OR “health care worker” OR “health care workers” OR practitioners OR specialists OR clinicians OR doctors OR nurses OR physicians OR physiotherapists OR “clinical team” OR “clinical staff“ OR “medical staff” OR “medical team” AND	MeSH terms in use since 1992 to refer to people working in the provision of health services, whether as individual practitioners or employees of health institutions and programs [19].
“Mobile technologies”	“Mobile technolog*” OR “mobile phone” OR “mobile device” OR “mobile phones” OR “mobile devices” OR “smart device” OR smartphone OR smartwatch OR “smart ring” OR “smart device” OR “smart devices” OR wearable* OR “health tracker” OR “activity tracker” OR “fitness tracker” OR “mobile app*” OR “health app*” OR “mobile health intervention” OR “mHealth intervention” OR “mobile health solution” OR “mHealth solution” OR “mHealth solutions” OR “mobile health tool” OR “mHealth technology”	These terms commonly refer to internet-enabled devices like smartphones, tablets, and smartwatches. These are the latest in a progression that includes two-way pagers, notebook computers, mobile telephones, GPS navigation devices, and more [20].

Inclusion Criteria

Types of Studies

Primary studies will be included irrespective of their design. Both qualitative and quantitative research findings from the selected studies will be integrated, with the use of qualitative data transformation technique methods [21]. Eligible studies will include clinical trials, nonrandomized controlled trials, cross-sectional studies, longitudinal studies, observational studies, case studies, and other types of qualitative studies. The studies must have been published in peer-reviewed scientific journals and conferences.

Types of Participants

The review will focus on the experiences of HCPs who have already used PGHD in their clinical practice, as part of standalone mHealth interventions, by personal initiative, or for any other reasons. The type of HCP is not being limited to specific medical specialities as long as the participants can be recognized as health care workers who are interacting directly with patients.

Types of Technology

The review will focus on mHealth solutions that allow for patient data to be collected outside of clinical settings by patients, using mobile apps or commercial mobile devices such as smartphones or tablets and wearable devices like smartwatches, smart rings, fitness bands, chest straps, and other wearable health trackers.

The current mobile and wearable technologies started to become more available to consumers at the beginning of the last decade. As of 2013, only a few mHealth interventions that aimed at assessing the impact of native apps for smartphones had been reported in the literature, all of which had been created only for research purposes and were not yet available in public app stores [2]; therefore, our search will be limited to articles published since 2013.

Exclusion Criteria

- The articles that explicitly indicate they are study protocols, scoping reviews, and systematic literature reviews will automatically be excluded.
- Studies on interventions based on SMS, chats, social media interactions, phone calls, or another type of two-way communications as the main method for data collection will not be included; we did not consider them to be mHealth solutions, as they are targeted for communication in general and require additional time and effort from HCPs not only to review data but also to maintain the communication between appointments.
- Studies based on interventions that required the use of specialized medical-grade devices that are not designed to be worn or meant to be used as mobile trackers will not be included.
- Studies related to nonelectronic PGHD.

Data Collection and Analysis

Selection of Studies

After the electronic search in all sources and the supplementary hand search of systematic reviews are finalized, the resulting articles will be imported into Covidence (Veritas Health Innovation) to conduct the screening process. Covidence will automatically identify duplicates and allows for multiple reviewers to perform the screening and selection process in a consensual manner.

The initial screening will be limited to the titles and abstracts. This part of the process will be done independently by 2 reviewers to reduce bias. Both reviewers in charge of this stage have a background in computer science and previous research experience with mHealth and PGHD. Before starting the screening process, the reviewers will complete a joint exercise to validate the reviewing methodology and ensure that both reviewers understand the inclusion and exclusion criteria correctly.

Once the reviewers have a preliminary list of candidate studies to be included, they will proceed with the full-text screening of those articles.

During the full-text screening, reviewers will also try to identify if multiple papers could be based on the same study. In this case, both reviewers will revise the possibly duplicated articles and decide, based on author names, study descriptions, and sample characteristics. In the case of duplications, the most recent article would be preferred; however, the final decision should be agreed upon by both reviewers, considering which papers better fits the inclusion criteria.

In case of disagreement in either the initial screening or during the full-text screening, both reviewers will discuss the reasons for disagreement. In case the disagreement persists, a third reviewer will act as an arbitrator and will review the article to decide whether or not the article should be included. The disagreements will be documented, and the reason for the final inclusion or exclusion will be recorded.

The search and screening results will be reported using a PRISMA flow diagram.

Data Extraction

The key information of the included articles will be extracted using the Data Extraction Form function offered in Covidence. The extraction task will be completed by the 2 initial reviewers and 2 additional reviewers, all of whom have previous research experience with the topics related to this review.

Each article will be assigned randomly to 2 reviewers. Each reviewer will extract the data independently and the data extracted by both reviewers will be compared using Covidence. In the case of differences in the extracted data, a consensus will be reached between the 2 primary reviewers. In the case of differences that could not be agreed upon by the 2 primary reviewers, the conflicting data will be discussed by the 4 reviewers to reach a consensus.

The data extraction form will assist in the extraction of relevant information from the selected studies, following the template

XSL•FO
RenderX

in Table 2. The main author will pilot the extraction of 5 articles, using the proposed extraction form, to identify possible adjustments that could be required before the data extraction process starts with the reviewing team.

In the case of papers that do not report complete descriptions of the intervention, outcomes, or other information relevant to this research, the article author will be contacted via email to ask for complementary information.

Table 2. Basic template of the data extraction form.

Item	Characteristics
Article general information	• Year of publication • Author(s)' name(s) • Country of origin
Characteristics of the study	• Objectives • Main findings
Research methods	• Sampling method • Sample size • Data collection method
Information about participants	• Profession or medical specialty • Main motivation of HCPs[a] to use PGHD[b]
Context of PGHD use	• Conditions being treated • Mobile technology used • Type of PGHD collected • The mechanism for PGHD visualization

[a]HCP: health care professional.

[b]PGHD: patient-generated health data.

Studies' Quality Assessment

The quality of included studies will be assessed in parallel to the data extraction process, using a quality assessment form that will be included in Covidence, following the checklist to assess the quality of studies proposed by Kitchenham [15].

Data Synthesis

The included studies might comprise qualitative and quantitative data that will need to be transformed into a qualitative format and be synthesized through narrative synthesis. For this, we will be using a descriptive narrative form with an appropriate table format. The extracted data will be organized in the table by type of technology, type of condition, type of participants, and type of data being collected or used to identify any interesting findings, trends, relationships, and limitations that can assist in addressing the proposed review questions.

A data coding strategy is suggested for the analysis. NVivo (QSR International) will be used to assist in the data coding strategy. The codes will be defined in accordance with the research objectives of the review. The strategy will be piloted with 5 studies, and any necessary changes to the strategy will be made and later reported in the full review.

Results

As of May 2022, preliminary searches have been done to refine the search strategy and assess the availability of studies on our research topic. Previous related systematic and scoping reviews have been found and evaluated. Systematic searches, data extraction, data synthesis, analysis, and the writing of the systematic review document are expected to be completed by February 2023.

Discussion

Expected Outcomes

The proposed systematic review will report on the use of PGHD produced by consumer-grade mobile technology, as complementary tools for HCPs in the clinical workflow. Considering that most research related to this topic has been done under controlled conditions, our interest lies in identifying the characteristics of PGHD that foster its use by HCPs. We assume these characteristics might comprise aspects such as the type of clinical activities where PGHD from consumer-grade devices could be useful and the particular characteristics of HCPs who are willingly using PGHD due to the realization of PGHD benefits to complement their current practices.

Previous research on PGHD has explored its effect on patient-clinician relationships [13], its use in clinical practices [11], and its use to facilitate prevention and health promotion [9]. Nevertheless, after examining these reviews, we have identified 3 determinant aspects for our review that will report on research gaps that previous reviews have not addressed in detail. The first aspect is that previous reviews did not limit their research to PGHD collected outside of the clinic but also included other types of PGHD as patient-reported outcomes collected during appointments with HCPs [13]. Second, the types of mobile technologies from which PGHD has been produced have not been limited to consumer-grade mobile or wearable devices but have also included medical-grade devices [9,11,13], which tend to be more accurate and more widely

XSL•FO
RenderX

accepted in the medical field. The last differentiating aspect is that previous research has not focused on understanding the specific experiences of HCPs who are already performing the role of PGHD reviewers to support their patients' care but mostly on their expectations as potential users or in a predominantly supportive role.

The use of PGHD is a relatively new trend, and its relevance might be different across countries, medical specialities, or clinical settings. Depending on the studies that will be included in this review, there may be an opportunity to provide a wider understanding of what types of HCPs trust PGHD from consumer-grade mobile solutions despite the potential challenges that its use might convey. We are interested in understanding why and how they have decided to use this type of data, assuming this knowledge could contribute to the design strategies of mHealth tools that could be integrated into clinical workflows.

Limitations

Some limitations to the design of this review include the exclusion of papers not written in English and considering only papers that explicitly mention PGHD (or its possible variations). PGHD is a relatively new definition, and it could be possible that some relevant papers on mHealth interventions might not explicitly address PGHD using that specific term but instead could have used other terms not included in our search string.

Acknowledgments

We would like to acknowledge the More Stamina Project research group for supporting the development of this work.

Authors' Contributions

SGM developed the research questions; designed the review, search, and selection strategies; and contributed meaningfully to the drafting and editing. MI aided in the development of the study methods and contributed meaningfully to the drafting and editing and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Increased workload, lack of resources, fear of infection, and the suffering and loss of residents have placed a significant emotional burden on regulated and unregulated direct care nursing staff (eg, registered nurses, licensed practical nurses, and care aides) in nursing homes (residential long-term care homes). Psychological distress and burnout related to COVID-19 have been cited among direct care staff within nursing homes. Studies have also emphasized the resilience of direct care staff, who, despite the significant challenges created by the pandemic, remained committed to providing quality care. To date, only one nursing home–specific review has synthesized evidence from 15 studies conducted early in the pandemic, which reported anxiety, posttraumatic stress disorder, and depression among direct care staff.

Objective: The objectives of this systematic review are to (1) synthesize all empirical evidence on the impact of the COVID-19 pandemic on direct care staffs' mental health, physical health, and work-life outcomes; (2) identify specific risks and protective factors; and (3) examine the effect of strategies or interventions that have been developed to improve these outcomes.

Methods: We will include all study designs reporting objective or subjective measurements of direct care staffs' mental health, physical health, and quality of work-life in nursing home settings during the COVID-19 pandemic (January 2020 onward). We will search multiple databases (MEDLINE, CINAHL, Embase, Scopus, and PsycINFO) and gray literature sources with no language restrictions. Two authors will independently screen, assess data quality, and extract data for synthesis. Given the heterogeneity in research designs, we will use multiple data synthesis methods that are suitable for quantitative and qualitative studies.

Results: As of December 2022, full text screening has been completed and data extraction is underway. The expected completion date is June 30, 2023.

Conclusions: This systematic review will uncover gaps in current knowledge, increase our understanding of the disparate findings to date, identify risks and factors that protect against the sustained effects of the pandemic, and elucidate the feasibility and effects of interventions to support the mental health, physical health, and quality of work-life of frontline nursing staff. This study will inform future research exploring how the health care system can be more proactive in improving quality of work-life and supporting the health and psychological needs of frontline staff amid extreme stressors such as the pandemic and within the wider context of prepandemic conditions.

Introduction

Overview

The COVID-19 pandemic has exposed nursing home (residential long-term care home) residents and staff to a diverse set of challenges affecting their physical, psychological, and social well-being [1,2]. Evidence from the 2003 severe acute respiratory syndrome outbreak and emerging COVID-19 studies suggest that there will be global phenomena such as increased anxiety, depression, and trauma experienced by health care workers, which will likely have long-term impacts [3-9]. An analysis conducted in February 2021 of national data sets for 22 countries reported that nursing home deaths accounted for 41% of the total COVID-19 deaths (9%-64%) [10]. Concerted action to address the needs of staff working in nursing homes is needed to prevent and manage the impact of COVID-19 [11]. Therefore, a systematic review to synthesize all empirical evidence on the effects of COVID-19 on regulated and unregulated frontline nursing staff (registered nurses [RNs], licensed practical nurses [LPNs], and care aides) working in nursing homes is warranted.

Background

Frontline nursing staff (RNs, LPNs, and care aides) working in nursing homes routinely experience challenges that are known to have negative effects on work-life. Prior to the COVID-19 pandemic, both regulated and unregulated direct care staff (RNs, LPNs, and care aides) experienced higher levels of burnout and mental health issues than the general population and difficulties meeting the daily care needs of residents [1,12-14]. Most nursing home residents have Alzheimer disease or another age-related dementia (~90% have cognitive impairment), multiple chronic diseases, recurrent medical problems, and complex emotional and social needs. The increasing complexity and dependency of resident populations, in the absence of commensurate resources, has led to unmanageable workloads for nursing home staff [12].

In the context of a COVID-19 outbreak, witnessing extreme suffering and the loss of residents with whom staff had long-term relationships has led to emotional exhaustion, which is a component of burnout [15]. Frontline nursing staff have also been subjected to substantial pressure from health authorities, who have introduced additional infection control and monitoring measures; from family members [16] who are concerned about residents' well-being; and from the public and media. Despite a general acknowledgment that the challenges observed during the COVID-19 crisis in nursing home settings, particularly those that have contributed to severe resident outcomes, are symptoms of more systemic issues [1], the media has highly scrutinized nursing home staff. Additionally, nursing home staff have received little recognition for caring for persons infected with COVID-19 compared to hospital staff [16-18].

Prior Work

Emerging evidence from nursing home settings across regions has generally reported higher rates of mental health symptoms, somatic symptoms, burnout, and reduced quality of work-life [15,19-21]. One study reported 71.3% (211/296) of the respondents had medium to high emotional exhaustion, and 64.2% (190/296) of the respondents had medium to high depersonalization [19]. The current and anticipated need for psychological or psychiatric support was 21.6% (64/296) and 41.0% (141/296), respectively [19]. Reports of job satisfaction vary. Two studies reported worsened job satisfaction [20,21], one of which compared nursing home staff data from COVID-19 to data from 2013 and noted an increase in burnout syndromes. In contrast, Blanco-Donoso and colleagues [15] found that 98.2% (329/335) of the participants agreed or totally agreed with the single item—*I feel satisfied to be able to help people*.

A descriptive study among Spanish nursing home staff reported 71% (149/210) of respondents had clinical stress, 29% (n=61) had clinical insomnia, and rates of clinical depression and anxiety were 49% (n=102) and 59% (n=124), respectively [16]. Riello and colleagues [22] found 44% (471/1071) of respondents passed the set threshold for moderate to severe anxiety and 44% (471/1071) of respondents passed the set threshold for moderate to severe symptoms of posttraumatic stress disorder (PTSD) [22]. A high risk of suicidality was found in 25% (10/40) of participants working in 2 nursing homes in Italy [23]. Previous COVID-19 infection was associated with a higher risk of suicidality [23].

Other studies examining individual and organizational risks and protective factors of mental health and work-life outcomes identified several modifiable and nonmodifiable characteristics. Factors influencing the rates and severity of mental health symptoms include access to personal protective equipment [15,22,24], professional support in the workplace [15,21,25], safety guidelines [24], psychological support [24], changes to work activities [25], increased workload [15,21], and direct contact with patients or colleagues who are COVID-19 positive [14,15,22]. Other factors increasing the risk of adverse outcomes include younger age [26], female sex [22,26], less education [22,26], and less work experience [26]. Shift workers, such as frontline nursing staff, have also been found to have higher rates of somatic symptoms [24]. Staff resilience has been associated with lower rates of anxiety, depression, insomnia, and stress [26].

Several reviews have been conducted during the COVID-19 pandemic in general health care worker populations. To date, however, only one review conducted by Gray and colleagues has synthesized a portion of the nursing home-specific evidence from 14 studies published between March 2020 and March 2021. This review reported a high prevalence of anxiety, PTSD, and depression among direct care staff in nursing home settings based on quantitative studies [27]. The synthesis of qualitative studies suggested various personal experiences among nursing

XSL•FO
RenderX

home care staff, including psychological and mental health concerns, feeling undervalued and abandoned, fear of contagion, poor working conditions, lack of skills and knowledge, and support and the positive impacts of COVID-19 [27].

The number of studies on the impact of COVID-19 on nursing home staff has rapidly accumulated since the publication of Gray's [27] review. An updated review is warranted to capture emerging studies and, most importantly, the enduring effects of COVID-19 as a sustained extreme stressor and potential effective interventions. This review is an important first step toward supporting the mental health of frontline staff during and after the COVID‐19 crisis and during other disease epidemics and pandemics. This is important for the health and well‐being of individual health care staff as well as nursing home residents.

Objective

The purpose of this systematic review is to synthesize the empirical evidence on the effects of COVID-19 on frontline nursing staff who provide direct resident care, which includes RNs, LPNs, registered psychiatric nurses, and health care aides (HCAs), also called personal support workers (PSWs), direct care assistants, or nursing assistants, who worked in nursing homes during the COVID-19 pandemic. This systematic review will combine and synthesizes both quantitative and qualitative evidence. Its specific objectives are as follows: (1) to assess the impact of the COVID-19 pandemic on mental health (eg, stress, distress, depression, anxiety, PTSD, well-being, and somatic symptoms) and work-life outcomes (eg, burnout, job satisfaction, responsive behaviors directed toward staff, moral injury, distress, and working short-staffed) of frontline nursing staff (regulated and unregulated) working in nursing home settings (residential long-term care home); (2) to identify specific risks and protective factors; and (3) to examine the types and feasibility of strategies or interventions that have been developed to improve the outcomes of interest.

Methods

Protocol Registration

This protocol is reported following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA-P) checklist (Multimedia Appendix 1) [28,29]. This protocol is registered with PROSPERO (CRD42021248420). Any amendments to this study protocol will be documented and filed with PROSPERO.

Eligibility Criteria

All empirical study designs reporting the outcomes of interest for frontline nursing staff (regulated and unregulated) working in a nursing home setting and providing direct care during the COVID-19 pandemic will be considered for inclusion, without restriction on publication language. Articles published in languages other than English will be translated by authorized translators. We will exclude review articles; however, original studies included in reviews will be sourced and screened for inclusion. Articles that do not report primary study results, such as editorials, commentaries, opinion papers, theoretical papers or discussions, and anecdotal evidence will also be excluded.

Population

Overview

Frontline nursing staff (regulated and unregulated) engage in direct contact with the resident (eg, physically providing care, administering medications, assisting with activities of daily living, providing social and emotional support, and assessing or developing care plans). In general, unregulated staff have a scope of employment defined by their job description rather than a scope of practice and are accountable to their employer. In contrast, regulated staff are governed by legislation, have legally defined scope of practice, and are answerable to an external nursing regulator that sets standards of practice and monitors the quality of care provided [30]. In contrast to synthesizing evidence on multiple workforce groups or settings, our review will investigate in detail the evidence available for frontline nursing staff to provide a comprehensive synthesis of a broader range of outcomes.

Inclusion Criteria

Frontline nursing staff include RNs, LPNs, registered psychiatric nurses, and HCAs, who are also called PSWs, direct care assistants, and nursing assistants. Studies may include other participant groups; however, they will limit data to only the subgroup of frontline nursing staff.

Exclusion Criteria

Nursing staff not providing direct care services (eg, management and administrative staff) will be excluded. Studies reporting on the outcomes of interest among frontline nursing staff exclusively from the perspective of a third-party informant, such as management (non–self-reported outcomes), will be excluded.

Concept

Overview

We will study the effects of the COVID-19 pandemic as an extreme, sustained stressor on health and work-life outcomes among frontline nursing staff working in nursing homes. For this study, exposure to the COVID-19 pandemic is not limited to nursing homes with confirmed cases of COVID-19.

Inclusion Criteria

These criteria include studies reporting mental health, physical health, or work-life outcomes among frontline nursing staff during the COVID-19 pandemic (after January 2020).

Exclusion Criteria

These criteria include studies examining the impact of infectious diseases other than the current COVID-19 pandemic on health and work-life outcomes among frontline nursing staff.

Context

Overview

According to the World Health Organization, nursing homes are responsible for the maintenance of well-being in older adults with a significant loss of functioning [31]. In this review, we define a nursing home (residential long-term care home) as a facility that provides living accommodations and 24-hour care

XSL•FO
RenderX

services [32]. Direct care provided in nursing home settings ranges from health care services by regulated health care workers (eg, RNs and LPNs) to personal care provided by unregulated health care workers (eg, HCAs and PSWs) such as assisting with meals and bathing [32]. Studies will not be limited to settings with confirmed staff or resident cases of COVID-19.

Inclusion Criteria

These criteria include studies conducted after January 2020 in nursing home settings (eg, long-term care, residential care, and aged care) regardless of the country of origin. We will include studies in which there is a mix of different settings and will limit data to only the subgroup of nursing home staff when possible. If this is not possible, we will include the mixed data and explore how the inclusion affects the results by completing sensitivity analyses.

Exclusion Criteria

Studies conducted exclusively in nonnursing home settings will be excluded.

Outcomes and Effects of Interest

Mental Health Outcomes

There is a wide range of mental health–related symptoms frontline nursing staff may experience [33]. Outcomes considered critical to this review include measures of mental health and well-being as these are anticipated to be highly impacted due to the conditions of COVID-19. Mental health describes an individual's emotional and psychosocial well-being; it is defined by the World Health Organization as a state of well-being determined by interconnected social, psychosocial, and biological factors [34]. In this review, measures of mental health include but are not limited to experiences or symptoms of stress, distress, depression, anxiety, PTSD, and well-being.

Physical Health Outcomes

Physical health outcomes include somatic symptoms (eg, headache, insomnia, and emotional exhaustion). Since mental health is interrelated with somatic symptoms [34], all reported physical health outcomes and experiences will be included.

Work-Life Outcomes

Work-life outcomes include but are not limited to experiences or symptoms of burnout, job satisfaction, work engagement, responsive behaviors directed toward staff, moral distress, moral injury, and working short-staffed.

Risks and Protective Factors

We will extract all identified risks and protective factors affecting nursing home staff mental health and work-life outcomes. A risk factor is a condition, characteristic, or behavior that increases the risk of disease or injury [35]. Risk factors that can negatively impact mental health and work-life outcomes include increased workload, negative colleague and management relationships, lack of personal protective equipment, poor pandemic response planning, short staffing, staff turnover, extended work hours or mandatory overtime, and inability to take time off.

In contrast, protective factors are conditions, characteristics, or behaviors that improve well-being [35]. Resilience has been identified as an important protective factor that reflects the ability to cope with the negative effects of stress or adversity [1]. Additional examples of protective factors are an adequate supply of personal protective equipment, staff access to mental health resources, proper communication between staff and management, and paid sick days.

Type and Feasibility of Strategies or Interventions

Examples of interventions include workplace‐based psychological support strategies (peer support networks, employee wellness programs, psychological first aid, flexible schedules, regular information updates, and additional training), additional psychological support (guided and nonguided strategies, such as web-based therapy, web-based well-being and sleep apps, journaling, relaxation techniques, mediation and mindfulness programs, yoga, and coherent breathing), and interventions promoting or supporting healthy lifestyle and self‐care: eating, sleeping, exercising, following a routine, avoiding excess social media, staying in touch with family and friends, and doing things that are enjoyable [36,37].

Search Strategy

A preliminary search of PubMed, Cochrane Library, Google Scholar (pages 1-10) and PROSPERO was conducted to ensure that no similar review is underway. The index terms and text words contained in the titles and abstracts of relevant papers were used to develop a full search strategy in consultation with a university health sciences librarian. We will conduct the search using combinations and synonyms of the core concept keywords for "COVID-19 pandemic," "direct care staff," "frontline staff," and "nursing home." We will search MEDLINE, CINAHL, Embase, Scopus, and PsycINFO databases, as well as sources of gray literature. These will include health discipline colleges and associations (eg, Registered Nurses Association of Ontario) and relevant conference programs (eg, Gerontological Society of America Annual Conference).

Additional sources of data will be identified by reviewing reference lists of relevant publications and reports, and contacting authors of relevant publications and reports to clarify published and seek unpublished information. The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. If reviews are identified, the citation list will be screened to ensure all relevant studies are included. To ensure all emerging intervention studies are included in our synthesis, we will repeat our search prior to publication. The results of the search will be reported in full and presented in a PRISMA flow diagram [28]. The search strategy is shown in Multimedia Appendix 2.

Data Collection and Analysis

Identifying Relevant Literature

Screening will be undertaken using Covidence, a web-based citation software program, that facilitates web-based collaboration and blinding of reviewers during screening activities. All team members will receive training on the application of Covidence prior to screening. Two team members

XSL•FO
RenderX

independently, using a 2-step process, will assess the results of the published and gray literature searches. In level 1, all records will be assessed against the following three screening questions: (1) Is the record a primary empirical study? (2) Is the study conducted in a nursing home (residential long-term care home) setting during the COVID-19 pandemic? (3) Does the study assess outcomes among frontline nursing staff that address the impact of the COVID-19 pandemic? All potentially relevant records, as well as those that do not contain enough information to determine eligibility, will be retained.

In level 2 screening, the full text of all retained records will be obtained and assessed for inclusion against the screening questions and inclusion criteria. Pilot testing, including the calculation of interrater agreement, will be completed at each stage of screening against the inclusion criteria for the review. All discrepancies will be resolved by consensus and, where necessary, by consulting a third senior team member. Reasons for exclusion will be documented. In situations where there are multiple reports (publications) for the same study that do not report additional outcomes or results, we will include the initial publication.

Data Extraction

We have adapted data extraction templates that were successfully used in past systematic reviews by the research team [38-40]. Using a small sample of eligible studies from the preliminary search, our study team worked collaboratively to establish and pilot-test the data extraction tool used for the review (Multimedia Appendix 3). The study team convened to compare the data extraction results from 2 reviewers and discuss the inconsistency that might stem from unclarity in the data extraction instructions and issues associated with the application of the tool. The discussions led to further modification and finalization of the tool. Google Forms will be used for the data extraction process so that reviewers can assess independently, and the results can be easily exported and compared.

Methodological Quality

Two reviewers will independently assess the quality of each included study using the Joanna Briggs Institute Quality Appraisal Forms (Checklist for Randomized Controlled Trials, Checklist for Quasi-Experimental Studies, Checklist for Cohort Studies, Checklist for Case-Control Studies, Checklist for Case Series, Checklist for Prevalence Studies, Checklist for Analytical Cross-Sectional Studies, Checklist for Qualitative Research) [41] and the Mixed Methods Appraisal Tool, version 2018 [42]. Disagreements will be resolved through consensus and, if necessary, by consulting a third senior team member. For intervention studies, the research team will investigate if protocols have been published. When available, the protocols will be compared to the final publication to assess the presence of reporting bias. Appraisal results will be summarized narratively. Given the emergent nature of the topic and the descriptive focus of this review, we will not exclude studies based on quality.

Data Synthesis

We will use a parallel-results convergent design to synthesize both quantitative and qualitative evidence. According to the typology of synthesis designs for synthesizing qualitative and quantitative evidence developed by Hong and colleagues, a parallel-results convergent design analyzes and presents qualitative and quantitative evidence separately. The integration occurs during the interpretation of results in the Discussion section [43]. Data synthesis will be conducted separately for each objective. Quantitative studies will be stratified by outcome of interest or intervention and analyzed accordingly. If 3 or more studies investigate the same outcome using comparable methods, we will conduct statistical synthesis (meta-analysis). Details of the statistical models, methods and effect estimates, and measures of statistical heterogeneity will be reported. Where statistical pooling is not possible, findings will be presented in a narrative form, including tables and figures to aid in data presentation. For qualitative studies, careful comparisons will be made between the studies included in the synthesis to identify concepts and themes that are common or similar across the studies.

Mental Health, Physical Health, and Work-Life Outcomes

For the included quantitative studies, we will summarize and map outcomes of interest and the instruments used to measure the outcome (eg, established valid instruments and self-developed instruments). We will group the findings of included quantitative studies that reported the same outcome into main categories of outcomes and report the prevalence of the outcomes by presenting the original scores of instruments and cutoffs. Using narrative synthesis, we will report what is known about the impact of the COVID-19 pandemic on frontline nursing staffs' work-life and mental health outcomes as well as how these outcomes have been examined. Narrative content analysis will be used to synthesize staffs' experiences of mental health and work-life outcomes and generate themes (with representative quotes). This will allow us to identify associations between the COVID-19 pandemic and outcomes that may not have been quantitatively investigated. More details are provided in Multimedia Appendix 4.

Risks and Protective Factors

A narrative description of patterns derived from the findings will be used to understand the risks and protective factors that influence the experiences of frontline nursing staff. This will involve grouping studies by focus, methods, and outcomes to make comparisons between them. Synthesis will include calculating the proportion of quantitative studies that report significant results by factor (eg, the percent of studies that report peer support is a significant protective factor or that lack of peer support is a significant risk factor). The proportion of qualitative studies that describe significant factors (risk or protective) will also be reported.

Type and Feasibility of Strategies or Interventions

We anticipate a limited number of randomized controlled trials in this field and heterogeneity in study designs, interventions, and outcome measures. Accordingly, a quantitative synthesis of intervention effects may not be possible. In this regard, we will narratively synthesize the types of interventions developed or tested (psychological interventions and individual, group, or

XSL•FO
RenderX

organizational-level intervention), the phase of the study (eg, feasibility study, pilot study, efficacy trial, and effectiveness trial), study design, and study findings.

Subgroups and Sensitivity Considerations

Where 3 or more studies investigate the same outcome using comparable methods, we will conduct subgroup analyses to determine whether results differ by (1) quality rating, (2) settings included in the study (multisetting vs nursing home only), and (3) the use of different measures of the same outcome. Gray et al [27] found evidence of worse outcomes among females and nurses when compared to other workforce groups [12,22,44]. If results indicate that other subgroups (eg, socioeconomically disadvantaged persons, racial or ethnic minorities, and unregulated staff) are disproportionately affected and there is an adequate number of studies with similar methods and outcomes representing each subgroup, we will conduct additional subgroup analyses. Comparison across or within countries may also be possible as emerging studies include large representative samples from over 20 countries, with the largest proportions from the United States, Canada, Spain, and the United Kingdom.

Review Quality

This review will be conducted in accordance with Cochrane's principles for systematic reviews [45], with adaptations for observational and qualitative study designs, which are frequently used in studies of staff mental health and quality of work-life outcomes. We will follow the PRISMA statement [46], a checklist of 27 essential items for transparent reporting of systematic reviews (Multimedia Appendix 1). We will also use the AMSTAR-2 tool, a 16-item checklist (developed as a quality appraisal tool for systematic reviews) to ensure our review meets quality standards and to avert any possible deficiencies in the conduct and reporting of our review [47].

Ethics Approval

Ethical approval is not required as this project does not involve primary data collection.

Results

Overview

This study was funded in 2021. As of December 2022, full-text screening is complete and data extraction is underway. The expected completion date is June 30, 2023. Our preliminary search identified approximately 10 studies published in 2020, over 40 studies in 2021, and approximately 15 studies published in the first 4 weeks of 2022 that meet our eligibility criteria. These are primarily observational studies; however, 4 intervention studies, including 1 randomized controlled trial conducted in nursing homes, were identified. Most studies sampled frontline staff from nursing homes only; however, a portion include staff from multiple settings (eg, hospital, home care, and intensive care).

Dissemination

Findings will be disseminated through conference presentations and publication in a peer-reviewed journal. Additionally, we will produce a plain-language summary of the findings for informing users on what is known on this topic and recommendations for use in practice. Any amendments made to this protocol when conducting the study will be outlined in PROSPERO and reported in the final manuscript.

Discussion

Overview

To date, there have been numerous COVID-19 studies of the impact on frontline nursing home staff with varied methods and, in some cases, disparate findings—leaving knowledge users with uncertainty. Therefore, a robust evaluation is required to gain a broader understanding of the impact of the sustained effects of COVID-19 on the nursing home workforce. This systematic review will uncover gaps in current knowledge to inform future research exploring how nursing homes can be more proactive in supporting the health and psychological needs of frontline nursing staff amid extreme stressors such as the pandemic and within the wider context of prepandemic conditions.

Summary

Findings from the preliminary search suggest that nursing home workers have worse mental health outcomes than staff working in other health care settings [6]. Studies comparing outcomes by service setting (eg, nursing home, hospital, and primary care) report higher rates in one or more of clinical depression, anxiety, stress, PTSD, and insomnia among nursing home staff [12,14,44,48]. One study found that nursing home staffs' risk of extended sick leave (<3 weeks) was almost 2-fold higher, while groups working in other health care had no elevated risk of sickness absence due to COVID-19 [49]. For frontline staff working in nursing homes, preexisting stressors may partially explain the increased risk of developing negative mental and physical health symptoms due to pandemic-related work conditions [12,16,50].

We identified 4 heterogeneous intervention studies in nursing home settings [36,51-54]. The first study aimed to prove the feasibility and effectiveness of treating anxiety and depressive symptoms among nurses who were highly mobilized during the acute phase of COVID-19 using a web-based (remote) Eye Movement Desensitization and Reprocessing (EMDR) protocol [36]. The authors concluded that web-based EMDR was both feasible and effective [36]. However, this study did not include a control group and all participants had received prior EMDR treatments from the therapist who provided the study intervention. This limits the ability to draw conclusions on the effectiveness of the EMDR protocol [36]. The second study was a randomized control trial that examined the effectiveness of self-help plus in reducing anxiety and posttraumatic symptomatology [51]. No difference in self-reported anxiety or posttraumatic symptomatology was found postintervention [51]. The third study used a mixed methods approach to evaluate the effectiveness of a web-based education program delivering just-in-time learning and best practices to improve staff confidence and comfort level when working with residents who were at risk, confirmed, or suspected of having COVID-19 [52]. The results indicated that the intervention effectively delivered

XSL•FO
RenderX

time-sensitive information and best practices to support nursing home staff [52]. Lastly, Lathren and colleagues [53] explored the feasibility and effects of self-compassion training for certified nursing assistants working in nursing homes (n=34). Self-compassion training was found to be feasible and beneficial for the stressors that certified nursing assistants experienced during the COVID-19 pandemic [53].

Strengths and Limitations

While there is significant interest in this topic, a preliminary search of the literature indicates that there is limited research available specifically focused on nursing home settings. Our inclusion of all designs will ensure that we provide the best evidence possible on the effects of the COVID-19 pandemic on frontline nursing staffs' mental health and work-life outcomes that are protective and those that increase risk, as well as the effects of interventions to limit negative outcomes.

Second, the heterogeneity between study designs, outcomes of interest, and how these are measured may limit our ability to statistically compare results. Therefore, our analysis will include descriptive analysis, which will synthesize all available and potentially actionable evidence. We will also conduct a subgroup analysis if sufficient data are available to compare results when different measures are used to capture the same outcomes.

A third potential challenge we may face is that an insufficient number of intervention studies will be captured based on the timing of this review. The search will be repeated before synthesis to ensure all available intervention studies are included. Finally, as with all reviews, misinterpretation of the original research or data extraction errors is possible. To minimize this risk, 2 team members will independently engage in these activities, and discrepancies will be discussed to reach consensus. Should we encounter unforeseen circumstances where we need to deviate from our protocol, we will document and report the change in the completed review.

Conclusions

Systematic reviews have a central place in informing decision-making from the level of individual patient care to health care policy makers [45,54]. To better understand the impact of the COVID-19 pandemic on frontline nursing staff health and work-life outcomes, identify the risks and protective factors, and determine which interventions are feasible and effective, a comprehensive synthesis of all existing evidence is needed. To date, there have been numerous COVID-19 studies related to its impact on frontline nursing home staff with varied methods and disparate findings, leaving knowledge users with uncertainty. This systematic review will inform the interpretation of the disparate findings to date and uncover gaps in current knowledge; doing so will guide future research exploring how the health care system can be more proactive in improving quality of work-life and supporting the health and psychological needs of frontline staff amid extreme stressors such as the pandemic and within the wider context of prepandemic conditions. Future research may examine specific interventions and policies to support nursing home staffs' well-being, ultimately promoting better work-life and optimizing nursing home staffs' ability to provide optimal quality of care to residents.

Acknowledgments

All authors meet the criteria for authorship stated in the Uniform Requirements for Manuscripts Submitted to Biomedical Journals. TT, YD, and CAE developed the study concept and design. TT, YD, and SS drafted the manuscript. All authors participated in the critical revision and approved the final manuscript. We would like to thank Ms Thane Chambers (Health Sciences Librarian, Faculty of Nursing, University of Alberta) for designing and conducting the search strategy. This work was supported by a Provincial Seniors Health and Continuing Care 2021 Knowledge Synthesis award, University of Alberta. The funders had no role in the design of the study; preparation, review, or approval of the manuscript; or decision to submit the manuscript for publication. TT is supported by a Canadian Nurses Foundation study award and the Gyro club of Edmonton Graduate Scholarship in Aging.

Data Availability

No data sets were generated or analyzed during the development of this protocol. We will include all data generated or analyzed during the systematic review in the published manuscript (and its Multimedia Appendices). CAE will have full access to all data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis and synthesis.

Abstract

Background: Anxiety is linked to decreased life quality and well-being. Living with an anxiety disorder results in higher personal and societal financial expenditure. Occupational therapists work with people living with anxiety in a variety of settings. A preliminary database search was conducted, and no current or underway systematic or scoping reviews on the topic were identified. Developing an overview of studies of occupational therapy interventions for people with anxiety is a necessary first step to understanding the existing knowledge and to increase the impact of future interventions. This scoping review will build on the findings of a previously conducted systematic review.

Objective: This scoping review will identify the following: (1) what occupational therapy interventions exist for adults with anxiety and (2) the intervention characteristics including outcomes used and impact observed.

Methods: This protocol was reviewed by an occupational therapist as part of a patient and public involvement consultation. The review will consider all studies and publications of occupational therapy that include community-dwelling adults with a diagnosis of anxiety who are aged 18 years and older and diagnosed with an anxiety disorder (Diagnostic and Statistical Manual of Mental Disorders [DSM-5-TR] criteria). Databases to be searched are MEDLINE, CINAHL, Cochrane Library, Science Direct, PsycArticles, Psychology & Behavioural Sciences Collection, Embase, PubMed, TRIP, Proquest, Social Care Online, JBI EBP database, OpenGrey, and OALster. Titles and abstracts will be screened against the inclusion criteria using Rayyan Qatar Computing Research Institute. Potentially relevant studies will be retrieved in full and assessed against the inclusion criteria. Articles published in English will be included. No date limiters will be used. Study selection will be completed by 2 independent reviewers. Data will be extracted using a data extraction tool.

Results: Data will be charted using the Template for Intervention Description and Replication (TIDieR) checklist in alignment with the review objectives. The scoping review will be reported in accordance with the Preferred Reporting Items for Systematic review and Meta-Analysis Protocols statement.

Conclusions: This scoping review will produce valuable information about community-based interventions used to improve participation, life quality, and well-being for adults with anxiety to support the development of occupational therapy interventions.

XSL•FO
RenderX

The findings will be disseminated through professional and National Health Service bodies, employer organizations, conferences, and research articles. The findings will be of value to health care professionals and researchers working to improve the lives of people living with anxiety.

Introduction

Background

Anxiety and stress-related disorders, conditions that involve excessive fear or worry about a current or anticipated future event, are the ninth-highest global cause of disability [1]. Anxiety disorders are highly persistent over a person's lifetime and are associated with elevated levels of disability, reduced quality of life, and decreased participation [2]. Living with an anxiety disorder results in higher personal and societal financial expenditure. For example, in the United Kingdom, the mean annual care costs for people living with anxiety are £71 million (US $84.2 million) [3]. In the United States, this figure is approximately US $52 billion [4].

Anxiety disorders, no matter the type or origin of the disorder, have a profound influence on an individual's ability to participate in their chosen activities in daily life to a level with which they are satisfied [5]. The stress associated with anxiety disorders reduces energy and the motivation to complete activities of daily living [6] and is linked to both resilience and occupational adaptivity, that is, any adjustment or behavior change in response to the demands of living [7]. Focusing on the biochemical or cognitive aspects of anxiety as part of a health intervention may not necessarily contribute to an improvement in an individual's participation in life activities. Additionally, poor functioning can continue after full or partial recovery from an anxiety disorder due to the longitudinal impact of psychosocial impairment, suggesting that participation in daily life appears to be independent of symptoms of anxiety [8]. It is also known that participation and functioning are a greater predictor of health care usage and cost than the severity of either anxiety or depressive symptoms [9]. These findings point to a need to identify the characteristics of interventions that focus on how individuals with anxiety participate in daily activities, as this will contribute to the development of more targeted and effective interventions in the future. Furthermore, interventions that are targeted more appropriately may potentially be more cost-effective [10].

The stories of those living with anxiety disorders emphasizes the impact that this condition has on people's everyday lives. This includes the effect that anxiety has on social relationships and feelings of shame and embarrassment:

> *I go to the bathroom and when I come back he says "where have you been?" I've been to the toilet. "You have been a long time." So trying to hide… (the attacks). He thinks it's stupid. It makes you feel ashamed.* [11]

The experience of anxiety is a complex phenomenon that affects people across cultures. In a study of adults living with anxiety in Iran, the participants explained the experience as "*it is like I am in a cage*" and fearing being both rejected or neglected by others, such as being mocked or losing popularity [11]. In the United Kingdom, some have explained the experience of anxiety and its impact as "*My head says I'm under attack and physically I feel like I'm under attack"* and "*it has prevented me from doing a lot of things*" [12]. This range of experiences further reinforces the need to explore the characteristics of interventions for people.

Occupational therapists have historically worked with people experiencing anxiety in a variety of settings. In a systematic review and narrative synthesis of occupational therapy interventions for people with anxiety disorders, Fox et al [13] were unable to make a judgment on overall clinical effectiveness due to the heterogeneity of the identified studies. As it was an effectiveness review, the authors highlighted the potential for replicability of the interventions in future research and as treatments, the characteristics of the identified studies, and their interventions were not charted in detail. It is also unclear if the authors adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement for reporting a systematic review, which the limits replicability and transparency of their review. In their conclusion, Fox et al [13] highlight that future research should report on the impact of occupational therapy interventions for people living with anxiety. The proposed scoping review seeks to further the authors' findings [13] by updating the search and exploring and understanding the current landscape of intervention characteristics of the interventions identified to aid the development of future interventions and research. A search of the CINAHL database has identified that studies have been conducted since 2019 that would add to the data.

The identification of potential intervention characteristics is crucial to the development of new complex interventions (those interventions with several interacting components) [14]. If too little time is spent on identifying characteristics in the early stage of the complex intervention development cycle, this may result in a flawed intervention that is lacking in clinical and cost-effectiveness [14]. Furthermore, identifying the characteristics of previous occupational therapy studies will benefit the design and future evaluation of new interventions

XSL•FO
RenderX

by examining how the research is conducted and identifying knowledge gaps [14,15]. This approach aligns with the development stage of the "development-evaluation-implementation process" for complex interventions as outlined by the Medical Research Council [15]. Adopting this approach will help to ensure that future interventions have a better chance of being effective when evaluated and of implementation, that is, being adopted in real-world settings [14].

A preliminary search of MEDLINE, the Cochrane Database of Systematic Reviews, and *JBI Evidence Synthesis* was conducted, and no current or underway systematic reviews or scoping reviews on the topic were identified. Thus, the objective of this scoping review is to examine the range and characteristics of occupational therapy interventions that have been reported to improve the participation, quality of life, and well-being of community-dwelling adults living with anxiety. This scoping review will create a map of community-based interventions used to improve participation, quality of life, and well-being for adults with anxiety. It is hoped that the findings of the review will support the development of occupational therapy interventions to empower people to live well with their condition by improving their quality of life, mood, and participation in meaningful occupations.

Review Questions

What Occupational Therapy Interventions Exist Globally for Adults With Anxiety?

Specifically, this review will collect and chart data to address the following subquestions: (1) what are the characteristics of the occupational therapy interventions identified? (2) What are the outcome measures used to evaluate the occupational therapy interventions identified? (3) What was the reported impact of occupational therapy interventions for adults with anxiety? (4) What are the implications for practice and future research of the occupational therapy interventions identified?

Methods

Study Design

The proposed scoping review will be conducted in accordance with the Joanna Briggs Institute (JBI) methodology for scoping reviews [16]. This scoping review protocol is registered on the Open Science Framework [17] and will be reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA-P) statement [18]. This scoping review protocol will be conducted using the JBI guidelines for scoping reviews to ensure a systematic methodology that can be replicated [16]. The planned review will be reported in line with the PRISMA Extension for scoping reviews [19].

Eligibility Criteria

Participants

The review will consider studies of occupational therapy that (1) include adults with a diagnosis of anxiety who are aged 18 years and older and are resident in their own home or a care setting and (2) include diagnoses such as generalized anxiety disorder, panic disorder, and anxiety disorder not otherwise specified as defined by DSM-5-TR (or earlier versions) criteria. Studies for exclusion will be those with people without a confirmed diagnosis of an anxiety disorder, those concerning pharmacological interventions, researches focused on diagnostics, researches focused on stress or stress-related disorders.

Concept

The concept being mapped within this scoping review will be occupational therapy interventions used to support the participation, well-being, and quality of life of people living with anxiety. The terms anxiety and stress are often used interchangeably in research. As a result, these terms require clarification. Bystritsky and Kronemyer [20] explain that stress tends to be an external stimulus arising from the environment. Alternatively, Hallion and Ruscio [21] describe anxiety as a persistent internal feeling of fear and worry that is intrusive in daily life. Clarifying these definitions suggests that it is more appropriate to focus solely on anxiety in this scoping review, rather than a combination of terms.

Occupation is viewed as the performance of chosen daily life tasks that provide desirable levels of pleasure, productivity, and restoration [22]. Examples of meaningful occupations may include (but is not exclusive to) walking in nature, interacting with the community (eg, leisure groups), or going to work (paid and unpaid). Occupational therapy interventions can be characterized as occupation based or occupation focused [22]. Occupation-based interventions therapeutically use the individual's participation in a chosen meaningful occupation in the context as it would unfold in that person's everyday life, for example, running, working, cooking, and as the method for evaluation. Occupation-focused interventions focus on training the specific skills required for the successful performance of an individual's chosen occupation, for example, the provision of compensatory or adaptive equipment or teaching alternative strategies during a personal care occupation such as toileting [22]. Interventions that are focused on changing a person's basal physiology are neither occupation based nor occupation focused.

The specific items of interest are the characteristics, outcome measures, impact, and implications for the practice of the identified interventions. Participation can be defined as the ability of a person to meaningfully engage and be satisfied with their activities of daily life and has been identified by the World Health Organization as essential to health [23,24]. For the purposes of this review, all types of occupational therapy interventions that support participation in meaningful occupation as the method for evaluation and intervention will be included. All modes of delivery will be incorporated, and any dosage or frequency of intervention will be considered. Examples of types of interventions include self-management, social support, and psychosocial interventions and their variants, and examples of modes of delivery include support groups, one-to-one sessions, telehealth, and digital delivery models.

XSL•FO
RenderX

Context

This scoping review will consider studies that specifically include community-based occupational therapy interventions in all countries for adults living with anxiety. This could include people with anxiety living in their own homes or other care settings.

Types of Sources

This scoping review will consider both experimental and quasi-experimental study designs including randomized controlled trials, nonrandomized controlled trials, before and after studies, and interrupted time-series studies. In addition, analytical observational studies including prospective and retrospective cohort studies, case-control studies, and analytical cross-sectional studies will be considered for inclusion. This review will also consider descriptive observational study designs including case series, individual case reports, and descriptive cross-sectional studies for inclusion.

Qualitative studies will also be considered that focus on qualitative data including, but not limited to, designs such as phenomenology, grounded theory, ethnography, qualitative description, action research, and feminist research. In addition, systematic reviews that meet the inclusion criteria will also be considered, depending on the research question. Text and opinion papers will also be considered for inclusion in this scoping review.

Review Team

The review is being conducted by a team comprised of a National Institute for Health and Care Research Clinical Doctoral Research Fellow (CL), academics (KB, IS, and JM), and an information specialist (MS).

Patient and Public Involvement

The scoping review protocol has been reviewed by an occupational therapist (AP) with experience of working in a community setting.

Search Strategy

The search strategy will aim to locate both published and unpublished studies. An initial limited search of MEDLINE, CINAHL, and PsycINFO was undertaken to identify articles on the topic. The text words contained in the titles and abstracts of relevant articles, and the index terms used to describe the articles were used to develop a full search strategy for PubMed, MEDLINE, CINAHL, JBI EBP database, PLoS, Social Care Online, The Cochrane Library, Science Direct, Embase, PsycArticles, Psychology & Behavioural Sciences Collection, TRIP database, OpenGrey, OALster, and ProQuest Dissertations & Theses (see Multimedia Appendix 1). The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. The reference list of all included sources of evidence will be screened for additional studies. The searches will be conducted by MS and CL.

Studies published in English will be included, as the resources for translation are not available, and no date limiters will be used.

Study or Source of Evidence Selection

Following the search, all identified citations will be collated and uploaded into the bibliographic citation management system, EndNote 20.2.1 (Clarivate Analytics), and duplicates removed [25]. The citations will be transferred to Rayyan Qatar Computing Research Institute to manage the screening process [26]. Following a pilot test, titles and abstracts will then be screened by two or more independent reviewers (CL and KB) for assessment against the inclusion criteria for the review. Potentially relevant sources will be retrieved in full, and their citation details imported into the JBI System for the Unified Management, Assessment, and Review of Information [27]. The full text of selected citations will be assessed in detail against the inclusion criteria by 2 independent reviewers (CL and KB). The reasons for the exclusion of sources of evidence at full text that do not meet the inclusion criteria will be recorded and reported in the scoping review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion, or with an additional reviewer (JM or IS). The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a Preferred Reporting Items for Systematic Reviews and Meta-analyses extension for scoping review (PRISMA-ScR) flow diagram [19].

Data Extraction

A data extraction form is provided (see Multimedia Appendix 2). The Template for Intervention Description and Replication (TIDieR) checklist will be used for data extraction [28]. This internationally recognized checklist for describing interventions will enable a systematic description of the interventions and their characteristics in sufficient detail to allow future replication (if required). Data will be extracted from papers included in the scoping review by 1 reviewer (CL) using the TIDieR checklist. A second reviewer (KB) will check the extracted data. The data extraction process will first be piloted by the 2 reviewers initially on 3 papers to ensure that TIDieR checklist is used consistently. The data extracted, in line with the TIDieR checklist items, will include specific details about the intervention rationale, materials, procedures, provider, delivery mode, location, dosage, modifications, and fidelity. Any disagreements that arise between the reviewers will be resolved through discussion, or with an additional reviewer. If appropriate, the authors of papers will be contacted to request missing or additional data, where required.

Ethical Considerations

Since the scoping review methodology consists of reviewing and collecting data from publicly accessible material, this study does not require ethical approval.

Results

The extracted data will be charted in tabular form using the TIDieR checklist [28]. A narrative summary will accompany the charted results and will describe how the results relate to the review's objective and question. The results will be presented following the TIDieR format and the main conceptual categories used in the extraction too, as well as gaps in the

XSL•FO
RenderX

literature. These will be presented in relation to the question of this scoping review.

Discussion

This scoping review will produce a map of the current body of research and community-based occupational therapy interventions that are used to improve participation, quality of life, and well-being of adults living with anxiety by building on the findings of a previously published systematic review [13].

To the best of our knowledge, this is the first scoping review to map the characteristics of community-based occupational therapy interventions for community-dwelling adults living with anxiety. The comprehensive information about the characteristics of such interventions, such as the outcome measures used and impact, will make an important contribution to the development of new occupational therapy interventions and future research. Identifying the characteristics and components of currently used interventions and published research is useful in optimizing the clinical and cost-effectiveness of future treatments and studies [14]. As anxiety is a global health issue, these findings will be of interest not only to clinicians and researchers in the United Kingdom but also to those in the international community working in this area.

As with any review, there are several limitations to conducting the proposed scoping review. While a rigorous identification and inclusion strategy has been outlined, there remains a risk that some data which may have provided further insights are inadvertently omitted. This risk is enhanced by the challenges of searching gray literature. In addition, as scoping reviews explore the breadth of a topic and not the depth, the reviewers cannot comment on the quality of the studies included in the scoping review. The proposed scoping review will synthesize the study limitations and findings as reported by the included literature. A methodological appraisal of the included studies will not be performed. Thus, the limitations and findings reported in the proposed review are not necessarily exhaustive or interrogated beyond the peer-review process of the published article. Finally, restricting the search strategy to articles only published in English means that articles that would be eligible for inclusion have the potential to be missed.

The review authors will use the findings of this scoping review to contribute to the co-production of a new complex intervention to help people with Parkinson to live well with anxiety, embedded within the UK National Health Service. Similarly, these findings will be of value to a wider audience of health care professionals and researchers involved in service development or research projects that aim to improve the lives of people living with anxiety.

Acknowledgments

The authors would like to thank Anna Paisey for her contributions to the development of this protocol.

Data Availability

All data relevant to the study are included in the article or uploaded as supplementary information.

Authors' Contributions

The design of the protocol was conducted by CL, IS, MS, JM, and KB. The drafting of the manuscript was done CL, IS, and KB. CL, IS, JM, and KB approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Major advances in different cancer treatment modalities have been made, and people are now living longer with cancer. However, patients with cancer experience a range of physical and psychological symptoms during and beyond cancer treatment. New models of care are needed to combat this rising challenge. A growing body of evidence supports the effectiveness of eHealth interventions in the delivery of supportive care to people living with the complexities of chronic health conditions. However, reviews on the effects of eHealth interventions are scarce in the field of cancer-supportive care, particularly for interventions with the aim of empowering patients to manage cancer treatment–related symptoms. For this reason, this protocol has been developed to guide a systematic review and meta-analysis to assess the effectiveness of eHealth interventions for supporting patients with cancer in managing cancer-related symptoms.

Objective: This systematic review with meta-analysis is conducted with the aim of identifying eHealth-based self-management intervention studies for adult patients with cancer and evaluating the efficacy of eHealth-based self-management tools and platforms in order to synthesize the empirical evidence on self-management and patient activation through eHealth.

Methods: A systematic review with meta-analysis and methodological critique of randomized controlled trials is conducted following Cochrane Collaboration methods. Multiple data sources are used to identify all potential research sources for inclusion in the systematic review: (1) electronic databases such as MEDLINE, (2) forward reference searching, and (3) gray literature. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for conducting the review were followed. The PICOS (Population, Interventions, Comparators, Outcomes, and Study Design) framework is used to identify relevant studies.

Results: The literature search yielded 10,202 publications. The title and abstract screening were completed in May 2022. Data will be summarized, and if possible, meta-analyses will be performed. It is expected to finalize this review by Winter 2023.

Conclusions: The results of this systematic review will provide the latest data on leveraging eHealth interventions and offering effective and sustainable eHealth care, both of which have the potential to improve quality and efficiency in cancer-related symptoms.

digital health; cancer supportive care; cancer-related symptoms; self-efficacy; supported self-management

Introduction

The incidence of cancer is rising, and it is estimated that by 2040, globally, more than 28 million people will experience cancer as new cancer cases [1]. It is expected that nearly half of Canadians will develop cancer in their lifetimes [2]. The main goal of a cancer treatment program is to cure or considerably prolong the life of patients and to ensure the best possible quality of life for cancer survivors [3]. Major advances in different cancer treatment modalities (ie, surgery, chemotherapy, radiotherapy, hormonal therapy, and biological response modifiers) have been made, and people are now living longer with cancer than they were in the past [3-5]. However, patients with cancer experience from a range of physical and psychological symptoms during their cancer journey. These symptoms are either directly related to the adverse effects of cancer or arise from the different types of treatments and may range from mild and temporary to severe, chronic, and life-threatening [6]. Moreover, symptoms impact daily physical function and can lead to or exacerbate psychological distress and worse health-related quality of life [7,8].

Globally, there is recognition that patients benefit from being actively engaged in their own health [9]. Active engagement of patients is considered critical to minimize the consequences of disease in daily living, support a better quality of life [10], and reduce health care costs [9].

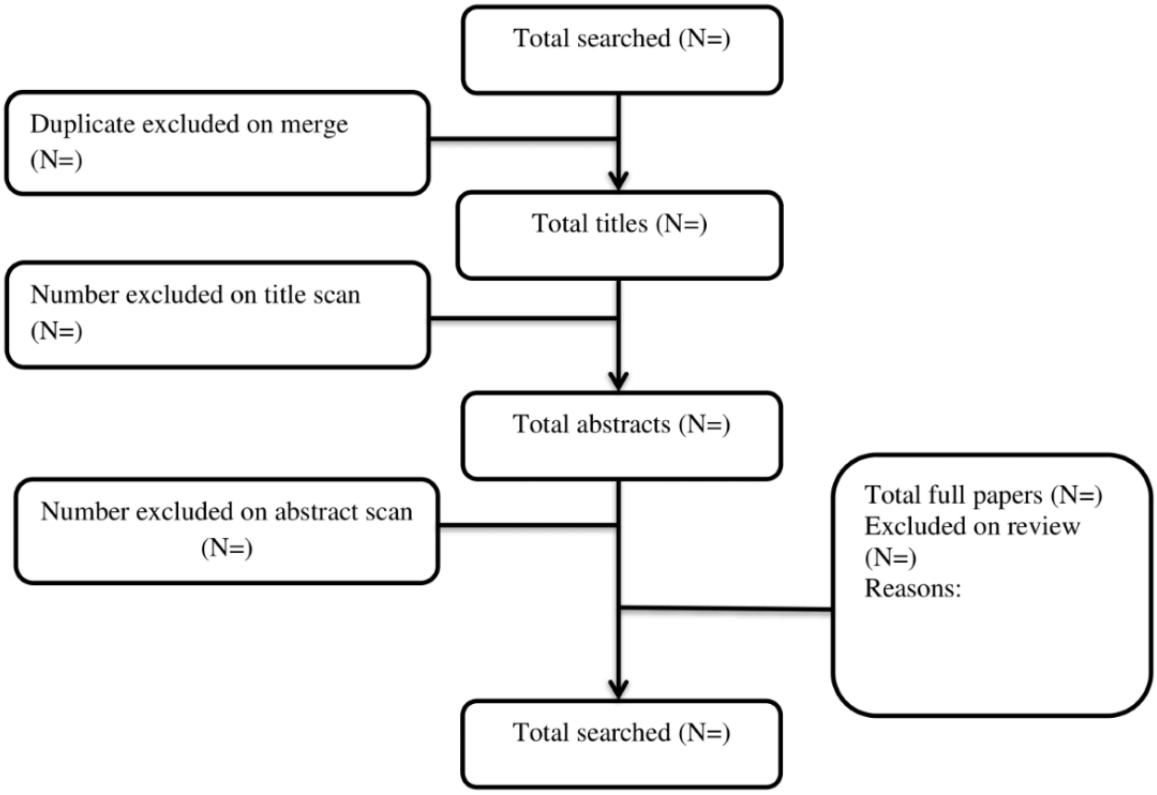
eHealth interventions could potentially enhance the clinical, organizational, and relational aspects of care by integrating patient databases for individualized treatment and real-time decision support. Moreover, it has been reported that electronic technology, by identifying decision support, care coordination, and continuity of care, could improve cancer care delivery [11]. This approach can empower patients to manage their symptoms, improve patient-professional interactions, prevent unplanned hospital admissions, and reduce health care costs [12,13]. Additionally, for nurses, working with innovations such as mobile health (mHealth) in practice is becoming essential as it may facilitate the provision of quality care [14].

Even though there is empirical evidence that substantiates the role of eHealth interventions in the delivery of supportive care to people living with the complexities of chronic health conditions [15-19], the effects of eHealth interventions specifically designed for supporting patients with cancer to manage cancer-related symptoms and the effects on outcomes, that is, symptom burden, are less clear [20,21].

Reviews on the effects of eHealth interventions are scarce in the field of cancer supportive care, particularly for interventions to increase patient activation and empower patients to self-manage cancer-related symptoms. There is substantial evidence that patients who have the appropriate information and skills are more likely to engage actively in their care and effectively manage the consequences of treatment, including their physical and psychological symptoms [13,22]. Furthermore, information on how these interventions were planned and carried out and who benefited from these approaches is still required [23].

We propose to conduct a systematic review with meta-analysis and methodological critique of the literature to answer the following PICO (Population, Intervention, Comparison, Outcomes) research question: What is the efficacy in cancer populations (population: any phase of cancer, treatment, survivorship, palliative, and end of life care) of eHealth interventions (intervention) compared to usual care or other active intervention (comparison) on symptom severity, psychological distress, self-management behaviors, health outcomes, and health use (emergency department use, unplanned visits to the health care provider, hospitalization, patient activation, and patient empowerment; outcomes).

This review aims to explore usage and effectiveness of eHealth interventions designed to support patients with cancer in managing cancer-related symptoms and the effects on outcomes. The findings could inform and promote evidence-informed oncology practice for eHealth interventions targeted at cancer and advance science in the field.



Methods

Overview

This systematic review to identify randomized controlled trials (RCTs) and meta-analyses follows methods as specified by the Cochrane Collaboration [24] and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines (see Figure 1) [25]. A broad search to identify trial evidence for eHealth interventions to empower cancer patients to manage their symptoms, increase patient activation, and improve patient-professional interactions will be conducted. We posed the following specific research questions.

XSL•FO
RenderX

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) chart: self-management and patient activation through eHealth review.

Primary Research Question

Are eHealth interventions (or programs) effective in reducing the physical or psychological effects of cancer and its treatment or improving other health outcomes (ie, function, health-related quality of life, health use, or costs) compared with usual care or other active treatment?

Secondary Research Questions

Does effectiveness (effect sizes [ESs]) of eHealth interventions (or programs) differ by patient or disease characteristics (age, race or ethnicity, education, cancer type, stage or phase in trajectory, treatment modality, or other antecedent personality variables such as optimism or trait anxiety), that is, effect modifiers?

Does effectiveness (ESs) of eHealth interventions (or programs) differ based on intervention design (delivery setting) or methods (eHealth-based self-management tools and platforms), training and qualities of the interventionist, intervention components, length of the intervention, or other potential mediators, that is, adherence to the intervention?

Literature Search Strategy

The search strategy was developed with assistance from a library information specialist. A computerized search of electronic databases will be conducted from January 2000 until January 2022 as follows: The Cochrane Central Registry of Controlled Trials (CENTRAL), Cochrane Library and Trials Registry and the Database of Abstracts of Reviews of Effectiveness (DARE), MEDLINE (2000 to January 2022), Embase (2000 to January 2022), CINAHL (2000 to January 2022), PSYCHINFO (2000 to January 2022), and CancerLit (2000 to January 2022). In addition, the gray literature databases, EAGLE (2000 to January 2022), openSIGLE (2000 to January 2022), and PsychEXTRA (2000 to January 2022) will be searched. The reasons for limiting the literature search from 2000 onwards are the development of internet technology and the use of internet-based support programs in the delivery of supportive care over the past 22 years [26].

Search Terms

The search for eligible studies will include search terms: self-manage* or “self-manage*” or self-car* or “self-care*”, behave* or cognitive* or train* or instruct* or patient education or “patient education” or “management plan*” or “management program* (AND) ehealth* or mHealth* or “mobile Health*” or Telehealth* (AND) terms for neoplasms, cancers, or cancer symptoms (fatigue, nausea or vomiting, pain, depression, anxiety, insomnia) and sensitive search terms for identifying randomized trials as subject headings specified by Cochrane [27]. The initial search strategy will be developed in MEDLINE (Multimedia Appendix 1) and will be adapted for all other databases.

Types of Studies

Eligible studies will be identified based on the inclusion or exclusion criteria described below.

Inclusion Criteria

The following inclusion criteria were used:

- RCTs, quasi-randomized, or controlled clinical trials with an intervention group and a comparison patient group (receiving another intervention or standard care)

XSL•FO
RenderX

- Interventions using eHealth technology (web-based interventions, mHealth, etc)
- Interventions targeted at improving self-management or patient activation in managing physical symptoms or psychological distress
- Include one of the following outcomes: physical health status or symptoms, psychological health status or psychological symptoms or health distress, quality of life
- Comparisons were made with usual care or another active intervention
- Adults (18 years or older) at any stage or type of cancer

Exclusion Criteria

The following exclusion criteria were used:

- Studies without an eHealth intervention in the self-management of cancer
- Studies that did not include usual care controls or active intervention controls
- Studies published in non-English language
- Interventions that do not include a formal analysis of effects or use valid instruments

Types of Outcome Measures

Primary Outcomes

We will be studying the following primary outcomes:

- Self-reported measures of physical health status or symptoms on valid and reliable scales
- Self-reported measures for psychological health status or symptoms, that is, depression or anxiety
- Quality of life or functioning is measured with valid and reliable scales

Secondary Outcomes

We will be studying the following secondary outcomes:

- Patient characteristics, including demographic and clinical data, and the intervention (intervention type, delivery, and intervention components)
- Participant's withdrawal from the studies
- Subjective and objective measures of physical function or disability
- Symptom limitations or interference
- Healthcare utilization (hospital admissions, emergency department use, urgent visits to the family physician), and other health care or social costs

Selection of Studies

Studies will be selected using Covidence software based on a review of the title, keywords, and abstract and coded using the following criteria: (1) include: an RCT, with a focus on cancer patient activation or self-management; (2) exclude: no self-management focus. Selecting studies includes these steps: (1) using a reference management software to merge search results and remove duplicates; (2) examine all titles initially to remove articles that are clearly not eHealth, followed by an abstract review (if there is any uncertainty, the abstract is included for a full text review); and (3) retrieve the full study reports and assess compliance with eligibility criteria independently by 2 reviewers. Agreement will be examined using interrater agreement (<75 nonagreement); disagreements will be resolved by consensus or in consultation with a third reviewer. Authors| will clarify study eligibility criteria or missing data results if necessary. Interventions with more than 1 article will also be retrieved and reviewed to complement the data abstraction and quality assessment of the study (Multimedia Appendix 2).

Data Abstraction and Management

Data will be abstracted using a data abstraction form developed for the review based on Cochrane methods. Data abstraction is independently assessed by 2 reviewers with reliability of coding assessed by computing Kappa, or percentage agreement, for categorical data and the intraclass correlation for continuous data. If any aspect of the study design and conduct is unclear, the study authors will be contacted to complete data abstraction. Two other review authors will check a random sample of the abstractions. Disagreements will be resolved by discussion, with arbitration by a third author if necessary, following an independent review of the study report in question. The data abstraction form will be pretested on a minimum of 5 studies. The abstracted data will include categories as per Cochrane: (1) source and setting; (2) methods; (3) participants; (4) experimental interventions (extent to which specific intervention components delivered as described [adherence]; number, length, and frequency of implementation of intervention components; and characteristics of the interventionists); (5) control treatment; (6) analysis; (7) adverse events; (8) outcome measures; (9) results; (10) conclusions of study authors; and (11) miscellaneous, that is, funding sources.

Assessment of Study Quality

A quality assessment will be performed by 2 review authors and checked by another author. A methodological quality assessment of studies will be conducted based on an adapted version of the Cochrane Collaboration Back Review Group criteria [28], which were previously used in other systematic reviews of internet-based interventions [29,30]. The Cochrane criteria was modified to better suit the type of examined studies: specification of eligibility criteria, randomized groups, treatment allocation concealed, groups similar at baseline, explicit description of interventions, description of compliance, description of dropout and comparison with completers, long-term follow-up (>3 months after postintervention assessment), timing of outcome assessment comparable, sample size described with power calculation, intention-to-treat analyses, and point estimates and measures of variability. The quality score could range from 0 to 12 points. For each study, all criteria will be scored as yes, no, or unclear, resulting in a maximum quality score of 12. In line with other researchers [29-31], studies obtaining at least two-thirds of the total score (ie, ≥8 points) will be considered high quality. Studies scoring 4 to 7 points will be rated as moderate quality, and studies scoring lower than 4 points will be rated as low quality.

Authors will be contacted with 2 reminders to complete missing data. Reviewers will be blinded to the authors of study reports. For each of these potential sources of bias, a judgment of yes (low risk of bias), no (high risk of bias), or unclear is assigned to each study (number of yeses is the single score or study). A

XSL•FO
RenderX

summary table of the risk of bias across studies will be developed for reporting purposes.

Data Analysis and ES Calculation

Outcomes will be analyzed as continuous or dichotomous variables depending on data reporting using standard statistical techniques. For continuous data (ie, symptom severity), a standardized mean difference with 95% CIs will be calculated as appropriate to facilitate comparison between intervention and controls with correction for differences in the direction of the scale. If reported as medians with ranges, means and SDs will be calculated [32]. For dichotomous outcomes, a relative risk ratio with 95% CIs is calculated.

Assessment of Heterogeneity

As per Cochrane, clinical heterogeneity (variability in the participants, interventions, and outcomes) [33,34] will be examined using the "I" squared statistic [35]. Random effects meta-analysis will be used if heterogeneity across studies cannot be explained; otherwise, a fixed-effects model will be used [33,36].

Subgroup Analysis

The following subgroup analysis will be conducted if the number of studies available for the analysis is adequate (10 studies for each characteristic modeled by participant characteristics and intervention components) as described below and based on the research questions posed:

1. Study intervention characteristics: The potential effect modifiers examined may include the characteristics of the intervention (length of follow-up, use of a number of components emphasized).
2. Study participant characteristics: Subgroup analysis will be conducted for disease stage (early and advanced), sex (male, female), and disease subtype, as some types of cancer may be associated with higher mortality.

Measurement of Treatment Effects and ES Calculation

A summary of findings table will be completed to synthesize the reporting of common primary outcomes: physical effects (function and symptoms), psychological effects (depression, anxiety, and health distress), and secondary outcomes (quality of life, health care use, and satisfaction) using the GRADEpro software. ES computations will be calculated using Hedges *g*. [37]. Where *g* cannot be computed directly from means and SDs based on the source paper, it will be computed indirectly from the available test statistics, for example, t, based on Rosenthal [38]. The estimates of *g* will be corrected for small-sample bias [37]. Given that outcomes could be differentially effective over different dimensions, particularly for symptoms, separate analyses for comparison, that is, physical symptoms (pain, fatigue, nausea or vomiting, insomnia), psychological symptoms (depression, anxiety, health distress), and separately for quality of life and use of health care services, will be conducted. For studies where a primary outcome is possible for the main analysis, this will require the identification of a primary outcome.

Sensitivity Analysis

A sensitivity analysis will be conducted to evaluate the robustness of the meta-analysis, that is, the effects of methodological quality on study outcomes, by assessing for associations between individual items in the methodological quality checklist and the study outcomes. When data can be pooled, sensitivity analysis will be conducted by pooling the "yes" versus "no" responses to risk. When the data cannot be pooled, the sensitivity analysis will be performed using a chi-square analysis as per Cochrane.

Results

The literature search and data collection started in October 2017, after making a work plan to design and run the systematic search strategies in databases and the timeframe for delivery of the search results with the Library and Information Services within the University Health Network. However, to provide a comprehensive snapshot of knowledge since the time of incorporation of data from studies identified during the first search, a second literature search was conducted in February 2022 to ensure new studies were included and increase the validity of the review. The literature search yielded a total of 10,202 publications. Data will be summarized, and if possible, meta-analyses will be performed to evaluate the effectiveness of eHealth interventions on the outcomes. Results are expected to be published in winter 2023.

Discussion

Recent literature has highlighted the utility of eHealth interventions with promising outcomes in cancer care, although mixed and inconclusive results were also presented [39]. The main contributions to this review will be the following: the use and effectiveness of eHealth interventions for supporting patients with cancer in managing cancer-related symptoms; identifying the key implications for better design, integration, and implementation that may have important effects on intervention outcomes; and a discussion, based on the data synthesized, on current gaps and limitations to inform better research toward all phases of development and evaluation of these interventions. Therefore, we will provide essential information for developing and implementing these interventions into clinical practice by providing recommendations based on the current best available evidence. The evaluation of the interventions might be limited by explicitly reporting the interventions. Any modifications or revisions made to the protocol will be presented in the final reports.

Abstract

Background: Self-management has become important as a complementary approach to the recovery of patients with mood disorders, and the need for a remote intervention program has been revealed in relation to the COVID-19 pandemic.

Objective: The aim of this review is to systematically review the studies for evidence on the effects of online self-management interventions based on cognitive behavioral therapy or psychoeducation for patients with mood disorders and to verify the statistical significance of the effectiveness of the interventions.

Methods: A comprehensive literature search will be conducted using a search strategy in nine electronic bibliographic databases and will include all randomized controlled trial studies conducted up through December 2021. In addition, unpublished dissertations will be reviewed to minimize publication bias and to include a wider range of research. All steps in selecting the final studies to be included in the review will be performed independently by two researchers, and any discrepancies will be resolved through discussion.

Results: Institutional review board approval was not required because this study was not conducted on people. Systematic literature searches, data extraction, narrative synthesis, meta-analysis, and final writing of the systematic review and meta-analysis are expected to be completed by 2023.

Conclusions: This systematic review will provide a rationale for the development of web-based or online self-management interventions for the recovery of patients with mood disorders and will be used as a clinically meaningful reference in terms of mental health management.

Introduction

Mood disorders are emotional disturbances that can be divided into depressive disorders and bipolar disorders [1]. Depressive disorder is a disease experienced by more than 300 million people worldwide, with 13.4% of women and 8.3% of men with the disability according to the World Health Organization [2]. Bipolar disorder, which is classified as a mood disorder along with depressive disorder, affects about 2% of the world's population and is the 10th most common disease in young adults [3,4]. For all ages, depressive disorder is the third most common

XSL•FO
RenderX

disease that leads to living with a disability, and the prevalence of major depressive disorder has been significantly increasing over the years [5]. The prevalence of bipolar disorder is also rapidly increasing year after year, and in general, bipolar disorder takes an average of 5 to 10 years from the time the disease occurs to an accurate diagnosis [6,7]. Despite effective treatment, 40% of those diagnosed with bipolar disorder experience frequent recurrence, with 20%-40% of those diagnosed with major depressive disorder experiencing recurrence within one year of recovery. This suggests that mood disorders are likely to be chronic [8].

Self-management is an individual's ability to manage the symptoms, treatment, physical and psychosocial consequences, and lifestyle changes inherent in living with a chronic condition. Promoting self-management prevents recurrence based on an understanding of one's disease, and it is becoming important as a complementary approach to optimizing recovery from mood disorders and improving quality of life [9,10]. Self-management of mental illness can be used as a primary low-intensity intervention, especially in individuals with mild to moderate symptoms, supplementing usual clinical therapies such as drugs and psychotherapy [11]. Among the psychosocial treatments corresponding to low-intensity interventions, cognitive behavioral therapy (CBT) or psychoeducation is particularly effective in improving the psychosocial functioning, treatment adherence, and clinical course of patients with depression [12]. CBT, one of the most studied types of depression prevention intervention, is considered an effective treatment type for adults with treatment-resistant depression by reducing depressive symptoms [13,14].

The demand for and necessity of online-based interventions are increasing due to the recent influence of the COVID-19 pandemic. Recently, as the cost for health care clients increases and mental illness patients face resource limitations due to delayed treatment time, several studies have shown that computer-based or internet-based treatments are as effective as face-to-face psychotherapy in treating mood disorders [15-19]. Online-based treatment is more cost-effective than face-to-face treatment in many aspects, and it has the advantage of facilitating learning and retention because the patient has easy access to the program. In addition, the patient's treatment progress and results can be monitored immediately, enabling prompt intervention before a crisis occurs [19].

Although the need for self-management for patients with mood disorders and the importance of online-based intervention is increasing, there is a lack of articles that have conducted systematic reviews of the literature on this topic. Therefore, to establish a theoretical basis, we will integrate the research results of online interventions based on either CBT or psychoeducation for mood disorders in a comprehensive perspective through a systematic review of the literature. Furthermore, we will verify the effect of the intervention through a meta-analysis.

Methods

This protocol is reported in line with the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) statements [20], and the systematic review will be conducted and reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [21]. The systematic review protocol was registered under CRD42022299474 in PROSPERO.

Identification of the Search Question

What is the evidence that online-based interventions to enhance self-management for people with mood disorders improve clinical and health outcomes?

Search Strategy

The search strategy will be conducted by the researchers using an electronic database and search engine. A comprehensive literature search written in English will be conducted in five bibliographic databases, including PubMed, Embase, PsycINFO, CINAHL, and CENTRAL. A comprehensive literature search written in Korean will be conducted in the Research Information Sharing Service (RISS) and KoreaMED. The search will be limited to peer-reviewed journal articles available in English and Korean published until December 2021. In this study, gray literature will also be included in the review to minimize publication bias. The gray literature will be searched using Google Scholar, ProQuest Dissertations & Theses Global, and RISS.

In developing an initial search strategy based on PubMed, we adopted not only MeSH (Medical Subject Headings) terms but also synonyms and analogues as free-text terms and combined them with appropriate Boolean operators. The search strategy will be reviewed by a librarian with extensive experience in searching databases. Search strategies developed based on PubMed will be syntactically adjusted when applied to other databases. The search string will be searched using various terms such as Textbox 1. All search results will be imported from EndNote (Clarivate), a citation management software, and will be managed by researchers.

Eligibility Criteria

Studies will be included if they were conducted on adults older than 18 years, assessed those who have been diagnosed with depressive disorder or bipolar and related disorders, or who meet the diagnostic criteria. Studies will also be included if they performed online-based self-management interventions based on CBT or psychoeducation, provided sufficient information to calculate the effect size, and were conducted as a randomized controlled trial. Studies will be excluded if they were preliminary studies with no control/comparison group, performed online-based self-management interventions as part of another intervention or in combination with another intervention, or do not give access to the full text. Specifically, studies will be selected according to PICOS (Participants, Interventions, Comparisons, Outcomes, and Study Design), which is presented below.

Participants

The participants in the systematic review will be adults 18 years or older who have been diagnosed with or meet the diagnostic criteria for depressive disorders or bipolar and related disorders. Specifically, depressive disorders include major depressive disorder, persistent depressive disorder, and disruptive mood dysregulation. Bipolar and related disorders include bipolar I disorder, bipolar II disorder, and cyclothymic disorder.

Interventions

In the systematic review, we will include interventions provided in online or mobile form based on CBT or psychoeducation. Interventions should be aimed at promoting self-management in patients with mood disorders. Studies in which interventions were conducted in conjunction with or as part of other interventions will be excluded because the effectiveness of the intervention cannot be independently evaluated.

Comparisons

The comparison groups will be adults 18 years or older with a diagnosis of depressive disorder or bipolar and related disorders who received the following interventions: wait-list control, treatment as usual, face-to-face self-management interventions, and online self-management interventions that are not based on CBT and psychoeducation.

Outcomes

The primary outcomes of interest in this review will be treatment efficacy demonstrated through changes in scores for manic or depressive symptoms and quality of life. The secondary outcomes of interest will be the improvement of social functioning confirmed through the degree of change in social relationship and adaptation scores, as well as the feasibility and acceptability of the intervention calculated by the dropout rates.

Study Design

The study design to be included in the systematic review will be a randomized controlled trial with access to the full text. In addition, unpublished dissertations will be included in the review to minimize the risk of publication bias.

Study Selection

All steps will be carried out independently by two authors with strict application of specific qualification criteria. Studies will be assessed by having their eligibility considered by the first author and then revised by the second author. Disagreement will be resolved through discussion. Studies retrieved from the databases listed above using a search strategy will be stored in EndNote, and then, duplicate studies will be removed through manual review by the authors and an automatic function of EndNote. A primary screening will be conducted by two authors independently, where the studies with titles and abstracts indicating that they do not meet the eligibility criteria will be removed. If at least one author identifies that a study is likely to meet the eligibility criteria, the study will not be excluded

XSL•FO
RenderX

from the full-text screening. A full-text screening to select studies for final inclusion in this review will follow, which will be conducted independently by the authors. If there is disagreement at this step, the study will be reviewed and discussed together to decide whether to include it. Studies excluded from the full-text screening will be listed with the reason for exclusion, and all screening and selection processes will be reported through the PRISMA flow diagram [21].

Data Extraction

Data will be independently extracted to electronic data extraction sheets by two authors, and they will be mutually re-evaluated. Information extracted from the studies will include trial characteristics, including first author, publication year, and participant number; intervention and control/comparison group characteristics, including diagnosis, diagnostic criteria characteristics, means of providing intervention, duration of intervention, and intervention contents; and outcome characteristics (outcome measures and results). If additional confirmation of unreported data or details is required, the study authors will be contacted to request materials. The extracted data will be saved and managed in the Excel (Microsoft Corporation) sheet (Multimedia Appendix 1). Based on the data in the Excel sheet, the diagnosis and inclusion criteria of patients to whom the intervention was applied, the type of intervention, the type of outcome measurements to evaluate the effect, and the results will be summarized and presented in a table.

Risk of Bias and Quality Assessment

For the final selected randomized controlled trial studies, two authors will conduct an independent quality assessment using the Cochrane Risk of Bias tool [22]. This tool consists of five areas where bias can be applied to research results. The five areas are as follows: (1) risk of bias arising from the randomization process, (2) risk of bias due to deviations from the intended interventions, (3) risk of bias due to missing outcome data, (4) risk of bias in the measurement of the outcome, and (5) risk of bias in the selection of the reported result. Disagreements between the authors will be resolved through discussion. Even if the result of the quality assessment for the final selected study has a high risk of bias, the study will not be excluded.

Results

Systematic literature searches, data extraction, narrative synthesis, meta-analysis, and final writing of the systematic review and meta-analysis are expected to be completed by 2023.

Narrative Synthesis

We will discuss important features of the final selected study, such as publication year, number of participants, gender, age range, diagnosis and diagnostic criteria characteristics, and the type and nature of interventions provided.

Meta-analysis

We will calculate risk ratios for dichotomous outcomes and standard mean differences (SMDs) for continuous data using complex meta-analysis software such as Review Manager (RevMan) or R (R Foundation for Statistical Computing). We will also define outcomes based on all follow-ups and adopt the most well-validated psychometric measure if there are multiple measures of the same outcome. If possible, we will contact the original author to request missing data. The statistical method of handling missing data will depend on whether the data are randomly missing. We will figure out the effect size for the intervention outcome using the SMD. The effect size will be calculated by applying either a random-effects model or a fixed-effects model according to the I^2 statistic that confirms homogeneity. In addition, we will analyze whether the direction of the effect size of each study and the confidence interval between the studies overlap through a forest plot. Funnel plots will be used to estimate the presence of publication bias. If sufficient studies are available, we will conduct the following subgroup analysis: CBT-based interventions, psychoeducation-based interventions, and CBT and psychoeducation mixed interventions.

Discussion

This protocol has outlined detailed inclusion and exclusion criteria for determining eligible studies, which include a description of the target population and intervention of interest as well as comparisons, study design, and outcome measures. We also have mentioned our search strategy, data extraction, quality assessment, and synthesizing method such as meta-analysis to inform the direction of this study.

Depressive disorder and bipolar disorder have a high potential to become chronic diseases due to frequent relapses, so the importance of self-management is increasingly emphasized. Recently, due to the impact of COVID-19, interest in remote interventions without time and place restrictions has increased. Therefore, our research will systematically review and analyze the evidence for the effectiveness of online-based self-management interventions as a complementary approach for the recovery of patients with mood disorders. To comprehensively approach interventions for the self-management of patients with mood disorders, this study includes CBT and psychoeducation as intervention studies.

The strength of this systematic review is that it will take a standardized approach to the review method by adhering to systematic review guidelines such as the PRISMA 2020 statements and checklist. In addition, the inclusion of unpublished dissertations without limitation by year of publication will reduce publication bias and increase the range of our search. However, this review will have potential limitations in language bias, since it will only include studies published in English and Korean that the researchers can read and interpret.

Nevertheless, considering the increasing prevalence and severity of mood disorders, the effectiveness of online self-management interventions derived from this systematic review and meta-analysis can be used as clinically meaningful evidence in terms of mental health. Additionally, we believe that this study will provide the necessary data to form the theoretical basis for the development of online-based self-management interventions for the recovery of patients with mood disorders in the future.

Abstract

Background: Type 2 diabetes mellitus is a chronic disease that contributes to an increasing global burden on the health system. It has a high chance of leading to macrovascular complications and cardiovascular disease. As an inflammatory condition, it would be essential to target inflammatory pathways when developing therapeutic drugs for type 2 diabetes mellitus.

Objective: We aimed to evaluate the effect of vitamin D on markers of inflammation and lipid profile among adult patients with diabetes.

Methods: A systematic review will seek studies published on Embase, Google Scholar, PubMed, Web of Science, and Science Direct. This planned systematic review and meta-analysis will be limited to randomized controlled trials; moreover, the search will include published studies regarding the effects of vitamin D on pro-inflammatory cytokines and lipid profiles. The review will include studies published from inception until December 30, 2022. The study identification and selection will be based on the eligibility criteria by 2 independent reviewers. Additionally, a meta-analysis will only be performed if more than 2 studies are available and explore the same outcomes, and this will be analyzed using RevMan (version 5.4.1). The quality and risk of bias will be assessed following the Cochrane risk of bias tool and Jadad checklist.

Results: The process for searching literature review has already started, and this is conducted independently by 2 reviewers using a predefined eligibility and "participants, intervention, comparator, and outcome" criteria. This systematic review and meta-analysis will not require any direct involvement of patients and the public; thus, no ethical approval was required.

Conclusions: The findings obtained from the proposed study will be presented in scientific seminars, journal clubs, and conferences and published in peer-reviewed journals.

Introduction

Type 2 diabetes (T2D) mellitus is a chronic disease associated with an increased mortality rate [1] due to impaired pathways that regulate homeostatic and inflammatory responses. According to the 2021 International Diabetes Federation report, about 537 million people are estimated to have diabetes worldwide, and this number is expected to reach 783 million in 2045 [2]. T2D is challenging; it affects individual health, while putting a financial burden on the health care system [3,4].

Despite the availability and use of glucose-lowering pharmacological drugs, such as metformin [5], there is a continuous rise in death due to secondary complications associated with T2D globally. The population with T2D reportedly dies from cardiovascular disease more frequently than healthy individuals [6]. Moreover, other patients experience severe side effects from pharmacological drugs [7]. Thus, this is the motivation for exploring different pharmacological and nutraceutical agents to find one with potent antihyperglycemic and hypolipidemic potentials.

Other studies have explored the beneficial impact of natural antioxidants on glucose control, inflammation, and lipid metabolism in metabolic conditions [8-11]. For their distinct antioxidant benefits, many dietary compounds, including vitamin D, are increasingly being taken as supplements. Vitamin D, also called calciferol [12], is a membrane antioxidant and a member of fat-soluble vitamins that alleviates inflammation by inhibiting nuclear factor kappa-beta activity [13,14]. The direct stimulation of pancreatic β cells to release insulin [15], anti-inflammatory effects [16] to reduce chronic inflammation brought on by insulin resistance, and downregulation of elevated parathyroid hormone levels [17], which inhibit insulin secretion [18], are some of the protective mechanisms of vitamin D that have been proposed. In addition to being present in dietary supplements, a small amount can be found in oily fish, red meat, egg yolk, liver, and fortified cereals [19].

A previous meta-analysis confirmed vitamin D's beneficial effects in regulating blood glucose; however, the improvement was minimal [20]. This effect might be attributed to vitamin D's unique property in alleviating oxidative stress and inflammation [21]. Although previous quantitative studies have shown that vitamin D supplementation in patients with T2D can reduce inflammation [22,23] and lipid profiles [24], the results are inconsistent, and the markers evaluated are not common. Additionally, the effect of vitamin D supplementation on diabetes-related complications is controversial since most randomized controlled trials (RCTs) conducted used small sample sizes or have used different doses of vitamin D. Consistently, quantitative evidence has not looked at these parameters simultaneously to explore the antioxidant effect of vitamin D in T2D. This led us to propose this systematic review and meta-analysis that will simultaneously investigate the antioxidant benefits of vitamin D in all these parameters in T2D. We aimed to conduct this systematic review and meta-analysis to evaluate the impacts of vitamin D supplementation in T2D and help to further clarify its beneficial impact on inflammation and lipid profile in patients with T2D. This information is essential for understanding the health benefits of this dietary antioxidant and reducing the number of T2D individuals who succumb to cardiovascular disease complications associated with T2D.

Methods

Overview

This systematic review and meta-analysis protocol is prepared in accordance with the PRISMA-P (Preferred Reporting Items for Systematic review and Meta-Analysis Protocols) 2015 checklist [25] and the population, intervention, comparison, and outcome (PICO) guideline [26]. The protocol for this systematic review and meta-analysis is registered with the International Platform of Registered Systematic Review and Meta-analysis Protocols (INPLASY202260022) and is reported according to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist (Multimedia Appendix 1).

Purpose of the Study

This proposed study aimed to evaluate the effect of vitamin D on markers of inflammation and lipid profile among adult patients with T2D.

The research question is "Can supplementation with vitamin D improve inflammation and ameliorate dyslipidemia in T2D?" This protocol will subscribe to PICO guidelines [26]. Participants are adult patients with T2D. The intervention will be vitamin D supplementations of any dose, and the comparators are placebo or healthy patients without treatment.

The outcomes are inflammation and dyslipidemia, and the study design includes RCTs.

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria will be carried out following our PICO guidelines. The review will include RCTs that have focused on adult patients with T2D. There will be no language limitations, and all studies published from inception until December 30, 2022, will be considered. The reviews, books, letters, and animal studies experimenting with diabetes will be excluded. Furthermore, cross-sectional studies, cohort studies, case-control studies, and case reports will all be excluded.

Search Strategy and Information Sources

Reviewer 1 (RM) and reviewer 2 (KM) will independently conduct a comprehensive literature search through different databases (eg, Embase, Google Scholar, Web of Science, PubMed, and Science Direct). The following keywords (Medical Subject Headings terms), including their synonyms, will be applied in all databases: "Vitamin D," "calciferol," "Dihydroxycholecalciferol," and "type 2 diabetes mellitus." Furthermore, the evidence will be sought from RCTs published from inception until December 30, 2022, with no restriction regarding publication language. The preliminary search strategy is presented in Table 1 and Table 2.

Table 2. Search strategy on PubMed with filter according to study designs (randomized controlled trials).

Items	MeSH[a] terms	Search
7	6	(Type 2 diabetes mellitus[MeSH Terms]) AND (((vitamin D[MeSH Terms]) OR (Calciferol[MeSH Terms])) OR (1,25-Dihydroxycholecalciferol[MeSH Terms])). Filters: Randomized Controlled Trial

[a]MeSh: Medical Subject Headings.

Study Selection

The search will be conducted independently by 2 reviewers (RM and KM) to ensure accuracy and consistency based on the eligibility criteria. Firstly, keywords, titles, and abstracts will be screened, followed by retrieval of the full study. Mendeley desktop reference manager (version 1.19.4) will be used to save studies retrieved through web-based database search or manual reference screening. All studies that meet the inclusion criteria will be subjected to a data collection process and quality assessment. For any discrepancy, the 2 reviewers will conclude by discussing and reevaluating the study in dispute. The Shiny app [27] will be used to create a PRISMA flow diagram showing study selection.

Data Items and Collection

The data will be extracted following the eligibility criteria. The 2 reviewers RM and KM will conduct data extraction independently and then compare the spreadsheet; in case of disagreement, they will discuss and review the study again. The information sought from each study for extraction will include the author and year of publication, the country where the study was conducted, sample size, participants' gender and age, form of vitamin D and its dosage, duration of treatment, lipid profiles, and pro-inflammatory markers. Data will be confirmed by contacting investigators if insufficient information has been provided in the published article.

Risk of Bias

The risk of bias will be assessed using the methods recommended in the Cochrane risk of bias assessment tool [28]; assessment includes 6 domains; selection, attention, reporting, performance, attrition, and other bias. Judgments will be used to determine whether the bias is a high-risk or low-risk bias, is unclear due to insufficient information, or is a potential bias. The Jadad guideline will be used to assess the quality of individual studies [29]. The author (RM) and supervisor (KM) will discuss and resolve any bias and come to a consensus should there be any disagreement.

Subgroup Analysis

Following initial data analysis, we will evaluate the level of heterogeneity based on I^2 [30] and Q tests. If the I^2 is moderate ($I^2 \geq 50\%$), we will explore the source of heterogeneity by performing subgroup analysis [31]. This will be based on the form of vitamin D, its dosage, BMI, study quality, the origin of the study, age, and the duration of the intervention.

Publication Bias

Publication bias among the included studies will be assessed and visualized graphically through funnel plots [32] if there are more than 10 studies included in the meta-analysis. In case of no publication bias, the funnel plot will form a symmetrical (ie, inverted) funnel. In contrast, if bias is present due to smaller studies without statistically significant effects, the funnel plot will show an asymmetrical shape.

Sensitivity Analysis

Sensitivity analyses will be performed to evaluate the robustness and stability [33] of our effect size by using one study exclusion approach at a time based on the study with a high risk of bias, small sample size, or the largest sample size.

Certainty of Evidence

We will evaluate the certainty of our evidence by using the Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) approach [34] using the web-based GRADEprofiler. This approach takes into consideration the risk of bias, imprecision, inconsistency, indirectness, publication bias, and effect size. The evidence will be rated as low, moderate, or high based on 2 independent reviewers' ratings. The overall findings will be presented in a summary of the findings table.

XSL•FO
RenderX

Data Analysis

Statistical analysis will be conducted using the Review Manager (RevMan; version 5.4; Cochrane Collaboration). Each study reviewer (RM and KM) will independently extract data as mean, SD, and sample size in each group. Where mean and SD values are not reported, the estimation will be made using a web-based calculator by Hozo et al [35]. The forest plots will be used to determine the pooled estimates and classify the level of heterogeneity based on I^2 and P values [36]. The estimated pool will be reported as either mean difference or standardized mean difference and 95% CIs.

Furthermore, a chi-square test (χ^2) and I^2 will assess the heterogeneity among the included studies [37,38]. An I^2 of 0% to 50% will be considered low to minimal heterogeneity, while an I^2 above 50% will be considered moderate heterogeneity.

Consistently, sources of heterogeneity will be explored through subgroup analysis, and sensitivity analysis will be used to assess the stability of the re-analyzed pool estimates. $P<.05$ will be considered statistically significant. In case meta-analysis cannot be performed due to insufficient data or the number of studies, qualitative synthesis will be performed [39].

Ethical Considerations

There will be no involvement from patients and the public in this study. This study synthesizes data from studies that were already peer-reviewed and published. Thus, no ethical approval is required.

Results

The proposed systematic review and meta-analysis is anticipated to be complete and submitted for review by December 30, 2023. Hence, the full results will be discussed in detail following a comprehensive search and data analysis. This systematic review and meta-analysis will not require any direct involvement of patients and the public; thus, no ethical approval is required. The search for literature has already started on MEDLINE using PubMed as a search engine; this is performed independently by 2 reviewers to avoid risk of bias.

Discussion

In this proposed systematic review and meta-analysis, we will explore the impacts of vitamin D supplementation on markers of inflammation, including tumor necrosis factor-alpha, interleukin-6, and C-reactive protein in patients with T2D. Furthermore, we will evaluate the effect of vitamin D on lipid profile (triglycerides, total cholesterol, low-density lipoprotein, and high-density lipoprotein) in adult patients with T2D. Thus, the findings in this systematic review and meta-analysis will provide insights into the use of this natural antioxidant, vitamin D, as a supplementation in patients with T2D to aid in the prevention of complications associated with T2D. The proposed review will include studies published from inception to December 2022, thus gathering old and current evidence about vitamin D. Additionally, the review will be conducted independently to avoid bias in selection and extraction. One of the major anticipated limitations is methodological heterogeneity due to the use of different doses of vitamin D and duration of intervention, different age groups, and patients with other metabolic conditions in addition to T2D. However, subgroup analysis will be performed according to these confounders to find the source of heterogeneity. This will be through classification of studies based on quality (eg, good or low), doses, age, and duration of intervention. Our discussion will examine the implications of our findings, the limitation of the systematic review, and directions for further research on the use of vitamin D as a supplement in T2D for the amelioration of inflammation and dyslipidemia and prevention of secondary complications.

Acknowledgments

We thank the University of South Africa for the payment of article processing charges. The author(s) received no specific funding for this work.

Data Availability

Information and data involving literature search, data extraction, and data analysis will be made available by the corresponding author upon request following the publication of the manuscript.

Authors' Contributions

KM and RM were in charge of the study conceptualization and design as well as methodology. KM provided resources and RM prepared the original draft and wrote the manuscript. KM supervised the study. KM also helped in the writing, reviewing, and editing of the manuscript. Both authors (RM and KM) have read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Journal articles describing randomized controlled trials (RCTs) and systematic reviews with meta-analysis of RCTs are not optimally reported and often miss crucial details. This poor reporting makes assessing these studies' risk of bias or reproducing their results difficult. However, the reporting quality of diet- and nutrition-related RCTs and meta-analyses has not been explored.

Objective: We aimed to assess the reporting completeness and identify the main reporting limitations of diet- and nutrition-related RCTs and meta-analyses of RCTs, estimate the frequency of reproducible research practices among these RCTs, and estimate the frequency of distorted presentation or spin among these meta-analyses.

Methods: Two independent meta-research studies will be conducted using articles published in PubMed-indexed journals. The first will include a sample of diet- and nutrition-related RCTs; the second will include a sample of systematic reviews with meta-analysis of diet- and nutrition-related RCTs. A validated search strategy will be used to identify RCTs of nutritional

XSL•FO
RenderX

interventions and an adapted strategy to identify meta-analyses in PubMed. We will search for RCTs and meta-analyses indexed in 1 calendar year and randomly select 100 RCTs (June 2021 to June 2022) and 100 meta-analyses (July 2021 to July 2022). Two reviewers will independently screen the titles and abstracts of records yielded by the searches, then read the full texts to confirm their eligibility. The general features of these published RCTs and meta-analyses will be extracted into a research electronic data capture database (REDCap; Vanderbilt University). The completeness of reporting of each RCT will be assessed using the items in the CONSORT (Consolidated Standards of Reporting Trials), its extensions, and the TIDieR (Template for Intervention Description and Replication) statements. Information about practices that promote research transparency and reproducibility, such as the publication of protocols and statistical analysis plans will be collected. There will be an assessment of the completeness of reporting of each meta-analysis using the items in the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) statement and collection of information about spin in the abstracts and full-texts. The results will be presented as descriptive statistics in diagrams or tables. These 2 meta-research studies are registered in the Open Science Framework.

Results: The literature search for the first meta-research retrieved 20,030 records and 2182 were potentially eligible. The literature search for the second meta-research retrieved 10,918 records and 850 were potentially eligible. Among them, random samples of 100 RCTs and 100 meta-analyses were selected for data extraction. Data extraction is currently in progress, and completion is expected by the beginning of 2023.

Conclusions: Our meta-research studies will summarize the main limitation on reporting completeness of nutrition- or diet-related RCTs and meta-analyses and provide comprehensive information regarding the particularities in the reporting of intervention studies in the nutrition field.

Introduction

Background

Nutrition research provides evidence to support public health policies, advances in clinical practice, and improved quality of life for patients. Reporting diet- and nutrition-related randomized controlled trials (RCTs) requires particular attention to field-specific methodological aspects, such as baseline dietary patterns, food intake assessment instruments, and statistical analysis methods [1-3]. Strategies to deal with methodological limitations and increase transparency in nutrition research include prioritizing large and long-term RCTs, pre-registering protocols and statistical analyses, clearly defining and standardizing methods for data collection and outcomes assessment, and promoting data sharing [4-7]. Guidelines on how to handle sensitive issues, such as public-private partnerships and working with industry, are available [8,9]. All of these recommendations, however, require complete and transparent reporting, which is also crucial when these nutrition- or diet-related RCTs are pooled in a systematic review or meta-analysis. Clearly specified methods for identifying, selecting, and appraising primary studies included in systematic reviews are essential to a systematic review being of high enough quality to inform clinical practice [10,11]. Systematic reviews are the cornerstones of therapeutic evaluation as they assess and grade the available body of evidence on interventions.

Inappropriate reporting of research often means an important and avoidable source of that research wasted [12], with consequences for research consumers such as scientists, clinicians, policy makers, the media, and patients [13,14]. Researchers can minimize this source of waste by adhering to reporting guidelines, which define a minimum set of information required when reporting medical research to ensure its usefulness [15]. One of the first reporting guidelines was the Consolidated Standards of Reporting Trials (CONSORT) for writing up reports of RCTs, developed in 1996 and updated in 2001 and 2010. CONSORT consists of a 25-item checklist and flow diagram to help authors report their RCTs [16]. Item 5 of CONSORT 2010 concerns an RCT's intervention. To improve reporting completeness and replicability of interventions, CONSORT item 5 was extended into a 12-item reporting guideline, "the Template for Intervention Description and Replication" (TIDieR) [17]. Other extensions are also available for specific designs (eg, crossover trials) [18], interventions (eg, nonpharmacologic treatment interventions) [19], and data (eg, harms) [20]. Similar guidance to improve reporting completeness for systematic reviews and meta-analyses—the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) Statement—was developed in 2009 and updated in 2020 [21].

Journal endorsement of these reporting guidelines is associated with better reporting [22-24]. For example, a Cochrane review including meta-research studies assessing the reporting completeness of RCTs demonstrated a standardized mean difference of 0.68 (99% CI 0.38 to 0.98) on the aggregate score of all CONSORT items in favor of CONSORT-endorsing journals over nonendorsers. Allocation concealment, scientific rationale in the introduction, sample size, and sequence generation were also more adequately described in RCTs published in CONSORT-endorsing journals [22]. A study evaluating journal instructions for authors found that 27 out of 33 high-impact nutrition and dietetic journals with an impact factor over 2.88 mentioned CONSORT [23]. In a cross-sectional

XSL•FO
RenderX

study in the field of nursing, the median rates of adherence to the PRISMA statement were 73% (IQR 59.5%-94.6%) for reviews published in journals that endorsed PRISMA and 64.9% (IQR 17.6%-92.3%) for reviews published in journals that did not endorse PRISMA [24]. As far as we know, the correlation between reporting completeness and journal endorsement of PRISMA has not been explored in the nutrition field.

Few studies assessed reporting completeness of nutrition research. Although previous studies have found poor reporting in nutrition- and diet-related studies [25-31], most focused on the association of particular funding sources with methodological and reporting quality [25-27,30,31] or risk of bias [28,29]. We identified only 1 systematic review of RCTs assessing the quality of reporting in RCTs of dietetic interventions in primary care. The authors found that none of the 27 included RCTs reported all CONSORT items, with a median of 11.5 of the 28 items completely met, 8 partially met, and 10 not met at all. The items most often not reported were "a description of where the full protocol can be accessed (n=26, 96%), "registry number and name of trial registry" (n=23, 85%), "mechanism used to implement the random allocation sequence" (n=22, 81%), and "who generated the random allocation sequence, enrolled participants and assigned participants" (n=22, 81%) [32]. We did not find any study assessing the completeness of reporting of systematic reviews in nutrition. One scoping review evaluated 57 studies that assessed adherence to individual PRISMA items, where 79% (n=45) of them focused on therapeutic interventions and related to surgery clinical areas. It identified 11 items that are fewer than 67% of systematic reviews adhered to, including structured summary, protocol and registration, search, data items, risk of bias in individual and across studies (in both methods and results sections), additional analyses, and funding [11].

CONSORT and TIDieR do not cover all possible practices to enhance research reproducibility, such as the inclusion of data-sharing and code-sharing statements. A survey of a random sample of 149 biomedical articles published between 2015 and 2017 found that 18.3% discussed publicly available data [33]. Similarly, an automated assessment of all PubMed Central articles estimated that in 2020, overall 15% of articles had a data-sharing statement and 3% had a code-sharing statement [34].

"Spin," as defined by Boutron et al [35], is the use of specific reporting strategies, from whatever motive, to highlight that the experimental treatment is beneficial, despite a statistically nonsignificant difference for the primary outcome, or to distract the reader from statistically nonsignificant results.

Spin is frequently found in the medical literature, regardless of study design, and its presence can affect the interpretation of results. A systematic review of 35 reports which investigated spin found that more than 56% of trials included spin in their abstract (n=13) and main text (n=16) and that 26.3% of systematic reviews (n=2) included spin in their main text [36]. We did not identify any studies assessing reproducible research practices or the presence of spin in nutrition systematic reviews or meta-analyses.

Objectives

This protocol describes 2 independent meta-research studies that aim to (1) assess the reporting completeness of diet- and nutrition-related RCTs, identify their main reporting limitations, and estimate the frequency of reproducible research practices among them; and (2) assess the reporting completeness of systematic reviews with meta-analysis of diet- and nutrition-related RCTs, identify their main reporting limitations, evaluate their risk of bias, and estimate the frequency of spin among them.

Methods

Design and Research Questions

Two meta-research studies will be conducted to answer the research questions presented in Textbox 1. Both protocols are registered in the Open Science Framework (doi: 10.17605/OSF.IO/BF47G and 10.17605/OSF.IO/ZTFYX).

Textbox 1. Research questions.

Meta-research study of diet- and nutrition-related randomized controlled trials (meta-research study 1)

- What is the proportion of items adherent to CONSORT (Consolidated Standards of Reporting Trials) and TIDieR (Template for Intervention Description and Replication) in a sample of published randomized controlled trials of diet- or nutrition-related interventions?
- What is the frequency of reproducible research practices among these randomized controlled trials?

Meta-research study of systematic reviews with meta-analysis of diet- and nutrition-related randomized controlled trials (meta-research study 2)

- What is the proportion of items adherent to PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) in a sample of published systematic reviews with meta-analysis of diet- and nutrition-related randomized controlled trials?
- What is the risk of bias in these reviews?
- What is the frequency of spin in the abstract and the main text of these reviews?

Eligibility Criteria

For meta-research study 1, we will include diet- and nutrition-related RCTs published in peer-reviewed journals. We will consider self-identification as an RCT as an inclusion criterion. All diet- and nutrition-related RCTs, regardless of the population or outcomes evaluated or the framework design will be included (eg, noninferiority, superiority, or exploratory).

XSL•FO
RenderX

There will be an exclusion of non-RCTs, pilot and feasibility trials, studies that assess pharmaceutical or herbal medicines as an intervention, and trials without isolated nutrition- or diet-related interventions (meaning that trials combining more than 1 intervention will not be eligible). RCTs that do not include any term related to the categories of intervention described in Textbox 2 in their titles or abstracts will be excluded.

For meta-research study 2, systematic reviews will be included with meta-analysis of diet- and nutrition-related RCTs published in peer-reviewed journals. All Cochrane publications will be excluded as their moderate to high methodological quality is likely to ensure a high level of reporting completeness [37].

Textbox 2. Categories of nutrition- or diet-related interventions.

- Food (whole food, food products, specially formulated foods)
- Breastfeeding
- Complete diet or dietary patterns
- Complete nutrition formulas (enteral or parenteral)
- Supplementation or supplements (single or multiple nutrients, bioactive nonnutrients, and plant components)
- Nutrition education, counseling, and coordination of care

We adapted the categories proposed by Naude et al [37] to include "shared foods of complete diet and dietary patterns" and "enteral or parenteral formulas" and remove "nutrition-related policies."

For both meta-research studies, the language of publications will not be an eligibility criterion aiming to avoid language bias. Our team has researchers proficient in English, Portuguese, and Spanish. If necessary, Google Translate or private translation services will be used to extract data from publications in other languages. The nutrition intervention categories of interest are listed in Textbox 2 [37].

Literature Research

For meta-research study 1, we will use the search strategy developed by Durão et al [38] to identify RCTs of nutritional interventions [32]. For meta-research study 2, a search strategy is constructed using nutrition- and diet-related terms [38] combined with a validated search strategy to identify systematic reviews or meta-analyses [39]. No limitation will be set for language during the literature search. PubMed search is conducted (via the National Library of Medicine) using the search strategies presented in Multimedia Appendices 1 and 2. There will be a search for RCTs (June 1, 2021, to June 1, 2022) and systematic reviews with meta-analysis (July 01, 2021, to July 01, 2022) indexed in 1 calendar year.

Study Selection and Sample Size

For both meta-research studies, we will organize the retrieved reports in EndNote (Clarivate). We will remove duplicates using EndNote's automated deduplication, then manually check for and exclude any remaining duplicates. The final library without duplicates to Rayyan will be imported [40], where 2 reviewers will independently determine the eligibility of each report in a 2-stage process. They will screen titles and abstracts and select all RCTs and systematic reviews with meta-analysis assessing any diet- or nutrition-related intervention. Liberal acceleration will be applied, in which both reviewers must exclude a record for it to be excluded, while only 1 reviewer must include a record for it to be included. The reviewers will then read the full texts to confirm study eligibility. In both screening rounds, any discrepancies will be resolved through discussion between the reviewers (FS and JL, acknowledged), with adjudication by a third reviewer (MSM). All reviewers have experience in conducting systematic reviews.

The eligible RCTs and systematic reviews with meta-analysis will be grouped according to the intervention categories described in Textbox 2, and the proportion of RCTs and systematic reviews in each category is calculated. A convenience sample of 100 RCTs will be randomly selected for inclusion in meta-research study 1 and 100 random systematic reviews with meta-analysis for meta-research study 2 that meet the above criteria, with no formal sample size calculation. We aim to maintain the proportion of each intervention category (Textbox 2) in both meta-research studies, for example, for a given intervention category that comprises, say, 50% of the total sample of potentially eligible RCTs, we will randomly select 50 of those for our sample of 100 RCTs. A web-based random number generator will be used to create the list of publications to include from an enumerated sequence of all studies in each intervention category [41].

A flowchart will be presented to demonstrate each step of the study selection process. A list of the studies excluded at the full-text screening stage will be presented with reasons for their exclusion for both meta-research studies.

Data Extraction

For meta-research study 1, a total of 2 reviewers will independently extract data from the selected RCTs to evaluate their reporting completeness, identify their main reporting limitations, and assess their use of predefined reproducible research practices. We have developed a data extraction form (Multimedia Appendix 3) that includes (1) publication data, such as PMID, first author's name, journal in which the RCT was published, and the journal's field according to Web of Science. (2) Basic description of RCT data, categorized into population, intervention, comparator, outcome, and study design (PICOS) domains, adapted from Naude et al [37]. (3) Use of practices that promote research transparency and reproducibility, such as the use of CRediT [42] to acknowledge authorship;

XSL•FO
RenderX

availability of a full protocol publication, statistical analysis plan, and materials/data/code; open access; disclosure of funding source; and disclosure of conflicts of interest. All these practices will be categorized as "yes or no."

An additional data extraction form to evaluate adherence to items from CONSORT [16], its extensions for abstracts [43], harms [20], crossover [18], nonpharmacological [19], cluster trials [44], and TIDieR [15] statements will be developed. Each item will be evaluated as fully reported, not reported, partially reported, or not applicable. As there is an inclusion of RCTs published after the COVID-19 pandemic began, items from the CONSERVE reporting guideline will also be included. CONSERVE was developed to improve the reporting completeness of trials modified due to the COVID-19 pandemic or other extenuating circumstances [45] (Multimedia Appendix 4).

For meta-research study 2, a total of 2 reviewers will independently extract data from the selected systematic reviews with meta-analysis of nutrition- or diet-related RCTs. We have developed a data extraction form (Multimedia Appendix 5) to capture (1) Publication data, such as PMID, first author's name, journal in which the meta-analysis was published, and the journal's field according to Web of Science. (2) Meta-analysis research questions, categorized into PICOS domains, adapted from those used by Naude et al [37]. (3) The presence of spin in the abstract and the main text, classified into four main categories: (A) misleading reporting, including 10 items in the main text and 8 items in the abstract; (B) misleading interpretation, including 13 items in the main text and 10 items in the abstract; (C) inappropriate extrapolation, including 5 items in the main text and 3 items in the abstract, as proposed by Yavchitz et al [46]; and (D) methodological quality according to the ROBIS tool. Phases 2 and 3 of the tool will be followed to make an overall judgment of risk of bias (which will be rated as low, high, or unclear) [47].

An additional data extraction form to evaluate adherence to PRISMA [21], its extensions [48,49], and TIDieR [15] items was also developed (Multimedia Appendix 6).

For both studies, we will pilot-test the data extraction forms on 5 randomly selected full-texts before proceeding with full data extraction to ensure consistency in the interpretation of data items and refine the data extraction form, if necessary. All extracted information will be entered directly into the study databases using REDCap [50]. Any disagreement between the pairs of reviewers will be resolved by a third reviewer.

Data Analysis

For both meta-research studies, descriptive aspects of included publications (ie, data on bibliometrics, PICOS, research transparency practices, presence of spin, and risk of bias) will be presented both as absolute and relative frequencies, either in diagrams or tables.

For meta-research 1, calculation of an aggregate score of adherence to all CONSORT, its extensions, CONSERVE, and TIDieR items will be presented. The items of relevant reporting guidelines' checklists in 170 questions with categorical answers (Multimedia Appendix 3) were fragmented. Most questions presented 2 options as answers (yes or no), whereas some questions presented 3 or 4 options as answers (yes, no, partially, or not applicable). Answers "yes" will be scored as 1 point, while answers "no" will be scored as 0 points and answers "partially" will be scored as 0.5 points. Answers such as "not applicable" will be discounted for that particular study. Therefore, the final score can range from 0 to 170.

For meta-research 2, we will similarly calculate an aggregate score of adherence to all PRISMA, its extensions, and TIDieR items. For meta-research 2, all items of the corresponding reporting guidelines were fragmented into 114 questions with the same possible categorical answers (and respective attributable scores) described above (Multimedia Appendix 6). Thus, the final score for the meta-research of meta-analyses can range from 0 to 114.

In the final report, the results will be presented as frequencies (and respective percentages in relation to the total number of relevant studies) for individual items and proportion of the total achievable score for individual studies. No data aggregation or cutoff points are anticipated for the descriptive analyses.

The general features between RCTs and meta-analyses with above-average and below-average reporting score proportions were also compared, which are stratified by the mean or median value (depending on the distribution) using the Student *t* test or Mann-Whitney test for quantitative variables and the chi-square test for categorical variables. Logistic regression models will be constructed to explore the determinants of reporting completeness.

Any changes to the protocol will be detailed and justified in the publications describing the results of the study.

Ethical Considerations

As both meta-research studies will involve reviewing and collecting evidence from previously published papers, ethical approval is not required. Both meta-research studies will be reported according to the PRISMA adaptation for meta-epidemiological methodology research [51]. Any updates and amendments to this protocol will be described and justified in the final publications. The results will be published in peer-reviewed journals.

Results

The literature search for the first meta-research study retrieved 20,030 records and 2182 were potentially eligible. Among them, 100 nutrition- or diet-related RCTs were randomly selected for data extraction.

The literature search for the second meta-research study retrieved 10,918 records and 850 were potentially eligible. Among them, a random sample of 100 systematic reviews with meta-analysis was selected for data extraction.

Data extraction of both meta-research studies is currently in progress and the completion is expected by the beginning of 2023.

Discussion

We presented the protocols of 2 independent meta-research studies aiming to investigate the completeness of reporting and the frequency of research transparency practices in a random sample of nutrition- or diet-related RCTs and meta-analyses published in journals indexed in PubMed.

Nutrition interventions have particular challenges that need careful consideration during all study phases and detailed communication of research questions and findings. Thus, well-written and complete reporting of RCTs and meta-analyses of RCTs are crucial to support scientific integrity, ethical standards, safety, and validation of study methods and findings [4]. Inappropriate reporting of research frequently means an important and avoidable source of research waste [12], with consequences for scientists, clinicians, policy makers, the media, and patients [13,14]. Researchers can minimize this waste by adhering to CONSORT [16], TIDieR [17], and PRISMA [21] when reporting their work. Indeed, additional practices to enhance research reproducibility such as the adoption of reproducible workflows and open science practices, including data and code-sharing, can benefit nutrition- and diet-related research [52].

The complexity of reporting intervention studies depends on the type of intervention under investigation, as well as knowledge of relevant extensions of general reporting guidelines for specific fields. Nutrition- or diet-related interventions have several particularities, and a detailed evaluation of whether RCTs and meta-analyses of nutritional interventions adhere to CONSORT [16] and PRISMA [21] statements, respectively, is essential. As per our knowledge, this will be the first meta-research study addressing the main reporting limitations of nutrition- or diet-related intervention studies.

At 1-year interval, we identified 2182 and 850 publications describing potentially eligible RCTs and systematic reviews with meta-analysis, respectively. These numbers illustrate the relevance of these types of publications in the nutrition research field, as well as the need for a detailed evaluation of their reporting completeness and transparency. The fact that our samples do not represent all publications in this field has been acknowledged as a study limitation. However, our search strategy choices are based on the premise that the eligible publications retrieved should provide enough evidence to fulfill our aims, as they reflect a recent body of scientific literature indexed in the main database for medical research. While not including Cochrane reviews is also a limitation of our research, their inclusion could bias our findings since these publications follow specific guidelines (eg, for content, structure, and format), and have overall higher methodological quality than standard peer-reviewed publications. Future research could explore the main differences between Cochrane and non-Cochrane systematic reviews of nutritional- or diet-related interventions.

These meta-researchers will inform further deliberations around the need to develop specific reporting guidelines for nutrition- and diet-related RCTs and systematic reviews with meta-analysis since this evaluation can shed light on the main reporting limitations in the area. Our meta-research studies will fill this gap. Therefore, we aim to help increase in the transparency and reproducibility of studies involving nutrition- or diet-related interventions.

Acknowledgments

We are grateful to Julia Lima, who was one of the reviewers involved in the title and abstract screening of the retrieved records for both meta-researches.

Data Availability

Data will be maintained in .csv, .txt, .ris, .docx, and .pdf format for storage for the period of the study and beyond. Extracted data will be deposited in digital open access repositories, such as UK Data Service or Oxford Research Archive.

Authors' Contributions

All authors have made substantial contributions to the development of this protocol through discussions on the topic. MMS, SK, SH, GK, GSC, JC, SL, ARAA, CJV, and FG jointly conceived the idea of this project. FS, MMS, SK, SD, CC, CL, ARAA, MP, LCI, CJV, and GK contributed to the study design and development of research questions. FS and SK constructed the search strategy for both meta-research and ran them. FS, MMS, and GC constructed the data extraction forms. FS and MMS led the writing of the manuscript. All authors provided detailed comments on earlier drafts and approved this final version.

Conflicts of Interest

FS received a postdoctoral fellowship from COPPETEC Foundation. MMS, SK, JAdeB, and GC are funded by Cancer Research UK (grant number C49297/A27294). MP is supported by an Australian Research Council Discovery Early Career Researcher Award (DE200101618). CJV has received honoraria from The Obesity Society and his University has received funds to support his research from National Cattlemen’s Beef Association, Alliance for Potato Research and Education, the Gordon and Betty Moore Foundation, and NIH.

Abstract

Background: Women often experience many unique health issues and conditions throughout their working lives. The Internet of Things (IoT) is a system of interrelated digital devices that can enable data exchanges over a network without human-to-human or human-to-computer interaction. The usage of applications and IoT in improving women's health has recently increased worldwide. However, there has been no consensus on the effectiveness of IoT in improving women's health outcomes.

Objective: This systematic review and network meta-analysis (NMA) aims to assess and synthesize the role of apps and the IoT in improving women's health and to identify the ranking of interventions for ensuring better results for each stated outcome.

Methods: Our systematic review and NMA will be conducted in accordance with the guidelines of the Cochrane Handbook. We will comprehensively search the following electronic databases: PubMed (including MEDLINE), Cochrane Central Register of Controlled Trials, Embase, Cumulative Index to Nursing and Allied Health Literature (ie, CINAHL), PsycINFO, ClinicalTrials.gov, and the World Health Organization International Clinical Trials Registry, along with other resources to identify relevant randomized controlled trials that have assessed the effects of various apps and the IoT with regard to improving working-aged women's health in high-income countries. We will segment and analyze the results of the included studies based on age categories (women undergoing a preconception period, those undergoing gestational and postpartum periods, and menopausal and pre- and postmenopausal women) and the medical history (women who have a specific medical condition—eg, cancer or diabetes—and women who do not have them) separately. Two independent reviewers will perform the study selection, data extraction, and quality assessment. Our primary outcomes include health status, well-being, and quality of life. We will perform pairwise meta-analysis and NMA to estimate the direct, indirect, and relative effects of apps and the IoT on women's health outcomes. We will also assess the hierarchy of interventions, statistical inconsistencies, and certainties of evidence for each outcome.

XSL•FO
RenderX

Results: We plan to conduct the search in January 2023 and are currently discussing search strategies with the literature search specialists. The final report is planned for submission to a peer-reviewed journal in September 2023.

Conclusions: To the best of our knowledge, this review will be the first to identify the ranking of IoT intervention for ensuring working-aged women's health outcomes. These findings may be of great use to researchers, policy makers, and others with an interest in the field.

Introduction

Since the 1990s, the global labor force participation rate has been decreasing gradually. The Asia-Pacific region has experienced an overall decline in labor participation, which is believed to be mainly responsible for the global decline [1]. However, for regions outside of Africa, it has been estimated that the labor force participation rate will decrease, and this trend is projected to continue until at least 2030 [1,2]. Although women are less likely to participate in the labor market than men [1], women's participation has increased gradually owing to increased education and employment opportunities [3].

However, certain lifestyle changes, which occurred because of women's social advancement, have affected their health. For instance, women often perceive their health to be worse than do men because of certain social and biological factors [4], and consistently report higher stress levels [5]. A delay in marriage and the increasing age of conception have been correlated with higher chances of infertility in women, and over 186 million people (both men and women) have experienced infertility worldwide [6]. As opposed to primary infertility, secondary infertility is mainly related to lifestyle-related risks. A previous review has provided evidence of an association between lifestyle behaviors and infertility, including obesity, stress, a disturbed circadian clock, smoking, alcohol, and exercise [7]. Women's social advancement is associated with changes in their daily lives. Compared to working men, the double burden of job demands and domestic responsibilities has made women vulnerable to developing noncommunicable diseases [8].

Moreover, women experience considerable hormonal changes, unique health issues, and conditions throughout their lives [9,10]. Life stages of working-aged women are generally divided into reproductive age, pregnancy and delivery, and a climacteric period [9]. They may experience many unique health issues and conditions throughout their lives (eg, from preconception periods and menopause to several gynecological conditions) [11,12]. The prevalence of obesity in women of reproductive age has been increasing worldwide. Furthermore, it is associated with the risk of reduced fertility and the development of obesity-related comorbidities [13]. During pregnancy, maternal medical conditions, including hypertension, diabetes, and obesity, increase the risk of adverse outcomes, such as preterm delivery, low birth weight, and infant death [14-16]. Furthermore, the development of maternal medical conditions is associated with a risk of developing chronic disease later in life [13,17]. For example, women who develop gestational diabetes have a higher risk of developing type 2 diabetes in the future [17]. Women in the climacteric periods are exposed to the risk of developing chronic diseases, such as obesity, metabolic syndrome, diabetes, cardiovascular disease, depression, and cancer [18]. These diseases are associated with their lifestyle habits [9,18,19]. Lifestyle factors can impact the gynecological well-being of women throughout their lives and will affect the future health of subsequent generations [20]. Thus, it is necessary to strive to prevent and improve common medical conditions in women, taking into account their lifestyles throughout the overall life stages.

While women live longer than men [21], women are more affected and bear a heavier burden of living with disability [22]. Ensuring women's health and control over their own fertility can contribute to economic development; furthermore, ensuring women's health is important for ensuring the health and economic well-being of subsequent generations [23]. In summary, continuous care throughout women's lives is necessary, which, in turn, is important for maintaining community- and national-level economic development.

In 2022, a total of 5 billion people (63% of the global population) used the internet, and this figure continues to increase annually [24]. In 2009, the concept of smart health care was introduced. Since then, attempts to use the Internet of things (IoT) and other technologies to manage information related to people's health and address health care have been expanded [25]. IoT is a system of interrelated digital devices that can enable data exchanges over a network without human-to-human or human-to-computer interactions [26,27]. The IoT is increasingly being used to ensure and improve women's health worldwide (eg, monitoring [28-30] and providing interventions [30,31]). The IoT, which can be used daily and continually without human interactions, could successfully provide the opportunities and motivation necessary for women to engage in good lifestyle behaviors. Among IoT interventions, smart health care systems are used for health prevention and improvement. Smart health care is mainly used in home care, self-care, and acute care settings, where self-care systems allow

XSL•FO
RenderX

people to monitor their own health conditions and access that information through wearable devices and smartphones [26,32]. Working-aged women would use these devices throughout the day, including at work and at home, to manage their lifestyles on their own. Previous studies have revealed the effectiveness of IoT in encouraging lifestyle behavioral changes and improving people's health. A previous systematic review has shown that personalized mobile interventions for people (64% of which were women) improved lifestyle behaviors [33]. Some primary studies have reported that interventions that use IoT have improved women's lifestyles [34-36] and health outcomes (eg, adverse pregnancy outcomes [35] and markers indicating hemodynamic functions [36]). However, there are various types of IoT interventions, such as exercise, diet, sleep, and combinations of these. Nonetheless, there are no systematic reviews assessing the effectiveness of the IoT among working-aged women, and no true consensus about the effectiveness of the IoT in improving women's health outcomes has been established [33,37]. Systematic reviews and network meta-analyses (NMAs) can compare 3 or more interventions simultaneously on the basis of the results of existing primary studies in a single analysis and provide an overall statistic and up-to-date summary of the state of research knowledge on an intervention [38]. Therefore, a rigorous evaluation that considers all forms of the IoT is necessary for generating evidence and promoting appropriate integration and usage of technologies within existing health systems in order to improve women's health outcomes.

Methods

Study Design

This systematic review and NMA aims to assess and synthesize the role of IoT in improving women's health and to identify the ranking of interventions of apps and IoT for ensuring better results among women in high-income countries. NMA can combine any direct and indirect evidence into a single effect size [38]. Our NMAs will estimate the direct, indirect, and relative effects of IoT on women's health outcomes and identify the ranking of interventions for ensuring the best results for each stated outcome.

This protocol adheres to the guidelines of the Cochrane Handbook for Systematic Reviews of Interventions [38] and reports its review findings based on the Preferred Reporting Items for Network Meta-Analyses (PRISMA-NMA) extension statement for reporting systematic reviews incorporating NMA of health care interventions [39]. We will report the results of each population group (women who are undergoing their preconception period, women undergoing their gestational and postpartum periods, and menopausal and pre- and postmenopausal women) separately. The review protocol is registered under the "International Prospective Register for Systematic Reviews" (PROSPERO) database (CRD42022384620) [40].

Inclusion and Exclusion Criteria

This study used the PICOS framework (P: participants, I: interventions, C: comparison, O: outcomes, and S: study design) to determine the eligibility criteria for including studies in its review.

Participants

The study participants are working-aged women in high-income countries, as defined by the World Bank in 2023 [41]. To prevent heterogeneity in the objectives and settings of IoT interventions, we focused on high-income countries because the global burden of disease differs across high-income and low- and middle-income countries [42]. The Organization for Economic Co-operation and Development (ie, OECD) has defined the working-age population as those aged from 15 to 64 years [43]. We will segment and analyze studies based on women who are undergoing their preconception period, women undergoing their gestational and postpartum periods, and menopausal and pre- and postmenopausal women. This study will include women of reproductive age (15-49 years old) as women in the preconception period. It will also include middle-aged women (40-64 years) as menopausal and pre- and postmenopausal women. Although this study's inclusion criteria show some overlap between the age categories, we will segment on the basis of the purposes of IoT interventions and populations of the included studies. Regarding studies focused on mixed populations (eg, those that include men), we will include only those studies that separate the data based on gender or those that include over 80% of women participants who meet our inclusion criteria.

Intervention and Comparison

We will include studies that have investigated IoT interventions to improve women's health compared to the use of standard care, no intervention, or another intervention not using the IoT (eg, education or exercise without the IoT). The IoT in the medical field includes functions such as relaying medical information through mobile health or telemedicine, collecting data, and monitoring. Although there are various types of IoT, we will include the application areas, such as collecting and monitoring data with the sensors of smartphones and wearable devices, as the form of IoT. We will include studies that have targeted both male and female populations if the relevant IoT intervention has been designed to improve women's health. If studies have investigated combinations of IoT interventions with other modes, we will also include studies that revealed IoT intervention as the primary intervention component.

Outcomes

Primary Outcomes

The outcomes for all included populations will be health status, including the number of cases diagnosed or treated (eg, cases of obesity and mental disorder), well-being, and quality of life.

Outcomes for women in their preconception periods include live birth (defined as the delivery of a live fetus after 20 completed weeks of gestation) or ongoing pregnancy (defined as evidence of a gestational sac with fetal heart motion at 12 weeks, as confirmed through ultrasonography.

Outcomes for women in the gestational and postpartum periods include health status, including the number of cases diagnosed

XSL•FO
RenderX

or treated, including those of high-risk pregnancy (eg, gestational hypertension, gestational diabetes, and preterm birth).

Neonatal outcomes include low birth weight (defined as a birth weight less than 2.5 kg) and perinatal mortality.

Outcomes for middle-aged women include health status, including the number of cases diagnosed or treated (eg, diabetes, metabolic syndrome, hyperlipidemia, and hypertension).

Secondary Outcomes

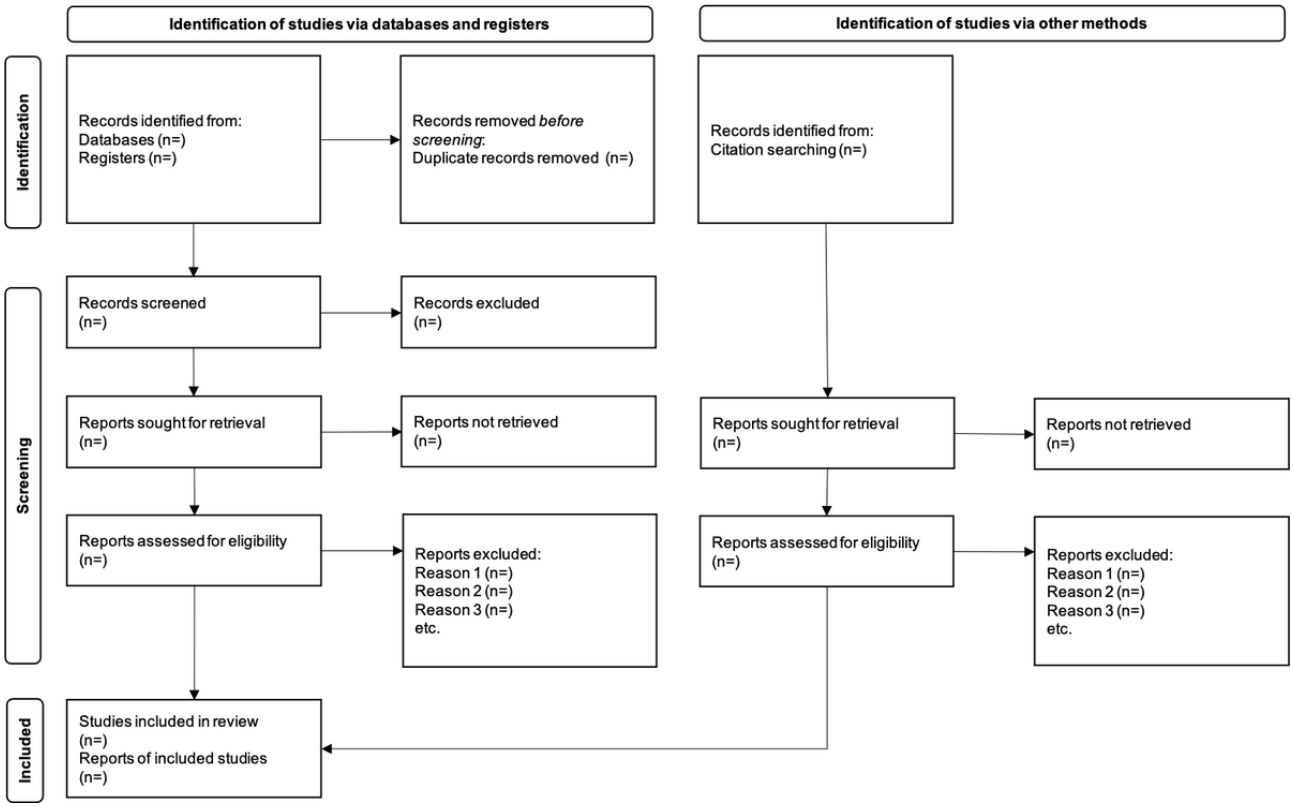
Outcomes for all included populations are lifestyle and behavioral changes, including maintaining a healthy weight (measured as BMI in kg/m², % weight loss, or number of people with a BMI between 18.5 and 25 kg/m² [2]), maintaining healthy sleep behavior (sleeping 7 or more hours per night on a regular basis), stopping or reducing alcohol intake (measured as alcoholic drinks per day, with 1 drink of >10 g of ethanol), increasing physical activity (in accordance with the World Health Organization's standards; measured as minutes of moderate to vigorous physical activity per week or number of people reaching the World Health Organization's recommendation of doing 150 minutes of moderate - intensity physical activity per week, preferably based on the Global Physical Activity Questionnaire or other validated scales), and quitting or ceasing smoking and other substances (measured as the number of people not smoking or the number of people not using other substances).

If the studies report outcomes across different time points, this review will select the time point at the end of the relevant intervention.

Types of Study

We will include individual randomized controlled trials (RCTs) and cluster-RCTs to investigate the effects of IoT interventions on women's health. We will exclude reviews, qualitative studies, observational studies, cross-sectional studies, case studies, commentaries, editorials, expert opinions, and letters.

Searching the Literature



We will perform a comprehensive search to identify any relevant studies that meet our eligibility criteria by using the following electronic databases: PubMed (including MEDLINE), Cochrane Central Register of Controlled Trials, Embase, Cumulative Index to Nursing and Allied Health Literature (ie, CINAHL), and PsycINFO; there will be no restrictions on languages and publication dates. We will search ClinicalTrials.gov (clinicaltrials.gov) and the World Health Organization International Clinical Trials Registry (apps.who.int/trialsearch/) to identify additional ongoing studies. We will develop search strategies for each electronic database addressing the review question. The search strategies will use keywords and controlled vocabulary as follows: participants: *woman*, interventions: *IoT* (eg, *mobile application*, *wearable electronic device*, and *smart device*), and study design: *RCT*. We will also check the reference lists of included reports and relevant systematic reviews to identify additional potential studies. The complete review will report the detailed search strategies for all electronic databases.

Study Selection

We will screen the relevant studies in accordance with the PRISMA guidelines (the PRISMA flow diagram is shown in Figure 1) [44]. First, we will exclude any duplicate studies. Two reviewers will independently screen the titles and abstracts of all the retrieved studies. Furthermore, 2 authors will independently assess the full texts of all potentially eligible studies. The Rayyan tool will be used for screening during the study selection. Any disagreements between reviewers will be resolved through discussion. If an agreement is not reached, we will discuss the issue with a third reviewer to make the final decision. We will also manage the selected studies by using the bibliographic citation management software EndNote X9.

XSL•FO
RenderX

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow diagram.

Data Extraction

Two authors will independently extract data from each of the included studies using a predesigned data extraction form using Excel (Microsoft Inc). We will extract data regarding the characteristics of included studies (eg, study setting, participants, interventions, comparisons, study design, and outcome measures, including primary and secondary outcomes). Any discrepancies will be resolved through discussion with a third author. In case of any unclear or missing information, we will contact the authors to collect the relevant data.

Risk of Bias Assessment

Two reviewers will independently assess the risk of bias for each outcome using the Cochrane Collaboration's risk of bias assessment tool 2.0 [45]. We will assess the following domains: those related to the randomization process, deviations from intended interventions, missing outcome data, measurement of the outcomes, and selection of the reported results. The overall risk of bias will be discerned as follows: low risk of bias, some concerns, or high risk of bias [45]. Any disagreement will be resolved through discussion with a third reviewer.

Data Synthesis

We will perform the NMA on age categories (preconception periods, gestational and postpartum periods, and middle-aged women) and medical history (women who have a specific medical condition; eg, cancer or diabetes, and women who do not have them) separately. We will present the network structure of IoT interventions and the estimated direct, indirect, and relative effects for each outcome. First, we will conduct a pairwise meta-analysis using a fixed effects model to estimate the pooled effect size of all direct evidence for each combination of outcomes. In case of considerable heterogeneity, we will use a random effects (DerSimonian and Laird) model. Then, we will perform NMAs for primary and secondary outcomes to compare the individual IoT interventions. For dichotomous variables, we will use risk ratios or odds ratios and the corresponding 95% CIs. For continuous variables, we will calculate the mean difference or standardized mean difference using 95% CIs. If the measurements of intervention effects with regard to each outcome have been reported using different scales, we will use a standardized mean difference and 95% CIs. We will narratively describe the results if studies are insufficient for conducting a meta-analysis. Heterogeneity will be examined using the estimated value of τ and the chi-square test and assessed graphically using horizontal lines in the forest plots for each outcome. Furthermore, heterogeneity will be examined using I^2 statistics, with a value greater than 75% indicating considerable heterogeneity [38]. For pairwise meta-analysis with an adequate number of included studies, publication bias will be tested using funnel plots and the Egger test; for NMA, we will use a comparison-adjusted funnel plot to identify possible-small study effects [46,47]. A surface under the cumulative ranking curve (SUCRA) will be used for ranking probabilities of interventions to identify the most effective intervention. A larger SUCRA value indicates a better rank of intervention [46]. A subgroup analysis for the primary outcome will be performed for the types of IoT (single approach and combination) and types of IoT devices (wearable devices worn on the body and other devices not worn). To assess the robustness of the results, sensitivity analysis will be performed, excluding studies at a high risk of bias.

XSL•FO
RenderX

Inconsistency Assessment

We will assess any inconsistencies between direct and indirect evidence by using local and global approaches. Regarding the evaluation of global inconsistencies, we will demonstrate the design by using a treatment interaction model and infer the presence of any inconsistency based on a chi-square test. Regarding the evaluation of local inconsistencies, we will use the side-splitting method and assess the disagreement between direct and indirect effects. We will consider a *P* value of <.05 to indicate statistical significance.

Certainty of Evidence Assessment

We will assess the certainty of the evidence for primary outcomes by using the Grades of Recommendation, Assessment, Development and Evaluation method for NMA [48]. We will assess the following factors: risk of bias, inconsistency, indirectness, imprecision, and publication bias; furthermore, we will classify the certainty of evidence as follows: high, moderate, low, or very low. We will also aim to assess the certainty of evidence for each of the direct estimates, indirect estimates, and relative estimates. If only direct or indirect evidence is available for a given comparison, we will consider their ratings as the network ratings. If both types of evidence are available, we will consider the higher ratings of the evidence as the network ratings. We will summarize the results for primary outcomes in a "summary of findings" table (Multimedia Appendix 1) [49].

Results

We aim to conduct our search in January 2023 and are currently discussing search strategies with literature search specialists. We will estimate their relative ranking for women's health outcomes by conducting the NMA. This study is expected to identify the most effective IoT modality in improving women's health outcomes. The final report is planned for submission to a peer-reviewed journal in September 2023.

Discussion

To the best of our knowledge, this will be the first comprehensive systematic review and NMA of RCTs, which aims to assess and synthesize the role of apps and the IoT in improving women's health and to identify the ranking of interventions for ensuring better results among women for each stated outcome. Recently, the number of women with issues and conditions related to their lifestyle habits has been increasing [8]. Problems with lifestyle habits are known to lead to the development of future noncommunicable diseases [7], and improving women's lifestyles will help prevent and improve their common medical conditions. As such, our systematic review's findings will have the potential to influence a large proportion of the population, including women and their subsequent generations. These findings may be of great use to health care providers, policy makers, and others who have an interest in this field. Furthermore, our results can be extensively used in improving the health of women both presently and in subsequent generations.

Acknowledgments

We would like to thank Cochrane Japan for providing their support in our search for relevant studies for our review.

Data Availability

All data generated or analyzed during this study will be included in the full review article and its supplementary information files.

Conflicts of Interest

There are no conflicts of interest to declare. This work is supported by the Japan Agency for Medical Research and Development (22rea522103h0001).

Abstract

Background: The clinical activities developed by pharmacists in a hospital environment can improve health outcomes and generate savings for hospitals. However, to determine whether pharmaceutical interventions are cost effective, it is essential to define a method according to which cost-effectiveness is intended to be measured. In addition, the quality of economic assessments and the amount of information present in systematic reviews in the literature make it difficult to analyze the effects of this intervention.

Objective: This paper aims to provide an overview of systematic reviews on the pharmacoeconomic impact of the performance of pharmaceutical care in hospitals.

Methods: A systematic search of the Cochrane Library databases, PubMed or MEDLINE, LILACS, Scopus, Web of Science, Google Scholar, and Open Thesis will be performed using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement. The search will involve the use of keywords determined using the Medical Subject Headings database to define the search terms and include the following terms: “pharmacoeconomics,” “pharmaceutical care,” and “hospital.” The study designs to be included will be systematic reviews of good quality. Studies will be included that address pharmacoeconomics; studies that evaluated pharmaceutical care in hospitals; and studies published in Portuguese, English, or Spanish. The primary outcome sought in the systematic reviews will be the cost ratio in monetary units and the outcomes in monetary or natural units. The secondary economic outcomes considered will be determined based on factors associated with the drugs and translated into benefit, efficacy, or utility.

Results: It is intended to start this overview in January 2023. Thus far, only previous searches have been carried out to contextualize the theme and build the protocol.

Conclusions: This overview will determine the pharmacoeconomic impact of pharmaceutical care interventions in the hospital environment. In addition, this study will point out which clinical outcomes in natural units are impacted by the performance of pharmaceutical care and the strengths and limitations of each approach. It will also identify gaps in the literature and areas for future work.

KEYWORDS

pharmacoeconomics; pharmaceutical care; hospital; overview; cost-effectiveness; cost benefit; cost-utility

Introduction

Within the scope of pharmacy, clinical pharmaceutical services promoted actions that improve clinical and economic outcomes [1-3]. In clinical practice, pharmaceutical activities focused on patient care are performed in close cooperation with the health team to offer the best patient care. Clinical activities developed by these pharmacists in a hospital environment can minimize medication errors, improve the results of pharmacotherapy, and decrease treatment costs [4-6]. In this sense, research that describes and economically evaluates the provision of pharmaceutical care in hospitals has been identified in the literature since the 1970s [7].

However, to determine whether pharmaceutical interventions are cost effective, it is essential to define a method according to which the intervention is intended to be measured, taking into account the limitations of each step and the potential for generalizing the results to assist in the decision-making process [7,8]. There are 4 basic types of studies related to this issue, which are cost-minimization, cost-benefit, cost-effectiveness, and cost-utility analyses. These analyses differ fundamentally from each other in terms of how health outcomes are measured and compared [1,7].

Pharmacoeconomics has, therefore, emerged as a tool to optimize the use of financial resources for health care without prejudice about the quality of treatment, to reconcile therapeutic needs with the costing possibilities for decision-making, having a crucial role in clinical decisions, management pharmacotherapy, and drug use guidelines [2,9].

It is worth mentioning that several studies, systematic reviews, and meta-analyses have shown that pharmaceutical care generates savings for hospitals and health systems, and pharmaceutical care is one of the strategies to improve patient health outcomes [9-12]. However, there is no information synthesis of the existing information about this service, making it difficult to take the data resources used [13]. Thus, this study is aimed at providing an overview of systematic reviews on the pharmacoeconomic impact of the performance of pharmaceutical care in hospitals [14-16].

Methods

Overview

This study protocol is reported according to the reporting guidelines provided in the Statement of Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols (PRISMA-P) [17]. The review protocol was registered in PROSPERO (CRD42019140665).

Information Sources and Search Strategy

A systematic search of the Cochrane database, PubMed, Medline, LILAC, Scopus, Web of Science, Google Scholar, and Open Thesis will be conducted. The search strategy will use terms from the Medical Subject Headings and Descriptores en Ciencias de la Salud databases, as follows: (pharmacoeconomics); (‘Pharmaceutical economics’) (‘pharmacy economics’); (‘Pharmacy economic’); (‘Pharmaceutical economics’); and (‘Clinical pharmacy services’), (‘clinical pharmacy service’), (‘pharmaceutical care’), (‘pharmacy service, hospital’), (hospital), (hospitals). See Textbox 1 for a detailed search strategy.

Textbox 1. Search strategy—PubMed or Medline (no time limit).

((“economics, pharmaceutical”[MeSH Terms] OR (“economics”[All Fields] AND “pharmaceutical”[All Fields]) OR “pharmaceutical economics”[All Fields] OR “pharmacoeconomics”[All Fields]) OR (“economics, pharmaceutical”[MeSH Terms] OR (“economics”[All Fields] AND “pharmaceutical”[All Fields]) OR “pharmaceutical economics”[All Fields] OR (“pharmaceutical”[All Fields] AND “economics”[All Fields])) OR (“economics, pharmaceutical”[MeSH Terms] OR (“economics”[All Fields] AND “pharmaceutical”[All Fields]) OR “pharmaceutical economics”[All Fields] OR (“pharmacy”[All Fields] AND “economics”[All Fields]) OR “pharmacy economics”[All Fields]) OR (“economics, pharmaceutical”[MeSH Terms] OR (“economics”[All Fields] AND “pharmaceutical”[All Fields]) OR “pharmaceutical economics”[All Fields] OR (“pharmacy”[All Fields] AND “economic”[All Fields]) OR “pharmacy economic”[All Fields]) OR “economics, pharmaceutical”[mesh]) AND ((“pharmacy service, hospital”[MeSH Terms] OR (“pharmacy”[All Fields] AND “service”[All Fields] AND “hospital”[All Fields]) OR “hospital pharmacy service”[All Fields] OR (“clinical”[All Fields] AND “pharmacy”[All Fields] AND “services”[All Fields]) OR “clinical pharmacy services”[All Fields]) OR (“pharmacy service, hospital”[MeSH Terms] OR (“pharmacy”[All Fields] AND “service”[All Fields] AND “hospital”[All Fields]) OR “hospital pharmacy service”[All Fields] OR (“clinical”[All Fields] AND “pharmacy”[All Fields] AND “service”[All Fields]) OR “clinical pharmacy service”[All Fields]) OR “pharmacy service, hospital”[mesh]) AND ((“hospitals”[MeSH Terms] OR “hospitals”[All Fields] OR “hospital”[All Fields]) OR “hospitals”[mesh])

Inclusion Criteria

The eligibility criteria were defined according to the PICO strategy (that is, population, intervention, comparison, and result) with the following variables: (1) pharmacoeconomic studies (cost-minimization, cost-benefit, cost-effectiveness, and cost-utility analyses), (2) studies that evaluated pharmaceutical care in hospitals, and (3) studies published in Portuguese, English, or Spanish.

Exclusion Criteria

Systematic reviews in which the interventions performed by pharmacists in the health team are not distinguishable—(1) overviews; (2) systematic reviews that analyze nonclinical activities, such as medication handling, storage, administration (including vaccines); or (3) other logistical activities—will be excluded.

XSL•FO
RenderX

Study Design

This study will provide an overview of systematic reviews. The overview seeks to meet the need for evaluating and synthesizing the results of systematic reviews. In addition to optimizing and improving access to information and decision-making, assisting in the synthesis of information for health professionals, managers, researchers, and patients is also crucial [18]. Thus, the following publications obtained from a systematic search of more than one database of literature will be considered: publications that specify the review question, eligibility criteria, and selection of the studies involved; in which data collection was performed by two or more reviewers; in which the risk of bias in the included studies was evaluated; and in which information is synthesized using a quantitative or qualitative approach.

Population of the Included Studies

Studies that included hospitalized patients who were using at least one medication will be considered.

Scenarios of the Included Studies

Studies conducted in hospitals anywhere in the world will be considered as long as they meet the inclusion criteria.

Intervention or Comparison

Studies comparing the clinical results of patients receiving pharmaceutical care services to those of patients for whom there were no pharmacist interventions will be considered.

Outcomes of Interest

The primary result will be the ratio of cost (currency unit) to the outcome (currency unit or natural units, for example, years of life or quality-adjusted life-years). This is usually presented as an outcome. The secondary economic results will be the determinants or factors associated with medications translated into benefits (such as days of hospitalization avoided; days of work that will be lost; and materials, labor, and equipment that could be relocated), effectiveness (in terms of parameters such as years of life gained, lives saved, cholesterol reduction, mmHg of reduced blood pressure, number of cases prevented, time of symptoms, and reduction of recurrence rates), and usefulness (quality-adjusted life-years).

Screening and Selection of Studies

All articles identified in the literature search will be screened by 2 reviewers, regardless of duplicate removal using EndNote (Clarivate Plc). The titles and abstracts of the articles returned from the initial searches will be selected based on the eligibility criteria described above (“Inclusion Criteria”). The full texts will be examined in detail and selected for eligibility. The references of all articles considered will be searched manually to identify any relevant reports lost in the search strategy. Any disagreements will be resolved by discussion, if necessary. A PRISMA flowchart showing details of the included and excluded studies at each stage of the study selection process will be provided.

Data Extraction and Management

A data extraction form will be designed using Google Forms. Google Forms will allow the management of articles and allow authors to collaborate simultaneously. The review team will receive training on how to use Google Forms before the start of the study to ensure the calibration of the forms and methods of data collection. The data to be collected in this overview will be conducted via the items described in Table 1.

XSL•FO
RenderX

Table 1. Elements for data collection.

Aspects of data collection	Description of key items to be extracted
Research site characteristics of the studies included in the review	• Review objectives • Numbers of studies and patients included • Period chosen to search for studies • Eligibility criteria • Profile of the patients included in the studies • Diagnostics or comorbidities of the patients studied
Hospital characteristics of the studies included in the review	• Size of the hospital characterized by the number of beds and employees • Geographic locations of the primary studies • Any other relevant resources presented in each review about the primary studies
The pharmacoeconomic evaluation method used	Economic: • Cost-benefit • Cost-effectiveness • Cost minimization • Cost utility Humanistic: • Quality of life • Patient preferences • Patient satisfaction
Results of clinical services	• Reduced hospital stay • Hospital readmission • Decrease in adverse drug events • Types of pharmaceutical care • Improvement or worsening of the clinical parameters evaluated

Study Characteristics

The following data will be extracted from the studies selected: name of the first author, study design, year of publication, journal, year (or period) of the study, sample size, scenario, and geographic location of the study, among others. Data relevant to the evaluation of the methodological quality of the studies will be collected.

Methodological Quality Assessment

The evaluation of the methodological quality of systematic reviews will be performed using the Revised Assessment of Multiple Systematic Reviews (R-AMSTAR) instrument. R-AMSTAR is a revised version of AMSTAR, which consists of 11 items with good content validity for measuring the methodological quality of systematic reviews. It is widely accepted and used because of its reliability and reproducibility. Before the start of the assessment, the items that make up the list will be widely discussed, and a manual will be created to guide the interpretation of the R-AMSTAR items to ensure consistency in the analysis.

For the evaluation of systematic reviews, the following items will be considered: conducting a project; the selection of studies and data extraction search in pairs; the scope of the bibliographic research; the analysis of the type of publication (for example, theses, dissertations, and book chapters); the availability of the included and excluded studies; providing the characteristics of the included studies, evaluation, and documentation of the scientific quality of the included studies; the use of the scientific quality of the studies included in the formulation of the conclusions; the suitability of the methods used to combine the findings of the studies; the assessment of the likelihood of publication bias; and the inclusion of conflicts of interest.

Summary of the Data

Data from each study will be used to create tables of evidence for a general description of the included studies. Monetary values will be presented as mean and standard deviation, and natural outcomes will be presented by descriptive methods. We will also establish a model of quality effects to examine how the quality of each study changes the average result. A comparison of the review methods will be performed in terms of the eligibility criteria (ie, criteria used to identify eligible patients, study designs, and end points of interest), details of bibliographic search (ie, dates, databases, main differences in the strategies employed, and taking into account language restrictions), end point definitions used, and rigorous review methods (as reflected by variations in R-AMSTAR assessments and other aspects of the study methodology). The statistical program SPSS version 17.0 (IBM Corp) will be used to calculate the kappa index to verify the agreement in the selection of studies included among the authors, thus decreasing the chance of missing out on a study and the possibility of bias. In addition to the above, the Risk of Bias in Systematic Reviews tool will be used, which assesses both the risk of bias and the relevance of the research question to be answered [19].

Ethics Approval and Dissemination

The review will be performed under “Master's research” approved by the Ethics Committee of the University Hospital of the Federal University of Sergipe (CAAE:

XSL•FO
RenderX

66439017.3.0000.5546; seem: 2.300.170). The results will be submitted to indexed journals. We will present at national and international meetings.

Results

It is intended to start this protocol in January 2023. Thus far, only previous research has been carried out to contextualize the topic and build the protocol. Our objective is to understand the economic impact of pharmaceutical care performance in hospitals, especially about the ratio between cost (economic unit) and outcome (economic or natural units). We also hope to achieve the following: understand the determinants or factors associated with drugs translated into tools, effort, and utility; support health care policy decision makers to improve the optimization of the treatment of these patients so that it can be replicated in other settings of the health care system; and increase the safety and lives of the patients.

Discussion

This protocol will determine the pharmacoeconomic impact of pharmaceutical care interventions in the hospital environment. In addition, this study will point out which clinical outcomes in natural units are impacted by the performance of pharmaceutical care. Although studies have shown the positive clinical, economic, and human benefits of the interventions of pharmaceutical care for patients and institutions, the subject is not yet exhausted, and the analysis of robust scientific evidence can improve the significance of the results. This study will identify and fill the knowledge gaps in the field [20].

According to De Rijdt et al [21], the economic evaluations of clinical pharmacy services, for the most part, have a series of methodological limitations related to the absence of a control group without pharmaceutical care interventions, the limited scope of costs and results, focus being limited to direct health costs, the exclusion of the cost of employing pharmacists, the use of intermediate outcomes, the exclusion of health benefits, and the absence of incremental cost analysis.

In their assessment of pharmaceutical care, Touchette et al [20] reported that most studies were conducted in hospitals with the most common types of pharmacotherapeutic monitoring and disease management services. The authors highlight the variation in the quality of studies, with less than half being considered good or reasonable [19]. In this sense, it is necessary to better understand the effects of these pharmaceutical interventions, which makes it possible to define strategies to facilitate their implementation and integration in hospital care. Consequently, it is possible to overcome their negative effects and optimize the positive effects to use them to their full potential as a tool to support pharmaceutical care and ultimately improve the results [22].

Any changes made to this protocol during the course of the study will be reported in the final manuscript and reported in PROSPERO. The results will be made public through publication in a peer-reviewed journal. There are several limitations to our planned systematic review. We plan to identify reviews that are indexed in specific databases, which may restrict the inclusion of systematic reviews that are not in the selected databases. Furthermore, there is a limitation related to the language, since the search for manuscripts will be performed in only 3 languages (Portuguese, English, and Spanish).

Acknowledgments

We thank the Coordination for the Improvement of Higher Education Personnel (CAPES), Financial Code 001, for partially financing this study in the form of a scholarship to the authors. We also thank the Laboratory of Teaching and Research in Social Pharmacy (LEPFS) researchers. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

Concept and design of the study were carried out by FJRdA, FVF, CASS, IMdCB, and DdPLJ. FJRdA, MCR, CASS, and ADdOF refined the methodology and used the data extraction tools. FJRdA, FVF, MCR, CASS, and DPdLJ drafted the manuscript. IMdCB, ADdOF, and DPdLJ revised the manuscript critically for content. The final approval of the version to be published was done by FJRdA, FVF, and DPdLJ.

Conflicts of Interest

None declared.

Abstract

Background: A hallmark of gastrointestinal cancer, especially pancreatic cancer, is the dense stromal tumor microenvironment in which cancer-associated fibroblasts (CAFs) represent the major stromal cell type. Preclinical studies have demonstrated that depletion of fibroblast activation protein (FAP)–positive CAFs results in increased survival.

Objective: We present the protocol for a systematic review and meta-analysis that aim to assess the currently available evidence on the effect of FAP expression on survival and clinical characteristics in gastrointestinal cancers.

Methods: The literature search and data analysis will be conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 statement. The databases PubMed/MEDLINE, Web of Science Core Collection, Cochrane Library, and ClinicalTrials.gov will be searched via their respective online search engines. A meta-analysis comparing patients with and without FAP overexpression with the following outcomes will be performed: postoperative survival (overall and median survival; 1-, 2-, 3-, and 5-year survival rates), histological differentiation (grading), local tumor invasion, lymph node metastases, and distant metastases. Odds ratios will be calculated for binary data, and weighted mean differences and relative SD differences will be determined for continuous data. The 95% CI, heterogeneity measures, and statistical significance will be reported for each outcome. The chi-square and Kruskal-Wallis tests will be used to evaluate statistical significance. A *P* value of <.05 will be considered statistically significant.

Results: Database searches will commence in April 2023. The meta-analysis will be completed by December 2023.

Conclusions: In recent years, several publications on FAP overexpression in gastrointestinal tumors have been published. The only published meta-analysis on this topic dates to 2015. It included 15 studies on various solid tumors and only 8 studies focusing exclusively on gastrointestinal tumors. The expected results of the present analysis will provide new evidence on the prognostic value of FAP in gastrointestinal tumors and thereby support health care professionals and patients in their decision-making.

Introduction

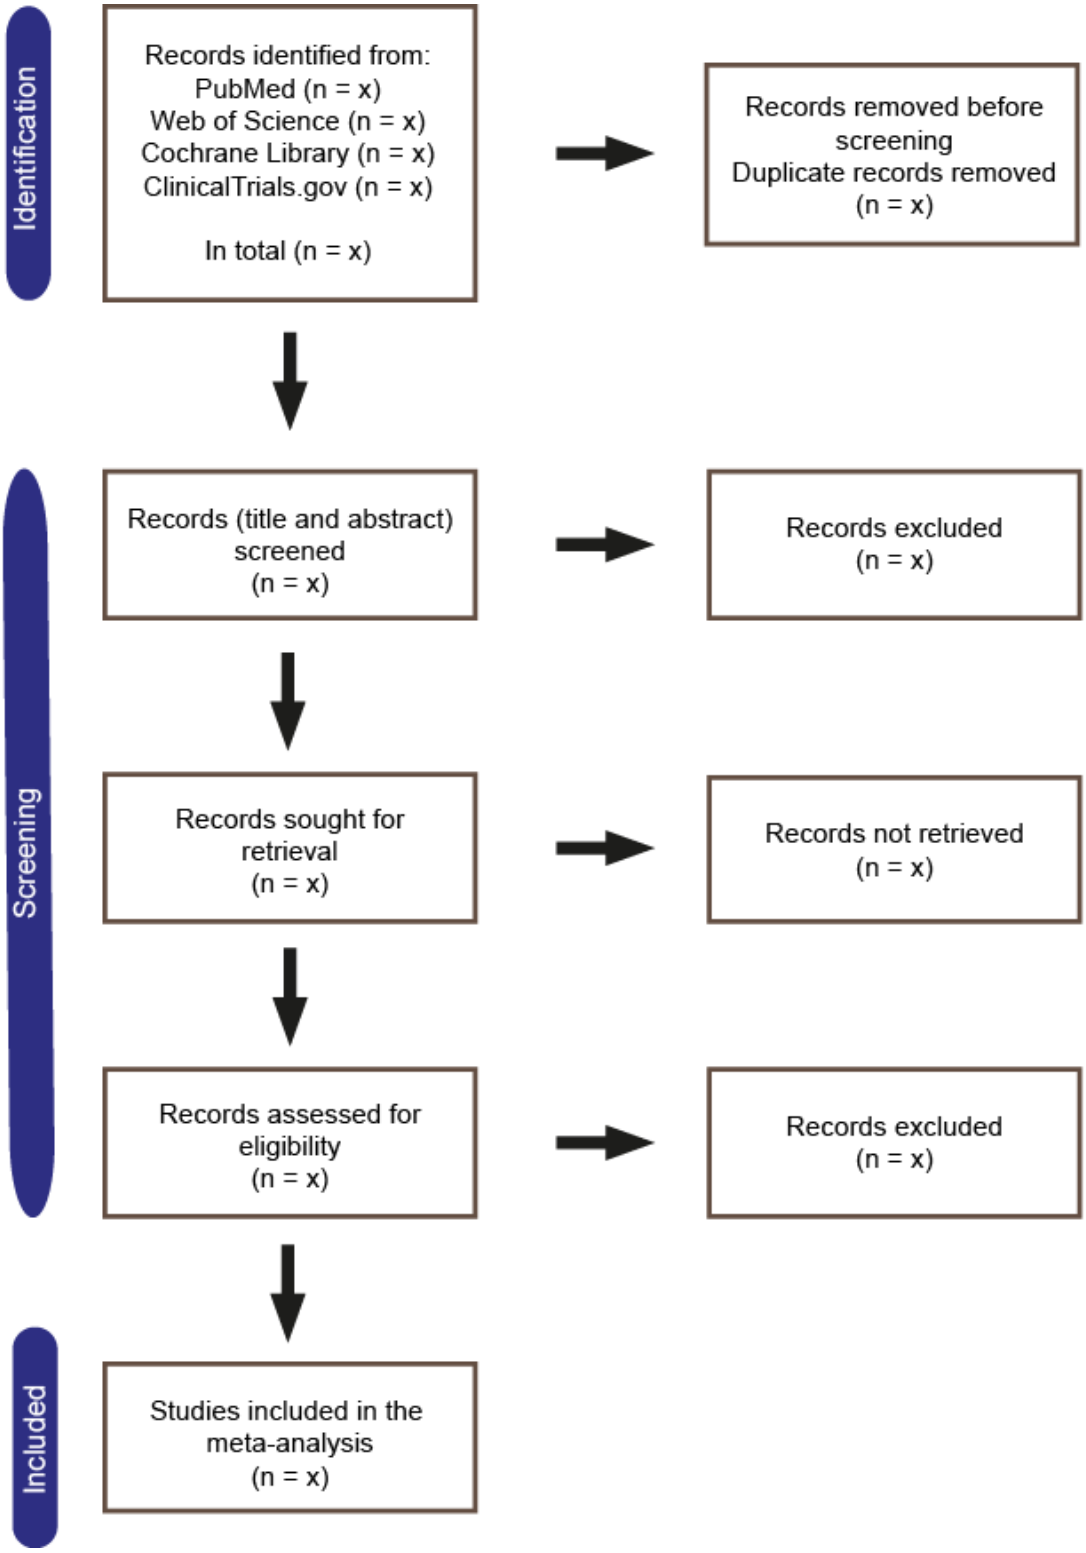
Cancers of the gastrointestinal (GI) tract include colorectal, esophageal, liver, pancreas, and stomach cancer. These 5 major types of GI cancer represented 26% of the global cancer incidence and 35% of all cancer-related deaths in 2018 [1]. A hallmark of GI cancers, especially pancreatic cancer, is the dense stromal tumor microenvironment where cancer-associated fibroblasts (CAFs) represent the major stromal cell type [2]. CAFs reprogram the immune microenvironment and promote cancer proliferation, migration, invasion, and metastasis [3,4]. To that end, depleting CAFs has been considered a promising therapeutic strategy for patients with GI cancer. However, in a preclinical pancreatic cancer mouse model, depletion of the major CAF marker α–smooth muscle actin (α-SMA)–positive cells led to invasive, undifferentiated tumors and reduced animal survival [5]. Thus, targeting CAFs may also have tumor-promoting effects due to their functional heterogeneity. Therefore, identification and specific targeting of tumor-promoting CAF subtypes and markers are emerging strategies [6]. CAFs represent highly heterogeneous subpopulations with different functions, which can be both tumor promoting and tumor restraining [7]. To identify and characterize CAF subtypes, a number of markers have been identified, such as desmin, fibroblast activation protein (FAP), fibroblast-specific protein, podoplanin, α-SMA, and vimentin [8,9].

FAP is a type II transmembrane serine protease, which shares a high-sequence identity with dipeptidyl peptidase 4 [10]. In most adult tissues, expression of FAP is low to undetectable. FAP expression becomes highly upregulated in multiple types of cancer, and it is predominantly observed in CAFs [11]. In a preclinical study, it was shown that FAP activates macrophages and promotes liver inflammation and fibrosis [12]. FAP plays a key role in promoting tumor progression and metastasis, further shaping the immunosuppressive tumor microenvironment [13]. Other preclinical studies have demonstrated that pharmacological inhibition or deletion of FAP-positive CAFs results in the attenuation of tumor growth and increased survival in pancreatic cancer models [14,15]. A recent study further consistently showed that tumor-promoting FAP-positive CAFs and tumor-restraining α-SMA–positive CAFs regulate signaling pathways differently [15].

To assess the currently available evidence on the effect of FAP expression on survival and clinical characteristics in GI cancers, we plan to conduct a systematic review and meta-analysis. With this research protocol, we further aim to achieve reproducibility and transparency of our meta-analysis on the published literature as previously demonstrated [16,17].

Methods

The literature search and data analysis will be conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 statement [18]. The study has been registered in the PROSPERO (International Prospective Register of Systematic Reviews) database (CRD42022372194) [19].



Search Strategy

The databases PubMed/MEDLINE, Web of Science Core Collection, Cochrane Library, and ClinicalTrials.gov will be searched via their respective online search engines. Citavi 6 (Swiss Academic Software GmbH) will be used as an automatic deduplication system for the studies retrieved from the various databases (Figure 1). The search will be performed on studies published between database inception and a defined search date. The search strategies used in each database are displayed in Table 1.

Titles and abstracts will be evaluated independently in a standardized manner by 2 authors to assess eligibility for inclusion or exclusion. All the potential studies identified from the search will be coded as either “retrieve” (eligible, potentially eligible, or unclear) or “do not retrieve.” For studies coded “retrieve,” 2 reviewers will independently screen the full text and recommend inclusion or exclusion. Disagreements between the reviewers will be resolved by consensus; if no agreement can be reached, a third reviewer will decide whether to include the respective study. The reference lists of the included studies will be manually searched to find additional relevant articles.

Inclusion and Exclusion Criteria

Only articles in the English language will be considered. Studies comparing patients with and without FAP overexpression in GI tumors and reporting on at least one of the following a priori defined outcomes will be included: postoperative survival (overall and median survival; 1-, 2-, 3-, and 5-year survival rates), histological differentiation (grading), local tumor invasion (as defined in the included studies), lymph node metastases, and distant metastases. Review articles, case reports, case series with less than 5 patients, commentaries, and letters will not be included (Table 2). Details of the study selection process will be summarized in a flowchart according to the recommendations of the PRISMA 2020 statement (Figure 1).

Table 2. Inclusion and exclusion criteria.

	Inclusion criteria	Exclusion criteria
Article or study type	• Comparative observational studies • Randomized controlled trials	• Reviews • Case reports • Case series with less than 5 patients • Commentaries • Letters
Study population	• Patients with gastrointestinal tumors in which fibroblast activation protein expression was measured	• Other patients
Reported outcomes	Any of the following: • Median overall survival • 1-, 2-, 3-, or 5-year survival • Histological differentiation (grading) • Local tumor invasion • Lymph node metastases • Distant metastases	• None of the outcomes mentioned as inclusion criteria
Language	• English	• Other languages

Data Collection

Data from the included studies will be extracted separately by 2 authors and stored in a dedicated database. The following descriptive data will be documented for each selected study: first author, year of publication, inclusion period of the study, country and city where the study was conducted, sample size, and mean or median follow-up time. The distribution of the following patient characteristics will be documented: tumor type, histopathological tumor stage (using the UICC [Union for International Cancer Control] TNMG [tumor, node, metastasis, grade] classification system), presence and type of neoadjuvant therapy, presence and type of adjuvant therapy, FAP detection method, FAP antibody, FAP location, number of FAP-positive cases, and cutoff for overexpression.

The following predefined outcomes will be extracted: postoperative survival (overall and median survival, 1-, 2-, 3-, and 5-year survival rates), histological differentiation (grading), local tumor invasion (as defined in the included studies), lymph node metastases, and distant metastases. Subgroup analysis will be performed for location of FAP expression (tumor stroma or tumor cells or both) and tumor type (colon cancer, esophageal cancer, gastric cancer, hepatocellular carcinoma, cholangiocellular carcinoma, pancreatic cancer, and rectal cancer).

For each observational study, the risk of bias will be assessed using the ROBINS-I (Risk of Bias in Non-randomized Studies of Interventions) tool suggested by the Cochrane Collaboration [20]. For randomized controlled trials, the RoB 2 (Risk of Bias 2), the Cochrane risk-of-bias tool for randomized trials, will be used [21].

Statistical Analysis

A meta-analysis comparing patients with and without FAP overexpression with the following outcomes will be performed: postoperative survival (overall and median survival, 1-, 2-, 3-, and 5-year survival rates), histological differentiation (grading), local tumor invasion (as defined in the included studies), lymph node metastases, and distant metastases. Random-effects models will be used. The ReviewManager (RevMan) software (version 5.4; Cochrane Collaboration) will be used. The magnitude of the effect estimate will be visualized by forest plots. Odds ratios will be calculated for binary data, and weighted mean differences and relative SD differences will be determined for continuous data. The 95% CI, heterogeneity, and statistical significance will be reported for each outcome. The chi-square and Kruskal-Wallis tests will be used to evaluate statistical significance. A P value of <.05 will be considered statistically significant. If studies do not report mean and SD, these will be calculated using the methods described by Cochrane Collaboration guidelines [22] and Hozo et al [23].

Sensitivity analyses will be conducted according to the ascertained risk of bias as described above. For these, all studies with a high or serious risk of bias will be excluded, and the analyses of the outcomes, as described above, will be conducted.

XSL•FO
RenderX

Results

Database searches will commence in April 2023. Extraction of data from individual studies will be performed by May 2023. Data appraisal, preparation, summarization, and analysis will start in June 2023. The meta-analysis will be completed by December 2023.

Discussion

This systematic review and meta-analysis will synthesize all available evidence on the clinical implications of FAP overexpression in GI tumors.

In recent years, several studies on this topic have been published. The last published meta-analysis on this topic dates to 2015 and included 15 studies about various solid tumors and only 8 studies focusing exclusively on GI tumors [24].

The main limitation of the present meta-analysis is that we do not expect randomized controlled trials on this topic to be available. Nevertheless, to ensure transparency and reduce the risk of bias, this review will be conducted according to the defined protocol presented here and will be reported following the recommendations stipulated in the PRISMA 2020 statement [18].

The expected results will provide new information on the prognostic value of FAP in GI tumors and thereby support health care professionals and patients in their decision-making, as well as aid in patient selection for multimodal cancer therapy.

Abstract

Background: The incidence of postoperative spinal infection (PSI) ranges from 0% to 10%, with devastating effects on the patient prognosis because of higher morbidity while increasing costs to the health care system. PSIs are elusive and difficult to diagnose, especially in the early postoperative state, because of confusing clinical symptoms, rise in serum biomarkers, or imaging studies. Current research on diagnosis has focused on serum biomarkers; nevertheless, most series rely on retrospective cohorts where biomarkers are studied individually and at different time points.

Objective: This paper presents the protocol for a systematic review that aims to determine the inflammatory biomarker behavior profile of patients following elective degenerative spine surgery and their differences compared to those coursing with PSIs.

Methods: The proposed systematic review will follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement. This protocol was registered at PROSPERO on January 19, 2022. We will include studies related to biomarkers in adult patients operated on for degenerative spinal diseases and those developing PSIs. The following information will be extracted from the papers: (1) study title; (2) study author; (3) year; (4) evidence level; (5) research type; (6) diagnosis group (elective postoperative degenerative disease or PSI); (7a) region (cervical, thoracic, lumbosacral, and coccygeal); (7b) type of infection by anatomical or radiological site; (8) surgery type (including instrumentation or not); (9) number of cases; (10) mean age or individual age; (11) individual serum biomarker values from the preoperative state up to 90 days postoperative for both groups, including (10a) interleukin-6, (10b) presepsin, (10c) erythrocyte sedimentation rate, (10d) leukocyte count, (10e) neutrophil count, (10f) C-reactive protein, (10g) serum amyloid, (10h) white cell count, (10i) albumin, (10j) prealbumin, (10k) procalcitonin, (10l) retinol-associated protein, and (10m) Dickkopf-1; (11) postoperative days at symptoms or diagnosis; (12) type of organism; (13) day of starting antibiotics; (14) duration of treatment; and (15) any biases (including comorbidities, especially those affecting immunological status). All data on biomarkers will be presented graphically over time.

XSL•FO
RenderX

Results: No ethical approval will be required, as this review is based on published data and does not involve interaction with human participants. The search for this systematic review commenced in February 2021, and we expect to publish the findings in mid-2023.

Conclusions: This study will provide the behavior profile of biomarkers for PSI and patients following elective surgery for degenerative spinal diseases from the preoperative period up to 90 days postoperative, providing cutoff values on the day of diagnosis. This research will provide clinicians with highly trustable cutoff reference values for PSI diagnosis. Finally, we expect to provide a basis for future research on biomarkers that help diagnose more accurately and in a timely manner in the early stages of illness, ultimately impacting the patient's physical and mental health, and reducing the disease burden.

Introduction

Overview

The incidence of postoperative spinal infection (PSI) ranges from 0% to 10% depending on several factors related to the patient, the surgical intervention [1], and conditions of the health care system. PSI, otherwise called surgical site infection, has devastating effects on the patient prognosis because of higher morbidity [2] and mortality while increasing costs to the health care system [3]. PSI accounts for half of the readmissions following spinal surgery [3] and increases the cost of health care from US $150,000-$200,000 [4,5] per patient. Spinal infections affect the patient's physical and mental health but also the health care system and the society by increasing the burden of economic cost and even indirect expenditures such as absence from work that will affect the patient's capability to afford its treatment, making this a negative circle of factors that will ultimately affect the patient's quality of life [6].

PSI occurs either by direct inoculation during surgery, by the incursion of skin pathogens through the skin incision [7], or because of hematogenous spread [8] where *Staphylococcus aureus* and *Escherichia coli* are the pathogens most frequently involved. Multiple studies have determined the clinical factors involved in the genesis of PSI, including diabetes, coronary artery disease, traumatic injuries, male gender, age >60 years, BMI>35, smoking, malnutrition, a score >3 in the American Society Anesthesiologist, a posterior approach, spinal fusion, prolonged surgical time, multilevel surgery, and transfusion [9-15]. Unfortunately, most patients requiring spinal surgery have these conditions, where multiple comorbidities increase the burden [16]. Therefore, preoperative evaluation and management of any preventable risk factor are of utmost importance to prevent PSI, which can lead to significant morbidity, sepsis, and even death [17].

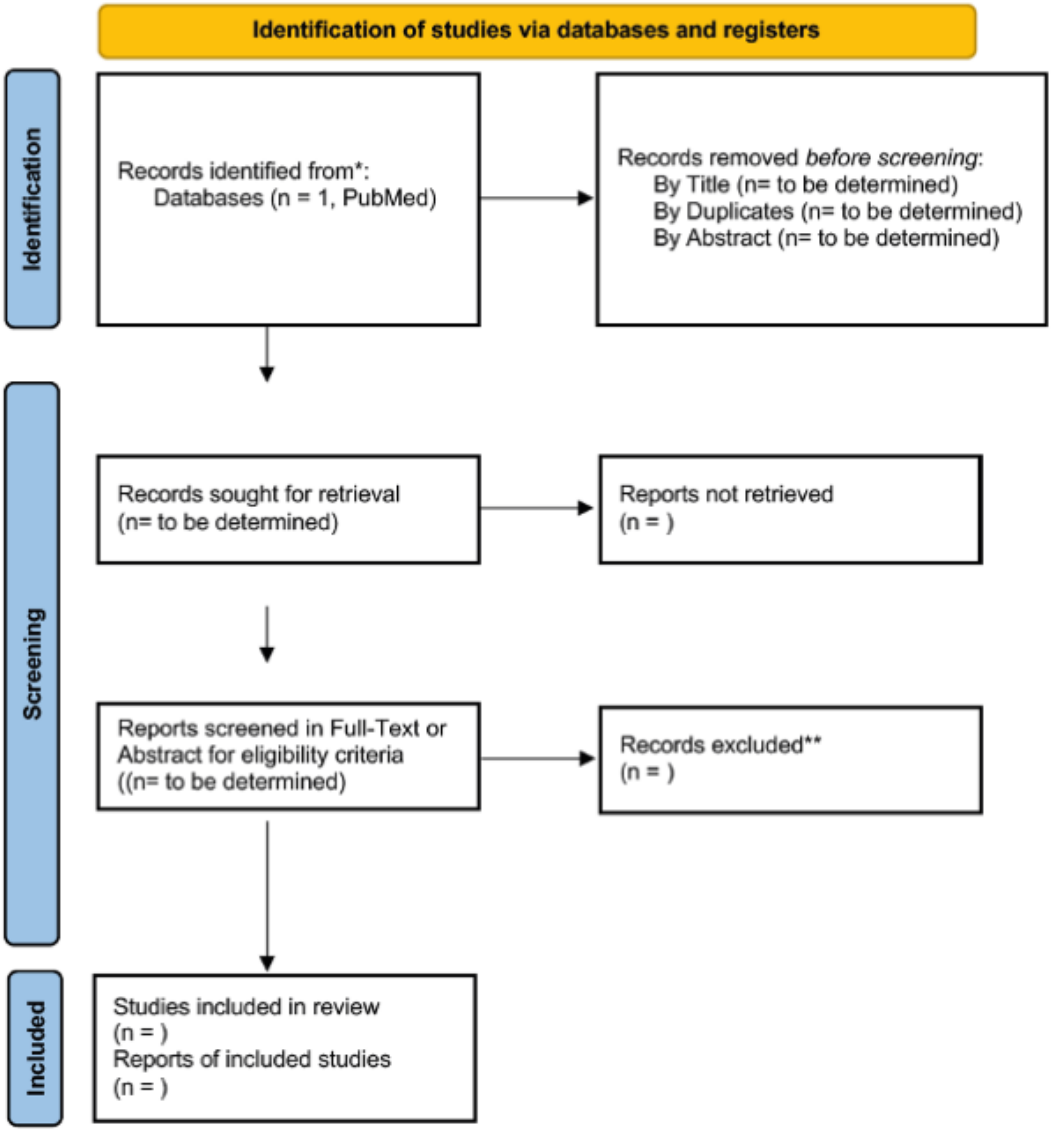
PSIs require a high level of suspicion as they are difficult to diagnose [18], especially in the early postoperative state, because of many confounding factors. The mainstay for diagnosing de novo spine infection is a triad of clinical symptoms, serum tests (biomarkers and blood cultures), and correlative imaging [19]. All these 3 parameters are affected in PSI, as clinical symptoms (usually pain) can be attributed to postoperative pain and muscle contracture, rise in serum biomarkers can be explained by inflammatory changes or conditions associated with surgery, and early postoperative imaging studies such as simple or enhanced MRI cannot distinguish between these entities clearly as postoperative changes are not so different [18-20]. These situations lead us to rely on blood cultures [20] that often take 5 days to offer accurate results with high false negative rates, ultimately requiring reintervention with tissue sample as the last step in the diagnosis, where under challenging cases it is not infrequent to repeat the diagnostic protocol because of negative results on biopsy or failed response to medical treatment.

Current research has focused on serum biomarkers to detect spinal infection at the early stages of disease [21,22]; nevertheless, most rely on retrospective cohorts or case series and a scarcity of prospective cohorts. Adding to this problem is that serum biomarkers are studied individually and at different time points while having a heterogenous group of patients who had undergone spinal surgery because of a diversity of spine affections treated with different surgical procedures. Therefore, this protocol aims to collect all the available information currently investigated related to biomarkers and PSI and elective surgery for degenerative spinal disease in order to provide the biomarkers' behavior profile from the preoperative day up to postoperative day 90 to guide differential diagnosis based on cutoff values among these groups.

We made a simple revision on PubMed before proceeding to the protocol and systematic review to look in advance for any research of this type, finding no similar review on biomarkers in current literature.

Objective

This systematic review aims to determine the behavior profile of inflammatory biomarkers among patients following elective degenerative spine surgery and their differences compared to those coursing with PSI.



XSL•FO
RenderX

Methods

Overview

The proposed systematic review will follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [23]. This protocol was registered on PROSPERO on January 19, 2022, with registration number CRD42022304645 (February 19, 2022). Figure 1 presents the flow diagram of the methodology.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

Search Strategy

The search strategy will aim to locate all published studies on biomarker evaluation among patients following elective degenerative spine surgery and their differences with those coursing with PSI. An initial search was made on the PubMed database to identify if there was any other review on the topic that would reunite all biomarkers in a single study, finding no one. We will use the PubMed, Embase, and Latindex databases to search among titles and abstracts for the specific word search criteria from 1984 to the present.

Keyword criteria included "Postoperative spinal infection" and a combination of either one of the following: "Biomarker," "Marker," "Detection," "C Reactive Protein," "CRP," "Erythrocyte Sedimentation Rate," "ESR," "Procalcitonin," "PCT," "Retinol Binding Protein," "Albumin," "Prealbumin," "Transferrin," "Neutrophil/Lymphocyte Count," "Neutrophil," "Lymphocyte," "Dickkopf1," and "DKK1." Multimedia Appendix 1 shows the full search strategy for PubMed in detail. We will include papers predominantly in English and other languages where information is readily available.

Review Question and Keywords

Our review question is as follows: What is the behavior profile of inflammatory biomarkers among patients following elective degenerative spine surgery and their differences from those coursing with a PSI?

Keyword criteria included the following: "Postoperative spinal infection" and a combination of either one of the following: "Biomarker," "Marker," "Detection," "C Reactive Protein," "CRP," "Erythrocyte Sedimentation Rate," "ESR," "Procalcitonin," "PCT," "Retinol Binding Protein," "Albumin,"

XSL•FO
RenderX

"Prealbumin," "Transferrin," "Neutrophil/Lymphocyte Count," "Neutrophil," "Lymphocyte," "Dickopf1," and "DKK1" from January 1, 1984, to June 4, 2022. Multimedia Appendix 1 shows the full search strategy for PubMed in detail. We will include papers predominantly in English and other languages where information is readily available.

Inclusion Criteria

Participants

We will include studies with adult patients (>15 years old), studies related to biomarkers in patients operated on for degenerative spinal diseases, and those developing a PSI, and studies with raw data and means. We will exclude all studies of pediatric patients (<15 years old) and patients operated on for any other etiology such as tumors, trauma, congenital diseases, and so on, and studies where the biomarker parameters could not be obtained within the text, figures, or tables.

Concept

The concept is to gather all the information related to the inflammatory biomarker's behavior profiles among patients following elective degenerative spine surgery and their differences with those coursing from PSI in the perioperative period, the early postoperative period (in hospital) up to 90 days (most agreed time limit to consider an early spinal infection). This information will help us draw a profile curve for biomarkers and each group of patients, aiding in differential diagnosis among them.

Context

Types of Sources

The review will be limited to Evidence Level IV and above (case series, case-control studies, retrospective, prospective cohorts, randomized and nonrandomized clinical trials, and previous systematic reviews, if any). We will not include editorials, individual case reports, or experimental, nonhuman, or nonclinical studies.

Information Sources

We will only conduct this systematic review in the PubMed, Embase, and Latindex databases.

Study and Source of Evidence Selection

We will collect the full search strategy results in Excel. At this point, the first author (RRJAI) and the second author (FJP) will make the first exclusion process based on titles and duplicates. Later, they will make the second exclusion process based on abstracts. Next, all papers that will require full-text reading will be handled in Mendeley; both authors will read them independently for inclusion criteria; in case of disagreement, we will include papers after a joint decision with the third author (RMWC). Then, the former author will perform the data extraction, and the second author will verify this process; we will also solve any disagreement in a joint decision with the third author. Next, we will record the reasons for exclusion in Excel. Finally, we will report the full results of the search in the final paper and present it using the PRISMA checklist.

Data Extraction

The first author will perform data extraction manually, and the second author will verify this process. The following information will be extracted from the papers: (1) study title; (2) study author; (3) year; (4) evidence level; (5) research type; (6) diagnosis group (elective postoperative degenerative disease or PSI); (7a) region (cervical, thoracic, lumbosacral, and coccigeal); (7b) type of infection by anatomical or radiological site; (8) surgery type (including instrumentation or not); (9) number of cases; (10) mean age or individual age; (11) individual serum biomarker values from the preoperative state, postoperative day 1 up to 90 days for both groups and also at day of diagnosis (within the 90 postoperative days) for the PSI group including (10a) interleukin-6 (IL-6), (10b) presepsin (PSP), (10c) erythrocyte sedimentation rate (ESR), (10d) leukocyte count, (10e) neutrophil count, (10f) C-reactive protein (CRP), (10g) serum amyloid, (10h) white cell count (WCC), (10i) albumin (Alb), (10j) prealbumin, (10k) procalcitonin (PCT), (10l) retinol-associated protein, and (10m) Dickkopf-1 (DKK1); (11) postoperative days at symptoms or diagnosis; (12) type of organism; (13) day of starting antibiotics; (14) duration of treatment; and (15) any biases (including comorbidities, especially those affecting immunological status).

We will modify the proposed data extraction schema as needed. We will detail any modifications in the full review report. We will solve any disagreements between the reviewers through discussion with the third author.

Data Analysis and Presentation

We will present the extracted data in a tabular form and as a narrative summary as required. The table will report the following variables: (2) study author; (3) year; (4) evidence level; (5) research type; (6) diagnosis group; (7a) region (cervical, thoracic, lumbosacral, coccigeal); (7b) type of infection by anatomical or radiological site; (8) surgery type (including instrumentation or not); (9) number of cases; (10) mean age or individual age; (11) postoperative days at symptoms or diagnosis; (12) type of organism; (13) day of starting antibiotics; (14) duration of treatment; and (15) any biases (including comorbidities, especially those affecting immunological status).

We will use graphical representations for the following variables to compare the behavior profile of each biomarker concerning time from the preoperative state up to 90 days postoperative among the 2 groups (elective postoperative spine degenerative disease vs PSI): (10a) IL-6, (10b) PSP, (10c) ESR, (10d) leukocyte count, (10e) neutrophil count, (10f) CRP, (10g) serum amyloid, (10h) WCC, (10i) Alb, (10j) prealbumin, (10k) PCT, (10l) retinol-associated protein, and (10m) DKK1.

Results

No ethical approval will be required, as this review is based on published data and does not involve interaction with human participants. The search for this systematic review commenced in February 2021, and we expect to publish the findings in mid-2023. The plan for dissemination, however, is to publish the review's findings in a peer-reviewed journal and present

XSL•FO
RenderX

findings at high-level international conferences to share knowledge to help establish more timely and accurate diagnoses to benefit patients.

Discussion

Overview

PSI is an elusive illness that can be challenging to demonstrate even in the context of advanced laboratory and imaging diagnostic studies [24,25]. Early diagnosis aids in achieving a good prognosis and contains the devastating consequences of spinal infections, reducing morbidity and health care costs [26,27]. Current research is focused on the behavior of serum biomarkers in the early postoperative period [17], where the white blood cell count, CRP, ESR, serum amyloid A, and PCT have been established as the conventional biomarkers [24]. Research for these biomarkers, as well as other new ones, relies primarily on retrospective cohorts on a single-measurement basis [11,22,28-32] with few prospective studies performed up to date [17,24,29], representing a significant limitation in the validity of results. Although several biomarkers exist in current research, they are studied individually [17] for a heterogenous group of illnesses in the spectrum of spinal infection with patients undergoing different surgical procedures [17]. As a result, cutoff values to determine abnormal inflammatory biomarker response in the postoperative period are lacking and vary widely depending on the severity of the illness [17] and the extent of the surgical procedure [33].

To have a point of comparison, we will summarize key findings in each of the biomarkers studied up to date. The acute-phase CRP is the biomarker most studied in the scientific literature related to spinal infections due to its availability and feasibility in clinical practice [34]. Its serum concentrations have served to diagnose spinal infection, monitor response to treatment, and detect relapse [34]. The difficulty in using it to detect PSI is having a trustable cutoff value for the inflammatory response expected from the surgical procedure itself [34], which depends on the extent of the procedure [33] and the severity of the illness [17]. Although no clear cutoff values can be drawn from the conclusion of the research and there exist contrasting evidence, it seems that CRP rises in the second and third postoperative day of noninfected patients, lowering its concentrations thereafter; this rise is dependent on the extent of surgery, but the behavior is similar for both of them [34]. As a result, secondary rises [32] or persistently high CRP serum concentrations beyond this period are suspicious of PSI, specifically after postoperative day 7 [35,36]. Nevertheless, these findings can derive from other noninfectious conditions in the postoperative period or have no obvious explanation [32]. Provided that CPR is most sensitive but not that specific (100% and 91.7%), other biomarkers such as PCT have demonstrated remarkable usefulness in differentiating inflammatory response as a result of surgery from that of spinal infection (100% specificity and 95.2% specificity) [37] provided that PCT does not seem to be affected because of the extent of surgery and rises in the first postoperative day remaining steadily low there forward [37]; unfortunately, it does not differentiate infection in other anatomical regions and there also exists evidence reporting no difference in PCT concentration among patients with and without postoperatory spinal infections [38], adding to the lack of a clear cutoff value to consider infection. The neutrophil-to-lymphocyte ratio is another marker that has constantly demonstrated diagnostic usefulness in the early postoperative period, with reported cutoff values ranging from 3.21 to 3.87 for differentiating postoperatory state from a spinal infection; however, this information is based on retrospective cohorts [25,38]. Finally, many other biomarkers, such as IL-6, retinol-binding protein, prealbumin, and PSP, among others, have been studied with contradictory evidence and no clear practical usefulness [1,11,22,24]. The expression of DKK1 has been recently evaluated in the context of osteomyelitis [39] and infectious processes [40-42] but as far as we know, there exist no reports of spinal infections. We include this marker in the systematic review to confirm that there exist no previous studies in this respect as to establish a starting point for a research line in this direction. We consider DKK1 a valuable marker to be investigated provided that its expression affects bone repair after damage by the Wnt/β-catenin molecular signaling pathway for osteoclast and osteoblast induction, where DKK1 functions as an inhibitory factor (that can be induced by infections), therefore impeding bone renewal [40]. By the relationship DKK1 has with infections and impeding bone repair after damage (such as a surgical insult), we consider it an important factor to be investigated in the context of postoperatory spinal infection.

Therefore, this protocol aims to direct many of these limitations found in previous research. We expect to reunite all the information gathered from previous retrospective and prospective series to provide results based on a large sample. Simultaneously, we expect to obtain the mean serum concentrations for different biomarkers over time from the preoperative period up to the postoperative day 90 by extracting data from different series with different time approaches. By using these 2 strategies, we aim to draw time-dependent behavior profiles for each of the biomarkers to have a robust reference of average values and confidence intervals in the postoperative period and abnormal cutoff values and ranges for PSI. Also, we expect to be able to draw specific cutoff values for the different surgical procedures performed; nevertheless, this objective will be ultimately dependent on finding an appropriate surgical procedure description and the sample size obtained from the included studies. We consider that our findings will help clinicians and surgeons make more evidence-based timely decisions that benefit the patients with early treatment, avoiding long-term complications and increases in health care costs with the ultimate impact on morbidity, disability, and mortality. Additionally, our study will be the first and more robust research in this respect by relating all the biomarkers that have shown utility in the diagnosis of spinal infection on a single systematic review taking into consideration the full perioperative period and the different surgical techniques employed.

Finally, there are also limitations to consider in our research. For example, several studies have an incomplete reporting of results due to data gathering bias, such as a lack of protocol for taking blood samples derived from retrospective research. Also,

XSL•FO
RenderX

some retrospective and prospective studies that evaluate biomarkers have directness biases as they are evaluated as a secondary objective that impacts outcomes, prognosis, or are considered among different risk factors. Nevertheless, these limitations are unavoidable based on the available literature.

Conclusions

In conclusion, this study will provide the biomarkers' behavior profile for PSI and patients following elective surgery for degenerative spinal diseases from the preoperative period up to 90 days postoperative and provide cutoff values on the day of diagnosis. Our research will hopefully aid in the differential diagnosis of these groups early by summarizing all research done in this respect. It will eventually provide clinicians with a better background to establish their diagnosis based on highly trustable information based on cutoff values from this systematic review. Shortly, we also expect this review to provide a basis for more robust prospective studies and even clinical trials on biomarkers to establish a more accurate and timely diagnosis of the early stages of the disease, which will ultimately impact the patient's physical and mental health, reducing the burden of disease.

Abstract

Background: Studies have shown that mobile health technologies (mHealth) enhance the use of maternal health services. However, there is limited evidence of the impact of mHealth use by community health workers (CHWs) on the use of maternal health services in sub-Saharan Africa.

Objective: This mixed method systematic review will explore the impact of mHealth use by CHWs on the use of the maternal health continuum of care (antenatal care, intrapartum care, and postnatal care [PNC]), as well as barriers and facilitators of mHealth use by CHWs when supporting maternal health services.

Methods: We will include studies that report the impact of mHealth by CHWs on the use of antenatal care, facility-based births, and PNC visits in sub-Saharan Africa. We will search 6 databases (MEDLINE, CINAHL, Web of Science, Embase, Scopus, and Africa Index Medicus), with additional articles identified from Google Scholar and manual screening of references of the included studies. The included studies will not be limited by language or year of publication. After study selection, 2 independent reviewers will perform title and abstract screening, followed by full-text screening to identify the final papers to be included. Data extraction and risk-of-bias assessment will be performed using Covidence software by 2 independent reviewers. We will use a Mixed Methods Appraisal Tool to perform risk-of-bias assessments on all included studies. Finally, we will perform a narrative synthesis of the outcomes, integrating information about the effect of mHealth on maternal health use and barriers and facilitators of mHealth use. This protocol follows the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines.

Results: In September 2022, we conducted an initial search in the eligible databases. After removing duplicates, we identified 1111 studies that were eligible for the title and abstract screening. We will finalize the full-text assessment for eligibility, data extraction, assessment of methodological quality, and narrative synthesis by June 2023.

XSL•FO
RenderX

Conclusions: This systematic review will present new and up-to-date evidence on the use of mHealth by CHWs along the pregnancy, childbirth, and PNC continuum of care. We anticipate the results will inform program implementation and policy by highlighting the potential impacts of mHealth and presenting contextual factors that should be addressed to ensure the success of the programs.

Introduction

Background

Sub-Saharan Africa (SSA) continues to have the highest burden of maternal morbidity and mortality in the world [1]. About two-thirds of all maternal deaths occur in this region alone [2], despite containing only 15% of the global population [3]. Low use of antenatal care (ANC), unattended home births, and low use of postnatal care (PNC) have been identified as some of the biggest contributors to high maternal morbidity and mortality [4]. Consequently, policy makers and researchers in many SSA countries are beginning to realize the need for innovative ways of increasing access to and improving the quality of care along the pregnancy, childbirth, and postpartum continuum of care [5].

In SSA, mobile health (mHealth) technologies hold the potential to enhance use and quality of care during pregnancy, childbirth, and postpartum continuum of care, and thereby contribute to the reduction of maternal morbidity and mortality [6]. Currently, there is no universal definition of mHealth [7,8]. The World Health Organization defines mHealth as the use of mobile and wireless devices to support public health and medical practices [9]. When used appropriately, mHealth can be used to enhance use and quality of care. Additionally, mHealth can improve communication between providers and patients, and serve as a tool for education and mobilization [10]. Due to these anticipated benefits, there is a push to introduce mHealth to community health workers (CHWs) [11]. This is now possible in many SSA countries due to increased mobile and wireless device coverage and reduced cost of mHealth technologies [12,13].

CHWs act as a bridge between communities and health facilities by directly providing preventive health services, health promotion, and social mobilization among other home-based services [14,15]. Their role in the provision of health services is also vital as they help to address cultural barriers to accessing health services [16]. Finally, CHWs act as voices of social change by advocating for the health and social needs of the communities they serve [17]. If implemented well, these roles help improve the use of key health services, including maternal health services. Mobile health technologies may enhance the key roles of CHWs.

Despite the potential positive impact, the use of mHealth technologies is associated with challenges, especially in low- and middle-income countries. These include technological challenges, such as concerns with data security and privacy [18], multiple platforms of mHealth, some of which are not interoperable [19], poor network [13], lack of power [20], and high initial and maintenance costs [21]. Additional social factors also affect the use of mHealth including low literacy [22], insufficient training [23], cultural unacceptability [24,25], apps designed in languages other than the language of the users [24], and lack of integration into national health systems [10].

Recent reviews of the use of mHealth among CHWs have mainly focused on pilot projects and the mHealth implementation process and uptake [21,26]. Some reviews have shown that mHealth use by CHWs is linked to increased motivation, performance, and overall retention of CHWs [19,23]. Mobile health has supported the training of CHWs [27], improved patient adherence to scheduled appointments [28], and improved data collection, analysis, and use [29]. However, little is known about the effect of mHealth use by CHWs on the use of maternal health services in SSA.

Study Objectives

Due to the relative novelty and potential challenges associated with implementation in SSA, the impact of mHealth on maternal health outcomes will depend on addressing barriers while building on facilitators to implementation. This review will explore the use of mHealth by CHWs in SSA along the pregnancy, childbirth, and postpartum continuum of care. Specifically, we will assess the evidence on the effect of mHealth on maternal health use, while exploring how programs identified barriers and facilitators that may impact the implementation of mHealth.

Review questions include the following:

1. Does the use of mHealth by CHWs increase utilization of maternal health services (ANC, facility-based births, and PNC) in SSA?
2. What are the facilitators and barriers of mHealth use by CHWs in programs designed to increase the utilization of maternal health services (ANC, facility-based births, and PNC) in SSA?

While the first review question will be answered by quantitative study designs, the second review question will be answered by

XSL•FO
RenderX

both qualitative and quantitative study designs. Initially, we conducted a preliminary search of PROSPERO, MEDLINE, and JBI Evidence Synthesis, and no current or in-progress systematic reviews on the topic were identified.

Methods

We have used the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines to structure this protocol [30].

Ethics Approval

Ethical approval is not required as the data collection will not directly involve any human subjects or identifiable patient data.

Eligibility Criteria

Participants

In this review, participants include (1) pregnant women at any gestational age, (2) pregnant women during intrapartum care, and (3) women within 42 days after giving birth. We will include these women when using ANC, intrapartum care, and PNC. Women accessing these services and having coexisting conditions, for example eclampsia, will also be included.

Intervention

The use of mHealth by CHWs to improve maternal health use is the focus of the review. Mobile health devices will include portable and wireless devices such as cell phones, feature phones, tablets, portable media players, and GPS trackers, among others. We will classify the mHealth tools based on the 12 "signal functions" defined by Labrique et al [31] (Table 1).

Table 1. Common mobile health uses.

Number	Common mobile health uses
1	Client education and behavior change communication
2	Point of care diagnostics and sensors
3	Registries or vital events tracking
4	Data collection and reporting
5	Electronic health records
6	Clinical decision support
7	Provider-to-provider communication
8	Scheduling and work plan management
9	Provider capacity building
10	Human resource management
11	Supply chain management
12	Financial transactions and incentives

CHWs will be defined based on the World Health Organization definition, "health workers based in communities, who are either paid or volunteers, who are not professionals, and who have fewer than 2 years of training but at least some training" [32]. We developed the CHW search strategy based on commonly known names for CHWs in various contexts [33]. We will include CHWs who were working in mHealth programs designed to increase the use of maternal health services (as stand-alone programs or integrated with other clinical programs), and which are implemented in SSA as defined by the World Bank Group country classification [34].

Comparator

For interventional studies included in this review, the comparator will be CHW programs that are not using mHealth interventions.

Outcomes

Our outcomes will include the following:

1. Measures of the use of mHealth on the use of maternal health services along the continuum of care:
   - ANC: total number of ANC visits, women who attended ANC in the first trimester, women who attended 4 or more ANC visits, and women with 8 or more ANC visits
   - Facility-based births: women who gave birth at health facilities
   - PNC: total number of PNC visits; women who attended PNC within 2 days, 3-7 days, and 8-42 days after giving births
   - Other maternal and reproductive health outcomes or services such as abortions, caesarean sections, family planning, and neonatal and child health outcomes will be excluded.
2. Facilitators to mHealth use by the CHWs
3. Barriers to mHealth use by the CHWs

Study Designs

We will include the following study designs: (1) randomized controlled designs, (2) observational studies with competent counterfactual designs (eg, quasi-experimental studies), (3) nonexperimental quantitative studies, (4) qualitative studies, and (5) mixed methods studies. Protocols, case series or reports, abstracts and conference proceedings, commentaries, policy briefs and other policy documents, systematic reviews, and

XSL•FO
RenderX

other summary-type articles will be excluded. Although systematic reviews and other summary-type articles will be excluded, we will check the references in these articles to identify additional papers.

Information Sources and Search Strategy

We will search the following databases for potential studies: (1) Scopus, (2) MEDLINE, (3) CINAHL, (4) Web of Science, (5) Embase, and (6) Africa Index Medicus. Additional articles will be searched using Google Scholar and hand searching in references of all included studies. Study search will not be limited to a time or language. The sample component of search terms and search strategy is presented in Table 2. The search strategy was formulated by JCFK, who is a medical information specialist at Vrije Universiteit Amsterdam, the Netherlands.

Study Selection and Data Extraction

JCFK will retrieve all studies from eligible databases based on the search strategy. CK will export all articles to Covidence computer software [35]. Covidence is a web-based collaboration software that is used to screen studies, perform risk-of-bias assessment and extract data. After the removal of duplicates, CK and HRZ will independently review titles and abstracts to select potential articles that meet the inclusion criteria. Following the identification of potentially eligible studies, CK and HRZ will independently review the studies in full to identify studies that meet the inclusion criteria. Disagreements during the title and abstract review and the full-text screening will be resolved by TvdA. An audit trail regarding the included and excluded studies and studies that required discussion will be maintained. Reasons for study exclusion will include studies conducted outside SSA, mHealth use by cadres of health care workers other than CHWs, and studies reporting outcomes other than those specified in this study.

We will design and pretest a data collection tool that will be used in Covidence software (Figure 1). The data collection tool will include the following:

1. Study characteristics: author, year of publication, and study design
2. Context: country and geographical scope
3. Programmatic context: type of CHWs and description of CHW work
4. Mobile health intervention characteristics: mHealth platforms, devices used, delivery method, and intervention description
5. Summary of main findings

Figure 1. Data extraction tool. CHW: community health workers.

Date	Author	Year of publication	Country	Study design	Context	Geographical location/context	CHW description and roles	Outcome description	MHealth devices	MHealth platform	MHealth delivery methods	MHealth Signal functions	Description of mHealth Intervention	Main Findings

Assessment of Methodological Quality

All included articles will undergo an independent assessment of methodological quality using the Mixed Methods Appraisal Tool (MMAT), 2018 version, by CK and HRZ [36]. MMAT is used to systematically appraise qualitative, quantitative, and mixed methods studies. MMAT is short but comprehensive and easy to use and has been validated and used extensively in reviews [37-40]. Disagreements will be resolved by TvdA. Details of the main domains of the MMAT tool are found in Multimedia Appendix 1. All studies, regardless of the results of their methodological quality, will undergo data extraction and synthesis.

RenderX

Data Analysis and Synthesis

Since we are including a diverse range of mHealth tools, we anticipate heterogeneous findings from the included studies. As such, we will conduct a narrative synthesis of the results. We will not perform meta-analyses or subgroup analyses. We will follow 3 of the 4 steps of narrative synthesis as outlined by Popay et al [41], which are as follows:

1. A preliminary synthesis of summary findings of the included studies—we will tabulate all results and describe all variables as extracted from eligible studies. For research question 1, we will describe the direction and size of the effect of mHealth across the maternal health continuum of care: ANC, facility-based births, and PNC. For research question 2, we will qualitatively identify barriers and facilitators using a thematic analysis approach [42]. Using this approach, familiarization with the studies will occur during full-text eligibility and data extraction. This will be followed by the development of codes, which will then be organized as themes. The themes will be categorized using the socio-technical analysis framework by Davis et al [43] to group the barriers and facilitators into the following 6 main domains: people, goals, building and infrastructure, technology, culture, and processes and procedures (Figure 2) [43].
2. Exploring the relationships in the data within and between the studies, including explanations of variability in summary findings—we will describe factors that explain the differences in outcomes and barriers and facilitators to mHealth within and between the studies separately. This will be followed by the integration of the results of the two research questions. This is the process in which the two study aims will be linked to describe how mHealth might have led to the effect on maternal health outcomes.
3. A methodological quality assessment for the included studies, as described above.

Figure 2. Socio-technical analysis framework.

Results

In September 2022, we conducted an initial search in the 6 databases plus hand searching in Google Scholar. After removing duplicates, we identified 1111 studies that were eligible for the title and abstract screening. We anticipate finalizing the full-text assessment for eligibility, data extraction, assessment of methodological quality, and narrative synthesis by June 2023. Dissemination of results, including publication of the final manuscript, will follow the PRISMA reporting guidelines [44].

Discussion

This systematic review will present new and up-to-date evidence on the use of mHealth by CHWs along the pregnancy, childbirth, and PNC continuum of care. Based on the selected databases, we will present a comprehensive synthesis of the existing evidence on the effect of mHealth on the use of maternal health services. Additionally, we will explore the barriers and facilitators of mHealth use, allowing the exploration of factors that shape the implementation of mHealth.

The review is focused on SSA, a region that is currently struggling with the low use rates of maternal health services and identifying ways to improve maternal health outcomes, including a reduction in morbidity and mortality, is a priority [45]. As mHealth use continues to be promoted as one of the innovative ways to improve maternal health use in SSA, we anticipate the results of this review to be important to program implementers, policy makers, and researchers [46,47]. For implementers and policy makers, the results will inform how to use mHealth interventions based on what has been shown to work in other contexts. Additionally, the review will also highlight the present contextual factors that should be addressed to ensure the success of the programs. In the context of implementation, the review has the potential of providing valuable insights on how to modify programs that are currently being implemented to optimize outcomes, support justification for program scale-up, and support the inclusion of mHealth recommendations in policy guidelines. For researchers, we hope that the findings will open a scholarly discussion, create a reproducible process that enables future updates of the review, and based on identified gaps, inform areas of future research. This systematic review is also part of a PhD thesis by the first author.

XSL•FO
RenderX

The review has 2 main limitations. Firstly, we will include peer-reviewed publications only. This may lead to publication bias as some of the information on mHealth may be found in gray literature or may not be published at all. Secondly, we are including maternal health continuum of care outcomes, leaving out other maternal health outcomes.

This systematic review will present the current evidence on the use of mHealth by CHWs in SSA. Therefore, we hope the review will support the use of mHealth for improved maternal health outcomes in SSA.

Acknowledgments

The authors acknowledge Stella Chibvunde, who provided support during the submission of the manuscript. The study did not receive any funding.

Authors' Contributions

CK, THD, TvdA, and IOOA conceptualized and designed the study. CK, HRZ, THD, DP, and JCFK were responsible for validity and data collection. Writing of the original draft was done by CK. Review and approval for submission were carried out by CK, THD, AVK, JCFK, JM, DP, IOOA, and TvdA.

Conflicts of Interest

None declared.

Abstract

Background: Advancements in cancer treatments have successfully improved central nervous system (CNS) cancer survivorship and overall quality of life. As a result, the awareness of the importance of fertility preservation techniques is increasing. Currently, a range of established techniques, such as oocyte cryopreservation and sperm cryopreservation, are available. However, oncologists may be hesitant to refer patients to a reproductive specialist.

Objective: The primary aim of the proposed systematic review is to assess the best evidence for fertility preservation techniques used in patients with CNS cancers. It also aims to evaluate outcomes related to their success and complications.

Methods: This protocol was produced in adherence with the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols). Electronic databases will be systematically searched to identify studies that meet our eligibility criteria. Studies will be included if they report at least one type of fertility preserving or sparing technique in male patients of any age and female patients aged <35 years. Animal studies, non-English studies, editorials, and guidelines will be excluded from the review. From the included studies, data will be extracted and synthesized by using a narrative approach and summarized in tables. The primary outcome will be the number of patients successfully undergoing a fertility preservation technique. The secondary outcomes will include the number of retrieved oocytes, the number of oocytes or embryos vitrified for cryopreservation, clinical pregnancy, and live birth. The quality of the included studies will be assessed by using the National Heart, Lung, and Blood Institute risk-of-bias tool for any type of study.

Results: The systematic review is expected to be completed by the end of 2023, and results will be published in a peer-reviewed journal and on PROSPERO.

Conclusions: The proposed systematic review will summarize the fertility preservation techniques available for patients with CNS cancers. Given the improvement in cancer survivorship, it is becoming increasingly important to educate patients about fertility preservation techniques. There are likely to be several limitations to this systematic review. Current literature is likely to be of low quality due to insufficient numbers, and there may be difficulty in accessing data sets. However, it is our hope that the results from the systematic review provide an evidence base to help inform the referral of patients with CNS cancers for fertility preservation treatments.

fertility; reproduction; central nervous system; CNS cancer; neuro-oncology; cancer; awareness; electronic database; tool; fertility preservation; patient; treatment; reproductive; oncology; infertility; in vitro fertilization; artificial insemination; human reproduction; reproduction; gynecology; gynecologist; assisted reproductive technology; gestational surrogacy; surrogate; fertility tourism; test tube baby; intracytoplasmic sperm injection

Introduction

Central nervous system (CNS) cancers are the most prevalent cancers in 15- to 19-year-olds [1]. Infertility is one of the most common long-term issues experienced by young, female cancer survivors [2]. With advances in chemoradiotherapy and surgery meaning that survival from these cancers has considerably improved, there is an increased awareness of the impact that this has on cancer survivors' quality of life [1]. CNS cancers can impact patients' fertility in a variety of ways. Tumor infiltration, radiotherapy, and cranial surgery can all damage the hypothalamic-pituitary axis. In addition, chemoradiotherapy treatments can also be gonadotoxic, resulting in premature ovarian insufficiency and impaired fertility [3,4]. National Institute for Health and Care Excellence guidelines recognize the clinical importance of establishing fertility preservation techniques in those wishing to preserve their future reproductive potential [5].

There are several techniques available to women who are concerned about their future fertility, although many of these techniques have been considered experimental until recently. Embryo cryopreservation is the most established fertility preservation technique [6]. However, recent advances make oocyte cryopreservation an alternative option for those without a partner. Embryo or mature oocyte cryopreservation involves the hyperstimulation of the ovary to induce multiple follicles to grow [7]. Following retrieval, mature oocytes or embryos obtained via in vitro fertilization are cryopreserved and stored for use in the future [8]. For prepubertal girls, there is only one emerging technique available [9]. Ovarian tissue cryopreservation involves the transplantation of frozen-thawed ovarian tissue into the pelvic cavity after treating the CNS tumor. Although previous studies have shown successful results with this technique, there are concerns about tumor reseeding [10]. For patients undergoing radiotherapy, ovarian transposition, or oophoropexy, may be utilized as a fertility sparing method; the ovaries are surgically repositioned to be outside of the radiation field, thus minimizing their radiation damage [11]. For men, sperm cryopreservation is an established and effective technique for fertility preservation [12].

More young adults with CNS cancers see future family building as a possibility. However, oncologists may be hesitant to refer patients to a reproductive specialist, despite societal support and patient interest. This may be due to a reluctance to send mixed messages about prognoses, discomfort in discussing fertility or sexuality, and a lack of knowledge or time [12]. Our systematic review aims to summarize the available evidence concerning fertility preservation techniques used in the context of patients with CNS cancers.

Methods

Protocol and Registration

The protocol was developed in adherence with the recommendations of the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines. The systematic review will also adhere to the recommendations of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. The protocol has been prospectively registered on PROSPERO (registration number: CRD42022352810). Any changes in the protocol will be amended in PROSPERO and reported once the systematic review is complete.

Eligibility Criteria (Study Designs and Types of Studies)

Studies will be included in this systematic review if they are a systematic review, case series, case report, interventional trial (nonrandomized and randomized controlled studies), cohort study, case-control study, or cross-sectional study reporting at least one type of fertility preservation technique among neuro-oncology patients. If multiple publications report results from the same patient cohort, then each study will be included, provided that distinct outcomes are reported. If these publications report duplicate outcomes, only the study with the largest population will be included. Grey literature will not be included in the review. Animal studies, non-English studies, editorials, and guidelines will be excluded from the review.

Participants, Population, and Exposure

The review will focus on male and female patients of any age with a primary CNS tumor of any World Health Organization tumor grade. Such tumors may include medulloblastomas, ependymomas, astrocytomas, primitive neuroendocrine tumors, glioblastomas, germinomas, pineal tumors, gliomas, craniopharyngiomas, pineoblastomas, and CNS lymphomas. Participants must have received at least one type of fertility preservation or fertility sparing technique to be included. These may include medical therapy before chemotherapy, ovarian transposition, embryo cryopreservation, oocyte vitrification, ovarian tissue cryopreservation, or sperm cryopreservation. Participants who did not receive or were not referred for a fertility preservation technique will be excluded. If aggregate data prevent the identification of data meeting all the inclusion criteria, the paper will be excluded.

Outcome of Interest

The primary outcome of the systematic review will be the number of patients successfully undergoing a fertility preservation technique. The systematic review is interested in fertility-related outcomes for patients undergoing fertility preservation techniques. These may be reported quantitatively or qualitatively. Therefore, the secondary outcomes include the

XSL•FO
RenderX

success rates of different fertility preservation techniques, including, for example, the number of retrieved oocytes, the number of oocytes or embryos vitrified for cryopreservation, the rate of sperm cryopreservation, clinical pregnancy, and live birth. The number of oocytes retrieved reflects the effectiveness of fertility preservation protocols, and the number of oocytes or embryos vitrified for cryopreservation implies the potential for oocyte fertilization and embryo transfer [13]. A clinical pregnancy will be defined as at least one intrauterine pregnancy sac with yolk sac or original cardiac pulsations on a B-ultrasound examination. A live birth will be defined as the birth of a healthy infant not requiring admission to the neonatal intensive care unit, at 28 weeks gestation or more, during the follow-up period [14].

Search Methods

We will perform a literature search of the following databases: PubMed, MEDLINE, Cochrane, Google Scholar, and Embase. A combination of Medical Subject Headings terms will be used to identify relevant articles. The search strategy will be developed in collaboration with a university librarian (Textbox 1). The search will be limited to articles published in the English language. To ensure the relevance of papers, the search strategy will be limited to papers published in the last 20 years (2002-2022). References will be hand-searched to identify other potential sources to be included. Grey literature will not be searched for the review.

Textbox 1. Provisional search terminology.

Search string

- ("Fertility preservation" OR "Ovary preservation" OR "Oocyte preservation" OR "Gonadal preservation" OR "Sperm preservation" OR "Semen preservation" OR "Fertility cryopreservation" OR "Ovary cryopreservation" OR "Embryo cryopreservation" OR "Gonadal cryopreservation" OR "Sperm cryopreservation" OR "Testicular cryopreservation" OR "Ovariopexy" OR "Ovarian transposition" OR "Fertility sparing" OR "Ovarian tissue cryopreservation" OR "cryopreservation" OR "oocyte retrieval" OR "Ovary retrieval" OR "Gonadal retrieval" OR "OTC") AND ("Brain tumour" OR "Brain cancer" OR "Brain neoplasm" OR "Cerebral neoplasm" OR "Cerebellar neoplasm" OR "Medulloblastoma" OR "Ependymoma" OR "Primitive neuroectodermal tumour" OR "Primitive neuroectodermal cancer" OR "Primitive neuroectodermal neoplasm" OR "Astrocytoma" OR "Glioblastoma" OR "Germinoma" OR "Central nervous system tumour" OR "CNS tumour" OR "Central nervous system cancer" OR "CNS cancer" OR "Central nervous system neoplasm" OR "CNS neoplasm" OR "Pineal tumour" OR "Pineal cancer" OR "Pineal neoplasm" OR "Pinealoma" OR "Glioma" OR "Craniopharyngioma" OR "Pineoblastoma" OR "CNS lymphoma")

Selection of Studies

The titles and abstracts of studies produced by the search will be collated by using reference management software, and duplicates will be removed. Two authors will jointly screen the titles and abstracts of the search results. The full texts of potentially relevant studies will then be retrieved and assessed against the predefined inclusion and exclusion criteria. When a consensus cannot be reached, a third reviewer will be consulted. When a full-text article cannot be obtained, the corresponding author of that article will be contacted. The selection process will be documented by using the PRISMA flowchart to report how studies were identified, screened, and included.

Data Extraction, Management, and Synthesis

A standardized data extraction form will be developed and piloted before use. Data will be extracted from 10% of the selected studies by 2 reviewers independently. Concordance between the two reviewers will be statistically assessed by using the Kendall τ statistic. If concordance is met, the reviewers will each extract data from 50% of the remaining papers. If concordance is not met, discrepancies will be resolved via discussion, and data will be extracted from a further 10% of the studies and reassessed.

The following parameters will be extracted from each paper: primary author, publication date, study design, country, participant demographics (number, gender, age, duration of symptoms, type of brain tumor, tumor stage, age at treatment, radiation dose to ovaries [grays], radiation dose to the hypothalamic-pituitary axis [grays], and description of study participants), inclusion and exclusion criteria, the existence of pre-existing conditions affecting fertility, the type of neuro-oncology intervention(s), the type of fertility preservation, age at fertility preservation, the method of conception, the number of attempts at pregnancy, the outcome(s) measured and the value of the outcome(s) measured, and treatments (including teratogenic treatments) received during pregnancy. Individual study data will be combined and synthesized in a table. The following outcomes and end points may be included: pregnancy outcomes, the number of oocytes retrieved, ovarian tissue cryopreservation, follicle characteristics, sperm characteristics, rates of sperm cryopreservation, the number of metaphase-2 oocytes retrieved and vitrified, and neonatal outcomes. When data are missing, the authors will be consulted for further completing data.

Given the anticipated heterogeneity in study designs and outcomes, a meta-analysis may not be feasible. A narrative synthesis of the data will be performed. Tables will be used to summarize and present participant demographics, fertility preservation techniques, and outcomes. If possible, a subgroup analysis will be performed by stratifying women into age groups (<35 years and >35 years of age) and by pre-existing conditions affecting fertility (eg, polycystic ovary syndrome).

Quality Assessment

All included studies will be assessed for quality and risk of bias by using the National Heart, Lung, and Blood Institute risk-of-bias tool for any type of study. The two reviewers will rate each domain of the included studies as having a low, high, or unclear risk of bias. These ratings will then be used to provide an overall quality score for the methodology of the article. Discrepancies between the two reviewers will be resolved through discussion with a third reviewer to achieve a consensus.

XSL•FO

Results

This is a protocol for a systematic review; therefore, the results cannot be presented. The results of the study will be submitted for publication in a peer-reviewed journal and presented on PROSPERO. The systematic review is expected to be completed by the end of 2023.

Discussion

Given that cancer survivorship is increasing, it is becoming increasingly important to educate oncologists about fertility preservation techniques for patients who wish to preserve their fertility. Our systematic review aims to present a comprehensive summary of fertility preservation techniques used in neuro-oncology patients. To the best of our knowledge, this will be the first systematic review to evaluate these techniques in neuro-oncology patients. Current literature on the subject is largely comprised of small case series and is likely to be of limited quality due to insufficient numbers, difficulty in accessing data sets, and combined cohorts. This may limit the conclusions drawn in the systematic review. Our hope is that the review classifies the success rates of fertility preservation techniques and any complications experienced by the patients undertaking them.

Current guidance recommends that patients should be provided with information about the effects of cancer therapies on fertility before or during cancer treatment and that patients should be recommended for fertility preserving or sparing treatments as appropriate [15]. Through our review, we hope to provide clinicians with an overview of appropriate treatments to develop the understanding of treatments available. We also hope that the review facilitates the future development of frameworks to help guide clinician and patient discussions.

There are likely to be several limitations for the systematic review. The quality of current literature is likely to be low due to insufficient case numbers, difficulty in accessing data sets, and aggregate cohorts, limiting the conclusions that may be drawn from the systematic review. There is also likely to be significant heterogeneity in the outcomes reported in the studies. Therefore, it is likely that a meta-analysis will not be able to be performed. Moreover, there are multiple mediating variables, such as treatment type, tumor stage, and radiation dose, that must be considered when assessing fertility outcomes.

Abstract

Background: Opioid use disorder (OUD) during pregnancy presents a significant risk to maternal, fetal, and neonatal health, increasing the likelihood of adverse events, such as maternal overdose, pregnancy loss, stillbirth, preterm birth, low birth weight, and neonatal abstinence syndrome. In order to reduce the risk of these outcomes, the standard of care for OUD during pregnancy in many jurisdictions within the United States and Canada is opioid agonist therapy (OAT). OAT refers to prescription medications that alleviate or eliminate opioid withdrawal symptoms, so that opioid use can be managed more safely. Although OAT has been recognized as a safe option for pregnant people with OUD, many jurisdictions do not have treatment guidelines regarding pharmacological options, dosing recommendations, side effect management, and individual preferences. There is currently a lack of systematic evidence on the impacts of different OAT regimens on pregnancy outcomes.

Objective: We aim to evaluate the impacts of specific OAT agents on pregnancy outcomes and inform recommendations for practitioners treating pregnant people with OUD.

Methods: The MEDLINE, Embase, CINAHL, and PsycINFO databases will be searched for published quantitative studies assessing pregnancy outcomes for individuals on OAT. Given the substantially increased risk of preterm birth, low birth weight, small for gestational age, and stillbirth among pregnant people with OUD, these four end points will comprise our primary outcomes. Database searches will not be restricted by date, and conference abstracts will be restricted to the past 2 years. Titles, abstracts, and full-text articles will be independently screened by 2 reviewers. Data will be extracted independently and in duplicate, using a data extraction form to reduce the risk of reviewer bias. The risk of bias within individual studies will be assessed by using the appropriate CASP (Critical Appraisal Skills Programme) checklists. For studies that consider the same research questions, interventions, or outcomes, meta-analyses will be conducted to synthesize the pooled effect size. In the event that studies cannot be compared directly, results will be synthesized in a narrative account. Between-study heterogeneity will be measured by using the τ^2 statistic. If more than 10 studies are available for pooling, publication bias will be evaluated by using the Egger regression test.

Results: As of January 2023, a total of 3266 abstracts have been identified for screening. Data extraction is expected to commence in February 2023.

Conclusions: The topic of OAT and its effect on pregnancy is an understudied area that has the potential to improve health outcomes, clinical practice, education, and community advocacy. The results of our review will be used to inform clinical practice guidelines and improve health outcomes for pregnant people. Findings will be disseminated to diverse groups of stakeholders, including policy makers, clinicians, community partners, and individuals with lived experience of drug use.

Introduction

Opioid use disorder (OUD) during pregnancy presents a significant risk to maternal, fetal, and neonatal health, increasing the likelihood of adverse events, such as maternal overdose, pregnancy loss, stillbirth, preterm birth, low birth weight, and neonatal abstinence syndrome [1,2]. Although OUD during pregnancy is associated with considerable harms, the withdrawal symptoms associated with sudden cessation are also extremely harmful to both the person who is pregnant and the fetus [3,4].

In order to reduce the risk of these outcomes, the standard of care for OUD during pregnancy in many jurisdictions within the United States and Canada is opioid agonist therapy (OAT) [3]. OATs are prescription medications that alleviate or eliminate opioid withdrawal symptoms so that OUD can be managed more safely. Buprenorphine and methadone are both recommended as first-line treatments in many jurisdictions, with buprenorphine increasingly being recommended as the preferred therapeutic option, given its established safety profile and simple treatment regimen [3]. Other options, such as slow-release oral morphine, can also be used for individuals who do not respond to first- or second-line therapies [3]. The ongoing use of OAT throughout pregnancy is considered safe for both the person who is pregnant and the fetus [3-5].

Although OAT offers a relatively safe option for managing OUD during pregnancy, many health care providers are unfamiliar with how best to prescribe OAT throughout a pregnancy, and many jurisdictions do not have established treatment guidelines. A consistent dosage can be difficult to maintain as the body changes during pregnancy, putting the person who is pregnant at risk of experiencing withdrawal symptoms or overdose both during the pregnancy and post partum [6-8]. These limitations, in combination with the fact that OAT can produce side effects (eg, nausea, vomiting, and constipation) [9] and that some pregnant people may simply prefer to continue using opioids, can increase the complexity of treatment regimens and approaches for ensuring that pregnant people receive prenatal care that is the most appropriate for them.

Although there is considerable literature to suggest that OAT is preferable to opioid use during pregnancy, to our knowledge only 1 systematic review has been conducted that considers the impacts of OAT on pregnancy outcomes. This living systematic review, which was conducted by Minozzi and colleagues [10], offers the most up-to-date evidence from randomized controlled trials (RCTs) to support the use of OAT during pregnancy. However, the authors note that the small number of RCTs considering this topic (n=4) makes it difficult to draw firm conclusions about the relative benefits of different OAT regimens, and further research is still needed [10]. Given the limited number of studies and participants available for inclusion from RCTs, we sought to build upon the existing knowledge base by evaluating observational studies that have been conducted to evaluate impacts of various types of OAT on pregnancy outcomes. Although observational studies include greater bias and heterogeneity when compared to RCTs, the inclusion of additional studies containing larger numbers of participants can offer valuable insights into the real-world impacts of OAT on pregnancy outcomes.

Methods

Protocol and Registration

This systematic review protocol follows the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist [11] and has been registered in the PROPSERO database (ID number: CRD42022332082). The full systematic review will also follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines.

Research Question

The systematic review will seek to address the question “What impact do different forms of OAT have on pregnancy outcomes among pregnant people with opioid use disorder?”

Eligibility Criteria

The population of interest in our review will be pregnant people with OUD. The exposure will be OAT (eg, methadone, buprenorphine/naloxone [Suboxone], slow-release oral morphine, hydromorphone, and naltrexone). The primary outcomes of interest for the review will be preterm birth (ie, gestational age<37 weeks), low birth weight (ie, <2500 g), small for gestational age birth weight (ie, birth weight<10th percentile for gestational age), and stillbirth. Although many other maternal and infant health outcomes are impacted by OAT, we have opted to limit the scale of our results by restricting our analysis to these four outcomes, given the substantially increased risk of these outcomes among people with OUD [12-14] and the widespread availability and uniformity of the data that have been collected on these outcomes, which will facilitate comparisons between studies. Study eligibility criteria are presented in Table 1. Our planned start date for data extraction is February 1, 2023.

Setting	• No restrictions	• None

Information Sources and Search Strategy

We will search MEDLINE, Embase, CINAHL, and PsycINFO to identify studies relevant to our review. Search terms are aligned with the eligibility criteria described above, including variations on "opioid agonist therapy," "pregnancy," "opioid use," and each of the pregnancy outcomes of interest. These terms were used as keywords and mapped onto Medical Subject Headings terms. Our search strategy was developed in consultation with a medical librarian at the University of British Columbia to ensure that there were no major omissions in our approach (the MEDLINE search strategy is presented in Textbox 1).

Study Selection and Data Extraction

From our database searches, we will remove any duplicate articles and then import all articles into Covidence (Veritas Health Innovation Ltd) [15]. Titles and abstracts will be reviewed in 1 stage, followed by a separate full-text screening of the remaining articles. During each stage, studies that do not meet the review criteria will be excluded. Each stage will be conducted by 2 investigators independently and in duplicate. Any disagreements will be resolved by consensus.

A data extraction form will be developed prior to article analysis. Data on study types, settings, sample sizes, types of OAT, primary and secondary outcomes, main study results, and recommendations will be extracted. Extraction will be conducted by 2 investigators independently and in duplicate and then reviewed collaboratively. Any additions that need to be made

XSL•FO
RenderX

to the extraction form will be discussed between the two investigators.

Risk of Bias

Given our inclusion of observational studies, which inherently contain some risk of bias, the risk of bias within individual studies will be assessed by using the CASP (Critical Appraisal Skills Programme) cohort study checklist and CASP case-control study checklist [16]. These checklists comprise 12 and 11 questions, respectively, that seek to analyze a study's validity, results, and clinical utility; bias is assessed with regard to the exposure, outcome, study design, and analysis. Bias in each full-text study will be assessed by 2 reviewers independently using the CASP checklists. Disagreements will be resolved by consensus. Issues such as heterogeneity in outcome measures, OAT dosage, and reporting will be explored as potential issues.

Data Synthesis

A PRISMA flowchart will be developed to indicate the number of articles identified and how many were excluded (including reasons for exclusion) at each stage of evaluation. For studies that consider the same research questions, interventions, or outcomes, meta-analyses will be conducted to quantitatively synthesize the pooled effect size of OAT on each outcome (ie, preterm birth, stillbirth, low birth weight, and small for gestational age) [17]. Subgroup analyses will be conducted by outcome and type of OAT regimen. However, given the likelihood of heterogeneity between studies, a meta-analysis may not be appropriate in all cases. In the event of studies with research designs, interventions, and outcomes that cannot be compared directly, the results of the data extraction will be synthesized in a narrative account [17,18]. Between-study heterogeneity will be measured by using the τ^2 statistic, which captures the variance between studies and is better suited than other measures of heterogeneity to evaluate observational studies with large sample sizes [19]. If more than 10 studies are available for pooling, publication bias will be evaluated by using the Egger regression test [20]. If publication bias is detected, pooled estimates will be adjusted by using the trim and fill technique, which corrects for publication asymmetry [20,21].

Results

A search strategy has been finalized with a medical librarian at the University of British Columbia. The initial search has yielded 3266 abstracts for screening. Data extraction is expected to commence in February 2023, and final results should be available within 6 months of the publication of this protocol.

Discussion

Our proposed systematic review will be the first to synthesize observational data on the effect of different OAT options on pregnancy outcomes for people with OUD. The topic of OAT and its effect on pregnancy is an understudied area that has the potential to improve health outcomes, clinical practice, education, and community advocacy. The results of our review will primarily be used to inform clinical practice guidelines for OAT prescribing practices among pregnant people and subsequently improve health outcomes for both pregnant individuals and their infants. The results of our study will generate pertinent considerations for future research to continue improving the knowledge available on the effect of OAT on pregnancy.

This systematic review faces some limitations. There will be a degree of heterogeneity among the studies selected due to the variability of the research methodologies, settings, and OAT regimens and dosages being studied. We will evaluate this issue during data extraction and will adjust our analysis strategy accordingly. Further, in order to mitigate the risk of reviewer bias, we will have 2 reviewers independently screen and assess (ie, quality assessment) each study in our review. There is also a risk of missing pertinent literature on our research topic. We have consulted a medical librarian at the University of British Columbia and developed a broad search strategy to maximize the likelihood of identifying relevant articles. Lastly, publication bias is a general limitation of systematic reviews. We will attempt to mitigate this issue by including abstracts that have been published within the last 2 years, but we may miss some studies that did not reach the publication stage. We will adjust our conclusions based on evidence of publication bias as appropriate.

Our systematic review will synthesize relevant literature and integrate the vast observational data available on OAT and its impacts on adverse events during pregnancy. The findings of our study will contribute to improved clinical care and health for all pregnant people who use opioids for the duration of their pregnancies and beyond.

Acknowledgments

LAW is supported by a doctoral award from the CIHR (Canadian Institutes of Health Research).

We would like to acknowledge Ursula Ellis, the medical librarian at the University of British Columba, for her assistance in creating the search strategy to be used in the systematic review and Dr Lianping Ti for her guidance in developing the study and protocol.

Data Availability

Data sharing is not applicable to this article, as no data sets were generated or analyzed during the study.

Abstract

Background: Effective dissemination of research to health and social care practitioners enhances clinical practice and evidence-based care. Social media use has potential to facilitate dissemination to busy practitioners.

Objective: This is a protocol for a systematic review that will quantitatively synthesize evidence of the effectiveness of social media, compared with no social media, for dissemination of research evidence to health and social care practitioners. Social media platforms, formats, and sharing mechanisms used for effective dissemination of research evidence will also be identified and compared.

Methods: Electronic database searches (MEDLINE, PsycINFO, CINAHL, ERIC, LISTA, and OpenGrey) will be conducted from January 1, 2010, to January 10, 2023, for studies published in English. Randomized, nonrandomized, pre-post study designs or case studies evaluating the effect of social media on dissemination of research evidence to postregistration health and social care practitioners will be included. Studies that do not involve social media or dissemination or those that evaluate dissemination of nonresearch information (eg, multisource educational materials) to students or members of the public only, or without quantitative data on outcomes of interest, will be excluded. Screening will be carried out by 2 independent reviewers. Data extraction and quality assessment, using either the Cochrane tool for assessing risk of bias or the Newcastle-Ottawa Scale, will be completed by 2 independent reviewers. Outcomes of interest will be reported in 4 domains (reach, engagement, dissemination, and impact). Data synthesis will include quantitative comparisons using narrative text, tables, and figures. A meta-analysis of standardized pooled effects will be undertaken, and subgroup analyses will be applied, if appropriate.

Results: Searches and screening will be completed by the end of May 2023. Data extraction and analyses will be completed by the end of July 2023, after which findings will be synthesized and reported by the end of October 2023.

Conclusions: This systematic review will summarize the evidence for the effectiveness of social media for the dissemination of research evidence to health and social care practitioners. The limitations of the evidence may include multiple outcomes or methodological heterogeneity that limit meta-analyses, potential risk of bias in included studies, and potential publication bias. The limitations of the study design may include potential insensitivity of the electronic database search strategy. The findings from this review will inform the dissemination practice of health and care research.

Introduction

Background

Health and social care researchers aim for their research findings to be accessible and useful for practitioners to help them deliver best, evidence-based clinical care and improve patient outcomes [1-4]. Thus, as part of continuing professional development, practitioners need to access relevant high-quality research evidence [5,6]. Research evidence is defined as information provided by a research study; information may derive from original studies (primary research), reviews (secondary research), or evidence-based guidelines [6]. Effective strategies are required to deliver relevant research evidence to practitioners [2,7,8] because dissemination of research evidence without delay is recommended to maximize its benefits [9,10].

Dissemination is defined as active approaches that use specific channels and planned strategies to get research evidence to a specific audience (who can make use of it and enact research benefits) [10]. Challenges of dissemination to practitioners include organizational barriers, limited professional opportunities, time constraints, and accessing relevant articles within the exponentially increasing volume of research evidence produced each year [8,11-13]. Social media has potential to overcome some of the barriers to dissemination [7,8].

Social media is defined as a collection of web-based platforms that allow the creation and exchange of user-generated content [14]. Open social media are accessible to anyone; closed social media groups have eligibility parameters that limit user participation [15]. The number of people who use social media globally has risen from millions to billions in the last 20 years; its advantages include not being limited in time and space [7,16]. Thus, professional use of social media by health and social care practitioners represents an opportunity for effective dissemination of research evidence [15]. Indeed, social media is increasingly used to disseminate health and social care research [8,15,17-21].

Social media use in health care has been studied and reviewed extensively [22-28]. Reviews concur about benefits and risks of social media for reputation, communication, information sharing, and public health messages. For health care professionals, social media has also been used effectively for education and day-to-day communications [25,29,30].

The existing reviews of social media for dissemination of health care research have narratively synthesized benefits and risks, described similarities, differences, and qualitative experiences, or provided commentaries on the mechanisms and potential uses of social media for dissemination [15,25,26,31]. However, they are heterogeneous in terms of study design and perspectives [15,26,31]. In 2018, a review of reviews about effective uses of social media in public health and medicine included little evidence concerning dissemination [25]. In 2020, a review highlighted 4 research dissemination case studies [26]. An unpublished preprint review, which identified 4 randomized controlled trials and 37 quantitative or descriptive studies, identified Twitter as a prominent platform for dissemination [31]. A subsequent review in 2022 highlighted the communication mechanisms and potential of social media for both 1-way knowledge mobilization (ie, dissemination) and 2-way knowledge mobilization (ie, more complex multidirectional integrated knowledge translation involving collaborative interactions between researchers and practitioners) [15]. The existing reviews are health care focused; no reviews have investigated dissemination to social care practitioners.

Although quantitative reports and comparisons of social media for dissemination of research evidence in health care are emerging [18-20,32], it is not yet clear how consistent or robust their findings are. To date, no quantitative synthesis or meta-analysis has been undertaken to investigate the effectiveness of open social media for dissemination of research evidence to health and social care practitioners.

Objective

The objective of this systematic review is to quantitatively synthesize evidence of the effectiveness of social media, compared to no social media, for dissemination of research evidence to health and social care practitioners. The social media platforms, formats, and sharing mechanisms used for effective dissemination of research evidence will also be identified and compared.

The specific research questions are as follows: (1) how effective is open social media for dissemination of research evidence for health and social care practitioners, compared to no social media input? (2) Which social media platforms, formats, and sharing mechanisms are used for dissemination of research evidence for health and social care practitioners? (3) What is the comparative effectiveness for dissemination of research evidence to health and social care practitioners between different social media platforms (eg, Facebook vs Twitter), different formats of social media posts (eg, text vs infographic vs video), and different social media–sharing mechanisms (eg, site-wide shares vs special interest groups vs live social media events vs influencer endorsements)

Methods

Design

The inception and design of this systematic review, of articles available from January 1, 2010, to January 10, 2023, incorporated patient and public involvement via consultations with a stakeholder group. This protocol follows PRISMA-P (Preferred Reporting Items for Systematic Reviews and

XSL•FO
RenderX

Meta-Analyses) guidelines [33]. The protocol has been registered with the International Prospective Register of Systematic Reviews (PROSPERO; registration number: CRD42022378793).

Eligibility

Table 1 summarizes the population, intervention, comparisons, and outcomes of interest. The target population will be practitioners, defined as health and social care professionals, including, but not limited to, some of the largest groups of registered practitioners in the United Kingdom; that is, nurses, doctors, social workers, midwives, pharmacists, physiotherapists, occupational therapists, radiographers, and paramedics [34-38]. We will include both individual professions and collective groups of practitioners.

Table 1. Definitions of participants, intervention, comparisons, and outcomes. The numbers in square brackets denote prioritization for analyses if more than one outcome is reported in a single study, according to the most reported outcomes. Prioritization will ensure outcomes are only represented once per study in quantitative synthesis and meta-analysis.

Term	Definition
Participants	
Practitioners	• Postregistration health and social care professionals, either as groups incorporating a range of disciplines (eg, workers at hospitals and other health and social care settings, clinicians and health and social care professionals) or as individual professions (eg, the largest registries of UK practitioners include 758,303 nurses and midwives [34], 355,250 doctors [35], 91,191 social workers [36], 79,628 pharmacists and pharmacy technicians [37], 60,783 physiotherapists [38], 41,732 occupational therapists [38], 39,497 radiographers [38], and 33,219 paramedics [38], and other disciplines. Similar profiles of common health and social care professions were expected in other geographical locations).
Intervention	
Research evidence	• Human, health and social care–related research, originating from published, peer-reviewed journal articles, that could be relevant for practitioners. Information posted on social media might be a direct link to these research articles, abstracts, or repackaged information from a single peer-reviewed research article source; eg, summaries such as microblogs, blogs, press articles, conference presentations or posters, infographics, or educational videos.
Social media	• Open social media platforms, including, but not limited to, social networking and media-sharing sites and apps, that allow any user to make a one-to-many post and to interact by responding to posts. The largest of these social media sites in 2018 in terms of active users included Facebook (2.26 billion), YouTube (1.90 billion), WhatsApp (1.33 billion), Instagram (1 billion), WeChat (1 billion), Tumblr (624 million), TikTok (500 million), Reddit (355 million), Twitter (329.5 million), and Pinterest (245.5 million) [16].
Comparison	
Dissemination	• Comparison of effectiveness of dissemination to practitioners using open social media vs no social media (between and within group comparisons) and comparison between social media platforms, sharing mechanisms, and formats.
Outcomes	
Reach	• Number of practitioners who access a research evidence–related social media post. • Number of impressions [1], views [2], or accesses [3] of a research evidence–related social media post.
Engagement	• Number of positive responses (eg, likes) to a research evidence–related social media post. • Number of interactions (eg, shares [1], comments [2], or fresh social media posts triggered [3]) with a research evidence–related social media post.
Direct dissemination	• Number of times an original research article is accessed (eg, link clicks [1] or HTML views [2]). • Number of times an original research article is downloaded (eg, PDF download). • Altmetric score of an original research article.
Impact	• Number of citations [1] of an original research article or [2] impact factor of journal. • Measures of changes in thinking or practice of health and social care practitioners linked to a research evidence–related social media post targeted at health or social care practitioners.

The intervention will be open social media used for dissemination of research evidence. We define research evidence as information from peer-reviewed articles featuring empirical findings that have met the publication standards of their specialty. Evidence may take the form of an original research article, or a group of original research articles identified and synthesized systematically. In this review, only research evidence that is professionally relevant to health and social care practitioners will be considered; however, our definition includes open-access research evidence (and social media posts where practitioners are the target audience), even when other audiences, like the general public, also have access.

XSL•FO
RenderX

We define open social media as social networking and media-sharing sites or platforms that allow any user to make a one-to-many post and to interact by responding to posts. Our definition of social media differs from broader existing definitions of social media, such as that of Kaplan and Haelein [14], who consider social media as web-based applications that allow the creation and exchange of user-generated content. Our more focused definition was used to target social media with the greatest potential for knowledge mobilization between the different communities of research and clinical settings. The current literature in knowledge mobilization has highlighted the importance of open, 2-way interaction to create linkage between communities and facilitate knowledge sharing. In this context, dissemination of research is an active, relational, multidirectional, and collaborative process that interacts with the standpoint of those who access, share, discuss, and use it [39,40]. Thus, we do not include mass media press articles, wikis, and blogs with no, or limited, facility for user interactions, purely communication-based applications or closed, fee-paying, or invite-only social media groups. However, these will be considered if they are highlighted using open social networking or media sharing sites, used as part of onward information sharing, or are groups that can be freely joined by any interested user (eg, by following a link available on open social networking and media-sharing sites).

We define social media–sharing mechanisms as the ways in which research evidence might be featured or interacted with, including, but not limited to, open sharing to the entire forum, live social media events, influencer endorsement, and accessible special interest groups that can be joined or followed. We define social media formats as including a variety of media types, including, but not limited to, text, illustrative pictures, visual abstracts, infographics, videos, and podcasts.

The study inclusion and exclusion criteria are summarized in Textbox 1. Full-text, English-language studies will be included if they make quantitative comparison between dissemination of research evidence for health and social care practitioners using social media versus a controlled “no social media” condition (between group). Studies will also be included that quantify changes from baseline conditions to follow-up after an open social media campaign for dissemination of research evidence to health and social care practitioner (within group or case series data). Studies quantitatively comparing dissemination of research evidence for health and social care practitioners between different social media platforms, sharing mechanisms, and formats will also be included. Studies comparing topics of social media posts or research evidence will be excluded.

Textbox 1. Summary of inclusion and exclusion criteria.

Inclusion criteria:

- Peer-reviewed journal articles, study types including randomized controlled trials, case-controlled comparisons nonrandomized comparisons, pre-post designs, cohort studies, and case reports.
- Articles published after 2010.
- English-language articles or translations in English available.
- Articles that quantitatively evaluate and compare open group social media in terms of reach, engagement, dissemination, and impact of research evidence for postregistration health and social care practitioners.

Exclusion criteria:

- Study types including protocols, reviews, opinion pieces, and conference abstracts.
- Articles published before 2010.
- Articles not available in English.
- Study populations not including health and social care practitioners (eg, no mention of practitioners, only focused on students, service users, patients, or the general public).
- Social media interventions used only for sharing non health and social care–related research topics or other sorts of information (eg, multisource clinical education delivery, day-to-day interpersonal communications, and organizational or administrative information), closed, private, or invite-only groups, professional identity and reputation purposes, recruitment, or posts without a social networking component (eg, a blog or press article without signposting on social media networking sites).
- Comparisons between information topics only (without other comparisons, eg, between social media and control conditions, or between social media sites, or types of media).
- Articles that do not provide sufficient quantitative data on outcomes of interest or those reporting only qualitative data.

Information Sources

Searches will be carried out from January 1, 2010, to January 10, 2023. Preliminary searches revealed that there was unlikely to be relevant literature prior to 2010; whereas after 2010, reports of social media use in research dissemination increased. Searches will be carried out in electronic bibliographic databases including MEDLINE (Ovid), PsycINFO (Ovid), CINAHL plus (EBSCO), ERIC (EBSCO), LISTA, and OpenGrey. Search engines, including PubMed, elicit, and Google Scholar, will also be used for citation searches and reference harvesting. Bibliographic hand-searching of relevant systematic reviews and included articles will also be carried out. The search strategy

XSL•FO
RenderX

is likely to be adequate to ameliorate selection and detection biases.

Search Strategy

The search strategies were informed by previous review searches [15,31,41] (see the search terms in Table 2 and the example search strategies in Multimedia Appendix 1).

Table 2. Summary of key search terms.

Key term	Search terms
Practitioners	• [Health, healthcare, health care, medical, hospital, social care] and [practitioner, professional, provider, staff, employee] or clinician • Nurse, midwife, doctor, physician, social worker, pharmacist, physiotherapist, physical therapist, occupational therapist, radiographer, or paramedic
Intervention	• Research evidence, information, research, data, knowledge, dissemination, sharing, knowledge mobilisation, knowledge translation.
Social media	• Social media, social network, open network, media sharing, social web, or social software • Facebook, YouTube, WhatsApp, Instagram, WeChat, Tumblr, TikTok, Reddit, Twitter, Pinterest, Flickr, Googl,, microblog, podcast, webcast, Tweet, or video sharing
Outcomes	• Dissemination, reach, engagement, impact, quantitative, evaluation, comparison, access, views, impressions, likes, share, comments, posts, HTML views, altmetric, download, citation, in practice, knowledge use
Timeframe	• January 2010-January 2023
Language	• English
Subjects	• Human

Data Management

The search results will be exported to, and deduplicated in, Endnote online (Clarivate), then imported into Rayyan software (Rayyan Systems) for title, abstract, and full-text screening [42].

Selection of Studies

Two reviewers (SRL and SQM) will independently screen titles and abstracts for eligibility. Potentially eligible studies will be obtained in full text and the eligibility criteria applied. Two of 5 independent reviewers (from a team including SRL, SQM, LB, HG, and FL) will screen all full-text articles against the eligibility criteria. If no consensus can be reached between reviewers, eligibility will be settled by a third reviewer (HB). Articles will be included only if they provide sufficient quantitative data to allow extrapolation of mean (SD) outcome data per social media post for 2 comparable groups. Reasons for article exclusion will be recorded according to the PRISMA recommendations [43].

Data Extraction

The data will be extracted from included full-text articles by 2 of 5 reviewers (SRL and SQM/LB/HG/FL) independently using a data extraction form developed a priori and adapted from the previous relevant reviews [26,31] (see Multimedia Appendix 2). Consensus on extracted data accuracy will be achieved by discussion and settled by a third reviewer (HB) in the case of disagreement. Corresponding authors of eligible studies will be contacted to request additional data when required.

Outcome Data

The quantitative outcomes will be grouped into 4 domains (reach, engagement, dissemination, and impact; Table 1) [27,44]. Outcome measures will be grouped by domain because a heterogeneous range of outcomes and study designs are characteristic of the social media literature [15,25]. There is no primary outcome because dissemination of research evidence via social media is a complex multidimensional behavior that cannot be distilled into a single outcome [25,27]. Different outcomes measuring the same concept will be combined for meta-analysis wherever appropriate. Where multiple outcomes reporting the same concept are reported in a single study, hierarchical outcome prioritization will be used, preferentially selecting the most frequently reported variables (see Table 1).

The difference between group means for each comparison group will be obtained, or the mean difference from baseline to follow-up in pre-post designs. To accompany means, SD and 95% CI will be extracted. Wherever possible missing means and SDs will be calculated from other reported statistics (eg, median and IQR, as per Cochrane Handbook instructions Section 5.6 and Chapter 6) [45]. For each outcome, data will be simplified by dividing by the number of social media posts, to yield comparable quantitative data per research evidence–related social media post.

Risk of Bias and Quality Rating of Evidence

For randomized controlled trials, the Cochrane tool for assessing risk of bias (ROB-2) will be used [46]. For nonrandomized controlled trials, the Newcastle-Ottawa Scale (NOS) [47] will be used to assess risk of bias, as per 2019 Cochrane recommendations [45]. Both the ROB-2 and the NOS will be

XSL•FO
RenderX

adapted to suit the types of studies selected in this systematic review because studies testing social media dissemination are unlikely to use typical participant grouping designs. The NOS was selected in preference to the latest Cochrane tool for assessing risk of bias in nonrandomized studies (ROBINS; consisting of ROBINS-I for intervention studies and ROBINS-E for exposure studies [48,49]). This was because the complexity of these tools will not allow adaptation to alternative study designs and 1 tool (ROBINS-E for exposure studies) is still in development.

ROB-2 consists of 34 items, divided into 6 scoring domains that differentiate between lower risk of bias and higher risk of bias [46]. The maximum rating of the NOS is 9, a score of 0-3 is considered high risk of bias, 4-6 considered a medium risk of bias, and 7-9 considered a low risk of bias (Multimedia Appendix 3) [47]. Risk of bias will be included in results tables and figures that describe each included study.

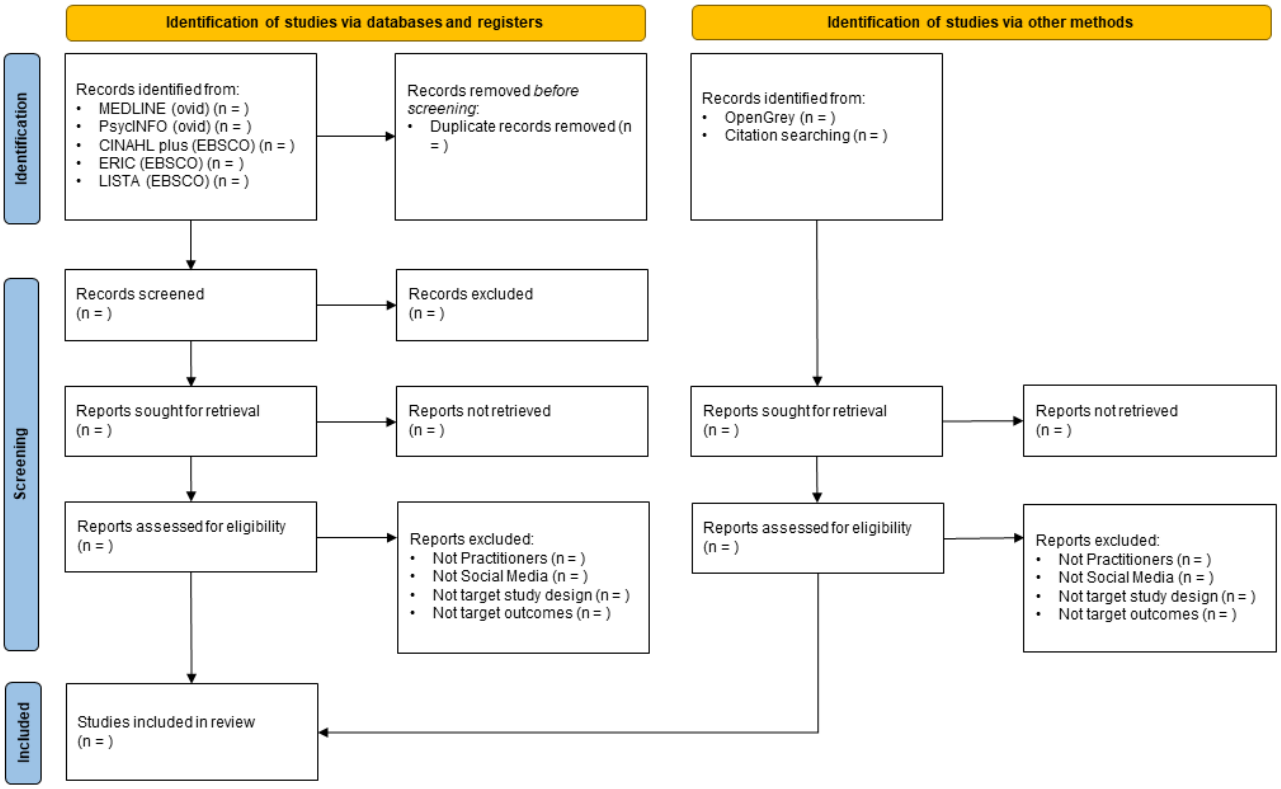
Data Synthesis

Results will be summarized narratively with text, tables, and figures. Quantitative comparisons between studies and groups will include mean, SD, and simplified group means weighted per research evidence–related social media post.

Between, and within for pre-post designs, group differences, SDs, and standardized effect sizes (eg, Cohen *d* or Hedges *g*) will be used to compare effects between included studies. Effect sizes of ≥0.8 will be defined as large, ≥0.5 as moderate, and ≥0.2 as small [50].

For outcomes that are available in a sufficient number of studies, pooled effects will be tested in meta-analyses using RevMan (version 5.3; The Cochrane Collaboration). Heterogeneity will be tested using I^2. To test pooled effects, a fixed-effects model will be used if I^2 is less than 50% or a random-effects model will be used if I^2 is greater than 50%. If a comparison has I^2>75% it will be removed from meta-analysis and synthesized narratively instead. Subgroup analyses will be used for heterogeneous study groups. Publication bias will be assessed using funnel plots.

Confidence in Cumulative Evidence



For each outcome, the uncertainty of the evidence base will be evaluated based on the grading of recommendations assessment, development, and evaluation approach [51]. This includes the following 5 domains: study limitations, imprecision, indirectness, inconsistency, and publication bias. The grading of recommendations assessment, development, and evaluation domains will be used to upgrade or downgrade evidence after initial assessment. Quality of evidence will be categorized as high, moderate, low, or very low [52,53].

Results

Searches and screening will be completed by the end of May 2023 and recorded in a PRISMA flowchart (Figure 1) [43].

Data extraction and analyses will be completed by the end of July 2023, after which findings will be synthesized.

Discussion

Overview

We expect that this study will be completed by the end of October 2023. This review will synthesize evidence of the effectiveness of open social media for dissemination of research evidence to health and social care practitioners. We anticipate that we will find evidence that social media is effective, although there may be variation between its effect on the 4 outcome domains (reach, engagement, direct dissemination, and impact).

The previous reviews have highlighted the potential of social media for a variety of purposes in health care [15,25,26,31,54], although dissemination of research evidence currently accounts for only 1% of health research concerning social media [55]. Two existing reviews suggest that social media might be effective to improve direct dissemination and impact of research articles [31] and reach and engagement with clinical guidelines [54]; however, quantitative syntheses and meta-analyses were not performed.

Qualitative reviews have highlighted strategies that may enhance the dissemination of research evidence on social media [15,26,31,54]. These include enlisting people with expertise in social media at the planning stage, using professional social media marketing services and involving target users in content design. Use of multiple social media platforms is implicated, although Twitter is most often highlighted for professional use. Social media formats include using media that are accessible, relevant, useful, authentic, credible, and visually appealing to target users, a range of multimedia formats (including good quality images and infographics, text, videos, and podcasts, with images highlighted as being particularly important for social media reach and engagement). Social media–sharing mechanisms include involving key influencers and networks with the most connectedness in the field (such as organizational newsletters, journals, or individuals) to enhance social filtering, creating or enlisting existing web-based communities of practice, identifying and using key hashtags, posting at planned times (potentially including weekdays, weekday evenings, and weekends), posting regularly for a sustained campaign, and coordinating engagement events (such as journal clubs, question and answer sessions, or live interviews).

This systematic review will be the first to use quantitative, meta-analytical synthesis of evidence for the effectiveness of social media for research dissemination to practitioners. The limitations of the evidence may include multiple outcomes or methodological heterogeneity that limit meta-analyses, potential risk of bias in included studies, and potential publication bias. The limitations of the study design may include potential insensitivity of the electronic database search strategy to specific professional disciplines or social media platforms; however, bibliographic citation searching of included articles and relevant systematic reviews is likely to compensate for this. As social media are rapidly evolving, this systematic review will need to be repeated regularly to consider the impact of new and favored platforms and the search strategy revised to account for this.

The conclusions of this systematic review will inform the use of social media for the dissemination of research evidence to health and social care practitioners. This information will be important for researchers, research funders, and governmental bodies who have a remit to share their research evidence to inform practice and care. The findings of this review could be complemented by investigation of different practitioners' attitudes and experiences of professional social media use so that targeted dissemination strategies could be developed. Future research directions include quantitative synthesis and meta-analysis of evidence for the effectiveness of closed social media groups for the dissemination of research evidence to health and social care practitioners. The interaction between closed and open social media may enhance knowledge sharing and engagement [15].

Dissemination Plan

The findings from this systematic review will be disseminated through a peer-reviewed journal article, presentations at academic conferences and promoted using social media.

Acknowledgments

This study presents independent research funded by National Institute of Health and Care Research (NIHR) UK (NIHR evidence [2022/01]). The views expressed are those of the authors and not necessarily those of the National Health Service, the NIHR, or the Department of Health.

Data Availability

The data sets generated and analyzed during this study will be available from the corresponding author on reasonable request. The full search strategy is available in Multimedia Appendix 1.

Abstract

Background: Transcranial magnetic stimulation (TMS) is a widely used noninvasive brain stimulation technique for psychiatric and cognitive disorders. In recent years, deep TMS (dTMS) has shown promise as an enhanced form of TMS able to stimulate deeper brain structures and target broader networks. Various magnetic Hesed-coil (H-coil) designs—a novel feature of dTMS—have been used to stimulate brain regions implicated in the pathophysiology of specific psychiatric and cognitive disorders, thereby producing therapeutic effects. Given the novelty of dTMS in psychiatry, little is known about the clinical efficacy of dTMS across psychiatric and cognitive disorders—that is, whether dTMS performs superiorly to sham or control.

Objective: In this paper, we outline a protocol for a systematic review investigating the clinical efficacy of dTMS. The primary objective is to conduct a systematic review of the literature on dTMS for psychiatric and cognitive disorders and, if feasible, a meta-analysis to compare the efficacy of active dTMS versus sham/control for psychiatric disorders. Dementia and related cognitive disorders will also be examined. A secondary objective will be to examine subgroup differences (by age, sex, H-coil design, and dTMS parameters [ie, pulses per session, percentage of motor threshold, etc]) to evaluate whether dTMS differentially influences clinical outcomes based on these factors.

Methods: A comprehensive search of the APA PsycINFO, Embase, MEDLINE, and PubMed databases will be conducted using keywords such as “H-coil” and “dTMS.” Two authors (AD and MD) will be responsible for screening relevant articles, assessing article eligibility (according to predetermined inclusion and exclusion criteria), and data extraction. All included articles will undergo a quality and risk of bias assessment. Data from included articles will be summarized qualitatively in a systematic review. If a sufficient number of equivalent studies are available, a meta-analysis will be performed to (1) determine the effect of active versus sham dTMS (or another control arm) across psychiatric and cognitive disorders, and (2) examine subgroup effects of clinical outcomes.

Results: The preliminary search rendered a total of 1134 articles from the APA PsycINFO, Embase, and MEDLINE databases. After full-text screening, 21 eligible articles remained. One additional article was identified from the references section of an existing systematic review. In total, 22 eligible articles were included. Data extraction and quality of assessment procedures are ongoing.

Conclusions: We will outline the evidence relating to the clinical efficacy of dTMS in various psychiatric and cognitive disorders. The results of the prospective systematic review will provide clinicians with valuable insight into the clinical (ie, participant age,

XSL•FO
RenderX

sex, psychiatric or cognitive disorder, etc) and methodological factors (ie, H-coil design, dTMS parameters, etc) which may contribute to dTMS efficacy, and thereby may assist clinicians in their decision to prescribe dTMS for specific psychiatric and cognitive disorders.

Introduction

Psychiatric [1,2] and cognitive disorders [3] are leading causes of disability and burden worldwide and are associated with substantially poorer quality of life [4-7]. From 1990 to 2019, the number of disability-adjusted life-years due to psychiatric disorders has increased globally from 80.8 million to 125.3 million. [2] Of greater concern, it is estimated that 20%-60% of patients with psychiatric disorders are treatment-resistant to first-line medications [8]. In particular, treatment resistance occurs in approximately one third of patients with major depressive disorder [9,10], 30%-60% of patients with schizophrenia [11-13], and 40%-60% of patients with obsessive-compulsive disorder [14,15]. As for cognitive disorders, dementia is on the rise as a leading cause of global mortality [16]. Further, older adults with mild cognitive impairment show an increased risk of mortality [17,18]. Currently, there are no effective treatment options to delay the progression of mild cognitive impairment and dementia [19], nor are there effective interventions to manage the behavioral and psychological burdens of such conditions [20-23].

Given the prevalence of treatment resistance in response to first-line pharmacological interventions in psychiatric disorders, as well as the lack of available treatment options to effectively treat and manage cognitive disorders, new effective treatments are urgently needed. One such technique is brain stimulation.

Brain stimulation methods have shown increasing promise and widespread acceptance as nonpharmacological interventions to treat various psychiatric [24,25] and cognitive disorders [26,27]. Electroconvulsive therapy [28] and transcranial magnetic stimulation (TMS) [29,30] are the most commonly used treatments, which involve the stimulation of the brain through electrical currents and magnetic pulses, respectively. Traditional single-pulse TMS is used to explore brain functioning, whereas repetitive TMS (rTMS) is administered to induce brain activity that lasts beyond the stimulation period [31]. These noninvasive stimulation techniques offer potentially propitious therapy for neurological and psychiatric disorders [32]. Research on other therapy options, such as vagus nerve stimulation [33,34] and deep brain stimulation [35-37], have continued to accumulate, offering further insight into these treatment options for psychiatric disorders.

Another promising method—known as deep TMS (dTMS)—is a noninvasive technique allowing for stimulation of deeper cortical areas and presumably deeper neural networks [38,39]. Since the approval of dTMS in 2013 by the US Food and Drug Administration for major depressive disorder [40], this method of intervention has gained popularity for the treatment of diverse psychiatric disorders.

The aim of dTMS is to modulate brain activity by applying an electrical current over the scalp. Brief magnetic pulses cause widespread neural depolarization in deep regions of the brain, resulting in reduced focal distribution of the electric field [41]. Trains of pulses can be delivered at high-frequency stimulation (>5 Hz) to increase neuronal excitability or at low-frequency stimulation (~1 Hz) to reduce neural excitability [42]. The use of a Hesed-coil (H-coil) dTMS system is a relatively novel noninvasive method that stimulates deeper regions of the brain in comparison to traditional rTMS [43,44]. While traditional TMS figure-8 coils generally stimulate subdural cortical targets up to 0.7 cm [44], dTMS target areas are up to 4 cm beneath the surface depending on the chosen H-coil [45]. More than 20 different types of H-coils have been developed to effectively stimulate specific brain structures [46]. The H-coil configuration received clearance from the US Food and Drug Administration for the treatment of major depression (H1-coil), obsessive-compulsive disorder (H7-coil), and smoking cessation (H4-coil), and anxious depression, in 2013, 2018, 2020, and 2021, respectively. Various H-coil designs have been shown to be safe and efficacious in the treatment of various neuropsychiatric conditions [47-49].

H-coils have complex winding designs and broad dimensions to encompass a larger surface area for stimulation of the electric field [46]. The different types of H-coil designs reflect the subdural depth and volume of stimulation, as well as the region of stimulation. The H1-coil was designed to stimulate the bilateral prefrontal cortex with preference to the left dorsolateral prefrontal cortex of approximately 1.8 cm subdurally [50]. The volume of stimulation for the H1-coil configuration typically encompasses 18 cm^3 [51]. Further, the H7-coil design primarily stimulates 3 cm of subdural depth and 40.3 cm^3 of breadth in the medial prefrontal cortex and anterior cingulate cortex [51], while the H4-coil targets the bilateral insula and ventrolateral and dorsolateral prefrontal cortex with a depth of 1.5 cm and a volume of 15.2 cm^3 [45]. In comparison, the traditional figure-8 coil used in rTMS stimulates 0.7 cm below the scalp, encompassing a volume of 3 cm^3 [51]. The most commonly used dTMS protocol involves high-frequency (18-20 Hz) and high-intensity (120% of the resting motor threshold) stimulation delivered for 20 days [41].

XSL•FO
RenderX

Given the increasing interest in the application of dTMS in psychiatry [52], it is critical that its clinical effects are systematically appraised. As dTMS is a relatively novel form of therapy for psychiatric and cognitive disorders, assessments of its clinical efficacy are limited within the empirical body of literature.

A single systematic review and meta-analysis have examined the clinical efficacy of dTMS for treatment-resistant depression [52]. The authors highlight dTMS as an effective intervention, especially when administered in conjunction with antidepressants. However, systematic reviews examining the clinical efficacy of dTMS for other psychiatric conditions remain sparse. One systematic review [53] explored the effects of rTMS in patients with posttraumatic stress disorder. However, only 1 sham-controlled dTMS study [49] was included in this review. Another systematic review [54] examined the effects of dTMS for substance use disorders; however, clinical efficacy was not appraised due to the limited number of sham-controlled trials.

To date, no systematic review has investigated the clinical efficacy of dTMS across multiple psychiatric and cognitive disorders, as determined by the examination of sham-controlled or controlled (without sham coil) trials. There is a growing need for a new systematic review to synthesize the findings of recent dTMS clinical trials in patients with various psychiatric and cognitive disorders, including Alzheimer disease [55], attention-deficit or hyperactivity disorder [56], obsessive-compulsive disorder [57], posttraumatic stress disorder [58], and substance use disorder [59]. Thus, the objective of the proposed systematic review and prospective meta-analysis is to compare the efficacy of dTMS active treatment versus sham stimulation (or another type of control treatment) across psychiatric disorders and pertinent cognitive disorders.

Specifically, the proposed systematic review that follows this paper's protocol will aim to:

1. Systematically review and summarize existing research to examine the clinical efficacy of dTMS versus sham/controls for psychiatric disorders and (if available) cognitive disorders.
2. Integrate statistical results of included clinical trials in a meta-analysis, if feasible (ie, adequate numbers of substantively equivalent studies are present), to determine the effect of dTMS active stimulation versus sham (or control arm) across psychiatric and pertinent cognitive disorders.
3. Conduct subgroup analyses (by age, gender, coil design, and dTMS parameter) to determine if dTMS differentially influences clinical outcomes within these subgroups.

Methods

Search Strategy

A systematic search of the PubMed, APA PsycINFO, Embase, and MEDLINE databases will be conducted to identify relevant articles. The Cochrane database will also be explored for pertinent articles. Two authors (AD and MD) will be responsible for independently conducting the searches. The core keywords used in the searches will include "dTMS," "deep rTMS," "deep TMS," "deep transcranial magnetic stimulation," and "H-coil." Table 1 provides a summary of the search terms that will be used for each database. Automatic filters will be applied to limit search results to clinical trials and randomized controlled trials. No date limits will be applied. Moreover, a manual search of existing meta-analyses and systematic reviews on dTMS for psychiatric and cognitive disorders will be conducted to identify other potential articles from the reference section.

Table 1. Search strategies used to identify relevant articles from databases. Searches will be limited to clinical trials and randomized controlled trials written in English. No date limits will be applied.

Databases	Search strategy	Final search terms
PubMed, Cochrane, and OVID (APA PsycINFO, Embase, and MEDLINE)	1. dTMS 2. "deep TMS" 3. "deep transcranial magnetic stimulation" 4. "deep rTMS" 5. "deepTMS" 6. "H-coil*" 7. "H coil*"	1 or 2 or 3 or 4 or 5 or 6 or 7

Study Selection: Inclusion and Exclusion Criteria

All articles will be independently screened and assessed for eligibility by 2 authors (AD and MD) according to the predetermined inclusion criteria. We will include clinical trials reporting the clinical effect of dTMS interventions for psychiatric and cognitive disorders compared to a sham-controlled or control arm. The full inclusion and exclusion criteria are presented in Textbox 1.

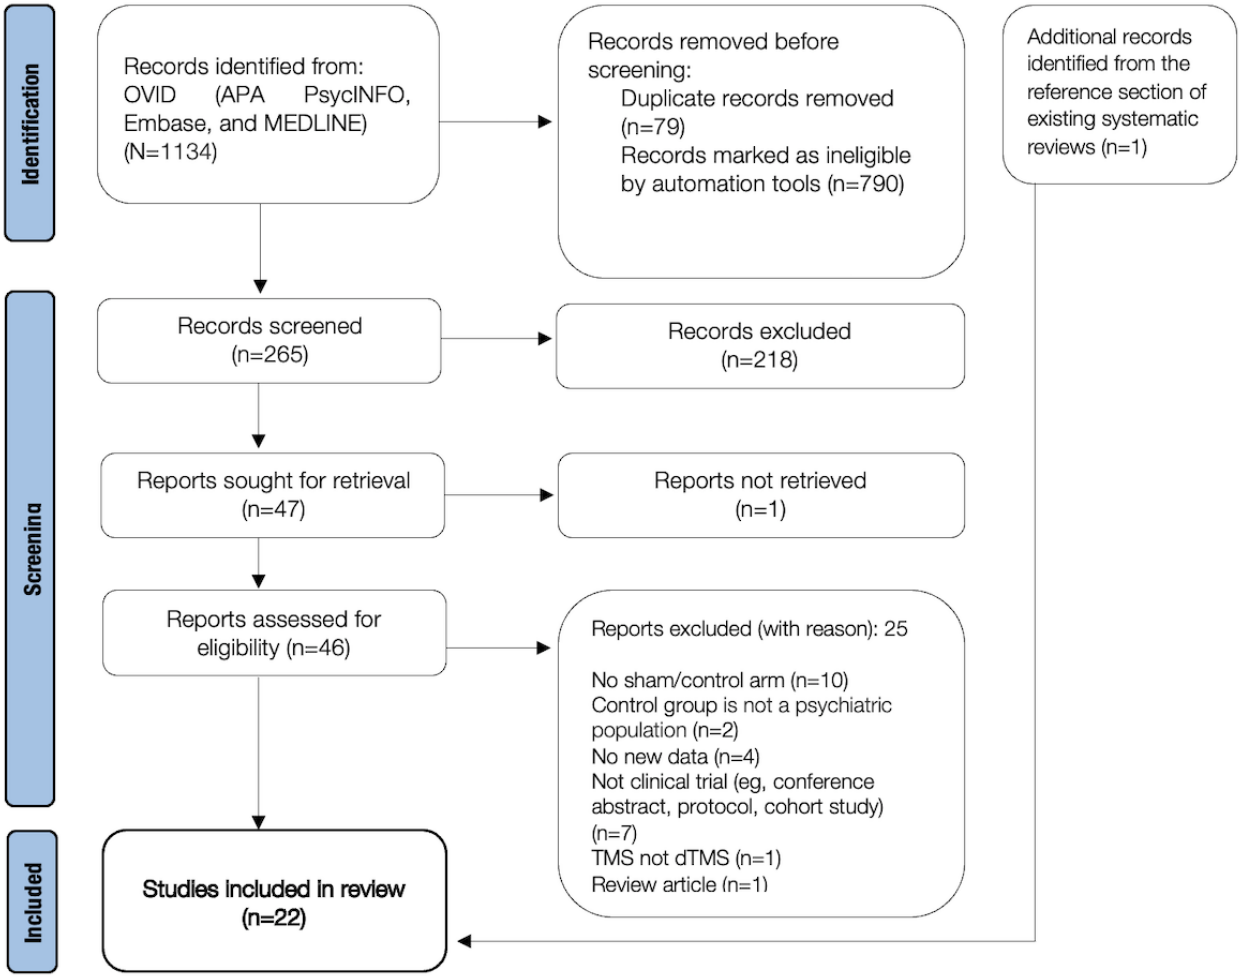
XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Article type
  - Clinical trials and randomized controlled trials
  - Studies including a sham or control condition
  - Studies comparing active deep transcranial magnetic stimulation to a sham or control condition
  - Articles of any publication year
- Study participants
  - Participants with a valid diagnosis of a psychiatric or cognitive disorder according to a recognized diagnostic manual (ie, the Diagnostic and Statistical Manual of Mental Disorders, Fourth or Fifth edition [DSM-IV, DSM-5], the International Classification of Diseases, Eleventh edition [ICD-11]), or a clinician
- Language
  - Articles written in English

Exclusion criteria:



- Article type
  - Conference abstracts
  - Letters to the editor
  - Books
  - Literature reviews, systematic reviews, or meta-analyses
  - Case reports or case studies.
- Study participants
  - Participants are healthy individuals
- Language
  - Articles not written in English

Article Screening

Two authors (AD and MD) will conduct the abstract and full-text screening of relevant articles. Articles will be screened in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) [60] guidelines. In line with PRISMA guidelines, authors are required to report the number of records identified, included, and excluded articles (with reasons) at each stage of the screening process. PRISMA guidelines help authors ensure that potentially eligible records are being appropriately sorted and organized throughout the early systematic review process. Articles that meet the inclusion criteria upon the initial abstract screening will then become eligible for the full-text screening. Articles that meet the inclusion criteria after the full-text screening will be included in the review. The number of articles included and excluded (and the reasons for exclusion) will be reported at each stage in the screening process and will be visually represented by a PRISMA flowchart (Figure 1). The 2 reviewers (AD and MD) will consult with each other in the case article eligibility is unclear. Article eligibility discrepancies that cannot be resolved by the 2 reviewers (AD and MD) will be resolved by a third reviewer (JM).

XSL•FO
RenderX

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flowchart. The title-abstract and full-text screenings of potentially eligible reports were performed. Articles were excluded at each stage of the screening progress according to the inclusion and exclusion criteria. dTMS: deep transcranial magnetic stimulation; TMS: transcranial magnetic stimulation.

Risk of Bias and Quality Assessment

All articles will be assessed according to the grading of recommendations, assessment, development, and evaluations (GRADE) checklist [61,62] to evaluate the quality of data and risk of bias. Two reviewers (AD and MD) will rate articles as having a "high" or "low" risk of bias. Specifically, included articles will be assessed for selection bias, performance bias, detection bias, attrition bias, and reporting bias. Selection bias will be evaluated by identifying whether researchers used a random sequence generation and allocation concealment. Assessment of performance bias will involve determining if study personnel and participants were blinded. To calculate detection bias, reviewers will verify if studies implemented a blinding of outcome assessment. Attrition bias will be assessed by determining if at least 80% of enrolled participants were included in the final analyses (ie, comparing intention-to-treat participants to per-protocol analyses). We will also assess article quality by taking into consideration participant sample sizes and study design (ie, inclusion of control condition, baseline vs posttreatment assessment of psychiatric or cognitive symptoms) while determining the clinical efficacy of dTMS treatment.

Data Extraction

The following data variables will be extracted from each included article: country of publication, study type, comparison type (ie, active dTMS vs sham, or standard drug therapy, or another control type), participant sample size, participant sex, and mean age. The psychiatric or cognitive disorder diagnosis and diagnostic criteria (eg, Diagnostic and Statistical Manual of Mental Disorders, 4th edition; Diagnostic and Statistical Manual of Mental Disorders, 5th edition; International Classification of Diseases, 11th edition) of patients will be recorded. Regarding treatment procedures, this study will report treatment duration, number of treatment sessions, H-coil type, and the brain regions of interest (ie, target region of stimulation). Additionally, this study will report the dTMS parameters, including frequency (Hz), intensity, pulses per session, time per session, trains per session, and intertrain interval duration. Posttreatment comparisons between dTMS efficacy in active versus sham/control groups will be reported, including data on remission rates, response rates, or posttreatment score changes on psychiatric and cognitive rating scales. Remission criteria and response criteria will also be reported. Additionally, we will include data related to side effects and adverse events. Table 2 provides an outline of the specific variables that will be extracted from studies, with respect to sample characteristics,

XSL•FO
RenderX

dTMS parameters, clinical efficacy outcomes, and study design. Data from included articles will be collected and stored using Excel (Microsoft Corp) or other equivalent software. Additionally, quality assessment according to the GRADE guidelines [61,62] will be conducted for each article and recorded in a table.

The proposed systematic review will evaluate the clinical efficacy of dTMS for psychiatric and cognitive disorders by comparing active versus sham dTMS treatment groups (ie, sham-controlled trials), as well as active versus control groups (ie, without a sham coil). To do this, we will compare response rates, remission rates, and the overall efficacy of the dTMS treatment in active versus sham/control conditions. Additionally, if at least 4 substantively equivalent investigations are present in a given area, we will perform a meta-analysis to ascertain aggregate clinical effects across studies in sham/control trials. Further subgroup analyses will be conducted on age, sex, H-coil type, and dTMS parameters to the extent possible. Risk of bias and article quality assessments will be used when considering evidence and analyzing data from included studies. Moreover, the study will summarize the proposed review's findings on the clinical efficacy of dTMS for psychiatric and (if available) cognitive disorders, identify evidence that may assist clinicians in their practice, and highlight future directions for research.

Table 2. Study characteristics that will be recorded from eligible articles.

Information category	Data to be extracted
Sample characteristics	• Age • Gender • Psychiatric or cognitive disorder diagnosis • Diagnostic criteria • Sample size
Deep transcranial magnetic stimulation (dTMS) parameters	• Brain region of interest (ie, location of brain stimulation) • Coil type or design (ie, H-coil variety) • dTMS stimulation frequency (Hz) • dTMS stimulation intensity (MT%) • Pulses per session • Time per session (min) • Trains per session; inter-train intervals
Results: clinical efficacy	• Test statistics for active versus sham/control group comparisons • Test statistics for subgroup comparisons (ie, age, sex, dTMS parameter, coil design, etc) • *P* values, CI values, t test values, Cohen d, Hedges g (where reported), for active vs sham/control group comparisons • Adverse events • Remission rates and remission criteria • Response rate and response criteria • Qualitative statistics for active versus sham group comparisons
Study design	• Control type (ie, sham-controlled; control activity) • Comparison type (eg, active vs sham stimulation) • Treatment duration • Randomized versus nonrandomized • Single-blind vs double-blind

Statistical Analysis

For the prospective meta-analysis, analyses will be conducted using Stata (StataCorp). Heterogeneity will be assessed using the Q test, I^2, and τ^2. A random effects model will be used, if appropriate, to account for potential between-studies variance in treatment effect.

Results

The proposed systematic review aims to evaluate the clinical efficacy of active dTMS versus sham/control in various psychiatric (and if available) cognitive disorders. Additionally, a meta-analysis will be performed (if a sufficient number of studies are available) exploring the effects of dTMS parameters, age, sex, and H-coil type on clinical outcomes.

Thus far, 22 eligible studies have been included from the following databases: APA PsycINFO, Embase, and MEDLINE (refer to Multimedia Appendix 1). A search of the APA PsycINFO, Embase, and MEDLINE databases resulted in 1134 articles. A total of 790 articles were removed by OVID automation tools which limited articles to English, human participants, and clinical trials. Additionally, 79 duplicate records were removed by automation tools. After screening the abstracts of the remaining 265 articles, 218 were excluded. The full texts of the remaining 47 articles were then screened for eligibility. One report could not be retrieved. Following the full-text screening, 25 articles were excluded for the following reasons: (1) not having a sham or control condition (n=10); (2) the control group was not a psychiatric population (n=2); (3) no new data were reported (n=4); (4) not a clinical trial (n=7); (5) intervention was with TMS, not dTMS (n=1); and (6) being a review article (n=1). One additional article was identified

XSL•FO
RenderX

from the reference section of an existing systematic review. The PubMed search did not render any additional articles.

A search of the Cochrane database still needs to be performed to identify other potential articles. The data extraction process is ongoing. Once the data extraction is complete, we will determine if there are enough suitable articles to conduct a meta-analysis. We aim to have this project complete by the end of 2023.

Discussion

Objectives and Limitations

The preliminary screening stages of the ongoing systematic review have rendered a total of 22 eligible articles comparing the efficacy of dTMS to a sham/control condition. While dTMS treatment has been shown to effectively alleviate clinical symptoms for psychiatric and cognitive disorders, the current state of literature lacks insight into the clinical efficacy of dTMS interventions across such disorders. Data from all 22 articles identified in the preliminary search may help to bridge this gap in the literature by conducting a comprehensive systematic review, and prospective meta-analysis, to determine the efficacy of dTMS across diverse psychiatric and cognitive disorders.

The proposed review will be the first, to our knowledge, to evaluate the clinical efficacy of dTMS across psychiatric and pertinent cognitive disorders. The knowledge gathered from this systematic review holds great clinical value. First, it can inform clinicians about the potential clinical benefits of dTMS in specific psychiatric populations. Second, by further conducting subgroup analyses (whereby a meta-analysis is deemed appropriate), this study aims to identify subgroup variables that may affect clinical outcomes following dTMS treatment. This subgroup data has valuable clinical implications, as the identification of such clinical and methodological factors may influence clinicians' decisions to support dTMS over another treatment regimen. Thus, future dTMS treatments can be tailored to fulfill the patient's needs and customize treatments to optimize therapeutic effects.

The systematic review that follows this protocol may have limitations. First, sham-controlled studies exploring the clinical efficacy of dTMS are limited. Second, there may not be sufficient studies to examine the clinical efficacy of dTMS for each psychiatric and cognitive disorder. Thus, a meta-analysis may not be possible for all conditions, which may hinder assessments of subgroup variables potentially influencing dTMS efficacy.

Conclusions

In this protocol, the authors openly review the methodological procedures of a systematic review (and prospective meta-analysis) designed to effectively determine the clinical efficacy of dTMS for psychiatric and cognitive disorders. This protocol was published to ensure the originality of this research and to contribute to data availability.

Acknowledgments

Abstract

Background: The prevalence of nonsuicidal self-injury (NSSI) is a major concern in public health. Two main factors (individual and environmental) cause NSSI. Studies addressing NSSI often consider it as an emotion regulation strategy. Studying NSSI within the framework of attachment theory is reasonable since the capacities to regulate emotion come into existence in the framework of attachment in the first periods of a child's growth. Primary studies addressing this topic are not frequent, and no systematic review has been conducted.

Objective: This systematic review and meta-analysis protocol aims to investigate the relationship between NSSI and attachment style and finding its relationship based on study design, study type, different types of attachments, and gender.

Methods: All studies on the relationship between NSSI and attachment will be included in this systematic review. We will include observational studies (cross-sectional, cohort, and case control) through searches in electronic databases via PubMed, CINAHL, Embase, Web of Science, ProQuest, Scopus, PsycINFO, and Google Scholar as complementary search. Qualitative studies, case studies, case series, and letters to the editor will be excluded. There will be no language limitation. Moreover, there will be no limitations regarding the study participants' age, gender, nationality, sexual orientation, and psychological problems. Funnel plots were examined if 10 or more studies are included, and the Begg and Egger statistical tests were used to assess the risk of bias. All similar data will be combined through the "metan" command by Stata statistical package (StataCorp). A fixed-effects or random-effects model, considering methodological similarities or differences, will be selected to determine a combination model.

Results: We will summarize the selection of the eligible studies using a flowchart. The results will be presented in a table of evidence. The results of the meta-analysis will be depicted using diagrams and tables.

Conclusions: It seems necessary to carry out such systematic and comprehensive meta-analysis to present a summary of the published articles in terms of the relationship between NSSI and attachment. The results from this review will be used to improve our knowledge of the role of the upbringing of children and NSSI behavior and will help design appropriate interventions to address NSSI.

Introduction

Background

Nonsuicidal self-injury (NSSI) is defined as a direct [1], repeated and socially unacceptable injury to a person's body tissue [2], a deliberate destruction of one's own body tissue [3], and without suicidal thoughts [4]. It includes cutting, scratching, or burning the surface of one's body, as well as hitting with objects, and inflicting direct damage to one's skin or bones by a person [5]. This is a common character in borderline personality disorder [6], and was one of the initial criteria of borderline personality disorder [7]. The criteria for NSSI were presented in Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), but it needs further empirical study to be mentioned in the next version of DSM. The criteria for NSSI include the following: the person having intentionally injured surface parts of their own body such as cutting, burning, biting, and scratching skin for at least 5 days over the past year; this act cannot have been culturally influenced [8]; the intentional injury should have been associated with negative emotions and feelings such as pervasive anxiety, stress, anger, and confusion; and this act must have been committed to achieve a specific goal [9].

It usually begins in adolescence, the age of onset has been reported to be between 14 and 16 years [10], and its rate decreases in late adolescence [11]. As a common psychiatric symptom, it puts adolescents at greater risk than other age groups [12]. The prevalence of this disorder in teenagers has been reported 16% [13]. Sex differences are also important in this disorder, which occurs more commonly in girls [14]. The prevalence of NSSI in teenage girls is reported to be 19% [15]. There are also cultural differences in the prevalence of these behaviors. The overall prevalence of NSSI (32.6%) is higher in Asian countries compared with Western countries (19.4%) [16].

According to the prevalence of this disorder in different ages and cultures, there are various predisposing factors based on the results of qualitative research. One of the etiological factors, for instance, is attachment styles [17,18]. Generally, the predisposing factors for the development of NSSI can be divided into individual and environmental factors [19]. Adolescence is a period of physical and psychological growth, and it is important because of changes related to puberty, identity, and independence. This stage is accompanied by important and sudden changes such as physical, sexual, cognitive, emotional, and moral changes, as well as changes in desires, values, and patterns. All these factors together create difficulties for teenagers, and training, support, time, and patience are required to answer their questions or have their problems solved. If teenagers cannot manage and solve their problems, they may turn to inappropriate practices such as NSSI [20].

On the other hand, attachment styles are known to be one of the environmental factors, which play an important role in the onset, formation, and maintenance of NSSI in adolescents [21]. Based on the research results, insecure attachment plays an important role in the tendency of people to NSSI [22]. Unfavorable family conditions in the early years of life have been identified as risk factors for presenting NSSI. There are correlations between NSSI and parental absence [23], poor quality of relationship with parents [24,25], and a lack of social support [26].

Attachment is a deep and enduring emotional bond that connects one person to another across time and space. Attachment is an emotional bond between child and the primary caregiver. The caregiver's response pattern can help regulate the child's emotional states so that the child can develop a secure attachment style. On the other hand, an inconsistent response pattern or less responsive caregiving can lead to an insecure attachment pattern that causes emotional dysregulation [21]. Some empirical studies have discussed the relationship between insecure attachment and NSSI. In a sample of adult psychiatric patients, they found that preoccupied attachment was associated with lifelong NSSI, but emotional pain partially moderated the relationship between a dysfunctional attachment pattern and NSSI [27].

A longitudinal study showed that the dysfunctional attachment between adolescents and their mothers is associated with a higher frequency of NSSI, which is mediated by increased rates of confused identity style [28]. The quality of attachment to parents through self-compassion, as self-reported by patients, provides us with insights into how such a disorder can emerge in adolescents. All of these results indicate that an insecure attachment pattern increases the likelihood of engaging in NSSI or can maintain it [29]. Despite the importance of these findings, studies in this field, especially among the adolescent population, are scarce [21]. Therefore, the authors will conduct a systematic review and meta-analysis to investigate the relationship between NSSI and attachment.

Objectives

The primary goal of this systematic review is to investigate the relationship between NSSI and attachment. The secondary objectives are as follows: (1) examine the relationship between NSSI and attachment according to the study type (interventional and observational studies); (2) examine the relationship between NSSI and attachment according to the study approach (cross-sectional, retrospective, and longitudinal); (3) examine the relationship between NSSI and attachment based on different types of attachment (attachment to the primary caregiver, romantic attachment, attachment to peers, etc); (4) examine the relationship between NSSI and attachment based on gender; (5) examine the relationship between NSSI and attachment based on different age groups; and (6) examine the relationship between NSSI and attachment based on studying the difference in findings (heterogeneity) in this relationship and investigating its potential reasons.

Methods

Guidelines and Registration

This study is a systematic review that will be reported based on the recommendations of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2009 checklist. The study protocol was registered with the International Prospective Register of Systematic Reviews (CRD42021226455).

Eligibility Criteria

Study Type

We will include observational studies (cross-sectional, cohort, and case control) that have investigated the relationship between NSSI and attachment. Qualitative studies, case studies, case series, and letters to the editor will be excluded. There will be no limitation regarding the language of the citations.

Participants

Patients of all age groups (including children, adolescents, youth, and adults), nationalities, sexual orientations, and psychological disorders will be eligible to be included.

Intervention

This study will investigate the relationship between NSSI and attachment. Any study that has defined NSSI with any instrument and has assessed its relationship with at least one of the attachment types, including caregiver attachment, romantic attachment, or peer attachment (by any definition criteria or means) will be eligible. In addition, the studies that have defined NSSI according to the description provided by DSM-5 for NSSI, considering the abovementioned factors, will be eligible.

Data Sources and Search Strategy

Electronic Databases

To identify the relevant literature, Search Syntax is developed for 6 platforms to search in different databases. The search will run in MEDLINE (PubMed), SCIE, SSCI, ESCI, CPCI-S, BKCI-S (Web of Science), Scopus, Embase, PsycInfo, Coronavirus Research Database, Publicly Available Content Database (ProQuest) for thesis and dissertations, and other gray literature.

There will be no language restrictions. There will be no publication date restrictions. Google Scholar will be used as a complementary search. Multimedia Appendix 1 shows the search syntax in each database.

Other Sources

In addition to electronic databases, other sources, including conference proceedings, dissertations, and previously published review articles, will be searched. Furthermore, 2 key journals (the first 2 journals with the highest record in Scopus search output) will be searched, and citation searching of the previous review articles as well as the included citations will be performed.

Data Collection and Analysis

Selection

After completing the search in the databases, the outputs will be exported to the Mendeley reference manager (Elsevier). The titles and abstracts will be screened for possible selection. In order to increase productivity between the 2 individuals who perform the screening, a checklist was prepared. This checklist includes a table consisting of 3 to 5 inclusion and exclusion criteria, categorized as “yes,” “no,” and “not reported,” to which the screeners can respond by reading the abstract or the title of the article. The report of the 2 main variables of the study (attachment and NSSI) is necessary in these articles, and the answer to rest of the inclusion criteria can be “yes” or “not reported for inclusion.” This table is shown in Multimedia Appendix 2. Subsequently, the full texts of the preliminary studies likely to be included in this article will be reviewed. Based on the criteria defined in the protocol, 2 researchers will review the full texts. Any inconsistency between the 2 researchers will be resolved through consensus to make the final list of the included studies.

Data Extraction

The data extraction process will be accomplished independently by 2 reviewers through the reading of the full texts of the preliminary studies using a data collection form, which comprises the following: (1) study identification data (ie, first author, publication date, journal name, type of the study, study design, sampling method, and location); (2) background data (ie, age, gender, number of participants studied, specific population groups, inclusion and exclusion criteria of the studies, and education level of the participants); and (3) data related to the primary objective of the systematic review (ie, the relationship between NSSI and attachment) as well as the secondary objectives (ie, the relationship between NSSI and attachment based on study type, study approach, different types of attachment, gender, and age groups). In order to select the appropriate effect size, we will use correlation coefficient and mean difference or standardized mean difference.

We will use the sample size as well as the mean and standard deviation of the independent variable or its subsets in NSSI and non-NSSI groups in those studies that have not reported the desired effect size measures directly. In addition, in case the required data are depicted in graphs, these will be converted to numerical data using the web-based WebPlotDigitizer tool (Ankit Rohatgi). Further, when the required data are not reported in the preliminary studies, we will try to acquire the missing data via correspondence with the corresponding authors. If the required data cannot be acquired after 3 contacts via email, that particular study will be excluded. Two reviewers will be responsible for the data extraction process separately. In case of any inconsistency between the reviewers, this will be resolved by consensus.

Data Analysis

The relative data of one of the effect size measures mentioned earlier will be combined through the “metan” command by Stata, version 13.0 (StataCorp). In order to determine a combination model, a fixed-effects or random-effects

XSL•FO
RenderX

model—considering the methodological similarities or differences—will be selected.

Quality Assessment

The quality assessment of the included studies will be performed using the Joanna Briggs Institute checklist. Two reviewers will conduct this process separately. Then, the agreement between the 2 reviewers will be assessed, and in case of inconsistency, consensus will be used.

Heterogeneity Assessment

To assess the heterogeneity between the primary studies, we will use Cochran *Q* test and the inconsistency index (I^2). In addition, heterogeneity classification will be conducted using the classification method proposed by Higgins as follows: 0% to 24.9% (mild heterogeneity), 25% to 49.9% (moderate heterogeneity), 50% to 74.9% (severe heterogeneity), and 75% to 100% (highly severe heterogeneity).

Subgroup Analysis

Subgroup analysis will be performed based on variables such as age, gender, type of the study, design of the study, quality of the study, different types of attachments, and time periods.

Publication Bias

In order to assess publication bias, funnel plots (if 10 or more primary studies are included) will be depicted and examined. In addition, the Begg and Egger statistical tests will be used to assess the publication bias. *P* values of <.1 will be considered as considerable publication bias.

Sensitivity analysis will be conducted using the one-out remove method and the "metaninf" command in Stata software. Furthermore, subgroup analysis or meta-regression will be used in order to explore the effect of methodologic quality on the meta-analysis results. In case of considerable difference between high- and low-quality studies, the conclusion will be made using high-quality studies.

Ethical Considerations

Since this systematic review is limited to the published articles, it does not require ethical approval.

Results

We will summarize the selection of the eligible studies by a flowchart. The results will be presented in a table of evidence. The results of the meta-analysis will be depicted using diagrams and tables.

Discussion

We will investigate studies regarding the relationship between NSSI and attachment without any limitations regarding the age, nationality, gender, or psychological problems of the participants. We will analyze heterogeneity sources among the primary studies. Despite increasing attention to this phenomenon in recent years, we have observed the lack of meta-analyses on the relationship between attachment—in particular, various types of attachment—and NSSI. Therefore, it seems necessary to conduct a comprehensive systematic review with meta-analysis to elucidate this relationship in detail. The findings of this review will be used to improve our knowledge of the role of the upbringing of children and NSSI behavior and will help design appropriate interventions to address NSSI. Additionally, this review will provide new evidence for psychologists and health policy makers. The advantage of this review is that we will search the gray literature and will not impose any language restriction.

Acknowledgments

We are especially indebted to Dr Kamali, Faculty member of Iran University of Medical Sciences, who has been supportive during the syntax development process in our research.

All authors declared that they had insufficient or no funding to support the open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Authors' Contributions

SA and MAM conceived the study idea and design. All authors drafted the first protocol. SA and FM reviewed the protocol. All authors developed the search strategy and methods of the systematic review. LF extensively reviewed the manuscript and incorporated intellectual inputs. All authors have read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Age-related macular degeneration (AMD) is recognized as the leading cause of vision loss in older people. Considering the phenomenon of aging societies worldwide, the prevalence of AMD is expected to increase gradually in the future. AMD can be divided into early, intermediate, and late stages, with the early and intermediate stages being mainly asymptomatic, and the late stage being classified as geographic atrophy, neovascular AMD, or both. Current pharmacological treatments for neovascular AMD include anti–vascular endothelial growth factor agents, such as ranibizumab, pegaptanib, and aflibercept. Additionally, it has been reported that the off-label use of intravitreally administered bevacizumab is effective. It is also lower cost than other agents, which makes it an interesting pharmacological approach.

Objective: This review aims to evaluate the efficacy, safety, and efficiency of bevacizumab for the treatment of neovascular AMD.

Methods: This review will only consider randomized controlled clinical trials that compare the use of bevacizumab with another pharmacological agent or a placebo in patients aged 50 years and older who are diagnosed with vascular AMD. It will exclude studies that include participants diagnosed with polypoidal choroidal vasculopathy or retinal angiomatous proliferation. To identify and select relevant articles, we will develop a highly sensitive search strategy and apply it in MEDLINE via the PubMed platform. Upon selection of the studies and analysis of the titles, abstracts, and full texts, the results will be presented according to the Preferred Reporting Items of Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The analysis and extraction of the data will be performed by 2 independent reviewers. Risk of bias will be evaluated with the Critical Appraisal Skills Programme (CASP) checklist. Finally, the same reviewers will also perform a quality assessment of the included studies with the Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) tool.

Results: The search strategy, after the application of the inclusion and exclusion criteria, identified 15 randomized clinical trials, which are currently being analyzed. This project has no funding and it has been developed by a multidisciplinary research team of pharmacologists and orthoptists. The study was initiated in May 2021 and it is expected to conclude by the end of 2023.

XSL•FO
RenderX

Conclusions: This review will provide a synthesis of current information and underlying evidence about the off-label use of bevacizumab in neovascular AMD. It will provide a clearer vision of a possible new pharmacological approach, as well as the most suitable treatment designs, for the treatment of neovascular AMD.

KEYWORDS

wet macular degeneration; age-related macular degeneration; AMD; neovascular age-related macular degeneration; nAMD; bevacizumab; drug therapy

Introduction

Age-related macular degeneration (AMD) is closely associated with visual impairment and is considered the leading cause of vision loss in elderly people [1-3]. Indeed, it is reported that 9% of all cases of blindness are related to the progression of this disease [4]. AMD frequency increases with age, and the disease is known to be progressive and degenerative [1,5]. It is estimated that around 200 million people are affected by AMD, and in aging societies, the prevalence of this disease may increase in the near future [3-6]. In addition to age, there are other risk factors for AMD, such as environmental factors, obesity, atherosclerosis, smoking, genetic background, and metabolic and functional factors [2,7].

AMD can be divided into early, intermediate, and late stages. The early and intermediate stages are mainly asymptomatic and represent about 90% of cases [6-8]. Late AMD is classified into 2 main types: dry (geographic atrophy) AMD and neovascular (wet or exudative) AMD. Late AMD is the main cause of AMD-associated visual impairment [2,4,5,8]. AMD diagnosis and grading are based on color fundus examinations in people aged 50 years and older [9]. There are some differences to be aware of between the 2 main types of AMD. Nonadvanced AMD is characterized by typical whitish-yellow focal drusen localized between the retinal pigment epithelium and the Bruch membrane (BrMb). On the other hand, wet AMD is known to induce new abnormal vessels in the macula, resulting in neovascular AMD (nAMD) [10].

AMD pathogenesis is not yet fully understood, but there is already evidence to elucidate the process underlying the onset and progression of this disease [8,10,11]. Both atrophic AMD and nAMD are related to the dysfunction or death of all constituents of the photoreceptor–retinal pigment epithelium–(RPE)–BrMb–choriocapillaris complex, as these constituents work in combination. The development of each type of AMD seems to be associated with the location where the initiating events occur [11]. Atrophic AMD development is characterized initially by the formation of large, confluent drusen and hyperpigmentation, which can be accompanied by RPE dysfunction, leading to risk of geographic atrophy [11,12]. On the other hand, neovascular AMD is associated with the initial loss of choroidal vasculature, which affects the photoreceptor-RPE-BrMb-choriocapillaris complex and appears to be caused by reduced blood supply due to stenosis of the large vessels. An inflammatory environment is established by the accumulation of proinflammatory cytokines, promoting the progression of AMD [11,13]. The RPE remains intact due to the stenosis in the large vessels, but becomes hypoxic and starts to release angiogenic substances, including vascular endothelial growth factor (VEGF), which stimulates the formation of new vessels in the choriocapillaris; this is known as choroidal neovascularization [11].

Because of the process underlying the development of nAMD, current pharmacological treatments are characterized by the intravitreal administration of molecules specifically targeting VEGF [4,14]. The drugs currently accepted by the regulatory authorities for the treatment of this condition include pegaptanib, ranibizumab, aflibercept, and brolucizumab [4,8]. The off-label use of bevacizumab has also been reported for the treatment of nAMD. Bevacizumab is a drug commonly used in oncology for the treatment of metastatic colorectal cancer, breast cancer, and lung cancer [2,4,14]. Indeed, some authors have reported that the intravitreal administration of bevacizumab has a positive influence in cases of nAMD; furthermore, it has a lower cost for the community in comparison with currently used drugs, such as ranibizumab [2,14,15]. Therefore, given the rise in bevacizumab use in nAMD, it would be interesting to specifically evaluate its long-term influence on the onset and progression of this disease. Thus, this project aims to undertake a systematic review and meta-analysis of the evidence concerning the off-label use profile of bevacizumab in the treatment of nAMD through the identification and critical appraisal of clinical studies. One of our specific objectives is to summarize and analyze the current evidence on the clinical outcomes regarding the efficacy, safety, and efficiency of bevacizumab treatment for nAMD. In addition, considering the lack of evidence from current reviews regarding different treatment designs and their influence on outcomes, this review will also aim to fully describe different regimens and determine if there are significant differences between them.

Methods

Research Question

The research group follows the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analysis–Protocols (PRISMA-P) for the elaboration of this protocol [16]. This study proposes to answer the following research question: Is bevacizumab more efficient than other pharmacological approaches while having a comparable efficacy

XSL•FO
RenderX

and safety profile for the treatment of patients diagnosed with nAMD?

Participants

In accord with the natural history of AMD and the American Academy of Ophthalmology Preferred Practice Patterns, the study will only include participants diagnosed with nAMD aged 50 years or older [17]. Textbox 1 shows the eligibility criteria.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Participants diagnosed with neovascular age-related macular degeneration and aged 50 years or older
- Treatment with bevacizumab and another pharmacological agent or placebo
- Presentation of outcomes related to the efficacy, safety, and efficiency of the treatment
- Randomized clinical trial

Exclusion criteria

- Participants diagnosed with polypoidal choroidal vasculopathy or retinal angiomatous proliferation
- Treatment switched during the study
- Studies written in a language other than English
- Studies published before 2010

Intervention and Comparison

Patients diagnosed with nAMD and treated with intravitreal bevacizumab will be compared to patients who receive other accepted treatments, such as other anti-VEGF drugs (eg, ranibizumab), or to those who receive a placebo.

Outcomes

We will analyze several outcomes to evaluate the influence of intravitreal bevacizumab in nAMD in comparison with other established treatments or placebo; these outcomes are related to the efficacy, safety, and efficiency profiles.

Study Design

This review will only consider randomized controlled trials.

Search Strategy

This review will use MEDLINE, via the PubMed platform, to develop a highly sensitive search strategy to identify and select relevant and eligible studies. Multimedia Appendix 1 presents the search strategy developed for the MEDLINE database.

Selection Process

Titles and abstracts of retrieved studies will be screened, and the full text of potentially eligible articles will be assessed by 2 independent reviewers. In case of discrepancies, a third reviewer will be included to make a final decision. Inclusion and exclusion criteria will be applied throughout this process to decide whether a study is included or excluded. Relevant data will be extracted from the included studies and inserted in a customized data extraction document by the 2 independent reviewers. The search results will be presented in the final systematic review and presented as a PRISMA flow diagram. In addition, the reasons for excluding studies will be organized and will also be presented in the final flow diagram. As previously mentioned, we will only include articles written in English and published after 2010.

Data Collection Process

The retrieved studies from the MEDLINE database will be exported and analyzed through a systematic reviews web application (Rayyan; Qatar Computing Research Institute), which will be used throughout the review for study screening and overall management. The data will be extracted by the same 2 independent reviewers and will include specific parameters concerning the population, intervention, and comparison, as well as outcomes related to the efficacy, safety, and efficiency profiles of the treatments applied. Once again, in case of conflict between the reviewers, a third reviewer will be included to make a final decision. The included studies will be descriptively analyzed and presented in a tabular format. Additionally, the studies excluded from the quantitative synthesis will be subjected to a qualitative analysis in order to gather all available important data. For methodologically and statistically homogeneous studies, we will perform meta-analyses using random effects models to quantify a pooled estimate of the effect of systemic versus ocular adverse events. Meta-analyses will be undertaken separately for each specific study design. We will also consider other subgroup analyses, for instance, of age groups (ie, 50-70 years and >70 years). We will also quantify heterogeneity of the studies using the I^2 statistic and the Kendall τ rank correlation if high values are found; to try to explain heterogeneity across studies, a meta-regression will be conducted. This technique can be performed if there is a suspected variable that may lead to differences in treatment effects across studies. For meta-analysis, we will use the R (version 4.0.5; R Foundation for Statistical Computing) packages *metafor* and *meta*.

Data Items

During the process of data collection, we will consider several parameters that we will extract and organize, including efficacy outcomes (visual acuity, presence of neovascularization, and retinal thickness), safety outcomes (presence of macular atrophy,

XSL•FO
RenderX

endophthalmitis, leakage, and increased intraocular pressure), and efficiency outcomes (administered dose, number of administrations, frequency of administration, duration of treatment, and cost versus benefits of the treatment compared with ranibizumab or placebo).

Risk of Bias Assessment

All the selected studies will be assessed to evaluate their methodological quality and potential for risk of bias by the same 2 independent reviewers. In case of discrepancies between these 2 reviewers, an additional reviewer will be included to make a final decision. To evaluate the quality and risk of bias in experimental studies, the Critical Appraisal Skills Programme (CASP) randomized controlled trials checklist will be used. We will derive domain-specific and overall quality grading for each study as follows: low risk of bias (A), moderate risk of bias (B), and high risk of bias (C). In addition, we will evaluate the potential of publication bias with funnel plots and the Begg test and Egger test with the trim and fill approach to explore the possible influence of publication bias on the results.

Registration and Reporting

The protocol for this systematic review was submitted and registered in 2021 in PROSPERO (CRD42021244931). This protocol follows the PRISMA-P guidelines for the development of systematic reviews and meta-analysis. In case there are modifications to the protocol, they will be reported in the final paper with the rationale behind the origin of such amendments.

Results

The study has included 15 randomized controlled clinical trials after applying the inclusion and exclusion criteria, and the data of interest are being thoroughly extracted. A multidisciplinary research team of pharmacologists and orthoptists has been working on the review since May 2021, as well as on the delineation of the protocol, and it is expected that the final results will be released by the end of 2023.

Discussion

AMD is closely associated with blindness and has a significant impact on social, health, and economic factors in society. Currently, this disease has no cure and pharmacological treatment aims to slow its rate of progression. Current drug therapies that are accepted for the treatment of nAMD are costly, and bevacizumab may be a possible alternative treatment. The off-label use of bevacizumab in the treatment of nAMD was first reported in 2006, and since then an increase in its use has been demonstrated [2]. Indeed, this drug is now associated with treatment for this disease, taking into account that its efficacy is noninferior compared to ranibizumab, a well-known drug used in this context [18]. According to some of the data being evaluated at the moment, it is already possible to affirm that bevacizumab demonstrates noninferiority compared to ranibizumab and that both drugs need a similar number of administrations to have a comparable effect on outcomes related to efficacy [19,20].

Considering the latest reviews on this topic, it is possible to observe that there is already sufficient information regarding the efficacy and safety profiles of bevacizumab in comparison to other pharmacological approaches [21,22]. However, it is also essential to understand the efficiency of bevacizumab compared with other options, since current approaches are relatively costly, and continuous administration is necessary to slow the rate of progression of the nAMD. After understanding the cost-benefit profile of bevacizumab in comparison with other established treatment molecules, it will be possible to make clinical decisions more effectively, benefiting both the health system and patients.

Thus, the findings from this review will allow a clearer vision of the use of bevacizumab in the treatment of nAMD, as well as its efficacy, safety, and efficiency compared to other drugs and to placebo. Additionally, this key strengths of this study will include synthesizing the information available about the off-label use of bevacizumab in patients diagnosed with nAMD; clarifying the current evidence on the off-label use of bevacizumab in the nAMD context for its efficacy, safety, and efficiency; and developing a comprehensive and highly sensitive search strategy, which will allow the identification of current papers and their underlying evidence. Based on the currently available literature, we are in a position to objectively evaluate bevacizumab for the treatment of nAMD in comparison to other drugs accepted by the respective regulatory authorities.

Abstract

Background: Irritable bowel syndrome (IBS) is associated with various gastrointestinal and nongastrointestinal symptoms and reduced quality of life. A diet low in fermentable oligo-, di-, monosaccharides, and polyols (FODMAPs) is one therapeutic option for IBS. Although the efficacy of the low FODMAP diet has been reported in several systematic reviews, the efficacy-effectiveness gap of the low FODMAP diet has not yet been assessed.

Objective: This systematic review aims to compare the efficacy of the low FODMAP diet from efficacy randomized controlled trials (RCTs) with the effectiveness of studies conducted in "real-world" settings.

Methods: RCTs, prospective and retrospective cohort studies, and retrospective audits assessing the low FODMAP diet in adults with IBS will be searched in 4 databases: Embase, MEDLINE, CENTRAL, and CINAHL. Two independent reviewers will perform study selection, data extraction, and risk of bias assessment and assess selected quality aspects from the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) protocol. Outcomes assessed are stool frequency, stool consistency, abdominal pain, overall symptom scores, adequate symptom relief, IBS-specific quality of life, and diet adherence. Data will be summarized with forest plots without summary statistics, tables, and narrative descriptions.

Results: The search, title and abstract screening, and full-text screening were completed in March 2021, and an updated search was done in May 2022. As of May 2023, data analysis is almost finished, and manuscript writing is in progress. Submission of the manuscript is expected by July 2023.

Conclusions: The findings of this systematic review will compare the efficacy of the low FODMAP diet for IBS found in RCTs to the diet's real-world effectiveness.

Introduction

Chronic disorders are a major contributor to the global burden of disease [1]. Many of the health problems contributing to the burden of disease involve inflammatory processes [2]. Dietary risks accounted for 255 million disability-adjusted life-years globally in 2017 [3]. Thus, nutrition and nutrition interventions play a key role in improving global health and reducing the impact of inflammatory processes [4,5].

Irritable bowel syndrome (IBS) is a chronic disease common in both Western and developing countries, affecting up to 20% of the global population [6]. It is associated with various, sometimes severe, gastrointestinal, and nongastrointestinal symptoms and often results in a reduced quality of life, reduced work performance, and increased use of health care services [7,8]. IBS belongs to the disorders of the gut-brain axis, which are characterized by abnormalities in intestinal motility, visceral sensitivity, mucosal and immune function, intestinal microbiota, and stimulus processing by the central nervous system. To this day, only symptomatic treatments are available [9].

In the past 2 decades, research has shown that a diet low in fermentable oligo-, di-, monosaccharides, and polyols (FODMAPs), or the "low FODMAP diet," reduces gastrointestinal symptoms in patients with IBS. The rate of patients with IBS reaching a clinically relevant symptom reduction may even be higher with the low FODMAP diet than with spasmolytics [10]. Several systematic reviews have summarized available data on the efficacy of the low FODMAP diet for IBS [11-20]. The majority concluded that patients with IBS benefit from following the low FODMAP diet, in comparison to either a usual diet, a high FODMAP diet, other IBS diets, or "sham" diets [11-18]. Accordingly, several IBS guidelines now list the low FODMAP diet as one possible therapeutic intervention [21-24]. Additionally, a recent expert review on the role of diet in IBS concluded that the low FODMAP diet is "currently the most evidence-based diet intervention for IBS" [25].

The low FODMAP diet includes an initial elimination phase, during which FODMAP-rich foods are excluded to individually confirm the diet's efficacy [26]. Subsequently, the individual tolerance of the FODMAPs should be tested to allow patients with IBS to follow an individually adapted FODMAP diet [27]. The therapeutic efficacy of reducing the intake of FODMAPs is explained by decreased osmotic activity due to the remaining carbohydrates retaining less water in the intestine, reduced gas production by gut microbiota, and influences on intestinal motility [28]. Evidence on the long-term efficiency of the low FODMAP diet is still limited. Recently, studies have reported on the long-term maintenance of symptom improvement after FODMAP reintroduction. After 1 year, 65% of the participants of a small follow-up study (n=18) reported adequate symptom relief [29], and in a questionnaire study, at least 50% of participants (n=211) reported improvement of abdominal pain, bloating, wind, urgency to open bowels, and also reduced health care usage [30].

Health service research distinguishes between efficacy and effectiveness studies. The former examines the fundamental efficiency of new interventions under ideal conditions, while the latter measures the efficiency of the same interventions in everyday practice [31]. Efficacy studies tend to overestimate the efficiency because of strictly defined study populations and study procedures [32]. The magnitude of this efficacy-effectiveness gap varies from no gap detected to large differences. For example, the systematic review by Ankarfeldt et al [33] concluded that there was no efficacy-effectiveness gap on blood glucose–lowering drugs—although this may have been influenced by the limited number of included studies and different biases masking such an effect. In comparison, a meta-analysis of current systemic cancer therapies found that the median overall survival was 5.2 months less in real-world data than reported in randomized controlled trials (RCTs) [34]. To date, the potential efficacy-effectiveness gap has not been investigated in the low FODMAP diet. Therefore, the systematic review described in this protocol aims to compare the efficacy of the low FODMAP diet conducted by RCTs with the effectiveness of studies conducted in "real-world" settings.

"Real-world" refers to data collected in a setting as close as possible for usual outpatient or ambulatory treatment of patients with IBS. The term was deliberately chosen because "effectiveness studies" sometimes refer to RCTs with a broader defined population and treatment protocol but not necessarily a true representation of real-world data.

Methods

Overview

The review was registered with the International Prospective Register of Systematic Reviews (PROSPERO) in November 2021 (CRD42021278952). If not mentioned otherwise, this protocol has been developed based on the Cochrane Handbook for Systematic Reviews of Interventions version 6.1 [35] and the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) reporting guidelines [36]. The guidance for the clinical evaluation of drugs for the treatment of IBS published by the United States Food and Drug Administration (FDA) [37] served as "core outcome set" but had to be adapted because of the different nature of nutrition care–related studies. Also, the FDA guideline focuses on IBS constipation and IBS diarrhea, but a range of studies investigating the low FODMAP diet included patients with IBS with all subtypes or did not report outcomes per IBS subtype.

Eligibility Criteria

The eligibility criteria are structured according to Population, Intervention, Comparison, Outcomes, and Study Design (PICOS). To address the objective of this study, the review will apply 2 PICOS. The first includes RCTs on the low FODMAP diet's efficacy. The second focuses on the low FODMAP diet's effectiveness in real-world settings (Table 1).

XSL•FO
RenderX

Table 1. Study eligibility criteria based on the PICOS[a] criteria, with time points and settings.

PICOS part	Efficacy PICOS	Real-world data PICOS
Population		
Inclusion	• Adults (≥18 years of age). • Diagnosed with IBS[b] according to Rome II, III and IV, NICE[c], the German S3 guideline, Manning criteria, and Kruis score. • Patients likely to represent the subjects studied in efficacy studies (eg, excluding patients with additional conditions potentially influencing the efficacy of the low FODMAP[d] diet, such as gastrointestinal surgery). • Patients with clinically relevant baseline outcome scores, allowing for relevant improvements through the intervention.	• Adults (≥18 years of age). • Diagnosed with IBS according to Rome II, III and IV, NICE, the German S3 guideline, Manning criteria, and Kruis score. • Patients likely to represent the "usual" patients in the institution conducting the study.
Exclusion	• Animal studies. • Studies on FODMAP contents and reduction of FODMAP contents in foods.	• Animal studies. • Studies on FODMAP contents and reduction of FODMAP contents in foods.
Intervention		
Inclusion	• Low FODMAP diet for at least 4 weeks. • Low FODMAP diet is either carried out independently by participants or provided to them.	• Low FODMAP diet for at least 4 weeks. • Low FODMAP diet is carried out by participants independently in their daily life.
Exclusion	• Studies conducted with exclusive enteral nutrition. • Studies investigating single FODMAPs. • Studies in which the low FODMAP diet was implemented without any support from a health professional.	• Studies conducted with exclusive enteral nutrition. • Studies investigating single FODMAPs. • Studies in which the low FODMAP diet was implemented without any support from a health professional.
Control		
Inclusion	• Other dietary interventions for IBS for at least 4 weeks, such as a high FODMAP diet, traditional IBS diets, sham diets, anti-inflammatory diets, probiotics, and fiber supplements. • Control intervention is either carried out independently by participants or provided to them (eg, high FODMAP meals provided).	• No control group is necessary. • If there is a control intervention, participants need to carry it out independently at home.
Exclusion	• Studies conducted with exclusive enteral nutrition. • Studies conducted with healthy controls.	• Studies conducted with exclusive enteral nutrition.
Outcomes—critical		
Inclusion	• Stool frequency. • Stool consistency. • Abdominal pain.	• Stool frequency. • Stool consistency. • Abdominal pain.
Exclusion	• N/A[e]	• N/A
Outcomes—important		
Inclusion	• Overall symptom scores such as IBS-SSS[f] or assessment of gastrointestinal symptoms with a visual analog scale. • Number or percentage of patients with adequate symptom relief. • IBS-specific quality of life. • Adherence to the low FODMAP diet.	• Overall symptom scores such as IBS-SSS or assessment of gastrointestinal symptoms with a visual analog scale. • Number or percentage of patients with adequate symptom relief. • IBS-specific quality of life. • Adherence to the low FODMAP diet.
Exclusion	• N/A	• N/A
Time points		
Inclusion	• Baseline. • After the FODMAP elimination phase (sometimes also the end of intervention). • After the FODMAP reintroduction (if part of the study). • After the follow-up time point (if part of the study).	• Baseline. • After the FODMAP elimination phase (sometimes also the end of intervention). • After the FODMAP reintroduction (if part of the study). • After the follow-up time point (if part of the study).

XSL•FO

PICOS part	Efficacy PICOS	Real-world data PICOS
Exclusion	• N/A	• N/A
Study design		
Inclusion	• Randomized controlled trials with inclusion and exclusion criteria typical for efficacy studies (see above), including crossover trials.	• Randomized controlled trials with openly formulated inclusion and exclusion criteria (see above), prospective and retrospective cohort studies as well as retrospective audits.
Exclusion	• All other types of studies.	• Case reports and qualitative studies.
Context		
Inclusion	• Studies in any ambulatory or outpatient setting.	• Studies in any ambulatory or outpatient setting.
Exclusion	• N/A	• N/A

[a]PICOS: Population, Intervention, Comparison, Outcomes. and Study Design.

[b]IBS: irritable bowel syndrome.

[c]NICE: National Institute for Health and Care Excellence.

[d]FODMAP: fermentable oligo-, di-, monosaccharides, and polyols.

[e]N/A: not applicable.

[f]IBS-SSS: IBS Severity Scoring System.

The publication period is not restricted, as the first studies on the low FODMAP diet were published in 2006. Publication language is limited to English, German, French, and Italian because of practical reasons. Studies must be published as a full manuscript, or authors must provide relevant information.

The criterion of clinically relevant symptoms has been included in the efficacy PICOS based on the FDA Guidance for Industry: *Irritable Bowel Syndrome—Clinical Evaluation of Drugs for Treatment* [37]. The definition in the guidance will be applied. Alternatively, we will accept other literature-based descriptions of "clinically relevant symptoms" or when study authors have considered the baseline data as clinically relevant. Studies included in the real-world data PICOS do not need to meet this criterion, as the FDA guidance focuses on efficacy studies, and literature on instituting the low FODMAP diet in practices reports that the low FODMAP diet can be applied in mild IBS symptoms as well [26].

For the differentiation between patients in efficacy or real-world studies, we developed a rating system based on the "eligibility" domain of the Pragmatic Explanatory Continuum Indicator Summary (PRECIS-2) tool. The PRECIS-2 tool allows studies to be designed explicitly on a 5-point continuum scale (5=very pragmatic, 4=rather pragmatic, 3=equally pragmatic and explanatory, 2=rather explanatory, and 1=very explanatory) [38].

According to the literature [26], the low FODMAP diet can be applied in practice in the following situations: (1) there is a diagnosis of IBS but no "red flags" that would require further investigation; (2) mild to severe symptoms are present, and a relationship between the symptoms and the diet is assumed; and (3) there is no history of eating disorders or orthorexia.

Studies will be included in the real-world data PICOS, if they receive more than 3 points (more pragmatic), and in the efficacy PICOS, if they receive 3 points or less. This cutoff was chosen based on a pilot test of the system, in which studies scoring 3 points or less still tended to be "classic RCTs," while those scoring more than 3 points were more pragmatic studies.

Deductions of a half or full point per aspect mentioned below will be applied if subjects are excluded because: (1) they are not expected to respond equally to the intervention (based on health conditions or dietary restrictions in the exclusion criteria list); (2) there are challenges (eg, from ethics) unrelated to the intervention (based on the exclusion of specific population groups where the low FODMAP diet would be applied in usual practice); (3) they were unable to meet strict guidelines regarding medication adjustments, including prebiotics, probiotics, and supplements; (4) they are expected to be less able to attend appointments (eg, psychological problems, lower motivation); and (5) they have not strictly adhered to the intervention.

The outcomes are divided into critical and important outcomes as recommended by the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) criteria [39]; outcomes of limited importance have not been defined. The critical outcomes are based on the FDA guidance for the clinical evaluation of IBS drugs [37] but have been adapted. The important outcomes include outcomes often applied in studies on the low FODMAP diet, which are relevant from a patient's or dietitian's perspective. Studies will not be excluded based on the outcomes reported, but reporting will focus on the critical and important outcomes.

Search Strategy

The search strategy includes databases: Embase (Elsevier interface, 1947 onward), MEDLINE (PubMed interface, 1966 onward), Cochrane Central Register of Controlled Trials (Wiley interface, current issue), and CINAHL (EBSCOhost interface, 1937 onward); trial registries: ClinicalTrials.gov and WHO-Portal International Clinical Trial Registry Platform; dissertations: LILACS, Open Access Theses, and Dissertations,

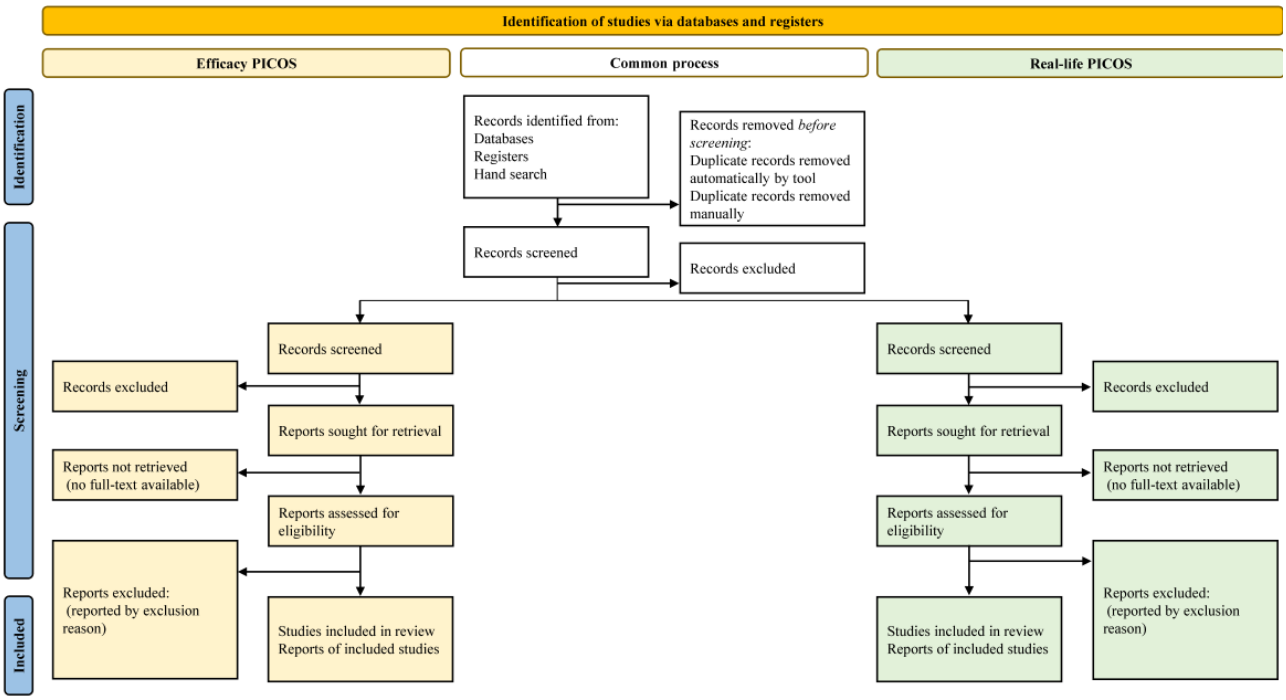
and ProQuest Dissertation & Theses Global; gray literature; and hand searched journals: *Gut*, *American Journal of Gastroenterology*, *Journal of Gastroenterology and Hepatology*, *Gastroenterology*, *Alimentary Pharmacology and Therapeutics*, *Neurogastroenterology & Motility*, *Journal of Human Nutrition and Dietetics*, *Journal of the Academy of Nutrition and Dietetics*, *European Journal of Nutrition*, *Clinical Nutrition*, *International Journal of Clinical Practice*, *Journal of Nutrition*, and *Nutrients*.



The search will be conducted once for both PICOS categories together. The search criteria will include the terms and synonyms of FODMAPs and IBS listed below and the Medical Subject Headings (MeSH) term for IBS. At the time of the search, no MeSH term existed for FODMAPs. The search criteria will be adopted to the different databases based on the following: synonyms for FODMAPs: "FODMAP" OR "FODMAPS" OR "Fermentable, poorly absorbed, short-chain carbohydrates," OR "Fermentable oligosaccharides, disaccharides, monosaccharides, polyols"; synonyms for IBS: "Irritable Bowel Syndromes" OR "Syndrome, Irritable Bowel" OR "Syndromes, Irritable Bowel" OR "Colon, Irritable" OR "Irritable Colon" OR "irritable bowel syndrome" (MeSH Terms).

Further restrictions in the search (eg, study design) will not be applied to not miss potentially eligible studies. Search results will be imported in Covidence (Veritas Health Innovation Ltd), a web-based software facilitating study selection, quality assessment, and data extraction in systematic reviews.

Study Selection

Reports found in the search process will be imported to Covidence, where duplicates detected by the system will automatically be removed. Two reviewers will do the screening independently. After each round, the 2 reviewers and the first author of this study protocol will resolve conflicts. The title and abstract screening will be done in 2 rounds. First, reports clearly not eligible for both PICOS categories will be excluded (eg narrative reviews, FODMAP content analyses, pediatric studies, and studies on other disorders than IBS). Then, the remaining reports will be separated in 2 distinct "reviews" in Covidence, and eligible studies will be determined by a second round of title and abstract screening followed by full-text screening performed for each "review" separately, based on the eligibility criteria of each PICOS (Figure 1).

Figure 1. Example overview of the search strategy, reported according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [36]. PICOS: Population, Intervention, Comparison, Outcomes, and Study Design.

Data Extraction

Data extraction will be done in Covidence, using both predefined and added fields by the review team. Data extraction will be piloted with some studies, and educational sessions will facilitate a common understanding of data extraction. Two reviewers will independently extract the data. Conflicts will be resolved by the 2 reviewers, and the first author of this protocol will be rechecking the original information in the publications. For each study, the information found in Table 2 will be extracted. If needed, the study authors will be contacted to clarify uncertainties or be asked for additional information. Data will be transferred into RevMan (version 5.4; Cochrane Collaboration) software for data synthesis.

XSL•FO
RenderX

Table 2. Overview of the data to be extracted.

Covidence field	Data to be extracted
Study identification	Sponsorship, country, setting, author's contact details, year of study, aim of study, type of publication, ethical approval, and publication language.
Methods	Study design, number of centers, method of randomization, blinding, and analysis (intention to treat per protocol).
Intervention	Interventions (name for each group), intervention description, definition of symptom improvement after the intervention, duration of participation, duration of the treatment period, duration follow-up, timing, providers, and implementation.
Population	Inclusion criteria, exclusion criteria, group differences, sample size calculation, and baseline characteristics (assessed for eligibility randomized, participants per group, dropouts per group, dropout reasons, age, gender, BMI, predominant bowel habit, and diagnostic criteria).
Outcomes	Outcome measures based on the critical and important outcomes for this review, time points evaluated.

Risk of Bias and Quality Assessment

Two reviewers will independently assess the studies' risk of bias. In Covidence, disagreements will be resolved by rechecking the original information in the publications and by a discussion among the reviewers. Several tools will be used due to the range of studies included [35]: the revised tool for Risk of Bias in randomized trials (RoB 2) [40], the newly available test version of RoB 2 for crossover studies [41], and the Risk Of Bias In Non-randomized Studies—of Interventions (ROBINS-I) assessment tool for nonrandomized studies [42]. The RoB 2 version for crossover studies will be applied despite being a test version because it is largely identical to the original RoB 2 but has been supplemented with an additional domain for bias due to period and carryover effects [42]. We will not fully implement the GRADE system but still use specific parts of it for additional quality assessment, such as indirectness of evidence, imprecision, large magnitude of an effect, and the effect of plausible residual confounding.

Data Analysis

Data analysis will be done in RevMan (version 5.4; Cochrane Collaboration). We will not perform a meta-analysis, as we expect heterogeneous outcome measures in the real-world data PICOS. Where available, mean values of measurements of a specific period (eg, mean or median of a screening period, mean or median of the last 2 weeks of the elimination phase) will be reported. If not available, single measurements will be included. Dichotomous data (adequate symptom relief) will be reported as risk ratios and risk differences with 95% CIs. In studies without a control group, results will be presented as a percentage of participants reaching adequate symptom relief. Continuous data will be reported as "mean difference" or as "standardized mean difference" if different measures were applied, both with 95% CIs. We will also apply this to studies without a control group, using baseline data as a comparison. Results will be presented as forest plots without the summary measure, in tables, or narratively.

Data will be analyzed per PICOS separately. If at least 5 studies per subgroup can be included, we will apply the following subgroups: (1) Efficacy PICOS: diet is provided during the intervention period, elimination phase only; diet is implemented independently, elimination phase only; diet is implemented independently, elimination, and reintroduction phase; and multicomponent interventions (not only low FODMAP diet). (2) Real-live data PICOS: diet is implemented independently, elimination phase only; diet is implemented independently, elimination and reintroduction phase; and multicomponent interventions (not only FODMAP nutrition).

These subgroups have been chosen as the effects measured may be influenced by the individual factors.

Ethical Considerations

Ethical approval is not required for this study because only data made available through publication are used for the systematic review. The results will be submitted for publication in a relevant peer-reviewed journal. Any changes from the protocol during the conduct of the systematic review will be described in the manuscript.

Results

The literature search, title and abstract screening, and full-text screening were completed in 2021. As of May 2023, we are in the progress of finalizing data analysis and writing the publication. We expect to submit the publication by July 2023. This work has been financially supported by the "Spendenstiftung Bank Vontobel" in Zurich, Switzerland.

Discussion

Principal Findings

In the systematic review, we will compare the effectiveness of the low FODMAP diet in efficacy RCTs to the effectiveness of real-world data in adult patients with IBS. This comparison will focus on the following outcomes: stool frequency, stool consistency, abdominal pain, overall symptoms, adequate symptom relief, IBS-related quality of life, and adherence to the low FODMAP diet. The findings of this systematic review will allow health professionals to compare their outcomes with the results of this systematic review and potentially initiate quality improvement projects if their results are lower than expected in comparison to the results of this systematic review.

Current Research

Research output on the effect of the low FODMAP diet is still high. Current research topics include the long-term efficiency, impact on gut microbiota, and response predictors. Data on long-term outcomes of the low FODMAP diet, however, are still scarce. Nevertheless, these data are of great importance as

XSL•FO
RenderX

the effort of a restrictive 3-phase diet, such as the low FODMAP diet, is only worthwhile if symptom relief persists. Few recent studies confirmed maintenance of symptom improvement after FODMAP reintroduction with 1- or 2-year follow-up. Two recent studies reported a 50% or more symptom improvement among participants who followed an individualized low FODMAP diet after almost 1 year [29,30]. Symptom improvement may be related to continued partial adherence to the low FODMAP diet. In a retrospective cross-sectional study (n=90), almost 80% of the participants reported partial adherence after nearly 2 years, which was associated with less abdominal pain [43]. In acknowledgment of the limited RCTs available assessing long-term effect, this systematic review will still endeavor to assess all available evidence on such long-term outcomes.

There are known potential negative effects of the low FODMAP diet on the gut microbiota, due to the elimination of fructans and galactans, which are both important prebiotics. A recent meta-analysis on the effect of the low FODMAP diet on gut microbiota concluded that studies consistently reported a reduction of bifidobacteria during the low FODMAP elimination phase, but they found no indications for broad systematic changes in the gut microbiota [44]. Thus, more research on the long-term effects of the low FODMAP diet on the gut microbiota is needed. Promisingly, a small follow-up study (n=18) found no difference in bifidobacteria abundance between baseline and 1 year [29].

Evidence on predictors of symptom relief is essential as studies have reported roughly a 70% rate of satisfactory symptom relief after following the low FODMAP diet [45]. Therefore, a better understanding of such predictors would enable applying the low FODMAP diet only in patients with IBS with a probability of a higher success rate, while those with a lower chance of symptom relief could be given alternative therapies sooner. Baseline gut microbiota has been discussed as one predictor by Vervier et al [46], who identified 2 distinct microbiota clusters in patients with IBS. The health-like cluster had a gut microbiota profile similar to healthy household members, whereas the pathogenic-like cluster gut microbiota differed greatly from the healthy-household members. When eating a low FODMAP diet, gut microbiota of the pathogenic-like cluster shifted toward a more health-associated profile, and participants experienced strong symptom improvement (measured by a decrease of 194 points on the IBS Severity Scoring System). In the health-like cluster, the low FODMAP diet did not affect the gut microbiota, and participants experienced a clinically relevant but less pronounced symptom reduction (−114 points) [46]. Therefore, having a gut microbiota of the pathogenic-like cluster may lead to better symptom improvement and could be an important predictor for the benefit of the low FODMAP diet.

Systematic reviews and meta-analyses directly assessing the efficacy-effectiveness gap remain scarce. In contrast, systematic reviews seem to increasingly include observational data due to the faster availability of such data but often without sufficient differentiation between efficacy and effectiveness data [47]. Some of the systematic reviews and meta-analyses on the low FODMAP diet in patients with IBS included a range of study designs but did not clearly distinguish between these designs in data analysis [12,14-16,18]. This may be critical, especially if meta-analyses are performed [47]. This systematic review will prevent this by categorizing the included studies as either efficacy or real-world studies and summarizing the outcomes separately.

Limitations of this systematic review are related to the aim of comparing efficacy RCTs with real-world data. First, we will include RCTs in both PICOS categories, as RCTs may be clearly efficacy studies but also report on effectiveness, which would fit more in the “real-world” category. Our systematic review includes 2 PICOS to enable the differentiation of efficacy and effectiveness studies by using specific eligibility criteria representing these 2 types of studies. However, the differentiation between study populations representative of typical efficacy or effectiveness studies remains a challenge. Therefore, we developed and pretested a rating system based on the eligibility domain of the PRECIS-2 tool [38]. Based on the pretest, we are confident that the rating system will sufficiently distinguish between efficacy and real-world studies. Furthermore, the PRECIS-2 (by using all domains) has already been successfully used retrospectively by other researchers [48-50]. However, it should be acknowledged that the retrospective use of PRECIS-2 has not been well established. Second, to include as much real-world data as possible, we will include studies with different study designs in the real-world PICOS. We hypothesize that this will entail some challenges in data analysis and interpretation as some of the data will be from observational studies without control group.

Conclusions

This protocol describes the methods of a systematic review that will compare the effectiveness of the low FODMAP diet in efficacy RCTs to the effectiveness of real-world data in adult patients with IBS. To our knowledge, this will be the first systematic review with this focus. The results will help to fill the efficacy-effectiveness evidence gap of the impact of the low FODMAP diet in adult patients with IBS and help identify research needs related to the efficacy-effectiveness gap in this field. Furthermore, the systematic review may reveal research needs with regards to long-term efficiency of the low FODMAP diet. Lastly, the systematic review will allow us to compare outcome measurements currently used in efficacy and real-world studies and whether the quality of reports on real-world studies is sufficient to compare data to efficacy studies.

Acknowledgments

SJ mainly developed the proposal. All authors contributed to developing the protocol and read, provided feedback for, and approved the final proposal. We greatly thank Joyce Haddad for the thorough language revision. This work has been financially supported by the “Spendenstiftung Bank Vontobel” in Zurich, Switzerland.

Abstract

Background: Parkinson disease (PD) is the second most prevalent neurodegenerative disease, with around 10 million people with PD worldwide. Current assessments of PD symptoms are conducted by questionnaires and clinician assessments and have many limitations, including unreliable reporting of symptoms, little autonomy for patients over their disease management, and standard clinical review intervals regardless of disease status or clinical need. To address these limitations, digital technologies including wearable sensors, smartphone apps, and artificial intelligence (AI) methods have been implemented for this population. Many reviews have explored the use of AI in the diagnosis of PD and management of specific symptoms; however, there is limited research on the application of AI to the monitoring and management of the range of PD symptoms. A comprehensive review of the application of AI methods is necessary to address the gap of high-quality reviews and highlight the developments of the use of AI within PD care.

Objective: The purpose of this protocol is to guide a systematic review to identify and summarize the current applications of AI applied to the assessment, monitoring, and management of PD symptoms.

Methods: This review protocol was structured using the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) and the Population, Intervention, Comparator, Outcome, and Study (PICOS) frameworks. The following 5 databases will be systematically searched: PubMed, IEEE Xplore, Institute for Scientific Information's Web of Science, Scopus, and the Cochrane Library. Title and abstract screening, full-text review, and data extraction will be conducted by 2 independent reviewers. Data will be extracted into a predetermined form, and any disagreements in screening or extraction will be discussed. Risk of bias will be assessed using the Cochrane Collaboration Risk of Bias 2 tool for randomized trials and the Mixed Methods Appraisal Tool for nonrandomized trials.

Results: As of April 2023, this systematic review has not yet been started. It is expected to begin in May 2023, with the aim to complete by September 2023.

Conclusions: The systematic review subsequently conducted as a product of this protocol will provide an overview of the AI methods being used for the assessment, monitoring, and management of PD symptoms. This will identify areas for further research in which AI methods can be applied to the assessment or management of PD symptoms and could support the future implementation of AI-based tools for the effective management of PD.

KEYWORDS

artificial intelligence; machine learning; Parkinson disease; Parkinson; neurodegenerative; review method; systematic review

Introduction

Parkinson disease (PD) is the second most prevalent neurodegenerative disease worldwide, with around 10 million people with PD worldwide [1]. This number represents a 2.5-fold increase in prevalence over the past generation [2,3]. PD is a neurological disorder associated with motor and nonmotor features [4] affecting multiple aspects of movement, including planning, initiation, and execution [5]. Management of PD is very complex over the course of the disease due to its progressive nature [6]. Developments of digital technologies have allowed for the remote, objective monitoring of symptoms, allowing care teams to take data-driven approaches to care, producing large amounts of data [7]. Artificial intelligence (AI) methods have been applied to data sets to improve the timeliness of care for patients, assist with analysis, and reduce health care provider burden [8]. The existing research has primarily focused on the application of AI methods in the diagnosis of PD or the management of motor symptoms [9,10], despite nonmotor symptoms (NMS) causing a significant burden for people with PD, as well as reduced quality of life, and being the main contributor to the overall cost of care [11,12]. It is important to understand how the range of AI methods can be applied to all symptoms experienced by people with PD to aid with monitoring and disease management, as well as assisting the patient to understand their disease profile more clearly and facilitate better self-management [13].

PD is most commonly characterized by a resting tremor, bradykinesia, and rigidity, accompanied with changes in posture and gait. During the development of PD, motor symptoms are observed prior to cognitive and behavioral changes, such as dementia [14]**.** Despite being defined as a movement disorder, people with PD can also be affected by a wide range of symptoms spanning beyond the classic motor symptoms [4]. NMS affect all people with PD and can include constipation, urinary dysfunction, sleep disturbances, and depression [15,16]. The National Institute for Health and Care Excellence acknowledges that NMS are considered a significant burden for people with PD, and their recognition and management is an important yet unmet need of PD [17]. Evidence shows that NMS can occur at any stage of the disease, with some NMS occurring prior to the onset of motor symptoms [18]. Generally, the assessment and characterization of both motor and NMS rely on clinical assessment with follow-ups occurring every 6-12 months for stable patients, according to the National Institute for Health and Care Excellence guidelines [19]. The appropriate assessment of symptoms affecting people with PD is vital for an effective clinical management and managing symptom severity [20,21]. This assessment methodology aims to allow for both the subjective and objective assessment of the impact of PD to achieve a clear overall impact of the disease for people with PD [22]; however, this is not always achieved. These assessments lack granularity during disease or medication cycles; these assessments represent only a small portion of a patient's life and may not adequately capture the nuances of a highly variable condition [7,23]. The quality of the information collected is limited by patients' and care partners' recall about their recent symptom burden, which can be worsened by the cognitive impairments associated with PD. An international survey published in 2010 highlighted that 62% of patients with PD do not declare NMS including pain, sexual difficulty, sleep dysfunction, or bowel incontinence either due to embarrassment or not being aware that such symptoms are linked to PD [16]. As a result, some symptoms, particularly NMS, are often overlooked or undeclared by people with PD, which results in incorrect disease management, impacting upon quality of life for both the patient and their care partner, and increased care needs and costs [16].

The remote monitoring of PD symptoms has become increasingly common because it can allow patients to self-manage their condition at home [24-26]. Digital technologies allow for the at-home monitoring of patients through smart devices, sensors, and other tools. At-home monitoring allows for the continuous oversight of disease presentation in an objective manner to ensure no symptoms are forgotten, overlooked, or misinterpreted [23,27]. Several studies have proposed and evaluated the use of wearable devices and smartphones with built-in sensors for monitoring both motor and NMS for people with PD [27-30]. By enabling long-term data collection in a nonclinical setting, digital technologies can reduce the burden on clinical data collection and allow clinicians to spend contact time with patients more meaningfully. The wealth of available data and improved clinical efficiency has the potential to facilitate the diagnosis, monitoring, and management of PD. The present applications of wearable devices include assessing gait (including freezing of gait), tremor, bradykinesia, rigidity, sleep dysfunction or disturbance, blood pressure, and detecting falls [31]. Data from accelerometers and gyroscopes on various parts of the body can also allow for the estimation of the Unified Parkinson's Disease Rating Scale scores and determine bradykinesia in both scripted and unscripted conditions [32-35]. The analysis of such large amounts of data, however, can be extremely time-consuming and subject to variation in analyses [23].

The implementation of AI is being extensively used in a variety of health care and medical contexts, including biomedicine, diagnostics, living assistance, biomedical information process, and biomedical research [36-38]. In PD, AI has been explored for both diagnostic support and disease monitoring. Wearables combined with machine learning algorithms have been reported to sufficiently discriminate between healthy participants and patients with PD, with an accuracy of over 90%. The prediction of symptom severity using motor symptoms and various algorithms and sensors has also reported high accuracy results [39]. Specific data sets that have been used to support clinical decision-making in PD care include handwriting patterns [40],

XSL•FO
RenderX

gait [41], and neuroimaging [42]. At present, the application of AI appears to be primarily focused on the motor aspects of the disease, despite some NMS data being routinely recorded via wearable or smart devices [43]. The assessments of NMS in PD carry the same limitations as any other semiobjective rating scale, including intra- and interobserver inconsistencies and bias. Further, many NMS are not as easy to track remotely in the way motor symptoms are; for example, multiple motor symptoms, including tremor, bradykinesia, and gait or freezing of gait are detectable using gyroscopes and accelerometers usually embedded within wearable devices. Due to the large amount and wide range of NMS, as well as accessibility for the assessment of the symptom, a large portion cannot be objectively identified in the same way. Multiple research studies have focused on NMS being present in early disease states and are therefore focused on use for diagnostic purposes [44-46]. The tracking of NMS using digital technologies reduces the likelihood of the patient or carer misreporting symptoms and provides a much larger data set, eradicating the issue with clinical assessments providing only a *snapshot* in time. Implementing AI methods for NMS assessment and management can contribute toward improving patient and carer quality of life by addressing NMS more appropriately [47], staging people with PD [48], providing more tailored care [49], and potentially reducing the likelihood of NMS being overlooked.

A vast number of publications and systematic reviews have assessed the application of AI into the diagnosis of PD [9,39]. Additional reviews have focused on the management of individual symptoms [50], assessment using wearables [31], individual treatment options in relation to machine learning [51], or both diagnosis and management [21,39]; however, no systematic reviews were identified that comprehensively identify the use of all AI methods specifically for disease and symptom management following diagnosis. A search of PROSPERO and PubMed for a range of keyword combinations including "artificial intelligence," "machine learning," "deep learning," and "Parkinson" identified a range of different reviews; however, none focused on AI for PD symptom and disease management.

To address this lack of comprehensive reviews, this review aims to identify the current uses of all AI applications across the assessment, management, and monitoring of symptoms of PD and identify the challenges and pitfalls of the current application of AI in PD. To achieve this aim, we will provide a comprehensive overview of the current state of the literature; assess and compare the type of AI applied; and identify the challenges and barriers and provide recommendations for the use of AI within this population.

Methods

Overview

The methodology for this review has been generated in accordance with the PRISMA-P (Preferred Reporting Items for Systematic review and Meta-Analysis Protocols) [52], as displayed in Multimedia Appendix 1, as well as the population, intervention, comparison, outcomes, and study (PICOS) framework [53,54].

Eligibility Selection Criteria

The PICOS-type framework, as detailed in Table 1, is based on the research aim stated above.

Table 1. Population, intervention, comparison, outcomes, and study (PICOS) framework.

Population	People diagnosed with PD[a]
Intervention	AI[b] tools, including all machine learning approaches and deep learning approaches for the assessment, management, or monitoring of PD symptoms.
Comparator	No comparator is required.
Outcomes	The primary objective is to identify and summarize the AI methods for the assessment, monitoring, and management of PD symptoms. Therefore, the primary outcome will be to identify and compare the different AI methods used in the assessment, monitoring, and management of PD symptoms. Comparison between models will be made using accuracy data. The secondary outcome is to identify the current challenges, barriers, or pitfalls with the application of AI in PD.
Study types	Qualitative, quantitative, and mixed methods studies that use any form of AI in the assessment, monitoring, or management of PD symptoms will be eligible for inclusion. Reviews, protocols, and papers that describe interventions without evaluating them will be excluded.

[a]PD: Parkinson disease.

[b]AI: artificial intelligence.

Search Strategy

Five databases will be searched for appropriate publications—PubMed, IEEE Xplore, Institute for Scientific Information's Web of Science, the Cochrane Library, and Scopus. The databases were chosen as they were frequently searched in previous systematic reviews on PD and machine learning and have a wide range of coverage of digital technology and health. The following search terms were developed following an initial review of the literature and used to develop the search terms and search strategy. Search items will include Medical Subject Headings (MeSH) terms and keywords related to machine learning, PD, and symptom management. The search terms that will be used in this review are grouped into 3 themes (Table 2). The search string will be created using the following structure: "Artificial intelligence" (MeSH or keyword) AND "Parkinson's disease" (MeSH or keyword) AND "intended use" (MeSH or keyword). Multimedia Appendix 2 shows a sample search string. The reviews will be hand searched for relevant studies.

XSL•FO
RenderX

Table 2. Search terms.

Category	MeSH[a]	Keywords (in title or abstract)
Artificial intelligence	"Artificial intelligence" and "Machine learning"	"Artificial intelligence" OR "machine learning" OR "deep learning" OR "neural network" OR "neural networks" OR "supervised machine learning" OR "unsupervised machine learning" OR "reinforcement learning"
Parkinson disease	"Parkinson's disease"	"Parkinson's disease" OR "Parkinson's" OR "Parkinson" OR "Parkinson disease"
Intended use	N/A[b]	"assessment" OR "monitoring" OR "management"

[a]MeSH: Medical Subject Headings

[b]N/A: not applicable.

Inclusion Criteria

Any study will be included that uses any AI method (ie, machine learning, deep learning, or algorithm) to detect (ie, the identification of symptoms), monitor (ie, maintain an objective oversight of symptoms), or manage (ie, use of symptoms data to reduce symptom burden, reduce prevalence of symptom, or support clinical decision-making) any symptom of PD. The AI method will not be limited and will include all machine learning, deep learning, or algorithm approaches. No restrictions will be placed on the symptom in question; however, a diagnosis of PD must be present. Studies with any type of sampled population will be eligible for inclusion, with no restrictions on age, gender, or country. Interventions with comparisons to control groups with no intervention, irrelevant interventions, or minimal interventions will all be included.

Exclusion Criteria

Due to the progressive nature of the digital health field with continuous adaptations being made, in addition to a clear increase in the number of papers published from this date, any study published before 2010 will be excluded [55]. Studies that address the use of AI in the diagnosis of PD or the management of symptoms related to PD without a diagnosis of PD (eg, Alzheimer disease, sleep disturbance, etc) will be excluded. Studies that assess symptoms in the context of diagnosis or assess related symptoms with a different neurological diagnosis will be excluded. Studies written in any other language aside from English will be excluded, as the research team do not have the capabilities to read them or the resources to have them translated. Studies that focus on Parkinsonian conditions (eg, progressive supranuclear palsy and multiple system atrophy) that are not PD will be excluded. Reviews, protocols, and papers that describe interventions without evaluating them will be excluded (Textbox 1).

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Year: 2010 to present
- Article type
  - Detection, monitoring, or management of one or more symptoms of Parkinson disease (PD) using any artificial intelligence (AI) method
  - Randomized controlled trials; qualitative, quantitative, cohort, and case studies
- Language: English
- Population
  - Human studies of any gender, age, or country
  - Diagnosis of PD

Exclusion criteria

- Year: any article published before 2010
- Article type:
  - Studies that assess symptoms in the context of diagnosis
  - Symptoms of PD without a diagnosis
  - Reviews, protocols, practice guidelines, commentaries, letters, editorials, conference abstracts, and posters without full texts
  - Studies that assess related symptoms with a different neurological diagnosis
  - Studies using Parkinsonian conditions that are not PD (eg, multiple system atrophy or progressive supranuclear palsy)
- Language: non-English
- Population: animal models

Screening and Article Selection

The references returned from the database searches will be exported into the citation management software EndNote 20 (Clarivate) for storage and duplicate removal. The screening will take place in the following three stages: (1) EndNote's search function will be used to screen the articles using keywords in comparison to the inclusion and exclusion criteria, and exclude any studies that are evidently ineligible; (2) the remaining references (titles and abstracts only) will be screened by 2 independent reviewers; and (3) the full texts of the studies will then be screened by 2 independent reviewers to determine the final set of papers for inclusion. Any disagreement between the reviewers will be discussed until a consensus is achieved. If a consensus cannot be achieved, a third reviewer will be consulted to determine the outcome. Details of the screening and selection process will be recorded in a PRISMA-P [52] flow diagram to ensure reproducibility of the study. Stage 1 EndNote 20 searches will be recorded and included in the final review as an appendix.

Data Extraction

The full text of each article included in the final set will be assessed by 2 independent reviewers to extract the data outlined in Table 3. As outlined above, any discrepancies between reviewers will be discussed and resolved by an additional reviewer if a consensus cannot be achieved.

XSL•FO
RenderX

Table 3. Article information and data extraction.

Article information	Data to be extracted
General study information	• Year of publication • Country of study • Sample demographics (including age, gender, and target population) • Initial sample size • Analyzed sample size
Model characteristics	• AI[a] method • Delivery of the AI method (eg, app, web portal, etc) • Aim of intervention • Target user or audience of intervention (eg, people with PD[b], PD care partners, or HCPs[c]) • Purpose of the AI method (ie, symptom assessment, monitoring, and management) • Symptoms assessed • Data collection method or technique (eg, wearable sensor, smartphone app, etc)
Evaluation or validation	• Effectiveness, accuracy, specificity, or sensitivity of method (if reported) • Test training sets of data and their percentages • Effectiveness, efficacy, usability, acceptability, and feasibility outcome measures (if reported)

[a]AI: artificial intelligence.

[b]PD: Parkinson disease.

[c]HCP: health care provider.

Quality Appraisal and Risk of Bias Assessment

Risk of bias for all of the included studies will be independently assessed by 2 reviewers. Any discrepancies between reviewers will be discussed and resolved by a third reviewer if necessary. For randomized controlled trials, risk of bias will be assessed using the Cochrane Collaboration Risk of Bias 2 tool [56,57]. For nonrandomized studies, the Mixed Methods Appraisal Tool will be used [58] due to its appraisal of most common study types and designs.

Data Analysis and Synthesis

If there are sufficient studies, we plan to conduct a meta-analysis of outcome measures; however, there is a possibility that it may not be feasible due to the expected heterogeneity of studies. If meta-analysis is possible, the design will be guided by [59], and heterogeneity will be assessed using I^2 statistic [60]. The primary outcome for meta-analysis will be classification accuracy of symptoms and is expressed at a proportion between 0 and 1 (eg, percentage rate and area under the curve). The extracted data will be summarized using descriptive analysis to provide the outcomes measured, machine learning tools used, and symptoms assessed. The risk of bias in the studies will be considered in the synthesis.

Ethical Considerations

There are no ethical issues of concern in this secondary analysis of published data.

Results

As of April 2023, database searches have not yet begun. The full systematic review is expected to be completed and submitted for publication by September 2023.

Discussion

Principal Findings

This paper describes the protocol for a systematic review to identify the current uses of AI for people with PD in the assessment, monitoring, and management of PD symptoms. The results from this review will improve knowledge about the way PD is managed using AI methods. With increasing need for the effective management of the wide-ranging symptoms of PD and the accelerated use of computational technologies in PD care, a comprehensive analysis of the research surrounding the use of these tools for symptom assessment, monitoring, and management is necessary. This review will identify how AI is currently being used with this population, as well as its potential benefits and limitations.

There has been a recent increase in the focus of digital health and computational technologies for the diagnosis and management of PD, and several reviews have been conducted [10,31,39,61]. This review aims to be the first to summarize the evidence of the use of AI for disease and symptom management for PD. This review differs from the aforementioned reviews as it places no restriction on the symptom in question; for example, in [61], the authors focus on freezing of gait or on the diagnosis of PD only. The results from this review will therefore provide a more thorough overview of the management of PD using AI methods and the potential benefits to the patient, health care professional, and service.

Limitations

A limitation from this review that may impact the conclusions we are able to make is the inclusion of all PD symptoms and their assessment or management via AI. As there are reportedly over 40 symptoms of PD [62], some symptoms may feature more heavily within the literature than others; therefore, conclusions for certain symptoms may be easier to draw than

XSL•FO
RenderX

others. It is anticipated that there will be a high level of heterogeneity of outcomes in addition to the inclusion of qualitative and quantitative studies, which may result in difficulty when comparing the effects. When extracting data, it may be possible to compare the effects in subgroups (eg, symptom type, gender, etc). Finally only studies written in the English language will be included in this review; therefore, relevant articles may be missed as a result.

Conclusions

From this review, we anticipate that the findings will provide insight into the current uses of AI in disease management for people with PD and may inform future research or developments for the implementation of AI-based tools for PD management from research to practice. As this review has the potential to impact upon technological advancements and clinical management, the results will be disseminated through peer-reviewed publication.

Acknowledgments

This research was funded in association with research from NHSX Digital (Grant CENT/DIGHP/PK9/2022-01-20/A). The views expressed throughout this review do not reflect those of NHSX Digital and are of the authors only. The funding body were not involved in any components of this review, including the decision to publish.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study. Data sets generated and analyzed from the prospective full review will be available from the corresponding author upon request.

Authors' Contributions

The review topic was conceived by KB. The protocol was written by KB, with final revision by MMI, AH, EM, and CC.

Abstract

Background: Respondent-driven sampling (RDS) is a nonprobability sampling technique that allows the extrapolation of its outcome to the target population. This approach is typically used to overcome the difficulties in studying hidden or difficult-to-reach groups.

Objective: The purpose of this protocol is to generate a systematic review on the accumulation of biological and behavioral data of female sex workers (FSWs) through different surveys that use the RDS method from around the world in the near future. The future systematic review will discuss the initiation, actualization, and problems of RDS during the accumulation of biological and behavioral data of FSWs through surveys from around the world.

Methods: The behavior and biological data of FSWs will be extracted from peer-reviewed studies published between 2010 and 2022 and that are acquired through RDS. Using PubMed, Google Scholar, the Cochrane database, Scopus, Science Direct, and the Global Health network, all papers that are available will be obtained using the search phrases “respondent-driven” and “Female Sex Workers” OR “FSW” OR “sex workers” OR “SW.” According to STROBE-RDS (Strengthening the Reporting of Observational Studies in Epidemiology for Respondent-Driven Sampling) criteria, the data will be retrieved through a data extraction form and will be organized using World Health Organization classifications of areas. The Newcastle-Ottawa Quality Assessment Scale will be used to measure bias risk and overall study quality.

Results: The future systematic review that will be generated from this protocol will offer evidence for or against the claim that using the RDS technique to recruit participants from “hidden” or “hard-to-reach” populations is the best strategy. The results will be disseminated through a peer-reviewed publication. Data collection started on April 1, 2023, and the systematic review is expected to be published by December 15, 2023.

Conclusions: A minimum set of parameters for specific methodological, analytical, and testing procedures, including RDS methods to evaluate the overall quality of any RDS survey, will be provided by the future systematic review, in accordance with this protocol, to assist researchers, policy makers, and service providers in improving RDS methods for the surveillance of any key population.

Introduction

Background

The respondent-driven sampling (RDS) method is a nonprobability sampling method that approximates probability sample design, allowing for the extrapolation of results to the target population. This method is generally used to address the limitations of studying hidden or hard-to-reach populations [1]. The term "hard-to-reach population" emerged in the early 1990s in public health to refer to the comparatively lower socioeconomic and moderate to low literacy groups, ethnic minority groups, and those who are not successfully reached by health workers from different health campaigns. Social science workers coined the term "hidden population" to refer to the group of people with an inadequate sampling frame. This situation can occur when they belong to an unorthodox occupational group (female sex workers [FSWs]) or closed social groups (men who have sex with men) or have outlawed behaviors (people who inject drugs) or small population size, among others [1].

Initially, RDS was developed [2] as a chain-reference sampling technique by which a data-tracing path is obtained from one person to another, based on their relationship consecutively. This method combines aspects from snowball sampling, stochastic Markov chain modelling, and the theory of biased networks (homophily model) [1]. The authors also rely on the theory describing the "small world" phenomenon that each person indirectly associates with another person through approximately 6 intermediaries, no matter how large the network. If this premise is true, it would mean that even the most socially isolated individuals can be reached in the sixth wave of a reference chain, starting from any arbitrarily chosen individual [2]. Other theoretical bases for the "small world" phenomenon come from sociology—particularly from behavioral theories that study obedience or social control based on the group of belonging [2]. This theoretical background justifies the idea of incentive and peer involvement in recruitment [2].

RDS has been used in several countries to collect data from populations at high risk of HIV exposure, FSWs, men who have sex with men, people who use or inject drugs, and other such people considered "hard-to-reach" due to social stigma and the exercise of unsocial activities [1,3]. Over the decades, this widely accepted sampling technique is used, with the recommendations of organizations such as the US Centers for Disease Control and Prevention, the Joint United Nations Programme on HIV/AIDS (UNAIDS), the World Health Organization (WHO) Global Fund, and others, to generate data on the baseline, conduct trend analysis for prevalence estimation, and study risk behaviors and the impact of the program on HIV and other sexually transmitted infections through biological and behavioral assessments [3]. The sampling technique has proved feasible and successful in recruiting hidden populations of people who inject drugs in a variety of settings, resulting in the rapid acquisition of long and varied recruitment chains. It has been used in several countries to collect both behavioral and biological data from sex workers (eg, Vietnam and India) and men who have sex with men (eg, Bangladesh, Cambodia, Uganda, and the United States) [3,4]. RDS starts with a fixed number of participants called "seeds," which are carefully chosen by the surveillance team from the target population, and samples are built through the passing of a coupon from one peer to the next. A small number of coupons are generated for each participant, limiting the overcontribution of participants with a greater number of ties to other people in the same network. These coupons allow researchers to observe the procedure of recruitment by limiting participants from having to deliver individual information about their recruits [5]. Individuals who are participating and recruiting peers for the survey are provided with "incentives" to ensure ongoing participation and proper recruitment. This participation and recruitment process may result in a long recruitment chain made up of plentiful "waves" of recruits. The arrangement of the sample becomes less reliant on the purposefully selected seeds as recruitment chains get elongated [6]. Statistical modifications for variation in network sizes and recruitment efforts are used after the sample collection to generate data on estimates that are representative of the population's network [1,2,5].

FSWs are also hard to reach because they are mostly mobile and regularly change solicitation points—districts and towns within and across states or provinces [7-9]. Some FSWs are difficult to locate as they engage in part-time sex work. Higher-paid sex workers, such as those who solicit through the internet and agents, have the capacity to remain hidden [8-10]. However, previous involvement with RDS is limited and needs further evaluations to validate these methods. Furthermore, little is known about the feasibility of this sampling technique as a method of recruiting hidden populations of FSWs in settings where the organization of sex work and access to FSWs is highly controlled and where there is little or no contact between the target population and local services [7,11].

Objective

In the context of this background, the purpose of this protocol is to generate a systematic review on the accumulation of biological and behavioral data of FSWs through different surveys that use the RDS method from around the world in the near future. The future systematic review will discuss the initiation, actualization, and problems of RDS during the accumulation of biological and behavioral data of FSWs through surveys from around the world.

Methods

Overview

The protocol has been developed in accordance with the STROBE-RDS (Strengthening the Reporting of Observational Studies in Epidemiology for Respondent-Driven Sampling) guideline (Multimedia Appendix 1) [11]. This protocol has been registered in PROSPERO (CRD42022346470).

Review Items

According to the STROBE-RDS [12] guideline, the following items will be captured in the review:

1. Author

XSL•FO
RenderX

2. Year of publication along with period of study
3. Country or geographical location of study
4. Presurvey assessment (if any)
5. Number of RDS data collection sites
6. Interview methods
7. Numbers of initial and final seeds along with the maximum number of waves
8. Amount of primary and secondary incentives
9. The target sample size and sample size obtained finally
10. Design effect used in sample size calculation
11. The duration of data collection (in weeks)
12. Maximum number of coupons distributed to each recruiter
13. Whether equilibrium or convergence was assessed or not
14. Whether the data were adjusted for network size
15. Use of software for statistical analysis

Electronic Database and Search Terms

All available articles will be retrieved using PubMed, Google Scholar, the Cochrane database, Scopus, Science Direct, and the Global Health network. Search terms will include "respondent-driven" OR "RDS" and "Female Sex Workers" OR "FSW" OR "sex workers" OR "SW." The full search terms are presented in Multimedia Appendix 2.

Inclusion Criteria

The inclusion criteria are as follows:

1. Peer-reviewed literature published only in English in a physical or web-based format that reported using RDS
2. Article published from January 2010 to December 2022
3. Articles on FSWs only

FSWs are defined as those who are cisgender female and have ever exchanged sex for money or goods within the last 12 months.

Exclusion Criteria

Duplicates, irrelevant articles (eg, protocols, presentations, flyers, and those not strictly addressing RDS methodology) along with reviews, opinion pieces, editorials, commentaries, and studies that are not intended to report population-based estimates will be excluded from the initial extraction.

Selection of Eligible Studies

We will obtain the full text of articles or other documents reporting studies identified as being potentially eligible for inclusion. Two suitably qualified reviewers will screen titles and abstracts of articles identified by the search strategy independently using the data extraction form (Multimedia Appendix 3). Any study selected as being potentially eligible by either reviewer will be retained for review of the full text. If no abstract is available electronically and eligibility cannot be judged from the title alone, the full text of the article will be retrieved and screened. The abstracts of articles identified through additional searches will be reviewed in the same manner as those identified through database searches.

Strategy for Data Synthesis

The data will be extracted from full-text published articles through Epi Inf (version 6.0) [13] using a modified data extraction form (Multimedia Appendix 3) according to the STROBE-RDS guideline.

The data will be arranged into 6 subtables in a Microsoft Excel spreadsheet based on WHO classifications of regions [14], such as the African Region, Region of the Americas, South-East Asian Region, European Region, Eastern Mediterranean Region, and Western Pacific Region.

Deduplication

Mendeley bibliographic software [15] will be used for reference management. The following rules will be used to remove duplicate hits from the database:

1. Compare the title or various combinations of the author, year, secondary title, volume, issue, and pages through "deduplication";
2. Visually compare the full records of suspected duplicates; and
3. Save duplicates in a separate database.

Risk of Bias and Quality Assessment

The evaluation of articles through the title, abstract, and entire text of the manuscripts will be performed prior to the addition of it to the ultimate analysis. Assessment will be performed with the help of the Newcastle-Ottawa Quality Assessment Scale [16].

Ethical Consideration

Formal ethical approval is not required as primary data will not be collected.

Results

The future systematic review that will be generated from this protocol will offer evidence for or against the claim that using the RDS technique to recruit participants from "hidden" or "hard-to-reach" populations is the best strategy. The results will be disseminated through a peer-reviewed publication. Data collection started on April 1, 2023, and the systematic review is expected to be published by December 15, 2023.

Discussion

A systematic review will be generated from this protocol and will provide evidence in support of or against the hypothesis that the application of the RDS technique is an effective approach to recruiting participants from "hidden" or "hard-to-reach" populations. This peer-to-peer recruitment is driven by legitimate coupons, making it successful among populations that are stigmatized or who practice behaviors that are considered illegal in the existing social structure.

Similar to any systematic review protocol, this protocol and the future review will also be restricted by the comprehensiveness of the published articles and whether researcher publish their study in open access and peer-reviewed journals. Moreover, the included articles on surveys that accumulate biological data would lead to further studies.

As sex work also carries occupational risk, this approach is expected to be appropriate and the best suited for this high-risk

XSL•FO
RenderX

population [17]. The future systematic review, as conducted according to this protocol, will help researchers, policy makers, and service providers to improve the RDS methods for the surveillance of any key population, by providing a minimum set of parameters of specific methodological, analytical, and testing procedures, including RDS methods to evaluate the overall quality of any RDS survey [18].

Acknowledgments

All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Conflicts of Interest

None declared.

Abstract

Background: Considering the soaring health-related costs directed toward a growing, aging, and comorbid population, the health sector needs effective data-driven interventions while managing rising care costs. While health interventions using data mining have become more robust and adopted, they often demand high-quality big data. However, growing privacy concerns have hindered large-scale data sharing. In parallel, recently introduced legal instruments require complex implementations, especially when it comes to biomedical data. New privacy-preserving technologies, such as decentralized learning, make it possible to create health models without mobilizing data sets by using distributed computation principles. Several multinational partnerships, including a recent agreement between the United States and the European Union, are adopting these techniques for next-generation data science. While these approaches are promising, there is no clear and robust evidence synthesis of health care applications.

Objective: The main aim is to compare the performance among health data models (eg, automated diagnosis and mortality prediction) developed using decentralized learning approaches (eg, federated and blockchain) to those using centralized or local methods. Secondary aims are comparing the privacy compromise and resource use among model architectures.

Methods: We will conduct a systematic review using the first-ever registered research protocol for this topic following a robust search methodology, including several biomedical and computational databases. This work will compare health data models differing in development architecture, grouping them according to their clinical applications. For reporting purposes, a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram will be presented. CHARMS (Critical Appraisal and Data Extraction for Systematic Reviews of Prediction Modelling Studies)–based forms will be used for data extraction and to assess the risk of bias, alongside PROBAST (Prediction Model Risk of Bias Assessment Tool). All effect measures in the original studies will be reported.

Results: The queries and data extractions are expected to start on February 28, 2023, and end by July 31, 2023. The research protocol was registered with PROSPERO, under the number 393126, on February 3, 2023. With this protocol, we detail how we will conduct the systematic review. With that study, we aim to summarize the progress and findings from state-of-the-art decentralized learning models in health care in comparison to their local and centralized counterparts. Results are expected to clarify the consensuses and heterogeneities reported and help guide the research and development of new robust and sustainable applications to address the health data privacy problem, with applicability in real-world settings.

XSL•FO
RenderX

Conclusions: We expect to clearly present the status quo of these privacy-preserving technologies in health care. With this robust synthesis of the currently available scientific evidence, the review will inform health technology assessment and evidence-based decisions, from health professionals, data scientists, and policy makers alike. Importantly, it should also guide the development and application of new tools in service of patients' privacy and future research.

Introduction

Background

The current health paradigm challenges are unprecedented in their nature and scope. Stemming from a growing [1], aging [1], and comorbid [2] global population, disability is becoming an increasingly large share of the burden of disease and of the already unsustainable health care costs [3-6]. Faced with the need to invest in more effective and preventive strategies, improved research and development are essential to address these unwavering issues [2].

To do so, robust evidence-based health knowledge is needed, as a way of enabling improved planning and provision of care. Presently, many data-driven approaches are commonplace in biomedical sciences and clinical research. These include examples from epidemiological surveillance [7] and cancer prognosis [8] to drug discovery [9,10] and mortality prediction [11].

Thus, access to data has been the foundation for better health models, both in their precision and validity to represent different medical conditions [12,13] and patients [14,15]. In parallel, alongside recent digital transitions and new tools and infrastructures, data analysis has become more powerful and faster than ever [16]. This gave rise to data science [17], resulting from the complex merger of traditional statistics disciplines combined with other subjects.

In particular, data mining techniques have elevated the computational functionality, especially for cognitive and analytic processes that are hard to develop algorithmically [18]. Thus, machine learning models, such as decision trees, linear regression, and support vector machines are now abundant in health research [19,20]. Deep neural networks brought to light even more sophisticated applications of natural language processing and computer vision, both effective and powerful [21,22].

Supported by robust software and hardware, these new model development approaches rely on the availability of large and high-quality training databases. Hence, the concept of big data emerged, referring to the need for comprehensive data sets to sustain the inferential process in both their internal and external validities. While it is often characterized by a few key dimensions (volume, variety, velocity, value, veracity, and variability), many other features (eg, venue and volatility) can be of relevance [23,24]. However, concerns regarding privacy protection—a fundamental human right [25]—are rising amid increasing numbers of misconducts and violations [26,27].

Limitations of Current Strategies

In response to both data demands and privacy challenges, 2 groups of arguments can be made in favor of transitioning traditional approaches toward a new data science paradigm.

First, to generate and use high-quality big data to support precision and generalizability assumptions, findable, accessible, interoperable, and reusable (FAIR) principles [28] ought to be adopted. In theory, following these criteria is important to develop new scientific studies and validate, or otherwise reproduce, at least part of already available works [29,30]. In practice, FAIR principles are hard to comply with, for several reasons.

Starting with "findable," few health data catalogs are available, and some are no longer being updated [31-33]. Considering access, while new instruments [34-37] have presented legislation and guiding frameworks on how data should be used and shared, their impact is controversial and their implementation is often complex, especially for medical research purposes [38-44]. Even follow-up developments, like the European Health Data Space [45], are viewed with skepticism by some member states regarding its practical feasibility and results [46,47].

Furthermore, data use is often limited by its interoperable characteristics. Technical heterogeneity due to different electronic health record systems, data standards, and data exchange protocols makes it difficult to share and integrate health data across multiple parties. Given all the challenges stated, reusability is practically impossible, outside some rare contexts [48,49].

Additionally, another set of arguments can be presented referring to the need for a systematic approach that does not rely on individuals' actions nor benefits from their limitations. First, we recognize that individuals are not capable of always acting with their own (or collective) interests in mind [50]. Specifically in their health data sharing attitudes, even though people may be aware of the value of data and potential privacy issues, their actions are often contrasting to their stated beliefs [51,52].

Then, we place the onus and burden of sustainable privacy protection on the system itself and are not reliant on the constant and best behavior of every individual agent [53]. Some

XSL•FO
RenderX

successful global data sharing efforts [48,54,55] have already proven that after the demanding set up, it is possible to not only improve access to data but also protect privacy by design [56].

New Technological Solutions

In response to these demands, recent breakthroughs in some computational domains, including secure processing units [57,58], differential privacy [59,60], and homomorphic encryption [61,62], have offered technical alternatives for the use of data in a privacy-preserving fashion. Being one of the more interesting approaches, decentralized learning architectures [63,64] enable data scattered across different silos (eg, health care providers) to be used to develop or validate pre-existing models. By combining the information derived from data present in each silo, it is possible to create more precise and generalizable models.

In general, local models are first developed using the party's own data. Second, only the model parameters (ie, information) are shared, usually with a central coordinator, responsible for aggregating the different local instances to create a new decentralized model. Throughout this process, data remain unmoved and are not accessed or manipulated by third parties.

Accordingly, such models can be produced without mobilizing or otherwise sharing the data set itself by parceling out the inferential process, on top of distributed computation principles [65]. By cyclically repeating this process, we can improve the model performance and include newly available data, fostering the development of continuously updated real-world evidence-based knowledge.

The potential for developing health care applications and generating value is clear [66]. Sharing models developed using different data sets can make the distributed solutions more comprehensive and adequate, due to robust internal and external validations. These approaches are useful to study medical conditions [67-69], especially those with limited prevalence or few observations, and prevent inadequate care due to mis- or underrepresentation of certain groups of patients [70].

Subsequently, significant agreements, like the one achieved between the United States and the European Union [71], promise a new platform for these technologies to be implemented while respecting their differing legislative frameworks. Such consensus can have a seismic impact on the way data science is conducted.

In the meantime, there still are many ongoing challenges regarding decentralized learning [18,72]. Some relevant issues are a lack of objective and measurable standard definitions of privacy and security [73], and server-client trust and honesty assumptions to computationally intensive and energetically demanding tasks [61,74]. Other important problems are the heterogeneity in distributed data and environments as well as fairness and respect for individual and local preferences [73].

However, above all else, the most pressing undertaking remains assessing the validity, relevance, and applicability of already published and available tools to inform and justify subsequent health technological appraisals and their implementation in real-world settings.

To do so, we must address the following questions: are decentralized health data models' performance superior (or noninferior) to current (centralized and local) approaches? and what are the reported privacy gains and the main resource demands?

Aims and Objectives

The systematic review based on this protocol aims to, first, compare the performance among health data models developed or validated using decentralized learning approaches (eg, federated and blockchain) to those developed using nondecentralized methods (eg, centralized and local). These can include applications such as automated diagnosis, segmentation of lesions or features, as well as mortality prediction.

The performance metrics used for model comparison will be the following: area under the receiver operating characteristic (AUROC) curve, F_1 score, Jensen-Shannon distance, sensitivity (or recall), specificity, accuracy, precision (or positive predictive value), negative predictive value, Dice score, as well as any metrics regarding the convergence step. Comparisons will be made only among models using the same type of data (eg, tabular and images) and clinical application (eg, diagnostic and survival). Our secondary aims are to compare the privacy compromise (eg, privacy budget) and resource use (eg, computation power and wall-time) among these health data models using different architectures.

With this review study, our goal is to summarize the progress and findings from state-of-the-art decentralized learning models in health care, in comparison to their currently used counterparts. These results are expected to clarify the consensuses and heterogeneities reported and help guide the research and development of new robust and sustainable applications to address the health data privacy problem, with applicability in real-world (clinical) settings.

Methods

Eligibility Criteria

Regarding the inclusion criteria, relevant studies are original research papers (including published, unpublished, and preprints) targeting one or multiple specific human medical conditions. They should be comparing 2 types of health model learning approaches—one decentralized (eg, federated and blockchain) and other nondecentralized (eg, centralized and local). For this review, decentralized learning architectures are defined as a machine learning approach to use data available from multiple parties, without sharing them with a single entity, to extract information [18].

As there may be some confusion regarding the terms "decentralized" and "distributed," we consider the first as the most appropriate and rigorous designation of our study field, including federated and blockchain architectures. The latter is broader in scope and refers to a computational subject that includes, but also precedes, the current advances and innovations [65]. Nevertheless, studies will be included regardless of the adopted terminology if the definition or methodologies used

XSL•FO
RenderX

are in accordance with the above definition of decentralized learning architectures. Both types of models must report at least one of the following model performance metrics: AUROC curve, F_1 score, Jensen-Shannon distance, sensitivity (or recall), specificity, accuracy, precision (or positive predictive value), negative predictive value, Dice score, as well as any metrics regarding the convergence step.

Regarding the exclusion criteria, papers published before 2012 will not be considered for this analysis, due to the following reasons. First, the earliest decentralized learning framework proposals in health care are only introduced [75,76] or applied [77] after this year. Second, seminal studies detailing and developing the current definition of these concepts were published in 2016 [78,79], with related works being as available as early 2014 [63,80,81]. Moreover, in no systematic review for health care implementations are there primary studies published before 2016 [82-86].

Each synthesis will consider studies with common types of clinical applications (intervention, diagnosis, etiology, prevention, prognosis or prediction, quality of life or meaning, and therapy), types of models, and types of data used. Whenever possible, they will be grouped by health problems.

Information Sources

Recognizing the interdisciplinarity nature of the research being made on health data models, several databases will be queried—some more specific to biomedical scientific research (ie, PubMed, SpringerLink, and Lippincott Williams & Wilkins), some more specific to computer science and informatics engineering (ie, the Association for Computing and Machinery Digital Library or Guide to Computing Literature and IEEE Xplore), while others were more general (ie, Wiley Online Library, Scopus, Web of Science, and Lens).

Moreover, 2 registries for systematic reviews (Cochrane Database of Systematic Reviews and PROSPERO) were surveyed for submissions related to these topics, in order to look for additional primary papers. Furthermore, queries were also conducted in databases, which included research papers not peer-reviewed or otherwise unpublished (eg, medRxiv and arXiv). For every listed source, searches are expected to be conducted during March 2023.

Five experts in relevant scientific fields (from data science, health informatics, and decentralized learning approaches) will be contacted to ask for suggestions of additional bibliography not included in the selection process, without the knowledge of the selected or rejected papers. Such recommendations will be considered worthy of consideration and included if eligibility criteria are met. Due to the reasons stated in the eligibility criteria, it was deemed appropriate to restrict the search to papers published in 2012 or later.

Search Strategy

Overview

Given the recency of this research domain and the expected limited number papers, it was imperative to devise a broad search strategy. This was materialized in choices such as including several databases, as well as using synonyms and wildcards in the query.

However, due to the popularity of some of the query terms—for example, distributed, model, training, and health—some procedures were adopted to filter noise. For instance, words like “distributed” and “model” should have a limited number of words in between, for the finding to be relevant. Moreover, search engines have heterogeneous features, which make it difficult to conduct the desired exploration.

Hence, a composite search strategy was adopted. The first part, optimizing for comprehensiveness, was focused on writing the query and electing relevant filters for each database used (see “Part 1—Database Query” section, Table 1, and Figure 1). Subsequently, a filtration process was applied, using regular expressions (RegEx) code, to make up for the lacking features of the databases used—such as word proximity limits, operators, and metadata fields searched (see “Part 2—Results Filtration” section).

Table 1. General query terms by group.

Group	Terms
A—Model architecture	decentrali*, distributed, federated, central*, multi-party computation, blockchain
B—Model synonym	learn*, model*, network*, AI[a], artificial intelligence, ML[b], machine learning, train*, tensor*, perceptron, algorithm*
C—Health related	health*, medic*, clinic*, patient*, physician*, doctor*
D—Performance metrics	AUROC[c], ROC[d], receiver operating characteristic curve, F_1, Jensen-Shannon, sensitivity, recall, specificity, accuracy, precision, predictive value, Dice, conversion

[a]AI: artificial intelligence.

[b]ML: machine learning.

[c]AUROC: area under the receiver operating characteristic.

[d]ROC: receiver operating characteristic.

risk of bias assessment [88]. These forms will be piloted before the data collection process.

After completion, retrieved data will be compared to check for errors or inconsistencies and discuss any doubts. The researchers will decide by consensus on the last version of the database of the data collected.

Data Items

A pilot study was conducted to refine the list of relevant data variables to collect, using 100 papers of a developing query. The complete list of variables for collection (whenever available) is the following.

First, general attributes are to be collected, namely, title, author or authors, abstract, publication date, country or countries of the research institutions, type of publication, the journal or publisher, as well as the PICO (Population, Intervention, Comparison, and Outcomes) question.

Specific data points regarding health topics, the type of clinical application (eg, diagnostic and survival), and the applicable medical domain will also be registered.

Concerning the data used, information about the data set size, namely, the number of observations or cases, the number of variables, and the volume in megabytes or gigabytes will be detailed. As far as the nature of the data goes, it will be marked as either synthetic or real, and, in the latter, whether the data were collected for the study (primary source) or not (secondary source). The original data holders will be described by their number, type, and localization, as well as the storage architecture used (eg, centralized, decentralized, and local). Other data points will be the places (geographical and institutional) where data were analyzed, the ethics and legal permissions reported, as well as the data type used (eg, text and images), alongside their format (eg, tabular), and conversion processes.

The type of all models reported are, for example, deep neural network and decision trees, and their performance metrics are specifically AUROC curve, F_1 score, Jensen-Shannon distance, sensitivity or recall, specificity, accuracy, precision or positive predictive value, negative predictive value, Dice score, as well as any metrics regarding the convergence step. The training methods will also be registered, including their update routine (rounds, epochs, quorum, update frequency, update content, and protocols for data communication) and statistical methods used. The validation process used will also be described.

Regarding the architectures used, their type, data flow, and client type (cross-silo vs cross-device vs both) will be extracted, as well as the personalization or customization step and the aggregation methods used. Importantly, we will detail all the model architectures and types compared, and their hypothesis tests.

For our secondary aim, we will collect data on the privacy cost measures (privacy budget, k-anonymity, fingerprinting, entropy, or others) and resource consumption (from computer resources, hardware and software specs, and energy to time and number of rounds), as well as additional security and privacy protection measures.

Lastly, we will record the reason for using decentralized approaches, whether the data and code used are available, and the reported challenges and limitations. No assumptions will be made regarding missing or unclear information—those findings will be reported as such.

Study Risk of Bias Assessment

For each selected paper, the CHARMS [88] and PROBAST (Prediction Model Risk of Bias Assessment Tool) [89] checklists will be used to assess the risk of bias of included research works. The full results of such an appraisal will be presented on a table and considered for the discussion of the results. If deemed relevant, depending on the final list of results, other more specific tools may be used.

Effect Measures

All the effect measures in the original studies will be presented. Whenever unavailable, and if possible, the difference between the AUROC curve estimates for the models of different architectures will be calculated. When multiple rounds of model development, validation, or application exist, the difference in time and rounds to a set performance target will be calculated.

If multiple values for each model are available, the median and mean values will also be used to calculate the differences. If AUROC curve values are not available, other commonly found metrics may also be used.

Synthesis Methods

A qualitative analysis of the evidence will be conducted alongside a descriptive synthesis of the results. Each synthesis will consider the types of clinical applications, models, and data used. Whenever possible they will be grouped by health problems.

Missing data will be reported as “Missing.” Whenever a synthesis method is not applicable, it will be labeled as “Not Applicable.”

Due to the heterogeneity of the applications and model characteristics, it is not expected to be able to synthesize results in a quantitative fashion. Accordingly, neither a meta-analysis nor a sensitivity analysis will be performed.

Reporting Bias Assessment

For every eligible study, the authors will look up preresearch registers of protocols and check for differences in the published work. Additionally, they will assess whether any pertinent statistics or analyses are unreported. All corresponding authors will be contacted to assess if they have any nonreporting experience with any version of their published work or regarding other unpublished research, as suggested by Ammenwerth and de Keizer [90].

Questions may include the following: Which information systems did you evaluate in the last 3 years? Where did you publish the results? and If you did not publish them, what were the reasons for that decision? (here, some common reasons could be selected or added using free text fields).

Moreover, specific efforts will be made to identify omissions of some measured outcomes, as well as selective reporting of

XSL•FO
RenderX

only "significant" findings from among several analyses undertaken.

Certainty Assessment

Certainty assessment procedures will be performed if appropriate instruments are available at the time of review completion.

Other Information

Efforts will be made to make available the query links (or prompts) for each database used, as well as the RegEx filtering code, the templates for data collection forms, and the data extracted from the included studies, and any other resources, which might be used for the subsequent review.

Results

The queries and data extractions are expected to start on February 28, 2023, and end by July 31, 2023. The research protocol was registered with PROSPERO, under the number 393126, on February 3, 2023.

It is expected that the systematic review will summarize the progress and findings from state-of-the-art decentralized learning models in health care, in comparison to their local and centralized counterparts. These results will help in clarifying the consensus and heterogeneities reported among different models and studies, as well as guide the research and development of new robust and sustainable applications to address the health data privacy problem, with applicability in real-world (clinical) settings.

Discussion

Principal Findings

As the systematic review is yet to be conducted, no specific results can be reported at this time. However, this will be the first systematic review on the comparison of decentralized health data models to more common local or centralized approaches that is both comprehensive and focused on objective performance metrics. Due to our exhaustive search strategy and the plurality of data sources identified, this work will present the clearest situational assessment yet of the application of these technologies in health care.

We hope that, by highlighting effective models and their developments, as well as identifying those which underperformed, we can shed light on more fruitful and interesting directions for our peers. In addition, by considering the development costs and privacy gains, as reported in the primary papers, it is expected that this review may be useful for health technology assessment and evidence-based decisions, from health professionals, data scientists, and policy makers alike.

By providing the original search queries and documentation on the methods used, we open the possibility for researchers to use this protocol and upcoming supplemental materials to not only audit and validate our work but also conduct updated versions of this review as new evidence is published.

Strengths and Limitations

While decentralized health data models are a nascent and growing field of research, all appropriate steps will be taken to ensure a comprehensive and exhaustive search of available literature. To do so, we will consider a variety of sources (both specific to bio- and computational sciences and generalist databases), as well as preprint works. Alongside these efforts, a substantive yet clear search and selection procedures have been detailed, with 3 authors selecting primary papers for inclusion in the review. Together, these will also increase the sensitivity and specificity of the search results and the studies included for analysis.

Moreover, this protocol is already registered with PROSPERO and is written in accordance with the PRISMA 2020 guidelines, which will confer more validity and accountability for the results provided. In conjunction with the review, these actions will allow for reproducible and auditable work. For instance, it may be useful, with the necessary adaptations, to repeat this study, when even more evidence is available.

Some limitations of this work include the expected heterogeneity among primary studies, complicating synthesis and comparability among models, and the rapid evolution of the field. Given the unusual population (the P in PICO) of this systematic review, the appraisal of the primary studies may be made difficult by a lack of appropriate tools to assess the risk of bias, especially in reporting, and the certainty of the findings.

Comparison With Prior Work

While there are some systematic reviews on the topic already available, they present several important shortcomings in the size and scope [82-84], the specificity of health care applications [85], and the capability and comprehensiveness of query prompts [86]. Moreover, to the best of our knowledge, none of them were accompanied by a protocol publication or registry before the corresponding review.

Therefore, a more robust and valid synthesis of the currently available scientific evidence must be conducted. We consider the proposed systematic review is capable of achieving that result.

Conclusions

Increasing pressure to develop better, more effective, and cost sensitive care, juxtaposed with the privacy-preserving principles and methodologies, has created a considerable demand for alternative health data model development, validation, and application procedures.

While decentralized approaches, such as those built with federated and blockchain architectures, promise considerable gains for extracting information out of health data, there is much uncertainty regarding how they compare to current centralized and local models, as well as their associated privacy gains and their resource consumptions.

This protocol is the first, at the time of this writing, to outline a systematic review on health data decentralized models, aiming not only to capture the rich variety and complexity of available

XSL•FO
RenderX

research but also to generate a rigorous and comprehensive assessment of the synthesis of their results and conclusions.

It is expected that such work will have implications for this budding research field and policy making, especially for those working with health data privacy matters. This review will highlight the advances and shortcomings of these approaches to better inform the development and application of new tools in service of patients' privacy while hoping to guide future research.

Acknowledgments

All authors, except the second listed, are researchers of the project "Secur-e-Health: Privacy preserving cross-organizational data analysis in the healthcare Sector" (ITEA 20050), cofinanced by the North Regional Operational Program (NORTE 2020) under the Portugal 2020 and European Regional Development Fund, with the reference NORTE-01-0247-FEDER-181418. The funding agency did not have a role in either the study design, the data analysis, the manuscript preparation, or the submission of this work. The authors would like to recognize the contributions made by Diogo Nogueira-Leite and Bernardo Sousa Pinto in the suggestions made to earlier versions of this protocol.

Data Availability

Documentation will be provided regarding the specific queries used, tailored to each source, including their adapted formulation and filters, to ease reproducibility. Whenever possible, a direct URL link will be included. In addition, the code used to compile and filter the results of the various extraction files will be freely available in a GitHub repository. The original lists of all papers (as extracted) as well as other reports with all those subjected to the screening process will be accessible in the same repository. Moreover, the original data collected from each of the studies included in the review will be shared in a Research Data Repository.

Conflicts of Interest

Abstract

Background: Allergic diseases affect around 40% of the pediatric population worldwide. The coexistence of asthma, allergic rhinitis, eczema, and food allergy renders allergy treatment and prevention challenging. Infant feeding strategies recommend avoiding allergenic foods to prevent allergy development and anaphylaxis. However, recent evidence suggests that early consumption of food allergens during weaning in infants aged 4-6 months could result in food tolerance, thus reducing the risk of developing allergies.

Objective: The aim of this study is to systematically review and carry out a meta-analysis of evidence on the outcome of early food introduction for preventing childhood allergic diseases.

Methods: We will conduct a systematic review of interventions through a comprehensive search of various databases including PubMed, Embase, Scopus, CENTRAL, PsycINFO, CINAHL, and Google Scholar to identify potential studies. The search will be performed for any eligible articles from the earliest published articles up to the latest available studies in 2023. We will include randomized controlled trials (RCTs), cluster RCTs, non-RCTs, and other observational studies that assess the effect of early food introduction to prevent childhood allergic diseases.

Results: Primary outcomes will include measures related to the effect of childhood allergic diseases (ie, asthma, allergic rhinitis, eczema, and food allergy). PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines will be followed for study selection. All data will be extracted using a standardized data extraction form and the quality of the studies will be assessed using the Cochrane Risk of Bias tool. A *summary of findings* table will be generated for the following outcomes: (1) total number of allergic diseases, (2) rate of sensitization, (3) total number of adverse events, (4) improvement of health-related quality of life, and (5) all-cause mortality. Descriptive and meta-analyses will be performed using a random-effects model in Review Manager (Cochrane). Heterogeneity among selected studies will be assessed using the I^2 statistic and explored through meta-regression and subgroup analyses. Data collection is expected to start in June 2023.

XSL•FO
RenderX

Conclusions: The results acquired from this study will contribute to the existing literature and harmonize recommendations for infant feeding with regard to the prevention of childhood allergic diseases.

Introduction

Background

There has been a steep increase in the reported prevalence of common childhood allergic diseases (namely asthma, allergic rhinitis, eczema, and food allergy) in the last few decades [1-3]. According to Asher and Pearce [1], the International Study of Asthma and Allergies in Childhood concluded in the early 2000s reported that the prevalence of asthma, allergic rhinitis, and eczema had risen to over 30% in most industrialized countries. In addition, asthma is prevalent among approximately 300 million people worldwide, and by 2025, a further 100 million will likely be affected [4]. It is therefore crucial to evaluate the effectiveness of early life prevention techniques in order to lower the burden of childhood allergic diseases.

Infant feeding guidelines recommend early initiation of breastfeeding, including exclusive breastfeeding for the first 6 months of life and continued breastfeeding up to and after 2 years of age. Additionally, weaning or complementary feeding—defined as the provision of nutrition in the form of liquid or solid other than breast milk or infant milk formula—is introduced to neonates by 6 months of age, depending on the achievement of developmental milestones and the availability of safe complementary foods [5,6]. Besides providing essential nutrients to the growing infants, weaning exposes the developing gut microbiome to different antigens, thus influencing immune system development [7]. Food sensitization frequently occurs early in life and is often the first sign of future allergic disease; this is because the infant's immune system has yet to develop, if at all, an allergic phenotype [8]. Food items with allergenic properties may resist digestion and enhance allergenicity. Hence, susceptible infants who did not develop tolerance will manifest an allergic phenotype. Additionally, the preservation of "beneficial" gut microbiota in the neonate prevents immunity alteration that subsequently predisposes him/her from developing an allergy [9]. As a result, many researchers propose nutritional allergy interventions during this period, such as prolonged breastfeeding, early introduction of foods, maternal avoidance diets during pregnancy and lactation, use of hypoallergenic formulas, and early allergen avoidance, albeit with varying degrees of success [8,10,11].

The landmark study, Learning Early About Peanut Allergy, was one of the first to suggest early introduction of peanuts to reduce the development of peanut allergies [12]. In 2016, the Enquiring about Tolerance study expanded to multiple allergenic food items (ie, peanuts, cooked eggs, cow's milk, sesame, whitefish, and wheat) and observed a significant reduction in the prevalence of food allergies in the studied population [13]. These studies, along with others, appear to offer an effective and robust strategy to minimize the burden of allergy in the general population [10,14].

Living with allergic disease affects the quality of life of both patients and their guardians, considering the increasing health care costs. The determinants of health-related quality of life (HRQoL) in children with allergies traverse beyond biophysiological parameters and the symptom status of the child (such as physical limitations and emotional stress) and may include family dynamics and socioeconomic status, the community in which they live (ie, restrictions on participation in activities and social interaction), and organizational and policy-related factors (eg, inadequate food labelling and public information on allergies) [15-17]. Thus, effective allergy management strategy, including allergy prevention is imperative to avert allergic episodes that can be life-threatening.

Current recommendations for infant feeding require more consensus in the area of early life nutrition, specifically for prevention of childhood allergic diseases [18]. Moreover, an increasing number of studies have been examining the effect of early food introduction on reducing allergic sensitization, thus promoting allergy tolerance in these children [19-21]. We acknowledge earlier reports; however, most reviews have focused on the development of food allergies as well as having a diverse methodological approach [22-25]. In addition, there are diverse dietary patterns that may influence the development and progression of allergic diseases and their phenotypic expression in Asian populations. Although the published studies might have promising findings, less is understood about the potential harm that might result from the population-based guidelines and public health programs [26]. Thus, the aim of this systematic review is to identify evidence regarding the effect of early food introduction in preventing childhood allergic diseases.

Objective

This study aims to systematically review and carry out a meta-analysis of the effectiveness of early food introduction in preventing childhood allergic diseases.

Methods

This systematic review and meta-analysis will be conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [27]

XSL•FO
RenderX

(Multimedia Appendix 1) and the Cochrane Handbook for Systematic Reviews of Interventions [28].

Study Population and Selection Criteria

Inclusion Criteria

Our inclusion criteria will be based on the PICOS framework where the population of interest ("P") is defined as comprising healthy infants who were introduced to early feeding, the intervention ("I") is early introduction of complementary food (allergenic and nonallergenic) as a method of weaning when an infant approaches 4 months of age (ie, before turning 6 months old)—complementary food introduction is defined by the provision of nutrition other than breast milk or infants' milk formula [29]. Weaning may involve liquid food, as in formula feeding, or solid food that provides essential nutrients to an infant and the developing gut microbiome while influencing immune development [30]. We will accept other interventions that were not specified in this study and were defined by individual authors if they do not involve any pharmacological agent. We will compare ("C") our study cohort with infants who have been initiated on complementary feeding (ie, weaning) in accordance with the standard infant feeding guidelines as described by the studies included in this meta-analysis. The World Health Organization and United Nations International Children's Emergency Fund recommend early initiation of breastfeeding, including exclusive breastfeeding for the first 6 months of life followed by continued breastfeeding for up to 2 years and beyond [31]. Additionally, adequate complementary foods are recommended from the beginning of 4 months to latest 6 months of age to all neonates [32]. The outcomes ("O") are categorized as (1) primary outcomes including the total number of cases presented with asthma, allergic rhinitis, eczema, and food allergy (a reproducible hypersensitivity reaction to certain food items) and (2) secondary outcomes such as allergic sensitization (ie, the presence of elevated total and specific immunoglobulin E (IgE) levels to an allergen [33]) and total number of adverse events from allergen exposure. We will also evaluate studies reporting improvement in HRQoL, measured using validated scales (eg, Pediatric Allergic Disease Quality of Life Questionnaire, Food Allergy Quality of Life Questionnaires, and Pediatric Quality of Life Inventory) as well as all-cause mortality. We will include studies ("S") that are randomized controlled trials (RCTs) or cluster-RCTs, non-RCTs, and other observational studies that evaluate the effectiveness of early food introduction for preventing childhood allergic diseases. All published reports from inception up to October 2023 will be included.

Exclusion Criteria

Excluded studies are those that enrolled infants older than 6 months, those that involved food interventions among infants with congenital abnormalities (eg, dysmorphism), those not published in English, all unpublished trials and abstracts, and those describing multicomponent management (studies including the use of drugs). We will also exclude studies where infants initiated on supplementary feeding before the age of 4 months and those in which infants were initiated on certain immune suppressors (eg, steroids). We will exclude cross-over studies due to concerns about the carryover effects. We will also exclude all observational studies, any short communication, case report, and guidelines. Table 1 summarizes the PICOS search strategies, and sources of review for this study.

Table 1. PICO[a] search strategies and sources of review.

	Sources based on the PRISMA[b] checklist
Population	Healthy infants at recruitment as outlined by study authors.
Intervention	Early food introduction or early weaning when an infant approaches 4 months of age and before turning 6 months old.
Comparison	Infants initiated on complementary feeding (weaning) in accordance with standard infant feeding guidelines as described by the author.
Outcome	Primary outcome: total number of events of allergic disease (including asthma, allergic rhinitis, eczema, and food allergy). Secondary outcomes: rate of sensitization (level of total and specific immunoglobulin E), total number of adverse events, improvement of health-related quality of life measured using validated scales, and all-cause mortality.

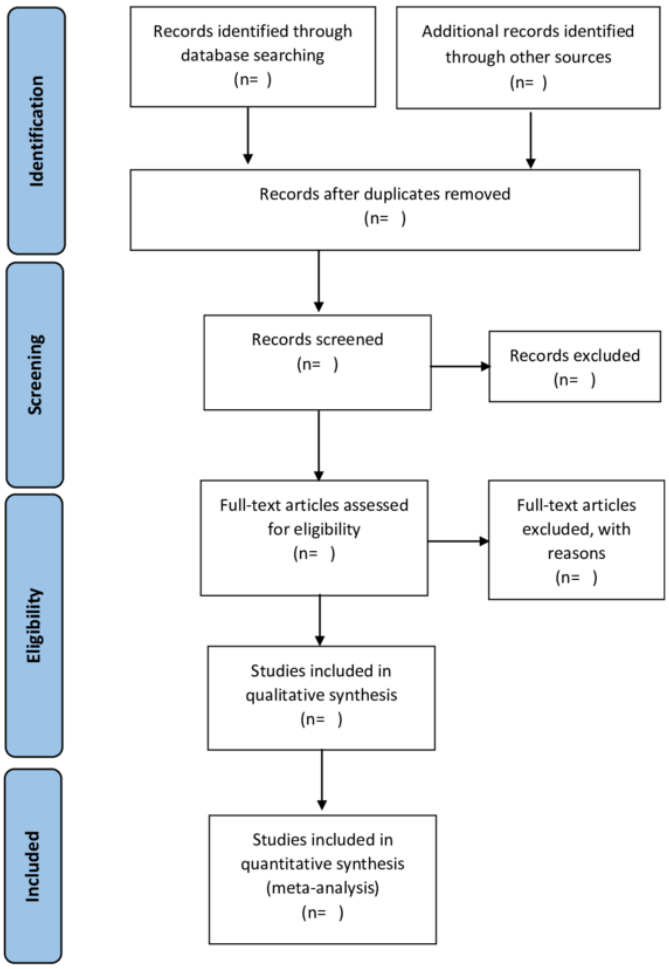
[a]PICOS: population, intervention, compare, outcomes, and studies.

[b]PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Search Strategy

A systematic and comprehensive literature search will be conducted in various databases including PubMed, CENTRAL, Embase, Scopus, PsycINFO, CINAHL, and Google Scholar from inception to October 2023. A search strategy will be developed for PubMed and adapted for use with other electronic databases (Multimedia Appendix 2). The search will include MeSH terms and keywords relating to the study population ("childhood" OR "children" OR "paediatric" OR "pediatrics" OR "infants"), intervention ("early food introduction" OR "weaning" OR "complementary feeding" OR "supplementary feeding"), and outcomes ("allergies" OR "allergy" OR "allergic diseases" OR "asthma" OR "allergic rhinitis" OR "eczema" OR "dermatitis" OR "food allergy" OR "sensitization").

Data Collection



Standard Cochrane methods will be used, as described in the Cochrane Handbook for Systematic Reviews of Interventions [34]. Two authors will independently screen all the titles and abstracts to examine all the potential studies. We will code them as "retrieve" (eligible, or potentially eligible or unclear) or "do not retrieve." We will retrieve full-text reports or publications, and 2 other review authors will independently screen the full text to identify studies for inclusion and will identify and record the reasons for exclusion of the ineligible studies. We will use

XSL•FO
RenderX

a standardized data extraction form in accordance with the Cochrane Handbook for Systematic Reviews of Intervention [28]. Data will be independently extracted in accordance with general information (author, source, date of publication, country, and language), study (type of study, study duration, sample size, and control group selection), participants (age, sex, and type of allergy), types of intervention (food avoidance upon diagnosis and food challenge), and, lastly, outcomes (allergic episodes, admissions or emergency visits, duration of illness, and quality of life measured using validated scales) [28].

We will resolve any disagreement through discussion or consult a third review author if necessary. We will identify and exclude duplicates, and if multiple or overlapped reports of the same study are found, we will group them under a single study ID, and assign the report with the most amount of relevant information as the primary publication. We will record the selection process in sufficient detail to complete a PRISMA flow diagram (Figure 1) and construct a table describing the characteristics of the excluded studies [35]. We will resolve any discrepancies through discussion and by involving a third author.

Figure 1. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart for reporting studies.

Quality Assessment of the Included Studies

Two reviewers will independently assess the quality of the included studies. The methodological quality of selected studies will be assessed using the Cochrane Risk of Bias Tool [36] for RCTs and cluster-RCTs, which includes the following domains: allocation concealment of random sequence generation, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective outcome reporting, and other bias. We will use ACROBAT-NRSi (A Cochrane Risk Of Bias Assessment Tool for Non-Randomized Studies), which evaluates the risk of bias in the results of non-RCTs studies that compare the health effects of 2 or more interventions [37]. We will use Newcastle-Ottawa scale for observational studies and evaluate the quality parameters (selection, comparability, and outcome) of the selected studies [38]. We will make judgments on each of the abovementioned criteria regarding whether the study has a high, low, or unclear risk of bias. We will summarize the risk-of-bias judgements with justification for each of the domains listed in the *Risk of bias* table. Any disagreement among the review authors will be resolved by discussion to achieve a consensus.

Summary of Findings Table

We will create a *summary of findings* table by tabulating the following outcomes: (1) total number of allergic diseases (asthma, allergic rhinitis, eczema, and food allergy), (2) rate of sensitization (level of total and specific IgE), (3) total number of adverse events, (4) improvement of HRQoL measured using validated questionnaires, and (5) all-cause mortality [39]. We will use the following 5 GRADE (Grading of Recommendations Assessment, Development and Evaluation) elements to assess

XSL•FO
RenderX

the quality of the body of evidence as it relates to the prespecified outcomes: quality of evidence, consistency of effect, imprecision, indirectness, and publication bias. We will assess the quality of evidence for all outcomes using the GRADE methodology [40].

Data Analysis

Statistical Analysis

A meta-analysis will be conducted if there are at least 2 similar studies with broadly similar populations, interventions, and outcome measures using a random-effects model in Review Manager (Cochrane) [41]. A random-effects model will be used if studies are statistically heterogeneous; otherwise, we will use a fixed-effects model. For the random-effects model, we will conduct a sensitivity check by using the fixed-effects model to reveal differences in the results. We will include a 95% CI for all estimates. We will report skewed data as medians and IQRs. Studies will be considered as being sufficiently similar if the relevant outcome data are available in the group originally allocated or if the intervention, such as early food introduction in the allocated group, belongs to the same category—for example, the same amount of food (eg, frequency or total daily intake)—and if only frequencies are reported, we will include binary comparisons; for example, weekly versus never and daily versus never. The primary data analysis will include proportions or the frequency of childhood allergic diseases and types of food (allergenic and nonallergenic).

Assessment of Heterogeneity

The clinical heterogeneity of the results of the included studies will be assessed on the basis of the similarity of their populations, interventions, outcomes, and follow-up if we can pool sufficient studies together. We will consider populations as similar when they are in the same categories of age with outcomes measured in similar ways as stated in the eligibility criteria. We will consider interventions as similar if they fall into the same category as indicated in the abovementioned types of interventions. The outcomes will be considered as similar when they are measured at similar events as stated in the eligibility criteria. We will estimate the treatment effects of individual RCTs and examine heterogeneity among RCTs by inspecting forest plots and quantifying the impact of heterogeneity using the I^2 statistic [42].

Assessment of Reporting Biases

We will generate and examine a funnel plot to explore possible small biases in studies if we can pool more than 5 RCTs in a single meta-analysis.

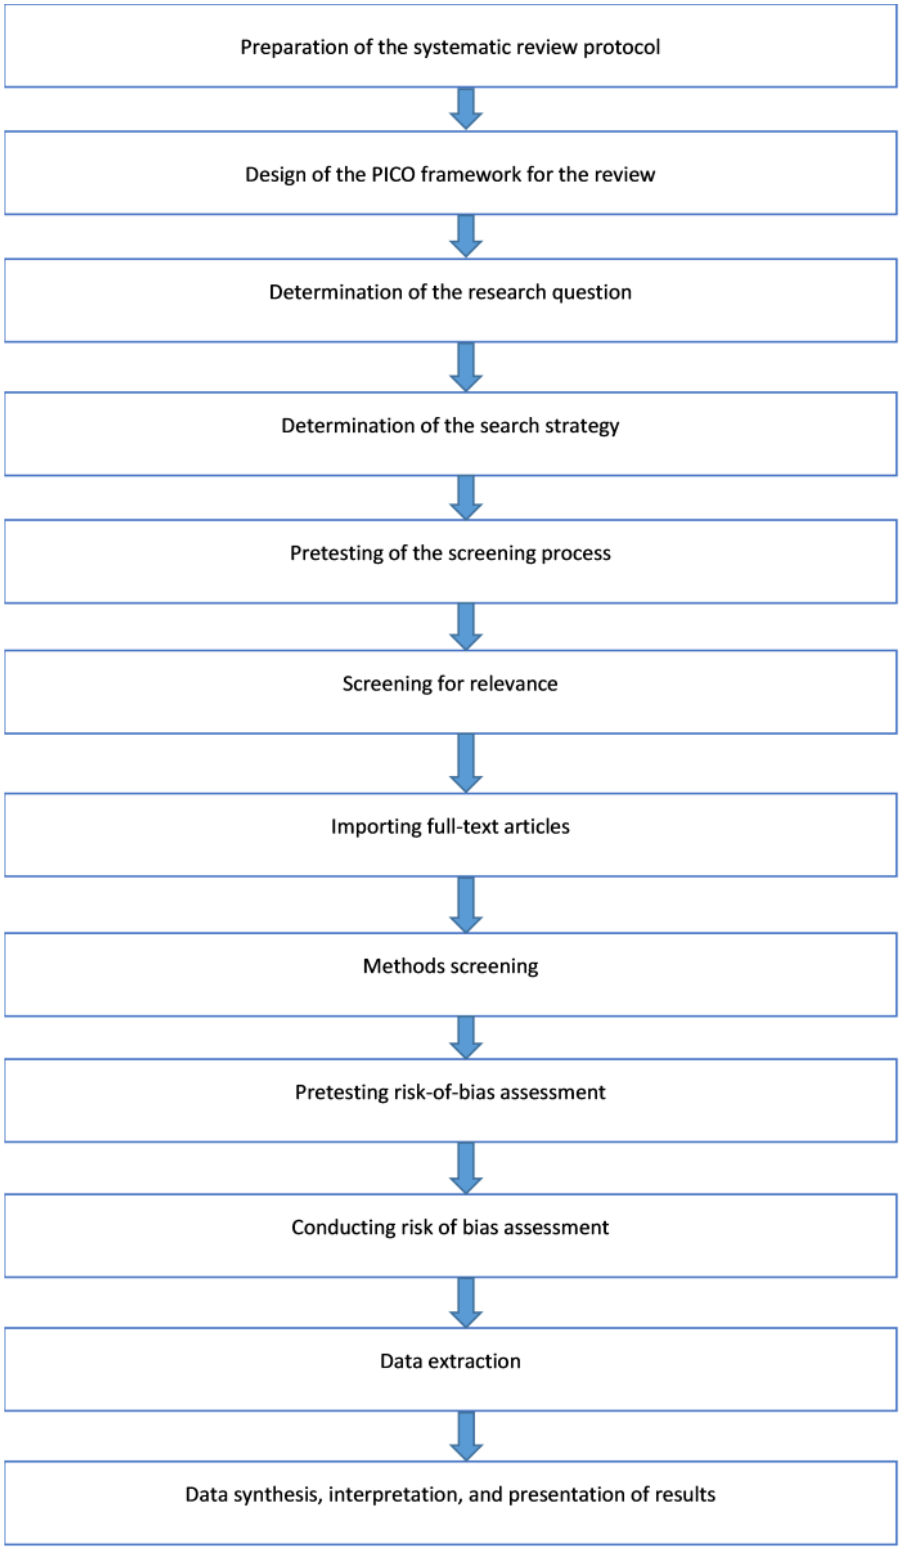
Ethics and Dissemination

This systematic review is registered with the National Medical Research Register, Ministry of Health Malaysia (ID: NMRR ID-22-01049-HQ4). This protocol registered in PROSPERO (CRD42021256776). We will present the findings of this review in National and international conferences and continuous medical education initiatives, and we will disseminate our findings to policy makers and top managements (stakeholders) of Ministry of Health Malaysia.

Results

The protocol has been registered in PROSPERO and we initiated the review on June 1, 2023, and the results are expected by October 1, 2023. This systematic review and meta-analysis shall contribute an update to the existing literature on infant feeding with emphasis on the risk of childhood allergic diseases.

Discussion



Anticipated Findings

This protocol outlines the methods for a systematic review of the literature to assess the effectiveness of early food introduction in the prevention of childhood allergic diseases. Figure 2 illustrates a flow diagram of the study process to be followed as a guide for this review in terms of literature search using keywords identified through discussion among authors, the screening of shortlisted studies following a standardized framework, and the process of full text retrieval. This will be followed by quality assessment with data extraction for evidence synthesis and finally publishing of the study results.

We take note of 2 similar systematic reviews and meta-analyses that are closely related to our study [23,43]. However, their methodology (in terms of population variability and age of weaning) and diverse outcomes are different from those based on our study objective. In our study, we aim specifically to evaluate the effectiveness of early food introduction in infants aged 4-6 months irrespective of risks, and to evaluate outcomes related to 4 common allergic diseases in children. We believe that our findings will provide a reasonable and robust update to the existing literature.

Figure 2. Flow diagram of the study process. PICOS: population, intervention, compare, outcomes, and studies.

Reaching Conclusions

We will base our conclusions only on findings from the quantitative or narrative synthesis of the studies included in this review. The conclusions can be used as guidelines for top managers and stakeholders for evidence-informed policy on infant feeding guidelines for the prevention of childhood allergic diseases. Our implications for research will suggest priorities for future research and outline the remaining uncertainties in the area.

Acknowledgments

We would like to thank the Director General of Health, Ministry of Health Malaysia, for his support in this study.

Data Availability

The original contributions shown in the study are contained within this systematic review and its multimedia appendices; further inquiries can be addressed to the corresponding author.

Authors' Contributions

All authors contributed to conceptualization and the development of the study plan. AFAA, C-LT, and NAM are responsible for title registration, development of the overall study methodology, and evidence rating schemes. AFAA and RMAG will conduct the literature searches, manage the references, and draft the intellectual content. NAM, SMS, and AFAA and will oversee the data extraction process and revision of the final manuscript with specific input from all other coauthors.

Conflicts of Interest

None declared.

Abstract

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder that affects millions of children worldwide, with a current prevalence of approximately 1 in 54 children in the United States. Although the precise mechanisms underlying ASD remain unclear, research has shown that early intervention can have a significant impact on cognitive development and outcomes in children with ASD. Physical activity interventions have emerged as a promising intervention for children with ASD, but the efficacy of different types of interventions remains unclear.

Objective: This study protocol aims to update the knowledge on extant literature and explore the efficacy of physical activity intervention strategies on cognitive functions in children with ASD.

Methods: A systematic review and network meta-analysis (NMA) will be conducted following the PRISMA-NMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols for Network Meta-Analyses) statement. A total of 9 bibliographic databases (APA PsycInfo, CENTRAL, Dimensions, ERIC, MEDLINE Complete, PubMed, Scopus, SPORTDiscus, and Web of Science) will be systematically searched to screen eligible articles based on a series of inclusion and exclusion criteria. A study will be considered for inclusion if it is not classified as a systematic review with or without meta-analysis, was published from inception to present, includes children aged 0 to 12 years with ASD, quantitively measures cognitive outcomes, and examines treatment comprising at least 1 physical activity intervention strategy. The internal validity and quality of evidence will be evaluated using the Grading of Recommendations Assessment, Development, and Evaluation framework. Statistical analyses will be performed in the RStudio software (version 3.6; RStudio Inc) with the *BUGSnet* package and the Comprehensive Meta-Analysis software (version 3.3; Biostat Inc). The results of our NMA will be illustrated through network diagrams accompanied by geometry and league tables. Further, to rank the interventions based on their efficacy, we will use the surface under the cumulative ranking curve.

Results: Our preliminary search identified 3778 potentially relevant studies. The screening of the studies based on the inclusion and exclusion criteria is ongoing, and we anticipate that the final number of eligible studies will be in the range of 30 to 50.

Conclusions: This study will provide a comprehensive review of the literature on physical activity interventions for children with ASD and will use NMA to compare the efficacy of different types of interventions on cognitive outcomes. Our findings will have important implications for clinical practice and future research in this area and will contribute to the growing body of evidence supporting the use of physical activity interventions as a key component of early intervention for children with ASD.

Introduction

Background

Autism spectrum disorder (ASD) is a lifelong developmental disorder. Individuals with ASD commonly present symptoms of insufficient social interaction and communication and repeated and restricted behavior patterns that have a negative impact on daily functions. The lack of adapting, planning, and organizing skills has a negative influence on personal, physical, mental, academic, vocational, and social domains. The onset of ASD typically presents during the ages of 1 to 2 years, whereas some symptoms may be observed during the first year after birth [1]. Some categories of ASD have been specified such as Asperger syndrome, childhood disintegrative disorder, and pervasive developmental disorder [2]. The World Health Organization has indicated that children with ASD exhibit deficits in cognitive functions, characterized by social impairment, abnormalities, and repetitive stereotypic behavior [3,4]. Approximately 17% of children were diagnosed with a range of complex neurodevelopmental disabilities between the ages of 3 and 17 years; 1 in 54 children was diagnosed with ASD [5,6]. The diagnosis rate in children has continuously increased, moving from 1.1% to 2.5% in the past decades [7,8]. Although the prevalence of diagnoses is increasing, many evidence-based interventions are still in their developmental stages. Specifically, the effectiveness of physical activity interventions in children with ASD is not yet fully understood.

Childhood is a critical period for neurodevelopment, especially for the development of children's memory, attention, creativity, motor skills, and executive functions (EFs) [9]. ASD is a complex neurodevelopmental disorder, and its prognosis is impacted by environmental, genetic, and physiological factors [1]. Several neurotransmitters, including brain-derived neurotrophic factors, which contribute to brain development, demonstrate correlations with ASD and other neurodevelopmental impairments [10]. The connectivity of the frontal cortex and prefrontal cortex with other parts of the brain was found to be related to ASD behavioral symptoms [11-13]. High risk for an atypical development of the ability to recognize and attribute mental states was found in the autism population [14]. Language and joint attention for social functioning and cognitive control behaviors have been shown to be linked to changes in the early maturation of the brain [9,14-16]. An imbalanced process of integrating information such as contextual or sensory perception might be related to ASD symptoms [17].

Cognitive function is manifested as the ability to process thoughts, such as learning and solving problems [18]. Cognitive function has been categorized into EFs and non-EFs. EFs present an individual's adaptive skills and ability to conduct goal-oriented meaningful actions [19]. Non-EFs include complex attention, learning and memory, visual function, language function, and social function [1]. Solomon et al [20] indicated that EF hypothesis is an influential cognitive theory of ASD, which proposes that "deficits in planning, inhibitory control, attentional set shifting and working memory are central to the disorder." Social and communication skills are part of the characteristics of cognitive function, which individuals with ASD usually lack, and are also impacted by the age and development window [21]. In children, cognitive function develops along with the human brain [22]. An example of proneurogenic modulators is exercise, which increases the level of brain-derived neurotrophic factors, endocannabinoids, and microbiota diversity, leading to hippocampal neurogenesis and long-term changes in cognitive function [23,24]. Various interventions for children with ASD have been studied, such as music therapy, which has been shown to improve social interaction in preschool children with ASD [14]. In addition, physical activity is an effective approach to improve cardiovascular fitness and cognitive function in children and adolescents [25].

Evidence shows that physical training positively impacts the cognitive function of adults and their offspring, which is encouraging for investigations on the effect of physical activity on youth [26]. In this study, we expect to use a statistical methodology to explore the effectiveness of different types of physical activity intervention strategies (PAIS) on cognitive function in children. We believe that this study is a promising starting point to guide future health-related practices in youth. Closely related to the release of dopamine in the human body, physical activities have also been proven to provide emotional support to children, such as by lowering levels of anxiety or depression [27]. Promising evidence has been accumulated of physical activity leading to improvements in cognition, including improvements in both academic and behavioral performances in children with ASD [3,28-31]. Liang et al [32] reported that chronic exercise interventions are beneficial for overall EFs, especially for cognitive flexibility and inhibitory control in children and adolescents with ASD. Several studies have indicated a significant increase in social engagement in children with ASD after they participated in physical activities, especially in group activities [33-35]. Furthermore, physical activity proved beneficial in reducing stereotypical behaviors within the population of children with ASD [36].

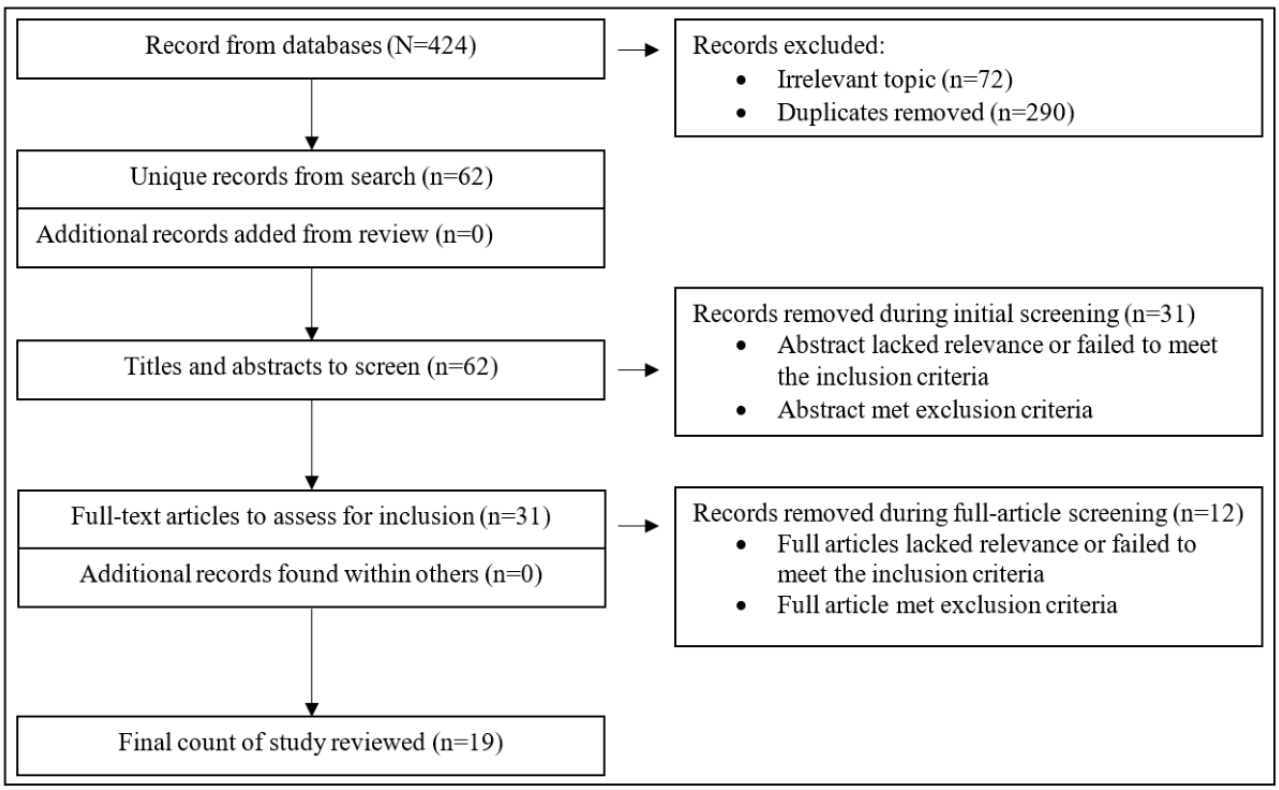
In prior research, various types of PAIS were investigated individually or through narrow groups. In this study, a full range of PAIS will be examined. PAIS include aerobic exercises, mindfulness practices, school physical education programs, and Montessori methods [32,37]. Fang et al [38] concluded favorable results for the effect of exergaming interventions on cognitive functions, but synthesis results from a follow-up meta-analysis are lacking. Horseback riding was found to be beneficial for cognitive functioning, social interaction, and sensory processing improvement in children with ASD [33,35]. Some other physical activities, such as yoga and dance, were also introduced as interventions for children with ASD, which led to positive outcomes in behavioral functioning [39]. The clinical conditions

XSL•FO
RenderX

of participants, as well as the session frequencies and lengths of the interventions, need to be researched more. Hence, there is an urgent need for researchers to explicitly examine what type of PAIS is the most beneficial for children with ASD.

Systematic reviews and pairwise meta-analyses cannot be used to compare treatment effects across interventions and indirect effects. Therefore, the network meta-analysis (NMA) is proposed as a novel analysis technique in the field of physical activity and health promotion to fill this gap and satisfy the urgent need [40]. To the best of our knowledge, this will be the first NMA applied to systematically review and analyze the efficacy of PAIS on cognitive functions in children with ASD. Therefore, our expectation is to explore PAIS based on selected direct and indirect head-to-head trials to suggest important considerations for decision-making in the field of pediatric health promotion.

Mini Review



Overview

To gain a comprehensive overview of the existing literature as well as justify the necessity of conducting an NMA on PAIS for children and adolescents with ASD, we conducted a mini review based on the systematic reviews and meta-analyses in the current literature. The literature search was conducted on PubMed, APA PsycInfo, SPORTDiscus, Web of Science, CENTRAL, ERIC, SocINDEX, MEDLINE Complete, and Dimensions. The keywords used for the literature search involved 4 domains: intervention mode, cognitive performance, population, and autism. Combinations of the keywords regarding each domain were “physical activity OR PA OR exercise OR sport*” AND “cognitive function OR cognition OR executive function OR inhibitory control OR memory OR communication OR stereotyp* behavior*” AND “children OR kid* OR teenager OR students” AND “autism spectrum disorder OR ASD.” Eligible studies should meet the following criteria: (1) systematic review or meta-analysis written in English and published between 2001 and 2021, (2) inclusion of children or adolescents with ASD, (3) review of PAIS, and (4) examination of the effects of PAIS on cognitive functions.

Literature Search

Two authors (LL and AW) independently conducted the search and screening process. The initial search resulted in 424 studies. Of these 424 studies, after the removal of 362 (85.4%) duplicate and irrelevant items, 62 (14.6%) items remained for the next phase of screening. Of these 62 articles, 31 (50%) articles were excluded based on abstract examination, leaving 31 (50%) articles for full-text review. Of these 31 articles, the final step of screening removed 12 (39%) articles because of the following reasons: no cognitive outcomes were measured (n=10, 32%) and populations other than children or adolescents were included (n=2, 6%). Therefore, a total of 19 (61%) of the 31 systematic reviews with or without meta-analysis met the inclusion criteria. The process of study selection is presented in Figure 1.

Figure 1. Flowchart of searching and screening in mini review.

Characteristics of the Included Studies

The median publication year of these studies was 2019 (range 2008-2021), which implies a rapid increase in the number of published review papers on the relevant topic in recent years. The number of studies included in each review ranged from 7 to 41. A variety of types of the included review papers was identified, such as systematic review (9/19, 47%), meta-analysis

XSL•FO
RenderX

(7/19, 37%), and systematic review with meta-analysis (3/19, 16%). In addition to individuals with ASD, the included review studies also examined individuals with cognitive impairment due to one of the following reasons: attention-deficit/hyperactivity disorder, cerebral palsy, developmental delay, developmental coordination disorder, and Down syndrome. Common symptoms observed in individuals with these disorders are difficulties in paying attention, performing tasks, and engaging in social interaction [1]. Most studies focused on children and adolescents [14,32,34,41-51], whereas Fang et al [38], Fragala-Pinkham et al [52], Healy et al [53], Lang et al [54], Ruggeri et al [55], and Sowa and Meulenbroek [56] conducted studies involving both children and adult participants. Experimental groups were compared with their counterparts, that is, active behavioral control groups, waiting list control groups, or standard care groups. The study characteristics are illustrated in Table 1.

The PAIS applied in the intervention arms typically consisted of two or three 30- to 60-minute sessions per week for 8 to 16 weeks. Overall, 3 (16%) of the 19 studies included only randomized controlled trials (RCTs) [14,47,50], and others (16/19, 84%) partially included quasi-experimental designs with controlled trials [32,41-44,48,49,51,53-56], cohort study [34], pre- and posttest and case-control studies [38,45,52], and descriptive study [46]. Moreover, 1 (5%) of the 19 studies lacked a clear definition of the age range of children and a discussion of the risk of bias (RoB) [41]. The interventions implemented in the included studies were conducted through various types of physical activities. Physical exercise– and motor skill–related interventions, such as aerobic exercise, resistance training, and aquatic activities, were mostly adopted in the clinical practice [32,34,41-56]. In addition, 2 (11%) of the 19 studies investigated effects of exergaming and technology interventions for individuals with ASD [38,43].

The included studies investigated the effects of physical activity interventions on cognitive functions, with small to moderate effect sizes on the improved global EF [32,50]. Specifically, the included reviews reported enhanced performance in terms of working memory, attention, task switching, and inhibitory control [34,50]. The evidence also indicated the beneficial effects of social functioning and communication skills, which can be attributed to the group-based activity performed during the interventions [42,44]. Learning and memory outcomes due to PAIS were not fully explored in the selected studies. The other limitation of the included systematic review and meta-analysis studies was the combination of children and adolescent groups. However, age was recognized as a significant confounder in ASD research. Although common clinical treatments, including educational, family, speech, and occupational therapies, showed favorable effects, widely supportive evidence showed that physical activity was beneficial for children's lifelong cognitive and motor development. Therefore, it is necessary to explore the effects of PAIS treatment on children's cognitive outcomes from the perspective of physical activity and health promotion. Results are encouraging because various types of evidence showed that PAIS were effective in enhancing cognitive function in children with ASD; the foundation for the future in-depth data analysis has been established.

Table 1. Characteristics of the studies included in the mini review.

Study	Study type	Participant, n	Study population	Intervention used (intervention arm)	Outcome measures[a]	Main outcomes
Aleksandrovic et al [41], 2016	SR[b]	13	Children (aged <18 years and with ASD[c])	Aquatic activities (Armbruster or Halliwick methods or the constant time delay procedure for learning swimming skills and social and floor warm-up activities)	MS[d] (ABC-2[e], WOTA[f], HAAR[g], YMCA[h] checklist, and Aquatic Skills Assessment)	Aquatic skills were effectively improved
Bremer et al [34], 2016	SR	13	Children and youth (aged ≤16 years; at least one participant with a diagnosis of ASD or PDD[i])	Physical exercise intervention (jogging, swimming, yoga or dance, horseback riding, and martial arts)	CF[j]+SF[k] (GARS-2[l], SRS[m], sensory profile, ABC-C[n], ABC[o], VABS-2[p], frequency of child specific behaviors, BOSS[q], SSBS-2[r], and BASC-2[s])	Improvements in stereotyped behaviors, social behavior cognition, and attention
Cameron et al [42], 2020	SR	17	Children (aged 3-6 years) with autism, CP[t], Down syndrome, DCD[u], DD[v]	Fundamental motor skill group intervention by primary researcher	MS (PDMS-2[w]: GMQ[x])	Results were inconclusive to support motor-based interventions in this age group owing to variability in intervention types
Case and Yun [43], 2019	MA[y]	18	Preschool (aged 3-5 years) and school-aged children (aged 6-17 years) with ASD	FMS[z] (direct instruction activities), PA[aa] (whole body movement and coordination activities), technology (eg, video games), EAT[ab] (eg, horseback riding)-based interventions	MS (PDMS, PDMS-2, TGMD[ac], TGMD-2, TGMD-3 BOT-2[ad], M-ABC[ae], and M-ABC-2)	Overall effect size on gross motor outcomes (δ=0.99; *P*<.001), FMS (*g*=0.68; *P*<.001), PA (*g*=1.20; *P*=.003), technology (*g*=1.42; *P*=.21), and EAT (*g*=1.20; *P*=.005)
Chan et al [44], 2021	MA	12	Children and adolescents (aged <18 years and with ASD)	Individual, combined, or group-based PA (eg, Karate, horseback riding, aquatic, mind-body, football, outdoor adventure, or active recreation)	SF (GARS-2, SRS, VABS, ATEC[af], and SSIS[ag])	COM[ah] (SMC[ai]=.27, 95% CI 0.06 to 0.48) and social functioning (SMC=.39, 95% CI 0.15 to 0.63)
Fang et al [38], 2019	SR	10	Children and young adults (aged 5 to 21 years and with ASD)	Exergaming (eg, platforms and games included DDR[aj], cybercycling, FroggyBobby, Xbox Kinect, Nintendo Wii, and Makoto Arena)	CF+MS (physical outcomes [eg, BMI and jump distance] and cognitive outcomes [eg, BRIEF[ak]])	Favorable results for the effect of exergaming interventions on participants' physical and cognitive functions
Ferreira et al [45], 2019	SR and MA	8 (SR) + 8 (MA)	Children and youngsters (aged <16 years and with ASD)	Aerobic exercise, Kata techniques training, and ball exercise	CF (GARS-2, SSB[al], and stereotypic behavior observations)	PA was effective in reducing stereotypic behavior (SMD[am]=1.11; *P*=.009)
Fragala-Pinkham et al [52], 2021	SR	8	Children and young adults (aged 7 to 26 years and with ASD, Down syndrome, or UID[an])	Lower extremity cycling (eg, learning to ride a 2-wheeled bicycle, stationary cycling, and CO-OP[ao] approach)	CF+MS (eg, cycling time and distance, cycling skill checklist, KT[ap], KTFist[aq], TOLT[ar], and PPT-C[as])	Weak evidence and heterogeneous results regarding MS and CF in children and young adults with intellectual disabilities between cycling and control groups
Healy et al [53], 2018	MA	29	Youth (aged 2 to 22 years and with ASD)	Recreational activities in APE[at], PE[au], and other settings (eg, yoga, kata program, aquatic skill program, dance, mind-body exercise, and a combination of all activities)	CF+MS (psychometric tools or scales were not specifically discussed)	Overall positive moderate effect exhibited (*g*=0.62; *P*<.001); cognitive function (*g*=0.28, 95% CI −1.19 to 1.74), psychomotor function (*g*=1.21, 95% CI 0.41 to 1.66)

XSL•FO
RenderX

Study	Study type	Participant, n	Study population	Intervention used (intervention arm)	Outcome measures[a]	Main outcomes
Howells et al [46], 2019	SR and MA	11 (SR) + 7 (MA)	Children (aged 5 to 12.9 years and with ASD)	Individual and group PA (eg, included a range of blocking, punching, sticking, and kicking techniques; climbing rope ladder or rope elevator; horse riding; group sport games)	SF+COM (VABS, SRS, BASC-T, and GARS-2)	Nonsignificant effect for communication (g=0.13, 95% CI −0.12 to 0.38) and a significant improvement in overall social functioning (g=0.45, 95% CI 0.19 to 0.72)
Huang et al [47], 2020	MA	12	Children and adolescents (aged 3 to 18 years and with ASD)	PA interventions (eg, Kata techniques, therapeutic horseback, outdoor activity, karate, aquatic sport, trampoline, table tennis, Tai Chi, and exergaming)	CF+MS+SF+COM (GARS-2, BOT-2, SRS, PPVT-4[av], SALT[aw], ATEC, ABC, MABC-2[ax], CBS[ay], and WCST[az])	Significant positive effects on social interaction (SMD=−0.58, 95% CI −0.87 to −0.29), COM (SMD=−0.29, 95% CI −0.55 to −0.04), stereotyped behavior (SMD=−0.13, 95% CI −0.46 to 0.20), and motor skills (SMD=1.02, 95% CI 0.33 to 1.71)
Lang et al [54], 2010	SR	18	Children, adolescents, and adults (aged 3 to 41 years and with ASD)	PA (eg, walking, jogging, playing catch with a ball, riding a stationary bike, swimming, and weight training)	CF+PF (psychometric tools or scales were not specifically discussed)	Exercise decreased stereotypy, aggression, off-task behavior, and elopement
Liang et al [32], 2021	SR and MA	14 (SR) + 7 (MA)	Children (aged 5 to 17 years and with ASD)	Physical activity or exercise on EFs[ba] (exergaming, jogging, table tennis, progressive muscle relaxation, martial arts, basketball, etc)	CF (BRIEF, Stroop, CTT[bb], HKLLT[bc], DSFBT[bd], FPT[be], TOLT, GNG[bf], CBTT[bg], Hearts and Flowers test, and attention sustained test)	Positive effect on global EFs (g=0.34, 95% CI 0.08 to 0.60), CF (g=0.31, 95% CI 0.05 to 0.57), IC[bh] (g=0.49, 95% CI 0.19 to 0.80]), and WM[bi] (g=0.21, 95% CI −0.09 to 0.51)
Petrus et al [48], 2008	SR	7	Children (aged 4 to 15 years and with ASD)	PA or exercise (eg, aquatic, jogging, ball playing, and aerobic exercise)	CF+MS (stereotypical behaviors and MS were observational measured in frequency, duration, or counts)	Exercise might reduce stereotypic behaviors in the short term
Ruggeri et al [55], 2020	SR	41	Children and adolescents (aged 3 to 19 years and with ASD)	Motor and physical activity (eg, soccer, exergaming, throwing, aquatic, fitness or strength, horse riding, hippotherapy, stationary biking, gymnastic, and indoor climbing programs)	MS+ML (eg, VABS-2, BOT, BOT-2, MABC-2, PDMS-2, TGMD-2, TGMD-3, m-PEDI[bj], ASC[bk], YMCA checklist, HAAR, SCS[bl], and GAS[bm])	Motor skill and learning, body structure, and function outcomes were improved with various PA interventions
Semple [49], 2019	SR	8	Youth (aged 3 to 18 years and with ASD)	Yoga, mindfulness-based interventions, Qi Gong, and meditation	CF+MS+SF+COM (psychometric tools or scales were not specifically discussed)	Improvements in prosocial behaviors, social cognition, communication, motivation, and motor control via yoga and mindfulness-based interventions
Sowa and Meulenbroek [56], 2012	MA	16	Children, adolescents, and adults (aged 4 to 41.3 years and with ASD)	Individual and group PA interventions (eg, jogging, therapeutic horseback rides, bike riding, walking, stationary cycling, aquatic exercising, and swimming)	MS+SF+COM (psychometric tools or scales were not specifically discussed)	Individual programs exhibited positive effects on motor skills (r=−0.32; P=.004) and social interactions (r=−0.62; P<.001) compared with group programs
Zhang et al [50], 2020	MA	11	Children (age: N/A[bn]) with ADHD[bo] or ASD	Chronic PA intervention (eg, rhythm, integrated PA, modified aerobic games, exergaming, and taekwondo)	CF+MS (BOT-2, WCST, TGMD-2, Stroop test, Flanker task, CBTT, etc)	Significant improvement in overall EF, IC, cognitive flexibility, and gross MS (SMD ranged from 0.85 to 1.30); no significant improvements in working memory and fine MS

The Present NMA Protocol

An insight into the direction of future research was provided based on the preliminary findings of the mini review. Previous outcomes suggested that varying types of PAIS were effective in improving cognitive functions and motor performance, reducing frequency of the symptoms, and enhancing social and communication skill development in children with ASD and other cognitive impairments. The quality of evidence is concerning because of the limited number of meta-analyses on RCTs [53]; we expected to simply include true experimental designs (eg, RCTs), which might ensure robust synthesis results and increase the power to detect the effects of interventions [51,57]. The age groups were heterogeneous in nature, whereas we expected to focus particularly on children and explore the efficacy of PAIS on their cognitive performances. However, the limitation of the pairwise meta-analysis procedure was that it was only appropriate for discerning outcome effects "between a selected intervention strategy and a selected comparison or control condition" [40]. Whereas pairwise meta-analyses only allowed the comparison of multiple outcomes from a single treatment, NMA would allow the comparison of the efficacies of multiple PAIS on multiple outcomes [58]. Concomitantly, there is a need to conduct an NMA to obtain a more accurate estimation of the efficacy of PAIS in the population. We aim to provide an updated review of the extant literature in the field of physical activity and health promotion using an appropriate network meta-analytic model. Therefore, the following protocol was developed based on the findings and limitations identified in the mini review.

Methods

Overview

This review protocol has been registered in PROSPERO (CRD42021279054). The NMA will comply with the PRISMA-NMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols for Network Meta-Analyses) statement [59,60]. A component-based Bayesian framework NMA will be conducted following the procedures described in the subsequent sections [61].

Search Strategy

The following 9 bibliographic databases will be searched: APA PsycInfo, CENTRAL, Dimensions, ERIC, MEDLINE Complete, PubMed, Scopus, SPORTDiscus, and Web of Science. In general, the search will be limited to RCTs in English published from inception to present. Keywords combinations and MeSH (Medical Subject Headings) terms used in the search are listed in Table 2.

XSL•FO
RenderX

Table 2. Flowchart of search strategy.[a]

Concept	Keywords
1. Outcome: cognitive functions	• "Cognitive function*" or "cognitive outcomes" or executive function* or "neurocognitive tasks" or questionnaires or inventory or task* or restricted repertoire or autism spectrum disorder (MeSH[b] terms) or children behavior disorder (MeSH terms) or autistic disorder (MeSH terms) or stereotypic movement (MeSH terms) or motor skills disorder (MeSH terms) or cognition (MeSH terms) or communication disorder (MeSH terms) or learning disabilities (MeSH terms) or DSM-V[c] (MeSH terms)
2. Participants: children and adolescents	• Children or adolescent* or young people or school-aged or teen or young adult* or youth or kids or teenager* • Exclude (NOT): smoking or drinking or criminal* or injury or injuries or accident* or trauma or adult* or older adult* or elderly or seniors or geriatric*
3. Exposure: comparator	• Control* or "control group" or subject* or "human subjects" or human-related or waiting list
4. Exposure: exercise types	• "Physical activity" or intervention* or exercise* or fitness or "physical exercise" or sport* or psychomotor or motor activity or recreational sport* or school-based or computerized training or hybrid or games or aerobic or "martial arts" or Tai Chi or "mindfulness practice" or classroom curricula or Montessori methods or "resistance training"
5. Design	• Experimental* or clinical trial or randomized control trial* or RCT[d] or nonrandomized comparison or NRS[e] • Exclude (NOT): observational studies or cross-sectional or case control or cohort or systematic review or meta-analysis or report or protocol or qualitative or mixed method

[a]The bibliographic databases will be searched including PubMed, SPORTDiscus, APA PsycInfo, MEDLINE Complete, ERIC, Scopus, Web of Science, CENTRAL, and Dimensions. We will use "OR" to separate keywords within each concept and "AND" to separate each concept. MeSH terms will be used for PubMed search only. Google Scholar will be used for cross validation for search results from multiple bibliographic databases.

[b]MeSH: Medical Subject Headings.

[c]DSM-V: Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.

[d]RCT: randomized controlled trial.

[e]NRS: nonrandomized studies.

Inclusion and Exclusion Criteria

The following subsections on population, intervention, comparator, outcomes, and study design explicate the various elements of Population, Intervention, Comparison, Outcome Measures, and Design (PICOS), which is the framework used in this study to facilitate the literature search [58].

Population

Studies including children aged between 0 and 12 years with a diagnosis of ASD (Asperger syndrome, autism, or unspecified developmental disorder) with varying severity (mild, moderate, or severe) will be accepted. The study should include at least 1 diagnostic criterion regarding the Diagnostic and Statistical Manual of Mental Disorder [1], International Statistical Classification of Diseases and Related Health Problems, or Autism Diagnostic Observation Schedule. In addition, demographic information, including age, gender, and sample size, should be reported.

Intervention

Studies intended to increase cognitive functions in participants with ASD using physical activity or exercise interventions will be included. Studies evaluating physical activity exhibited in school-based physical education, exergaming, mindfulness practice (eg, yoga, martial arts, and Tai Chi), aerobic exercise and sports, and any types of therapeutic physical activity interventions will be included.

Comparison

Studies with comparators such as active behavioral control group, waiting list control group, and standard care group will be eligible for inclusion in the network of evidence.

Outcome Measures

Studies should report mean differences in cognitive function measurements between the beginning of the intervention and follow-up test. Studies should have obtained at least 1 validated outcome measurement of cognitive functions. Study features must include the measurement tool with either objective or self-reported patterns.

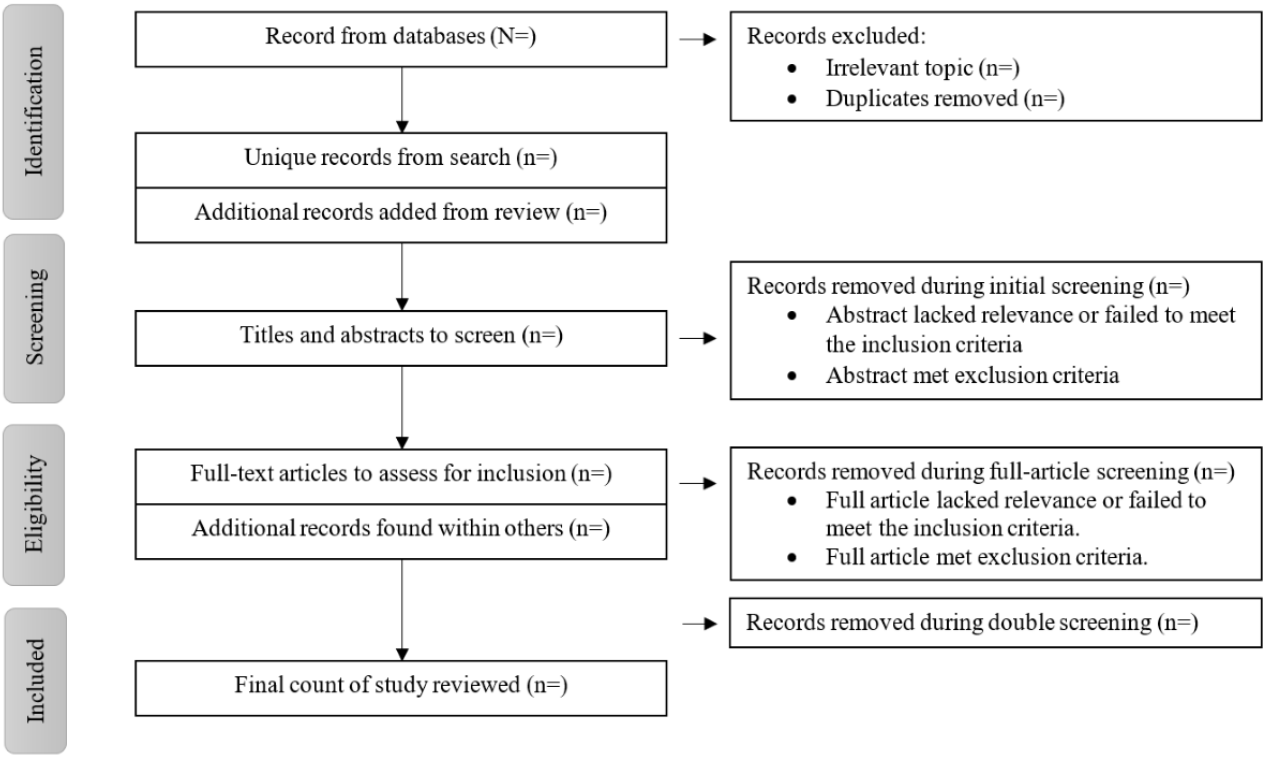
Design

RCTs should have assessed the outcome measures before (baseline) and after the intervention; the study should have included >1 session of intervention.

Exclusion Criteria

The following studies were excluded: studies including participants who were aged >12 years or were unable to conduct psychomotor movements, studies not involving an RCT, studies where the intervention lasted <8 weeks, and studies not written in English.

Study Selection and Data Extraction



Recording and managing related literature will be accomplished using the Mendeley software (Mendeley Ltd). Two authors will independently screen the titles and abstracts of the searched

XSL•FO
RenderX

peer-reviewed studies based on the preestablished criteria for inclusion. A third reviewer will be involved to initiate a full-text evaluation if any conflicted selections occur. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart illustrates the search and screening processes (Figure 2).

Study characteristics, including author information, publication year, mean age in sample, diagnostic criteria for ASD, study period, intervention arms, and study design, will be summarized using Microsoft Excel (version 2010; Microsoft Corp). Specifically, we will adopt a thematic organization approach to categorize intervention arms within all relevant RCTs into six predefined categories: (1) school physical education programs, (2) exergaming, (3) aerobic exercise and sports, (4) mindfulness practice, (5) computerized and noncomputer games combination, and (6) therapeutic physical activity interventions [32,37]. The project administrator will serve as the coordinator, dealing with potential disagreements or unclearly defined PAIS categories. Internal discussions and consultation with an experienced researcher in physical activity and health promotion are considered 2 solutions for disagreements and uncertainties. The interrater agreement rate, Cohen *k*, between reviewers regarding the eligibility criteria of the study will be reported [62]. Note that grouped and ungrouped or supervised and unsupervised intervention arms will be separated as 1 effect size per treatment [51]. Quantified outcomes (mean of the intervention arms and comparators, SDs, and 95% CIs) will be extracted from the aforementioned categories, including measurement results regarding cognitive functions (eg, global EFs, working memory, thinking flexibility, inhibitory control, attention, or memory outcomes). In the NMA, we will compare the effects of the predefined intervention categories on participants' cognitive performance. Raw data (eg, sample sizes and *t*, *F*, or *P* values) will be extracted to help estimate the effect size if the means and SDs were not reported [51]. When necessary, the corresponding authors of selected studies will be contacted to obtain unpublished and missing data to allow for effect size estimates.

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of searching and screening.

Assessment of RoB

The Grading of Recommendations Assessment, Development, and Evaluation will be used to assess the quality of the selected studies in the NMA and pairwise meta-analysis [63-65]. Two authors will independently assess bias due to randomization, deviations from intervention, missing data, outcome measurement, and the selection of reported results in the selected RCTs. Each item is classified as high, some concerns, or less or unclear or no information upon RoB, and the results of the grading of evidence quality will then be generated as a table (Cochrane RoB tool; version 2.0 [66]). Homogeneity will be assessed by summarizing the selected study characteristics in a general table and observing whether the treatments and participant characteristics are suitable and comparable across all studies [40,58]. Consistency should be ensured such that direct evidence and indirect evidence essentially agree with each other without any discrepancies [40]. The R package (R Foundation for Statistical Computing) developed by van Valkenhoef et al [67] will be used to evaluate the inconsistency between indirect and direct comparisons via the node-splitting method. We evaluated consistency using a node-splitting technique that compares the direct and indirect estimates for each comparison. Transitivity will be qualitatively examined to ensure that direct trials do not differ with respect to the distribution of effect modifiers in which all treatments are jointly randomizable [68].

XSL•FO
RenderX

Statistical Analysis

The primary outcome for this study will be changes in cognitive functions. However, unlike physiological and biochemical indexes, cognitive performances were measured through preestablished validated psychometric instruments (illustrated in Table 1). Guiding through the approach applied by Désaméricq et al [69], the effect size will be calculated for each extracted result, and these effect sizes will then be combined into 3 cognitive scores, as listed in Multimedia Appendix 1. An omnibus composite unit free score of cognitive outcomes will be created by averaging all subordinate domain effect sizes within a study per intervention arm. Studies including multiple treatments or outcomes will provide the effect size of each treatment or outcome. Extracted data, such as sample size, treatment and control means and SDs for between-group designs, and preintervention and postintervention mean and SDs for within-group designs, will be converted to correlated summary results, standardized mean differences (SMDs), for NMA to explore the efficacy of PAIS on cognitive performance [70]. The effect sizes will be computed using SMD with 95% CIs between groups [32,71]. Hedges *g* in a random model will be used in consideration of potential variances across the selected studies if the number of studies is <20 [32,51,72]. Effect sizes will be classified as small, moderate, or high, respectively, with regard to the cutoff values of 0.2, 0.5, and 0.8 [32,73]. The calculations will be computed through a between-case SMD estimator, the web application *scdhlm* [74]. Heterogeneity will be evaluated through the means of Q test and I^2 values, considering statistical heterogeneity of 25% as low, 50% as medium, and 75% as high [32,75,76]. Sensitivity analyses will be conducted to determine whether any study separately influenced the overall results [77]. To minimize the impact of heterogeneous outcomes or extreme values, we will apply the threshold of *z* score 3.29 to screen out outliers in the mean effect scores [46,53,78]. The level of significance will be set at.05 in this study. The NMA will be performed in RStudio (version 3.6; RStudio Inc [79]) using the *BUGSnet* package (version 1.1.0 [80]).

Moderation Analysis

Moderation analysis will be conducted to examine the variability among potential sources owing to heterogeneous PAIS settings. Moderators such as participant age, exercise intensity, and intervention setting (eg, group vs individual) will be examined using robust variance estimation [51]. Our expectation is to provide another perspective of synthesis results to elicit the higher order outcomes from NMA. Moderation analysis will be performed in the Comprehensive Meta-Analysis software (version 3.3; Biostat Inc).

Ethical Considerations and Dissemination

The ethics approval process is exempted because this study will be based on findings of previous studies. This review protocol has been registered in PROSPERO with the aims of promoting transparency and minimizing the RoB [81]. Future results will be submitted to a peer-reviewed journal of the relevant field for consideration for publication.

Expected Findings

We expect to compare the effects of different PAIS on cognitive outcomes (overall and by domain) over a period of treatment (at least 8 weeks). We will perform an NMA; we will select all RCTs that consider PAIS as a treatment for cognitive outcomes in children with ASD. This study will bridge the gap and provide a novel perspective and robust evidence to clinicians and practitioners for future decision-making in children with ASD. Forecasted results will include study characteristics, qualitative appraisal of cognitive tasks and intervention technologies, and quality of the selected studies; visual demonstration of synthesis results such as network diagrams and associated geometry will be generated and evaluated, respectively. Expected results will be able to rank the efficacy of multiple PAIS (eg, aerobic exercise, mindlessness practices, school-based physical education programs, and exergaming) with effect size differences demonstrated between multiple treatments. In addition to network plots, results will be illustrated in tables of network characteristics, data plots, league tables and league heat plots, surface under the cumulative ranking curve plots, and rankograms. An in-depth discussion will be held. In general, results may reveal the rank efficacy of PAIS, in combination or as single treatment, on promoting cognitive functions and further social and communication skills in children with ASD. In addition, owing to the COVID-19 pandemic, social restrictions and isolation were enforced, which led to an increase in sedentary behavior and physical inactivity, which, in turn, increased the risks of cardiovascular disease and mental wellness crisis in children [82-84]. There are more concerns especially regarding children with ASD [85,86]. We will include an in-depth discussion of feasible interventions along with safety suggestions for programming during the global pandemic.

Results

Our preliminary search identified 3778 potentially relevant studies. The screening of the studies based on the inclusion and exclusion criteria is ongoing, and we anticipate that the final number of eligible studies will be in the range of 30 to 50.

Discussion

Principal Findings

With the described protocol, we aim to address the urgent need for effective PAIS to reduce the negative impact on cognitive outcomes in children with disabilities, including those with ASD. As noted in our mini review, research suggests that PAIS may have a positive impact on cognitive function in children with ASD, but there is limited information on the comparative effectiveness of different types of PAIS. Therefore, our study represents an important contribution to the field, as it is the first systematic review and NMA protocol to propose to examine the efficacy of PAIS on cognitive performance in children with ASD.

Preliminary results from the mini review suggested that several types of PAIS, including yoga, martial arts, and aerobic exercise, may have positive effects on cognitive performance in children with ASD. Specifically, we found that these interventions were

XSL•FO
RenderX

associated with improvements in cognitive flexibility, attention, and memory. Notably, our NMA will allow us to indirectly compare the effectiveness of different types of PAIS, providing valuable insights into which interventions may be most effective for improving cognitive function in this population.

Our study represents an important contribution to the literature on the efficacy of PAIS in improving cognitive performance in children with ASD. Although we have taken steps to minimize bias and ensure the quality of the study, as listed in Multimedia Appendix 2, there are some limitations that should be considered when interpreting our results. First, our study is limited by the quality and heterogeneity of the included studies. Although we have conducted a comprehensive search of multiple databases and used rigorous inclusion criteria, some relevant studies may have been missed. Second, as with any systematic review and NMA protocol, our study is limited by the quality and consistency of the data extracted from the included studies. We took steps to mitigate these issues by using a rigorous assessment of the RoB and data extraction processes. In addition, the statistical and moderation analyses we have planned will allow us to explore the sources of heterogeneity and potential moderators of treatment effects. Finally, we have adhered to ethical guidelines and plan to disseminate our findings to relevant stakeholders to facilitate the translation of research into practice.

Conclusions

Despite these limitations, we believe that our study provides valuable insights into the efficacy of PAIS for improving cognitive performance in children with ASD. Our findings suggest that clinicians and policy makers should consider incorporating PAIS into interventions aimed at improving cognitive function in this population. Furthermore, our study highlights the need for additional research in this area, including larger, well-controlled studies to further examine the comparative effectiveness of different types of PAIS. Overall, we hope that our study will contribute to the development of evidence-based interventions that can help improve outcomes for children with ASD.

Data Availability

This is not applicable at present, as this is a protocol paper. However, future and final data sets will be available from the corresponding author upon reasonable request.

Authors' Contributions

LL conceptualized this study. LL and AW contributed to the study conception and design and drafting the protocol. MEM and QF revised the draft critically for important intellectual content and gave final approval of the version for publication. MEM monitored the project administration. All authors contributed to the manuscript and approved the submitted version.

Conflicts of Interest

None declared.

Abstract

Background: Cognitive behavioral therapy (CBT) has shown to be highly effective for treating youth anxiety; yet, there is ongoing debate as to whether involving parents improves outcomes. For example, parents who attend may learn CBT skills to help their child in an ongoing way; yet, they could also distract their child from treatment depending on how they interact. As evidence has accumulated, reviews and meta-analyses have attempted to examine the most effective treatment format. These reviews often have high impact in the field; however, they use varied methodologies and draw on different primary studies. Different formats of CBT for youth anxiety have been developed in relation to parental involvement, including youth-only CBT (Y-CBT; where the youth alone attends treatment), youth and parent or family CBT (F-CBT; where youths and their parents attend together), and, most recently, parent-only CBT (P-CBT; where the parent alone attends).

Objective: This protocol describes an overview of systematic reviews comparing the relative efficacy of different formats of CBT for youth anxiety (Y-CBT, F-CBT, and P-CBT) over the study period. The protocol will also examine the moderating effects of variables on the efficacy of different formats; for example, youths' age and long-term outcomes.

Methods: We will analyze the results of systematic reviews that compare different levels and types of parental involvement in CBT for youth anxiety over the study period. A systematic review of medical and psychological databases (PsycINFO, PubMed, SCOPUS, Web of Science, Cochrane Library, and Embase) will identify reviews comparing the efficacy of different formats of parent involvement in CBT for youth anxiety. Data extraction will include (1) author names (and year of publication), (2) review design, (3) age range, (4) analysis type, (5) conclusions, and (6) moderators. This overview will present the relative efficacy of formats chronologically in a table and then describe the main results longitudinally in a narrative summary. A Measurement Tool to Assess Systematic Reviews, 2nd Edition (AMSTAR 2), quality rating will be given to each review, and the amount of primary study overlap across reviews will be quantified.

Results: The last search was conducted on July 1, 2022. The reviews were published between 2005 and 2022. We found a total of 3529 articles, of which we identified 25 for the final analysis.

Conclusions: This overview will compare and report the relative efficacy of Y-CBT, P-CBT, and F-CBT for youth anxiety over the study period, describe the heterogeneity across reviews and primary studies, and consider the moderating effect of relevant variables. It will describe the limitations of an overview, including the potential for nuance in the data to be lost, and provide conclusions and recommendations for conducting systematic reviews regarding parental involvement for CBT for youth anxiety.

KEYWORDS

anxiety; cognitive behavioral therapy; systematic review; youth; overview; review

Introduction

Background

Cognitive behavioral therapy (CBT) represents a revolution for treating anxiety in adults and children. The efficacy of CBT for youth anxiety has been established in systematic reviews [1-3] and overviews [4,5]. During CBT, the therapist transfers skills to young clients so they can better manage their anxiety symptoms. As researchers have attempted to improve CBT protocols, they have examined whether it is advantageous to also involve parents in treatment. This approach seems logical, as parents and families are sometimes implicated in the maintenance of a child's anxiety [6,7]. During CBT, parents can be coached in skills to manage their child's anxiety and these skills can vicariously help the parent manage their own anxiety [3,8]. Yet, researchers have questioned the necessity of parental involvement in every intervention [2,7]. For example, a parent's presence could increase the youth's reliance on them and reduce their autonomy [9]. Barmish and Kendall [3] influentially stated, "we must resist the intuitive appeal to conclude that the inclusion of parents as active participants in CBT is preferable to child-focused CBT until the data provide the needed support for such a claim." Whether parents enhance CBT for youth anxiety is one of the most frequently examined and contested topics in clinical psychology over the last 20 years.

Much of the debate regarding the merits of parental involvement in CBT has taken place in systematic reviews that have high impact in the field. These reviews provide a high-level analysis as they aggregate data from several primary studies. Yet, while these reviews are influential, they typically use different methodologies and only represent the accumulated evidence at a given time point. For example, the inclusion and exclusion criteria, types of studies available, and type of analysis conducted influences a systematic review's outcomes and conclusions. Overviews (systematic reviews of systematic reviews) can potentially provide greater coverage over time and a higher level of analysis than an individual systematic review [10,11]. Understanding how different reviews summate and report on available evidence regarding treatment formats over time provides context as to how the field has developed. Furthermore, while early studies on this topic examined youth-only CBT (Y-CBT; where the youth alone attends treatment) versus youth and parent or family CBT (F-CBT; where the youth and parent attend treatment together), newer formats have examined parent-only CBT (P-CBT; where the parent alone attends treatment; [1,12]) so that parents can learn skills on how to manage their children's anxiety. P-CBT can be advantageous when there is limited engagement with the youth or practical reasons prevent direct treatment. Moderating variables could also influence the efficacy of different treatment formats. For example, greater parental involvement may be influential for younger children [7], for longer-term outcomes [13], or when the parent is experiencing their own psychopathology [14].

This paper describes a novel protocol for an overview investigating the effects of parental involvement in CBT for youth anxiety over the study period. As results examine consistency and trends across individual reviews over time, we have permitted overlap (allowing primary studies in multiple reviews). As the reviews use varied methodologies and there is overlap, we displayed results as a narrative summary describing results for systematic reviews over time, rather than aggregating data (as in a meta-analysis). To our knowledge, this is the first overview to examine the effects of parental involvement in CBT for youth anxiety.

Objectives

Primary Research Question

Our primary objective is to explore the relative efficacy of CBT for youths with anxiety by comparing Y-CBT, P-CBT, and F-CBT over the study period. The dependent variable is any quantitative indication of the youth's anxiety (eg, recovery rates, youth- or parent-reported anxiety, treatment efficacy based on the level of evidence, etc).

Secondary Research Question

If the data permit, we will examine the moderating effect of variables including the youths' age, parents' psychopathology, and the long-term effects of Y-CBT, F-CBT, and P-CBT on youth anxiety. If any other theoretically interesting moderators are identified in the course of the literature review process, they may be included as well. This analysis will consider the effects of moderators on the relative efficacy of formats, and the results will be described in a narrative and interpreted in the discussion.

Methods

Protocol Registration

The protocol of this review is registered with the Open Science Framework [15].

Search Strategy

The search will be undertaken by clinical psychologists who treat anxious youths (SB and M Richardson). The final set of articles will be developed in conjunction with a university librarian (M Riba). The search strategy involves searching databases for articles that have 4 general categories: "Cognitive Behavior Therapy" AND "Youths" AND "Anxiety" AND "Review." Of the articles identified in this broad search, the screeners (M Richardson and SB) will hand-search articles related to "Parent/Family" treatments. We will also attempt to identify any additional eligible articles in a hand search. See Multimedia Appendix 1 for search queries in each database.

XSL•FO
RenderX

Databases

The search will be conducted in the following electronic databases: PsycINFO, Web of Science, PubMed, Cochrane Library, SCOPUS, and Embase.

Preferred Reporting Items for Systematic Reviews and Meta-Analyses

PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines have been followed in this systematic review. Data will be presented in a PRISMA flowchart.

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria for articles are summarized in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for articles.

Inclusion criteria:

- The article must state that it is a systematic review and involves a systematic search of medical or psychological databases (or both).
- The review must state that the treatment used is primarily cognitive behavioral therapy (CBT).
- The review must exclusively focus on the treatment of anxiety.
- The review should focus on treatment for a variety of anxiety disorders (mixed anxiety; >1 diagnoses) to reduce the potential differential effects of treatment on a particular anxiety disorder.
- The review must report a quantitative measure (eg, effect size, percent remission, etc) related to youth anxiety.
- Parental involvement in CBT can take any form (eg, cotherapist, psychoeducation, etc), as long as it is the focus of treatment.
- The review must discuss the relative efficacy of different formats for CBT; for example, it must make a direct comparison (eg, randomized controlled trials) or an indirect comparison (eg, comparison with to a control group) among the different formats of CBT for youth anxiety (youth-only CBT, youth and parent or family CBT, or parent-only CBT).
- The treatment must be intended for youths, so participants in reviews must be ≤21 years old.
- The treatment should be primarily face-to-face psychotherapy (ie, it should not be web-based or e-therapy).
- The included reviews must be in English-language peer-reviewed journals published from 2000 onward.

Exclusion criteria:

- Primary studies that are not systematic reviews.
- Reviews that focus on CBT and another concurrent treatment for the youth's anxiety (eg, CBT and psychiatric medication). However, if a review includes primary studies where some participants are receiving a concurrent treatment, it will be included.
- Reviews should not focus on comorbidity between anxiety and another disorder as the target of treatment (eg, anxiety and autism or epilepsy); however, if a review involves primary studies where participants have comorbid conditions, it will be included.
- A review with only a narrative description of results and no analysis.
- In line with the most recent Diagnostic and Statistical Manual, 5th Edition [16], reviews that focus on obsessive compulsive disorder and posttraumatic stress disorder are excluded; however, if studies within the selected reviews include youths with these diagnoses among anxiety disorders, they will be included.

Population, Intervention, Comparison, and Outcomes

The PICO is described as (1) population, comprising youths with anxiety; (2) intervention, involving P-CBT, Y-CBT, or F-CBT; (3) comparison, including other CBT formats different from the intervention (eg, P-CBT, Y-CBT, or F-CBT); and (4) outcome being the analysis of anxiety levels.

Screening Stages

Two clinical psychologists (SB and M Richardson) will be involved in screening all articles with the following steps: (1) duplicates will be removed in EndNote (Clarivate), (2) articles will be transferred to Covidence for data screening and extraction, (3) articles will initially be screened based on the title and abstract by the 2 independent coders who are clinical psychologists, (4) the full text of the remaining articles will be screened by the 2 independent clinical psychologists to identify the final articles to be included, and (5) any discrepancies in screening decisions will be resolved through discussion between the 2 clinical psychologists.

Data Extraction

The extracted data will include (1) author names (year of publication), (2) overall study design, (3) age range, (4) primary analysis type between different CBT formats (eg, controlled effect size where efficacy for a format is compared to another condition), and (5) conclusions regarding superiority among CBT formats. We may also code for other moderators such as youths' age, parents' psychopathology, long-term outcomes, and other variables identified through the literature review should there be adequate data.

XSL•FO
RenderX

Management of Extracted Data and Synthesis

The coders (SB and KI) will extract the abovementioned variables for all included studies. To provide the most comprehensive overview, we shall describe the main results from systematic reviews with a variety of outcome measures over time. In this overview, we are interested in the relative performance of different formats of CBT for youth anxiety over the study period. Data extracted from this overview will initially be chronologically tabulated. The results will then be summarized in a narrative, based on the analysis type and outcome of each review (the results will not be presented as an overall meta-analysis, and results of individual reviews will be described over time). The analysis will include comparison among treatment formats. A primary analysis will examine the relative efficacy of P-CBT, Y-CBT, and F-CBT over time. A secondary analysis will be exploratory considering the effects of moderating variables, such as the youths' age, parents' psychopathology, and long-term outcomes, if the data permit. A general discussion will follow at the end of the review.

Management of Overlap

In this overview, for the main analysis, we are interested in the relative performance of different CBT formats for youth anxiety over the study period. As individual systematic reviews were studied over time, overlap in primary studies across reviews is considered acceptable (ie, the same studies are included in multiple reviews published at different times). We are interested in how the accumulated data in each systematic review are reported over time.

In order to report the extent of overlap, we will include a citation matrix that visually displays the citation overlap across reviews [11,17,18]. We will also report the corrected covered area, which is a quantitative measure of primary study overlap across reviews [11,17,18]. We will also include some information or statistics about the degree of overlap across reviews (eg, the number of overlapping studies present in each review) [11].

Quality Assessment

Each systematic review will be graded using the Measurement Tool to Assess Systematic Reviews, 2nd Edition (AMSTAR 2) [19]. It has 16 items and 7 critical domains: protocol registration, adequate literature search, justification of excluding studies, risk of bias of individual studies, appropriateness of meta-analysis, consideration of risk of bias when interpreting results, and assessment of publication bias. We will report the proportion of studies that meet each critical domain. For the purposes of this study, the AMSTAR 2 rating was calculated as high (none or 1 noncritical weakness), moderate (more than 1 noncritical weakness), or low (1 or more critical weaknesses). Uncertainty in quality ratings will be resolved through discussion between the 2 clinical psychologists (SB and M Richardson).

Results

The last search was conducted on July 1, 2022. We identified 3529 articles across the search, which yielded 2189 unique articles. We found 25 systematic reviews that meet our criteria and compare CBT formats.

Discussion

Expected Findings

Youth anxiety is common and disruptive; however, CBT is a highly effective treatment for these conditions. Yet, there is ongoing debate regarding the most effective way to deliver CBT [3]. Parental involvement for youth anxiety has often been the norm; however, evidence for this approach has been mixed [2,8]. There are several systematic reviews examining parental involvement; yet, the majority of these are inconclusive [3]. This paper presents a novel protocol to answer this question by examining the results and conclusions of systematic reviews over time, rather than examining primary studies that are subject to heterogeneity. This overview examines trends and consistency in the efficacy of CBT formats as reported by reviews over time. This provides a high-level view of the topic by drawing on several systematic reviews over time. This overview will also consider potentially important moderators including youth's age, long-term outcomes, and parents' psychopathology.

Strengths and Limitations

The strengths of this overview are that it will be conducted as a complex search across several medical and psychological databases. We will also take stringent measures of quality using AMSTAR 2, involve experienced child anxiety clinicians for coding, and analyze study overlap across reviews. The inclusion criteria also allow for a broad search across reviews with varying methodologies in order to maximize the search. A potential limitation of this overview approach is that nuance in the data may be lost due to our focus exclusively on systematic reviews rather than primary studies; for example, recent primary studies may not be included in this analysis as they are not included in systematic reviews. Furthermore, this study only considers efficacy, such that other important variables including cost, acceptability, and impact on functioning are not analyzed. Finally, while trends and directions in effects described in this overview are informative, they do not imply statistical significance.

Conclusions

The results of this overview will inform clinicians about the most effective way to conduct anxiety interventions with youths. To date, clinical decisions regarding parental involvement are often based on mixed evidence and clinical intuition. This study will provide insight regarding how to tailor CBT for youths with anxiety by varying parental involvement depending on factors including the child's age. This overview will also provide recommendations for conducting and reporting systematic reviews regarding parental involvement for CBT for youth anxiety. The overview methodology over time may help to examine other clinical questions, where there is high heterogeneity across primary studies. The results of this novel overview will be widely disseminated and they are expected to influence clinical practice.

Abstract

Background: Stroke is a common cause of mortality and morbidity. Insufficient and untimely rehabilitation has been associated with inadequate recovery. Telerehabilitation provides an opportunity for timely and accessible services for individuals with stroke, especially in remote areas. Telerehabilitation is defined as a health care team's use of a communication mode (eg, videoconferencing) to remotely provide rehabilitation services. Telerehabilitation is as effective as facility-based rehabilitation; however, it is infrequently used due to implementation barriers.

Objective: The aim of the study is to explore the interaction between the implementation strategies, context, and outcomes of telerehabilitation of patients with stroke.

Methods: This review will follow four steps: (1) defining the review scope, (2) literature search and quality appraisal, (3) data extraction and evidence synthesis, and (4) narrative development. PubMed via MEDLINE, the PEDro database, and CINAHL will be queried till June 2023 and supplemented with citation tracking and a gray literature search. The relevance and rigor of papers will be appraised using the TAPUPAS (Transparency, Accuracy, Purposivity, Utility, Propriety, Accessibility, and Specificity) and Weight of Evidence frameworks. The reviewers will extract and synthesize data iteratively and develop explanatory links between contexts, mechanisms, and outcomes. The results will be reported according to the Realist Synthesis publication standards set by Wong and colleagues in 2013.

Results: The literature search and screening will be completed in July 2023. Data extraction and analysis will be completed in August 2023, and findings will be synthesized and reported in October 2023.

Conclusions: This will be the first realist synthesis, uncovering the causal mechanisms to explain how, why, and to what extent implementation strategies impact telerehabilitation adoption and implementation.

Introduction

Telerehabilitation of Patients With Stroke

Stroke is a common cause of mortality and morbidity in the United States, affecting nearly 800,000 persons yearly [1]. Even though early rehabilitation of patients with stroke is pivotal for adequate recovery [2], rehabilitation is frequently delayed and underused [3]. Insufficient and untimely rehabilitation has been partly attributed to distance and transport challenges to rehabilitation facilities, especially for rural dwellers, inducing geographic disparity [4]. Nevertheless, both urban and rural residents experience various limitations to accessing facility-based rehabilitation: increasing rehabilitation costs, medical staff shortages, inadequate transportation systems and, after March 2020, pandemic-related contact restrictions [5,6]. In addition, more restriction to care is inflicted by the attitudinal, architectural, economic, and sensory barriers representing the omnipresent societal discrimination against people with disability [7].

Telerehabilitation is at least as effective as facility-based rehabilitation [8-10] and is typically less costly [11]. For that, home-based telerehabilitation is a promising solution that provides an opportunity for timely, effective, and accessible services to a large base of patients [12], especially in low-resource rural areas [13].

Multiple forms of technology provide a medium for telerehabilitation: telephone, messaging, email, videoconferencing, web-based platforms, robots, and virtual reality [14]. Currently, telerehabilitation via phone and videoconferencing is considered a basic technology [15,16]. Advanced technology includes virtual reality as it creates a physical experience with multiple sensory inputs: tactile, visual, auditory, and olfactory [12,17,18]. Robotics use in telerehabilitation is another advanced and evolving technology with great potential to enhance motor functions and measure patient progress [19].

Telerehabilitation Implementation and the Interplay Between Context and Mechanisms

Most studies addressing telerehabilitation are feasibility and efficacy studies, leaving a gap in understanding the effective implementation of telerehabilitation [13,20]. Implementation science is “the scientific study of methods to promote the systematic uptake of research findings and other evidence-based practices into routine practice, hence aiming to improve the quality and effectiveness of health services” [21]. Many barriers hinder implementation: lack of knowledge and misbeliefs about the effectiveness of the intervention, inadequate planning for implementation, insufficient engagement of different stakeholders, and lack of resources, among others [22]. To overcome those barriers, implementation science pivots to designing and studying implementation strategies [23]. Implementation strategies are “methods or techniques to enhance a clinical program or practice’s adoption, implementation, and sustainability” [24]. Training, audit and feedback, coaching, and piloting are examples of implementation strategies.

While using the same strategies to enable implementation across various contexts is appealing, it brings limited success [25]. This is attributed to the multicomponent nature of implementation strategies and the complexity of the process of implementation that represents the interactions between the implementation strategy, the context of the setting in which implementation occurs, and the change process required for implementation [26,27].

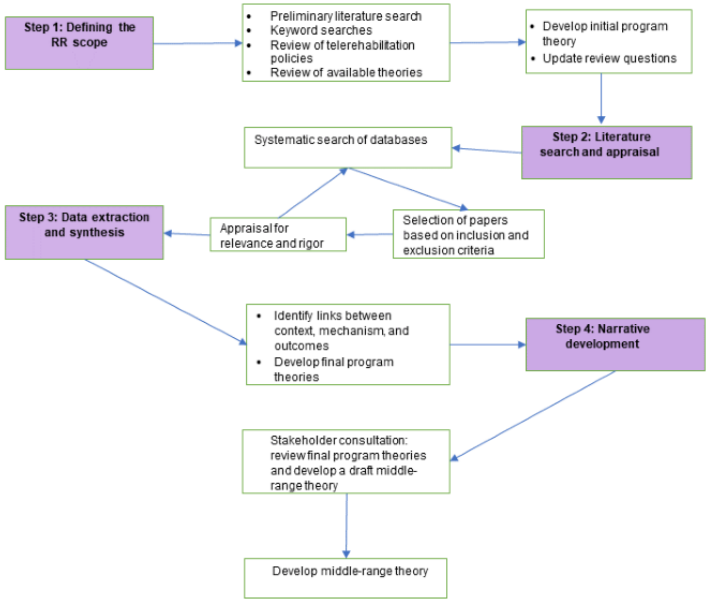
Understanding the mechanisms of implementation strategies is vital to determine how and which strategies work and in what context for telerehabilitation [24,28,29]. Mechanisms are dynamic processes that drive and generate outcomes, often involving the understanding and reasoning of actors involved in implementation [30]. Establishing a telerehabilitation Community of Practice is an implementation strategy that might enhance telerehabilitation adoption; however, it does not directly result in adoption [31]. Through an underlying mechanism (eg, cognitive participation of the Community of Practice members), stakeholders may decide to adopt the change. Mechanisms are not observable by themselves, but observable data suggest their existence [31]. For example, increased adoption could be measured, but cognitive participation might be inferred to but not directly observed.

Context, Mechanisms, and Outcomes (CMO) configurations are at the heart of realist synthesis. CMO configurations are hypothetical until they are tested and found explanatory to the relationship between the strategies and the outcomes of interest [32]. CMO configurations explain what worked, how it worked, and what the involved mechanisms are [33]. Ultimately, researchers can respond to “will it work in a different context?” [33]. Realist researchers understand that implementation strategies work selectively, and outcomes vary in different settings [34,35]. Thus, recognizing implementation strategies patterns, as well as outcomes patterns, provide insight into the success or failure continuum [34].

This realist review aims to develop generalizable theories by examining each study to uncover the mechanism through which an implementation strategy works and the effects of various contexts on making it work [35]. The reviewers will untangle the complexity of implementation strategies through a frequent enhancement of the theoretical explanations of the empirical findings [36,37]. The output of this realist synthesis is a refinement of how the strategy “works, for whom, in what circumstances, in what respects and why?” [38].

XSL•FO
RenderX

The purpose of this realist review is to synthesize a theoretical explanation of the adoption and implementation of telerehabilitation of patients with stroke. For practitioners, this review will offer empirically rooted strategies for facilitating the implementation of telerehabilitation.



Methods

Study Design

This study will follow the guidelines proposed by Rycroft-Malone et al [39] and Pawson [34]. To explain how the implementation of telerehabilitation of patients with stroke operates, we will develop a middle-range theory (MRT), subject to refinement and validation as it can be used in the future implementation of telerehabilitation.

The review steps are (1) clarifying the scope and initial program theory (IPT) development, (2) searching for evidence appraising primary studies, (3) extracting data and synthesizing evidence, and (4) narrative development of conclusions. Figure 1 summarizes the main steps involved in this realist review.

Figure 1. Flowchart of the RR steps. RR: realist review.

Step 1: Defining the Scope of the Review

The review team will formulate a descriptive and explanatory theoretical framework from the reviewed evidence. The focus of this review is on the implementation strategies of telerehabilitation. Implementation strategies are based on an initial practical understanding of the most effective way to deliver and implement an intervention, focusing on better implementation outcomes and addressing context-specific barriers to implementation.

Constructing a presynthesis conceptual framework marks the initial step in conducting a realist review [38]. This initial framework is referred to as IPT [40], which will provide an initial theoretical understanding of the implementation of telerehabilitation, necessary to explore implementation mechanisms. We will develop the IPT using concepts from multiple theoretical frameworks that researchers use for studying telemedicine adoption and implementation [41], namely: the Technology Acceptance Model, the Diffusion of Innovation Theory, the Theory of Interpersonal Behavior, the Perceived Usefulness, the Perceived Ease of Use, the Unified Theory of Acceptance and Use of Technology, and the Theory of Reasoned Action [42]. In addition, the review team will contribute their implementation science, telerehabilitation, and quality improvement knowledge and experience to refine the IPT [41]. The IPT will be refined and expanded as evidence arises throughout the iterative synthesis process [43]. The continuous iteration of the theory is essential to follow logic trails discovered in the literature to develop the understanding of telerehabilitation and its implementation.

Step 2: Literature Search and Quality Appraisal

The literature search is iterative and directed to answer the questions that arise as the review progress [34,44]. To gain familiarity with the size and type of the available literature, one reviewer (MMH) will use *PubVenn* [45], which provides a graphical display of the extent of the literature, and *PubReMiner* [46], which analyzes the literature indexed in the PubMed MEDLINE database for frequent terms, journals, and authors.

The review team will use the 4 theoretical domains of the Realist Synthesis of Implementation Strategies (RES-IS) model to guide literature search and data extraction [39]. RES-IS is developed to research implementation strategies using the realist synthesis approach. It represents implementation strategies in 4 theoretical domains: properties of change agents, system change, technologies, and education interventions [39]. The change agent refers to the individuals' attributes and the strategies they use to implement telerehabilitation successfully. Many terms are synonyms for change agents like facilitators, opinion leaders, knowledge brokers, champions, and experts. Systems changes refer to the organizational characteristics that facilitate the implementation and sustainment of telerehabilitation. Other

XSL•FO
RenderX

terms related to systems change include social networks, culture, leadership, learning organizations, teamwork, and collaboration. Properties of technologies refer to the telerehabilitation technology itself and other technologies involved in facilitating its implementation. Education and training include academic detailing, reflection, action learning, and adult learning [39].

The context of implementation is at the center of the RES-IS model for its ubiquitous influence on the use and effect of strategies. In addition, an implementation strategy can target different levels: audits can induce changes in policies at the organizational level or alter local practices at the unit or individual level [47]. The term dose refers to the needed frequency and intensity of an implementation strategy (eg, training) to activate mechanisms that bring about outcomes [24,39].

The review team will use PubMed via MEDLINE, the PEDro database, a physical therapy evidence database, and CINAHL to conduct the topical search. A health information specialist (MB) leads the literature search. After reviewing the outcome of this topical search, we will rerun the search strategy, applying a search filter to limit the results to systematic reviews, logic models, and opinion pieces rich in concept-based discussions [48].

After identifying index papers, the review team will use the CLUSTER approach to search for Citations, Lead Authors, Unpublished Material, Scholar Searches, Theories, Early Examples, and Related Projects [48]. The CLUSTER search will be iterative and repeated to enhance the finding of relevant theories. The reviewers will also explore telerehabilitation-specialized journals (eg, *International Journal of Telerehabilitation*, *Smart Homecare Technology and Health*, and *Annual Review of Cybertherapy and Telemedicine*). As part of the CLUSTER approach, the reviewers will use the identified index documents to conduct a citation search of the index documents on Google Scholar using *Publish or Perish* software (Anne-Wil Harzing). To reach more resources, the reviewers will consult the American Telemedicine Association, the American Physical Therapy Association, and The American Occupational Therapy Association.

Documenting the literature search—The literature search is iterative and sometimes opportunistic [48]. The reviewers will use the EndNote software (Clarivate) [49] to manage the literature search process. To keep track of the literature search output, a new folder on EndNote will be added. Each literature search (a folder on EndNote) will document the sampling strategy, type of studies included, approaches, range of years, limits, inclusions and exclusions, terms used, and electronic sources [48,50].

The review team will use Rayyan (Oatar Computing Research Institute), a review management platform [51], to facilitate papers' review and data extraction. To exclude irrelevant papers, 2 reviewers (MMH and AT) will screen the titles and abstracts. Based on the inclusion and exclusion criteria (Textbox 1), 3 reviewers (MMH, AT, and ST) will independently review the included full papers. The reviewers will meet regularly to discuss their decision on papers' inclusion. Disagreement will be resolved by examining the paper's language, focus, and inclusion criteria with another reviewer (MRR). Copies of papers or book chapters will be attached to the citation on Rayyan. Once saturation of the themes is achieved, the analysis of the included literature will conclude. Based on this analysis, the team may identify new inclusion criteria.

XSL•FO
RenderX

Textbox 1. Review inclusion and exclusion criteria.

Inclusion criteria

- I—Intervention
  - Home-based physical telerehabilitation of patients with stroke.
- S—Implementation strategy
  - Implementation strategies for telerehabilitation of patients with stroke.
- C—Context
  - Health care providers, for example, physicians, nurses, physiotherapists, and allied health professionals, are involved in home-based stroke telerehabilitation.
  - Patients with stroke and their caregivers (eg, family members, professional caregivers, volunteers, and so on).
  - Policy makers, decision makers, managers, leaders, and facilitators are involved in telerehabilitation.
  - Any setting (eg, inpatient, outpatient, and home) involved in the implementation and delivery of telerehabilitation for patients with stroke.
  - Studies based in the United States.
- M—Mechanisms
  - Fundamental processes are involved in or responsible for action or reaction triggered by the implementation strategy.
- O—Outcomes
  - Implementation outcomes guided by RE-AIM framework: Reach, Effectiveness of Implementation, Adoption, Implementation (fidelity and cost), and Maintenance. In addition, we will review Proctor's implementation outcome framework: acceptability, appropriateness, feasibility, efficiency, speed, timeliness, and representativeness or equity related to reaching and adoption.

Study design

- All study designs will be included.
- Include empirical and nonempirical sources (eg, books, guidelines, policies, editorials, opinion papers, dissertations, among others).
- Other materials such as podcasts and recorded lectures as supplementary materials to published scientific evidence will be sought for insights.

Exclusion criteria

- Non-English papers.
- Studies that are done outside the United States.
- Studies that show low rigor.
- Papers address telerehabilitation in patients with conditions other than stroke (eg, postoperative rehabilitation) or other than in patients' homes (eg, in the community).
- Papers with mere focus on cognitive and psychiatric rehabilitation of patients with stroke.
- Papers focused on the efficacy or effectiveness of telerehabilitation with no implementation-related details or insights.

The quality appraisal of the included papers will pass through 2 stages: the first stage will focus on relevance of the included papers to the objective of the review and the second one will evaluate their rigor. The review team developed criteria of relevance for this study (Textbox 2). The criteria for the relevance are to guide the team to include studies that can inform the MRT development [34].

XSL•FO
RenderX

Textbox 2. Criteria of study relevance to inform theory development.

High relevance

- Describe contextual factors of implementation of telerehabilitation for patients with stroke.
- Describe stakeholders' perspectives on the implementation of telerehabilitation.
- Describe implementation strategies of telerehabilitation for patients with stroke.
- Describe implementation outcomes of telerehabilitation for patients with stroke.
- Describe theories of implementation of telerehabilitation for patients with stroke

Moderate relevance

- Same as high relevance criteria but includes telerehabilitation for mixed patient populations that include other conditions in addition to stroke.

Low to no relevance

- Comparative studies of the effectiveness of telerehabilitation for patients with stroke that do not include implementation-related info.
- Describe the process of engineering the design of telerehabilitation technology for patients with stroke.
- Studies of prototypes and proofs-of-concept.

Assessment of rigor will be conducted through a combination of 2 different frameworks: TAPUPAS (Transparency, Accuracy, Purposivity, Utility, Propriety, Accessibility, and Specificity) framework, devised by Pawson et al [52], and Weight of Evidence (WoE) framework, devised by Gough [53,54].

TAPUPAS stands for Transparency, Accuracy, Purposivity, Utility, Propriety, Accessibility, and Specificity [52]. *Transparency* addresses whether the process of knowledge generation is open to external review and scrutiny [52]. Transparency extends beyond reporting research methods to how the researchers develop the research question, aims, and objectives [55]. *Accuracy* examines whether the researchers made accurate claims based on the results of their study [52,55,56]. *Purposivity* assesses the fit of the used methods for the purpose of the study [55]. Purposivity ensures the process of inquiry is methodologically sound and contextually appropriate. *Utility* considers the needs of the stakeholders and the fit of the study to satisfy those needs [56]. *Propriety* focuses on the ethical aspects of conducting the research [55]. *Accessibility* necessitates the dissemination and implementation of the research findings [55]. Both academic and nonacademic routes are appropriate for dissemination depending on who the end users are [55]. *Specificity* evaluates the methodological quality of the study and its conformance with the available standards [56].

WoE framework allows the opportunity to provide a grade for each of its 3 focus areas to be added up to an average grade for each paper [53]. WoE focus area A addresses the trustworthiness and coherence of the study, focus area B addresses appropriateness of the methods to the research question, focus area C assesses the relevance of evidence to the research question, and focus area D is the total grade based on the focus areas A, B, and C [53].

The focus area A of the WoE comprises 4 factors of the TAPUPAS framework: transparency, accuracy, accessibility, and specificity. The focus area B comprises purposivity. The focus area C comprises utility and propriety. Each focus area will be assigned a grade range from 1 (low quality), 2 (medium quality), or 3 (high quality) based on the TAPUPAS criteria within each of the WoE focus areas. For example, if a study is considered transparent and accurate, but it is not accessible or specific, it will receive a grade of 1.5 for WoE A [54]. The same logic will follow in the other focus areas. The score of WoE D will then reflect an overall average score, adding the scores of WoE A + B + C and dividing the total score by 3. Papers with WoE D score of 2 or more will be included. However, some papers with lower score, which provides important insight into the theory development will be included. In this case, the evidence generated out of inclusion of lower-quality studies will be marked as low-quality evidence.

Step 3: Data Extraction and Evidence Synthesis

Overview

As this is an explanatory review that uses original papers to answer the study questions, a realist approach will be used for data extraction and synthesis. Data extraction will be conducted based on Multimedia Appendix 1 [1,2,5-42,57-59] forms. Essential text from the primary studies will be included to answer the review question [60]. All parts of the included papers will be examined to identify pertinent information. The reviewers (MMH and AT) will extract and code text from each of the papers. Then the coded texts will be synthesized together to search for a relationship between the intervention, implementation strategy, context, mechanisms, and outcomes (ISCMO) [61]. The identified intervention, ISCMO will consider different strategies and telerehabilitation modes. Discussions of the review team will guide the evidence synthesis, and each ISCMO configuration will be examined against the available empirical evidence [61].

Coding

A coding manual developed by May et al [62] will be used to guide the coding process. This manual is based on Normalization Process Theory (NPT), linking its 12 primary constructs to the CMO configurations [62]. NPT is a sociological theory that was developed to support studying and evaluating the implementation of complex health care interventions [62-64].

XSL•FO
RenderX

In addition, the constructs of the NPT have been mapped to the CMO configuration [62], rendering it a perfect fit for this realist review. Four NPT constructs conceptualize the context: strategic intentions, adaptive execution, negotiating capability, and reframing organizational logics. Another 4 constructs inform the mechanism of implementation: coherence building, cognitive participation, collective action, and reflexive monitoring. Lastly, outcomes include intervention mobilization, normative restructuring, relational restructuring, and sustainment. May et al [62] provided descriptions and examples of the NPT constructs as part of the coding manual (Multimedia Appendix 2).

Three reviewers (MMH, AT, and ST) will independently code the primary studies using NVivo (version 12; QSR International), a computer-assisted qualitative data analysis platform [65]. NVivo supports code-based inquiry, searching, and theorizing combined with the ability to annotate and edit documents [66]. Given the complex and iterative nature of conducting a literature search and synthesis in realist review, it is essential to prioritize and maintain transparency in methods to ensure the credibility and rigor of the review process [57], an endeavor NVivo will support [65]. In addition to detailing analytical microprocesses that lead to theory generation, another key feature of NVivo is its ability to integrate different data sets [65]. NVivo will be used early in the synthesis process. Each concept of the initial theory will be given a node in NVivo, and each node will be a hub for related materials used in the analysis. Each node will be linked to a memo to describe the review team discussions and thoughts behind concepts. For subconcepts, we will create child nodes. Concepts that are not supported by empirical evidence will be kept within the NVivo file as "unsubstantiated." Once new evidence arises to support unsubstantiated concepts, we will bring those concepts back to the framework.

Coding will support the data extraction by assigning a salient and summative attribute to the extracted texts [58]. Data extraction and coding will link the primary studies, the research question, and the study findings [58]. Reviewers will meet regularly to discuss and consolidate the results.

Data will be combined and synthesized based on the following steps:

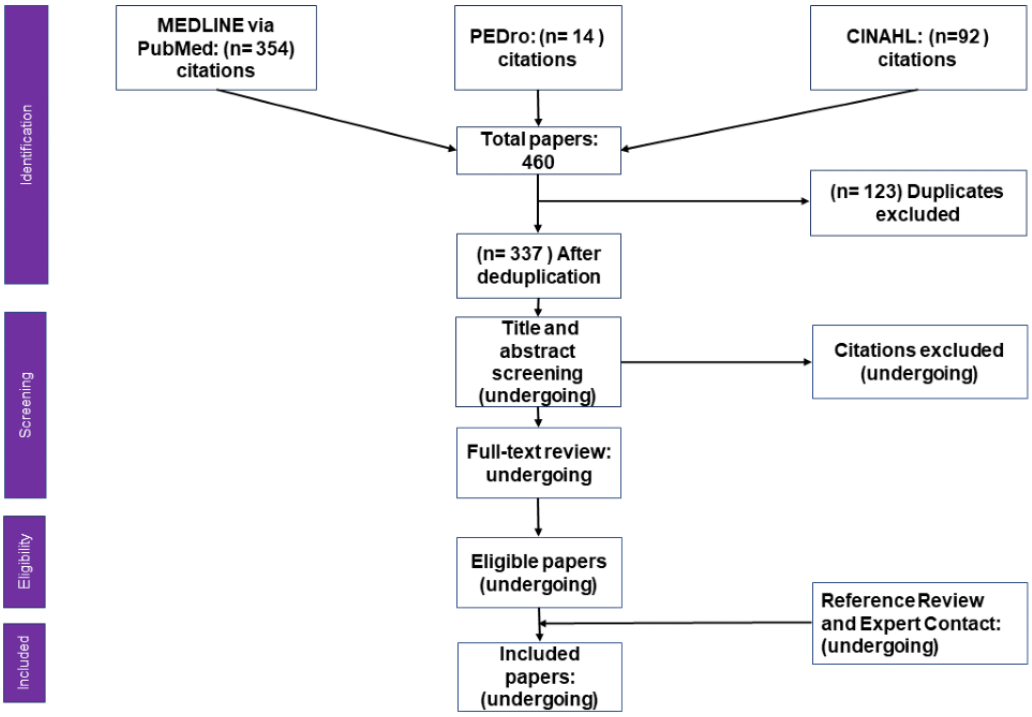
1. Three reviewers (MMH, AT, and ST) will organize extracted data into evidence tables; for example, to address the impact of systems characteristics on the implementation of telerehabilitation, the reviewers will form a table that includes the extracted data and source papers.
2. Three reviewers (MMH, AT, and ST) will independently identify themes from each paper. Themes are patterns across the included studies that are important to explain the implementation of telerehabilitation. Codes will then be refined based on discussions among the review team [59]. The same reviewers will meet regularly to discuss and challenge the themes.
3. Four reviewers (MMH, ST, AT, and MRR) will discuss and resolve differences, combine themes, and develop chains of inference (connections across papers linking the identified themes) through an iterative process [39]. The chains of inference will function as a basis for the ISCMO configurations,
4. Three reviewers (MMH, AT, and ST) will identify papers that contain the themes used to identify chains of inference.
5. Four reviewers (MMH, ST, AT, and MRR) will make connections among chains of inference, which will be an iterative process.
6. Four reviewers (MMH, ST, AT, and MRR) will use the chains of inference to generate ISCMO configurations confirmed by connecting back to the themes that emerged from the literature. The outcome of this step will be a comprehensive picture of implementation strategies, mechanisms, contexts, and outcomes chains [39,59]. The produced hypothesis will be used to create new program theories or refine them [39,59]. Then, we will provide a narrative based on the available evidence to support such a hypothesis.

Multimedia Appendix 3 contains outlines of the tables that will be used in each step.

Step 4: Narrative Development

A narrative synthesis will summarize the nature of the implementation strategy, context, mechanism, and outcome configurations, and the supportive evidence from the primary studies. One reviewer (MMH) will take the lead in coordinating the presentation of the narrative synthesis using text, summary tables, and a logic model. After developing the theoretical framework, one reviewer (MMH) will write the review for publication. The origins of the inferences, the hypothesis, the developed MRT, and the source of the primary evidence on which they are based will be documented and defended. The reasoning process used to create the chains of inference, the hypotheses, and the final MRT will be documented and reported to enhance transparency [59].

Ethics and Dissemination



Ethics approval is not required for this study as it is secondary research, synthesizing evidence from primary studies. The review team will disseminate the findings through peer-reviewed publications and conference presentations.

Results

Literature search and screening will be completed by the end of July 2023 and will be recorded in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart (Figure 2) [67]. A detailed search strategy is in Multimedia Appendix 4. Data collection will be based on the RES-IS model through forms that focus on the 4 domains (ie, properties of change agents, system change, technologies, and education interventions), their specific characteristics, and the impact of their interactions with the setting. Multimedia Appendix 1 gives more details on the planned data collection. The results of the review will be reported, following the RAMESES (Realist and Meta-Narrative Evidence Syntheses) standards (Multimedia Appendix 5) [36].

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.

Discussion

Telerehabilitation has the potential to bridge the access and timeliness gap of rehabilitation of patients with stroke. Yet, research on telerehabilitation implementation is still in its infancy. This review will enhance this field by developing a conceptual understanding of the interactions between different contexts and mechanisms of implementation. That will guide both implementation efforts at the practice level and future research at the academic level.

To our knowledge, this is the first realist review of the implementation of telerehabilitation for patients with stroke. A key strength of this review is that it will vet the causal mechanisms to explain how, why, and to what extent implementation strategies impact telerehabilitation implementation, a research gap not adequately explored. A further strength of the review is that it will examine the complex contexts in which various causal mechanisms are and are not activated. In addition, this review will inform future reviews by sharing our experience on using the recent NPT's coding manual [62].

Nonetheless, this review has some limitations. First, the evidence will be dependent on the availability and quality of relevant useful published data. This means that this review's findings and conclusions are limited to what have been published and it may restrict the ability to completely understand and describe the active causal mechanisms. To address this risk, the review team will use a comprehensive and iterative literature search that is expert-guided and source-diverse.

The potential impact of this review extends beyond academia and health care providers; policy makers stand to benefit from the insights gained as well. Delving into the causal mechanisms underpinning effective telerehabilitation implementation will yield essential information for designing experimental research studies that investigate how various strategies impact adoption, implementation, and sustainability. Armed with a deeper comprehension of these inner workings, decision makers can navigate adaptation efforts required for localizing policies pertaining to telerehabilitation implementation. This could lead to improved access and delivery of telerehabilitation services, ultimately resulting in better health outcomes for patients served by policy makers' initiatives.

Abstract

Background: Substantial inequities in cardiovascular disease occur between and within countries, driving much of the current burden of global health inequities. Despite well-established treatment protocols and clinical interventions, the extent to which the prehospital care pathway for people who have experienced an out-of-hospital cardiac event (OHCE) varies by ethnicity and race is inconsistently documented. Timely access to care in this context is important for good outcomes. Therefore, identifying any barriers and enablers that influence timely prehospital care can inform equity-focused interventions.

Objective: This systematic review aims to answer the question: Among adults who experience an OHCE, to what extent and why might the care pathways in the community and outcomes differ for minoritized ethnic populations compared to nonminoritized populations? In addition, we will investigate the barriers and enablers that could influence variations in the access to care for minoritized ethnic populations.

Methods: This review will use Kaupapa Māori theory to underpin the process and analysis, thus prioritizing Indigenous knowledge and experiences. A comprehensive search of the CINAHL, Embase, MEDLINE (OVID), PubMed, Scopus, Google Scholar, and Cochrane Library databases will be done using Medical Subject Headings terms themed to the 3 domains of context, health condition, and setting. All identified articles will be managed using an Endnote library. To be included in the research, papers must be published in English; have adult study populations; have an acute, nontraumatic cardiac condition as the primary health condition of interest; and be in the prehospital setting. Studies must also include comparisons by ethnicity or race to be eligible. Those studies considered suitable for inclusion will be critically appraised by multiple authors using the Mixed Methods Appraisal Tool and CONSIDER (Consolidated Criteria for Strengthening the Reporting of Health Research Involving Indigenous Peoples) framework. Risk of bias will be assessed using the Graphic Appraisal Tool for Epidemiology. Disagreements on inclusion or exclusion will be settled by a discussion with all reviewers. Data extraction will be done independently by 2 authors and collated in a Microsoft Excel spreadsheet. The outcomes of interest will include (1) symptom recognition, (2) patient decision-making, (3) health care professional decision-making, (4) the provision of cardiopulmonary resuscitation, (5) access to automated external defibrillator, and (6) witnessed status. Data will be extracted and categorized under key domains. A narrative review of these

XSL•FO
RenderX

domains will be conducted using Indigenous data sovereignty approaches as a guide. Findings will be reported according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines.

Results: Our research is in progress. We anticipate the systematic review will be completed and submitted for publication in October 2023.

Conclusions: The review findings will inform researchers and health care professionals on the experience of minoritized populations when accessing the OHCE care pathway.

Introduction

Cardiovascular diseases (CVDs) are the leading cause of mortality and morbidity globally [1,2]. However, the burden of disease is distributed inequitably between and within countries [3], contributing to the double burden of disease in low- and middle-income countries [4] and widening ethnic inequities in high-income countries [5-7]. Reducing the burden of CVDs will require a multipronged approach: reducing the exposure to the risk factors for disease as well as optimizing equitable access to existing treatment options [8,9].

Despite advances made in the treatment and prevention of CVDs, ethnic inequities remain. The widespread health inequities experienced by Indigenous populations and other ethnic groups in colonial nations [10,11] are driven by the differential exposure to the social determinants of health [12], racism [13-16], and the ongoing impacts of colonization [17,18]. As such, achieving health equity becomes an ethical imperative, underpinned by a fundamental right to health [19,20] and the understanding that some groups have experienced barriers to realizing these rights.

Addressing inequities in health requires a broad understanding of both the etiology and treatment of disease and the complex interplay between the social determinants of health. Further, the dominant attention on health behaviors and biological responses must be replaced by greater emphasis and critical appraisal of the root causes of inequitable health outcomes, particularly the effects of institutional racism and societal institutions [16] have on health outcomes. Lifting the research gaze further upstream provides the necessary information to inform interventions that will reduce ethnic health inequities. One area within the CVD care pathway that requires further exploration is access to prehospital care following an out-of-hospital cardiac event (OHCE).

The timeliness of care is crucial for positive outcomes. Every 30-minute delay to reperfusion (the restoration of blood flow to a damaged heart) following an ST-elevation myocardial infarction is associated with a 7.5% increased risk of death, and every 10-minute delay is associated with an additional 3.31 per 100 deaths [21]. The timeliness of care is even more important following a cardiac arrest, with the likelihood of survival increasing significantly if bystander cardiopulmonary resuscitation (CPR), defibrillation, or both is performed before emergency medical staff (EMS) arrive [22]. Within this field of research, differential access to care by ethnicity is well-documented [23], particularly following a cardiac arrest. However, no systematic review or attempt to map the care pathway has been undertaken for all nontraumatic, acute OHCEs.

This review will be undertaken as part of the Manawataki Fatu Fatu for Achieving Cardiovascular Care for Equity Studies (ACCESS) program [24], which has a specific focus on achieving equity for Māori and Pacific Islander peoples in Aotearoa, New Zealand. The initial scoping for this review identified that CVD inequities exist between ethnic groups in Aotearoa, New Zealand, with significantly higher CVD hospitalization and mortality rates among Māori (the Indigenous people of New Zealand) and Pacific Islander peoples compared with New Zealand European populations [25-27]. Poorer access to care for Māori and Pacific Islander peoples is likely to be an important contributor to these established inequities [28-30]. There is very little research about the experience of the care pathway for Māori and Pacific Islander peoples following an OHCE. What is known is that despite the higher burden of disease, Māori and Pacific Islander peoples experience delays to treatment [31] and barriers to CPR and defibrillation in the community [28,32]. Importantly, there appears to be limited (1) published literature in New Zealand and (2) opportunities to learn from the experiences of similar communities (ethnic minority groups) internationally. Therefore, a wider review, beyond New Zealand, was preferred.

The objective of this review is to identify the barriers and enablers to care for minoritized populations following an OHCE. The review also seeks to describe the OHCE care pathway that different ethnic groups experience, from the onset of symptoms until the receipt of care from a registered health professional. Within the review, prioritization will be given to research that illustrates the experience of the care pathway for Indigenous communities.

Methods

Overview

A pragmatic approach to this systematic review [33] will be undertaken. The overall research question seeks to simplify a complex interaction of diverse populations, systems, and variables that operate in the prehospital cardiac care space. Within this context, the review seeks to determine the service and system-level variables that affect a patients' journey along the care pathway. For the purposes of this review, the working definition of OHCE will be broad and includes (but is not limited to) cardiac arrest, myocardial infarction, arrhythmia, and chest pain.

Objectives

This systematic review aims to answer the question:

> *Among adults who experience an OHCE, to what extent and why might the care pathways in the community differ for minoritized populations compared with nonminoritized populations?*

The systematic review also aims to:

- Identify the barriers and enablers that could influence variations in the access to care for minoritized ethnic populations
- Describe what the care pathway in the community looks like for minoritized ethnic populations after an acute cardiac event compared to nonminoritized populations

Search Strategy

The search strategy, developed in consultation with a specialist librarian, will use a number of medical literature databases and search engines to identify literature for review. The sources include:

- CINAHL
- Embase
- MEDLINE (OVID)
- PubMed
- Scopus
- Google Scholar
- Cochrane Library

Different combinations of Medical Subject Headings (MeSH) terms and keywords related to ethnicity and race, equity, and CVD will be used. During the initial scoping for this review, a very limited number of articles related to the out-of-hospital care pathway in New Zealand were identified. The research question and therefore the search terms for the population of interest were broadened to include other minoritized ethnic communities globally. Although the scope of the review was expanded, the review will be underpinned by Kaupapa Māori research, which seeks to validate Māori experiences in the context of a colonized society [34]. Therefore, the MeSH terms for Māori and Pacific Islander peoples were added as specific search terms in recognition of this. The MeSH terms for Indigenous peoples have been included to capture research specific to other Indigenous or First Nations populations.

As relevant articles are identified, the reference lists will be checked for additional studies and reviews. The search will include articles relating to original research that are published in English with no exclusions due to research design or country setting. The date of publication will be limited to between January 1, 2000, and January 1, 2023. Textbox 1 outlines the search terms that will be used.

- Paramedic
- Emergency medical technician
- Community

Health condition

- Cardiac
- Coronary
- Cardiovascular
- Heart attack
- Arrest
- Myocardial infarction
- ST-elevation myocardial infarction (STEMI)
- Non-STEMI (NSTEMI)
- Chest pain
- Arrhythmia
- Ischemia
- Angina
- Acute coronary syndrome

Context

- Ethnicity
- Race
- Culture
- Indigenous peoples
- Disparity
- Inequity
- Inequality
- Equity
- Māori peoples
- Pacific Islander peoples

Inclusion and Exclusion Criteria

Textbox 2 outlines the inclusion and exclusion criteria that will be used.

XSL•FO
RenderX

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Outcomes are relevant to the research question
- Publication language: English
- Study population aged >18 years
- Cardiac event is nontraumatic
- Human subjects
- Based in prehospital settings
- All study types

Exclusion criteria

- Conference proceedings
- No English translation available
- No full text available
- Study population aged <18 years
- Cardiac event is a result of trauma

Types of Studies and Settings

All peer-reviewed, original research studies will be considered for inclusion. The "community" setting will include all settings in the prehospital phase, up to arrival at a hospital or emergency medical center. There will be no restriction by country.

Population

The population is broadly defined as all adults, aged 18 years and older, from minoritized ethnic communities who experience an acute, nontraumatic cardiac event outside of a hospital. The term "minoritized" is purposely chosen to reflect communities whose "collective cultural, economic, political, and social power has been eroded" [35]. The reference group is nonminoritized ethnic populations.

All types of acute cardiac events with a nontraumatic etiology will be considered, including but not limited to cardiac arrest, chest pain, arrhythmia, and myocardial infarction.

Outcomes

Any type of outcome measures will be included where ethnic and racial specific comparisons within a country are conducted. Analyses may include stratified analyses, the investigation of interactions or effect modification, and comparisons using qualitative data. Outcome measures from multicountry studies will be included if the ethnic groups analyzed are comparable. The primary outcomes will include the analysis of any factors that affect the pathways of care (time, journey, and the process taken to care) and barriers and enablers to prehospital care. This will include outcomes related to comorbidities, health education, symptom recognition, patient and EMS decision-making, care-seeking processes, access to CPR and automated external defibrillator, or informal care received before EMS contact. The secondary outcomes will be any gender analysis by ethnicity and race.

Critical Appraisal

The first author will undertake the literature search. Identified studies will be collated and managed in an EndNote library created for this review once the studies have been imported to the library. Duplicate entries will be removed before stage 1 of the critical appraisal process. During the initial review process, 2 authors will screen the title and abstract of each article to ensure that papers meet the inclusion criteria.

At stage 2 of the critical appraisal, the full text will be obtained for all articles, and every study will be evaluated by at least 2 authors using the Mixed Methods Appraisal Tool (MMAT) [36]. The MMAT provides a standardized table of quality assessment criteria that can be used for qualitative and quantitative research designs. All studies with Indigenous populations will also be reviewed using the CONSIDER (Consolidated Criteria for Strengthening the Reporting of Health Research Involving Indigenous Peoples) statement [37]. The CONSIDER statement provides a checklist that serves to strengthen Indigenous health outcomes by improving research practice and reporting. Study authors will be contacted to clarify results, resolve any uncertainties, and obtain additional information if needed. Risk of bias will be undertaken using the Graphic Appraisal Tool for Epidemiological studies. Assessment will be done at both study and outcome levels. Articles for inclusion will be identified by all review authors. The included reference lists for included articles will be scanned to identify further articles that may be eligible for inclusion. Articles identified at this stage will also be appraised using the MMAT and CONSIDER statement where appropriate. During the critical appraisal, any disagreement about the inclusion or exclusion of a paper will be resolved by discussion with all review authors.

Data Extraction

Data for extraction will include general study information, study characteristics, participant characteristics, and study results

XSL•FO
RenderX

measured on outcomes identified in this protocol. Appraisals and data extraction will be independently extracted by the authors and recorded in a form. A standardized data extraction form will be used, which will be piloted and refined to ensure that there is consistency between the multiple reviewers. Once finalized, the completed form will populate a Microsoft Excel spreadsheet that will be used for data analysis.

Each eligible study will have data extracted under 4 domains (Textbox 3).

Textbox 3. Extracted domains.

General study information

- Author
- Article title
- Year
- Country

Study characteristics

- Aims and objectives
- Study design and type
- Inclusion and exclusion criteria
- Recruitment procedures

Participant characteristics

- Sample size
- Ethnicity and race
- Number of male and female participants

Study results (outcomes)

- Primary outcomes
  - Variables in the care pathway from symptom onset to arrival at a hospital, including but not limited to:
    1. Time, journey, access to cardiopulmonary resuscitation or automated external defibrillator, witnessed by bystander or emergency medical staff (EMS), and informal care before EMS contact
    2. Health outcomes (comorbidities and survival)
    3. Barriers and enablers (health education; decision-making by EMS, patient, or witness; symptom recognition; and care-seeking processes)
- Secondary outcomes
  - Any gender analysis by ethnicity and race

Synthesis of Included Studies

The synthesis of the data will be underpinned by an Indigenous data sovereignty approach that requires researchers to critique how data about Indigenous peoples are collected, used, and analyzed [38,39]. A convergent integrated approach to the data synthesis [40] will be undertaken, whereby quantitative findings will be "qualitized" before conversion to narratives.

It is unlikely that this review will obtain sufficient data that are similar enough to conduct a meta-analysis. It is therefore expected that the authors will conduct a narrative synthesis of the data.

Reporting

The review findings will be reported according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [41]. The PRISMA 2020 flow diagram will be used to guide the recording of the number of articles identified, screened, included, and excluded.

Patient and Public Involvement

This is a protocol for a systematic review; therefore, no patients or public will be involved. However, the proposal and approach were informed by discussion with service providers in the prehospital sector in New Zealand. Patient consent for publication is not required.

Ethical Considerations

Ethics approval is not required for this systematic review as it is reviewing already anonymized, published data.

Results

Our research is in progress. We anticipate the systematic review will be completed and submitted for publication in October

XSL•FO
RenderX

2023. The findings of this review will be disseminated via a publication in a peer-reviewed journal as well as conference presentations and stakeholder meetings.

Discussion

Expected Findings

This paper presents a methodological description of a systematic review process that seeks to inform equity-based intervention and practice. CVD is the leading cause of mortality and morbidity globally. The rates of CVD-related morbidity and mortality have increased, particularly in low- to middle-income countries, [42]. Although population aging contributes to increasing CVD rates globally, barriers to accessing care widens the gap between countries [43] and within countries. For Indigenous and other minoritized ethnic peoples experiencing inequities, identifying the barriers to accessing care is vital for creating culturally grounded interventions that reduce the health inequities they experience [44,45]. This review will contribute to the existing body of knowledge by identifying the factors that improve access to care for different ethnic groups following an OHCE. By integrating an Indigenous quality appraisal tool and research methodology, the review will provide evidence with a uniquely positioned equity lens. It is intended that this will provide insight into areas where interventions can be targeted to increase access to care for ethnic groups in New Zealand and globally. The resulting systematic review will present an unbiased and detailed summary of the current evidence available about the experiences of minoritized populations accessing care following an OHCE compared with nonminoritized populations. The results of this review will inform researchers and emergency service providers on variables related to equity-centered service provision and intervention in the community setting.

Strengths and Limitations

The strengths of the resulting systematic review include the following:

- This systematic review of factors that facilitate access to care will be based upon a detailed search strategy that includes all study types from any country.
- The review will use a robust reporting tool and a validated quality appraisal checklist for critical appraisal of the literature.
- A social justice and equity lens will be applied to the selection and analysis of identified research.

The limitations of the resulting systematic review include the following:

- By restricting to the English language, this research is limited in its ability to identify articles relevant to other Indigenous people that are published in another language.
- By excluding gray literature, we will not capture the prehospital care reporting mechanisms that are often published as technical reports, for example.
- There is also the risk of publication bias where studies with nonsignificant findings may not be published and therefore will not be captured in our review.

Conclusion

This systematic review protocol illustrates the transparency of the research and provides a process for conducting a similar review.

Acknowledgments

This work was supported as part of a larger project grant funded by a joint grant from the Heart Foundation and Healthier Lives (National Science Challenge; grant 1819).

Data Availability

The data sets generated and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors' Contributions

RN developed the protocol and wrote the manuscript. MH, CG, BD, and SA critically reviewed and edited the manuscript. All authors contributed to the final review.

Conflicts of Interest

None declared.

Abstract

Background: Anxiety and alcohol use commonly co-occur. Previous research has demonstrated the bidirectional and mutually reinforcing nature of this relationship, with an increasing body of research investigating the mediating and moderating mechanisms driving this association. Within the existing mediation and moderation research, however, there have been contrasting findings and, at times, null results among some population groups.

Objective: This protocol outlines a systematic review and meta-analysis aiming to synthesize and clarify mediators and moderators in the anxiety-alcohol and alcohol-anxiety relationships.

Methods: Systematic searches will be conducted in the electronic databases Medline, PsycINFO, Embase, Cochrane Central Register of Controlled Trials, Scopus, and Web of Science to identify studies that investigated mediators and moderators of the relationship between anxiety and alcohol use, including clinical and subclinical levels. Studies that look at the relationship between anxiety and alcohol use outcomes, as well as alcohol use and anxiety outcomes, will be included in order to capture an in-depth understanding of the mechanisms driving the association in either direction. No limits will be placed on study year or study language. Included study designs will be observational studies, including cohort, cross-sectional, and longitudinal studies, and secondary analyses of randomized controlled trials reporting quantitative results. Selected studies will also have their reference lists hand-searched for other relevant papers. Study quality will be assessed with the Joanna Briggs Institute Checklists for Analytical Cross-Sectional Studies and Cohort Studies. Mediators and moderators will be narratively synthesized in line with the biopsychosocial framework, where results will be grouped into biological, psychological, and social or environmental factors. If the data are sufficiently homogeneous, a meta-analysis will be conducted with mediation and moderation analyses synthesized separately. The Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) framework will also be used to assess the strength of cumulative evidence.

Results: Electronic database searches were conducted in September 2022. After duplicates were removed, a total of 7330 titles and abstracts were screened. Full-text reviewing is currently under way, with the results expected to be available by the end of 2023.

Conclusions: Given the significant individual and societal impacts of co-occurring anxiety and alcohol use, this review will help clarify mechanisms linking these two concerns. Identified mechanisms, where possible, can then be targeted in prevention, early intervention, and treatment approaches to improve the outcomes for individuals experiencing co-occurring anxiety and alcohol use.

alcohol use; alcohol; anxiety; comorbidity; drinking; electronic databases; mediator; meta-analysis; moderator; prevention; systematic review

Introduction

Globally, anxiety disorders are the most common psychiatric disorders, with an estimated 301 million individuals experiencing one or more anxiety disorders in their lifetime [1]. Alcohol use is also highly prevalent, with an estimated 32.5% of people aged 15 years or older globally being current drinkers [2]. Among drinkers, high rates of risky drinking and alcohol use disorders are seen. A large nationally representative survey of 36,309 adults in the United States found 12.9% of individuals drink at high-risk levels, defined as 4+ standard drinks for women and 5+ standard drinks for men, at least weekly [3]. Additionally, among those who drink, 17.5% experienced an alcohol use disorder in the past year [3]. Comorbidity between mental health and substance use concerns is common, most notably between anxiety and alcohol use. Indeed, among individuals with an anxiety disorder, it is estimated that 20%-40% will also experience an alcohol use disorder in their lifetime [4]. When anxiety and alcohol use co-occur, symptom severity can be worse, and treatment adherence and outcomes are typically poorer compared to individuals with an anxiety or alcohol disorder alone [5,6].

Several theories have been proposed to explain the comorbid, bidirectional relationship between anxiety and alcohol use. Arguably, the most common is the self-medication model [7,8] which suggests individuals drink alcohol to alleviate symptoms of anxiety or general negative affect, in turn leading to a reliance on alcohol over time and the development of a subsequent alcohol use disorder. The use of alcohol for self-medication also aligns with other theories, including the tension-reduction theory [9] and the stress response dampening model [10]. Conversely, there is the opposite causal explanation that alcohol misuse and alcohol use disorders promote anxiety disorders, known as the substance-induced anxiety model or kindling or stress hypothesis [6,11,12]. Following prolonged periods of heavy alcohol consumption, withdrawal or cessation can lead to adaptations in the brain and wider nervous system, which can induce or worsen anxiety [6,11]. In addition to evidence of causal, bidirectional pathways between anxiety and alcohol, there is also support for a mutual-maintenance model also referred to as the "vicious cycle of comorbidity" [13]. This model demonstrates how the biopsychosocial outcomes of one disorder (eg, anxiety) will often serve to maintain or exacerbate the other disorder (eg, alcohol use disorder). An example of such a relationship can be seen when an individual with social anxiety who is self-medicating with alcohol develops a reliance on alcohol and over time experiences alcohol-related consequences like decreased productivity, interpersonal issues, and anxiety-induced withdrawal. These consequences exacerbate the initial anxiety and result in further drinking, thus maintaining the problematic feed-forward cycle [6,13]. Together, these theoretical frameworks suggest a complex bidirectional relationship between anxiety and alcohol use, with longitudinal and prospective studies confirming that experiencing an anxiety disorder or an alcohol use disorder can increase the risk of developing the other [14,15].

Previous critical and systematic reviews have established a strong body of evidence for a relationship between anxiety and alcohol use [12,16]. These reviews have typically focused on the temporal sequencing of the anxiety-alcohol relationship [16,17]; comorbidity between a specific anxiety disorder, for example, social anxiety disorder, and alcohol use [5,18-21]; the treatment of comorbid anxiety and alcohol use disorders [22-25]; or all of the above [12,26]. Yet, despite substantial existing research, the specific mechanisms driving anxiety and alcohol comorbidity are still poorly understood. The proposed systematic review will be the first to synthesize and clarify the specific mediators and moderators driving the relationship between anxiety and alcohol use.

Given the bidirectional nature of comorbid anxiety and alcohol use, the planned review will investigate the relationship in both directions. Figures 1 and 2 are path diagrams visually demonstrating the relationships that will be examined. Figure 1 illustrates anxiety as the exposure/predictor variable (X) and alcohol use as the outcome variable (Y), while Figure 2 illustrates the relationship in the opposite direction, where alcohol use is the exposure/predictor (X) and anxiety is the outcome (Y). As illustrated in Figures 1 and 2, a mediator or moderator is a third variable that affects the relationship between the exposure and outcome of interest [27]. Investigating mediators is warranted to better understand causal mechanisms that account for a relationship between X and Y [28]. In short, by identifying mediators, the proposed review will highlight factors explaining *how* or *why* the association between anxiety and alcohol, or alcohol and anxiety, occurs. If modifiable, these mediators can then be targeted in prevention, early intervention, and treatment approaches. To get a complete understanding of the anxiety and alcohol relationship, investigating the role of moderating variables is also necessary. The synthesis of moderators will highlight factors that affect the direction or strength of the relationship between X and Y [27]. As such, moderators can help understand *when* the relationship between anxiety and alcohol or alcohol and anxiety will occur. Given the breadth of possible mediating and moderating mechanisms studies can investigate, the review may identify mechanisms that can act as both a mediator and a moderator in the anxiety-alcohol relationship. An example of such a factor is positive alcohol use expectancies, with previous research identifying it as both a mediator and moderator in the relationships of interest [29-31].

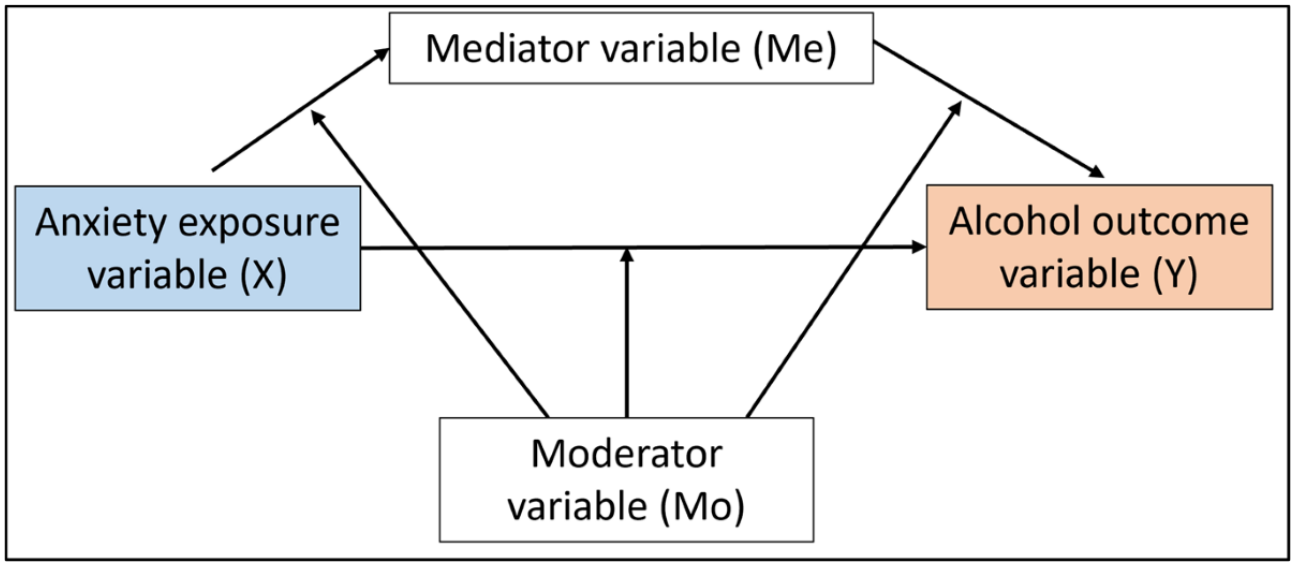
Figure 1. Diagram demonstrating the possible mediator (Me) and moderator (Mo) pathways between the exposure variable anxiety (X) and outcome variable alcohol (Y).



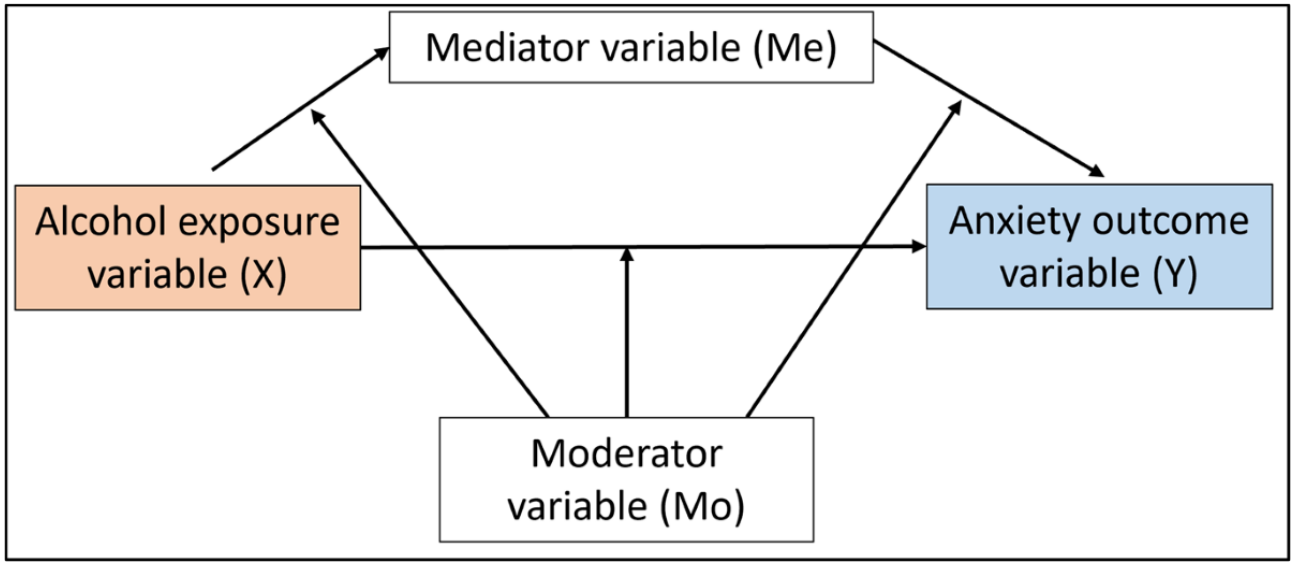


Figure 2. Diagram demonstrating the possible mediator (Me) and moderator (Mo) pathways between the exposure variable alcohol (X) and outcome variable anxiety (Y).

To our knowledge, this will be the first study to systematically identify and synthesize research on mediators and moderators of the comorbid anxiety and alcohol relationship. The outcomes of the review will specifically answer the following questions:

- What mediates the relationship between anxiety and alcohol use?
- What moderates the relationship between anxiety and alcohol use?

Methods

Guidelines and Registration

This protocol was written in accordance with the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) guidelines [32]. The systematic review has been registered in PROSPERO, the International Prospective Register of Systematic Reviews (CRD42023358402).

Eligibility Criteria

Guided by the population, exposure, outcome (PEO) framework for conducting systematic reviews of association (etiology) [33], the below criteria will be used to determine eligible studies and structure the search strategy.

Population

All human populations are of interest for the proposed systematic review, and as such, no limits will be placed on the study population or participant type. Animal studies will be excluded.

Exposure and Outcome

Given the bidirectional nature of anxiety and alcohol comorbidity, the proposed systematic review will include studies investigating these concerns in either direction. Therefore, studies where anxiety is the exposure and alcohol use is the outcome, as well as studies where alcohol use is the exposure and anxiety is the outcome, will be included.

XSL•FO
RenderX

A broad classification will be used to define the anxiety exposure and outcome in this review. Anxiety will be conceptualized in line with the Diagnostic and Statistical Manual of Mental Disorders-Fifth Edition (DSM-5), where anxiety disorders are differentiated from obsessive compulsive and related disorders, and trauma and related-stressor disorders [34]. Per the DSM-5, anxiety disorders include generalized anxiety, social anxiety (social phobia), separation anxiety, selective mutism, specific phobia, agoraphobia, and panic disorder. Both studies that assess disorder-level measures or subclinical symptom measures will be included in the review. In addition to these definitions of anxiety, studies reporting broad symptoms of anxiety or anxious traits, such as anxiety sensitivity (eg, Anxiety Sensitivity Index-3), will also be included.

Like anxiety, a broad classification will be used to define the alcohol use exposure or outcome. This review is interested in the full spectrum of alcohol use and related difficulties and will include, but is not limited to, studies reporting frequency or quantity of alcohol consumption; hazardous, binge, or risky drinking; and alcohol use disorders.

Only studies where both the exposure and outcome are measured in the same individual will be included in this review. Studies looking at mediators or moderators between parents and offspring will be excluded.

Study Characteristics

Observational studies including cohort, cross-sectional, and longitudinal studies, and secondary analyses of randomized controlled trials reporting quantitative results will be included. Studies only evaluating intervention or treatment outcomes, including mediators or moderators of an intervention, will be excluded. Additionally, studies only reporting prevalence data will be excluded. Studies must be published in a peer-reviewed journal, with reviews, meta-analyses, and information in books, reports, letters, or conference abstracts being excluded from this systematic review. No limits will be placed on publication year or study language.

Information Sources and Search Strategy

Searches will be conducted in the electronic databases Medline (Ovid), PsycINFO (Ovid), Embase (Ovid), Cochrane Central Register of Controlled Trials (Ovid), Scopus, and Web of Science. Search strategies will be tailored to each database and use a combination of keywords and subject headings or medical subject headings (MeSH) where appropriate. A total of 3 overarching themes of anxiety, alcohol, and mediator or moderator will be used to structure the search, with search terms combined using the Boolean operators “AND” and “OR.” No year or language limits will be imposed on any of the searches. The reference lists of eligible studies will also be hand-searched to find additional studies not picked up in the electronic database searches. Full search strategies for each database are presented in Multimedia Appendix 1.

Study Selection and Extraction

All identified studies will be imported into the web-based systematic review software Covidence [35], where duplicates will automatically be removed. All titles and abstracts will be screened by a primary reviewer, with a random sample of 50% screened independently by a second reviewer. The full text of potentially eligible studies, identified through screening, will then be reviewed and assessed against the eligibility criteria by both reviewers. Disagreement between reviewers at both stages will be resolved through consultation, and if required, a third reviewer. Cohen κ will be calculated at the screening and full-text stage to determine the interrater agreement between reviewers, with a κ statistic of 0.8 considered a strong level of agreement [36]. The results of the screening and study selection process will be summarized with a PRISMA flow diagram in the final systematic review.
